Theatre. it is given from the late valuable edition of our illustrious poet's works by Mr Malone. During the whole reign of James I. the theatre was in great prosperity and reputation: dramatic authors abounded, and every year produced a number of new plays; it became a fashion for the nobility to celebrate their weddings, birthdays, and other occasions of rejoicing, with masques and interludes, which were exhibited with surprising expence; our great architect, Inigo Jones, being frequently employed to furnish decorations, with all the luxuriance of his invention and magnificence of his art. The king and his lords, and the queen and her ladies, frequently performed in these masques at court, and the nobility at their private houses; nor was any public entertainment thought complete without them. This taste for theatrical entertainment continued during great part of the reign of King Charles I.; but, in the year 1633, it began to be opposed by the Puritans from the press; and the troubles that soon after followed entirely suspended them till the restoration of King Charles II. in 1660.

The king, at his restoration, granted two patents, one to Henry Killigrew, Esq. and the other to Sir William Davenant, and their heirs and assigns, for forming two distinct companies of comedians. Killigrew's were called the *King's Servants*, and Davenant's the *Duke's Company*. About ten of the company called the *King's Servants* were on the royal household establishment, having each ten yards of scarlet cloth, with a proper quantity of lace allowed them for liveries; and in their warrants from the lord chamberlain they were styled *gentlemen of the great chamber*.

Till this time no woman had been seen upon the English stage, the characters of women having always been performed by boys, or young men of an effeminate aspect, which probably induced Shakespeare to make so few of his plays depend upon female characters, as they must have been performed to great disadvantage. The principal characters of his women are innocence and simplicity, such are Desdemona and Ophelia; and his specimen of fondness and virtue in Portia is very short. But the power of real and beautiful women was now added to the stage; and all the capital plays of Shakespeare, Fletcher, and Ben Jonson, were divided between the two companies, by their own alternate choice, and the approbation of the court.

The king's servants seem to have been allowed to be the best company; and when the variety of plays began to be exhausted, they drew the greater audiences. Davenant, therefore, to make head against them, first added spectacle and music to action, and introduced a new species of plays, since called *dramatic operas;* among these were, *The Tempest*, *Psyche*, and *Circe;* which, with many others, were set off with the most expensive decorations of scenes and habits, and with the best voices and dancers.

In 1684 the two houses united, and continued together for ten years. In 1690 the play began at four o'clock; and, we are told, the ladies of fashion used to take the evening air in Hyde-park after the representation; by which it appears that the exhibitions were in summer too. The principal actors were, Betterton, Montfort, Kynaston, Sandford, Nokes, Underhill, and Leigh, commonly called *Tony Leigh;* the actresses were, Mrs Betterton, Barry, Leigh, Butler, Montfort, and Bracegirdle; and to this company, in this year, old Cibber was admitted as a performer in the lowest rank. It was a rule with the patentees, that no young person, who offered himself as an actor, should be admitted into pay till after at least half a-year's probation; and Cibber waited full three quarters of a year before he was taken into a salary of 10s. a-week.

In 1695 a new theatre was opened with Mr Congreve's comedy of Love for Love, which had such extraordinary success (says Cibber) that scarce any other play was acted there till the end of the season; but when the season ended, which appears to have begun in June, he does not tell us, and it is indeed difficult to guess; for though the company acted in summer, it seems improbable that they should shut up the house in winter, as it is difficult to conceive any reason for so doing. Congreve was then in such high reputation, that this company offered him a whole share (but into how many shares the whole was divided Colley has not told us) upon condition he would give them a new play every year. This offer he accepted, and received the advantage, though he never fulfilled the condition; for it was three years before he produced the *Mourning Bride*, and three more before he gave them the *Way of the World*.

It is not necessary that we give in detail the remaining history of the English stage: those who are anxious to be acquainted with it may consult Cibber's history of of the stage, continued by Victor, under the title of *A History of the Theatres of London and Dublin from the year* 1730. We shall only mention a few facts respecting the salaries of the players about that period, and the rise of the price of play tickets.

A difference having arisen in 1733 between the managers and actors, most of the actors set up for themselves at the little theatre in the Haymarket. Upon this the managers published the following account of their salaries, to show the public how little room they had to mutiny. To Mr Colley Cibber, from the time of letting his share till he left the stage, 12l. 12s, per week. Mr The. Cibber 5l. and his wife's whole salary till her death, without doing the company any service the greatest part of the winter; and his own also, during the time of his being ill, who performed but seldom till after Christmas. Mr Mills jun. 3l. under the same circumstances with regard to his wife. Mr Mills sen. 1l. per day for 200 days certain, and a benefit clear of all charges. Mr Johnston 5l. Mr Miller 5l. paid him eight weeks before he acted, besides a present of 10 guineas. Mr Harper 4l. and a present of 10 guineas. Mr Griffin 4l. and a present. Mr Shepard 3l. Mr Hallam, for himself and father (though the latter is of little or no service) 3l. Mrs Heron 5l. raised from 40s. last winter, yet refused to play several parts assigned her, *Gentleman's Magazine* for 1733.

omit, however, to inform our readers what Mr Malone says of the old plays, viz. that not one play published before 1592 will bear a second reading; and that exclusive of mysteries, moralities, and translations, there are but 34 pieces extant which were published before that period.

Theatre ‖ Thebes.

her, and acted but seldom this season. Mrs Butler 3l. per week. By these and other salaries, with the incident charges (besides clothes and scenes), the patentees are at the daily charge of 49l. odd money, each acting-day.

Till about the same time, the prices at the theatre were 4s. the boxes, 2s. 6d. the pit, 1s. 6d. the first gallery, and 1s. the second, except upon the first run of a new play or pantomime, when the boxes were 5s. the pit 3s. the first gallery 2s. and the second 1s. But Fleetwood thought fit to raise the prices for an old pantomime, which was revived without expence. This produced a riot for several nights, and at last a number deputed by the pit had an interview with the manager in the green room, where it was agreed, that the advanced prices should be constantly paid at the doors, and that such persons as did not choose to stay the entertainment should have the advanced part of their money returned. This was a very advantageous agreement for the manager; because, when the audience had once paid their money, very few went out or demanded their advanced money, and at last it settled in the quiet payment of the advanced price, as at this day.

It has been frequently a subject of debate, whether the stage be favourable to morals. We do not mean to enter into the controversy; but we shall make an observation or two. It will be allowed by all, that the intention of the players in acting, is to procure money; and the intention of the audience in attending the theatre, is to seek amusement. The players then will only act such plays as they believe will answer their intention. And what sort of plays are these? They are such as correspond with the opinions, manners, and taste, of the audience. If the taste of the audience be gross, therefore the plays will be gross; if delicate and refined, they will be the same. And if we go back to the time of Shakespeare, we shall find that this has been uniformly the case. The conclusion, we draw, is this, if the taste of the audience be pure, free from licentiousness, the plays will be the same, and the stage will be favourable to virtue.

For a view of the progress of the stage, and of the principal dramatic writers, see DRAMA, SUPPLEMENT.

THEBAID, a celebrated heroic poem of Statius, the subject of which is the civil war of Thebes, between the two brothers Eteocles and Polynices; or Thebes taken by Theseus.

THEBES, the name of a celebrated city of ancient Greece. It is supposed to have been built by Cadmus, about the year of the world 2555. This Cadmus, according to the Greeks, was the son of Agenor king of Sidon or of Tyre; but the Sidonians allow him to have been of no higher quality than his cook, and tell us that his wife was a musician at court, with whom he ran away into Greece. The Greek writers tells us, that being commanded by his father to go in search of his daughter Europa, whom Jupiter in the shape of a bull had carried off, and forbid to return without her, he built, or rebuilt, the city of Thebes, after having long sought her in vain. He was at first opposed by the Hyantes and Aones; the former of whom he defeated in battle, and forced to retire into Locris; the latter submitted, and were incorporated among his subjects.

1 Account of Cadmus the founder of Thebes.

Those who endeavour to extract some truth from the multitude of fables in which the early part of the Grecian history is obscured, are of opinion that Cadmus was one of the Canaanites expelled by Joshua; and that he was of the family of the Cadmonites mentioned by Moses and Joshua. He is universally allowed to have introduced the Phœnician letters into Greece, set up the first schools, and introduced brass; which, from him, had the name of *Cadmean* given to it. The government of Thebes continued for a long time monarchical; and the names of a number of its kings have been transmitted to us, with some account of their transactions; but very much obscured by fable.

2 Supposed to be one of the exiled Canaanites.

Though the Thebans had been famed in the early period of their history for their martial achievements, yet in process of time they seem to have degenerated. At the time of the invasion of Xerxes, they were the first people in Greece who were gained over to the Persian interest. On account of this conduct, they became very obnoxious to the other states, especially to the Athenians, whose power and renown increased every day, and threatened at last to swallow them up altogether, The Thebans being in no condition to oppose such a formidable power, put themselves under the protection of the Spartans, who, out of jealousy of the Athenians, readily forgave them; and so grateful were the Thebands for the kindness shown them at this time, that during the whole of the Peloponnesian war Sparta had not a more faithful ally. By these means they not only recovered the government of Bœotia, of which they had been formerly in possession, till deprived of it on account of their siding with the Persians, but their city became one of the first in Greece. By this prosperity the Thebans were so much elated, that, when the peace of Antalcidas came to be signed, they refused to agree to it, as they were thus once more deprived of the government of Bœotia; so that it was not without the utmost difficulty that they were overawed into it by the other states. Not content with forcing them to give up this point, however, the Spartans undertook to change the form of the Theban government, which at this time was a democracy, and accomplished through the treachery of those who had the care of the citadel.

3 The Thebans a degenerate stupid people.

4 Put themselves under the protection of the Spartans.

5 The form of government changed, and the citadel seized by the Spartans.

The Thebans continued under the power of the Spartans for four years; at the ead of which term a conspiracy being formed against them by some of the principal people in the city, among whom was a young nobleman named *Pelopidas*, the Spartans were massacred and driven out, and the citadel regained. During the tumult Epaminondas, afterwards the celebrated general, with a number of the best citizens, joined the party of Pelopidas; and the latter having called a general assembly of the Thebans, proclaimed liberty to them, and exhorted them in the strongest manner to fight for their country. This speech was received with the greatest acclamations; Pelopidas was unanimously proclaimed the preserver of Thebes, and was charged with the management of the war which was then to be declared against Sparta.

6 The Thebans recover their liberty under Pelopidas.

These transactions so much exasperated the Spartans, that they immediately sent their king Cleombrotus against them, though it was then the depth of winter. The Athenians, in the mean time, who had hitherto assisted the Thebans, declined any farther connection, lest they should draw upon themselves the resentment of the

7 War with Sparta.

Thebes. the Spartans. But they were soon after determined to act again on the same side, by an attempt which the Spartan general, Sphodnas, had rashly made on the Pyræus or harbour of Athens. Thus, by means of the Athenians, a powerful diversion was made in favour of the Thebans who gradually recovered all the towns of Bœotia, and at length began to act offensively against their enemies, and made a powerful invasion in Phocis. They had now many sharp encounters with them; which, though they did not amount to decisive battles,
8 The Spartans defeated by Pelopidas. yet did not fail to raise their courage, and depress that of the Spartans. In these encounters Pelopidas always signalized himself; and in the battle of Tanagra, where the Lacedæmonians were entirely defeated by the Athenians and their allies, Pelopidas had a principal share in the victory, and killed the Spartan general with his own hand. Soon after this, with a body of only 300 Thebans, he entirely routed and dispersed near 1000 Spartans; which was the greatest disgrace the latter had ever known; for till that time, whether in war with the Greeks or barbarians, they had never been overcome by an equal, much less by such an inferior number of troops.

These successes of the Thebans greatly alarmed the
9 Platæa and Thespia razed by the Thebans. Athenians, who continually sought to oppose their growing power. In this opposition they were joined by the Platæans, who on this account became extremely obnoxious to the Thebans, so that they at last came to a resolution to surprise their city. This they accomplished, and entirely destroyed it, together with Thespia, another city extremely well affected to Athens. Soon after this, the Thebans, encouraged by their success, began to think of enlarging their territories, and
10 Account of Epaminondas. of making encroachments on their neighbours, as they saw other states had done before them. This spirit of conquest is said to have been raised by their general Pelopidas; in which he was seconded by Epaminondas, a person who, though like him endowed with all the necessary qualities to make a complete captain or patriot, had till then preferred a private life, and lived in a constant course of virtue and the study of philosophy. He had as yet seldom appeared in public, except to get himself excused from those state employments which were so eagerly courted by others. This, however, had not hindered him from contracting an intimate friendship with Pelopidas, which had been daily improved by the correspondence of their tempers and principles, as well as by that zeal which both displayed for the good of their country; which last had made them, even before this time, appear together in action, and to such advantage, that Epaminondas's merit could be no longer concealed, nor indeed suffer him to continue longer in his beloved retirement: so that he saw himself, at length, deservedly placed at the head of the Theban troops; where he gave such early proofs of his future prowess and abilities as justly gave him the next rank to Pelopidas. Both came now to be considered in the same light, as generals in the field, as governors at home, and as complete statesmen in the council. When the general treaty for restoring peace to Greece came to be proposed by the Athenians, and was upon the point of being executed by the rest of the states, the Thebans refused to agree to it, unless they were comprehended in it under the name of *Bœotians*. This demand was as strenuously opposed by the other contracting powers as insisted on by Epaminondas, who was there as ambassador on the part of the Thebans. Agesilaus, in particular, told him in plain terms, that the Thebans ought to evacuate Bœotia, and leave the cities of it free and independent. To which it was answered by him, that the Lacedæmonians would do well to set them the example, by restoring Messenia to its ancient proprietors, and Laconia to its ancient freedom; for that the pretensions of the city of Thebes to Bœotia were as well founded, at least, as those of Sparta to those two countries. After this he went on, and showed how far Sparta had aggrandized herself at the expence of her neighbours: that peace might be indeed obtained, and upon a solid and lasting footing; but that this could not be otherwise than by bringing all to an equality. This bold though just remonstrance, in which not only Thebes, but Greece in general was concerned, failed not, however, to exasperate the haughty Spartan monarch; and the Athenians, who had till now looked upon the Thebans as dependents either on them or on the Macedonians, were not a little offended to hear their ambassadors talk in such high terms. The result of the conference was, that Agesilaus struck the name of *Thebes* out of the treaty, and declared war against them, about the year 371 B. C. 11 His difference with Agesilaus king of Sparta.

The Thebans were in no small consternation to see themselves engaged in a war with the powerful Spartans, without any ally to assist them; and the rest of the Grecian states having made peace with the latter, began to look upon the ruin of the former as unavoidable. However, they resolved to make the best defence they could; and put their army under the command of Epaminondas, assigning him, at his own request, six others to act as counsellors or assistants. The Theban army consisted at most but of 6000 men, whereas that of the enemy was at least thrice that number; but Epaminondas trusted most to his horse, wherein he had much the advantage both in quality and good management: the rest he endeavoured to supply by the disposition of his men, and the vigour of the attack. He even refused to suffer any to serve under him in the engagement, but such as he knew to be fully resolved to conquer or die. The two armies met at Leuctra, where the Spartans were defeated with great slaughter, as related under that article. 12 The Spartans declare war against Thebes. 13 Are entirely defeated at Leuctra.

The victorious general, desirous to improve this great victory, sent an herald, crowned with garlands, to communicate it in form to the Athenians, in hopes that this would be an effectual means to reunite them to the Theban interest. But it proved quite otherwise. Athens, which now looked upon them with a jealous eye, and had then in view the sovereignty of Greece, chose rather, if they could not wholly obtain it, to share it with Sparta, than to let the Thebans into the whole; and therefore even declined giving their herald audience. However, the Thebans took care to strengthen themselves by alliances; and, besides the Arcadians and Eleans, had got the Phocians, Locrians, Acarnanians, Eubœans, and other states, under their dependence: so that they were now in a condition to act offensively against the Spartans. Accordingly, under pretence of assisting the Arcadians, they entered Peloponnesus with a gallant army, with Epaminondas and Pelopidas at their head. Here they were joined by the Arcadian and other confederate forces; so that the whole amounted to 40,000, 14 The Athenians jealous of the Thebans. 15 The Thebans invade Peloponnesus with a formidable army, but are repulsed.

Thebes. some say 50,000 men, besides great numbers of those who followed the camp, rather for plunder than fighting, and were computed about 20,000 more. The army was divided into four columns, and moved straight towards Sellasia, the place of rendezvous, from which they pursued their journey with fire and sword towards Sparta. But here they were repulsed by Agesilaus, who was then returned to that metropolis.

To repair, in some measure, this disgrace, and at the same time to leave some lasting monument which should redound as much to his glory as to the mortification of the Spartans, Epaminondas left not their territories till he had restored the posterity of the old Messenians to their ancient dominions, out of which they

16 The Messenians restored to their ancient dominions. had been banished near 300 years; rebuilt their capital, and left a strong garrison for its defence. He was, however, nearly cut off in his return by Iphicrates, whom the Athenians had sent with 12,000 men to intercept him; but this last loitered so long at Corinth, that the Thebans had passed the defiles of Cenchreæ, the chief place where he could have obstructed his retreat had he taken possession of it in proper time. Epaminondas continued his march till he came in full view of the city of Corinth. He found the roads choked up with trees, rocks, stones, and every thing that could render them impassable; and the Corinthians well fortified, and resolute on a stout defence. But he came so furiously upon them, notwithstanding all these difficulties, that they abandoned all their entrenchments and

17 The Corinthians defeated. outworks to the Thebans, and fled into the city. Thither these pursued them sword in hand, and made an horrid slaughter of them; insomuch that Corinth must have unavoidably fallen into their hands, had their generals thought fit to pursue these advantages; but whether they were afraid of the Athenians falling upon them, or apprehended some dangerous ambush in a country with which they were but indifferently acquainted, or whether the army was too much weakened through so many fatigues, or, lastly, whether the coldness of the season, it being then the depth of winter, would not permit them to proceed farther, they immediately march-

18 Epaminondas and Pelopidas disgraced at Thebes. ed towards Bœotia. This gave such an advantage to their enemies, that they met with a very mortifying reception at their return to Thebes, where they were both arrested, and seized as state-prisoners, for having presumed to prolong their command four months longer than the time limited by law, which time took in almost the whole of their expedition from their first entrance into Peloponnesus. However, at last, the judges being ashamed to proceed any farther, they were both honourably acquitted.

This prosecution had been chiefly carried on and encouraged by Meneclides a discontented Theban, and a bold and able speaker, who, by his artful calumnies at the trial, had so far prevailed with the judges as to get Epaminondas deprived of the government of Bœotia for a whole year, though he could not gain the same advantage against Pelopidas, who was a greater favourite of the people, as being his senior.

19 War renewed with Sparta. By this delay the Spartans, with much difficulty, had recovered themselves from their great defeat at Leuctra, and settled their affairs in as good a posture as they could; but though they had repulsed the Thebans in Peloponnesus, yet from the exploits they had performed there, especially in the dismembering the whole kingdom of Messenia from them, they had still cause to fear what their forces might do under two such generals; and had accordingly taken due care to strengthen themselves against them, and to provide themselves with a great number of auxiliaries from other states, especially from that of Athens, with whom they had renewed their old treaty, and had agreed that each should have the command five days alternately. Soon after this treaty the Arcadians renewed the war, and took Pallene in Laconia by storm, put the garrison to the sword, and were presently assisted by the Argives and Eleans, and especially by the Thebans, who sent to them 7000 foot, and 500 horse under the command of Epaminondas. This so alarmed the Athenians likewise, that they immediately sent Gobrias with some forces to oppose his passage in good earnest; and he so behaved himself against the Thebans, that they were forced to abandon 20

The Thebans repulsed. Peloponnesus a second time. This ill success gave fresh occasion to the enemies of Epaminondas to blame his conduct in the highest terms, notwithstanding the singular bravery with which he and his troops had forced the pass. Even his friends could not but suspect him of partiality for the Spartans, in not pursuing his advantage over them, and making a greater slaughter of them when he had it in his power; whilst his enemies made it amount to no less than treachery to his country: so that their brave general was once more depriv- 21

Epaminondas degraded. ed of the government of Bœotia, and reduced to the condition of a private man. He did not continue long under this disgrace, before an occasion offered to make his services again of such necessity to the state, as to give him an opportunity to retrieve his fame, and wipe off the stain which his enemies had thrown upon him.

The Thessalians, who had groaned some time under the tyranny of the usurper Alexander, surnamed the 22

Pelopidas seized by Alexander of Pheræ. *Pheræan*, sent an ambassy to Thebes to implore their aid and protection; upon which Pelopidas was immediately sent as ambassador to expostulate with him on their behalf. He was then in Macedon, from whence he took the young prince Philip, afterwards the celebrated monarch, in order to protect and educate him; and, upon his return, marched directly to Pharsalus in Thessaly, in order to punish the treachery of some mercenaries, who had deserted the Thebans in that expedition; but when he came thither, he was surprised to be met by the tyrant at the head of a numerous army before that city, whilst his own was but as an handful of men in comparison of it. However, whether he supposed, or would be thought to do so, that Alexander came thither to justify himself, and answer to the complaints alleged against him, he went, with Ismenias his colleague, to him unarmed and unattended, not doubting but his character as ambassador from so powerful a republic, joined to his own character and authority, would protect them from insult or violence: but he found himself mistaken; for Alexander had no sooner got them into his hands, than he caused them to be seized and sent prisoners to Pheræa. 23

A Theban army sent to rescue him, defeated. The Thebans highly resenting the indignity offered to their ambassadors, sent immediately an army into Thessaly: but the generals were repulsed with great loss by the Pheræan usurper; and it was owing to Epaminondas, who was among them only as a private centinel, that they were not totally cut off. For the Thebans, finding

Thebes. finding themselves in such imminent danger, which they attributed to the incapacity of their generals, had immediately recourse to him, whose valour and experience had been so often tried; and, partly by persuasions and
24 Epaminondas restored. intreaties, and partly by threats, obliged him to take the command. This soon gave a different turn to their affairs, and converted their flight into a safe and regular retreat; for he took the horse and light-armed foot, and placed himself at their head in the rear, and charged the enemy with such vigour and bravery, that he obliged them to desist from their pursuit.

However, as the army had suffered such loss before as not to be able to pursue them in their turn, he was obliged to return with them to Thebes, with their pusillanimous generals; where the latter were fined 12,000 drachms each, and the former was reinstated in the command, and sent with a new reinforcement to repair the late dishonour, and prosecute their revenge. The news of his being in full march on this errand greatly alarmed the tyrant; but Epaminondas, preferring the safety of his imprisoned colleague to all other considerations, forbore pushing hostilities to extremes, for fear of provoking the enemy to wreak all his fury on him: to prevent which, he contented himself for a while hovering about with his army, and now and then with such slight skirmishes as should intimidate the tyrant, and bring him the sooner to make some satisfactory offers. Alexander
25 Rescues Pelopidas. being fully convinced of the superiority of the Theban general, was glad to accept of a truce of 30 days, and to restore Pelopidas and Ismenias to him; upon which he immediately withdrew his forces, and returned with them to Thebes.

By this time Thebes was raised to a sufficient height of reputation and glory to begin to aim in earnest at the sovereignty of Greece. The main obstacle to it was, that the other states grew so jealous of her present greatness, as to enter into the strongest alliances and confederacies to prevent its farther growth; so that not being able now to procure many allies at home, they made no difficulty to seek for them abroad; and the Lacedæmonians, by leading the van, gave them a plausible pretence to follow their steps, and procure an alliance with Persia, which at that time they found was ready to accept of the offers on any terms; the only question was, which of the three states should be preferred, Sparta, Athens, or Thebes. At the same time, the Thebans proposed to their new confederates to send likewise proper deputies to the Persian court, in order to support
26 Success of Pelopidas at the Persian court. their respective interests; which they readily agreed to. These were the Arcadians, Eleans, and Argives; at the head of whose deputation Pelopidas was sent on the behalf of the Thebans; which the Athenians being apprised of, appointed two on their part. These being all arrived at the Persian court, began to pursue each their respective interests; but Pelopidas had by that time gained such credit there, both for his singular address and his extraordinary exploits, that he was distinguished in a particular manner from all the other deputies, and was received by the king with manifest marks of honour and esteem, who freely owned himself convinced that the Thebans were the people on whom he could most safely depend; and after having greatly applauded the equity of his demands, ratified and confirmed them with great readiness, to the no small mortification of the other states. The substance of them was, that the liberties formerly granted to the other towns of Greece should be confirmed, that Messenia, in particular, should continue free and independent on the jurisdiction of Sparta; that the Athenians should lay up their fleet; and that the Thebans should be looked upon as the ancient and hereditary friends of Persia.

The Thebans took advantage of the dissensions which prevailed among the Greeks as a pretence for increasing their forces; and Epaminondas thought it a proper opportunity for his countrymen to make a bold effort to obtain the dominion at sea, as they had obtained it in a great measure at land. He proposed it to them in a public assembly, and encouraged their hopes from the experience of the Lacedæmonians, who in Xerxes's time had, with ten ships only at sea, gained the superiority over the Athenians, who had no fewer than 200; and added, that it would be a disgrace now to Thebes to suffer two such republics to engross the empire of so extensive an element, without putting in at least for their share of it. The people readily came into his proposal, not without extraordinary applause, and immediately ordered 100 galleys to be equipped; and in the mean while sent him to Rhodes, Chios, and Byzantium, to secure those states in their interest, and get what assistance he could from them. His negociations had all the success that could be wished for, notwithstanding the strenuous opposition of the Athenians, and of their admiral Laches, who was sent with a powerful squadron against him. But what more effectually thwarted all his measures, was the work that they found for him at land, and the obliging the Thebans to take part in the quarrels that then reigned among their neighbours: so that whatever projects they had concerted, proved abortive for the present; and the death of Epaminondas, which happened not long after, put an effectual stop to them. Thebes. 27 The Thebans propose to build a fleet.

During the absence of that general, and of his colleague Pelopidas, the Orchomenians, being spirited up by some Theban fugitives, had formed a design to change the Theban government into an aristocracy; and 300 horsemen of the former had been actually sent to put it in execution. Their project, however, was timely discovered by the vigilance of the magistrates, who caused them to be seized, and put immediately to death. They next sent a sufficient force against the city of Orchomenos, with orders to put all the men to death, and to sell the women and children for slaves, which was punctually done; after which they razed that noble city to the ground. Pelopidas was then on his way to Thessaly, at the head of a powerful army, whither he had been sent to assist the Thessalians, who still groaned under the tyranny of Alexander the Pheræan, and had made several brave efforts to recover their liberty, but had been still overpowered by that usurper. Being joined by the Thessalians, he encamped in the face of the enemy, though far superior in number, and consisting of above 20,000 men. A fierce engagement soon ensued, in which both sides fought with uncommon bravery. The place where the battle was fought was called *Cynocephala*, from several little hills on it, between which there ran a large plain. Both sides endeavoured at first to post themselves on these eminences with their foot, whilst Pelopidas ordered his cavalry to charge that of the enemy below; which they did with such success, that they soon put them to the rout, and pursued them over the plain. This obliged the tyrant to gain the tops of the hills, where he greatly 28 The city of Orchomenos razed. 29 Pelopidas marches against the Thessalian tyrant.

Thebes. greatly annoyed the Thessalians that endeavoured to force those ascents; so that Pelopidas was obliged to give over his pursuit to come to their relief. This immediately inspired the Thessalians with fresh courage, who began again to charge the enemy at several onsets; and soon threw them into such disorder, that they were forced to give way. Pelopidas no sooner perceived the advantage, than he began to look about for Alexander, with a design of engaging him. Having found him out as he was commanding his right wing, and endeavouring to rally his men, he moved directly to him; and being got near enough to be heard by him, challenged him to decide the battle by single combat with him. Alexander, instead of accepting the offer, turned about, and with all the speed he could ran to screen himself amongst his guards. Upon this Pelopidas charged him with such furious speed, that he obliged him to retire farther, and shelter himself within the thickest ranks; the sight of which made him attack with fresh vigour, and fight more desperately against him. He tried in vain several times to break through their ranks to reach him, cutting down great numbers of those that came forward to oppose him: his eagerness at length exposed him so far to the darts that were shot at him at a distance, that some of them went quite through his armour, and gave him a desperate wound or two, while the rest advanced and stabbed him in the breast with their spears.

30 Is killed.

It is scarcely possible for words to express the grief and despair which not only his brave Thebans, but likewise the Thessalians and other allies, showed at the sight of their slain general: some of the latter, who had perceived the danger he was exposed to, came down the hill with all possible speed to his relief; but when they perceived that they were come too late to save him, both they and the rest of the little army thought on nothing now but to revenge his death. They rallied accordingly both horse and foot, as quick as possible, and began to charge the enemy afresh, and with such desperate fury, that they at length gained a complete victory over them, and killed above 3000 of them in the pursuit, besides a much greater number which they had slain on the field of battle, though they still looked upon all these advantages as vastly too small to compensate the loss of their brave general.

31 Alexander defeated,

The news of his death had no sooner reached Thebes, than the whole city was seen in as deep a mourning as his army. However, they sent a reinforcement to it of 7000 foot and 700 horse, as well to revenge the death of that general, as to improve the victory he had gained over the enemy; by the help of which they fell so furiously on them, that they quickly broke and totally defeated the shattered remains of Alexander's army. Hereupon he was forced to sue for peace, and to accept it on such conditions as the conquerors thought fit to impose. He was at length dispatched in his bed by his wife Thebe, assisted by her brothers, about seven years after his defeat. His body was afterwards dragged along the streets, trodden under foot, and left a prey to the dogs.

32 and at last murdered.

33 Ambition of the Thebans.

All this while the Thebans were watching to improve every commotion that happened, every success they met with, to the forwarding of their then reigning and favourite project, of increasing their power above all the rest, and in their turn to give laws to Greece. Their late success in Thessaly, and the rupture between the Arcadians and Mantineans at the same time, about some consecrated money which the former had taken out of the temple of Olympias to pay their troops employed against the Eleans, and which the latter called a downright sacrilege, besides other discords that reigned in the other states of Greece, gave fresh encouragement to Thebes to set up for arbitress in those disputes; and so much the more, as those who had embezzled the sacred money, and wanted rather to embroil matters than to have them brought to light, sent that republic word that the Arcadians were just upon the point of revolting to the Spartans, and advised them to come and put an immediate stop to it. At the same time they dispatched some private directions to a Theban officer at Tegea, to apprehend several of their own people as disturbers of the peace. This was accordingly done, and several eminent persons were confined as prisoners of state: they were soon after discharged, and loud complaints were made against such arbitrary and unjust proceedings. The officer was accused before the Theban senate of having intermeddled in their affairs, and endeavoured to interrupt the good correspondence between the two states. It was even insisted on by some of the Tegeans, that he should be indicted and proceeded against by his principals; whilst the more moderate sort, who foresaw the consequences that were likely to attend such appeals, and that it would infallibly bring the Thebans upon them, loudly protested against their marching into their territories, and did all they could to prevent it. The Thebans, however, were become too powerful and ambitious to miss so fair an opportunity of getting once more footing in Peloponnesus, as they had long ago premeditated; and Epaminondas was so far from making a secret of their design, that he told the Arcadian deputies in justification of it, that as it was on their account that the Thebans engaged in the war, they had acted treacherously with them in making peace with Athens without their consent: however, that when he had joined his army on his march into Peloponnesus to assist his friends, he would soon see what proofs the Arcadians would give of their fidelity. This speech did not fail to alarm them greatly; especially as it was spoken in such a magisterial style and threatening tone. Even those who were best affected to the Thebans could not forbear expressing their dislike of it; and all that had the welfare of Peloponnesus at heart readily agreed with the Mantineans, that there was no time to be lost to use all proper means to prevent the impending storm.

34 Epaminondas displeases the states of Greece.

Athens and Sparta were accordingly applied to, and were easily prevailed upon to assist the Mantineans, and to come into a strict confederacy against the Thebans; and to prevent all disputes about the command of the army, it was agreed that each state should have it in its own territories; which plainly shows how terrified they all were at the apprehension of a fresh invasion of the Thebans: for this was a point which neither the Spartans nor Athenians would have so readily given up to the Arcadians, though these had formerly as strenuously insisted upon it, even when they were almost reduced to the last extremity, and had never been able to obtain it till now. But Epaminondas was then in full march at the head of his Bœotian troops, with some Eubœan auxiliaries, and a body of stout Thessalian horse; and was moreover to be joined by the Messenians, Argives, and several

35 A combination against Thebes.

Thebes.

several other nations, as soon as he had entered Peloponnesus. The confederate army against him had ordered their rendezvous at Mantinea, the place which they naturally concluded would be first attacked, as being the chief seat of those who had revolted from the Thebans. But whilst they were securing themselves on that side, Epaminondas, who wisely considered how far this confederacy and expedition must have drained the city of Sparta of its main strength, broke up privately from Nemæa, where he had lain for some time encamped, and marched all that night with a design to have surprised that important capital: but, his project being timely discovered, the vigilant king took care to disconcert it; so that, though the Theban general made several vigorous assaults on that city, he was so stoutly repulsed, and the Spartans behaved with such intrepid valour, that he was forced to retire and turn his thoughts against Mantinea, which he judged by this time to have been quite defenceless. He judged rightly indeed; for the place was not only drained of its troops, but likewise of its inhabitants, who took that opportunity, whilst the scene of war was in Lacedæmon, to gather in their harvest, and were scattered all over the country; so that he would not have met with any difficulty in gaining the town, had not the Athenian auxiliaries come unexpectedly to its relief, and given him a fresh repulse.

36 Epaminondas makes an unsuccessful attempt on Sparta,

37 and on Mantinea.

These two last defeats greatly exasperated the Theban general, who had never before experienced such disasters, and could not but foresee that they would not only lessen his reputation with his allies, but, if not timely retrieved, would sully the glory of all his former exploits. What added to his present difficulties was, that the time allotted him for his expedition was almost expired; so that he had but a short space left to undertake some brave achievement, which might recover his and his country's honour, and keep up the spirits of his auxiliaries, and those under his protection. He was moreover got very far into his enemy's country, and saw plain enough how narrowly they watched all his motions, and how well prepared they were to oppose him whatever attempt he resolved upon, whether to attack them or to retreat. Under all these difficulties, he rightly considered, that he must immediately resolve upon a decisive battle; in which, if his pristine fortune followed him, he might at once retrieve his affairs, and make himself master of Peloponnesus; or, if that failed him, as it lately had done, fall honourably in the attempt. In this engagement Epaminondas made the wisest disposition of his troops, attacked and fought with the most intrepid courage and conduct, and had opened himself a way through the Spartan phalanxes, thrown them into the utmost confusion, and made a terrible slaughter of them, insomuch that the field of battle was covered with their wounded and slain, when, in the heat of the fight, having ventured himself too far in order to give them a total overthrow, the enemy rallied again, pouring with their whole fury three volleys of darts at him, some of which he drew out and returned to them, till at length, being covered with wounds, and weakened with the loss of so much blood, he received a mortal wound from a javelin, and was with great difficulty rescued from the enemy by his brave Thebans, and brought alive, though speechless, into his tent. As soon as he had recovered himself, he asked his friends that were about him what was become of his shield; and being told that it was safe, he beckoned to have it brought to him, and kissed it. He next inquired which side had gained the victory; and being answered, The Thebans; he replied, Then all is well: and upon observing some of his friends bewail his untimely death, and leaving no children behind him, he is said to have answered, Yes; I have left two fair daughters, the victory of Leuctra, and this of Mantinea, to perpetuate my memory. Soon after this, upon drawing the point of the javelin out of his body, he expired.

38 Battle of Mantinea.

39 Epaminondas killed.

The consequence of this great general's fall, and of this bloody fight in which neither party could boast any great advantage over the other, but a great loss of men on both sides, insomuch that Xenophon makes it a drawn battle, was, that both parties agreed on a cessation of arms, and parted, as it were by consent, to take care of their wounded and slain. The Thebans indeed thus far gained the greater share of glory, that they renewed the fight, and after a most desperate contest, gained the victory over those Spartans that opposed them, and rescued the body of their dying general out of their hands. However, an effectual end was put to this bloody war, and a general peace agreed on by all but Sparta; who refused it only because the Messenians were included in it. But as to the Thebans, they had no great reason to boast of this dear-bought victory, since their power and glory began to decline from that very time; so that it may be truly said, that it rose and set with their great general. 40

40 Peace concluded.

On the death of Epaminondas, the Thebans relapsed into their former state of inactivity and indolence; and at last having ventured to oppose Alexander the Great, their city was taken, and the inhabitants slaughtered for several hours, after which the buildings were destroyed. It was rebuilt by Casander, but never afterwards made any considerable figure among the states of Greece. About the year 146 B. C. it fell under the power of the Romans, under which it continued till the extinction of their empire by the Turks. It is now called *Thive*, and, according to Dr Clarke, is about two and a half English miles in circumference. It contains about 300 houses, and many interesting antiquities. The present population live chiefly within what was anciently the citadel. The circuit of the walls can yet be traced, and many parts of them are still standing. There are two mosques in Thebes, and a great many Greek churches. It is seated between two small rivers, at the south-west side of a large plain, in E. Long. 23. 40. N. Lat. 38. 17.

41 State of Thebes to the present time.

THEBES, in Egypt, one of the most renowned cities of the ancient world. It was also called *Diospolis*, or the city of Jupiter, and was built, according to some, by Osiris, according to others by Busiris. Its length, in Strabo's time, was 80 furlongs, or ten miles; but this was nothing in comparison of its ancient extent, before it was ruined by Cambyses, which, we are told was no less than 420 stadia, or 52 miles and an half. The wealth of this city was so great, that, after it had been plundered by the Persians, what was found, on burning the remains of the pillage, amounted to above 300 talents of gold and 2300 of silver.

Ancient Universal History, vol. i.

Mr Bruce visited the ruins of this celebrated city; but informs us that nothing now remains except four temples, and these neither so entire nor magnificent as some others at a place called *Dendera*. Thebes has been

Thebes, Theft. been celebrated by Homer for its hundred gates; but Mr Bruce informs us, that no vestiges of these are now remaining, neither can we discover the foundation of any wall it ever had; "and as for the horsemen and chariots it is said to have sent out, all the Thebaid sown with wheat would not have maintained one half of them. Thebes, at least the ruins of the temples called *Medinet Tabu*, are built in a long stretch of about a mile broad, most parsimoniously chosen at the sandy foot of the mountains. The *Horti Pensiles*, or hanging gardens, were surely formed upon the sides of these hills, then supplied with water by mechanical devices. The utmost is done to spare the plain, and with great reason; for all the space of ground this ancient city has had to maintain its myriads of horses and men, is a plain of three quarters of a mile broad between the town and the river, upon which plain the water rises to the height of four and five feet. All this pretended populousness of ancient Thebes I therefore believe to be fabulous."

Bruce's Travels.

Mr Bruce, after examining the ground on which Thebes is supposed to have stood, thinks that it had no walls, and that consequently Homer's story of its having an hundred gates is misunderstood. The mountains of the Thebaid stand close behind the town, not in a ridge, but standing single, so that you can go round each of them. A hundred of these are said to be hollowed out for sepulchres and other purposes. These, he thinks, were the hundred gates of Homer; in proof of this they are still called by the natives *Beeban el Meluke*, "the ports or gates of the kings."

All that is said of Thebes by poets or historians after the days of Homer is meant of Diospolis, which was built by the Greeks long after Thebes was destroyed, as its name testifies; though Diodorus says it was built by Busiris. It was on the east side of the Nile, whereas ancient Thebes was on the west, though both are considered as one city. Splendid descriptions of the antiquities of Thebes were published in 1802 by Denon, and several additions have been made by late travellers.

THEFT, or Simple Larceny, is "the felonious taking and carrying away of the personal goods of another." This offence certainly commenced then, whenever it was, that the bounds of property, or laws of *meum* and *tuum*, were established. How far such an offence can exist in a state of nature, where all things are held to be common, is a question that may be solved with very little difficulty. The disturbance of any individual in the occupation of what he has seized to his present use, seems to be the only offence of this kind incident to such a state. But, unquestionably, in social communities, when property is established, any violation of that property is subject to be punished by the laws of society; though how far that punishment should extend is matter of considerable doubt.

By the Jewish law it was only punished with a pecuniary fine, and satisfaction to the party injured; and, in the civil law, till some very late constitutions, we never find the punishment capital. The laws of Draco at Athens punished it with death: but his laws were said to be written with blood; and Solon afterwards changed the penalty to a pecuniary mulct. And so the Attic law in general continued; except that once, in a time of dearth, it was made capital to break into a garden and steal figs: but this law, and the informers against the offence, grew so odious, that from them all malicious informers were styled *sycophants*; a name which we have much perverted from its original meaning. From these examples, as well as the reason of the thing, many learned and scrupulous men have questioned the propriety, if not lawfulness, of inflicting capital punishment for simple theft. And certainly the natural punishment for injuries to property seems to be the loss of the offender's own property; which ought to be universally the case, were all men's fortunes equal. But as those who have no property themselves are generally the most ready to attack the property of others, it has been found necessary, instead of a pecuniary, to substitute a corporal punishment; yet how far this corporal punishment ought to extend, is what has occasioned the doubt. Sir Thomas More and the Marquis Beccaria, at the distance of more than two centuries, have very sensibly proposed that kind of corporal punishment which approaches the nearest to a pecuniary satisfaction, viz. a temporary imprisonment, with an obligation to labour, first for the party robbed, and afterwards for the public, in works of the most slavish kind; in order to oblige the offender to repair, by his industry and diligence, the depredations he had committed upon private property and public order. But, notwithstanding all the remonstrances of speculative politicians and moralists, the punishment of theft still continues throughout the greatest part of Europe to be capital: and Puffendorf, together with Sir Matthew Hale, are of opinion that this must always be referred to the prudence of the legislature: who are to judge, say they, when crimes are become so enormous as to require such sanguinary restrictions. Yet both these writers agree, that such punishment should be cautiously inflicted, and never without the utmost necessity.

The Anglo-Saxon laws nominally punished theft with death, if above the value of twelvepence: but the criminal was permitted to redeem his life by a pecuniary ransom; as, among their ancestors the Germans, by a stated number of cattle. But in the 9th year of Henry I. this power of redemption was taken away, and all persons guilty of larceny above the value of twelvepence were directed to be hanged; which law continues in force to this day. For though the inferior species of theft, or petit larceny, is only punished by whipping at common law, or (by stat. 4 Geo. I. c. 11.) may be extended to transportation for seven years, as is also expressly directed in the case of the Plate-glass Company; yet the punishment of grand larceny, or the stealing above the value of twelvepence (which sum was the standard in the time of King Athelstan, 800 years ago), is at common law regularly death: which, considering the great intermediate alteration in the price or denomination of money, is undoubtedly a very rigorous constitution: and made Sir Henry Spelman (above a century since, when money was at twice its present rate) complain, that while every thing else was risen in its nominal value, and become dearer, the life of man had continually grown cheaper. It is true, that the mercy of juries will often make them strain a point, and bring in larceny to be under the value of twelvepence, when it is really of much greater value: but this, though evidently justifiable and proper when it only reduces the present nominal value of money to the ancient standard, is otherwise a kind of pious perjury, and does not at all excuse our common law in this respect from the imputation of severity,

verity, but rather strongly confesses the charge. It is likewise true, that by the merciful extensions of the benefit of clergy by our modern statute-law, a person who commits a simple larceny to the value of thirteen pence or thirteen hundred pounds, though guilty of a capital offence, shall be excused the pains of death; but this is only for the first offence. And in many cases of simple larceny the benefit of clergy is taken away by statute: as from horse-stealing in the principals and accessories both *before* and *after* the fact; theft by great and notorious thieves in Northumberland and Cumberland; taking woollen cloth from off the tenters, or linens, fustians, calicoes, or cotton goods, from the place of manufacture (which extends, in the last case, to aiders, assisters, procurers, buyers, and receivers); feloniously driving away, or otherwise stealing one or more sheep or other cattle specified in the acts, or killing them with intent to steal the whole or any part of the carcase, or aiding or assisting therein; thefts on navigable rivers above the value of forty shillings, or being present, aiding and assisting thereat; plundering vessels, in distress, or that have suffered shipwreck; stealing letters sent by the post; and also stealing deer, hares, and conies, under the peculiar circumstances mentioned in the Waltham black act. Which additional severity is owing to the great malice and mischief of the theft in some of these instances; and in others, to the difficulties men would otherwise lie under to preserve those goods, which are so easily carried off. Upon which last principle the Roman law punished more severely than other thieves the *Abigei* or stealers of cattle, and the *Balnearii* or such as stole the clothes of persons who were washing in the public baths; both which constitutions seem to be borrowed from the laws of Athens. And so, too, the ancient Goths punished with unrelenting severity thefts of cattle, or of corn that was reaped and left in the field: such kind of property (which no human industry can sufficiently guard) being esteemed under the peculiar custody of heaven.

Theft-Bote (from the Saxon *theof*, i. e. *fur*, and *bote*, *compensatio*), is the receiving of a man's goods again from a thief, after stolen, or other amends not to prosecute the felon, and to the intent the thief may escape; which is an offence punishable with fine and imprisonment, &c.

THELIGONUM, a genus of plants belonging to the class monœcia, and order of polyandria; and in the natural system ranging under the 53d order, *Scabridæ*. See Botany *Index*.

THEME, denotes the subject of an exercise for young students to write or compose on.

THEMISON, a physician of Laodicea, a disciple of Asclepiades. He founded the methodic sect, with a view to the more easily teaching and practising the art of medicine. (See Medicine, N° 37.). Themison gave the first account of diacodium, which was prepared of the juice and decoction of poppy-heads and honey.

THEMISTIUS, an ancient Greek orator and philosopher who flourished in the 4th century, was a native of Paphlagonia. He had great interest and favour with the emperors in his time, and though a heathen, was of a very tolerating spirit. He taught for many years at Constantinople, of which city he was made præfect by Julian and Theodosius; and lived to a great age. More than 30 of his orations are still extant, beside commentaries on several parts of Aristotle's works.

THEMISTOCLES, the renowned Athenian admiral, general, and patriot, who gained the battle of Salamis against the Persians. Being banished his country by his ungrateful fellow-citizens, he fled to Artaxerxes king of Persia: but, in order to avoid taking up arms against his country, he slew himself, 464 B. C. See Attica, N° 76, *et seq.*

THEOBALD, Lewis, the son of an attorney at Sittingbourn in Kent, was a well-known writer and critic in the early part of the 18th century. He engaged in a paper called the *Censor*, published in Mist's Journal, wherein, by delivering his opinions with too little reserve concerning some eminent wits, he exposed himself to their resentment. Upon the publication of Pope's Homer, he praised it in terms of extravagant admiration, yet afterwards thought proper to abuse it as earnestly; for which Pope at first made him the hero of his Dunciad, though he afterwards laid him aside for another. Mr Theobald not only exposed himself to the lashes of Pope, but waged war with Mr Dennis, who treated him more roughly, though with less satire. He nevertheless published an edition of Shakespeare, in which he corrected, with great pains and ingenuity, many faults that had crept into that poet's writings. This edition is still in great esteem; being in general preferred to those published by Pope, Warburton, and Hanmer. He also wrote some plays, and translated others from the ancients.

THEOBROMA, a genus of plants belonging to the class of polyadelphia, and order of pentandria; and in the natural system ranging under the 37th order, *Columniferæ*. See Botany *Index*.

THEOCRACY, in matters of government, a state governed by the immediate direction of God alone: such was the ancient government of the Jews before the time of Saul.

THEOCRITUS, the father of pastoral poetry, was born at Syracuse in Sicily. Two of his poems ascertain his age; one addressed to Hiero king of Syracuse, who began his reign about 275 years before Christ; and the other to Ptolemy Philadelphus king of Egypt. Hiero, though a prince distinguished in arms and political wisdom, does not seem to have been a patron of learning. This is supposed to have given birth to the 16th Idyllium. From Syracuse Theocritus went to Alexandria, where he seems to have found a munificent patron in Ptolemy Philadelphus, if we may judge from the panegyric which he composed on that prince (the 17th Idyllium). It has been said that Theocritus was strangled by Hiero, but we have not found evidence of this.

The compositions of this poet are distinguished, among the ancients, by the name of *Idylliums*, in order to express the smallness and variety of their natures: they would now be called *Miscellanies*, or *Poems on several Occasions*. The first nine and the eleventh are confessed to be true pastorals, and hence Theocritus has usually passed for nothing more than a pastoral poet; yet he is manifestly robbed of a great part of his fame, if his other poems have not their proper laurels. For though the greater part of his Idylliums cannot be called the songs of shepherds, yet they have certainly their respective merits. His pastorals ought to be considered as the foundation of his credit; upon this claim he will be admitted for the finisher as well as the inventor of his art, and will be acknowledged to have excelled all his imitators as much as originals usually do their copies.

The

The works of this poet were first published in folio by Aldus Manutius at Venice in 1495. A more elegant and correct edition was printed by Henry Stephens at Paris in 1566. An edition was published at Leipsic in 1765, with valuable notes by the learned Reiske. But what will most highly gratify the admirers of pastoral poetry, is an edition published in 1770, 2 vols. 4to, by Mr Thomas Wharton. It is accompanied by the scholia of the best editors, and the different readings of 15 MSS.

THEODOLITE, a mathematical instrument for measuring heights and distances. See MENSURATION and SURVEYING.

THEODORE, king of Corsica, Baron Nieuhoff in the county of La Marc in Westphalia. He had his education in the French service, and afterwards went to Spain, where he received some marks of regard from the duke of Riperda and Cardinal Alberoni; but being of an unsettled disposition, he quited Spain, and travelled into Italy, England, and Holland, in search of new adventures. He at last fixed his attention on Corsica, and formed the scheme of rendering himself sovereign of that island. He was a man of abilities and address; and having fully informed himself of every thing relating to Corsica, went to Tunis, where he fell upon means to procure some money and arms; and then went to Leghorn, from whence he wrote a letter to the Corsican chiefs Giafferi and Paoli, offering considerable assistance to the nation if they would elect him as their sovereign. This letter was consigned to Count Domenico Rivarola, who acted as Corsican plenipotentiary in Tuscany, and he gave for answer, that if Theodore brought the assistance he promised to the Corsicans, they would very willingly make him king.

Upon this he, without loss of time, set sail, and landed at Tavagna in the spring of the year 1736. He was a man of a very stately appearance, and the Turkish dress he wore added to the dignity of his mien. He had a few attendants with him; and his manners were so engaging, and his offers so plausible, that he was proclaimed king of Corsica before Count Rivarola's dispatches arrived to inform the chiefs of the terms upon which he had agreed. He brought with him about 1000 zequins of Tunis, besides some arms and ammunition, and made magnificent promises of foreign assistance; whence the Corsicans, who were glad of any support, willingly gave into his schemes. Theodore instantly assumed every mark of royal dignity. He had his guards and his officers of state; he conferred titles of honour, and struck money both of silver and copper. The silver pieces were few in number, and can now hardly be met with; the copper coins have on one side T. R. that is, "Theodorus Rex," with a double branch crossed, and round it this inscription, PRO BONO PUBLICO RE. CO. that is, "For the public good of the kingdom of Corsica: on the other side is the value of the piece; *Cinque solidi*, or five sous.

The Genoese were not a little confounded with this unexpected adventurer. They published a violent manifesto against Theodore, treating him with great contempt; but at the same time showing they were alarmed at his appearance. Theodore replied in a manifesto, with all the calmness and dignity of a monarch; but after being about eight months in Corsica, perceiving that the people began to cool in their affections towards him, he assembled his chiefs, and declared he would keep them no longer in a state of uncertainty, being determined to seek in person the support he so long expected. He settled an administration during his absence, recommended unity in the strongest terms, and left the island with reciprocal assurances of fidelity and affection. He went to Holland, where he was so successful as to obtain credit from several rich merchants, particularly Jews, who trusted him with cannon and other warlike stores to a great value, under the charge of a supercargo. With these he returned to Corsica in 1739; but by this time the French, as auxiliaries to the Genoese, had become so powerful in the island, that though Theodore threw in his supply of warlike stores, he did not incline to venture his person, the Genoese having set a high price on his head. He therefore again departed; and after many unavailing attempts to recover his crown, at length chose for retirement a country where he might enjoy the participation of that liberty which he had so vainly endeavoured to give his Corsicans; but his situation in England by degrees grew wretched, and he was reduced so low as to be several years before his death a prisoner for debt in the King's Bench. At length, to the honour of some gentlemen of rank, a charitable contribution was set on foot for him in the year 1753. Mr Boswell observes, that Mr Horace Walpole generously exerted himself for the unhappy Theodore, and wrote a paper in *The World* with great elegance and humour, soliciting a contribution for the unhappy monarch in distress, to be paid to Mr Robert Dodsley bookseller, as lord high treasurer. This brought him a very handsome sum, and he was set at liberty. That gentleman adds, that Mr Walpole has the original deed, by which Theodore made over the kingdom of Corsica in security to his creditors, and that he has also the great seal of the kingdom. Theodore died in 1756, and was buried in St Ann's churchyard, Westminster; where, in 1757, a simple unadorned monument of marble was erected to his memory by a gentleman, with an inscription, which, after mentioning some of the above particulars, concludes with the following lines:

> The grave, great teacher, to a level brings
> Heroes and beggars, galley-slaves and kings:
> But Theodore this moral learn'd ere dead,
> Fate pour'd its lesson on his living head,
> Bestow'd a kingdom and deny'd him bread.

THEODORET, bishop of St Cyricus in Syria, in the 4th century, and one of the most learned fathers of the church, was born in the year 386, and was the disciple of Theodorus Mopsuestia and St John Chrysostom. Having received holy orders, he was with difficulty persuaded to accept of the bishopric of St Cyricus, about the year 420. He discovered great frugality in the expences of his table, dress, and furniture, but spent considerable sums in improving and adorning the city of Cyricus. He erected two large bridges, public baths, fountains, and aqueducts, and laboured with great zeal and success in his diocese. Yet his zeal was not confined to his own church: he went to preach at Antioch and the neighbouring towns; where he became admired for his eloquence and learning, and had the happiness to convert multitudes of people. He wrote in favour of John of Antioch and the Nestorians, against Cyril's Twelve Anathemas: he afterwards attacked the opinions of Nestorius, and was deposed in the synod held by the Eutychians,

Eutychians at Ephesus; but was again restored by the general council of Chalcedon, in which he was present, in 451. It is thought that he died soon after; though others say that he lived till the year 457. There are still extant Theodoret's excellent Commentary on St Paul's Epistles, and on several other books of the Holy Scriptures. 2. His Ecclesiastical History from the time of Arius to Theodosius the Younger. 3. The History of the famous Anchorites of his time. 4. Epistles. 5. Discourses on Providence. And, 6. An excellent treatise against the Pagans, entitled, *De Curandis Græcorum Affectibus*; and other works. The best edition of all which is that of Father Sirmond in Greek and Latin, in 4 vols folio.

THEODOSIUS I. called the *Great*, was a native of Spain. The valour he had shown, and the great services he had done to the empire, made Gratian, when attacked by the Goths and Germans, to admit him as a partner in the government. He received the purple in 379, aged 43. See CONSTANTINOPLE, N° 77—88.

THEOGONY, from Θεος, *God*, and γονη, "seed, offspring," that branch of the heathen theology, which taught the genealogy of their gods.

Hesiod gives us the ancient theogony in a poem under that title. Among the most ancient writers, Dr Burne observes that theogony and cosmogony signified the same thing. In effect, the generation of the gods of the ancient Persians, fire, water, and earth, is apparently no other than that of the primary elements.

THEOGNIS, an ancient Greek poet of Megara in Achaia, flourished about the 59th Olympiad, 144 B. C. We have a moral work of his extant, containing a summary of precepts and reflections, usually found in the collections of the Greek minor poets.

THEOLOGY

1 Definition. IS a Greek word (θεολογια), and signifies that science which treats of the being and attributes of God, his relations to us, the dispensations of his providence, his will with respect to our actions, and his purposes with respect to our end. The word was first used to denote the fables of those poets and philosophers who wrote of the genealogy and exploits of the gods of Greece. It was afterwards adopted by the earliest writers of the Christian church, who styled the author of the Apocalypse, by way of eminence, ὁ θεολογος, *the Divine*.

Although every pagan nation of antiquity had some tutelary deities peculiar to itself, they may yet be considered as having all had the same theology, since an intercommunity of gods was universally admitted, and the heavenly bodies were adored as the *dii majorum gentium* over the whole earth. This being the case, we are happily relieved from treating, in the same article, of the truths of Christianity and the fictions of paganism, as we have elsewhere traced idolatry from its source, and shown by what means "the foolish hearts of men became so darkened that they changed the glory of the incorruptible God into an image made like to corruptible man, and to birds, and four-footed beasts, and creeping things." See POLYTHEISM.

The absurdities and inconsistency of the pretended revelation of the Arabian impostor have been sufficiently exposed under the words ALCORAN and MAHOMETANISM; so that the only theology of which we have to

2 Christian theology, treat at present is the *Christian* theology, which comprehends that which is commonly called *natural*, and that which is *revealed* in the scriptures of the Old and New Testaments. These taken together compose a body of science so important, that in comparison with it all other sciences sink into insignificance; for without a competent knowledge of the attributes of God, of the several relations in which he stands to us, and of the ends for which we were created, it is obvious that we must wander through life like men groping in the dark, strangers to the road on which we are travelling, as well as to the fate awaiting us at the end of our journey.

But if this knowledge be necessary to all Christians, it is doubly so to those who are appointed to feed the flock of Christ, and to teach the ignorant what they are to believe, and what to do, in order to work out their own salvation. The wisdom and piety of our ancestors have accordingly founded professorships of theology in all our universities, where the principles of our religion are taught in a systematic and scientific manner; and the church has ordained, that no man shall be admitted to the office of a preacher of the gospel who has not attended a regular course of such theological lectures. 3 to be studied carefully by those intended for the service of the church.

It must not, however, be supposed, that, by merely listening to a course of lectures however able, any man will become an accomplished divine. The principles of this science are to be found only in the word and works of God; and he who would extract them pure and unsophisticated, must dig for them himself in that exhaustless mine. To fit a man for this important investigation, much previous knowledge is requisite. He must study the works of God scientifically before he can perceive the full force of that testimony which they bear to the power, the wisdom, and the goodness of their author. Hence the necessity of a general acquaintance with the physical and mathematical sciences before a man enter on the proper study of theology, for he will not otherwise obtain just and enlarged conceptions of the God of the universe. See PHYSICS, N° 115. 4 Previous knowledge requisite for the prosecution of this study.

But an acquaintance with the physical and mathematical sciences is not alone a sufficient preparation for the study of theology. Indeed it is possible for a man to devote himself so wholly to any of these sciences, as to make it counteract the only purposes for which it can be valuable to the divine; for he who is constantly immersed in matter, is apt to suspect that there is no other substance; and he who is habituated to the routine of geometrical demonstration, becomes in time incapable of reasoning at large, and estimating the force of the various degrees of moral evidence. To avert these disagreeable consequences, every man, before he enters on the study of that science which is the subject of the present article, should make himself acquainted with the principles of logic, the several powers of the human mind, and the different sources of evidence; in doing which he will find the greatest assistance from Bacon's *Novum Organum*, Introduction. *ganum*, Locke's *Essay on the Human Understanding*, Reid's *Essays on the Intellectual and Active Powers of Man*, and Tatham's *Chart and Scale of Truth*. These works will teach him to think justly, and guard him against a thousand errors, which those who have not laid such a foundation are apt to embrace as the truths of God.

The man who proposes to study theology ought to have it in view as the ultimate end of his labours, to impart to others that knowledge which he may procure for himself. "Amongst the many marks which distinguish the *Christian* philosopher from the *Pagan*, this (says a learned writer†) is one of the most striking— the *Pagan* sought knowledge in a selfish way, to secret it for his own use; the *Christian* seeks it with the generous purpose (first in view, though last in execution) to impart it to others. The Pagan philosopher, therefore, having cultivated the *art of thinking*, proceeds to that of *speaking*, in order to display his vanity in the dexterous use of deceit. On the other hand, the *Christian philosopher* cultivates the *art of speaking*, for the sole purpose of disseminating the truth in his office of preacher of the gospel."

† *Warburton.*

As every man, before he enters on the proper study of theology, receives, at least in this country, the rudiments of a liberal education, it may perhaps be superfluous to mention here any books as peculiarly proper to teach him the art of speaking: we cannot however forbear to recommend to our student the attentive perusal of Quintilian's *Institutions*, and Dr Blair's *Lectures on Rhetoric and the Belles Lettres*. A familiar acquaintance with these works will enable him, if he be endowed by nature with talents fit for the office in which he proposes to engage, to express his thoughts with correctness and elegance; "without which, it has been well observed, that science, especially in a clergyman, is but learned lumber, a burden to the owner, and a nuisance to every body else."

No man can proceed thus far in the pursuits of general science without having been at least initiated in the learned languages; but he who intends to make theology his profession should devote himself more particularly to the study of Greek and Hebrew, because in these tongues the original scriptures are written. He who is incapable of consulting the original scriptures, must rest his faith, not on the sure foundation of the word of God, but on the credit of fallible translators; and if he be at any time called on to vindicate revelation against the scoffs of infidelity, he will have to struggle with many difficulties which are easily solved by him who is master of the original tongues.

5
Cautions to be observed in attending the lectures of a professor.

The student having laid in this stock of preparatory knowledge, is now qualified to attend with advantage the theological lectures of a learned professor; but in doing this, he should be very careful neither to admit nor reject any thing on the bare authority of his master. Right principles in theology are of the utmost importance, and can rest on no authority inferior to that of the word of God. On this account we have long been of opinion, that a professor cannot render his pupils so much service by a systematical course of lectures, as by directing their studies, and pointing out the road in which they may themselves arrive in the shortest time at the genuine sense of the sacred scriptures. In this opinion we have the honour to agree with the ablest lecturer ‡ in theology that we have ever heard. The authors of all systems are more or less prejudiced in behalf of some particular and artificial mode of faith. He, therefore, who begins with the study of them, and afterwards proceeds to the sacred volume, sees with a jaundiced eye every text supporting the peculiar tenets of his first master, and acts as absurd a part as he who tries not the gold by the coppel, but the coppel by the gold. Before our young divine, therefore, sit down to the serious perusal of any one of those *institutes* or *bodies of theology* which abound in all languages, and even before he read that which the nature of our work compels us to lay before him, we beg leave to recommend to his consideration the following

‡ *The late Dr Campbell of Aberdeen.*

Preliminary Directions for the Study of Theology.

6
Christian theology divided into two great parts.

Christian theology is divided into two great parts, *natural* and *revealed;* the former comprehending that which may be known of God from the creation of the world, even his eternal power and Godhead; the latter, that which is discovered to man nowhere but in the sacred volume of the Old and New Testaments.

7
First principles of theology communicated.

Concerning the extent of natural theology many opinions have been formed, whilst some have contended that there is no such thing. Into these disputes we mean not at present to enter. We believe that one of them could have had no existence among sober and enlightened men, had the contending parties been at due pains to define with accuracy the terms which they used. Whatever be the origin of religion, which we have endeavoured to ascertain elsewhere (see Religion, N°6—17.), it is obvious, that no man can receive a written book as the word of God till he be convinced by some other means that God exists, and that he is a Being of power, wisdom, and goodness, who watches over the conduct of his creature man. If the progenitor of the human race was instructed in the principles of religion by the Author of his being (a fact of which it is difficult to conceive how a consistent theist can entertain a doubt), he might communicate to his children, by natural means, much of that knowledge which he himself could not have discovered had he not been supernaturally enlightened. Between illustrating or proving a truth which is already talked of, and making a discovery of what is wholly unknown, every one perceives that there is an immense difference (A).

To beings whose natural knowledge originates wholly from

(A) The discriminating powers of Aristotle will not be questioned; and in the following extract made by Cicero from some of his works which are now lost, he expresses our sentiments on this important subject with his usual precision:——"Præclare ergo Aristoteles, SI ESSENT, inquit, qui sub terra semper habitavissent, bonis, et illustribus domiciliis, quæ essent ornata signis atque picturis, instructaque rebus iis omnibus, quibus abundant ii, qui beati putantur, nec tamen exissent unquam supra terram; ACCEPISSENT AUTEM FAMA ET AUDITIONE, ESSE QUODDAM NUMEN,

Preliminary Directions.

from sensation, and whose minds cannot, but by much discipline, advance from sense to science, a long series of revelations might be necessary to give them at first just notions of God and his attributes, and to enable them to perceive the relation between the effect and its cause, so as to infer by the powers of their own reason the existence of the Creator from the presence of his creatures. Such revelations, however, could be satisfactory only to those who immediately received them. Whenever the Deity has been pleased by supernatural means to communicate any information to man, we may be sure that he has taken effectual care to satisfy the person so highly favoured that his understanding was not under the influence of any illusion; but such a person could not communicate to another the knowledge which he had thus received by any other means than an address to his rational faculties. No man can be required to believe, no man indeed can believe, without proof, that another, who has no more faculties either of sensation or intellect than himself, has obtained information from a source to which he has no possible access. An appeal to miracles would in this case serve no purpose; for we must believe in the existence, power, wisdom, and justice of God, before a miracle can be admitted as evidence of any thing but the power of him by whom it is performed. See MIRACLE.

8 to the earliest mortals by repeated revelations;

9 and yet may be properly termed natural principles.

It is therefore undeniable that there are some principles of theology which may be called *natural*; for though it is in the highest degree probable that the parents of mankind received all their theological knowledge by *supernatural* means, it is yet obvious that some parts of that knowledge must have been capable of a proof purely rational, otherwise not a single religious truth could have been conveyed through the succeeding generations of the human race but by the immediate inspiration of each individual. We indeed admit many propositions as certainly true, upon the sole authority of the Jewish and Christian scriptures, and we receive these scriptures with gratitude as the lively oracles of God; but it is self-evident that we could not do either the one or the other, were we not convinced by natural means that God exists, that he is a being of goodness, justice, and power, and that he inspired with divine wisdom the penmen of these sacred volumes. Now, though it is very possible that no man or body of men, left to themselves from infancy in a desert world, would ever have made a theological discovery; yet whatever propositions relating to the being and attributes of the first cause and the duty of man, can be demonstrated by human reason, independent of written revelation, may be called *natural theology*, and are of the utmost importance, as being to us the first principles of all religion. Natural theology, in this sense of the word, is the foundation of the Christian revelation; for without a previous knowledge of it, we could have no evidence that the scriptures of the Old and New Testaments are indeed the word of God.

10 Natural theology to be studied before the doctrines of revelation.

Our young divine, therefore, in the regular order of his studies ought to make himself master of *natural theology* before he enter upon the important task of searching the scriptures. On this subject many books have been published in our own and other languages; but perhaps there is none more worthy of attention than the Religion of Nature delineated, by Mr Wollaston (B). It is a work of great merit, and bears ample testimony to its author's learning and acuteness: yet we think it ought to be read with caution. Mr Wollaston's theory of moral obligation is fanciful and groundless; and whilst we readily acknowledge that he demonstrates many truths with elegance and perspicuity, we cannot deny that he attempts a proof of others, for which we believe no other evidence can be brought than the declarations of Christ and his apostles in the holy scriptures. To supply the defects of his theory of morals, we would recommend to the student an attentive perusal of Cumberland on the Law of Nature, and Paley's Elements of Moral Philosophy. A learned author † affirms of Cumberland, that "he excels all men in fixing the

11 Books recommended.

† *Warburton.*

NUMEN, ET VIM DEORUM; deinde aliquo tempore, patefactis terræ faucibus, ex illis abditis sedibus evadere in hæc loca, quæ nos incolimus, atque exire potuissent: cum repente terram, et maria, cœlumque vidissent: nubium magnitudinem, ventorumque vim cognovissent, adspexissentque solem, ejusque tum magnitudinem, pulchritudinemque, tum etiam efficientiam cognovissent, quod is diem efficeret, toto cœlo luce diffusa: cum autem terras nox opacasset, tum cœlum totum cernerent astris distinctum et ornatum, lunæque luminum varietatem tum crescentis, tum senescentis, eorumque omnium ortus et occasus, atque in omni æternitate ratos, immutabilesque cursus: hæc cum viderent, PROFECTO ET ESSE DEOS, et HÆC TANTA OPERA DEORUM ESSE arbitrarentur." *De Nat. Deorum*, lib. ii. § 37.

From this passage it is evident, that the Stagyrite, though he considered the motions of the heavenly bodies, the ebbing and flowing of the sea, and the other phenomena of nature, as affording a complete *proof* of the being and providence of God, did not however suppose that from these phenomena an untaught barbarian would *discover* this fundamental principle of religion. On the contrary, he expressly affirms, that before a man can feel the force of the evidence which they give of this important truth, he must have HEARD of the existence and power of God.

(B) It may not be improper to inform the reader, that Mr Wollaston, the author of the Religion of Nature, was a different man from Mr Woolston, who blasphemed the miracles of our Saviour. The former was a clergyman of great piety, and of such moderate ambition as to refuse one of the highest preferments in the church of England when it was offered to him; the latter was a clergyman likewise, but remarkable only for gloomy infidelity, and a perverse desire to deprive the wretched of every source of comfort. In the mind of the former, philosophy and devotion were happily united; in the mind of the latter, there was neither devotion nor science. Yet these writers have been frequently confounded; sometimes through inadvertence from the similarity of their names; and sometimes, we are afraid, designedly, from a weak and bigotted abhorrence of every system of religion that pretends to have its foundation in reason and in the nature of things.

Preliminary Directions.

the true grounds of moral obligation, out of which natural law and natural religion both arise;" and we have ourselves never read a work in which the various duties which a man owes to his Maker, himself, and his fellow-creatures, are more accurately stated or placed on a surer basis than in the moral treatise of the archdeacon of Carlisle.

As Wollaston demonstrates with great perspicuity, the being and many of the attributes of God, it may perhaps appear superfluous to recommend any other book on that subject. The present age, however, having among other wonderful phenomena, witnessed a revival of *Atheism*, we would advise our student to read with much attention Cudworth's Intellectual System, and to read it rather in Mosheim's Latin translation than in the author's original English. It is well known that Cudworth wrote his incomparable work in confutation of Hobbes's philosophy; but instead of confining himself to the whimsies of his antagonist, which were in a little time to sink into oblivion, he took a much wider range, and traced atheism through all the mazes of antiquity, exposing the weakness of every argument by which such an absurdity had ever been maintained. In exhausting the metaphysical questions agitated among the Greeks concerning the being and perfections of God, he has not only given us a complete history of ancient learning, as far as it relates to these inquiries, but has in fact anticipated most of the sophisms of our modern atheists, who are by no means such discoverers as they are supposed to be by their illiterate admirers.

The student having made hismself master of natural theology, and carefully endeavoured to ascertain its limits, is now prepared to enter on the important task of searching the scriptures. In doing this, he ought to divest himself as much as possible of the prejudices of education in behalf of a particular system of faith, and sit down to the study of the sacred volume as of a work to which he is an entire stranger. He ought first to read it as a moral history of facts and doctrines, beginning with the books of Moses, and proceeding through the rest, not in the order in which they are commonly published, but in that in which there is reason to believe they were written (see SCRIPTURES). If he be master of the Hebrew and Greek languages, he will doubtless prefer the original text to any version; and in this perusal we would advise him to consult no commentator, because his object at present is not to study the doctrines contained in the bible, but merely to discover what are the subjects of which it treats. Many histories of the bible have been written; and were we acquainted with a good one, we should recommend it as a clue to direct the young divine's progress through the various books which compose the sacred volume. Stackhouse's history has been much applauded by some, and as much censured by others. It is not a work of which we can express any high degree of approbation; but if read with attention, it may no doubt be useful as a guide to the series of facts recorded in the scriptures. Between the Old and New Testaments there is a great chasm in the history of the Jewish nation; but it is supplied in a very able and satisfactory manner by Dr Prideaux, whose *Old and New Testament connected* is one of the most valuable historical works in our own or any other language. Shuckford's *Sacred and Profane History of the World connected* is likewise a work of merit, and may be read with advantage as throwing light on many passages of the Old Testament: but this author is not intitled to the same confidence with Prideaux, as his learning was not so great, and his partialities seem to have been greater.

12
How the scriptures are to be studied.

In thus making himself master of the history of the Old and New Testaments, the student will unavoidably acquire some general notion of the various doctrines which they contain. These it will now be his business to study more particularly, to ascertain the precise meaning of each, and to distinguish such as relate to the whole human race, from those in which Abraham and his posterity were alone interested. He must therefore travel over the sacred volume a second time; and still we would advise him to travel without a guide. From Walton's *Polyglot bible*, and the large collection called *Critici sacri*, he may indeed derive much assistance in his endeavours to ascertain the sense of a difficult text; but we think he will do well to make little use of commentators and expositors, and still less of system-builders, till he has formed some opinions of his own respecting the leading doctrines of the Jewish and Christian religions.

"Impressed (says an able writer) with an awful sense of the importance of the sacred volume, the philosophical divine will shake off the bias of prejudices however formed, of opinions however sanctioned, and of passions however constitutional, and bring to the study of it the advantage of a pure and impartial mind. Instead of wasting all his labour upon a number of minute and less significant particulars, and of refining away plain and obvious sense by the subtleties of a narrow and corrosive mind, his first object will be to institute a theological inquiry into the general design of the written word, and from principles fully contained and fairly understood, to illustrate the true *nature* and *genius of the religious dispensation* in all its parts. He will mark the difference between the first and second covenants, and observe the connection that subsists between them. He will trace the temporary economy of the *Old Testament*, and weigh the nature and intent of the *partial covenant* with the Jews; observing with astonishment how it was made introductory of better things to come: and he will follow it through the *law* and the *prophets* in its wonderful evolutions, till he see this vast and preparatory machine of providence crowned and completed in the eternal gospel. This *New Testament*, the last and best part of the religious dispensation, he will pursue through the sacred pages of that gospel with redoubled attention; contemplating the divine foundation on which it claims to be built, the supernatural *means* by which it was executed, and the immortal end which it has in view†."

In the course of this inquiry into the import of the sacred volume, the student will pay particular attention to the circumstances of the age and country in which its various writers respectively lived, and to the nature of the different *styles*, *analogical* and *parabolical*, in which it is written. He will likewise keep in mind that God, whom it claims for its author, is the parent of truth, and that all his actions and dispensations must be consistent with one another. He will therefore compare the different passages of the Old and New Testaments which relate to the same doctrine, or to the same event, reasonably concluding that the bible must be the best interpreter of itself; and though the opinions which he thus forms

† *Tatham's Chart and Scale of Truth.*

Preliminary Directions. forms may often be erroneous, they will seldom be dangerous errors, and may easily be corrected by mature reflection, or by consulting approved authors who have treated before him of the various points which have been the subject of his studies. Of this mode of proceeding one good consequence will be, that, having from the sacred scriptures formed a system of theology for himself, he will afterwards study the systems of other men without any violent prejudices for or against them; he will be so much attached to his own opinions as not to relinquish them in obedience to mere human authority, at the same time that he will be ready to give them up when convinced that they are not well-founded; and if he have read the scriptures attentively, he will have acquired such a love of truth as to embrace her wherever she may be found.

13 Approved systems of divinity. As we have supposed that every man, after having formed a theological system of his own, will consult the systems of others, it may perhaps be expected that we should here recommend those which, in our opinion, are most worthy of his attention. To do this, however, would, we apprehend, be an interference with the rights of private judgment. But lest we should be suspected of wishing to bias the mind of the young student toward the short system which we are obliged to give, we shall just observe, that by the divines of what is called the *Arminian school*, Episcopius's *Theologiæ Institutiones*, Limborch's *Theologia Christiana*, and Locke's *Reasonableness of Christianity*, have long been held in the highest esteem; whilst the followers of Calvin have preferred the *Institutiones* of their master, Turretine's *Institutio Theologiæ Elencticæ*, and Gill's *Body of Divinity*. This last work has many merits and many defects. Its style is coarse and tedious; and the author embraces every opportunity of introducing the discriminating tenets of his sect: but his book is fraught with profound learning, breathes the spirit of piety, and may be read with advantage by every divine who has previously formed the outlines of a system for himself.

14 Books recommended on the Mosaic dispensation. As the Jewish and Christian dispensations are closely linked together, being only part of one great whole, it is impossible to have an adequate notion of the latter without understanding the design of the former. Now, though the Mosaic religion is nowhere to be learned but in the Old Testament, it may be convenient for our student, after he has formed his own opinions of it from that sacred source, to know what has been written on the subject by others. For illustrating the ritual law, a learned prelate warmly recommends the *Ductor Dubitantium* of Maimonides, and Spencer's book entitled *De Legibus Hebræorum Ritualibus*. Both works have undoubtedly great merit; but our young divine will do well to read along with them *Hermanni Witsii Ægyptiaca*, and Dr Woodward's Discourse on the Worship of the Ancient Egyptians, where some of Spencer's notions are shortly and ably refuted. On the other parts of this dispensation, such as the nature of its civil government; the rewards and punishments peculiar to it (c); its extraordinary administration by appointed agents, endowed with supernatural powers, and with the gifts of miracles and prophecy; the *double sense* in which the latter is sometimes involved; and the language consequent on its nature and use—the reader will find much erudition and ingenuity displayed in the second part of Warburton's *Divine Legation of Moses demonstrated*. That work is entitled to a serious perusal; for it displays great learning and genius, and, we believe, the heaviest censures have fallen on it from those by whom it was never read.

15 Inquiry to be made into the reality of revelation. Having proceeded thus far in the course, the student's next business should be to inquire seriously what evidence there is that the doctrines which he has so carefully studied were indeed revealed in times past by God. He must already have perceived, in the nature and tendency of the doctrines themselves, strong marks of their origin being more than human; but he must likewise have met with many difficulties, and he must prepare himself to repel the attacks of unbelievers. Here he will find opportunities of exerting the utmost powers of his reasoning faculties, and of employing in the service of religion all the stores he may have amassed of human learning. The scriptures pretend to have been written by several men who lived in different ages of the world; but the latest of them in an age very remote from the present. His first business therefore must be to prove the authenticity of these books, by tracing them up by historical evidence to the several writers whose names they bear. But it is not enough to prove them authentic. They profess to have been written by men divinely inspired, and of course infallible in what they wrote. He must therefore inquire into the truth of this inspiration. The Bible contains a number of truths doctrinal and moral, which are called *mysteries*, and asserted to be the immediate dictates of God himself. To evince this great point to man, a number of supernatural *tests* and *evidences* are inseparably connected with those mysteries; so that if the former be true, the latter must be so likewise. He must therefore examine these tests and evidences, to establish the divinity of the Holy Scriptures; and in this part of his course he will find much assistance from many writers whose defences of the truth and divinity of the Christian religion do honour to human nature.

16 Books recommended on that subject. The first step towards the embracing of any truth is, to get fairly rid of the objections which are made to it; and the general objections made by deistical writers to the Christian revelation are by no writer more completely removed than by Bishop Butler, in his celebrated work entitled *The Analogy of Religion natural and revealed to the Constitution and Course of Nature*. This book therefore the student should read with attention and meditate on with patience; but as it does not furnish a *positive proof* of the divinity of our religion, he should pass from it to *Grotius de Veritate Religionis Christianæ*, and Stillingfleet's *Origines Sacræ*. Both these works are excellent; and the latter, which may be considered

(c) On this subject the reader will find many excellent observations in Bishop Bull's *Harmonia Apostolica*, with its several defences, and in a small book of Dr Wells's, entitled A Help for the Right Understanding of the several Divine Laws and Covenants, whereby man has been obliged through the several ages of the world to guide himself in order to salvation.

Preliminary Directions.

considered as an improvement of the former, is perhaps the fullest and ablest defence of revelation in general that is to be found in any language. In this part of the united kingdom it is now indeed scarcely mentioned, or mentioned with indifference; but half a century ago the English divines thought it a subject of triumph, and styled its author their *incomparable Stillingfleet*. Other works, however, may be read with great advantage, and none with greater than Paley's *Evidences of the Christian Religion*, and Leslie's *Short Method with the Deists;* which last work, in the compass of a very few pages, contains proofs of the divinity of the Jewish and Christian revelations, to which the celebrated Dr Middleton confessed (D), that for 20 years he had laboured in vain to fabricate a specious answer (E).

17. Jewish controversy to be studied,

Having satisfied himself of the truth of revelation in general, it may be worth the young divine's while to provide a defence of the Christian religion against the objections of modern Judaism. In this part of his studies he will need no other instruction than what he may reap from Limborch's work entitled *De Veritate Religionis Christianæ amica collatio cum erudito Judæo*. "In that disputation, which was held with Orobio, he will find all that the stretch of human parts on the one hand, or science on the other, can produce to varnish error or unravel sophistry. All the papers of Orobio in defence of Judaism, as opposed to Christianity, are printed at large, with Limborch's answers, section by section; and the subtilest sophisms of a very superior genius are ably and satisfactorily detected and exposed by the strong, profound, and clear reasoning, of this renowned remonstrant †." See OROBIO and LIMBORCH.

† *Warburton's Directions for the Study of Theology.*

18 and the various controversies among Christians themselves.

The various controversies subsisting between the several denominations of Christians, about points which separate them into different churches, ought next to be studied in the order of the course; for nothing is unimportant which divides the followers of that Master whose favourite precept was *love*. It has indeed been long fashionable to decry polemical divinity as an useless, if not a pernicious, study; but it is not impossible that this fashion has had its origin in ignorance, and that it tends to perpetuate those schisms which it professes to lament. We are, however, far from recommending to the young divine a perusal of the works of the several combatants on each side of a disputed question, till he has fitted himself for judging between them by a long course of preparatory study; and the only preparation which can fit him for this purpose is an impartial study of ecclesiastical history. He who has with accuracy traced the progress of our holy religion from the days of the apostles to the present time, and marked the introduction of new doctrines, and the rise of the various sects into which the Christian world is divided, is furnished with a criterion within himself by which to judge of the importance and truth of the many contested doctrines; whilst he who, without this preparation, shall read a multitude of books on any religious controversy, will be in danger of becoming a convert to his last author, if that author possess any tolerable share of art and ingenuity.

19 Importance of ecclesiastical history, and books recommended.

There are many histories of the Christian church which possess great merit, but we are acquainted with none which appears to us wholly impartial. Mosheim's is perhaps the most perfect compend (F); and one of its greatest excellencies is, that on every subject the best writers are referred to for fuller information. These indeed should often be consulted, not only to supply the defects necessarily resulting from the narrowness of the limits which the author, with great propriety, prescribed to himself; but also to correct his partial obliquities; for with all his merits, and they were many and great, he is certainly not free from the influence of prejudice. Indeed there is no coming at the true history of the primitive church, but by studying the works of the primitive writers; and the principal works of the first four centuries will amply reward the labour of perusing them (G). The rise and progress of the reformation in general, the most important period of church-history, may be best learned from Sleidan's book *De Statu Religionis et Reipublicæ, Carolo V. Cæsare, Commentarii;* the History of the Reformation of the Church of Scotland from Knox and Spotiswood; and that of the Church of England from the much applauded work of Bishop Burnet.

After this course of ecclesiastical history, the young divine may read with advantage the most important controversies which have agitated the Christian world. To enumerate these controversies, and to point out the ablest authors who have written on each, would be a tedious, and perhaps not a very profitable task. On one controversy, however, we are induced to recommend a very masterly work, which is Chillingworth's book against Knott, entitled *The Religion of Protestants a safe way to Salvation;* in which the school jargon of that Jesuit is admirably exposed, and the long dispute between

(D) This piece of information we had from the late Dr Berkeley, prebendary of Canterbury, who had it from Archbishop Seeker, to whom the confession was made.

(E) To these defences of revelation we might have added the collection of sermons preached at Boyle's lecture from 1691 to 1732, published in three volumes folio, 1739; the works of Leland; Bishop Newton's Dissertations on Prophecy; and above all, Lardner's Credibility of the Gospel History, with the Supplement to it. But there would be no end of recommending eminent writers on this subject. We have mentioned such as we most approve among those with whom we are best acquainted; but we must, once for all, caution the reader against supposing that we approve of *every* thing to be found in any work except the sacred Scriptures.

(F) The bishop of Landaff, in the catalogue of books published at the end of his Theological Tracts, recommends several other ecclesiastical histories as works of great merit; such as Dupin's, Echard's, Gregory's, and Formey's, together with *Paul Ernesti Jablonski Institutiones Historiæ Christianæ*, published at Frankfort in three volumes, 1754-67.

(G) For a proof of this position, and for a just estimate of the value of the *Fathers*, as they are called, see the introduction to Warburton's Julian, and Kett's Sermons at Bampton's Lectures.

Preliminary Directions. tween the Popish and Reformed churches placed on its proper ground, the Holy Scriptures.

20 Toleration. One of the most plausible objections to the study of polemical divinity, is its tendency to give a rigid turn to the sentiments of those long engaged in it; whilst we know, from higher authority that "the end of the commandment is charity." But for preserving charity in the minds of Christians, there are better means than absolute ignorance or indifference to truth. Charity is violated only when a church unreasonably restrains the inquiries of its own members, or exercises intolerance towards those who have renounced its jurisdiction. The injustice of the first species of ecclesiastical tyranny is exposed in a very masterly manner by Jeremy Taylor in his *Liberty of Prophecying*, and by Stillingfleet in his *Irenicum;* the injustice of the second, by Locke in his celebrated Letters on Toleration. The man who shall peruse these three works, and impartially weigh the force of their arguments, will be in little danger of thinking uncharitably of those from whose principles the love of truth may compel him to dissent.

In these directions for the study of theology, we might have enumerated many more books on each branch of the subject well deserving of the most attentive perusal; but he who shall have gone through the course here recommended, will have laid a foundation on which he may raise such a superstructure as will entitle him to the character of an accomplished divine. His diligence must indeed be continued through life; for when a man ceases to make acquisitions in any department of learning, he soon begins to lose those which he has already made; and a more contemptible character is nowhere to be found than that of a clergyman unacquainted with the learning of his profession. This learning, however, is not to be acquired, and indeed is scarcely to be preserved, by studying *bodies* or *institutes* of *theology;* and though we have mentioned a few generally approved by two rival sects of Christians, and must in conformity with the plan of our work, give another ourselves, we do not hesitate to declare, that the man who has carefully gone through the course of study which we have recommended, though it be little more than the outlines on which he is to work, may, with no great loss to himself, neglect ours and all other systems. For as an excellent writer *, whom we have often quoted, well observes, "to judge of the *fact* whether such a revelation containing such a principle, with its mysteries and credentials, was actually sent from God, and received by man, by examining the *evidences* and *circumstances* which accompanied it—the *time* when, the *place* where, the *manner* how, it was delivered—the *form* in which it descends to us—and in what it is *contained*—together with the particular *substance* and *burden* of it—and how every part is to be rightly *understood:* these are the various and extensive subjects which constitute the sublime office of THEOLOGIC REASONING and the PROPER STUDY OF DIVINITY." On this account we shall pass over slightly, many things which every clergyman ought thoroughly to understand, and confine ourselves, in the short compend which we are to give, to the chief articles of Christian theology. In doing this, we shall endeavour to divest ourselves of party prejudices; but as we are far from thinking that this endeavour will be completely successful (for we believe there is no man totally free from prejudice), we cannot conclude this part of the article more properly than with the following solemn CHARGE, with which a very learned divine ‡ always prefaced his Theological Lectures.

* *Tatham.*

‡ *Dr Taylor of Norwich.*

21 A charge to students of theology.

I. "I do solemnly charge you, in the name of the God of Truth, and of our Lord Jesus Christ, who is the Way, the Truth, and the Life, and before whose judgement-seat you must in no long time appear, that in all your studies and inquiries of a religious nature, present or future, you do constantly, carefully, impartially, and conscientiously, attend to evidence, as it lies in the Holy Scriptures, or in the nature of things, and the dictates of reason; cautiously guarding against the sallies of imagination, and the fallacy of ill-grounded conjecture.

II. "That you admit, embrace, or assent to no principle or sentiment by me taught or advanced, but only so far as it shall appear to you to be supported and justified by proper evidence from revelation or the reason of things.

III. "That if, at any time hereafter, any principle or sentiment by me taught or advanced, or by you admitted or embraced, shall, upon impartial and faithful examination, appear to you to be dubious or false, you either suspect or totally reject such principle or sentiment.

IV. "That you keep your mind always open to evidence: That you labour to banish from your breast all prejudice, prepossession, and party-zeal: That you study to live in peace and love with all your fellow Christians; and that you steadily assert for yourself, and freely allow to others, the unalienable rights of judgment and conscience."

PART I. OF NATURAL THEOLOGY.

SECT. I. *Of the Being and Attributes of God.*

HE who cometh to God, says an ancient divine †, deeply read in the philosophy of his age, must believe that he is, and that he is a rewarder of them who diligently seek him. This is a truth as undeniable as that a man cannot concern himself about a nonentity. The existence of God is indeed the foundation of all religion, and the first principle of the science which is the subject of this article. It is likewise a principle which must command the assent of every man who has any notion of the relation between effects and their causes, and whose curiosity has ever been excited by the phenomena of nature. This great and important truth we have elsewhere endeavoured to demonstrate (see METAPHYSICS, Part III. Chap. vi.); but it may be proved by arguments less abstracted than the nature of that article required us to use. Of these we shall give one or two, which we hope will be level to every ordinary capacity; while, at the same time, we earnestly recommend to the young divine a diligent study of those books on the

† *St Paul.*

22 The being of God proved from

Being and Attributes of God.

the subject which we have mentioned in the preceding directions.

23 propagation of animals.

We see that the human race, and every other species of animals, is at present propagated by the co-operation of two parents; but has this process continued from eternity? A moment's reflection will convince us that it has not. Let us take any one man alive, and let us suppose his father and mother dead, and himself the only person at present existing: how came he into the world? It will be said he was produced mechanically or chemically by the conjunction of his parents, and that his parents were produced in the same manner by theirs. Let this then be supposed; it must surely be granted, that when this man was born, an addition was made to the series of the human race. But a series which can be enlarged may likewise be diminished; and by tracing it backwards, we must at some period, however remote, reach its beginning. There must therefore have been a first pair of the human race, who were not propagated by the conjunction of parents. How did these come into the world?

Anaximander tells us *, that the first men and all animals were bred in warm moisture, inclosed in crustaceous skins like crab-fish or lobsters; and that when they arrived at a proper age, their shelly prisons growing dry, broke, and made way for their liberty. Empedocles informs us, that mother Earth at first brought forth vast numbers of legs, and arms, and heads, &c. which approaching each other, arranging themselves properly, and being cemented together, started up at once full grown men.

* See *Bentley's Boyle's Lectures.*

Surely those sages, or their followers, should have been able to tell us why the earth has not in any climate this power of putting forth vegetable men or the parts of men at present. If this universal parent be eternal and self-existent, it must be incapable of decay or the smallest change in any of its qualities; if it be not eternal, we shall be obliged to find a cause for its existence, or at least for its form and all its powers. But such a cause may have produced the first human pair, and undoubtedly did produce them, without making them spring as plants from the soil. Indeed the growth of plants themselves clearly evinces a cause superior to any vegetative power which can be supposed inherent in the earth. No plant can be propagated but from seed or slips from the parent stock; but when one contemplates the regular process of vegetation, the existence of every plant implies the prior existence of a parent seed, and the existence of every seed the prior existence of a parent plant. Which then of these, the oak or the acorn, was the first, and whence was its existence derived? Not from the earth; for we have the evidence of universal experience that the earth never produces a tree but from seed, nor seed but from a tree. There must therefore be some superior power which formed the first seed or the first tree, planted it in the earth, and gave to it those powers of vegetation by which the species has been propagated to this day.

24 and vegetables.

25 and from the laws of attraction and repulsion, &c.

Thus clearly do the processes of generation and vegetation indicate a power superior to those which are usually called the *powers of nature*. The same thing appears no less evident from the laws of attraction and repulsion, which plainly prevail through the whole system of matter, and hold together the stupendous structure. Experiment shows that very few particles of the most solid body are in actual contact with each other (see OPTICS, N° 63—68. PHYSICS, N° 23.); and that there are considerable interstices between the particles of every elastic fluid, is obvious to the smallest reflection. Yet the particles of solid bodies strongly cohere, whilst those of elastic fluids repel each other. How are these phenomena accounted for? To say that the former is the effect of attraction and the latter of repulsion, is only to say that two individual phenomena are subject to those laws which prevail through the whole of the classes under which they are respectively arranged; whilst the question at issue is concerning the ORIGIN OF THE LAWS THEMSELVES, the *power* which makes the particles of gold cohere, and those of air repel each other. Power without substance is inconceivable; and by a law of human thought, no man can believe a being to operate but where it is in some manner or other actually present: but the particles of gold adhere, and the particles of air keep at a distance from each other, by powers exerted where no matter is present. There must therefore be some substance endowed with power which is not material.

Of this substance or being the power is evidently immense. The earth and other planets are carried round the sun with a velocity which human imagination can scarcely conceive. That this motion is not produced by the agency of these vast bodies on one another, or by the interposition of any material fluid, has been shown elsewhere (see METAPHYSICS, N° 196—200. and OPTICS, N° 67.); and since it is a law of our best philosophy, *that we are not to multiply substances without necessity*, we must infer that the same Being which formed the first animals and vegetables, endowing them with powers to propagate their respective kinds, is likewise the cause of all the phenomena of nature, such as *cohesion*, *repulsion*, *elasticity* and *motion*, even the motions of the heavenly bodies themselves.

If this powerful Being be self-existent, intelligent, and independent in his actions and volitions, he is an original or first cause, and that Being whom we denominate GOD. If he be not self-existent and independent, there must be a cause in the order of nature prior and superior to Him, which is either itself the first cause, or a link in that series of causes and effects, which, however vast we suppose it, must be traced ultimately to some one Being, who is self-existent, and has in himself the power of beginning motion, independent of every thing but his own intelligence and volition. In vain have atheists alleged, that the series may ascend infinitely, and for that reason have no first mover or cause. An infinite series of successive beings involves an absurdity and contradiction (see METAPHYSICS, N° 288.): but not to insist on this at present, we shall only beg leave to consider such a series as a whole, and see what consequence will flow from the supposition. That we may with logical propriety consider it in this light, is incontrovertible; for the birth of each individual of the human race shows that it is made up of parts; but parts imply a whole as necessarily as an attribute implies its subject. As in this supposed series there is no cause which is not likewise an effect, nor any body moving another which was not itself moved by a third, the whole is undeniably equivalent to an infinite effect, or an infinite body moved: but if a finite effect must necessarily have proceeded from a cause, and a finite body in

26 Absurdity of an infinite series of effects.

Being and Attributes of God.

in motion must have been put into that state by a mover, is there a human mind which can conceive an infinite effect to have proceeded from *no* cause, or an infinite body in motion to have been moved by *nothing*? No, surely! An infinite effect, were such a thing possible, would compel us to admit an infinite cause, and an infinite body in motion a mover of infinite power.

This great cause is GOD, whose wisdom, power, and goodness, all nature loudly proclaims. That the phenomena which we daily see evince the existence of *one* such Being, has just been shown; and that we have no reason to infer the existence of *more* than *one*, is very evident. For, not to lay more stress than it will bear on that rule of Newton's, which forbids us to multiply substances without necessity, such a harmony prevails through the whole visible universe, as plainly shows it to be under the government of one intelligence. That on this globe the several elements serve for nourishment to plants, plants to the inferior animals, and animals to man; that the other planets of our system are probably inhabited, and their inhabitants nourished in the same or a similar manner; that the sun is so placed as to give light and heat to all, and by the law of gravitation to bind the whole planets into one system with itself—are truths so obvious and so universally acknowledged, as to supersede the necessity of establishing them by proof. The fair inference therefore is, that the solar system and all its parts are under the government of *one intelligence*, which directs all its motions and all the changes which take place among its parts for some wise purposes. To suppose it under the government of two or more intelligences would be highly unreasonable; for if these intelligences had equal power, equal wisdom, and the same designs, one of them would evidently be superfluous; and if they had equal power and contrary designs, they could not be the parents of that harmony which we clearly perceive to prevail in the system.

27 There is only one original cause.

But the Being capable of regulating the movements of so vast a machine, may well be supposed to possess infinite power, and to be capable of superintending the motions of the universe. That the widely extended system of nature is but one system, of which the several parts are united by many bonds of mutual connection, has been shown elsewhere (see PHYSICS), and appears daily more and more evident from our progress in physical discoveries; and therefore it is in the highest degree unreasonable to suppose that it has more than one author, or one supreme governor.

28 Of infinite power, wisdom, and

As the unity of design apparent in the works of creation plainly proves the unity of their Author, so do the immensity of the whole, and the admirable adjustment of the several parts to one another, demonstrate His power and His wisdom. On this subject the following beautiful reflections by Mr Wollaston are deserving of the most serious attention.

"In order (says that able writer *) to prove to any one the grandness of this fabric of the world, one needs only to bid him consider the *sun*, with that insupportable glory and lustre that surrounds it; to demonstrate its vast distance, magnitude, and heat; to represent to him the chorus of planets moving periodically, by uniform laws, in their several orbits about it; guarded some of them by secondary planets, and as it were emulating the state of the sun, and probably all possessed by proper inhabitants; to remind him of those surprising visits which the *comets* make to us, and the large trains of uncommon splendour which attend them, the far country from which they come, and the curiosity and horror which they excite not only among us, but in the inhabitants of other planets, who may also be up to see the entry and progress of these ministers of fate; to direct his eye and contemplation through those azure fields and vast regions above him up to the *fixed stars*, that radiant numberless host of heaven; and to make him understand how unlikely a thing it is that they should be placed there only to adorn and bespangle a canopy over our heads; to convince him that they are rather so many *other suns*, with their several systems of planets about them; to show him by the help of glasses still more and more of these fixed lights, and to beget in him an apprehension of their inconceivable numbers, and those immense spaces that lie beyond our reach and even our imagination: One needs but to do this (continues our author), and explain to him such things as are now known almost to every body; and by it to show, that if the world be not infinite, it is *infinito similis*, and undoubtedly the work of an INFINITE ARCHITECT.

* *Religion of Nature*, sect. v. prop. 14.

"But if we would take a view of all the *particulars* contained within that astonishing compass which we have thus hastily run over, how would wonders multiply upon us? Every corner, every part of the world, is as it were made up of *other* worlds. If we look upon this our earth, what scope does it furnish for admiration? The great variety of mountains, hills, valleys, plains, rivers, seas, trees, and plants! The many tribes of different animals with which it is stocked; the multifarious inventions and works of one of these, i. e. of us men; with the wonderful instincts of others, guiding them uniformly to what is best for themselves, in situations where neither sense nor reason could direct them. And yet when all these (heaven and earth) are surveyed as nicely as they can be by the help of our unassisted senses and of telescopes, we may discover by the assistance of good microscopes, in very small parts of matter, as many *new* wonders as those already discovered, new kingdoms of animals, with new and curious architecture. So that as our senses and even conception fainted before in the vast journeys we took in considering the expanse of the universe, they here again fail us in our researches into the principles and minute parts of which it is composed. Both the *beginnings* and the *ends* of things, the *least* and the *greatest*, all conspire to baffle us; and which way soever we prosecute our inquiries, we still meet with fresh subjects of amazement, and fresh reasons to believe that there are indefinitely more and more behind, that will forever escape our eagerest pursuits and deepest penetration.

"In this vast assemblage, and amidst all the multifarious motions by which the several processes of generation and corruption, and the other phenomena of nature, are carried on, we cannot but observe that there are stated methods, as so many forms of proceeding, to which things punctually and religiously adhere. The same *causes* circumstanced in the same manner produce always the same *effects*; all the *species* of animals among us are made according to one general *idea*; and so are those of *plants* also, and even of *minerals*. No new species are brought forth or have arisen anywhere; and the old are preserved and continued by the *old ways*.

"It appears, lastly, beyond dispute, that in the part

Being and Attributes of God.

and model of the world there is a contrivance for accomplishing certain ends. The sun is placed near the centre of our system, for the more convenient dispensing of his benign influences to the planets moving about him; the place of the earth's *equator* intersects that of her *orbit*, and makes a proper angle with it, in order to diversify the *year*, and create an useful variety of *seasons;* and many other things of this kind will be always observed, and though a thousand times repeated, be meditated upon with pleasure by good men and true philosophers. Who can observe the vapours to ascend, especially from the sea, meet above in clouds, and fall again after condensation, without being convinced that this is a kind of *distillation*, in order to clear the water of its grosser salts, and then by rains and dews to supply the fountains and rivers with fresh and wholesome liquor; to nourish the vegetables below by showers, which descend in drops as from a *watering-pot* upon a garden? Who can view the *structure* of a plant or animal, the indefinite number of its fibres and fine vessels, the formation of larger vessels, and the several members out of them, with the apt disposition of all these; the means contrived for the reception and distribution of *nutriment;* the *effect* this nutriment has in extending the vessels, bringing the vegetable or animal to its full growth and expansion, continuing the *motion* of the several fluids, repairing the decays of the body, and preserving *life?* Who can take notice of the several *faculties* of animals, their arts of saving and providing for themselves, or the ways in which they are provided for; the uses of plants to animals, and of some animals to others, particularly to mankind; the care taken that the several species should be propagated, without confusion, from their proper seeds; the strong inclination planted in animals for that purpose, the love of their young and the like.—Who (says our author) can observe all this, and not see a *design* in such *regular* pieces, so nicely wrought and so admirably preserved? If there were but one animal in existence, and it could not be doubted but that his eyes were formed that he might see with them, his ears that he might hear with them, and his feet to be instruments by which he might remove himself from place to place; if *design* and *contrivance* can be much less doubted, when the same things are repeated in the individuals of all the tribes of animals; if the like observations be made with respect to vegetables and other things; and if all these *classes* of things, and much more the *individuals* comprehended under them, be inconceivably numerous, as most unquestionably they are—one cannot but be convinced, from what so plainly runs through the nobler parts of the visible world, that not only *they*, but other things, even those that seem to be *less noble*, have their ends likewise, though not always perceived by capacities limited like ours. And since we cannot, with the Epicureans of old, suppose the parts of matter to have *contrived* among themselves this wonderful form of a world, to have taken by agreement each its respective *post*, and then to have pursued in conjunction constant *ends* by certain methods and measures *concerted*, there must be some other Being, whose wisdom and power are equal to such a mighty work as is the *structure* and *preservation* of the world. There must be some Almighty Mind who modelled and preserves it; lays the causes of things so deep; prescribes them such uniform and steady laws; destines and adapts them to certain purposes; and makes one thing to fit and answer another so as to produce one harmonious whole. Yes,

> These are thy glorious works, Parent of good!
> Almighty, thine this universal frame,
> Thus wondrous fair; Thyself how wondrous then!

How wondrous in wisdom and in power!"

29 Goodness.

But the GOODNESS of God is not less conspicuous in his works than His power or His wisdom. Contrivance proves design, and the predominant tendency of the contrivances indicates the disposition of the designer. "The world (says an elegant and judicious writer *) abounds with contrivances, and all the contrivances in it with which we are acquainted are directed to beneficial purposes. Evil no doubt exists; but it is never that we can perceive the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable from it; but it is not its object. This is a distinction which well deserves to be attended to. In describing implements of husbandry, one would hardly say of a sickle that it is made to cut the reaper's fingers, though from the construction of the instrument, and the manner of using it, this mischief often happens. But if he had occasion to describe instruments of torture or execution, this, he would say, is to extend the sinews; this to dislocate the joints; this to break the bones; this to scorch the soles of the feet. Here pain and misery are the very objects of the contrivance. Now nothing of this sort is to be found in the works of nature. We never discover a train of contrivance to bring about an evil purpose. No anatomist ever discovered a system of organization calculated to produce pain and disease; or, in explaining the parts of the human body, ever said, this is to irritate, this to inflame, this duct is to convey the gravel to the kidneys, this gland to secrete the humour which forms the gout. If by chance he came to a part of which he knows not the use, the most that he can say is, that to him it appears to be useless: no one ever suspects that it is put there to incommode, to annoy, or to torment. If God had wished our misery, he might have made sure of his purpose, by forming our senses to be as many sores and pains to us as they are now instruments of gratification and enjoyment; or, by placing us among objects so ill suited to our perceptions as to have continually offended us, instead of ministering to our refreshment and delight. He might have made, for instance, every thing we tasted bitter, every thing we saw loathsome, every thing we touched a sting, every smell a stench, and every sound a discord."

* Dr Paley.

Instead of this, all our sensations, except such as are excited by what is dangerous to our health, are pleasures to us: The view of a landscape is pleasant; the taste of nourishing food is pleasant; sounds not too loud are agreeable, while musical sounds are exquisite; and scarcely any smells, except such are excited by effluvia obviously pernicious to the brain, are disagreeable; while some of them, if not too long indulged, are delightful. Our lives are preserved and the species is continued by obeying the impulse of appetites; of which the gratification is exquisite when not repeated too frequently, to answer the purposes of the Author of our being. Since, then, God has called forth his consummate-

Being and Attributes of God.

nate wisdom to contrive and provide for our happiness, and has made those things which are necessary to our existence and the continuance of the race sources of our greatest sensual pleasures, who can doubt but that benevolence is one of his attributes; and that, if it were not impious to draw a comparison between them, it is the attribute in which he himself most delighteth?

But it is not from sensation only that we may infer the benevolence of the deity: He has formed us with minds capable of intellectual improvement, and he has implanted in the breast of every man a very strong desire of adding to his knowledge. This addition, it is true, cannot be made without labour; and at first the requisite labour is to most people irksome: but a very short progress in any study converts what was irksome into a pleasure of the most exalted kind; and he who by study, however intense, enlarges his ideas, experiences a complacency, which, though not so poignant perhaps as the pleasures of the sensualist, is such as endears him to himself, and is what he would not exchange for any thing else which this world has to bestow, except the still sweeter complacency arising from the consciousness of having discharged his duty.

That the practice of virtue is attended with a peculiar pleasure of the purest kind, is a fact which no man has ever questioned, though the immediate source of that pleasure has been the subject of many disputes. He who attributes it to a moral sense, which instinctively points out to every man his duty, and on the performance of it rewards him with a sentiment of self-approbation, must of necessity acknowledge benevolence to be one of the attributes of that Being who has so constituted the human mind. That to protect the innocent, relieve the distressed, and do to others as we would in like circumstances wish to be done by, fills the breast, previous to all reflection, with a holy joy, as the commission of any crime tears it with remorse, cannot indeed be controverted. Many, however, contend, that this joy and this remorse spring not from any moral instinct implanted in the mind, but are the consequence of early and deep-rooted associations of the practice of virtue with the hope of future happiness, and of vice with the dread of future misery. On the respective merits of these two theories we shall not now decide, but only observe, that they both lead with equal certainty to the benevolence of the Deity, who made us capable of forming associations, and subjected those associations to fixed laws. This being the case, the moral sense, with all its instantaneous effects, affords not a more convincing proof of his goodness, than that principle in our nature by which remote circumstances become so linked together, that the one circumstance never occurs without bringing the other also into view. It is thus that the pleasing complacency, which was perhaps first excited by the hopes of future happiness, comes in time to be so associated with the consciousness of virtuous conduct, the only thing entitled to reward, that a man never performs a meritorious action without experiencing the most exquisite joy diffused through his mind, though his attention at that instant may not be directed either to heaven or futurity. Were we obliged, before we could experience this joy, to estimate by reason the merit of every individual action, and trace its connection to heaven and future happiness through a long train of intermediate reasoning, we should be in a great measure deprived of the present reward of virtue; and therefore this associating principle contributes much to our happiness. But the benevolence of a Being, who seems thus anxious to furnish us with both sensual and intellectual enjoyments, and who has made our duty our greatest pleasure, cannot be questioned; and therefore we must infer, that the Author of Nature wishes the happiness of the whole sensible and intelligent creation.

30 Objections.

To such reasoning as this in support of the Divine Benevolence many objections have been made. Some of them appear at first sight plausible, and are apt to stagger the faith of him who has bestowed no time on the study of that branch of general science which is called *physics* (see PHYSICS). To omit these altogether in such an article as this might be construed into neglect; while it is certain that there is in them nothing worthy the attention of that man who is qualified either to estimate their force, or to understand the arguments by which they have often been repelled.

It has been asked, Why, if the Author of Nature be a benevolent Being, are we necessarily subject to pain, diseases, and death? The scientific physiologist replies, Because from these evils Omnipotence itself could not in our present state exempt us, but by a constant series 31
of miracles. He who admits miracles, knows likewise answered.
that mankind were originally in a state in which they were not subject to death; and that they fell under its dominion through the fault of their common progenitors. But the fall and restoration of man is the great subject of revealed religion; and at present we are discussing the question like philosophers who have no other data on which to proceed than the phenomena of nature. Now we know, that as all matter is divisible, every system composed of it must necessarily be liable to decay and dissolution; and our material system would decay and be dissolved long before it could serve the purposes of nature, were there not methods contrived with admirable wisdom for repairing the waste occasioned by perpetual friction. The body is furnished with different fluids, which continually circulate through it in proper channels, and leave in their way what is necessary to repair the solids. These again are supplied by food *ab extra*; and to the whole processes of digestion, circulation, and nutrition, the air we breath is absolutely necessary. But as the air is a very heterogenous fluid, and subject to violent and sudden changes, it is obvious that these changes must affect the blood, and by consequence the whole frame of the human body. The air indeed in process of time consumes even marble itself; and therefore we cannot wonder that as it is in one state the parent of health, it should in another be the source of disease to such creatures as man and other terrestrial animals. Nor could these consequences be avoided without introducing others much more deplorable. The world is governed by general laws, without which there could be among men neither arts nor sciences; and though laws different from those by which the system is at present governed might perhaps have been established, there is not the smallest reason to imagine that they could on the whole have been better, or attended with fewer inconveniences. As long as we have material and solid bodies capable of motion, liable to resistance from other solid bodies, supported by food,

Being and Attributes of God.

subject to the agency of the air, and divisible, they must necessarily be liable to pain, disease, corruption, and death, and that too by the very influence of those laws which preserve the order and harmony of the universe. Thus gravitation is a general law so good and so necessary, that were it for a moment suspended, the world would instantly fall to pieces; and yet by means of this law the man must inevitably be crushed to death on whom a tower shall chance to tumble. Again, the attraction of cohesion is a general law, without which it does not appear that any corporeal system could possibly exist: it is by this law too, or a modification of it, that the glands and lacteals of the human body extract from the blood such particles as are necessary to nourish the solids; and yet it is by means of the very same modification of the very same law that a man is liable to be poisoned.

32 Sickness, pain, and the dread of death serve good purposes.

Although the human body could not have been preserved from dangers and dissolution but by introducing evils greater on the whole than those to which it is now liable, why, it has sometimes been asked, is every disorder to which it is subject attended with sickness or with pain? and why is such a horror of death implanted in our breasts, seeing that by the laws of nature death is inevitable? We answer, That sickness, pain, and the dread of death, serve the very best purposes. Could a man be put to death, or have his limbs broken without feeling pain, the human race had long ago been extinct. Felt we no uneasiness in a fever, we should be insensible of the disease, and die before we suspected our health to be impaired. The horror which generally accompanies our reflections on death tends to make us more careful of life, and prevents us from quitting this world rashly when our affairs prosper not according to our wishes. It is likewise an indication that our existence does not terminate in this world; for our dread is seldom excited by the prospect of the pain which we may suffer when dying, but by our anxiety concerning what we may be doomed to suffer or enjoy in the next stage of our existence; and this anxiety tends more perhaps than any thing else to make us live while we are here in such a manner as to ensure our happiness hereafter.

Thus from every view that we can take of the works and laws of God, and even from considering the objections which have sometimes been made to them, we are compelled to acknowledge the benevolence of their Author. We must not, however, suppose the Divine benevolence to be a fond affection like that which is called benevolence among men. All human affections and passions originate in our dependence and wants; and it has been doubted whether any of them be at first disinterested (see PASSION): but he to whom existence is essential cannot be dependent; he who is the Author of every thing can feel no want. The Divine benevolence therefore must be wholly disinterested, and of course free from those partialities originating in self-love, which are alloys in the most sublime of human virtues. The most benevolent man on earth, though he wishes the happiness of every fellow-creature, has still, from the ties of blood, the endearments of friendship, or, perhaps

33 The divine benevolence coincident with justice.

from a regard to his own interest, some particular favourites whom, on a competition with others, he would certainly prefer. But the equal Lord of all can have no particular favourites. His benevolence is therefore coincident with justice; or, that which is called *divine justice*, is only benevolence exerting itself in a particular manner for the propagation of general felicity. When God prescribes laws for regulating the conduct of his intelligent creatures, it is not because he can reap any benefit from their obedience to those laws, but because such obedience is necessary to their own happiness; and when he punishes the transgressor, it is not because in his nature there is any disposition to which the prospect of such punishment can afford gratification, but because in the government of free agents punishment is necessary to reform the criminal, and to intimidate others from committing the like crimes.

The essence of this self-existent, all-powerful, infinitely wise, and perfectly good Being, is to us wholly incomprehensible. 34 God incomprehensible; That it is not matter, is shown by the process of argumentation by which we have proved it to exist: but what it is we know not, and it would be impious presumption to inquire. It is sufficient for all the purposes of religion to know that God is somehow or other present to every part of his work; that existence and every possible perfection is essential to him; and that he wishes the happiness of all his creatures. From these truths we might proceed to illustrate the perpetual superintendance of his providence, both general and particular, over every the minutest part of the universe: but that subject has been discussed in a separate article; to which, therefore, we refer the reader. (See PROVIDENCE). We shall only observe at present, that the manner in which animals are propagated affords as complete a proof of the constant superintendance of divine power and wisdom, as it does of the immediate exertion of these faculties in the formation of the parent pair of each species. For were propagation carried on by *necessary* and mechanical laws, it is obvious, that in every age there would be generated, in each species of animals, the very same proportion of males to females that there was in the age preceding. 35 but constantly present to his works. On the other hand, did generation depend on *fortuitous* mechanism, it is not conceivable but that, since the beginning of the world, several species of animals should in *some age* have generated nothing but *males*, and others nothing but *females*; and that of course many species would have been long since extinct. As neither of these cases has ever happened, the preservation of the various species of animals, by keeping up constantly in the world a due, though not always the same, proportion between the sexes of male and female, is a complete proof of the superintendance of Divine providence, and of that saying of the apostle, that it is "in God we live, move, and have our being."

SECT. II. *Of the Duties and Sanctions of Natural Religion.*

36 Reverence and gratitude due to God.

FROM the short view that we have taken of the divine perfections, it is evidently our duty to reverence in our minds the self-existent Being to whom they belong. This is indeed not only a duty, but a duty of which no man who contemplates these perfections, and believes them to be real, can possibly avoid the performance. He who thinks irreverently of the Author of nature, can never have considered seriously the power, the wisdom, and the goodness, displayed in his works; for whoever has a tolerable notion of these must be convinced, that he who performed them has no imperfection;

Duties and Sanctions of Natural Religion.

tion; that his power can accomplish every thing which involves not a contradiction; that his knowledge is intuitive, and free from the possibility of error; and that his goodness extends to all without partiality and without any alloy of selfish design. This conviction must make every man on whose mind it is impressed ready to prostrate himself in the dust before the Author of his being; who, though infinitely exalted above him, is the source of all his enjoyments, constantly watches over him with paternal care, and protects him from numberless dangers. The sense of so many benefits must excite in his mind a sentiment of the liveliest gratitude to him from whom they are received, and an ardent wish for their continuance.

37 Of whom no positive idea should be formed.

While silent gratitude and devotion thus glow in the breast of the contemplative man, he will be careful not to form even a mental image of that all-perfect Being to whom they are directed. He knows that God is not material; that he exists in a manner altogether incomprehensible; that to frame an image of him would be to assign limits to what is infinite; and that to attempt to form a positive conception of him would be impiously to compare himself with his Maker.

38 How he ought to be spoken of; and

The man who has any tolerable notion of the perfections of the Supreme Being will never speak lightly of him, or make use of his name at all but on great and solemn occasions. He knows that the terms of all languages are inadequate and improper, when applied directly to him who has no equal, and to whom nothing can be compared; and therefore he will employ these terms with caution. When he speaks of his mercy and compassion, he will not consider them as feelings wringing the heart like the mercy and compassion experienced by man, but as rays of pure and disinterested benevolence. When he thinks of the stupendous system of nature, and hears it, perhaps, said that God formed it for his own glory, he will reflect that God is so infinitely exalted above all his creatures, and so perfect in himself, that he can neither take pleasure in their applause, nor receive any accession of any kind from the existence of ten thousand worlds. The immense fabric of nature therefore only displays the glory or perfections of its Author to *us* and to other *creatures* who have not faculties to comprehend him in himself.

39 what is meant by serving him.

When the contemplative man talks of *serving* God, he does not dream that his services can increase the divine felicity; but means only that it is his duty to obey the divine laws. Even the pronoun *He*, when it refers to God, cannot be of the same import as when it refers to man; and by the philosophical divine it will seldom be used but with a mental allusion to this obvious distinction.

As the man who daily venerates the Author of his being will not speak of him on trivial occasions, so will he be still further from calling upon him to witness impertinences and falsehood (see OATH). He will never mention his name but with a *pause*, that he may have time to reflect in silence on his numberless perfections, and on the immense distance between himself and the Being of whom he is speaking. The slightest reflection will convince him that the world with all that it contains depends every moment on that God who formed it; and this conviction will compel him to wish for the divine protection of himself and his friends from all dangers and misfortunes. Such a wish is in effect a prayer, and will always be accompanied with adoration, confession, and thanksgiving (see PRAYER). But adoration, confessions, supplication, and thanksgiving, constitute what is called *worship*, and therefore the worship of God is a natural duty. It is the addressing of ourselves as his dependants to him as the supreme cause and governor of the world, with acknowledgements of what we enjoy, and petitions for what we really want, or he knows to be convenient for us. As if, ex. gr. I should in some humble and composed manner (says Mr Wollaston) pray to that "Almighty Being, upon whom depends the existence of the world, and by whose providence I have been preserved to this moment, and enjoyed many undeserved advantages, that he would graciously accept my grateful sense and acknowledgements of all his beneficence towards me; that he would deliver me from the evil consequences of all my transgressions and follies; that he would endue me with such dispositions and powers as may carry me innocently and safely through all future trials, and may enable me on all occasions to behave myself conformably to the laws of reason piously and wisely; that He would suffer no being to injure me, no misfortunes to befal me, nor me to hurt myself by any error or misconduct of my own: that he would vouchsafe me clear and distinct perceptions of things; with so much health and prosperity as may be good for me; that I may at least pass my time in peace, with contentment and tranquillity of mind; and that having faithfully discharged my duty to my family and friends, and endeavoured to improve myself in virtuous habits and useful knowledge, I may at last make a decent and happy exit, and find myself in some better state." 40

40 Divine worship a natural duty.

That an untaught savage would be prompted by *instinct* to address the Supreme Being in such terms as this, we are so far from thinking that to us it appears not probable that such a savage, in a state of solitude, would be led by instinct to suppose the existence of that Being. But as soon as the being and attributes of God were, by whatever means, made known to man, every sentiment expressed in this prayer must necessarily have been generated in his mind; for not to be sensible that we derive our existence and all our enjoyments from God, is in effect to deny his being or his providence; and not to feel a wish that he would give us what we want, is to deny either his goodness or his power.

41 Whether or not is public worship a duty of natural religion?

The worship of God therefore is a natural duty resulting from the contemplation of his attributes and a sense of our own dependence. But the reasoning which has led us to this conclusion respects only *private* devotion; for it is a question of much greater difficulty, and far enough from being yet determined, whether *public* worship be a duty of that religion which can with any propriety be termed *natural*. Mr Wollaston indeed positively affirms that it is, and endeavours to prove his position by the following arguments.

42 Arguments for it,

"A man (says he) may be considered as a member of some society; and as *such* he ought to worship God if he has the opportunity of doing it, if there be proper prayers used publicly to which he may resort, and if his health, &c. permit. Or the society may be considered as *one body*, that has common interests and concerns, and *as such* is obliged to worship the Deity, and offer one prayer. Besides, there are many who know not, of themselves

themselves how to pray; perhaps cannot so much as read. These must be taken *as they are;* and consequently some time and place *appointed* where they may have suitable prayers read to them, and be guided in their devotions. And further, towards the keeping mankind in order, it is *necessary* there should be some religion professed, and even established, which cannot be without public worship. And were it not for that sense of virtue which is *principally* preserved (so far as it is preserved) by national *forms* and *habits* of religion, men would soon lose it *all*, run wild, prey upon one another, and do what else the worst of savages do."

These are in themselves just observations, and would come with great force and propriety from the tongue or pen of a Christian preacher, who is taught by revelation that the Master whom he serves has commanded his followers "not to forsake the assembling of themselves together," and has promised, "that if two of them shall agree on earth as touching any thing that they shall ask, it shall be done for them of his Father who is in heaven." As urged by such a man, and on such grounds, they would serve to show the fitness of the divine command, and to point out the benefits which a religious obedience to it might give us reason to expect. But the author is here professing to treat of *natural* religion, and to state the duties which result from the mere relation which subsists between man as a creature and God as his creator and constant preserver. Now, though we readily admit the benefits of public worship as experienced under the Christian dispensation, we do not perceive any thing in this reasoning which could lead a pious theist to expect the same benefit previous to all experience. When the author thought of *national forms*

43 borrowed from revelation.

and *establishments of religion*, he certainly lost sight of his proper subject, and, as such writers are too apt to do, comprehended under the religion of nature what belongs only to that which is revealed. Natural religion, in the proper sense of the words, admits of no particular *forms*, and of no *legal establishment*. Private devotion is obviously one of its duties, because sentiments of adoration, confession, supplication, and thanksgiving, necessarily spring up in the breast of every man who has just notions of God and of himself: but it is not so obvious that such notions would induce any body of men to meet at *stated times* for the purpose of expressing their devotional sentiments in public. Mankind are indeed social beings, and naturally communicate their sentiments to each other; but we cannot conceive what should at first have led them to think that public worship at stated times would be acceptable to the self-existent Author of the universe. In case of a famine, or any other calamity in which the whole tribe was equally involved, they might speak of it to each other, inquire into its cause, and in the extremity of their distress join perhaps in one fervent petition, that God would remove it. In the same manner they might be prompted to pour forth occasional ejaculations of public gratitude for public mercies; but it does not follow from these incidental occurrences that they would be led to institute times and places and forms of national worship, as if they believed the omniscient Deity more ready to hear them in public than in private. That the appointment of such times and forms and places is beneficial to society, experience teaches us; and therefore it is the duty, and has been the practice, of the supreme magistrate, in every age and in every civilized country, to provide for the maintenance of the national worship. But this practice has taken its rise, not from the deductions of reason, but either from direct revelation, as among the Jews and Christians; or from tradition, which had its origin in some early revelations, as among the more enlightened Pagans of ancient and modern times.

We hope none of our readers will imagine that we mean, in any degree, to call in question the fitness or the duty of public worship. This is far from our intention; but while we are convinced of the importance and necessity of this duty, we do not apprehend that we lessen its dignity, or detract from the weight of almost universal practice, by endeavouring to derive that practice from its true source, which appears to us to be not human reason, but divine revelation.

44 The practice of virtue a duty of natural religion.

But whatever doubts may be entertained with respect to the origin of public worship, there can be none as to the foundation of moral virtue. Reason clearly perceives it to be the will of our Maker, that each individual of the human race should treat every other individual as, in similar circumstances, he would expect to be treated himself. It is thus only that the greatest sum of human happiness can be produced (see MORAL PHILOSOPHY, N° 17. and 135.); for were all men temperate, sober, just in their dealings, faithful to their promises, charitable to the poor, &c. it is obvious that no miseries would be felt on earth, but the few which, by the laws of corporeal nature, unavoidably result from the union of our minds with systems of matter. But the design of God in forming sentient beings was to communicate to them some portion, or rather some resemblance, of that felicity which is essential to himself; and therefore every action which in its natural tendency co-operates with this design must be agreeable to him, as every action of a contrary tendency must be disagreeable.

From this reasoning it follows, that we are obliged not only to be just and beneficent to one another, but also to abstain from all unnecessary cruelty to inferior animals.

45 Cruelty to the inferior animals a sin.

That we have a right to tame cattle, and employ them for the purposes of agriculture and other arts where strength is required, is a position which we believe has seldom been controverted. But if it is the intention of God to communicate a portion of happiness to all his creatures endowed with sense, it is obvious that we sin against him when we subject even the horse or the ass to greater labour than he is able to perform; and this sin is aggravated when from avarice we give not the animal a sufficient quantity of food to support him under the exertions which we compel him to make. That it is our duty to defend ourselves and our property from the ravages of beasts of prey, and that we may even exterminate such beasts from the country in which we live, are truths which cannot be questioned; but it has been the opinion of men, eminent for wisdom and learning, that we have no right to kill an ox or a sheep for *food*, but in consequence of the divine permission to Noah recorded in the ninth chapter of the book of Genesis. Whether this opinion be well or ill founded we shall not positively determine, though the arguments on which it rests are of such a nature as the reasoners of the present day would perhaps find it no easy task to answer; but it cannot admit of a doubt, that, in killing such animals, we are, in duty to *their* Creator and *ours*, bound to put them to the least possible pain. If this be granted, it is still more evident

Duties and Sanctions of Natural Religion.

evident that we act contrary to the divine will when we torture and put to death such animals as are confessedly not injurious to ourselves, or to any thing on which the comforts of life are known to depend. We are indeed far from being convinced with the poet, that insects and reptiles "in mortal sufferance feel as when a giant dies;" but their feelings on that occasion are certainly such, as that, when we wantonly inflict them, we thwart, as far as in our power, the benevolent purpose of the Creator in giving them life and sense. Let it be observed too, that the man who practises needless cruelty to the brute creation is training up his mind for exercising cruelty towards his fellow-creatures, to his slaves if he have any, and to his servants; and, by a very quick progress, to all who may be placed beneath him in the scale of society.

Such are the plain duties of natural religion; and if they were universally practised, it is evident that they would be productive of the greatest happiness which mankind could enjoy in this world, and that piety and virtue would be their own reward. They are however far from being universally practised; and the consequence is, that men are frequently raised to affluence and power by vice, and sometimes sunk into poverty by a rigid adherence to the rules of virtue.

This being the case, there can be no question of greater importance, while there are few more difficult to be answered, than, "What are the sanctions by which natural religion enforces obedience to her own laws?" It is not to be supposed that the great body of mankind should, without the prospect of an ample reward, practise virtue in those instances in which such practice would be obviously attended with injury to themselves; nor does it appear reasonable in any man to forego present enjoyment, without the well-grounded hope of thereby securing to himself a greater or more permanent enjoy-

46 Natural religion defective in its evidence of a future state.

ment in reversion. Natural religion therefore, as a system of doctrines influencing the conduct, is exceedingly defective, unless it affords sufficient evidence, intelligible to every ordinary capacity, of the immortality of the soul, or at least of a future state of rewards and punishments. That it *does* afford this evidence, is strenuously maintained by some deists, and by many philosophers of a different description, who, though they profess Christianity, seem to have some unaccountable dread of being deceived by their bibles in every doctrine which cannot be supported by philosophical reasoning.

47 The general expectation of a future state.

One great argument made use of to prove that the immortality of the soul is among the doctrines of natural religion, is the universal belief of all ages and nations that men continue to live in some other state after death has separated their souls from their bodies. "Quod si *omnium consensus naturæ vox est:* omnesque, qui ubique sunt, consentiunt esse aliquid, quod ad eos pertineat, qui vita cesserint: nobis quoque idem existimandum est: et si, quorum aut ingenio, aut virtute animus excellit, eos arbitramur, quia natura optima sunt, cernere naturæ vim maxime: verisimile est, *cum optimus quisque maxime posteritati serviat*, esse aliquid, cujus is post mortem sensum sint habiturus. Sed ut deos esse natura opinamur, qualesque sint, ratione cognoscimus, sic permanere animos arbitramur *consensu nationum omnium* *."

* Cicer. Tusc Quæst. lib. i. § 15, 15.

That this is a good argument for the truth of the doctrine, through whatever channel men may have received it, we readily acknowledge; but it appears not to us to be any proof of that doctrine's being the deduction of human reasoning. The popular belief of Paganism, both ancient and modern, is so fantastic and absurd, that it could never have been rationally inferred from what nature teaches of God and the soul. In the Elysium of the Greek and Roman poets, departed spirits were visible to mortal eyes; and must therefore have been clothed with some material vehicle of sufficient density to reflect the rays of light, though not to resist the human touch. In the mythology of the northern nations, as deceased heroes are represented as eating and drinking, they could not be considered as entirely divested of matter; and in every popular creed of idolatry, future rewards were supposed to be conferred, not for private virtue, but for public violence, on heroes and conquerors and the destroyers of nations. Surely no admirer of what is now called natural religion will pretend that these are part of its doctrines; they are evidently the remains of some primeval tradition obscured and corrupted in its long progress through ages and nations.

48 not the offspring of nature.

49 Opinions of the philosophers respecting a future state.

The philosophers of Greece and Rome employed much time and great talents in disquisitions concerning the human soul and the probability of a future state; and if the genuine conclusions of natural religion on this subject are anywhere to be found, one would naturally look for them in the writings of those men whose genius and virtues did honour to human nature. Yet it is a fact, that the philosophers held such notions concerning the substance of the soul and its state after death as could afford no rational support to suffering virtue, (see METAPHYSICS, Part III. chap. 4.). Socrates is indeed an exception. Confining himself to the study of ethics, that excellent person inferred by the common moral arguments (see MORAL PHILOSOPHY, N°232—246.), that the reality of a future state of rewards and punishments is in the highest degree probable. He was not, however, at all times absolutely *convinced* of this important truth; for a little before his death he said to some who were about him, "I am now about to leave this world, and ye are still to continue in it; which of us have the better part allotted us, God only knows *." And again, at the end of his most admired discourse concerning the immortality of the soul, delivered at a time when he must have been serious, he said to his friends who came to pay their last visit, "I would have you to know that I have great hopes that I am now going into the company of good men; yet I would not be too peremptory and confident concerning it †."

* *Plato in Apolog. Soc.*

† *Plato in Phæd.*

Next to Socrates, Cicero was perhaps the most respectable of all the philosophers of antiquity; and he seems to have studied this great question with uncommon care: yet what were his conclusions? After retailing the opinions of various sages of Greece, and showing that some held the soul to be the *heart*; others, the *blood* in the heart; some the *brain*; others, the *breath*; one, that it was *harmony*; another, that it was *number*; one, that it was *nothing* at all; and another, that it was a certain *quintessence* without a name, but which might properly be called ἐντελέχεια—he gravely adds, "Harum sententiarum quæ vera sit, Deus aliquis viderit: que verisimillima, magna questio est ‡." He then proceeds to give his own opinion; which was, that the soul was part of God.

‡ *Tusc. Quæst.* lib. i. § 9, 10, 11.

To us who know by other evidence that the soul is immortal, and that there will be a future state in which

all.

Duties and Sanctions of Natural Religion.

all the obliquities of the present shall be made straight, the argument drawn from the moral attributes of God, and the unequal distribution of the good things of this life, appears to have the force of demonstration. Yet none of us will surely pretend to say that his powers of reasoning are greater than were those of Socrates and Cicero: and therefore the probability is, that had we been like them destitute of the light of revelation, we should have been disturbed by the same doubts, and have said with the latter, on reading the arguments of the former as detailed by Plato, "Nescio quomodo, dum lego, assentior: cum posui librum, et mecum ipse de immortalitate animorum cœpi cogitare, assensio illa elabitur †."

† *Ibid.*

50 Without the light of revelation we should have doubted like them.

No one, we hope, will suspect us of an impious attempt to weaken the evidence of a future state. God forbid! The expectation of that state is the only support of virtue and religion; and we think the arguments we have stated elsewhere, and referred to on the present occasion, make the reality of it so highly probable, that, though there were no other evidence, he would act a very foolish part who should confine his attention wholly to the present life. But we do not apprehend that we can injure the cause either of virtue or of religion, by confessing, that those arguments which left doubts in the minds of Socrates and Cicero appear not to us to have the force of *complete demonstration* of that life and immortality which our Saviour brought to light through the gospel.

51 Natural religion has no means of certainly reconciling the Deity to sinners.

Were the case, however, otherwise; were the arguments which the light of nature affords for the immortality of the human soul as convincing as any geometrical demonstration—natural religion would still be defective; because it points out no method by which such as have offended God may be restored to his favour and to the hopes of happiness which by their sin they had lost. That he who knows whereof we are made would show himself placable to sinners, and that he would find some way to be reconciled, might perhaps be reasonably inferred from the consideration of his benevolence displayed in his works. But when we come to inquire more particularly *how* we are to be reconciled, and whether a *propitiation* will be required, *nature* stops short, and expects with impatience the aid of some particular revelation. That God will receive returning sinners, and accept of repentance instead of perfect obedience, cannot be certainly known by those to whom he has not *declared* that he will. For though repentance be the most probable, and indeed the only means of reconciliation which nature suggests; yet whether he, who is of purer eyes than to behold iniquity, will not require something further before he restores sinners to the privileges which they have forfeited, mere human reason has no way of discovering. From nature therefore arises no sufficient comfort to sinners, but anxious and endless solicitude about the means of appeasing the Deity. Hence those different ways of sacrificing, and those numberless superstitions which overspread the heathen world, but which were so little satisfactory to the wiser part of mankind, that, even in those days of darkness, the philosophers frequently declared that, in their opinion, those rites and oblations could avail nothing towards appeasing the wrath of an offended God, or making their prayers acceptable to him. Hence Socrates and one of his disciples are represented by Plato ‡ as expecting a person divinely commissioned to inform them whether sacrifices be acceptable to the deity, and as resolving to offer no more till that person's arrival, which they piously hoped might be at no great distance.

‡ *In Alcibiade.*

52 These doubts removed by the Scriptures.

This darkness of the pagan world is to us who live under the sunshine of the gospel happily removed by the various revelations contained in the scriptures of the Old and New Testaments. These taken together exhibit such a display of providence, such a system of doctrines, and such precepts of practical wisdom, as the ingenuity of man could never have discovered. The Christian, with the scriptures in his hands, can regulate his conduct by an infallible guide, and rest his hopes on the surest foundation. These scriptures it is now our business to examine.

PART II. OF REVEALED THEOLOGY.

53 Many pretences to revelation,

IN every civilized country the popular system of theology has claimed its origin from divine revelation. The Pagans of antiquity had their augurs and oracles; the Chinese have their inspired teachers Confucius and Fohi: the Hindoos have their sacred books derived from Brahma; the followers of Mahomet have their Koran dictated by an angel; and the Jews and Christians have the Scriptures of the Old and New Testaments, which they believe to have been written by holy men of old, who spake and wrote as they were moved by the Holy Ghost.

54 though the Jewish and Christian revelations are alone true.

That the claims of ancient Paganism to a theology derived from heaven, as well as the similar claims of the Chinese, Hindoos, and Mahometans, are ill founded, has been shown in various articles of this work, (see CHINA, HINDOSTAN, MAHOMETANISM, MYTHOLOGY, and POLYTHEISM); whilst under the words RELIGION, REVELATION, and SCRIPTURE, we have sufficiently proved the divine inspiration of the Jewish and Christian scriptures, and of course the divine origin of Jewish and Christian theology. These indeed are not two systems of theology, but parts of one system which was gradually revealed as men were able to receive it; and therefore both scriptures must be studied by the Christian divine.

There is nothing in the sacred volume which it is not of importance to understand; for the whole proceeds from the fountain of truth: but some of its doctrines are much more important than others, as relating immediately to man's everlasting happiness; and these it has been customary to arrange and digest into regular systems, called *bodies* or *institutes* of *Christian theology*. Could these artificial systems be formed with perfect impartiality, they would undoubtedly be useful, for the bible contains many historical details, but remotely related to salvation; and even of its most important truths, it requires more time and attention than the majority of Christians have to bestow, to discover the mutual connection and dependence.

55 Common divisions of revealed theology.

Artificial systems of theology are commonly divided into two great parts, the *theoretic* and the *practical*; and

Revealed Theology. and these again are subdivided into many inferior branches. Under the theoretic part are sometimes classed,

1. *Dogmatic* theology; which comprehends an entire system of all the dogmas or tenets which a Christian is bound to believe and profess. The truth of these the divine must clearly perceive, and be able to enforce on his audience: and hence the necessity of studying what is called,

2. The *exegesis*, or the art of attaining the true sense of the holy scriptures; and,

3. *Hermeneutic* theology, or the art of interpreting and explaining the scriptures to others; an art of which no man can be ignorant who knows how to attain the true sense of them himself.

4. *Polemical* theology, or controversy; and,

5. *Moral* theology, which is distinguished from moral philosophy, or the simple doctrine of ethics, by teaching a much higher degree of moral perfection than the mere light of reason could ever have discovered, and adding new motives to the practice of virtue.

The practical sciences of the divine are,

1. *Homiletic* or *pastoral* theology; which teaches him to adapt his discourses from the pulpit to the capacity of his hearers, and to pursue the best methods of guiding them by his doctrine and example in the way of salvation.

2. *Catechetic* theology, or the art of teaching youth and ignorant persons the principal points of evangelical doctrine, as well with regard to belief as to practice.

3. *Casuistic* theology, or the science which decides on doubtful cases of moral theology, and that calms the scruples of conscience which arise in the Christian's soul during his journey through the present world.

We have mentioned these divisions and subdivisions of the science of theology, not because we think them important, but merely that our readers may be at no loss to understand the terms when they meet with them in
56 Useless. other works. Of such terms we shall ourselves make no use, for the greater part of them indicate distinctions where there is no difference, and tend only to perplex the student. As the truths of Christianity are all contained in the scriptures of the Old and New Testaments, it is obvious that dogmatic theology must comprehend the speculative part of that which is called moral, as well as every doctrine about which controversy can be of importance. But no man can extract a single dogma from the bible but by the practice of what is here called the *exegesis*; so that all the subdivisions of this arrangement of theoretical theology must be studied together as they necessarily coalesce into one. The same thing is true of the three branches into which practical theology is here divided. He who has acquired the art of adapting his homilies to the various capacities of a mixed audience, will need no new study to fit him for instructing children, and the most ignorant persons who are capable of instruction; and the complete master of moral theology will find it no very difficult task to resolve all the cases of conscience which he can have reason to suppose will ever be submitted to his judgment. For these reasons we shall not trouble our readers with the various divisions and subdivisions of theology. Our preliminary directions will show them how we think the science should be studied; and all that we have to do as *system-builders* is to lay before them the view which the scriptures present to us of the being and perfections of God, his various dispensations to man, and the duties thence incumbent on Christians. In doing this, we shall follow the order of the divine dispensations as we find them recorded in the Old and New Testaments, dwelling longest on those which appear to us of most general importance. But as we take it for granted that every reader of this article will have previously read the whole sacred volume, we shall not scruple to illustrate dogmas contained in the Old Testament by texts taken from the New, or to illustrate doctrines peculiar to the Christian religion by the testimony of Jewish prophets.

God and his Attributes.

Sect. I. *Of God and his Attributes.*

57 The first revelation supposes the being of God to be a known truth.

In every system of theology the first truths to be believed are those which relate to the being and attributes of God. The Jewish lawgiver, therefore, who records the earliest revelations that were made to man, begins his history with a display of the power and wisdom of God in the creation of the world. He does not inform his countrymen, and expect them to believe, on the authority of his divine commission, that God *exists*; for he well knew that the being of God must be admitted, and just notions entertained of his attributes, before man can be required to pay any regard to miracles which afford the only evidence of a primary revelation. "In the beginning (says he) God created the heavens and the earth." Here the being of God is assumed as a truth universally received; but the sentence, short as it is, reveals another, which, as we shall afterwards shew, human reason could never have discovered.

There is nothing which the scriptures more frequently or more earnestly inculcate than the unity of the divine nature. The texts asserting this great and fundamental truth are almost numberless. "Unto thee (says Moses to his countrymen*) it was shewed, that thou mightest know that the Lord is God; there is *none else besides him*. Know therefore that the Lord *he is God* in *heaven above* and upon the *earth beneath: there is none else*." And again, "Hear, O Israel, the Lord our God is *one Lord*," or, as it is expressed in the original, "Jehovah our God is one Jehovah," one Being to whom existence is essential, who could not have a beginning and cannot have an end. In the prophecies of Isaiah, God is introduced as repeatedly declaring †, "I am Jehovah, and there is *none else*; there is *no God besides me*: that they may know from the rising of the sun and from the west, that there is *none besides me*: I am *Jehovah*, and there is *none else*: Is there a God besides me? Yea there is *no God*; I know not any." In perfect harmony with these declarations of Moses and the prophets, our Saviour, addressing himself to his Father, says ‡, "This is life eternal, that they might know *Thee, the only true God*, and Jesus Christ whom Thou hast sent;" and St Paul, who derived his doctrine from his divine Master, affirms §, that "an idol is nothing in the world; and that there is *none other God but one*."

* Deut. iv. 35, and 39, vi. 4.

† Isaiah xlv. 5, 6, 18, xliv. 8.

‡ John xvii. 3.

§ 1 Cor. viii. 4.

The unity of the divine nature, which, from the order and harmony of the world, appears probable to human reason, these texts of revelation put beyond a doubt. Hence the first precept of the Jewish law, and, according to their own writers, the foundation of their whole religion, was, "Thou shalt have none other gods before Me."

God and his Attributes.

Me." Hence, too, the reason of that strict command to Jews and Christians to give divine worship to none but God: "Thou shalt worship the Lord thy God, and him only shalt thou serve;" because he is *God alone*. Him only must we fear, because he alone hath infinite power; in him alone must we trust, because "he only is our rock and our salvation;" and to him alone must we direct our devotions, because "he only knoweth the hearts of the children of men."

58
Denotes a plurality of persons in the Godhead

The word אלהים does not indicate a plurality of gods. In the opinion, however, of many eminent divines, it denotes, by its junction with the singular verb, a plurality of persons in the one Godhead; and some few have contended, that by means of this peculiar construction, the Christian doctrine of the Trinity may be proved from the first chapter of the book of Genesis. To this latter opinion we can by no means give our assent. That there are three distinct persons in the one divine nature may be inferred with sufficient evidence from a multitude of passages in the Old and New Testaments diligently compared together; but it would perhaps be rash to rest the proof of so sublime a mystery on any single text of holy scripture, and would certainly be so to rest it on the text in question. That Moses was acquainted with this doctrine, we may reasonably conclude from his so frequently making a plural name of God to agree with a verb in the singular number; but had we not possessed the brighter light of the New Testament to guide us, we should never have thought of drawing such an inference. For supposing the word אלהים to denote clearly a plurality of persons, how could we have known that the number is neither more or less than three, had it not been ascertained to us by subsequent revelations?

There are indeed various passages in the Old Testament, of the phraseology of which no rational account can be given, but that they indicate more than one person in the Godhead. Such are those texts already noticed; "and the Lord God said, let US make man in OUR own image, after OUR likeness;" and "the Lord God said, behold the man is become like ONE of US." To these may be added the following, which are to us perfectly unintelligible on any other supposition; and "the Lord God said, let US go down, and there confound their language *." "If I be a *Master* (in the Hebrew *adonim*, MASTERS), where is my fear †?" "The fear of the Lord (JEHOVAH) is the beginning of wisdom, and the knowledge of the Holy (in the Hebrew HOLY ONES) is understanding ‡." "Remember thy Creator (Hebrew, thy CREATORS) in the days of thy youth §." "And now the LORD GOD and his SPIRIT hath sent me ||." "Seek ye out of the book of the LORD and read; for MY mouth it hath commanded, and his SPIRIT it hath gathered them *."

* Gen. xi. 6, 7.
† Mal. i. 6.
‡ Prov. ix. 10.
§ Eccl. xii. 1.
|| Isaiah xlviii. 16.
* Isaiah xxxiv. 16.

That these texts imply a plurality of divine persons, seems to us incontrovertible. When Moses represents God as saying, let us make man, the majesty of the plural number had not been adopted by earthly sovereigns; and it is obvious that the Supreme Being could not, as has been supposed, call on angels to make man; for in different places of scripture † creation is attributed to God alone. Hence it is that Solomon speaks of Creators in the *plural number*, though he means only the one Supreme Being, and exhorts men to remember them in the days of their youth. In the passage first quoted from Isaiah, there is a distinction made between the *Lord God* and his *Spirit*; and in the other, three divine persons are introduced, viz. the *Speaker*, the *Lord*, and the *Spirit* of the Lord. It does not, however, appear evident from these passages, or from any other that we recollect in the Old Testament, that the persons in Deity are three and no more: but no sober Christian will harbour a doubt but that the precise number was by some means or other made known to the ancient Hebrews; for inquiries leading to it would be naturally suggested by the form in which the high priest was commanded to bless the people. "The LORD bless thee and keep thee. The LORD make his face to shine upon thee, and be gracious unto thee. The LORD lift up his countenance upon thee, and give thee peace *."

† Job ix. 8. Isa. xlv. *passim.*

* Numb. vi. 24, 25, 26.

59
A Trinity in unity the doctrine of scripture.

The form of Christian baptism establishes the truth of the doctrine of the Trinity beyond all reasonable ground of dispute. "Go (says our blessed Saviour) and teach all nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost." What was it the apostles were to teach all nations? Was it not to turn from their vanities to the living God; to renounce their idols and false gods, and so to be baptized in the name of the Father, and of the Son, and of the Holy Ghost? What now must occur to the Gentile nations on this occasion, but that, instead of all their deities, to whom they had before bowed down, they were in future to serve, worship, and adore, Father, Son, and Holy Ghost, as the only true and living God? To suppose that GOD and TWO CREATURES are here joined together in the solemn rite by which men were to be admitted into a new religion, which directly condemns all *creature-worship*, would be so unreasonable, that we are persuaded such a supposition never was made by any converted Polytheist of antiquity. The nations were to be baptized in the name of three persons, in the *same manner*, and therefore, doubtless, in the *same sense*. It is not said in the name of GOD and his two faithful *servants*; nor in the name of GOD, and CHRIST, and the HOLY GHOST, which might have suggested a thought that *one* only of the three is God; but in the name of the FATHER, and of the SON, and of the HOLY GHOST. Whatever honour, reverence, or regard, is paid to the first person in this solemn rite, the same is paid to all three. Is he acknowledged as the object of worship? So are the other two likewise. Is he God and Lord over us? So are they. Are we enrolled as subjects, servants, and soldiers, under him? So are we equally under all. Are we hereby regenerated and made the temple of the Father? So are we likewise of the Son and Holy Ghost. "We will come (says our Saviour †) and make our abode with him."

† John xiv. 23.

If those who believe the inspiration of the scriptures could require any further proof that the Godhead comprehends a trinity of persons in one nature, we might urge the apostolical form of benediction; "The grace of our LORD JESUS CHRIST, and the love of GOD, and the communion of the HOLY GHOST, be with you all ‡." Would St Paul, or any other man of common sense, have in the same sentence, and in the most solemn manner, recommended his Corinthian converts to the love of God, and to the grace and communion of two creatures? We should think it very absurd to recommend a man at once to the favour of a king and a beggar;

‡ 2 Cor. xiii. 14.

God and his Attributes.

gar; but how infinitely small is the distance between the greatest earthly potentate and the meanest beggar, when compared with that which must for ever subsist between the Almighty Creator of heaven and earth and the most elevated creature?

60
Difficulties in this doctrine.

But how, it will be asked, can three divine persons be but one and the same God? This is a question which has been often put, but which, we believe, no created being can fully answer. The divine nature and its manner of existence is, to us, wholly incomprehensible; and we might with greater reason attempt to weigh the mountains in scales, than by our limited faculties to fathom the depths of infinity. The Supreme Being is present in power to every portion of space, and yet it is demonstrable, that in his essence he is not extended (see METAPHYSICS, N° 309, 310). Both these truths, his inextension and omnipresence, are fundamental principles in what is called *natural religion;* and when taken together they form, in the opinion of most people, a mystery as incomprehensible as that of the Trinity in unity. Indeed there is nothing of which it is more difficult to form a distinct notion than *unity* simple, and absolutely indivisible. Though the Trinity in unity, therefore, were no Christian doctrine, mysteries must still be believed; for they are as inseparable from the religion of nature as from that of revelation; and atheism involves the most incomprehensible of all mysteries, even the beginning of existence without a cause. We must indeed form the best notions that we can of this and all other myteries; for if we have no notions whatever of a Trinity in unity, we can neither believe nor disbelieve that doctrine. It is however to be remembered, that all our notions of God are more or less analogical; that they must be expressed in words which, literally interpreted, are applicable only to man; and that propositions understood in this literal sense may involve an apparent contradiction, from which the truth meant to be expressed by them would be seen to be free, had we direct and adequate conceptions of the divine nature. On this account it is to be wished that men treating of the mystery of the Holy Trinity, had always expressed themselves in scripture language, and never aimed at being wise above what is written; but since they have acted otherwise, we must, in justice to our readers, animadvert on one or two statements of this doctrine, which we have reason to believe are earnestly contended for by some who consider themselves as the only orthodox.

In the scriptures, the three persons are denominated by the terms FATHER, SON, and HOLY GHOST, or by GOD, the WORD, who is also declared to be God, and the SPIRIT OF GOD. If each be truly God, it is obvious that they must all have the same divine nature, just as every man has the same human nature with every other man; and if there be but ONE GOD, it is equally obvious that they must be of the same individual substance or essence, which no three men can possibly be. In this there is a difficulty; but, as will be seen by and by, there is no contradiction. The very terms FATHER and SON imply such a relation between the two persons so denominated, as that though they are of the same substance, possessed of the same attributes, and equally God, just as a human father and his son are equally men, yet the second must be personally subordinate to the first. In like manner, the HOLY GHOST, who is called the Spirit of God, and is said to *proceed from* the *Father*, and to be *sent* by the *Son*, must be conceived as subordinate to both, much in the same way as a son is subordinate to his parents, though possessed of equal or even of superior powers. That this is the true doctrine, appears to us undeniable from the words of our Saviour himself, who, in a prayer addressed to his Father, styles him * by way of pre-eminence, "the only true God," as being the fountain or origin of the Godhead from which the Son and the Holy Ghost derive their true divinity. In like manner, St Paul, when opposing the polytheism of the Greeks, says expressly †, that "to us there is but one God, THE FATHER, OF whom are all things, and we in, or for, him; and one LORD JESUS CHRIST, BY whom are all things, and we by him."

61
Subordination of the second and third persons.

* John xvii. 3.

† 1 Cor. viii. 6.

That the primitive fathers of the Christian church maintained this subordination of the second and third persons of the blessed Trinity to the first, has been evinced with complete evidence by Bishop Bull. We shall transcribe two quotations from him, and refer the reader for fuller satisfaction to *sect.* 4. of his *Defensio fidei Nicenæ*. The first shall be a passage cited from *Novatian*, in which the learned prelate assures us the sense of all the ancients is expressed. "Quia quid est Filius, non ex se est, quia nec innatus est; sed ex patre est, quia genitus est: sive dum verbum est, sive dum virtus est, sive dum sapientia est, sive dum lux est, sive dum Filius est, et quicquid horum est, non aliunde est quam ex Patre, Patri suo originem suam debens." The next is from Athanasius, who has never been accused of holding low opinions respecting the second person of the holy Trinity. This father, in his fifth discourse against the Arians, says, κατα γαρ τον Ιωαννην εν ταυτη τη αρχη ην ὁ λογος και ὁ λογος, ην προς τον θεον. Θεος γαρ εστιν ἡ αρχη, και επειδαν εξ αυτης εστι, δια τουτο και θεος ην ὁ λογος; *according to John, the Word was in this first principle, and the Word was God. For God is the principle; and because the Word is from the principle, therefore the Word is God.* Agreeably to this doctrine, the Nicene fathers, in the creed which they published for the use of the universal church, style the only begotten Son, GOD OF GOD, θεος εκ θεου.

62
Denied by some modern divines, but

Regardless however of antiquity, and of the plain sense of scripture, some modern divines of great learning contend, that the three persons in Deity are all *consubstantial*, *co-eternal*, *co-ordinate*, without *derivation*, *subordination*, or *dependence*, of *any sort*, as to nature or essence; while others affirm, that the second and third persons derive from the first their personality, but not their nature. We shall consider these opinions as different, though, from the obscurity of the language in which we have always seen them expressed, we cannot be certain but they may be one and the same. The maintainers of the former opinion hold, that the three persons called *Elohim* in the Old Testament, naturally independent on each other, entered into an agreement before the creation of the world, that one of them should in the fulness of time assume human nature, for the purpose of redeeming mankind from that misery into which it was foreseen that they would fall. This antemundane agreement, they add, constitutes the whole of that paternal and filial relation which subsists between the first and second persons whom we denominate Father and Son; and they hold, that the Son is said to be begotten before all worlds, to indicate that *He* who was before all worlds was *begotten*, or to *be* begotten, into the office of of redeemer; or, more decisively, to signify that he undertook that office before the creation, and *assumed* to himself some appearance or figure of the reality in which he was to execute it; and he is called μονογενης, or the only begotten, because he *alone* was begotten into the office of redeemer *.

* See *Ridgeley's Body of Divinity.*

63 The express doctrine of scripture.

To many of our readers we doubt not but this will appear a very extraordinary doctrine, and not easy to be reconciled with the unity of God. It is however sufficiently overturned by two sentences of holy scripture, about the meaning of which there can be no dispute. "In this (says St John †) was manifested the love of God towards us, because that God sent his only begotten Son into the world, that we might live through him." Taking the word *son* in its usual acceptation, this was certainly a wonderful degree of love in the Father of mercies to send into the world on our account a person so near related to him as an only son; but if we substitute this novel interpretation of the words *only begotten son* in their stead, the apostle's reasoning will lose all its force. St John will then be made to say, "In this was manifested the love of God toward us, because that God sent a divine person equal to himself, and no way related to him, but who had before the creation covenanted to come into the world, that we might live through him." Is this a proof of the love of the person here called God? Again, the inspired author of the epistle to the Hebrews, treating of our Saviour's priesthood, says, among other things expressive of his humiliation, that "though he was a SON, yet learned he obedience by the things which he suffered ‡." If the word *son* be here understood in its proper sense, this verse displays in a very striking manner the condescension of our divine Redeemer, who, though he was no less a person than the proper Son of God by nature, yet vouchsafed to learn obedience by the things which he suffered; but if we substitute this metaphorical sonship in place of the natural, the reasoning of the author will be very extraordinary. "Though this divine personage agreed before all worlds to suffer death for the redemption of man, yet learned he obedience by the things which he suffered." What sense is there in this argument? Is it a proof of condescension to fulfil one's engagement? Surely, if the meaning of the word *son*, when applied to the second person of the blessed Trinity, were what is here supposed, the inspired writer's argument would have been more to the purpose for which it is brought, had it run thus: "Though he was *not* a son, i. e. though he had made no previous agreement, yet condescended he to learn," &c.

† John iv. 9.

‡ Heb. v. 8.

The other opinion, which supposes the Son and the Holy Ghost to derive from the Father their personality, but not their nature, is to us wholly unintelligible; for personality cannot exist, or be conceived in a state of separation from all natures, any more than a quality can exist in a state of separation from all substances. The former of these opinions we are unable to reconcile with the unity of God; the latter is clothed in words that have no meaning. Both as far as we can understand them, are palpable polytheism; more palpable indeed than that of the Grecian philosophers, who though they worshipped gods many, and lords many, yet all held one God supreme over the rest. See POLYTHEISM, N° 32.

But if the Son and the Holy Ghost derive their nature as well as their personality from the Father, will it not follow that they must be posterior to him in time, since every effect is posterior to its cause? No; this consequence seems to follow only by reasoning too closely from one nature to another, when there is between the two but a very distant analogy. It is indeed true, that among men, every father must be prior in time as well as in the order of nature to his son; but were it essential to a man to be a father, so as that he could not exist otherwise than in that relation, it is obvious that his son would be coeval with himself, though still as proceeding from him, he would be posterior in the order of nature. This is the case with all necessary causes and effects. The visible sun is the immediate and necessary cause of light and heat, either as emitting the rays from his own substance, or as exciting the agency of a fluid diffused for that purpose through the whole system. Light and heat, therefore, must be as old as the sun; and had he existed from eternity, they would have existed from eternity with him, though still, as his effects, they would have been behind him in the order of nature. Hence it is, that as we must speak analogically of the Divine nature, and when treating of mind, even the Supreme mind, make use of words literally applicable only to the modifications of matter, the Nicene fathers illustrate the eternal generation of the second person of the blessed Trinity by this procession of light from the corporeal sun, calling him *God OF God, light OF light.*

64 The second and third persons not posterior to the first.

Another comparison has been made use of to enable us to form some notion, however inadequate, how three Divine persons can subsist in the same substance, and thereby constitute but one God. Moses informs us, that man was made after the image of God. That this relates to the soul more than to the body of man, has been granted by all but a few gross anthropomorphites; but it has been well observed *, that the soul, though in itself one indivisible and unextended substance, is conceived as consisting of three principal faculties, the *understanding*, the *memory*, and the *will*. Of these, though they are all coeval in time, and equally essential to a rational soul, the understanding is in the order of nature obviously the first, and the memory the second; for things must be perceived before they can be remembered; and they must be remembered and compared together before they can excite volitions, from being some agreeable, and others disagreeable. The memory therefore may be said to spring from the understanding, and the will from both; and as these three faculties are conceived to constitute one soul, so may three Divine persons partaking of the same individual nature or essence constitute one God.

* *Leslie's Socinian Controversy.*

65 No contradiction in the Catholic doctrine of the Trinity.

These parallels or analogies are by no means brought forward as proofs of the Trinity, of which the evidence is to be gathered wholly from the word of God; but they serve perhaps to help our labouring minds to form the justest notions of that mystery which it is possible for us to form in the present state of our existence; and they seem to rescue the doctrine sufficiently from the charge of contradiction, which has been so often urged against it by Unitarian writers. To the last analogy we are aware it has often been objected, that the soul may as well be said to consist of ten or twenty faculties as of three, since the passions are equally essential to it with the understanding, the memory, and the will, and are as different from one another as these three faculties are.

This,

This, however, is probably a mistake; for the best philosophy seems to teach us, that the passions are not innate; that a man might exist through a long life a stranger to many of them; and that there are probably no two minds in which are generated *all* the passions (see PASSION); but understanding, memory, and will, are absolutely and equally necessary to every rational being. But whatever be in this, if the human mind can be *conceived* to be one indivisible substance, consisting of different faculties, whether many or few, why should it be thought an impossibility for the infinite and eternal nature of God to be communicated to three persons acting different parts in the creation and government of the world, and in the great scheme of man's redemption.

66 Objections.

To the doctrine of the Trinity many objections have been made, as it implies the divinity of the Son and the Holy Ghost; of whom the former assumed our nature, and in it died for the redemption of man. These we shall notice when we come to examine the revelations more peculiarly Christian; but there is one objection which, as it respects the doctrine in general, may be properly noticed here. It is said that the first Christians borrowed the notion of a Triune God from the later Platonists; and that we hear not of a Trinity in the church till converts were made from the school of Alexandria. But if this be the case, we may properly ask, whence had those Platonists the doctrine themselves? It is not surely so simple or so obvious as to be likely to have occurred to the reasoning mind of a Pagan philosopher; or if it be, why do Unitarians suppose it to involve a contradiction? Plato indeed taught a doctrine in some respects similar to that of the Christian Trinity, and so did Pythagoras, with many other philosophers of Greece and the East (see PLATONISM, POLYTHEISM, and PYTHAGORAS); but though these sages appear to have been on some occasions extremely credulous, and on others to have indulged themselves in the most mysterious speculations, there is no room to suppose that they were *naturally weaker men* than ourselves, or that they were capable of inculcating as truths what they *perceived* to involve a *contradiction*. The Platonic and Pythagorean trinities never could have occurred to the mind of him who merely from the works of creation endeavoured to discover the being and attributes of the Creator; and therefore as those philosophers travelled into Egypt and the East in quest of knowledge, it appears to us in the highest degree probable, that they picked up this mysterious and sublime doctrine in those regions where it had been handed down as a dogma from the remotest ages, and where we know that science was not taught systematically, but detailed in collections of

67 Answered.

sententious maxims and traditionary opinions. If this be so, we cannot doubt but that the Pagan trinities had their origin in some primæval revelation. Nothing else indeed can account for the general prevalence of a doctrine so remote from human imagination, and of which we find vestiges in the sacred books of almost every civilized people of antiquity. The corrupt state in which it is viewed in the writings of Plato and others, is the natural consequence of its descent through a long course of oral tradition; and then falling into the hands of men who bent every opinion as much as possible to a conformity with their own speculations. The trinity of Platonism therefore, instead of being an objection, lends, in our opinion, no feeble support to the Christian doctrine, since it affords almost a complete proof of that doctrine's having made part of the first revelations communicated to man.

Having thus discovered that the one God comprehends three persons, let us now inquire what this triune God exerted when he created the heaven and the earth. That by the heaven and the earth is here meant the whole universe, visible and invisible, is known to every person acquainted with the phraseology of Scripture; and we need inform no man conversant with English writers, that by *creation*, in its proper sense, is meant bringing into *being* or making that to *exist* which existed not *before*. It must, however, be acknowledged, that the Hebrew word ברא does not always imply the production of substance, but very often the forming of particular organized bodies out of pre-existing matter. Thus when it is said* that "God *created* great whales, and every living creature that moveth, which the waters brought forth abundantly after their kind," and again, "that he *created* man male and female;" though the word ברא is used on both occasions, we are not to conceive that the bodies of the first human pair, and of these animals, were brought into being from nonentity, but only that they were formed by a proper organization being given to pre-existent matter. But when Moses says, "In the beginning God *created* the heaven and the earth," he cannot be supposed to mean, that "in the beginning God only gave form to matter already existing of itself;" for in the very next verse we are assured that after this act of creation was over, "the earth was still *without form* and void," or, in other words, in a chaotic state.

68 Creation taught by Moses.

That the Jews, before the coming of our Saviour, understood their lawgiver to teach a proper creation, is plain from that passage in the second book of the Maccabees, in which a mother, to persuade her son to suffer the cruellest tortures rather than forsake the law of his God, uses the following argument: "I beseech thee, my son, look upon the heaven and the earth, and all that is therein, and consider that God made them of things that were not." To the same purpose the inspired author of the epistle to the Hebrews, when magnifying the excellence of faith, says, "Through faith we understand that the worlds were framed by the word of God, so that things which are seen were not made of things which do appear;" where, as Bishop Pearson has ably proved †, the phrase μη εκ φαινομενων is equivalent to ουκ εξ οντων, in the quotation from the Maccabees.

The very first verse, therefore, of the book of Genesis informs us of a most important truth, which all the uninspired wisdom of antiquity could not discover. It assures us, that as nothing exists by chance, so nothing is necessarily existing but the three divine persons in the one Godhead. Every thing else, whether material or immaterial, derives its substance, as well as its form or qualities, from the fiat of that self-existent Being, "who was, and is, and is to come."

69 The whole universe not created at once.

It does not, however, follow from this verse, or from any other passage in the sacred Scriptures, that the whole universe was called into existence at the same instant; neither is it by any means evident that the chaos of our world was brought into being on the first of those six days during which it was gradually reduced into form. From a passage ‡ in the book of Job, in which we are told by God himself, that when the "foundation of the earth

* Gen. i. 21, 27.

† Exposition of the Creed.

‡ xxxviii. 7.

God and his Attributes.

earth was laid the morning stars sang together, and all the sons of God shouted for joy," it appears extremely probable that worlds had been created, formed, and inhabited, long before our earth had any existence. Nor is this opinion at all contrary to what Moses says of the creation of the stars; for though they are mentioned in the same verse with the sun and moon, yet the manner in which, according to the original, they are introduced, by no means indicates that all the stars were formed at the same time with the luminaries of our system. Most of them have been created long before, and some of them since, our world was brought into being; for that clause (ver. 16.) "he made the stars also," is in the Hebrew no more than "and the stars;" the words *he made* being inserted by the translators. The word verse therefore ought to be rendered thus, "and God made two great lights; the greater light to rule the day, and the lesser light with the stars to rule the night; where nothing is intimated with respect to the *time* when the stars were formed, any more than in that verse of the Psalms *, which exhorts us to give thanks to God who made the moon and stars to rule by night; for his mercy endureth "for ever." The first verse of the book of Genesis informs us that all things spiritual and corporeal derive their existence from God; but it is nowhere said that all matter was created at the same time.

* Psalm cxxxvi. 9.

That the whole corporeal universe *may have been* created at once must be granted; but if so, we have reason to believe that this earth, with the sun and all the planets of the system, were suffered to remain for ages in a state of chaos, "without form and void;" because it appears from other scriptures, that worlds of intelligent creatures existed, and even that some angels had fallen from a state of happiness prior to the era of the Mosaic cosmogony. That the sun and the other planets revolving round him were formed at the same time with the earth, cannot indeed be questioned; for it is not only probable in itself from the known laws of nature, but is expressly affirmed by the sacred historian, who relates the formation of the sun and moon in the order in which it took place; but there is one difficulty which has furnished ignorance with something like an objection to the divine legation of the Hebrew lawgiver, and which we shall notice.

70 The solar system created at once.

71 A difficulty solved.

Moses informs us, that on the *first day* after the production of the chaos, the *element of light* was created; and yet within a few sentences he declares, that the sun, the fountain of light, was not made till the *fourth day*. How are these two passages to be reconciled? We answer, That they may be reconciled many ways. Moses wrote for the use of a whole people, and not for the amusement or instruction of a few astronomers; and in this view his language is sufficiently proper, even though we suppose the formation of the sun and the other planets to have been carried on at the same time, and in the same progressive manner, with the formation of this earth. The voice which called light into existence would separate the fiery and luminous particles of the chaos from those which were opaque, and, on this hypothesis, consolidate them in one globe, diffusing an obscure light through the planetary system; but if the earth's atmosphere continued till the fourth day loaded with vapours, as from the narrative of Moses it appears to have done, the sun could not till *that day* have been *seen* from the earth, and may therefore, in popular language, be said with sufficient propriety to have been *formed* on the fourth day, as it was then made to *appear*. (See CREATION, N° 13.) But though this solution of the difficulty serves to remove the objection, and to secure the credit of the sacred historian, candour compels us to confess that it appears not to be the true solution.

The difficulty itself arises entirely from supposing the sun to be the sole fountain of light; but the truth of this opinion is not self-evident, nor has it ever been established by satisfactory proof. It is indeed to a mind divested of undue deference to great names, and considering the matter with impartiality, an opinion extremely improbable. The light of a candle placed on an eminence may in a dark night be seen in every direction at the distance of at least three miles. But if this small body be rendered visible by means of rays emitted from itself, the flame of a candle, which cannot be supposed more than an inch in diameter, must, during every instant that it continues to burn, throw from its own substance luminous matter sufficient to fill a spherical space of six miles in diameter. This phenomenon, if real, is certainly surprising; but if we pursue the reflection a little farther, our wonder will be greatly increased. The matter which, when converted into flame, is an inch in diameter, is not, when of the consistence of cotton and tallow, of the dimensions of the 20th part of an inch; and therefore, on the common hypothesis, the 20th part of an inch of tallow may be so rarefied as to fill a space of 113.0976 cubic miles! a rarefaction which to us appears altogether incredible. We have indeed heard much of the divisibility of matter *ad infinitum*, and think we understand what are usually called *demonstrations* of the truth of that proposition; but these demonstrations prove not the actual divisibility of real solid substances, but only that on trial we shall find no end of the ideal process of dividing and subdividing imaginary extension.

On the whole, therefore, we are much more inclined to believe that the matter of light is an extremely subtile fluid, diffused through the corporeal universe, and only excited to agency by the sun and other fiery bodies, than that it consists of streams continually issuing from the substance of these bodies. It is indeed an opinion pretty generally received, and certainly not improbable in itself, that light and electricity are one and the same substance (see ELECTRICITY-*Index*); but we know that the electrical fluid, though pervading the whole of corporeal nature, and, as experiments show, capable of acting with great violence, yet lies dormant and unperceived till its agency be excited by some foreign cause. Just so it may be with the matter of light. That substance may be "diffused from one end of the creation * to the other. It may traverse the whole universe, form a communication between the most remote spheres, penetrate into the inmost recesses of the earth, and only wait to be put in a proper motion to communicate visible sensations to the eye. Light is to the organ of sight what the air is to the organ of hearing. Air is the medium which, vibrating on the ear, causes the sensation of sound; but it equally exists round us at all times, though there be no sonorous body to put it in motion. In like manner, light may be equally extended at all times, by night as well as by day, from the most distant fixed stars to this earth, though it then only strikes our eyes so as to excite visible sensations when impelled by the sun or some other mass of

* *Nature displayed.*

God and his Attributes.

of fire." Nor let any one imagine that this hypothesis interferes with any of the known laws of optics; for if the rays of light be impelled in straight lines, and in the same direction in which they are supposed to be emitted, the phenomena of vision must necessarily be the same.

72 Moses a sound philosopher.

Moses therefore was probably a more accurate philosopher than he is sometimes supposed to be. The element of light was doubtless created, as he informs us, on the first day; but whether it was then put in that state in which it is the medium of vision, we cannot know, and we need not inquire, since there was neither man nor inferior animal with organs fitted to receive its impressions. For the first three days it may have been used only as a powerful instrument to reduce into order the jarring chaos. Or if it was from the beginning capable of communicating visible sensations, and dividing the day from the night, its agency must have been immediately excited by the Divine power till the fourth day, when the sun was formed, and endowed with proper qualities for instrumentally discharging that office. This was indeed miraculous, as being contrary to the present laws of nature: but the whole creation was miraculous; and we surely need not hesitate to admit a less miracle where we are under the necessity of admitting a greater. The power which called light and all other things into existence, could give them their proper motions by ten thousand different means; and to attempt to solve the difficulties of creation by philosophic theories respecting the laws of nature, is to trifle with the common sense of mankind: it is to consider as subservient to a law that very power by whose continued exertion the law is established.

Having thus proved that the universe derives its being, as well as the form and adjustment of its several parts, from the one supreme and self-existent God, let us here pause, and reflect on the sublime conceptions which such astonishing works are fitted to give us of the divine perfections.

73 Infinite power of the Creator.

And, in the first place, how strongly do the works of creation impress on our minds a conviction of the infinite power of their Author? He spoke, and the universe started into being; he commanded, and it stood fast. How mighty is the arm which "stretched out the heavens and laid the foundations of the earth; which removeth the mountains and they know it not; which overturneth them in his anger; which shaketh the earth out of her place, and the pillars thereof tremble! How powerful the word which commandeth the sun, and it riseth not; and which sealeth up the stars;" which sustaineth numberless worlds of amazing bulk suspended in the regions of empty space, and directs their various and inconceivably rapid motions with the utmost regularity! "Lift up your eyes on high, and behold, who hath created all these things? By the word of the Lord were the heavens made, and all the host of them by the breath of his mouth. Hell is naked before him, and destruction hath no covering. He stretcheth out the North over the empty place, and hangeth the earth upon nothing. He has measured the waters in the hollow of his hand, and meted out the heavens with a span; and comprehended the dust of the earth in a measure; and weighed the mountains in scales, and the hills in a balance. Behold! the nations are as a drop of the bucket, and are counted as the small dust of the balance; behold, he taketh up the isles as a very little thing. All nations before him are as nothing, and they are counted to him less than nothing, and vanity. To whom then will ye liken God, or what likeness will ye compare unto him * ?"

* Ps. xxxiii. 6, 9; Job ix. 4. &c. xxvi. 6; Isa. xi. 12.

74 His wisdom.

As the works of creation are the effects of God's power, they likewise in the most eminent manner display his wisdom. This was so apparent to Cicero, even from the partial knowledge in astronomy which his time afforded, that he declared † those who could assert the contrary void of all understanding. But if that great master of reason had been acquainted with the modern discoveries in astronomy, which exhibit numberless worlds scattered through space, and each of immense magnitude; had he known that the sun is placed in the centre of our system, and that to diversify the seasons the planets move round him with exquisite regularity; could he have conceived that the distinction between light and darkness is produced by the diurnal rotation of the earth on its own axis, instead of that disproportionate whirling of the whole heavens which the ancient astronomers were forced to suppose; had he known of the wonderful motions of the comets, and considered how such eccentric bodies have been preserved from falling upon some of the planets in the same system, and the several systems from falling upon each other; had he taken into the account that there are yet greater things than these, and "that we have seen but a few of God's works;"— that virtuous Pagan would have been ready to exclaim in the words of the Psalmist, "O Lord, how manifold are thy works! In wisdom hast thou made them all; the earth is full of thy riches."

† *De Nat. Deorum*, lib. ii.

75 and goodness.

That creation is the offspring of unmixed goodness, has been already shown with sufficient evidence (see METAPHYSICS, N° 312. and N° 29. of this article); and from the vast number of creatures on our earth endowed with life and sense, and a capability of happiness, and the infinitely greater number which probably inhabit the planets of this and other systems, we may infer that the goodness of God is as boundless as his power, and that "as is his majesty, so is his mercy." Out of his own fulness hath he brought into being numberless worlds, replenished with myriads of myriads of creatures, furnished with various powers and organs, capacities and instincts; and out of his own fulness he continually and plentifully supplies them all with every thing necessary to make their existence comfortable. "The eyes of all wait upon him, and he giveth them their meat in due season. He openeth his hand and satisfies the desires of every living thing; he loveth righteousness and judgment; the earth is full of the goodness of the Lord. He watereth the ridges thereof abundantly; he settleth the furrows thereof; he maketh it soft with showers, and blesseth the springing thereof. He crowneth the year with his goodness; and his paths drop fatness. They drop upon the pastures of the wilderness; and the little hills rejoice on every side. The pastures are clothed with flocks; the valleys also are covered with corn; they shout with joy, they also sing ‡." Survey the whole of what may be seen on and about this terraqueous globe, and say, if our Maker hath a sparing hand. Surely the Author of so much happiness must be essential goodness; and we must conclude with St John, that "God is love."

‡ Ps. cxiv. 15, 16. xxiii. 5. lv. 10. &c.

These attributes of power, wisdom, and goodness, so conspicuously

God and his Attributes.

conspicuously displayed in the works of creation, belong in the same supreme degree to each person in the blessed Trinity; for Moses declares that the heaven and the earth were created, not by *one* person, but by the *Elohim*. The λογος indeed, or second person, appears to have been the *immediate* Creator; for St John assures us *, that "all things were made by him, and that without him was not any thing made that was made." Some Arian writers of great learning (and we believe the late Dr Price was of the number) have asserted, that a being who was created himself may be endowed by the Omnipotent God with the power of creating other beings; and as they hold the λογος or *word*, to be a creature, they contend that he was employed by the Supreme Deity to create, not the whole universe, but only this earth, or at the utmost the solar system. "The old argument (says one of them), that no being inferior to the great Omnipotent can create a world, is so childish as to deserve no answer. Why may not God communicate the power of making worlds to any being whom he may choose to honour with so glorious a prerogative? I have no doubt but such a power may be communicated to many good men during the progress of their existence; and to say that it may *not*, is not only to limit the power of God, but to contradict acknowledged analogies."

76 The second person in the Trinity the immediate Creator.

* Ch. i. 3.

77 Creation peculiar to God.

We are far from being inclined to limit the power of God. He can certainly do whatever involves not a direct contradiction; and therefore, though we know nothing *analogous* to the power of *creating worlds*, yet as we perceive not any contradiction implied in the notion of that power being communicated, we shall admit that such a communication may be *possible*, though we think it in the highest degree *improbable*. But surely no man will contend that the *whole universe* was brought into existence by *any creature;* because that creature himself, however highly exalted, is necessarily comprehended in the notion of the universe. Now St Paul expressly affirms †, that, by the second person in the blessed Trinity, "were ALL *things* created that are in heaven, and that are in earth, *visible* and *invisible*, whether they be THRONES, or DOMINIONS, or PRINCIPALITIES, or POWERS; all things were created by him and for him; and he is before all things, and by him all things consist." Indeed the Hebrew Scriptures in more places than one ‡ expressly declare that this earth, and of course the whole solar system, was *formed*, as well as *created*, not by an inferior being, but by the *true* God, even *Jehovah* alone; and in the New Testament §, the Gentiles are said to be without excuse for not glorifying him as God, "because his eternal power and Godhead are clearly seen from the creation of the world." But if it were natural to suppose that the power of creating worlds has been, or ever will be, communicated to beings inferior to the great Omnipotent, this reasoning of the apostle's would be founded on false principles, and the sentence which he passed on the Heathen would be contrary to justice.

† Colos. iv. 17.

‡ Isa. xl. 12. xliv. 24. Jerem. x. 10—13.

§ Rom. i. 18—22.

But though it be thus evident that the λογος was the immediate Creator of the universe, we are not to suppose that it was without the concurrence of the other two persons. The Father, who may be said to be the fountain of the Divinity itself, was certainly concerned in the creation of the world, and is therefore in the apostle's creed denominated the "Father Almighty Maker of heaven and earth;" and that the Holy Ghost or third person is likewise a Creator, we have the express testimony of two inspired writers: "By the word of the Lord (says the Psalmist) were the heavens made, and all the host of them by the breath (Hebrew, SPIRIT) of his mouth." And Job declares, that the "SPIRIT of God made him, and that the breath of the Almighty gave him life." Indeed these three divine persons are so intimately united, that what is done by one must be done by all, as they have but one and the same will. This is the reason assigned by Origen * for our paying divine worship to each; *θρησκευόμεν ουν τον πατερα της αληθειας και τον υιον την αληθειαν οντα δυο τη υποστασει πραγματα, εν δε τη ομονοια, και τη συμφωνια και τη ταυτοτητι της βουλησεως*, "we worship the Father of truth, and the Son the truth itself, being two things as to hypostasis, but one in agreement, consent, and sameness of will." Nor is their union a mere agreement in will only; it is a physical or essential union: so that what is done by one must necessarily be done by the others also, according to that of our Saviour, "I am in the Father and the Father in me: The Father who dwelleth in me, he doth the works."

* *Contr. Cels.* p. 386.

SECT. II. *Of the Original State of Man, and the first Covenant of Eternal Life which God vouchsafed to make with him.*

78 Peculiarity of the expression in which God is said to make man.

In the Mosaic account of the creation, every attentive reader must be struck with the manner in which the supreme Being is represented as making man: "And God said, let us make man in our image, after our likeness; and let *them* have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth. So God created man in his own image; in the image of God created he him; male and female created he THEM. And God blessed them; and God said unto them, be fruitful, and multiply, and replenish the earth, and subdue it; and have dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth. And God said, behold, I have given you every herb bearing seed, which is upon the face of all the earth; and every tree, in the which is the fruit of a tree yielding seed: to you it shall be for meat. And God saw every thing that he had made, and, behold, it was very good. And the evening and the morning were the sixth day. Thus the heavens and the earth were finished, and all the host of them. And on the seventh day God ended his work which he had made; and he rested on the seventh day from all his works which he had made. And God blessed the seventh day and sanctified it: because that in it he had rested from all his work which God created and made ‡."

‡ Gen. i. 26, &c. ii. 1, 2, 3.

This is a very remarkable passage, and contains much important information. It indicates a plurality of persons in the Godhead, describes the nature of man as he came at first from the hands of his Creator, and furnishes data from which we may infer what were the duties required of him in that primeval state, and what were the rewards to which obedience would entitle him.

79 In his own image.

Of the plurality of Divine persons, and their essential union, we have treated in the preceding section, and proceed now to inquire into the specific nature of the first man. This must be implied in the *image of God*, in

Original State of Man.

in which he is said to have been created; for it is by that phrase alone that he is characterized, and his pre-eminence marked over the other animals. Now this image or likeness must have been found either in his body alone, his soul alone, or in both united. That it could not be in his body alone, is obvious; for the infinite and omnipotent God is allowed by all men to be without body, parts, or passions, and therefore to be such as nothing corporeal can possibly resemble.

80 Different opinions respecting the image of God.

If this likeness is to be found in the human soul, it comes to be a question in what faculty or power of the soul it consists. Some have contended, that man is the only creature on this earth who is animated by a principle essentially different from matter; and hence they have inferred, that he is said to have been formed in the Divine image, on account of the immateriality of that vital principle which was infused into his body when the "Lord God breathed into his nostrils the breath of life, and man became a living soul †." That this account of the animation of the body of man indicates a superiority of the human soul to the vital principle of all other animals, cannot, we think, be questioned; but it does not therefore follow, that the human soul is the only immaterial principle of life which animates any terrestrial creature. It has been shown elsewhere (see METAPHYSICS, N° 235.), that the power of sensation, attended with individual consciousness, as it appears to be in all the higher species of animals, cannot result from any organical structure, or be the quality of a compound extended being. The vital principle in such animals therefore must be immaterial as well as the human soul; but as the word *immaterial* denotes only a negative notion, the souls of men and brutes, though both immaterial, may yet be substances essentially different. This being the case, it is plain that the Divine image in which man was formed, and by which he is distinguished from the brute creation, cannot consist in the mere circumstance of his mind being a substance different from matter, but in some positive quality which distinguishes him from every other creature on this globe.

† Gen. ii. 7.

81 Calvinistic opinions.

About this characteristic quality various opinions have been formed. Some have supposed ‡ "that the image of God in Adam appeared in that rectitude, righteousness, and holiness, in which he was made; for God made man upright (Eccles. vii. 2.), a holy and righteous creature; which holiness and righteousness were in their kind perfect; his understanding was free from all error and mistakes; his will biassed to that which is good; his affections flowed in a right channel towards their proper objects; there were no sinful motions and evil thoughts in his heart, nor any propensity or inclination to that which is evil; and the whole of his conduct and behaviour was according to the will of God. And this righteousness (say they) was *natural*, and not personal and acquired. It was not obtained by the exercise of his free-will, but was created with him, and belonged to his mind, as a natural faculty or instinct." They therefore call it *original righteousness*, and suppose that it was lost in the fall.

‡ *Gill's Body of Divinity*, b. iii. ch. 3.

82 Objected to.

To this doctrine may objections have been made. It has been said that righteousness consisting in right actions proceeding from proper principles, could not be created with Adam and make a part of his nature; because nothing which is produced in a man without his knowledge and consent can be in him either virtue or vice. Adam, it is added, was unquestionably placed in a state of trial, which proves that he had righteous habits to *acquire*; whereas the doctrine under consideration, affirming his original righteousness to have been perfect, and therefore incapable of improvement, is inconsistent with a state of trial. That his understanding was free from all errors and mistakes, has been thought a blasphemous position, as it attributes to man one of the incommunicable perfections of the Deity. It is likewise believed to be contrary to fact; for either his understanding was bewildered in error, or his affections flowed towards an improper object, when he suffered himself at the persuasion of his wife to transgress the express law of his Creator. The objector expresses his wonder at its having ever been supposed that the *whole* of Adam's conduct and behaviour was according to the will of God, when it is so notorious that he yielded to the first temptation with which, as far as we know, he was assailed in paradise.

Convinced by these and other arguments, that the image of God in which man was created could not consist in original righteousness, or in exemption from all possibility of error, many learned men, and Bishop Bull § among others, have supposed, that by the image of God is to be understood certain gifts and powers supernaturally infused by the Holy Spirit into the minds of our first parents, to guide them in the ways of piety and virtue. This opinion they rest chiefly upon the authority of Tatian, Irenæus, Tertullian, Cyprian, Athanasius, and other fathers of the primitive church; but they think, at the same time, that it is countenanced by several passages in the New Testament. Thus when St Paul says ||, "and so it is written, The first man Adam was made a living soul, the last Adam was made a quickening Spirit;" they understand the whole passage as relating to the creation of man, and not as drawing a comparison between Adam and Christ, to show the great superiority of the latter over the former. In support of this interpretation they observe, that the apostle immediately adds, "howbeit, that was not first which is spiritual, but that which is natural, and afterwards that which is spiritual;" an addition which they think was altogether needless, if by the quickening Spirit he had referred to the incarnation of Christ, which had happened in the very age in which he was writing. They are therefore of opinion, that the body of Adam, after being formed of the dust of the ground, was first animated by a vital principle endowed with the faculties of reason and sensation, which entitled the whole man to the appellation of a living soul. After this they suppose certain graces of the Holy Spirit to have been infused into him, by which he was made a quickening spirit, or formed in the image of God; and that it was in consequence of this succession of powers communicated to the same person, that the apostle said, "Howbeit, that was not first which is spiritual, but that which is natural."

§ See his *English Works*, vol. iii.

83 Opinion of Bishop Bull and some of the ancient fathers.

|| 1 Cor. xv. 45, 46.

We need hardly observe, that with respect to a question of this kind the authority of *Tatian* and the other fathers quoted is nothing. Those men had no better means of discovering the true sense of the scriptures of the Old Testament than we have; and their ignorance of the language in which these scriptures are written, added to some metaphysical notions respecting the soul, which

which too many of them had derived from the school of Plato, rendered them very ill qualified to interpret the writings of Moses. Were authority to be admitted, we should consider that of Bishop Bull and his modern followers as of greater weight than the authority of all the ancients to whom they appeal. But authority cannot be admitted; and the reasoning of this learned and excellent man from the text of St Paul is surely very inconclusive. It makes two persons of Adam; a first,

84 ill-founded.

when he was a natural man composed of a body and a reasonable soul; a second, when he was endowed with the gifts of the Holy Spirit, and by them formed in the image of God! In the verse following too, the apostle expressly calls the second man, of whom he had been speaking, "the Lord from heaven;" but this appellation we apprehend to be too high for Adam in the state of greatest perfection in which he ever existed. That our first parents were endowed with the gifts of the Holy Ghost, we are strongly inclined to believe for reasons which shall be given by and by; but as these gifts were adventitious to their nature, they could not be that image in which God *made* man.

85 Other opinions.

Since man was *made* in the image of God, that phrase, whatever be its precise import, must denote something *peculiar* and at the same time essential to human nature; but the only two qualities at once natural and peculiar to man are his shape and his reason. As none but an anthropomorphite will say that it was Adam's shape which reflected this image of his Creator, it has been concluded that it was the faculty of reason which made the resemblance. To give strength to this argument it is observed †, that when God says, "let us make man in our image," he immediately adds, "and let them have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth;" but as many of the cattle have much greater bodily strength than man, this dominion could not be maintained but by the faculty of reason bestowed upon him and withheld from them.

† *Warburton's Divine Leg.* book ix.

If the image of God was impressed only on the mind of man, this reason seems to be conclusive; but it has been well observed ‡ that it was the whole man, and not the *soul alone*, or the *body* alone, that is said to have been formed in the divine image; even as the whole man, soul and body, is the seat of the new and spiritual image of God in regeneration and sanctification. "The very God of peace (says the apostle) sanctify you wholly; and may your whole *spirit*, *soul*, and *body*, be preserved blameless to the coming of our Lord Jesus Christ." It is worthy of notice, too, that the reason assigned for the prohibition of murder to Noah and his sons after the deluge, is, that man was made in the image of God. "Whoso sheddeth man's blood, by man shall his blood be shed; for in the image of God made he man." These texts seem to indicate, that whatever be meant by the image of God, it was stamped equally on the soul and on the body. In vain is it said that man cannot resemble God in shape. This is true, but it is little to the purpose; for man does not resemble God in his reasoning faculty more than in his form. It would be idolatry to suppose the supreme majesty of heaven and earth to have a body or a shape; and it would be little short of idolatry to imagine that he is obliged to compare ideas and notions together; to advance from particular truths to general propositions; and to acquire acknowledge, as we do, by the tedious processes of inductive and syllogistic reasoning. There can therefore be no direct image of God either in the soul or in the body of man; and the phrase really seems

‡ *Gill's Body of Divinity*, book iii. chap. 3.

86 True import of the phrase.

to import nothing more than those powers or qualities by which man was fitted to exercise dominion over the inferior creation; as if it had been said, "Let us make man in our image, after our likeness, that *they may have* dominion, &c." But the erect form of man contributes in some degree, as well as his rational powers, to enable him to maintain his authority over the brute creation; for it has been observed by travellers, that the fiercest beast of prey, unless ready to perish by hunger, shrinks back from a steady look of the human face divine.

By some *, however, who have admitted the probability of this interpretation, another has been devised for its being said that man was formed in the image of God. All the members of Christ's body, say they, were written and delineated in the book of God's purposes and decrees, and had an ideal existence from eternity in the divine mind; and therefore the body of Adam might be said to be formed after the image of God, because it was made according to that idea. But to this reasoning objections may be urged, which we know not how to answer. All things that ever were or ever shall be, the bodies of us who live at present as well as the bodies of those who lived 5000 years ago, have from eternity had an ideal existence in the Divine mind; nor in this sense can one be said to be prior to another. It could not therefore be after the idea of the identical body of Christ that the body of Adam was formed; for in the Divine mind ideas of both bodies were present together from eternity, and each body was formed after the ideal archetype of itself. It may be added likewise, that the body of Christ was not God, nor the idea of that body the idea of God. Adam therefore could not with propriety be said to have been formed in the image of God, if by that phrase nothing more were intended than the resemblance between his body and the body of Christ. These objections to this interpretation appear to us unanswerable; but we mean not to dictate to our readers. Every man will adopt that opinion which he thinks supported by the best arguments; but it is obvious, that whatever more may be meant by the image of God in which man was made, the phrase undoubtedly comprehends all those powers and qualities by which he is enabled to maintain his authority over the inferior creation. Among these the faculty of reason is confessedly the most important; for it is by it that man is capable of being made acquainted with the Author of his being, the relation which subsists between them, and the duties implied in that relation from the creature to the Creator.

* *Gill*, &c.

87 Religious instruction communicated to Adam.

That the first man, however, was not left to discover these things by the mere efforts of his own unassisted reason, we have endeavoured to show in another place; (see Religion, N° 5—10.); and the conclusion to which we were there led, is confirmed by the portion of revelation before us. The inspired historian says, that "God blessed the seventh day and *sanctified* it, because that in it he had rested from all his works, which he created and made;" but Adam could not have understood what was meant by the *sanctification* of a particular day, or of any thing else, unless he had previously received

Original State of Man.

received some religious instruction. There cannot therefore be a doubt, but that as soon as man was made, his Creator communicated to him the truths of what is called natural religion, which we have endeavoured to explain and establish in Part I. of this article; and to these were added the precept to keep holy the Sabbath-day, and set it apart for the purposes of contemplation and worship.

88 Institution of the Sabbath.

This was a very wise institution, as all the divine institutions must be. "The great end for which we are brought into life, is to attain the knowledge and be confirmed in the love of God. This includes obedience to his will in thought, word, and deed, or that course of conduct which can alone make us happy here, and fit us for everlasting glory hereafter. But of these things we cannot retain a proper sense without close and repeated application of thought; and the unavoidable cares and concerns of the present life occupying much of our attention, it is, in the nature of things, necessary that some certain portion of time should be appropriated to the purposes of religious instruction and the public adoration of our Creator, in whom we all live, and move, and have our being." Hence a very learned divine † has inferred, that though the particular time is a matter of positive appointment, the observation of a sabbath in general is a duty of natural religion, as having its foundation in the reason of things. See SABBATH.

† *Dr Taylor of Norwich.*

89 Duties of man in his original state,

Man therefore in his *natural* and original state was a rational and religious being, bound to do "justice, to love mercy, to walk humbly with his God, and to keep holy the Sabbath-day." These seem to be all the duties which in that state were required of him; for as soon as he was introduced into the terrestrial paradise and admitted into covenant with his Maker, he was placed in a *supernatural* state, when other duties were of course enjoined.

That our first parents were both made on the sixth day, Moses expressly affirms when he says ‡, that "God created them male and female, and blessed them, and called *their* name *Adam* (K), in the day when they were created:" but that they were introduced into the garden of Eden on that day, is an opinion which, however generally it may be received, seems not to be reconcileable with the plain narrative of the sacred penman. After telling us that on the sixth day God finished all his works, which he saw to be very good, and rested on the seventh day, he briefly recapitulates the history of the generations of the heavens and of the earth, gives us a more particular account of the formation of the first man, informing us that the "Lord God formed him out of the dust of the ground, and breathed into his nostrils the breath of life, when man became a living soul;" and then proceeds to say ‖, that the "Lord God planted a garden eastward in Eden, where he put the man whom he HAD *formed*." From this short history of the first pair it appears beyond dispute evident, that neither the man nor the woman was formed *in* the garden; and that from their creation some time elapsed before the garden was prepared for their reception, is likewise evident from a comparison of Gen. i. 29. with Gen. ii. 16, 17. In the first of these passages God gives to man, immediately after his creation, "every herb bearing seed which was upon the face of all the earth, and *every tree*, without exception, in which was the fruit of a tree bearing seed: to him he said it should be for meat." In the second, "he commanded the man saying, of every tree of the garden thou mayest freely eat; but of the tree of knowledge of good and evil, thou shalt not eat of it; for in the day thou eatest thereof thou shalt surely die." When the first grant of food was given, Adam and his wife must have been where no tree of knowledge grew, and they must have been intended to live at least so long in that state as that they should have occasion for food, otherwise the formal grant of it would have been not only superfluous, but apt to mislead them with respect to the subsequent restriction.

‡ Gen. i. 27. v. 2.

‖ Gen. ii. 7, 8, and 15.

90 before he was placed in the garden of Eden,

In this original state man was under the discipline of what we have called *natural religion*, entitled to happiness while he should perform the duties required of him, and liable to punishment when he should neglect those duties, or transgress the law of his nature as a rational and moral agent. This being the case, it is a matter of some importance, to ascertain, if we can, what the rewards and punishments are which natural religion holds out to her votaries.

That under every dispensation of religion the pious and virtuous man shall enjoy more happiness than misery; and that the incorrigibly wicked shall have a greater portion of misery than happiness, are truths which cannot be controverted by any one who admits, that the Almighty governor of the universe is a Being of wisdom, goodness, and justice. But respecting the rewards of virtue and the punishment of vice, more than these general truths seems not to be taught by natural religion. Many divines, however, of great learning and worth, have thought otherwise, and have contended, that from the nature of things the rewards bestowed by an infinite God upon piety and virtue must be eternal like their author. These men indeed appear willing enough to allow that the punishments with which natural religion is armed against vice must be only of a temporary duration, because reason, say they, is ready to revolt at the thought of *everlasting* punishment.

91 did not when performed, entitle him to eternal life.

This opinion, which confounds natural with revealed religion, giving to the former an important truth which belongs exclusively to the latter, has been so ably confuted by a learned writer, that we shall submit his arguments to our readers in preference to any thing which we can give ourselves.

"If reason doth, on the one hand, seem to revolt at *everlasting punishment*, we must confess that FANCY, on the other, (even when full plumed by *vanity*), hath scarcely force enough to rise to the idea of *infinite rewards*. How the heart of man came to consider this as no more than an adequate retribution for his right conduct during the short trial of his virtue here, would be

(K) The woman was some time afterwards distinguished by the name of Eve, חוה, because she was to be the mother of all living, and particularly of that blessed seed which was to bruise the head of the serpent. See *Parkhurst's Lexicon* on the word.

Original State of Man.

be hard to tell, did we not know what monsters PRIDE begot of old upon *Pagan philosophy*; and how much greater still these latter ages have disclosed, *by the long* incubation of *school-divinity* upon *folly*. What hath been urged from natural reason, in support of this extravagant presumption, is so very slender, that it recoils as you enforce it. First, you say, "that the soul, the subject of these eternal rewards, being *immaterial*, and so therefore unaffected by the causes which bring material things to an end, is, by its nature, fitted for eternal rewards.—This is an argument *ad ignorantiam*, and holds no farther.—Because an *immaterial* being is not subject to that mode of dissolution which affects *material* substances, you conclude it to be eternal. This is going too fast. There may be, and probably are, many natural causes (unknown indeed to us), whereby immaterial beings come to an end. But if the nature of things cannot, yet God certainly can, put a final period to such a being when it hath served the purpose of its creation. Doth ANNIHILATION impeach that wisdom and goodness which was displayed when God brought it *out of nothing*? Other immaterial beings there are, viz. the souls of brutes, which have the same natural security with man for their existence, of whose *eternity* we never dream. But pride, as the poet observes, *calls God unjust*,

92 Arguments to prove that they did inconclusive.

> If man alone engross not heaven's high care;
> Alone made *perfect* here, IMMORTAL there.

However, let us (for argument's sake) allow the human soul to be unperishable by nature, and secured in its existence by the unchangeable will of God, and see what will follow from thence—An *infinite* reward for virtue during one moment of its existence, because reason discovers that, by the law of nature, *some* reward is due? By no means. When God hath amply repaid us for the performance of our duty, will he be at a loss how to dispose of us for the long remainder of *eternity*? May he not find new and endless employment for reasonable creatures, to which, when properly discharged, new rewards and in endless succession will be assigned? Modest reason seems to dictate this to the followers of the *law of nature*. The flattering expedient of ETERNAL REWARDS for virtue here was invented in the simplicity of early speculation, after it had fairly brought men to conclude that the soul is immaterial.

"Another argument urged for the eternity of the rewards held out by natural religion to the practice of piety and virtue is partly physical and partly moral. The merit of service (say the admirers of that religion) increases in proportion to the excellence of that Being to whom our service is directed and becomes acceptable. An infinite being, therefore, can dispense no rewards but what are infinite. And thus the virtuous man becomes entitled to immortality.

"The misfortune is, that this reasoning holds equally on the side of the unmerciful doctors, as they are called, who doom the wicked to EVERLASTING PUNISHMENT. Indeed were this the only discredit under which it labours, the merciless doctors would hold themselves little concerned. But the truth is, that the argument from *infinity* proves just nothing. To make it of any force, both the parties should be *infinite*. This inferior emanation of God's *image*, MAN, should either be supremely good or supremely bad, a kind of deity or a kind of devil. But these reasoners, in their attention to the *divinity*, overlook the *humanity*, which makes the decrease keep pace with the accumulation, till the rule of logic, that the *conclusion follows the weaker* part, comes in to end the dispute *."

* Warburton's Divine Legation, book ix.

These arguments seem to prove unanswerably that immortality is not essential to any part of the compound being man, and that it cannot be claimed as a reward due to his virtue. It is not indeed essential to any created being, for what has not existence of itself, cannot of itself have perpetuity of existence (see METAPHYSICS, N° 272, &c.); and as neither man nor angel can be profitable to God, they cannot claim from him any thing as a debt. Both, indeed, as moral agents, have duties prescribed them; and while they faithfully perform these duties, they have all the security which can arise from the perfect benevolence of him who brought them into existence, that they shall enjoy a sufficient portion of happiness to make that existence preferable to non-existence; but reason and philosophy furnish no data from which it can be inferred that they shall exist for ever. Man is composed in part of perishable materials. However perfect Adam may be thought to have been when he came first from the hands of his Creator, his body, as formed of the dust of the ground, must have been naturally liable to decay and dissolution. His soul, indeed, was of a more durable substance; but as it was formed to animate his body, and had no prior conscious existence, it is not easy to conceive what should have led him, under an equal providence, where rewards and punishments were exactly distributed, to suppose that one part of him should survive the other. In his natural and original state, before the covenant made with him in paradise, he was unquestionably a mortal creature. How long he continued in that state, it seems not possible to form a plausible conjecture. Bishop Warburton supposes him to have lived several years under no other dispensation than that of natural religion; during which he was as liable to death as his fallen posterity are at present.

93 Adam before his introduction into paradise liable to death.

"We must needs conclude (says this learned writer*), that God having tried Adam in *the state of nature*, and approved of the good use he made of his free-will under the direction of that light, advanced him to a superior station in *Paradise*. How long, before this remove, man had continued subject to *natural religion* alone, we can only guess: but of this we may be assured, that it was some considerable time before the garden of Eden could naturally be made fit for his reception. Since Moses, when he had concluded his history of the creation, and of God's *rest* on, and *sanctification* of, the seventh day, proceeds to speak of the condition of this new world in the following terms: "*And God made every plant of the field before it was in the earth, and every herb of the field before it grew; for the Lord God had not caused it to rain upon the earth* ‡." Which seems plainly to intimate, that when the seeds of vegetables had been created on the third day, they were left to nature, in its ordinary operations, to mature by sun and showers. So that when in course of time Paradise was become capable of accommodating its inhabitants, they were transplanted thither."

* Divine Legation, book ix. chap. i.

94 How long he continued in that state.

‡ Gen. ii. 4, 5.

This reasoning is not without a portion of that ingenuity which was apparent in every thing that fell from the pen of Warburton; but it was completely confut-ed

Original State of Man

ed almost as soon as it was given to the public, and shown to be deduced from premises which could be employed against the author's system. If only the *seeds* of vegetables were created on the third day, and then left to nature, in its ordinary operations, to mature by sun and showers, the first pair must have perished before a single vegetable could be fit to furnish them with food; and we may suppose that it was to prevent this disaster that the garden of Eden was miraculously stored at once with full grown trees and fruit in perfect maturity, whilst the rest of the earth was left under the ordinary laws of vegetation. There is, however, no evidence that they were only the *seeds* of vegetables that God created. On the contrary, Moses says expressly *, that God made the earth on the third day bring forth the herb *yielding* seed after his kind, and the tree *yielding fruit* whose *seed* was in itself after his kind;" and when he recapitulates the history of the creation, he says, that God made, not every seed, but every *plant* of the field *before* it was in the earth, and every *herb* of the field *before* it grew. From the process of vegetation, therefore, nothing can be inferred with respect to the time of Adam's introduction into paradise, or to ascertain the duration of his original state of nature. If angels were created during the six days of which the Hebrew lawgiver writes the history, an hypothesis very generally received (see ANGEL), though in the opinion of the present writer not very probable, there can be no doubt but our first parents lived a considerable time under the law of nature before they were raised to a superior station in the garden of Eden; for it seems very evident that the period of their continuance *in* that station was not long. Of this, however, nothing can be said with certainty. They may have lived for years, or only a few days in their original state; but it is very necessary to distinguish between that state in which they were under no other dispensation than what is commonly called *natural religion*, entitled, upon their obedience, to the indefinite rewards of piety and virtue, and their state in Paradise when they were put under a new law, and by the free grace of God promised, if they should be obedient, a supernatural and eternal reward. Into that state we must now attend them, and ascertain, if we can, the precise terms of the first covenant.

* Gen. i. 12.

95 impossible to be known.

Moses, who in this investigation is our only guide, tells us, that the Lord God, after he had formed the first pair, "planted a garden eastward in Eden, and took the man and put him in the garden to dress it and to keep it. And the Lord God (continues he) commanded the man, saying, Of every tree of the garden thou mayest freely eat; but of the tree of the knowledge of good and evil thou shalt not eat of it; for in the day that thou eatest thereof, thou shalt surely die †." Here is no mention made of the laws of piety and moral virtue resulting from the relations in which the various individuals of the human race stand to each other, and in which all his creatures stand to God their Almighty and beneficent Creator. With these laws Adam was already well acquainted; and he must have been sensible, that as they were founded in his nature, no subsequent law could dispense with their obligation. They have been equally binding on all men in every state and under every dispensation; and they will continue to be so as long as the general practice of justice, mercy, and piety, shall contribute to the sum of human happiness. The new law peculiar to his paradisaical state was the command not to eat of the fruit of the tree of the knowledge of good and evil. This was a positive precept, not founded in the nature of man, but very proper to be the test of his obedience to the will of his Creator. The laws of piety and virtue are sanctioned by nature, or by that general system of rules according to which God governs the physical and moral worlds, and by which he has secured, in some state or other, happiness to the pious and virtuous man, and misery to such as shall prove incorrigibly wicked. The law respecting the forbidden fruit was sanctioned by the penalty of *death* denounced against disobedience; and by the subjects of that law the nature of this penalty must have been perfectly understood: but Christian divines, as we shall afterwards see, have differed widely in opinion respecting the full import of the Hebrew words which our translators have rendered by the phrase *thou shalt surely die*. All, however, agree that they threatened death, in the common acceptation of the word, or the separation of the soul and body, as one part of the punishment to be incurred by eating the forbidden fruit; and hence we must infer, that had the forbidden fruit not been eaten, our first parents would never have died, because the penalty of death was denounced against no other transgression. What therefore is said respecting the fruit of the tree of knowledge, implies not only a law but also a covenant (L), promising to man, upon the observance of one positive precept, immortality or eternal life; which is not essential to the nature of any created being, and cannot be claimed as the merited reward of the greatest virtue or the most fervent piety.

† Gen. ii. 8, 15, 16, 17.

96 The covenant of eternal life made with Adam in paradise.

This obvious truth will enable us to dispose of the objections which have been sometimes brought by freethinking divines against the wisdom and justice of punishing so severely as by death the breach of a mere positive precept; which, considered in itself, appears to be a precept of very little importance. We have only to reply, that as an exemption from death is not due either

(L) It does not appear that any transaction between God and mankind in general was denominated by a word equivalent to the English word *covenant* till the end of the fourth century, when such phraseology was introduced into the church by the celebrated Augustine, bishop of Hippo. That the phraseology is strictly proper, no man can suppose who reflects on the infinite distance between the contracting parties, and absolute dominion of the one over the other. To be capable of entering into a *covenant*, in the proper sense of the word, both parties must have a right either to agree to the terms proposed or to reject them; but surely Adam had no right to bargain with his Maker, or to refuse the gift of immortality on the terms on which it was offered to him. The word *dispensation* would more accurately denote what is here meant by the word *covenant*; but as this last is in general use, we have retained it as sufficient, when thus explained, to distinguish what man received from God upon certain positive conditions, from what he had a claim to by the constitution of his nature.

Original State of Man.

either to the nature or to the virtue of man, it was wise and just to make it depend on the observance of a positive precept, to impress on the minds of our first parents a constant conviction, that they were to be preserved immortal, not in the ordinary course of divine providence, but by the special grace and favour of God. The same consideration will show us the folly of those men who are for turning all that is said of the trees of knowledge and of life into figure and allegory. But the other trees which Adam and Eve were permitted to eat were certainly real trees, or they must have perished for want of food. And what rules of interpretation will authorise us to interpret *eating* and *trees* literally in one part of the sentence and figuratively in the other? A garden in a delightful climate is the very habitation, and the fruits produced in that garden the very food, which we should naturally suppose to have been prepared for the progenitors of the human race; and though in the garden actually fitted up for this purpose two trees were remarkably distinguished from the rest, perhaps in situation and appearance as well as in use, the distinction was calculated to serve the best of purposes. The one called the *tree of life*, of which, while they continued innocent, they were permitted to eat, served as a sacramental pledge or assurance on the part of God, that as long as they could observe the terms of the covenant their life should be preserved; the other, of which it was death to taste, was admirably adapted to impress on their minds the necessity of implicit obedience to the Divine will, in whatever manner it might be made known to them.

A question has been started of some importance, What would have finally become of men if the first covenant had not been violated? That they would have been all immortal is certain; but it is by no means clear that they would have lived for ever on this earth. On the contrary, it has been an article of very general belief in all ages of the church †, that the garden of Eden was an emblem or type of heaven, and therefore called *Paradise* (see PARADISE); and that under the first covenant, mankind, after a sufficient probation here, were to be translated into heaven without tasting death. This doctrine is not indeed explicitly taught in Scripture; but many things conspire to make it highly probable. The frequent communications between God and man before the fall (M), seem to indicate that Adam was training up for some higher state than the terrestrial paradise. Had he been intended for nothing but to cultivate the ground and propagate his species, he might have been left like other animals to the guidance of his own reason and instincts; which, after the rudiments of knowledge were communicated to him, must surely have been sufficient to direct him to every thing necessary to the comforts of a life merely sensual and rational, otherwise he would have been an imperfect animal. It is obvious too, that this earth, however fertile it may have originally been, could not have afforded the means of subsistence to a race of immortal beings multiplying to infinity. For these reasons, and others which will readily occur to the reader, it seems incontrovertible, that, under the first covenant, either mankind would have been successively translated to some superior state, or would have ceased to propagate their kind as soon as the earth should have been replenished with inhabitants. He who reflects on the promise, that, after the general resurrection, there is to be a new heaven and a new earth, will probably embrace the latter part of the alternative; but that part in its consequences differs not from the former. In the new earth promised in the Christian revelation, nothing is to dwell but righteousness. It will therefore be precisely the same with what we conceive to be expressed by the word heaven; and if under the first covenant this earth was to be converted into a similar place, where, after a certain period, men should never marry nor be given in marriage, but enjoy what divines have called the *beatific vision*, we may confidently affirm, that, had the first covenant been faithfully observed, Adam and his posterity, after a sufficient probation, would all have been translated to some superior state or heaven.

† *Bull's State of Man before the Fall.*

97 had it not been violated, entitled him to heaven,

98 and the gifts of divine grace.

To fit them for that state, the gifts of divine grace seem to have been absolutely necessary. To them it was a state certainly supernatural, otherwise a God of infinite wisdom and perfect goodness would not, for a moment, have placed them in an inferior state. But to enable any creature, especially such a creature as man, whom an ancient philosopher has justly styled ζωον μιμηλικον, to rise above its *nature*, foreign and divine aid is unquestionably requisite; and therefore, though we cannot persuade ourselves that the gifts of the Holy Ghost constituted that image of God in which man was originally made, we agree with Bishop Bull, that these gifts were bestowed on our first parents to enable them to fulfil the terms of the covenant under which they were placed.

On the whole, we think it apparent from the portions of scripture which we have examined, that Adam and Eve were endued with such powers of body and mind as fitted them to exercise dominion over the other animals; that those powers constituted that image of God in which they are said to have been formed; that they received by immediate revelation the first principles of all useful knowledge, and especially of that system which is usually called *natural religion*; that they lived for some time with no other religion, entitled to the natural rewards of piety and virtue, but all the while liable to death; that they were afterwards translated into paradise, where they were placed under a new law, with the penalty of death threatened to the breach of it, and the promise of endless life if they should faithfully observe it; and that they were endued with the gifts of the Holy Ghost, to enable them, if not wanting to themselves, to fulfil the terms of that covenant, which has been improperly termed the *covenant of works*, since it flowed from the mere grace of God, and conferred privileges on man to which the most perfect human virtue could lay no just claim.

99 It is therefore improperly called the covenant of works.

SECT. III. *Of the Fall of Adam, and its Consequences.*

FROM the preceding account of the primeval state of man,

(M) That there were such frequent communications, has been shown to be in the highest degree probable by the late Dr Law bishop of Carlisle. See his *Discourse on the several Dispensations of revealed Religion.*

Fall of Adam, and its consequences.

100 as it could be violated only by disobedience to one positive command.

man, it is evident that his continuance in the terrestrial paradise, together with all the privileges which he there enjoyed, were made to depend on his observance of one positive precept. Every other duty incumbent on him, whether as resulting from what is called the law of his nature, or from the express command of his God, was as much his duty before as after he was introduced into the garden of Eden; and though the transgression of any law would undoubtedly have been punished, or have been forgiven only in consequence of sincere repentance and amendment, it does not appear that a breach of the *moral* law, or of the commandment respecting the sanctification of the *Sabbath-day*, would have been punished with death, whatever may be the import of that word in the place where it is first threatened. The punishment was denounced only against eating the fruit of the tree of the knowledge of good and evil: For "the Lord God commanded the man, saying, Of every tree of the garden thou mayest freely eat, but of the tree of the knowledge of good and evil thou shalt not eat of it; for in the day that thou eatest thereof thou shalt surely die." To the word *death* in this passage divines have affixed many and different meanings. By some it is supposed to import a separation of the soul and body, while the latter was to continue in a state of conscious existence; by others, it is taken to imply annihilation or a state without consciousness; by some, it is imagined to signify eternal life in torments; and by others a spiritual and moral death, or a state necessarily subject to sin. In any one of these acceptations it denoted something *new* to Adam, which he could not understand without an explanation of the term; and therefore, as it was threatened as the punishment of only one transgression, it could not be the divine intention to inflict it on any other.

101 It was violated,

The abstaining from a particular fruit in the midst of a garden abounding with fruits of all kinds, was a precept which at first view appears of easy observation; and the penalty threatened against the breach of it was, in every sense, awful. The precept, however, was broken notwithstanding that penalty; and though we may thence infer that our first parents were not beings of such absolute perfection as by divines they have sometimes been represented, we shall yet find, upon due consideration, that the temptation by which they were seduced, when taken with all its circumstances, was such as no wise and modest man will think himself able to have resisted. The short history of this important transaction, as we have it in the third chapter of the book of Genesis, is as follows.

"Now the serpent was more subtile than any beast of the field which the Lord God had made; and he said unto the woman, Yea, hath God said, ye shall not eat of every tree of the garden? And the woman said unto the serpent, We may eat of the fruit of the trees of the garden; but of the fruit of the tree which is in the midst of the garden, God hath said, Ye shall not eat of it, neither shall ye touch it, lest ye die. And the serpent said unto the woman, Ye shall not surely die: For God doth know, that on the day ye eat thereof, then your eyes shall be opened, and ye shall be as gods, knowing good and evil. And when the woman *saw* that the tree was good for food, and that it was pleasant to the eyes, and a tree to be desired to make one wise, she took of the fruit thereof, and did eat, and gave also unto her husband with her, and he did eat."

102 in consequence of a most artful temptation,

To the less attentive reader this conversation between the serpent and the woman must appear to begin abruptly; and indeed it is not possible to reconcile it with the natural order of a dialogue, or even with the common rules of grammar, but by supposing the tempter's question, "Yea, hath God said, ye shall not eat of every tree of the garden?" to have been suggested by something immediately preceding either in words or in significant signs. Eve had undoubtedly by some means or other informed the serpent that she was forbidden to eat of the fruit on which he was probably feasting; and that information, whether given in words or in actions, must have produced the question with which the sacred historian begins his relation of this fatal dialogue. We are told that the woman *saw* that the tree was *good for food:* that it was pleasant to the eyes, and a tree to be *desired to make one wise:* but all this she could not have *seen*, had not the serpent eaten of its fruit in her presence. In her walks through the garden, it might have often appeared pleasant to her eyes; but previous to experience she could not know but that its fruit was the most deadly poison, far less could she conceive it capable of conferring wisdom. But if the serpent ate of it before her, and then extolled its virtues in rapturous and intelligible language, she would at once see that it was not destructive of animal life, and naturally infer that it had very singular qualities. At the moment she was drawing this inference, it is probable that he invited her to partake of the delicious fruit, and that her refusal produced the conference before us. That she yielded to his temptation need excite no wonder; for she knew that the serpent was by nature a mute animal, and if he attributed his speech to the virtues of the tree, she might infer, with some plausibility, that what had power to raise the brute mind to human, might raise the human to divine, and make her and her husband, according to the promise of the tempter, become as gods, knowing good and evil. Milton, who was an eminent divine as well as the prince of poets, makes her reason thus with herself.

Great are thy virtues, doubtless, best of fruits,
Tho' kept from man, and worthy to be admir'd;
Whose taste, too long forborn, at first essay
Gave elocution to the mute, and taught
The tongue not made for speech to speak thy praise.
* * * * *
——For us alone
Was death invented? or to us denied
This intellectual food, for beasts reserved?
For beasts it seems: yet that one beast which first
Hath tasted envies not, but brings with joy
The good befallen him, author unsuspect,
Friendly to man, far from deceit or guile.
What fear I then, rather what know to fear
Under this ignorance of good and evil,
Of God or death, of law or penalty?
Here grows the cure of all, this fruit divine,
Fair to the eye, inviting to the taste,
Of virtue to make wise: what hinders then
To reach, and feed at once both body and mind?

Paradise Lost, book ix.

Fall

Fall of Adam, and its consequences.

Full of these hopes of raising herself to divinity, and not, as has sometimes been supposed, led headlong by a sensual appetite, she took of the fruit and did eat, and gave to her husband with her, and he did eat. The great poet makes Adam delude himself with the same sophistry that had deluded Eve, and infer, that as the serpent had attained the language and reasoning powers of man, they should attain

> Proportional ascent, which could not be
> But to be gods, or angels, demi-gods.

103 and Adam and Eve turned out of paradise.

Thus was the covenant, which, on the introduction of our first parents into paradise, their Creator was graciously pleased to make with them, broken by their violation of the condition on which they were advanced to that supernatural state; and therefore the historian tells us, that "lest they should put forth their hand and take also of the tree of life and eat, and live for ever, the Lord God sent them forth from the garden of Eden to till the ground from whence they were taken (N)." Had they been so sent forth without any farther intimation respecting their present condition or their future prospects, and if the death under which they had fallen was only a loss of consciousness, they would have been in precisely the same state in which they lived before they were placed in the garden of Eden; only their minds must now have been burdened with the inward sense of guilt, and they must have *known* themselves to be subject to death; of which, though not exempted from it by nature, they had probably no *apprehension* till it was revealed to them in the covenant of life which they had so wantonly broken.

God, however, did not send them forth thus hopeless and forlorn from the paradise of delights which they had so recently forfeited. He determined to punish them for their transgression, and at the same time to give them an opportunity of recovering more than their lost inheritance. Calling therefore the various offenders before him, and inquiring into their different degrees of guilt, he began with pronouncing judgment on the serpent in terms which implied that there was mercy for man. "And the Lord God said unto the serpent, Because, thou hast done this, thou art cursed above all cattle, and above every beast of the field: upon thy belly shalt thou go, and dust shalt thou eat all the days of thy life; and I will put enmity between thee and the woman, and between thy seed and her seed: it shall bruise thy head, and thou shalt bruise his heel."

104 The tempter punished.

That this sentence has been fully inflicted on the serpent, no reasoning can be necessary to evince. Every species of that reptile is more hateful to man than any other terrestrial creature; and there is literally a perpetual war between them and the human race. It is remarkable too that the *head* of this animal is the only part which it is safe to bruise. His tail may be bruised, or even cut off, and he will turn with fury and death on his adversary: but the slightest stroke on the head infallibly kills him. That the serpent, or at least the greater part of serpents, go on their belly, every one knows; though it is said *, that in some parts of the east serpents have been seen with wings, and others with feet, and that these species are highly beautiful. If there be any truth in this story, we may suppose that these walking and flying serpents have been suffered to retain their original elegance, that mankind might see what the whole race was before the curse was denounced on the tempter of Eve: but it is certain that most of the species have neither wings nor feet, and that many of the most poisonous of them live in burning deserts, where they have nothing to eat but the dust among which they crawl †.

* Delany's Rev. examined with candour.

† See Bochart and Pliny on Serpents, with Bruce's Travels.

To this degradation of the serpent, infidels have objected, that it implies the punishment of an animal which was incapable of guilt; but this objection is founded in thoughtlessness and ignorance. The elegant form of any species of inferior animals adds nothing to the happiness of the animals themselves: the ass is probably as happy as the horse, and the serpent that crawls as he that flies. Fine proportions attract indeed the notice of man, and tend to impress upon his mind just notions of the wisdom and goodness of the Creator; but surely the symmetry of the horse or the beauty of the peacock is more properly displayed for this purpose than the elegance of the instrument employed by the enemy of mankind. The degradation of the serpent in the presence of our first parents must have served the best of purposes. If they had so little reflection as not yet to have discovered that he was only the instrument with which a more powerful being had wrought their ruin, they would be convinced, by the execution of this sentence, that the forbidden fruit had no power in itself to improve the nature either of man or of beast. But it is impossible that they could be so stupid as this objection supposes them. They doubtles knew by this time that some great and wicked spirit had actuated the organs of the serpent; and that when enmity was promised to be put between its seed and the seed of the woman, that promise was not meant to be fulfilled by serpents occasionally biting the heels of men, and by men in return bruising the heads of serpents! If such enmity, though it has literally taken place, was all that was meant by this prediction, why was not Adam directed to bruise the head of the identical serpent which had seduced his wife? If he could derive any consolation from the exercise of revenge, surely it would be greater from his revenging himself on his own enemy, than from the knowledge that there should be a perpetual warfare between his descendants and the breed of serpents through all generations.

We are told, that when the foundations of the earth were laid, the morning stars sang together, and all the sons of God shouted for joy; and it is at least probable that there would be similar rejoicing when the six days work of creation was finished. If so, Adam and Eve, who were but a little lower than the angels, might be admitted into the chorus, and thus be made acquainted with the existence of good and evil spirits. At all events, we cannot doubt but their gracious and merciful Creator

(N) The ideas which this language conveys are indeed *allegorical*; but they inform us of this, and nothing but this, that *immortal life was a thing extraneous to our nature*, and not put into our paste or composition when first fashioned by the forming hand of the Creator." *Warburton's Divine Legation*, book ix. chap. 1.

Fall of Adam, and its consequences.

Creator would inform them that they had a powerful enemy; that he was a rebellious angel capable of deceiving them in many ways; and that they ought therefore to be constantly on their guard against his wiles. They must have known too that they were themselves animated by something different from matter; and when they found they were deceived by the serpent, they might surely, without any remarkable stretch of sagacity, infer that their malignant enemy had actuated the organs of that creature in a manner somewhat similar to that in which their own souls actuated their own bodies. If this be admitted, the degradation of the serpent would convince them of the weakness of the tempter when compared with their Creator; and confirm their hopes, that since he was not able to preserve unhurt his own instrument of mischief, he should not be able finally to prevail against them; but that though he had bruised their heels, the promised seed of the woman should at last bruise his head, and recover the inheritance which they had lost. See PROPHECY, N° 9, 10.

105 Sentence passed on Adam and Eve.

Having thus punished the original instigator to evil, the Almighty Judge turned to the fallen pair, and said to the woman, "I will greatly multiply thy sorrow and thy conception: in sorrow shalt thou bring forth children; and thy desire shall be to thy husband, and he shall rule over thee. And unto Adam he said, Because thou hast hearkened unto the voice of thy wife, and hast eaten of the tree of which I commanded thee, saying, Thou shalt not eat of it; cursed is the ground for thy sake; in sorrow shalt thou eat of it all the days of thy life. Thorns also and thistles shall it bring forth unto thee, and thou shall eat the herb of the field. In the sweat of thy face shalt thou eat bread till thou return unto the ground; for out of it wast thou taken: for dust thou art, and unto dust shalt thou return."

Here is a terrible denunciation of toil and misery and death upon two creatures; who, being inured to nothing, and formed for nothing but happiness, must have felt infinitely more horror from such a sentence, than we, who are familiar with death, intimate with misery, and "born to sorrow as the sparks fly upward," can form any adequate conception of. The hardship of it, too, seems to be aggravated by its being severer than what was originally threatened against the breach of the covenant of life. It was indeed said, "In the day thou eatest thereof, thou shalt surely die:" but no mention was made of the woman's incurring sorrow in conception, and in the bringing forth of children; of the curse to be inflicted on the ground; of its bringing forth thorns and thistles instead of food for the use of man; and of Adam's eating bread in sorrow and the sweat of his face till he should return to the dust from which he was taken.

106 An obscure intimation given them of deliverance from it.

These seeming aggravations, however, are in reality instances of divine benevolence. Adam and Eve were now subjected to death; but in the sentence passed on the serpent, an obscure intimation had been given them that they were not to remain for ever under its power. It was therefore their interest, as well as their duty, to reconcile themselves as much as possible to their fate; to wean their affections from this world, in which they were to live only for a time; and to hope, with humble confidence, in the promise of their God, that, upon their departure from it, they should be received into some better state. To enable them to wean their affections from earth, nothing could more contribute than to combine sensual enjoyment with sorrow, and lay them under the necessity of procuring their means of subsistence by labour, hard and often fruitless. This would daily and hourly impress upon their minds a full conviction that the present world is not a place fit to be an everlasting habitation; and they would look forward, with pious resignation, to death, as putting a period to all their woes. Had they indeed been furnished with no ground of hope beyond the grave, we cannot believe that the Righteous Judge of all the earth would have added to the penalty originally threatened. That penalty they would doubtless have incurred the very day on which they fell; but as they were promised a deliverance from the consequences of their fall, it was proper to train them up by severe discipline for the happiness reserved for them in a future state.

After the passing of their sentence, the man and woman were turned out into the world, where they had formerly lived before they were placed in the garden of Eden; and all future access to the garden was for ever denied them. They were not, however, in the same state in which they were originally before their introduction into Paradise: They were now conscious of guilt; doomed to severe labour; liable to sorrow and sickness, disease and death: and all these miseries they had brought, not only on themselves, but also on their unborn posterity to the end of time. It may seem indeed to militate against the moral attributes of God, to inflict misery on children for the sins of their parents; but before any thing can be pronounced concerning the Divine goodness and justice in the present case, we must know precisely how much we suffer in consequence of Adam's transgression, and whether we have ourselves any share in that guilt which is the cause of our sufferings.

107 Doubtful whether men would have been exempted from pain under the first covenant.

That women would have had less sorrow in the bringing forth of children; that we should have been subjected to less toil and exempted from death, had our first parents not fallen from their paradisaical state—are truths incontrovertible by him who believes the inspiration of the Holy Scriptures; but that mankind would in that state have been wholly free from pain and every bodily distress, is a proposition which is not to be found in the Bible, and which therefore no man is bound to believe. The bodies of Adam and Eve consisted of flesh, blood, and bones, as ours do; they were surrounded by material objects as we are; and their limbs were unquestionably capable of being fractured. That their souls should never be separated from their bodies while they abstained from the forbidden fruit, they knew from the infallible promise of him who formed them, and breathed into their nostrils the breath of life; but that not a bone of themselves or of their numerous posterity should ever be broken by the fall of a stone or of a tree, they were not told, and had no reason to expect. Of such fractures, pain would surely have been the consequence; though we have reason to believe that it would have been quickly removed by some infallible remedy, probably by the fruit of the tree of life.

Perhaps it may be said, that if we suppose our first parents or their children to have been liable to accidents of this kind in the garden of Eden, it will be difficult to conceive how they could have been preserved from death, as

Fall of Adam, and its consequences.

as a stone might have fallen on their heads as well as on their feet, and have at once destroyed the principle of vitality. But this can be said only by him who knows little of the physical world, and still less of the power of God. There are many animals which are susceptible of pain, and yet not easily killed; and man in paradise might have resembled these. At any rate, we are sure that the Omnipotent Creator could and would have preserved him from death; but we have no reason to believe that, by a constant miracle, he would have preserved him from every kind of pain. Indeed, if, under the first covenant, mankind were in a state of probation, it is certainly conceivable that some one individual of the numerous race might have fallen into sin, without actually breaking the covenant by eating the fruit of the tree of knowledge; and such a sinner would undoubtedly have been punished by that God who is of purer eyes than to behold iniquity: but how punishment could have been inflicted on a being exempted from all possibility of pain as well as of death, we confess ourselves unable to imagine. Remorse, which is the inseparable consequence of guilt, and constitutes in our present state great part of its punishment, flows from the fearful looking for of judgment, which the sinner knows shall, in a future state, devour the adversaries of the gospel of Christ; but he, who could neither suffer pain nor death, had no cause to be afraid of future judgement, and was therefore not liable to the tortures of remorse. We conclude, therefore, that it is a mistake to suppose pain to have been introduced into the world by the fall of our first parents, or at least that the opinion contrary to ours has no foundation in the word of God.

108 though they would from death.

Death, however, was certainly introduced by their fall; for the inspired apostle assures us, that in *Adam all die* *; and again, that *through the offence of* ONE *many are dead* †. But concerning the full import of the word *death* in this place, and in the sentence pronounced upon our first parents, divines hold opinions extremely different. Many contend, that it includes death *corporal*, *spiritual* or *moral*, and *eternal*; and that all mankind are subjected to these three kinds of death, on account of their share in the guilt of the original transgression, which is usually denominated *original sin*, and considered as the source of all moral evil.

* Cor. xv. 22.

† Rom. v. 15.

That all men are subjected to death corporal in consequence of Adam's transgression, is universally admitted; but that they are in any sense partakers of his guilt, and on that account subjected to death spiritual and eternal, has been very strenuously denied. To discover the truth is of great importance; for it is intimately connected with the Christian doctrine of redemption. We shall therefore state, with as much impartiality as we can, the arguments commonly urged on each side of this much agitated question.

109 Doctrine of original sin stated.

Those who maintain that all men sinned in Adam, generally state their doctrine thus: "The covenant being made with Adam as a public person, not for himself only but for his posterity, all mankind descending from him by ordinary generation *sinned* in him and fell with him in that first transgression; whereby they are deprived of that original righteousness in which he was created, and are utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually; which is commonly called *original sin*, and from which do proceed all actual transgressions, so as we are by nature children of wrath, bond-slaves to Satan, and justly liable to all punishments in this world and in that which is to come, even to everlasting separation from the comfortable presence of God, and to most grievous torments in soul and body, without intermission, in hell fire for ever."

That which in this passage we are first to examine, is the sentence which affirms all mankind descending from Adam by ordinary generation to have *sinned* in him and fallen with him in his first transgression; the truth of which is attempted to be proved by various texts of Holy Scripture. Thus St Paul says expressly, that "by one man sin entered into the world, and death by sin; and so death passed upon all men, for that *all have sinned*. But not as the offence, so also is the free gift. 110
For if, through the *offence* of *one*, *many* be *dead*; much more the grace of God, and the gift by grace, which is by one man, Jesus Christ, hath abounded unto many; and not as it was by one that sinned, so is the gift (for the *judgment* was by *one* unto *condemnation*); but the free gift is of many offences unto justification. For if, by one man's offence, death reigned by one; much more they, who receive the abundance of grace and of the gift of righteousness, shall reign in life by one, Jesus Christ. Therefore as, by the *offence of one*, *judgment* came upon *all men* to *condemnation*; even so, by the righteousness of One, the free gift came upon all men unto justification of life. For as by one man's disobedience *many were made sinners*; so by the obedience of one shall many be made righteous *." In this passage the apostle assures us, that all upon whom death hath passed have *sinned*; but death hath passed upon infants, who could not commit actual sin. Infants therefore must have sinned in Adam, since death hath passed upon them; for death "is the wages only of sin." He tells us likewise, that by the offence of one, judgment came upon all men to condemnation; and therefore since the Righteous Judge of heaven and earth never condemns the innocent with the wicked, we must conclude, that all men partake of the guilt of that offence for which judgment came upon them to condemnation. These conclusions are confirmed by his saying expressly, that "by one man's disobedience many (*i. e.* all mankind) were *made sinners*;" and elsewhere†, that "there is none righteous, no *not one*;" and that his Ephesian converts "were dead in trespasses and sins, and were by *nature* children of wrath even as *others*." The same doctrine, it is said, we are taught by the inspired writers of the Old Testament. Thus Job, expostulating with God for bringing into judgment with him such a creature as man, says, "Who can bring a clean thing out of an unclean? Not one." And Eliphaz, reproving the patient patriarch for what he deemed presumption, asks ‡, "What is man that he should be clean, or he who is born of a woman that he should be righteous?" From these two passages it is plain, that Job and his unfeeling friend, though they agreed in little else, admitted as a truth unquestionable, that man inherits from his parents a sinful nature, and that it is impossible for any thing born of a woman by ordinary generation to be righteous. The psalmist talks the very same language; when acknowledging his transgressions, he says ||, "Behold I was shapen in iniquity, and in sin did my mother conceive me."

Argument for it.

|| Psalm li. 5.

Having

Fall of Adam, and its consequences.

111
Adam's guilt imputed to his posterity.

Having thus proved the fact, that all men are made sinners by Adam's disobedience, the divines, who embrace this side of the question, proceed to inquire how they can be partakers in guilt which was incurred so many ages before they were born. It cannot be by imitation; for infants, according to them, are involved in this guilt before they be capable of imitating any thing. Neither do they admit that sin is by the apostle put for the consequences of sin, and many said to be made sinners by one man's disobedience, because by that disobedience they were subjected to death, which is the wages of sin. This, which they call the doctrine of the Arminians, they affirm to be contrary to the whole scope and design of the context; as it confounds together sin and death, which are there represented, the one as the cause, and the other as the effect. It likewise exhibits the apostle reasoning in such a manner as would, in their opinion, disgrace any man of common sense, and much more an inspired writer; for then the sense of these words, "Death hath passed upon all men, for that all have sinned," must be, death has passed upon all men, because it hath passed upon all men; or, all men are obnoxious to death, because they are obnoxious to it. The only way therefore, continue they, in which Adam's posterity can be made sinners through his disobedience, is by the IMPUTATION of his disobedience to them; and his imputation is not to be considered in a *moral* sense, as the action of a man committed by himself, whether good or bad, is reckoned into him as his own; but in a *forensic* sense, as when one man's debts are in a legal way placed to the account of another. Of this we have an instance in the apostle Paul, who said to Philemon concerning Onesimus, "If he hath wronged thee, or oweth thee any thing (ελλογει), let it be imputed to me," or placed to and put on my account. And thus the posterity of Adam are made sinners by his disobedience; that being imputed to them and put to their account, as if it had been committed by them personally, though it was not.

Some few divines of this school are indeed of opinion, that the phrase, "By one man's disobedience many were made sinners," means nothing more than that the posterity of Adam, through his sin, derive from him a corrupt nature. But though this be admitted as an undoubted truth, the more zealous abettors of the system contend, that it is not the whole truth. "It is true (say they) that all men are made of one man's blood, and that blood tainted with sin; and so a clean thing cannot be brought out of an unclean. What is born of the flesh is flesh, carnal and corrupt: every man is conceived in sin and shapen in iniquity; but there is a difference between being *made sinners* and *becoming* sinful. The one respects the *guilt*, the other the *pollution* of nature; the one is previous to the other, and the foundation of it. Men receive a corrupt nature from their immediate parents; but they are made sinners, not by any act of their disobedience, but only by the imputation of the sin of Adam."

To illustrate this doctrine of imputed sin, they observe that the word κατεσταθησαν, used by the apostle, signifies *constituted* in a judicial way, ordered and appointed in the dispensation of things that so it should be; just as Christ was made sin or a sinner by imputation, or by that constitution of God which laid upon him the sins of all his people, and dealt with him as if he had been the guilty person. That this is the sense of the passage, they argue further from the punishment inflicted on men for the sin of Adam. The punishment threatened to that sin was death; which includes death corporal, moral, and eternal. Corporal death, say they, is allowed by all to be suffered on account of the sin of Adam; and if so, there must be guilt, and that guilt made over to the sufferer, which can be done only by *imputation*. A moral death is no other than the loss of the image of God in man, which consisted in righteousness and holiness; and particularly it is the loss of original righteousness, to which succeeded unrighteousness and unholiness. It is both a sin and a punishment for sin; and since it comes on all men as a punishment, it must suppose preceding sin, which can be nothing but Adam's disobedience; the guilt of which is made over to his posterity by *imputation*. This appears still more evident from the posterity of Adam being made liable to eternal death in consequence of his transgression; for the wages of sin is death, even death eternal, which never can be inflicted on guiltless persons. But from the passage before us we learn, that "by the offence of *one* judgment came upon all men to condemnation;" and therefore the guilt of that offence must be reckoned to all men, or they could not be justly condemned for it. That Adam's sin is imputed to his posterity, appears not only from the words, "by one man's disobedience many were made sinners;" but likewise from the opposite clause, "so by the obedience of One shall many be made righteous;" for the many ordained to eternal life, for whom Christ died, are made righteous, or justified, only through the imputation of his righteousness to them; and therefore it follows, that all men are made sinners only through the imputation of Adam's disobedience.

Fall of Adam, and its consequences.

112
the punishment of imputed guilt.

To this doctrine it is said to be no objection that Adam's posterity were not in being when his sin was committed; for though they had not then actual being, they had yet a virtual and representative one. They were in him both *seminally* and *federally*, and sinned in him *; just as Levi was in the loins of Abraham, and paid in him tithes to Melchizedeck †. From Adam they derive a corrupt nature; but it is only from him, as their federal head, that they derive a share of his guilt, and are subjected to his punishment. That he was a federal head to all his posterity, the divines of this school think evident from his being called a figure of Christ ‡; and the first Adam described as natural and earthly, in contradistinction to Christ the second Adam described as spiritual and the Lord from heaven; and from the punishment threatened against his sin being inflicted not on himself only, but on all his succeeding offspring. He could not be a figure of Christ, say they, merely as a man; for all the sons of Adam have been men as well as he, and in that sense were as much figures of Christ as he; yet Adam and Christ are constantly contrasted, as though they had been the only two men that ever existed, because they were the only two heads of their respective offspring. He could not be a figure of Christ on account of his extraordinary production; for though both were produced in ways uncommon, yet each was brought into the world in a way peculiar to himself. The first Adam was formed of the dust of the ground; the second, though not begotten by a man, was born of a woman. They did not therefore resemble each other in the manner of their formation, but in their office as

* Rom. v. 12.

113
Adam a federal head to his posterity.

‡ Rom. v. 14.

Fall of Adam, and its consequences.

covenant-heads; and in that alone the comparison between them is exact.

114 No cause of complaint in this constitution of things.

Nor have any of the posterity of Adam, it is said, reason to complain of such a procedure. Had he stood in his integrity, they would have been, by his standing, partakers of all his happiness: and therefore should not murmur at receiving evil through his fall. If this do not satisfy, let it be considered, that since God, in his infinite wisdom, thought proper that men should have a head and representative, in whose hands their good and happiness should be placed, none could be so fit for this high station as the common parent, made after the image of God, so wise, so holy, just, and good. Lastly, to silence all objections, let it be remembered, that what God gave to Adam as a federal head, relating to himself and his posterity, he gave as the Sovereign of the universe, to whom no created being has right to ask, "What dost thou * ?"

*See *Gill's Body of Divinity*.

115 St Augustine the author of this doctrine.

Such are the consequences of Adam's fall, and such the doctrine of original sin, as maintained by the more rigid followers of Calvin. That great reformer, however, was not the author of this doctrine. It had been taught so early as in the beginning of the fifth century, by St Augustine, the celebrated bishop of Hippo (see AUGUSTINE); and the authority of that father had made it more or less prevalent in both the Greek and Roman churches long before the Reformation. Calvin was indeed the most eminent modern divine by whom it has been held in all its rigour; and it constitutes one great part of that theological system, which, from being taught by him, is now known by the name of *Calvinism*.

116 Objections to it,

But if it was as sovereign of the universe that God gave to Adam what he received in paradise relating to himself and his posterity, Adam could in no sense of the words be a federal head; because, upon this supposition, there was no covenant. The Sovereign of the universe may unquestionably dispense his benefits, or withhold them, as seems expedient to his infinite wisdom; and none of his subjects or creatures can have a right to say to him, What dost thou? But the dispensing or withholding of benefits is a transaction very different from the entering into covenants; and a judgment is to be formed of it on very different principles. Every thing around us proclaims that the Sovereign of the universe is a being of perfect benevolence; but, say the disciples of the school now under consideration, the dispensation given to Adam in paradise was so far from being the offspring of benevolence, that, as it is understood by the followers of Calvin, it cannot possibly be reconciled with the eternal laws of equity. The self-existent and all-sufficient God might or might not have created such a being as man; and in either case there would have been no reason for the question "What dost thou?" But as soon as he determined to create him capable of happiness or misery, he would not have been either benevolent or just, if he had not placed him in a state where, by his own exertions, he might, if he chose, have a greater share of happiness than of misery, and find his existence, upon the whole, a blessing. They readily acknowledge, that the existence of any created being may be of longer or shorter duration, according to the good pleasure of the Creator; and therefore they have no objection to the apostolic doctrine, that "in Adam all die:" for immortality being not a debt, but a *free gift*, may be bestowed on any terms, and with perfect justice withdrawn when these terms are not complied with. Between death, however, as it implies a loss of consciousness, and the extreme misery of eternal life in torments, there is an immense difference. To death all mankind might justly be subjected through the offence of one; because they had originally no claim to be exempted from it, though that one and they too had remained for ever innocent: but eternal life in torments is a punishment which a God of justice and benevolence can never inflict but upon personal guilt of the deepest die. That we can personally have incurred guilt from a crime committed some thousands of years before we were born, is impossible. It is indeed a notion as contrary to Scripture as to reason and common sense: for the apostle expressly informs us *, "that sin is the transgression of some law;" and the sin of Adam was the transgression of a law which it was never in our power either to observe or to break. Another apostle † assures us, that "where no law is, there is no transgression"; but there is now no law, nor has been any these 5000 years, forbidding mankind to eat of a particular fruit; for, according to the Calvinists themselves ‡, Adam had no sooner committed his first sin, by which the covenant with him was broken, than he ceased to be a covenant-head. This law given him was no more; the promise of life by it ceased; and its sanction, death, took place. But if this be so, how is it possible that his unborn posterity should be under a law which had no existence, or that they should be in a worse state in consequence of the covenant being broken, and its promise having ceased, than he himself was before the covenant was first made? He was originally a mortal being, and was promised the supernatural gift of immortality on the single condition of his abstaining from the fruit of the tree of knowledge of good and evil. From that fruit he did not abstain; but by eating it fell back into his natural state of mortality. Thus far it is admitted that his posterity fell with him: for they have no claim to a supernatural gift which he had forfeited by his transgression. But we cannot admit, say the divines of this school, that they fell into his guilt; for to render it possible for a man to incur guilt by the transgression of a law, it is necessary not only that he have it in his power to keep the law, but also that he be capable of transgressing it by a *voluntary* deed. But surely no man could be capable of voluntarily eating the forbidden fruit 5000 years before he himself or his volitions existed. The followers of Calvin think it a sufficient objection to the doctrine of transubstantiation, that the same numerical body cannot be in different places at the same instant of time. But this ubiquity of body, say the remonstrants, is not more palpably absurd, than the supposition that a man could exert volitions before he or his will had any existence.

117 as inconsistent with the justice of God,

118 the scripture, and the nature of things.

* 1 John iii. 4.

† Rom. iv. 15.

‡ *Gill's Body of Divinity*, b. iii. ch. 10.

119 The word IMPUTATION removes no difficulties.

Nor will the introduction of the word *imputation* into this important question remove a single difficulty. For what is that we mean by saying that the sin of Adam is imputed to his posterity? Is the guilt of that sin transferred from him to them? So surely thought Dr Gill, when he said that it *is made over to them*. But this is the same absurdity as the making over of the sensible qualities of bread and wine to the internal substance of our Saviour's body and blood! This imputation either found the posterity of Adam guilty of his sin, or it made them so. It could not find them guilty for

for the reason already assigned; as well as because the apostle says expressly, that for the offence of *one* judgement came upon *all* men, which would not be true had *all* offended. It could not make them guilty; for this reason, that if there be in physics or metaphysics a single truth self-evident, it is, that the numerical powers, actions, or qualities, of one being cannot possibly be transferred to another, and be made its powers, actions, or qualities. Different beings may in distant ages have qualities of the same kind; but as easily may 4 and 3 be made equal to 9, as two beings be made to have the same identical quality. In Scripture we nowhere read of the actions of one man being imputed to another. "Abraham (we are told) believed in God, and it was counted to him for righteousness;" but it was his *own* faith, and not the faith of another man, that was so counted. "To him that worketh not, but believeth, his faith (not another's) is imputed for righteousness." And of our faith in him that raised Christ from the dead, it is said, that "it shall be imputed, not to our fathers or our children, but to us for righteousness."

120 Meaning of that word in Scripture.

When this phrase is used with a negative, not only is the man's own personal sin spoken of, but the non-imputation of that sin means nothing more but that it brings not upon the sinner condign punishment. Thus when Shemei "said unto David, Let not my lord *impute* iniquity unto me;" it could not be his meaning that the king should not think that he had offended; for with the same breath he added, Neither do thou remember that which thy servant *did perversely*, the day that my lord the king went out of Jerusalem, that the king should take it to his *heart*. For thy servant doth *know* that *I have sinned*." Here he plainly confesses his sin, and declares, that by intreating the king not to *impute it to him*, he wished only that it should not be so remembered as that the king should take it to heart, and punish him as his perverseness deserved. When therefore it is said †, that "God was in Christ reconciling the world to himself, not imputing to them their iniquities, the meaning is only that for Christ's sake he was pleased to exempt them from the punishment due to their sins. In like manner, when the prophet, foretelling the sufferings of the Messiah, says, that "the Lord laid on him the iniquity of us all," his meaning cannot be, that the Lord by *imputation* made his immaculate Son guilty of all the sins that men have ever committed; for in that case it would not be true that the "just suffered for the unjust," as the apostle expressly teaches ‡: but the sense of the verse must be, as Bishop Coverdale translated it, "through him the Lord pardoneth all our sins." This interpretation is countenanced by the ancient version of the Seventy, *και Κυριος παρεδωκεν αυτον ταις αμαρτιαις ημων*; words which express a notion very different from that of imputed guilt. The Messiah was, without a breach of justice, delivered for sins of which he had voluntarily offered to pay the penalty; and St Paul might have been justly charged by Philemon with the debts of Onesimus, which he had desired might be placed to his account. Had the apostle, however, expressed no such desire, surely Philemon could by no deed of his have made him liable for debts contracted by another; far less could he by *imputation*, whatever that word may mean, have made him virtually concur in the contracting of those debts. He could not have been justly subjected to suffering without his own consent; and he could not possibly have been made guilty of the sins of those for whom he suffered.

† 2 Cor. v. 19.

‡ 1 Peter iii. 18.

The doctrine of imputed guilt, therefore, as understood by the Calvinists, is, in the opinion of their opponents, without foundation in Scripture, and contrary to the nature of things. It is an impious absurdity (say they), to which the mind can never be reconciled by the hypothesis, that all men were in Adam both seminally and federally, and sinned in him, as Levi paid tithes to Melchizedeck in the loins of Abraham. The apostle, when he employs that argument to lessen in the minds of his countrymen the pride of birth and the lofty opinions entertained of their priesthood, plainly intimates, that he was using a bold figure, and that Levi's paying tithes is not to be understood in a strict and literal sense. "Now consider (says he) how great this man was, unto whom even the patriarch Abraham gave the tenth of the spoils. And, *as I may so say*, Levi also, who receiveth tithes, paid tithes in Abraham: for he was yet in the loins of his father when Melchizedeck met him." This is a very good argument to prove that the Levitical priesthood was inferior in dignity to that of Melchizedeck; and by the apostle it is employed for no other purpose. Levi could not be greater than Abraham, and yet Abraham was inferior to Melchizedeck. This is the whole of St Paul's reasoning, which lends no support to the doctrine of original sin, unless it can be shown that Levi and all his descendants contracted from this circumstance such a strong propensity to the *paying* of tithes, as made it a matter of extreme difficulty for them, in every subsequent generation, to comply with that part of the divine law which constituted them *receivers* of tithes. That all men were seminally in Adam, is granted; and it is likewise granted that they may have derived from him, by ordinary generation, diseased and enfeebled bodies: but it is as impossible to believe that moral guilt can be transmitted from father to son by the physical act of generation, as to conceive a scarlet colour to be a cube of marble, or the sound of a trumpet a cannon ball. That Adam was as fit a person as any other to be entrusted with the good and happiness of his posterity, may be true; but there is no fitness whatever, according to the Arminians, in making the everlasting happiness or misery of a whole race depend upon the conduct of any fallible individual. "That any man should so represent me (says Dr Taylor *), that when he is guilty, I am to be reputed guilty; when he transgresses, I shall be accountable and punishable for his transgression; and this before I am born, and consequently before I am in any capacity of knowing, helping, or hindering, what he doth: all this every one who useth his understanding must clearly see to be false, unreasonable, and altogether inconsistent with the truth and goodness of God." And that no such appointment ever had place, he endeavours to prove, by showing that the texts of Scripture upon which is built the doctrine of the Calvinists respecting original sin, will each admit of a very different interpretation.

121 Moral guilt cannot be transmitted from father to son.

* *Doctrine of Original Sin*, part iii.

122 The several texts on which this doctrine is built capable of a different interpretation.

One of the strongest of these texts is Romans v. 19. which we have already quoted, and which our author thus explains. He observes, that the apostle was a Jew, familiarly acquainted with the Hebrew tongue; that he wrote his epistle as well for the use of his own countrymen residing in Rome, as for the benefit of the Gentile converts; and that though he made use of the Greek language, tion it refers to our mortality, they think plain from the context; and Dr Taylor adds *, with some plausibility, that if the words refer to the guilt which we are supposed to derive from Adam, they will prove too much to serve the common scheme of original sin. They will prove that our natural and inherent pravity, so far from rendering us fit objects of wrath, may be urged as a reason why God should not even bring us into judgement; for the patriarch's whole expostulation runs thus, "Dost thou open thine eyes upon such a one, and bringest me into judgment with thee? Who can bring a clean thing out of an unclean?"

* *Scripture Doctrine*, part ii.

The other text, quoted from the same book, they think still less to the purpose; for Eliphaz is evidently contrasting the creature with the Creator; in comparison with whom, he might well say, without alluding to original guilt, "what is man that he should be clean? and he who is born of a woman that he should be righteous? Behold he putteth no trust in his saints; yea the *heavens* are not clean in his sight. How much more abominable and filthy is man, who drinketh iniquity like water?" He does not say, who derives by birth an iniquitous nature; for he knew well, that as we are born, we are the pure workmanship of God, "whose hands have fashioned and formed every one of us;" but "who *drinketh* iniquity like water," who maketh himself iniquitous by running headlong into every vicious practice.

Of the text quoted from the fifty-first psalm in support of the doctrine of original sin, Dr Taylor labours †, by a long and ingenious criticism, to prove that our translators have mistaken the sense. The word which they have rendered *shapen*, he shows to be used once by Isaiah, and twice in the book of Proverbs, to signify *brought forth;* and that which is rendered *conceived me*, is never, he says, employed in scripture to denote human conception. In this last remark, however, he is contradicted by a great authority, no less indeed than that of Mr Parkhurst ‡, who says, that the LXX constantly render it by κισσαω or εγκισσαω, and the Vulgate generally by *concipio*. Without taking upon us to decide between these two eminent Hebrew scholars, we shall only observe, that upon one occasion || it certainly denotes ideas much grosser than those which the Psalmist must have had of his mother's conception; and that there, at least, Dr Taylor properly translates it, *incalescebant*, adding, "de hoc vero incalescendi genere loqui Davidem nemo sanus existimare potest. Matrem enim incaluisse, aut ipsum calefecisse eo modo quo incalescerent Jacobi pecudes Regem dicere, prorsus indecorum et absurdum." He contends, however, that the original force of the word is *to be hot*, and that it is applied to *conception*, to *resentment*, to *warmth* by which the body is nourished, to *idolaters* in love with idols, and to the heat of metals. The heat of idolaters, of resentment, and of metals, are evidently foreign to the Psalmist's purpose; and the idea conveyed by the word *incalescere* being set aside for the reasons already assigned, there remains only the warmth by which the body is nourished, and of that warmth our ardour is confident that David spoke.

† *Ubi supra.*

‡ See his *Lexicon* on *the word* יחם.

|| Gen. xxx. 38, 39, 40, compared with xxxi. 10.

If this criticism be admitted, the whole verse will then run thus: "Behold I was born in iniquity, and in sin did my mother nurse me;" which hath no reference to the original formation of his constitution, but is a periphrasis of his being a *sinner from the womb*, and means nothing more than that he was a *great sinner*, or had contracted *early habits* of sin. He no more designed to signify in this verse, that by ordinary generation he had a nature conveyed to him which was "utterly indisposed, disabled, and opposite to all that is spiritually good, and wholly and continually inclined to evil," than he meant in another * to signify strictly and properly that "the wicked are estranged from the womb, and TELL LIES as soon as they are born;" or that Job meant to signify †, that from the moment he came from his mother's womb he had been a guide to the widow and a succour to the fatherless. All these are hyperbolical forms of expression; which, though they appear strained, and perhaps extravagant, to the phlegmatic inhabitants of Europe, are perfectly suited to the warm imaginations of the orientals, and to the genius of eastern languages. They mean not that Job was *born* with *habits of virtue*, that the wicked actually *walked*, and *spoke*, and *spoke lies* from the instant of their *birth*, or that the Psalmist was really *shapen* in *sin* and *conceived in iniquity*. This last sentence, if interpreted literally, would indeed be grossly impious: it would make the inspired penman throw the whole load of his iniquity and sin from off himself upon *him* who shaped, and upon *her* who conceived him; even upon that God "whose hands had made him and fashioned him, and whom he declares that he will praise for having made him fearfully and wonderfully," and upon that parent who conceived him with sorrow, and brought him forth with pain, and to whom the divine law commanded him to render honour and gratitude. "But if, after all (says Dr Taylor ‡), you will adhere to the literal sense of the text for the common doctrine of *original sin*, show me any good reason why you ought not to admit the literal sense of the text, *this is my body*, for *transubstantiation?* If you say, it is absurd to suppose that Christ speaks of his real natural body; I say, it is likewise absurd to suppose that the Psalmist speaks of his being really and properly shapen in iniquity, and conceived in sin. If you say, that the sense of the words *this is my body* may be clearly explained by other texts of scripture where the like forms of speech are used; I say, and have shown, that the Psalmist's sense may as clearly and evidently be made out by parallel texts, where you have the like kind of expression. If you say that transubstantiation is attended with consequences hurtful to piety, I say that the common doctrine of original sin is attended with consequences equally hurtful; for it is a principle apparently leading to all manner of iniquity, to believe that sin is natural to us, that it is interwoven and ingrafted into our very constitution from our conception and formation in the womb."

* Ps. lviii. 3.

† Job xxxi. 18.

‡ *Scripture Doctrine*, part ii.

123 Consequences of eating the forbidden fruit, according to the Arminians.

The Arminians having thus, as they think, proved that the posterity of Adam, are not in any sense rendered guilty by his sin, contend, that the death threatened against his eating of the forbidden fruit, and which, in consequence of his transgression, came upon all men, can mean nothing more than the loss of that vital principle which he received when God breathed into his nostrils the breath of life, and he became a living soul. Every thing beyond this is pure conjecture, which has no foundation in the scriptures of truth, and is directly contrary to all the notions of right and wrong which we

Fall of Adam, and its consequences.

we have been able to acquire from the study of those very scriptures. It is not conceivable from any thing in the history, that Adam could understand it of the loss of any other life than that which he had lately received, for no other life is spoken of to which the threatened death can be opposed; and in such circumstances, it was strange indeed, if by the word *death* he understood either eternal life in misery, or a necessity of continuing in sin. The sense therefore of the threatening, say they, is this: "I have formed thee of the dust of the ground, and breathed into thy nostrils the breath of life; and thus thou art become a living soul. But if thou eatest of the fruit of the tree of knowledge of good and evil, thou shalt cease to be a living soul; for I will take from thee the breath of life, and thou shalt return to the dust of which thou wast formed."

124 Some of them admit the depravity of human nature,

Thus far the Arminians of the present day are agreed in opposing the doctrine of the rigid Calvinists, and in stating their own notions of the consequences of Adam's fall; but from that event their adversaries deduce one consequence, which some of them admit and others deny. It is said that though we cannot possibly be partakers in Adam's guilt, we yet derive from him a moral taint and infection, by which we have a natural propensity to sin; that having lost the image of God, in which he was created, Adam begat sons in his own image; and in one word, that the sensual appetites of human nature were inflamed, and its moral and intellectual powers greatly weakened by the eating of the forbidden fruit. The heathens themselves acknowledged and lamented this depravity; though they were ignorant of the source from which it sprung. The scriptures assert it, affirming that no man can be born pure and clean; that whatever is born of the flesh, or comes into the world by ordinary generation, is flesh, carnal and corrupt; that the imagination of the thoughts of man's heart is only evil continually; that the heart is deceitful above all things and desperately wicked; and that out of it proceeds all that is vile and sinful *.

125 and illustrate it upon principles of natural knowledge,

This depravity of human nature, thus clearly deducible from scripture, and confirmed by the testimony of ages, an ingenious writer of the moderate Arminian school undertakes to illustrate upon the principles of natural knowledge. "We know (says he †), that there are several fruits in several parts of the world of so noxious a nature as to destroy the best human constitution on earth. We also know that there are some fruits in the world which inflame the blood into fevers and frenzies; and we are told that the Indians are acquainted with a certain juice, which immediately turns the person who drinks it into an idiot, leaving him at the same time in the enjoyment of his health and all the powers of his body. Now I ask Whether it be not possible, nay, whether it be not rational, to believe, that the same fruit, which, in the present infirmity of nature, would utterly destroy the human constitution, might, in its highest perfection, at least disturb, impair, and disease it? and whether the same fruit, which would now inflame any man living into a fever or frenzy, might not inflame Adam into a turbulence and irregularity of passion and appetite; and whether the same fluids, which inflame the blood into irregularity of passion and appetite, may not naturally produce infection and impair the constitution? That the forbidden fruit had the effect to produce irregularity of appetite, appears as from other proofs, so I think fully and clearly from the covering which Adam and Eve made use of soon after their offence; for there is no imaginable reason for that covering but one, and that one sufficiently demonstrates, that irregularity and violence of appetite, independent of the dominion of reason, was the effect of their offence. But the fruit which inflamed the sensual appetite might likewise debase their rational powers; for I ask, whether the same juice, which now affects the brain of an ordinary man so as to make him an idiot, might not affect the brain of Adam so as to bring his understanding down to the present standard of ordinary men? And if this be possible, and not absurd to be supposed, it is evident that the subsequent ignorance and corruption of human nature may be clearly accounted for upon these suppositions; nay, I had almost said upon any one of them. For it is universally known, that the infections and infirmities of the father affect the children yet in his loins; and if the mother be equally infected, must, unless removed by proper remedies, affect their posterity to the end of the world, or at least till the race become extinct. Therefore why all mankind might not by their first father's sin be reduced to the same condition of infirmity and corruption with himself, especially when the mother was equally infirm, and infected, I believe no man any way skilled in the knowledge of nature will so much as pretend to say."

This account of the corruption of human nature seems to be generally adopted by moderate divines, as well among the Calvinists as among the Arminians; but by the high-fliers in both schools it is rejected, on different principles indeed, with great indignation. The zealous Calvinist contends, that this hereditary corruption is not to be accounted for or explained by any principle of physical science, since it is part of that punishment which was inflicted on the race for their original sin. If we were not partakers of Adam's guilt, say they, we should not have been partakers of his corruption. The one is previous to and the foundation of the other. The depravity of human nature is a punishment for sin; and so it was threatened to Adam, and came upon him as such, and so to all his posterity, by the *ordination* and *appointment of God*; for which there can be no other foundation but the imputation of Adam's disobedience to them, nor can any thing else vindicate the righteousness of God. For if the law of nature was sufficient, why should this *original* taint infect men rather than the sins of their immediate parents ‡."

126 whilst other object the doctrine,

The more violent Arminians, on the other hand, deny that we inherit any moral taint whatever from Adam, or that the rational powers of our minds are naturally weaker than his were. Of that wonderful degree of perfection which is usually attributed to the first pair, they find no evidence in scripture. All that we learn of them, say they, is, that they fell from a state of exquisite happiness by yielding to a temptation less powerful by far than some others which many of their degenerate sons have successfully resisted. "I leave you to judge (says Dr Taylor §), whether Joseph, when he resisted the solicitations of his mistress, and Moses when he refused to be called the son of Pharaoh's daughter, choosing rather to suffer affliction with the people of God than to enjoy the pleasures of sin for a season, esteeming the reproach of true religion greater riches than the treasures of Egypt, did not exhibit proofs of regularity

Fall of Adam, and its consequences.

regularity of passions and appetites equal at least to what Adam displayed in the garden of Eden. When the three young men mentioned in the book of Daniel submitted to be burnt alive in a fiery furnace rather than worship Nebuchadnezzar's golden image; when Daniel himself resolved, rather than conceal the worship of God for one month only of his life, to be torn in pieces by hungry lions; and, to come nearer to our own times, when numbers of men and women, during the reign of Mary queen of England, chose rather to be burnt at a stake than renounce the reformed religion and embrace the errors of popery—surely all these persons exhibited a virtue, a faith in God and a steady adherence to what they believed to be the truth, far superior to what Adam displayed, when his wife gave him of the forbidden fruit, and he did eat." If it be said that these persons were supported under their trials by the grace of God strengthening them, the same will be said of Adam. He was undoubtedly supplied with every aid from the spirit of grace which was necessary to enable him to fulfil his duty; for being designed for more than mere animal life, even for the refined enjoyments of heaven, there is every reason to believe, as we have already observed, that he was put under the guidance of the Holy Ghost, to train him for that supernatural state of felicity. These communications of the spirit would of course be withdrawn when he forfeited his right to those privileges, on account of which they were originally vouchsafed to him; but that any positive malignity or taint was infused into his nature, that his mere rational powers were weakened, or his appetites inflamed by the forbidden fruit, there is no evidence to be found in scripture, or in the known constitution of things. The attributing of this supposed hereditary taint to the noxious qualities of the forbidden fruit, is a whimsical hypothesis, which receives no countenance from any well authenticated

127 and deem the physical illustration of it whimsical;

fact in natural history. After the numberless falsehoods that have been told of the poison tree of Java, something more would be requisite than the common evidence of a lying voyager to give credit to the qualities of the Indian tree, of which the fruit instantly turns the wisest man into an idiot: and yet for this singular story our ingenious author vouchsafes not even that evidence, slight as it generally is. The inference drawn from the covering used by our first parents is contradicted by every thing that we know of human nature; for surely no man inflamed to the utmost with the fire of animal love, ever turned his eyes from a naked beauty ready and eager to receive him to her embrace. Yet this, it seems, was the behaviour of Adam and Eve in such a state! According to our author, the juice of the forbidden fruit had rendered their carnal appetites violent and independent of reason; according to the scripture, they were both naked; and as they were husband and wife, there was no law prohibiting them from gratifying these inflamed appetites. In such circumstances, how did they conduct themselves: One would naturally imagine that they immediately retired to some shady grove, and pleased themselves in all the soft dalliances of wedded love. Their conduct however, was very different. We are told, that "they sewed fig-leaves together, and made themselves aprons to cover their nakedness:" And this transaction is brought as a proof of the impetuosity of their carnal appetites. The truth is, that the carnal appetite appears not to be naturally more violent than is necessary to answer the end for which it was implanted in the human constitution. Among savages the desires of animal love are generally very moderate; and even in society they have not often, unless inflamed by the luxurious arts of civil life, greater strength than is requisite to make mankind attend to the continuation of their species. In the decline of empires highly polished, where the difference of rank and opulence is great, and where every man is ambitious of emulating the expence of his immediate superiors, early marriages are prevented by the inability of most people to provide for a family in a way suitable to what each is pleased to consider as his proper station; and in that state of things the violence of animal love will indeed frequently produce great irregularities. But for that state of things, as it was not intended by the Author of nature, it is perhaps unreasonable to suppose that provision should be made; and yet we believe it will be found, upon due consideration, that if the desires of animal love were less violent than they are, the general consequences would be more pernicious to society than all the irregularities and vices which these desires now accidentally produce; for there would then be no intercourse between the sexes whatever except in the very highest stations of life. That our constitution is attended with many sensual appetites and passions, is true; and that there is a great danger of their becoming excessive and irregular in a world so full of temptation as ours is, is also true; but there is no evidence that all this is the consequence of Adam's fall, and far less that it amounts to a *natural propensity* 128

128 maintaining that we have no natural propensity to sin.

to sin. For I presume (says Dr Taylor), that by a natural propensity is meant a necessary inclination to sin, or that we are necessarily sinful from the original bent and bias of our natural powers. But this must be false; for then we should not be sinful at all, because that which is necessary, or which we cannot help, is not sin. That we are weak and liable to temptation, is the will of God holy and good, and for glorious purposes to ourselves; but if we are wicked, it must be through our own fault, and cannot proceed from any constraint, or necessity, or taint in our constitution."

Thus we have given as full and comprehensive a view as our limits will permit of the different opinions of the Calvinists and Arminians respecting the consequences of Adam's fall. If we have dwelt longer upon the scheme of the latter than of the former, it is because every Arminian argument is built upon criticism, and appeals to the original text; whilst the Calvinists rest their faith upon the plain words of scripture as read in our translation. If we might hazard our own opinion, we should say that the truth lies between them, and that it has been found by the moderate men of both parties, who, while they make use of different language, seem to us to have the same sentiments. That all mankind really sinned in Adam, and are on that account liable to most grievous torments in soul and body, without intermission, in hell fire for ever, is a doctrine which cannot be reconciled to our natural notions of God. On the other hand, if human nature was not somehow debased by the fall of our first parents, it is not easy to account for the numberless phrases in scripture which certainly seem to speak that language, or for the very general opinion of the Pagan philosophers and poets respecting the golden age and the degeneracy of man. Cicero, in a quotation preserved

129 The opinions of moderate men among the Calvinists and Arminians the same, and countenanced by general tradition.

Theology from the fall of Adam to the coming of Christ.

preserved by St Augustine from a work that is now lost has these remarkable words, "Homo non ut a matre sed ut a noverca natura editus est in vitam, corpore nudo, et fragili, et infirmo; animo autem anxio ad molestias, humili ad timores, molli ad labores, prono ad libidines; in *quo tamen inest tanquam obrutus quidam divinus ignis ingenii et mentis* ||." Nor do we readily perceive what should induce the more zealous Arminians to oppose so vehemently this general opinion of the corruption of human nature. Their desire to vindicate the justice and goodness of God does them honour; but the doctrine of inherent corruption militates not against these attributes; for what we have lost in the first Adam has been amply supplied to us in the second; and we know from the highest authority that the duties required of us are in proportion to our ability, since we are told, that "unto whomsoever much is given, of him shall much be required."

|| Vide *D. Aug.* lib. iv. *contra Pelagium.* Vide etiam *M. Tull. Cicer. Consol.*

Sect. IV. *View of Theology from the fall of Adam to the coming of Christ.*

We have dwelt long on the original state of man, his introduction into the terrestrial paradise, the privileges to which he was there admitted, his forfeiture of those privileges, and the state to which he was reduced by transgressing the law of his Maker; but the importance of these events renders them worthy of all the attention that we have paid to them. They paved the way for the coming of Christ and the preaching of the gospel, and unless we thoroughly understand the origin of the gospel, we cannot have an adequate conception of its design. By contrasting the first with the second Adam, St Paul gives us clearly to understand, that one purpose for which Christ came into the world and suffered death on the cross, was to restore to mankind that life which they had lost by the fall of their original progenitor. The preaching of the gospel therefore commenced with the first hint of such a restoration; and the promise given to Adam and Eve, that "the seed of the woman should bruise the head of the serpent," was as truly evangelical as these words of the apostle, by which we are taught, that "this is a faithful saying and worthy of all acceptation, that Christ Jesus came into the world to save sinners †." The former text taken by itself is indeed obscure, and the latter is explicit; but both belong to the same system, for the Scriptures contain but two covenants or dispensations of God to man, in which the whole race is included.

† 1 Tim. i. 15.

130
Christianity may be said to have commenced with the fall.

Christianity therefore is indeed very near as old as the creation; but its principles were at first obscurely revealed, and afterwards gradually developed under different forms as mankind became able to receive them, (see Prophecy, N° 5. &c.). All that appears to have been at first revealed to Adam and Eve was, that by some means or other one of their posterity should in time redeem the whole race from the curse of the fall; or if they had a distinct view of the means by which that redemption was to be wrought, it was probably communicated to them at the institution of sacrifices, (see Sacrifice). This promise of a future deliverer served to comfort them under their heavy sentence; and the institution of sacrifices, whilst it impressed upon their minds lively ideas of the punishment due to their transgression, was admirably calculated to prepare both them and their posterity for the great atonement which, in due time, was to take away the sins of the world.

131
Revelations frequent in the early ages of the world.

Our first parents, after their fall, were so far from being left to fabricate a mode of worship for themselves by those innate powers of the human mind of which we daily hear so much, and feel so little, that God was graciously pleased to manifest himself to their *senses*, and visibly to conduct them by the angel of his presence in all the rites and duties of religion. This is evident from the different discourses which he held with Cain, as well as from the complaint of that murderer of being hid from his face, and from its being said, that "he went out from the presence of the Lord and dwelt on the east of Eden." Nor does it appear that God wholly withdrew his visible presence, and left mankind to their own inventions, till their wickedness became so very great that his spirit could no longer strive with them. The infant state of the world stood in constant need of his supernatural guidance and protection. The early inhabitants of this globe cannot be supposed to have been able, with Moses ||, to look up to him who is *invisible*, and perform a worship purely rational and spiritual. They were all tillers of the ground, or keepers of cattle; employed in cultivating and replenishing this new world; and, through the curse brought upon it by their forefather, forced, with him, to eat their bread "in the sweat of their brow." Man in such circumstances could have little leisure for speculation; nor has mere speculation, unless furnished with principles from another source, ever generated in the human mind adequate notions of God's nature or providence, or of the means by which he can be acceptably worshipped. Frequent manifestations, therefore, of his presence would be necessary to keep a tolerable sense of religion among them, and secure obedience to the divine institutions; and that the Almighty did not exhibit such manifestations, cannot be inferred from the silence of that very short history which we have of those early ages. Adam himself continued 930 years a living monument of the justice and mercy of God; of his extreme hatred and abhorrence of sin, as well as of his love and long suffering towards the sinner. He was very sensible how sin had entered into the world, and he could not but apprise his children of its author. He would at the same time inform them of the unity of God, and his dominion over the evil one; of the means by which he had appointed himself to be worshipped; and of his promise of future deliverance from the curse of the fall. Such information would produce a tolerable idea of the Divine Being, and afford sufficient motives to obey his will. The effects of it accordingly were apparent in the righteous family of Seth, who soon distinguished themselves from the posterity of Cain, and for their eminent piety were honoured with the appellation of *the sons of God*. Of this family sprang a person so remarkable for virtue and devotion, as to be exempted from Adam's sentence and the common lot of his sons; for after he had walked with God 300 years, and prophesied to his brethren, he was translated that he should not see death. Of this miraculous event there can be no doubt but that his contemporaries had some visible demonstration; and as the fate of Abel was an argument to their reason, so the translation of Enoch was a proof to their senses of another state of life after the present. To Adam himself, if

|| Heb. xi. 23.

if he was then alive (s), it must have been a lively and affecting instance of what he might have enjoyed, had he kept his innocence: it must have been a comfortable earnest of the promised victory over the evil one; and have confirmed his hope, that when the head of the serpent should be completely bruised, he and his posterity would be restored to the favour of their Maker, and behold his presence in bliss and immortality.

132 yet vice, and probably idolatry, soon became prevalent.

Notwithstanding this watchful care of God over his fallen creature man, vice, and probably idolatry, spread through the world with a rapid pace. The family of Seth married into that of Cain, and adopted the manners of their new relations. Rapine and violence, unbounded lust and impurity of every kind, prevailed universally; and when those giants in wickedness had filled the earth with tyranny, injustice and oppression; when the whole race was become entirely carnal—God, after raising up another prophet to give them frequent warnings of their fate for the space of 120 years, was at length obliged, in mercy to themselves as well as to the succeeding generations of men, to cut them off by a general deluge. See DELUGE.

133 Pure religion for some time after the flood;

Thus did God, by the spirit of prophecy, by frequent manifestations of his own presence, and by uninterrupted tradition, make ample provision for the instruction and improvement of the world for the first 1600 years. After the deluge he was pleased to converse again with Noah, and make in his person a new and extensive covenant with mankind, (see PROPHECY, N° 11.). Of his power, justice, and goodness; of his supreme dominion over the earth and the heavens; of his abhorrence of sin, and his determination not to let it go unpunished—that patriarch and his family had been most awfully convinced: nor could they or their children, for some time, want any other argument to enforce obedience, fear, and worship. The sons of Noah were an hundred years old when the deluge overwhelmed the earth. They had long conversed with their ancestors of the old world, had frequented the religious assemblies, observed every Sabbath day, and had been instructed by those who had seen Adam. It is therefore impossible that they could be ignorant of the creation of the world, of the fall of man, or of the promise of future deliverance from the consequences of that fall; or that they could offer their sacrifices, and perform the other rites of the instituted worship, without looking forward with the eye of faith to that deliverance seen, perhaps obscurely, through their typical oblations.

134 Idolatry, however, the cause of the dispersion from Babel.

In this state of things religion might for some time be safely propagated by tradition. But when by degrees mankind corrupted that tradition in its most essential parts; when, instead of the one Supreme God, they set up several orders of inferior deities, and worshipped all the host of heaven; when, at the same time they were uniting under one head, and forming a universal empire under the patronage of the Sun their chief divinity (see BABEL)—God saw it necessary to disperse them into distinct colonies, by causing such discord among them as rendered it impossible for any one species of idolatry to be at once universally established.

After this dispersion, there is reason to believe that particular revelations were vouchsafed wherever men were disposed to regard them. Peleg had his name prophetically given him from the dispersion which was to happen in his days; and not only his father Eber, but all the heads of families mentioned from Noah to Abraham, are with much plausibility supposed to have had the spirit of prophecy on many occasions. Noah was undoubtedly both priest and prophet; and living till within two years of the birth of Abraham, or, according to others, till that patriarch was near 60 years old, he would surely be able to keep up a tolerable sense of true religion among such of his descendants as sojourned within the influence of his doctrine and example. His religious son Shem, who lived till after the birth of Isaac, could not but preserve in tolerable purity the faith and worship of the true God among such of his own descendants as lived in his neighbourhood.

But though the remains of true religion were thus preserved among a few righteous men, idolatry had in a short time prevailed so far among the sons of Noah, that God saw it expedient not only to shorten the lives of men, but also to withdraw his presence from the generality, who had thus rendered themselves unworthy of such communications; and to select a particular family, in which his worship might be preserved pure amidst the various corruptions that were overspreading the world.

135 The call of Abraham was

With this view Abraham was called, and, after many remarkable trials of his faith and constancy, admitted to a particular intimacy and friendship with his Maker. God entered into a peculiar covenant with him, engaging to be his present guide, protector, and defender; to bestow all temporal blessings upon him and his seed; and to make some of those seed the instruments of conveying blessings of a higher kind to all the nations of the earth.

136 to prevent the universal spreading of idolatry.

It was doubtless for his singular piety that Abraham was fixed upon to be the parent of that people, who should preserve the knowledge of the unity of God in the midst of an idolatrous and polytheistic world; but we are not to imagine that it was for his sake only that all this was done, or that his less worthy descendants were by the equal Lord of all treated with partial fondness for the virtues of their ancestor; it was for the benefit of mankind in general that he was called from his country, and from his father's house, that he might preserve the doctrine of the divine unity in his own family, and be an instrument in the hand of Providence (and a fit one he was) to convey the same faith to the nations around him. Accordingly, we find him distinguished among the neighbouring princes, and kings reproved for his sake; who being made acquainted with his prophetic character, desired his intercession with God. History tells us of his conversing on the subject of religion with the most learned Egyptians, who appear to have derived from him or some of his descendants the rite of circumcision, and to have been for a while stopt in their progress towards the last stage of that degrading idolatry which afterwards rendered their national worship the opprobrium of the whole earth, (see POLYTHEISM, N° 28.) We are informed that his name was held in the greatest veneration all over the East; that the Magians, Sabians, Persians,

(s) According to the Samaritan chronology, he was alive; according to the Hebrew, he had been dead 57 years.

Theology from the fall of Adam to the coming of Christ.

Persians, and Indians, all glory in him as the greatest reformer of their respective religions: and to us it appears extremely probable, that not only the Brachmans, but likewise the Hindoo god Brahma *, derive their names from the father of the faithful. As he was let into the various counsels of the Almighty, and taught to reason and reflect upon them; as he was fully apprised of the overthrow of Sodom and Gomorrah, with the particular circumstances of that miraculous event; and as he had frequent revelations of the promised Redeemer, whose day he longed earnestly to see, and seeing it was glad—there can be no doubt but that he and his family took care to propagate these important doctrines in every nation which they visited; for the only reason which we can conceive for his being made to wander from place to place was, that different people might be induced to inquire after his profession, his religion, and his hopes.

* See *Asiatic Researches* and *Newt. Chron.*

137
Occasional revelations given to other pious men.

But though the Supreme Being was pleased to manifest himself in a more frequent and familiar manner to Abraham, he by no means left the rest of the world without sufficient light. Lot professed the true religion in the midst of Sodom. In Canaan we meet with Melchizedeck, king and priest of the most high God, who blessed Abraham, and to whom that patriarch himself did homage. Abimelech king of Gerar receiving an admonition from the Lord, immediately paid a due regard to it; and the same sense of religion and virtue descended to his son. Laban and Bethuel acknowledged the Lord, and the former of them was even favoured with a vision. In Arabia, we find Job and his three friends, all men of high rank, entering into the deepest disquisitions in theology; agreeing about the unity, omnipotence, and spirituality of God; the justice of his providence, with other fundamental articles of true religion; and mentioning divine inspiration or revelation as a thing not uncommon in their age and country † (U). Balaam appears to have been a true prophet: and as he was unquestionably a man of bad morals, the natural inference is, that the gift of prophecy was then, as afterwards, bestowed on individuals, not for their own sakes, but for the sake of the public; and that, as in "every nation, he who feareth God and worketh righteousness is accepted of him;" so in those early ages of the world, when mankind were but children in religious knowledge, they were blessed with the light of divine revelation wherever they were disposed to make a proper use of it.

† Job iv. 12, 15, 16, 17. vi. 10. xxiii. 12.

138
A second purpose for which Abraham was called.

Very few, however, appear to have had this disposition; and therefore God was pleased to adopt Abraham and part of his posterity as the race from which the great Redeemer was to spring, to train them up by degrees in suitable notions of their Creator, and gradually to open up to them, as they were able to receive it, the nature of that dispensation under which "all the nations of the earth were to be blessed in the patriarch's seed, (see PROPHECY, N° 13.). For this purpose, he held frequent correspondence with them; and to strengthen and confirm their faith, to fix and preserve their dependence on the one God of heaven and earth, he daily gave them new promises, each more magnificent than that which preceded it. He blessed Isaac, miraculously increased his substance, and soon made him the envy of the neighbouring princes. He foretold the condition of his two sons, renewed the promise made to Abraham, and blessed the adopted son Jacob, with whom he condescended to converse as he had conversed with Abraham and Isaac; renewing to him the great promise; bestowing upon him all kinds of riches; and impressing such terror upon all the cities which were round about him as prevented them from hurting either him or his family.

All this was indeed little enough to keep alive even in the mind of Jacob a tolerable sense of duty and dependence on his Creator. After the first vision he is surprised, and hesitates, seemingly inclined to make a kind of stipulation with his Maker, "If (says he) God will be with me, and will keep me in this way that I go, and will give me bread to eat, and raiment to put on, so that I come again to my father's house in peace, *then* shall the Lord be my God †." It appears not to have been till after many such revelations, blessings, and deliverances, and being reminded of the vow which on this occasion he had vowed, that he set himself in good earnest to reform the religion of his own family, and to drive out from it all strange gods *. So little able, in that age, were the boasted powers of the human mind to preserve in the world just notions of the unity of the Godhead, that we see there was a necessity for very frequent revelations, to prevent even the best men from running headlong into polytheism and idolatry.

† Gen. xxviii. 20. 21.

* Gen. xxxv. 2.

Thus was God obliged to treat even with the patriarchs themselves, by way of positive covenant and express compact; to promise to be their God if they would be his people; to give them a portion of temporal blessings as introductory to future and spiritual ones; and to engage them in his service by immediate rewards, till they could be led on to higher views, and prepared by the bringing in of a better hope to worship him in spirit and in truth. With regard to what may be called the *theory* of religion, mankind were yet scarcely got out of their childhood. Some extraordinary persons indeed occasionally appeared in different countries, such as Enoch, Noah, Abraham, and Job, with many others, who had a more enlarged prospect of things, and entertained more worthy sentiments of the divine dispensations and of the ultimate end of man; but these were far superior to the times in which they lived, and appear to have been providentially raised up to prevent the savage state and savage idolatry from becoming universal among men. See SAVAGE.

139
The patriarchal worship of those early ages performed in faith.

The worship which was practised by those holy men appears to have consisted principally of the three kinds of sacrifice mentioned elsewhere (see SACRIFICE); to which were doubtless added prayers and praises, with the

(U) There are great disputes among the learned respecting the antiquity and the author of the *book* of Job, and whether it be a history of events, or a poem which has its foundation in history. All sober men, however, are agreed, that there really was such a *person* as Job, eminent for patience under uncommon sufferings; and that he was of very remote antiquity. The LXX give us the names of his father and mother, and say that he was the fifth from Abraham.

the more valuable oblation of pure hands and devout hearts. Such of them as looked forward to a future redemption, and had any tolerable notion of the means by which it was to be effected, as Abraham certainly had, must have been sensible that the blood of bulls and of goats could never take away sin, and that their sacrifices were therefore valuable only when they were offered in faith of that great promise, "which they, having seen it afar off, were persuaded of, and embraced: and confessed that they were strangers and pilgrims upon earth."

That such persons looked for "a better country, even a heavenly one," in a future state, cannot be questioned; for they knew well how sin and death had entered into the world, and they must have understood the promise made to their original progenitor, and repeatedly renewed to themselves, to include in it a deliverance at some period from every consequence of the first transgression. They were to all intents and purposes Christians as well as we.

140 Of a future Redeemer.

They indeed placed their confidence in a Redeemer, who in the fulness of time was to appear upon earth, while we place ours in a Redeemer that has been already manifested; they expressed that confidence by one mode of worship, we express it by another; but the patriarchal worship had the same end in view with the Christian—the attainment of everlasting life in heaven.

141 Such faith, however, not general.

The generality of men, however, appear not, in the early age of which we now write, to have extended their views beyond the present life. From the confused remains of ancient tradition, they acknowledged indeed some superior power or powers, to whom they frequently applied for direction in their affairs; but in all probability it was only for direction in temporal affairs, such as the cultivation of the ground, or their transactions with each other. In the then state of things, when no part of the world was overstocked with inhabitants, and when luxury with its consequences was everywhere unknown, virtue and vice must have produced their natural effects; and the good man being happy here, and the wicked man miserable, reason had no data from which to infer the reality of a future state of rewards and punishments. Those who were blessed with the light of revelation undoubtedly looked forward to that state with a holy joy; but the rest worshipped superior powers from worldly motives. How many of those powers there might be, or how far their influence might reach, they knew not. Uncertain whether there be one Supreme Governor of the whole world, or many co-ordinate powers presiding each over a particular country, climate, or place—gods of the hills and of the valleys, as they were afterwards distinguished—they thought that the more of these they could engage in their interest the better. Like the Samaritans therefore, in after times, they sought, wherever they came, the "the manners of the god of the land," and served him, together with their own gods.

142 The purpose for which the Israelites were made to sojourn in Egypt.

Thus was the world ready to lose all knowledge of the true God and his worship, had not he been graciously pleased to interpose, and take effectual care to preserve that knowledge in one nation, from which it might be conveyed to the rest of mankind at different times, and in greater or less degrees, as they should be capable of receiving it. To this purpose he made way for the removal of Jacob and his family to one of the most improved and polished countries of the world; and introduced them into it in a manner so advantageous, as to give them an opportunity of imparting much religious knowledge to the natives. The natives, however, were gross idolaters; and that his chosen people might be as far as possible from the contagion of their example, he placed them upon the borders of Egypt, where, though they multiplied exceedingly, they were by their very occupation * still kept a separate people, and must have been rendered, by a long and severe oppression, in a great degree averse to the manners and religion of their neighbours. This aversion, however, seems to have gradually become less and less; and before they were miraculously redeemed from their house of bondage, they had certainly lost all correct notions of the unity of God, and the nature of his worship, and had adopted the greater part of the superstitions of their task-masters. Of this we need no other proof than what is implied in the words of Moses ‡, when he said unto God, "Behold, when I come unto the children of Israel, and say

143 Consequences of it.

unto them, the God of your fathers hath sent me unto you; and they shall say unto me, WHAT IS HIS NAME? what shall I say unto them?" Had not the destined lawgiver of the Hebrews been aware that his countrymen had adopted a plurality of gods, this difficulty could not have occurred to him; for *names* are never thought of but to distinguish from each other beings of the same kind; and he must have remembered, that in Egypt, where the multitude of goods was marshalled into various classes, the knowledge of their names was deemed of great importance. This we learn likewise from Herodotus, who informs us §, that the Pelasgi, after settling in Greece, thought it necessary to consult the oracle of Dodona, whether it would be proper to give to their own gods the names of the Egyptian divinities? and that the oracle, as might have been supposed, assured them that it would. Indeed the Hebrews during their residence in Egypt had acquired such an attachment to the idolatrous worship of the country, that it appears never to have left them entirely till many ages afterwards, when they were carried captive into Babylon, and severely punished for their repeated apostasies; and so completely were they infatuated by these superstitions at the era of their exodus, that, as the prophet Ezekiel informs us ||, they rebelled against God, and would not cast away their abominations, or forsake the idols of Egypt, even in the *very day* that the hand of Omnipotence was lifted up to bring them forth of that land in which they had been so long and so cruelly oppressed. In such a state of things, to have suffered them to remain longer in Egypt, could have served no good purpose; and therefore to fulfil the promise which he had given to Abraham, God determined to deliver them out of the hands of the Egyptians by means which should convince both them and their offspring of his own supremacy over heaven and earth.

144 Moses appointed to bring them out of Egypt.

As Moses was the person appointed to deliver God's message to Pharaoh, and to demand of him leave for the Israelites to go three days journey into the wilderness to serve the God of their fathers, it was necessary that he should be endowed with the power of working miracles to evince the reality of his divine mission. Without a conviction that his claims were well founded, neither Pharaoh nor his own countrymen could reasonably have been expected to listen to the proposals of a man who, though blessed in his youth with a princely education, had come directly on his embassy from the humble employment

§ Lib. ii. cap. 52, 53.

|| Ch. xx.

Theology from the fall of Adam to the coming of Christ.

ployment of a shepherd, which he had for many years exercised in the country of Midian. To prove that he was really sent by God, any visible and undoubted controul of the laws of nature would have been abundantly sufficient; but he was to prove not only this truth, but also the unity of the Divine nature; and the miracles which he was directed to work were executions of judgement against the very gods of Egypt †.

† Exod. xii. 12.

145 The propriety of the miracles which he wrought

When Pharaoh first turned a deaf ear to his request, though enforced by the conversion of a rod into a serpent, at the command of Jehovah he smote with the same rod upon the waters in the river, which were instantly converted into blood, and occasioned the death of all the fishes that swam in them. To any people this miracle would have been a proof of Divine agency: but it was in a particular manner calculated to open the eyes of the blind and infatuated Egyptians, who considered the Nile as one of their greatest gods, and all the fishes that it contained as subordinate divinities. They called that noble river sometimes *Sirius*, sometimes *Osiris*, sometimes *Canobus* (see CANOBUS), and not unfrequently Ωκεαμης (x); and adored it as the parent of all their deities. What then must the people have thought when they found their most revered god, at the command of a servant of Jehovah, converted into blood, and all his sacred offspring into stinking carcases? To conceive their consternation, if it can be conceived, the reader must remember, that the Egyptian priests held blood in the utmost abhorrence, as a thing of which the very touch would deeply pollute them, and require immediate and solemn expiation. The same sacred river was a second time polluted, when it sent forth frogs, which covered all the land of Egypt, and died in the houses, in the villages, and in the fields; thus rendering it impossible for the people to avoid the touch of dead bodies, though from every such contact they believed themselves to contract an impurity, which, in the case before us, must have been the more grievous, that in the whole country there was not left a pool of uninfected water to wash away the stain.

146 to evidence the vanity of idol worship.

The third plague inflicted on the Egyptians was, the converting of the dust of the land into lice, upon man and upon beast, throughout the whole kingdom. To see the propriety of this miracle as a judgment upon their idolatry, we must recollect their utter abhorrence of all kinds of vermin, and their extreme attention to external purity above every other people perhaps that has hitherto existed on the face of the earth. On this head they were more particularly solicitous when about to enter the temples of their gods; for Herodotus informs us, that their priests wore linen raiment only, and shaved off every hair from their heads and bodies, that there might be no *louse* or other detestable object upon them when performing their duty to the gods. This plague therefore, while it lasted, made it impossible for them to perform their idolatrous worship, without giving such offence to their deities as they imagined could never be forgiven. Hence we find, that on the production of the lice, the priests and magicians perceived immediately from what hand the miracle had come, and exclaimed, "This is the finger of God!" The fourth plague seems to have been likewise acknowledged to be the finger of God, if not by the magicians, at least by Pharaoh; for in a fit of terror he agreed that the Israelites should go and serve the Lord. That he was terrified at the swarms of flies which infested the whole country, except the land of Goshen, will excite no wonder, when it is known that the worship of the fly originated in Egypt; whence it was carried by the Caphtorim to Palestine; by the Phœnicians to Sidon, Tyre, and Babylon; and from these regions to other parts of the world. The denunciation of this plague was delivered to Pharaoh early in the morning, when he was on the banks of the Nile, probably paying his accustomed devotion to his greatest god; and when he found himself and his people tormented by a swarm of subordinate divinities, who executed the judgment of Jehovah in defiance of the power of the supreme *numen* of Egypt, he must have been convinced, had any candour remained in his mind, that the whole system of his superstition was a mass of absurdities, and that his gods were only humble instruments at the disposal of a Superior Power. He was not, however, convinced; he was only alarmed, and quickly relapsed into his wonted obstinacy. The fifth plague therefore, the murrain among the cattle, brought death and destruction on his most revered gods themselves. Neither Osiris, nor Isis, nor Ammon, nor Pan, had power to save his brute representatives. The sacred bull, and heifer, and ram, and goat, were carried off by the same malady which swept away all the other herds of deities, these *dii stercorei*, who lived on grass and hay. The impression of this punishment must have been awful on the minds of the Egyptians, but perhaps not equal to that which succeeded it.

In Egypt there were several altars on which human sacrifices were offered; and from the description of the persons qualified to be victims, it appears that those unhappy beings must have been foreigners, as they were required to have bright hair and a particular complexion. The hair of the Israelites was much brighter than that of the Egyptians, and their complexions fairer; and therefore there can be little doubt but that, during their residence in Egypt, they were made to furnish the victims demanded by the bloody gods. These victims being burnt alive on a high altar, and thus sacrificed for the good of the nation, their ashes were gathered together by the priest, and scattered upwards in the air, that a blessing might be entailed on every place to which an atom of this dust should be wafted. Moses too, by the direction of the true God, took ashes of the furnace, probably of one of those very furnaces in which some of his countrymen had been burnt, and sprinkling them towards heaven in the sight of Pharaoh, brought boils and blains upon all the people, of so malignant a nature, that the magicians and the other ministers of the medical gods, with which Egypt abounded beyond all other countries, could not themselves escape the infection.

The powers of darkness were thus foiled; but the heart of the monarch was still hardened. Destruction was therefore next brought on him and his country by the elements, which were among the earliest idol deities not

(x) Whence came the Greek word ωκεανος, *the ocean*.

Theology from the fall of Adam to the coming of Christ.

not only of the Egyptians, but of every other polytheistic nation. "The Lord rained hail on the land of Egypt; so that there was hail, and fire mingled with the hail, such as there was none like it in all the land of Egypt since it became a nation. And the hail smote throughout all the land of Egypt all that was in the field, both man and beast; and the hail smote every herb of the field, and broke every tree of the field." This was a dreadful calamity in itself; and the horror which it excited in the minds of the people must have been greatly aggravated by the well-known fact, that Egypt is blessed with a sky uncommonly serene; that in the greatest part of it rain has never been seen at any other time since the creation of the world; and that a slight and transient shower is the utmost that in the ordinary course of nature falls anywhere throughout the country. The small quantity of vegetables which was left undestroyed by the fire and the hail was afterwards devoured by locusts, which by a strong east wind were brought in such numbers from Arabia, where they abounded at all times, that they covered the whole face of the earth, and did eat every herb of the land, and all the fruit of the trees, so that there remained not any green thing in the trees or in the herbs of the field through all the land of Egypt.

The ninth plague which the obstinacy of Pharaoh brought upon his country, whilst it severely punished the Egyptians for their cruelty to the Hebrews, struck at the very foundation of all idolatry. We have elsewhere shown, that the first objects of idolatrous worship were the contending powers of light and darkness (see POLYTHEISM); and that the benevolent principle, or the power of light, was everywhere believed to maintain a constant superiority over the power of darkness. Such was the faith of the ancient Persians; and such, as a very learned writer has lately proved, was likewise the faith of the earlier Egyptians. It was therefore with wisdom truly divine, that God, to show the vanity of their imaginations, brought upon these votaries of light, who fancied themselves the offspring of the sun, a preternatural darkness, which, for three days, all the powers of their supreme deity, and his subordinate agents, could not dispel.

The tenth and last plague brought on this idolatrous people was more universally and severely felt than any which had preceded it. It was likewise, in some sense, an instance of the *lex talionis*, which requires an eye for an eye, and a tooth for a tooth, &c. Moses was commanded, at his first interview with Pharaoh, to say, "Thus saith the Lord, Israel is my son, even my first-born. Let my son go that he may serve me: and if thou refuse to let him go, behold, I will slay thy son, even thy first-born." Before this threat was put in execution, every attempt was made to soften the hardened heart of the obstinate tyrant. The waters of his sacred river were turned into blood, and all the fishes that it contained slain; frogs were brought over all the land to pollute the people; the ministers of religion were rendered so impure by vermin, that they could not discharge their wonted offices; the animals most revered as gods, or emblems of gods, were cut off by a murrain; the elements, that were everywhere worshipped as divinities, carried through the land a devastation, which was completed by swarms of locusts; the ashes from the sacred furnace, which were thought to convey blessings whithersoever they were wafted, were made to communicate incurable disease; a thick and preternatural darkness was spread over the kingdom, in defiance of the power of the great Osiris; and when the hearts of the people and their sovereign continued still obdurate, the eldest son in each family was slain, because they refused to let go Israel, God's first-born. From this universal pestilence the Israelites were preserved by sprinkling the door-posts of their houses with the blood of one of the animals adored in Egypt; a fact which, as it could not be unknown to Pharaoh or his subjects, ought to have convinced that people of the extreme absurdity of their impious superstitions. This effect it seems not to have had; but the death of the first-born produced the deliverance of the Hebrews; for when it was found that there was not a house where there was not one dead, "Pharaoh called for Moses and Aaron by night, and said, Rise up, and get you forth from among my people, both you and the children of Israel; and bless me also. And the Egyptians were urgent upon the people, that they might send them out of the land in haste; for they said, We be all dead men (Y)." The wonted obstinacy of the monarch indeed very soon returned; and his subjects, forgetting the loss of their children, joined with him in a vain attempt to bring back to bondage the very people whom they had been thus urgent to send out of the land; but their attempt was defeated by Jehovah, and all who engaged in it drowned in the Red sea.

147 Reason of detaining the Israelites so long in the wilderness.

The God of Israel having thus magnified himself over the Egyptians and their gods, and rescued his people from bondage by such means as must not only have struck terror and astonishment into the whole land, but also have spread his name through all the countries which had any communication with that far-famed nation, proceeded to instruct and exercise the Hebrews for many years in the wilderness. He inculcated upon them the unity of the Godhead; gave them statutes and judgments more righteous than those of any other nation; and by every method consistent with the freedom of moral agency guarded them against the contagion of idolatry and polytheism. He sent his angel before them to keep them in the way, took upon himself the office of their supreme civil governor, and by his presence directed them in all their undertakings. He led them with repeated signs and wonders through the neighbouring nations, continued to try and discipline them

(Y) For this account of the plagues of Egypt, we are indebted to the very valuable *Observations* on the subject published by *Mr Bryant*. We have not quoted the authorities by which the learned and pious author supports his opinions; because it is to be hoped, that for a fuller account of these important transactions the reader will have recourse to his work, of which we have given only a very brief abstract. For much of the preceding parts of this section, we acknowledge our obligations to Bishop Law's admirable discourse on the *Several Dispensations of Revealed Religion.*

Theology from the fall of Adam to the coming of Christ.

them till they were tolerably attached to his government and established in his worship, and introduced them into the Promised Land when its inhabitants were ripe for destruction. At their entrance into it, he gave them a summary repetition of their former laws, with more such ordinances, both of a ceremonial and moral kind, as were both suited to their temper and circumstances, as well as to prefigure, and by degrees to prepare them for, a more perfect dispensation under the Messiah.

148
Great objects of the Jewish law.

The Jewish law had two great objects in view; of which the first was to preserve among them the knowledge of the true God, a rational worship springing from that knowledge, and the regular practice of moral virtue: and the second was to fit them for receiving the accomplishment of the great promise made to their ancestors, by means analogous to those which a schoolmaster employs to fit his pupils for discharging the duties of maturer years. Every thing in that law peculiar to itself, its various ceremonies, modes of sacrificing, the sanctions by which it was enforced, and the theocratic government by which it was administered, had a direct tendency to promote one or other of these ends; and keeping these ends in view, even the minutest laws, at which impious ignorance has affected to make itself merry, will be discovered by those who shall study the whole system, and are at the same time acquainted with the genius of ancient polytheism, to have been enacted with the most consummate wisdom.

It is not easy for us, who have been long blessed with the light of revelation, to conceive the propensity of all nations, in that early age of the world, to the worship of false gods, of which they were daily adding to the number. It is indeed probable, from many passages of Scripture, as well as from profane authors of the greatest antiquity, that one supreme *numen* was everywhere acknowledged: but he was considered as an extramundane being, too highly exalted to concern himself with the affairs of this world, the government of which, it was believed, he had delegated to various orders of subordinate deities. Of those deities, some were supposed to have the charge of one nation and some of another. Hence it is, that we read of the gods of Egypt, the gods of the Amorites, and the gods of the different nations around Palestine. None of those nations denied the existence of their neighbour's gods; but all agreed, that while the Egyptians were the peculiar care of Osiris and Isis, the Amorites might be the favourites of Moloch, the Phœnicians of Cronus, and the Philistines of Dagon; and they had no objection occasionally to join with each other in the worship of their respective tutelary deities. Nay, it was thought impiety in foreigners, while they sojourned in a strange country, not to sacrifice to the gods of the place. Thus Sophocles makes Antigone say to her father, that a stranger should both venerate and abhor those things which are venerated and abhorred in the city where he resides; and another author *, who, though comparatively late, drew much of his information from ancient writings which are now lost, assures us, that this complaisance proceeded from the belief that the "several parts of the world were from the beginning distributed to several powers, of which each had his peculiar allotment and residence."

* *Celsus apud Aug.*

From this notion of local divinities, whose power or partial fondness was confined to one people, the Israelites, on their departure from Egypt, appear not to have been free (z). Hence it is, that when the true God first tells them, by their leader Moses †, that if they would obey his voice indeed and keep his covenant, then they should be a PECULIAR TREASURE to him above all people: to prevent them from supposing that he shared the earth with the idols of the heathen, and had from partial fondness chosen them for his *portion*, he immediately adds, for ALL THE EARTH IS MINE. By this addition he gave them plainly to understand that they were chosen to be his peculiar treasure for some purpose of general importance; and the very first article of the covenant which they were to keep was, that they should have no other gods but him. So inveterate, however, was the principle which led to an intercommunity of the objects of worship, that they could not have kept this article of the covenant but in a state of separation from the rest of mankind ‡; and that separation could neither have been effected nor continued without the visible providence of the Almighty watching over them as his peculiar treasure. This we learn from Moses himself, who, when interceding for the people after their idolatrous worship of the golden calf, and intreating that the presence of God would still accompany them, adds these words §: "For wherein shall it be known here that I and thy people have found grace in thy sight? Is it not in that THOU GOEST WITH US? So shall we be SEPARATED, I and thy people, from all the people that are on the face of the earth." On this separation every thing depended; and therefore to render it the more secure, Jehovah was graciously pleased to become likewise their supreme Magistrate, making them a "kingdom of priests and a holy nation," and delivering to them a digest as well of their civil as of their religious laws.

§ Exod. xxxiii. 16.

150
Of their theocratic government,

The Almighty thus becoming their King, the government of the Israelites was properly a THEOCRACY, in which the two societies, civil and religious, were of course incorporated. They had indeed after their settlement in the Promised Land, at first, temporary *judges* occasionally raised up; and afterwards permanent magistrates called *kings*, to lead their armies in war, and to give vigour to the administration of justice in peace: but neither those judges nor those kings could abrogate a single law of the original code, or make the smallest addition to it but by the spirit of prophecy. They cannot

(z) It is not indeed evident that they had got entirely quit of this absurd opinion at a much later period. Jephtha one of their judges, who, though half paganized (as Warburton observes) by a bad education, had probably as correct notions of religion as an ordinary Israelite, certainly talked to the king of Ammon as if he had believed the different nations of the earth to be under the immediate protection of different deities: "Wilt not thou (says he) possess that which Chemosh THY GOD giveth thee to possess! So whomsoever the Lord OUR GOD shall drive out from before us, them will we possess." (Judges xi. 24.).

Theology from the fall of Adam to the coming of Christ.

not therefore be considered as supreme magistrates, by whatever title they may have been known; for they were to go out and come in at the word of the priests, who were to ask counsel for them of the Lord, and with whom they were even associated in all judicial proceedings, as well of a civil as of a spiritual nature *. Under any other than a theocratic government, the Hebrews could not have been kept separate from the nations around them; or if they could, that separation would not have answered the great purpose for which it was established. "The people, on their leaving Egypt, were sunk into the lowest practices of idolatry. To recover them by the discipline of a separation, it was necessary that the idea of God and his attributes should be impressed upon them in the most *sensible* manner. But this could not be commodiously done under his character of God of the universe: under his character of King of Israel, it well might. Hence it is, that we find him in the Old Testament so frequently represented with affections analogous to human passions. The civil relation in which he stood to the Israelites made such a representation natural; the grossness of their conceptions made the representation necessary; and the guarded manner in which it was always qualified prevented it from being mischievous †." Hence too it is, that under the Mosaic dispensation, idolatry was a crime of state, punishable by the civil magistrate. It was indeed high treason, against which laws were enacted on the justest principles, and carried into effect without danger of error. Nothing less indeed than penal laws of the severest kind could have restrained the violent propensity of that headstrong people to worship, together with their own God, the gods of the Heathen. But penal laws enacted by human authority for errors in religion are manifestly unjust; and therefore a theocratic government seems to have been absolutely necessary to obtain the end for which the Israelites were separated from the surrounding nations.

† *Warburton's Div. Leg.* book v. sect. 2.

151
and of the ritual law,

It was for the same purpose that the ritual law was given, after their presumptuous rebellions in the wilderness. Before the business of the golden calf, and their frequent attempts to return into Egypt, it seems not to have been the Divine intention to lay on them a yoke of ordinances; but to make his covenant depend entirely on their duly practising the rite of circumcision; observing the festivals instituted in commemoration of their deliverance from bondage, and other signal services vouchsafed them; and keeping inviolate all the precepts of the decalogue (A), which, if they had done, they should have even lived in them ‡. But after their repeated apostasies, and impious wishes to mix with the surrounding nations, it was necessary to subject them to a multifarious ritual, of which the ceremonial parts were solemn and splendid, fitted to engage and fix the attention of a people whose hearts were gross; to inspire them with reverence, and to withdraw their affections from the pageantry of those idle superstitions which they had so long witnessed in the land of Egypt. To keep them warmly attached to their public worship, that worship was loaded with operose and magnificent rites, and so completely incorporated with their civil polity as to make the same things at once duties of religion and acts of state. The service of God was indeed so ordered as to be the constant business as well as entertainment of their lives, supplying the place of all other entertainments; and the sacrifices which they were commanded to offer on the most solemn occasions, were of such animals as the Egyptians and other Heathens deemed sacred.

‡ *Divine Leg.* book iv. sect. 6.

152
instanced in their sacrifices,

Thus a heifer without blemish was in Egypt held sacred to the goddess Isis, and worshipped as the representative of that divinity; but the same kind of heifer was by the ritual law of the Hebrews commanded to be burnt without the camp, as the vilest animal, and the water of separation to be prepared from her ashes *. The goat was by the Egyptians held in great veneration as emblematical of their ancient god Pan, and sacrifices of the most abominable kind were offered to the impure animal (see PAN); but God, by his servant Moses, enjoined the Israelites to offer goats themselves as sacrifices for sin, and on one occasion to dismiss the live animal loaded with maledictions into the wilderness †. The Egyptians, with singular zeal, worshipped a calf without blemish as the symbol of Apis, or the god of fertility; and it appears from the book of Exodus, that the Israelites themselves had been infected with that superstition. They were, however, so far from being permitted by their Divine lawgiver to consider that animal as sacred, that their priests were commanded to offer for themselves a young calf as a sin-offering ‡. No animal was in Egypt held in greater veneration than the ram, the symbol of their god Ammon, one of the constellations. It was therefore with wisdom truly divine, that Jehovah, at the institution of the passover, ordered his people to kill and eat a young ram on the very day that the Egyptians began their annual solemnities § in honour of that animal as one of their greatest gods; and that he enjoined the blood of this divinity to be sprinkled as a sign on the two side-posts and upper door-post of the house in which he was eaten. Surely it is not in the power of imagination to conceive a ritual better calculated to cure the Israelites of their propensity to idol worship, or to keep them separate from the people who had first given them that propensity, than one which enjoined them to offer in sacrifice the very creatures which their superstitious masters had worshipped as gods. "Shall we (said Moses) sacrifice the abominations of the Egyptians before their eyes, and will they not stone us?"

* Num. xix.

† Levit. xvi.

‡ Levit. ix.

§ *Spencer de Legibus, Heb. Rit.* lib. ii. cap. iv.

But it was not against Egyptian idolatry only that the ritual law was framed: the nations of Syria, in the midst of whom the Israelites were to dwell, were addicted to many cruel and absurd superstitions, against which it was as necessary to guard the people of God as against the brute-worship of Egypt. We need not inform any reader of the book of Moses that those nations worshipped

(A) Of these precepts we think it not necessary, in an abstract so short as this, to waste the reader's time with a formal and laboured defence. To the decalogue no objection can be made by any man who admits the obligations of natural religion; for, except the observation of the Sabbath-day, it enjoins not a single duty which does not by the confession of all men result from our relations to God, ourselves, and our fellow-creatures.

Theology from the fall of Adam to the coming of Christ.

ped the sun and moon and all the host of heaven; or that it was part of their religion to propitiate their offended gods by occasionally sacrificing their sons and their daughters. From such worship and sacrifices the Israelites were prohibited under the severest penalties; but we cannot consider that prohibition as making part of the *ritual* law, since it relates to practices impious and immoral in themselves, and therefore declared to be abominations to the Lord. The Phœnicians, however, and the Canaanites, entertained an opinion that every child came into the world with a *polluted nature*, and that this pollution could be removed only by a *lustral fire*. Hence they took their new-born infants, and with particular ceremonies made them pass through the flame of a pile sacred to Baal or Moloch, the symbols of their great god the sun. Sometimes this purgation was delayed till the children had arrived at their tenth or twelfth year, when they were made either to leap through the flame, or run several times backwards and forwards between two contiguous sacred fires; and this lustration was supposed to free them from every natural pollution, and to make them through life the peculiar care of the deity in whose honour it was performed *. The true God, however, who would have no fellowship with idols, forbade all such purgations among his people, whether done by fires consecrated to himself or to the bloody deities of the Syrian nations. "There shall not be found (says he) among you any one that maketh his son or his daughter to pass through the fire †."

153 and in the laws respecting eating and drinking, and agriculture.

* *Spencer*, lib. ii. cap. 13.

† Deut. xvii. 10. xii. 29. and Levit. xx. 2, &c.

There are, in the Jewish law, few precepts more frequently repeated than that which prohibits the seething of a kid in his mother's milk ‡; and there being no moral fitness in this precept when considered absolutely and without regard to the circumstances under which it was given, infidel ignorance has frequently thought fit to make it the subject of profane ridicule. But the ridicule will be forborne by those who know that, among the nations round Judea, the feasting on a kid boiled in its mother's milk was an essential part of the impious and magical ceremonies celebrated in honour of one of their gods, who was supposed to have been suckled by a she-goat. Hence, in the Samaritan Pentateuch, the text runs thus: "Thou shalt not seeth a kid in its mother's milk; for whoever does so, is as one who sacrifices an abominable thing, which offends the God of Jacob §." Another precept, apparently of very little importance, is given in these words: "Ye shall not round the corners of your heads, neither shalt thou mar the corners of thy beard ||." But its wisdom is seen at once, when we know that at funerals it was the practice of many of the heathens, in that early period, to round the corners of their heads, and mar their beards, that by throwing the hairs they had cut off on the dead body, or the funeral pile, they might propitiate the shade of the departed hero; and that in other nations, particularly in Phœnicia, it was customary to cut off all the hair of their heads except what grew on the crown, which, with great solemnity, was consecrated either to the sun or to Saturn *. The unlearned Christian, if he be a man of reflection, must read with some degree of wonder such laws as these: "Thou shalt not sow thy vineyard with divers seeds, lest the fruit of thy seed which thou hast sown and the fruits of thy vineyard be defiled. Thou shalt not plough with an ox and an ass together. Thou shalt not wear a garment of divers sorts, or of woollen and linen together †." But his wonder will cease when he knows that all these were practices from which the Sabian idolaters of the east expected the greatest advantages. Their belief in magic and judicial astrology led them to imagine, that by sowing different kinds of corn among their vines they should propitiate the gods which were afterwards known in Rome by the names of Bacchus and Ceres; that, by yoking animals so heterogeneous as the ox and the ass in the same plough, they should by a charm secure the favour of the deities who presided over the affairs of husbandry; and that a garment composed of linen and woollen, worn under certain conjunctions of the stars, would protect its owner, his flocks, his herds, and his field, from all malign influences, and render him in the highest degree prosperous through the whole course of his life ‡. But magical ceremonies were always performed in order to render propitious good or evil demons (see MAGIC); and therefore such ceremonies, however unimportant in themselves, were in that age most wisely prohibited in the Mosaic law, as they naturally led those who were addicted to them to the worship of idols and impure spirits.

‡ *Spencer*, lib. ii. cap. 30, 31, 33.

If the whole ritual of the Jewish economy be examined in this manner, every precept in it will be found to be directed against some idolatrous practice of the age in which it was given. It was therefore admirably calculated to keep the Israelites a separate people, and to prevent too close an intercourse between them and their Gentile neighbours. The distinction made by their law between clean and unclean animals (see SLAVERY, N° 33.) rendered it impossible for them, without a breach of that law, to eat and drink with their idolatrous neighbours; their sacred and civil ceremonies being directly levelled against the Egyptian, Zabian, and Canaanitish superstitions, had a tendency to generate in their minds a contempt of those superstitions; and that contempt must have been greatly increased by their yearly, monthly, and daily sacrifices, of the very animals which their Egyptian masters had worshipped as gods.

154 The Mosaic laws enforced by temporal sanctions.

That these laws might have the fuller effect on minds gross and carnal, they were all enforced by temporal sanctions. Hence it is that Moses assured them that if they would hearken to God's judgments, and keep them, and do them, they should be blessed above all people; threatening them at the same time with utter destruction if they should at all walk after other gods, and serve them, and worship them §. Nor were these temporal rewards and punishments held out only to the nation as a collective body; they were promised and threatened to every individual in his private capacity as the certain consequences of his obedience or disobedience. Every particular Hebrew was commanded to honour his father and mother, that it might go well with him, and that his days might be prolonged; whilst he who cursed his father or his mother was surely to be put to death. Against every idolater, and even against the wilful transgressor of the ceremonial law, God repeatedly declared that he would set his face, and would cut off that man from among his people: and that individuals, as well as the nation, were in this life actually rewarded and punished according to their deserts, has been proved by Bishop Warburton ||. Indeed the Mosaic

§ Deut. *passim*.

|| *Div. Leg.* book. v. sect. 4.

Theology from the fall of Adam to the coming of Christ

saic law, taken in its literal sense, holds out no other prospects to the Israelites than temporal happiness; such as health, long life, peace, plenty, and dominion, if they should keep the covenant; and temporal misery, viz. diseases, immature death, war, famine, want, subjection, and captivity, if they should break it. "See (says Moses), I have set before thee this day life and good, death and evil; in that I command thee this day to love the Lord thy God, to walk in his ways, and to keep his commandments, and his statutes, and his judgements, that thou mayest live and multiply; and the Lord thy God shall bless thee in the land whither thou goest to possess it. But if thine heart turn away, so that thou wilt not hear, but shalt be drawn away, and worship other gods, and serve them; I denounce unto you this day, that ye shall surely perish, and that ye shall not prolong your days upon the land whither thou passest over Jordan to possess it." And elsewhere, having informed them that, upon their apostasy, their land should be rendered like Sodom and Gomorrah, he adds, that all men should know the reason of such barrenness being brought upon it, and should say, "Because they have forsaken the covenant of the Lord God of their fathers, which he made with them when he brought them forth out of the land of Egypt, the anger of the Lord was kindled against this land, to bring upon it all the curses that are written in this book *."

* Deut. xxx. 15—19. xxxix. 25.

155 Whence it has been rashly inferred that the ancient Hebrews had no hope beyond the grave.

From this fact, which scarcely any man of letters will venture to deny, some divines have concluded, that the ancient Israelites had no hope whatever beyond the grave; and that in the whole Old Testament there is not a single intimation of a future state. That many of the lower classes, who could neither read nor write, were in this state of darkness, may be true; but it is impossible that those who understood the book of Genesis could be ignorant that death came into the world by the transgression of their first parents, and that God had repeatedly promised to redeem mankind from every consequence of that transgression. They must likewise have known that, before the deluge, Enoch was translated into heaven without tasting death; that afterwards Elijah had the same exemption from the common lot of humanity; and that, as God is no respecter of persons, every one who served him with the zeal and fidelity of these two prophets would, by some means or other, be made capable of enjoying the same rewards. The God of Abraham, Isaac, and Jacob, was not the God of the dead, but of the living.

In the earliest periods of their commonwealth, the Israelites could, indeed, only *infer*, from different passages of their sacred books, that there would be a general resurrection of the dead, and a future state of rewards and punishments; but from the writings of the prophets it appears, that before the Babylonish captivity that doctrine must have been very generally received. In the Psalms, and in the prophecies of Isaiah, Daniel, and Ezekiel, there are several texts which seem to us to prove incontrovertibly, that, at the time when these inspired books were written, every Israelite who could read the scriptures must have had some hopes of a resurrection from the dead. We shall consider two of these texts, because they have been quoted by a very learned and valuable writer in support of an opinion the reverse of ours.

In a sublime song, composed with a view to incite the people to confidence in God, the prophet Isaiah has these remarkable words; "Thy dead men shall live; together with my dead body shall they arise. Awake and sing, ye that dwell in the dust; for thy dew is as the dew of herbs, and the earth shall cast out the dead *." We agree with Bishop Warburton that these words are figurative, and that they were uttered to give the Israelites consolation in very disastrous times. The purpose of the prophet was to assure them, that though their community should, in Babylon, be as completely dissolved as a dead body reduced to dust, yet God would restore them to their own land, and raise that community again to life. This was indeed a prophecy only of a temporal deliverance; but as it is expressed in terms relating to the death and resurrection of man, the doctrine of a resurrection must then have been well known, and generally received, or such language would have been altogether unintelligible.

156 This opinion confuted.

* Chap. xxvi. 19.

The prophet Ezekiel, when the state of things was most desperate, is carried by the Spirit into a valley full of dry bones, and asked this question; "Son of man, can these bones live?" To which he answers: "O Lord God, though knowest †." He was not asked if *all* the dead would rise at the last day; but only if the particular bones *then* presented to him could live at *that time*, and while other bones were mouldering in corruption: and to such a question we cannot conceive any answer that a man brought up in the belief of a general resurrection could have given, but—"O Lord God, thou knowest." Had Ezekiel been a stranger to the doctrine of a general resurrection, or had he not believed that doctrine, he would doubtless have answered the question that was put to him in the negative; but convinced that *all* men are at *some* period to rise from the dead, "that every one may receive the things done in his body, according to that he hath done, whether it be good or bad," he very naturally said, that God alone knew whether the bones then exhibited to him in the valley would rise before the general resurrection.

† Chap. xxxvii. 3.

157 The hope of the Hebrews, however, not from their own law,

But though the more intelligent and righteous Israelites certainly "all died in faith, and not having received the promises, but having seen them afar off, were persuaded of them and embraced them, confessing that they were strangers and pilgrims on earth, who desired a better country, that is, a heavenly one ‡," we are not to suppose that this heavenly desire arose from any thing taught in the law of Moses. That law, when taken by itself, as unconnected with prior and subsequent revelations, makes no mention whatever of a heavenly inheritance, which St Paul assures us § was given 420 years before to Abraham by a promise which may be traced back to the first ray of comfort vouchsafed to fallen man in the sentence passed on the original deceiver. "Wherefore then served the law? It was added (says the apostle), because of transgressions, till the seed should come to whom the promise was made." The transgressions here alluded to were polytheism and idolatry, which, with a train of cruel and detestable vices, had overspread the whole world; and the primary attention of the law was to stem the torrent of these corruptions, for which we have seen it was admirably calculated; and, like a schoolmaster, to instruct the Israelites in the unity and worship of Jehovah, and thus by degrees bring them to Christ.

‡ Heb. xi. 3, &c.

§ Gal. iii. 16—19.

But

But though it is apparent that a future state of rewards and punishments made no part of the Mosaic dispensation, yet the law had certainly a spiritual meaning to be understood when the fulness of time should come. Every Christian sees a striking resemblance between the sacrifice of the paschal lamb, which delivered the Israelites from the destroying angel in Egypt, and the sacrifice of the Lamb of God, which taketh away the sin of the world. Indeed the whole ritual of sacrifice must have led the more intelligent of them to faith in a future sacrifice; by which, while the heel of the seed of the woman should be bruised, the head of the serpent should be completely crushed (see SACRIFICE); and as prophets were raised up from time to time, to prepare them for the coming of the Messiah, and to foretel the nature of his kingdom, there can be no doubt but that those inspired teachers would lay open to them, as far as was expedient, the temporary duration of the Mosaic

158 Why the law was typical.

law, and convince them that it was only the shadow of better things to come. From the nature of their ritual, and the different prophecies vouchsafed them, which became more and more explicit as the time approached for their accomplishment, they must surely have been led to expect redemption from the curse of the fall by the sufferings of their Messiah; but that any one of them knew precisely the *manner* in which they were to be redeemed, and the nature of that religion which was to supersede their own, is wholly incredible. Such knowledge would have made them impatient under the yoke of ordinances to which they were subjected; for after the Christian faith came into full splendour, mankind could be no longer under the tuition of such a schoolmaster as the law, which "had only a *shadow* of good things; and so far from their reality, not even the very *image* of them*." Through these shadows, however, the Jews, aided by the clearer light of prophecy, though it too shone in a dark place, might have seen enough of God's plan of redemption to make them acknowledge Jesus of Nazareth, when he came among them working miracles of mercy, for the Messiah so long promised to their forefathers, and in whom it was repeatedly said, that all the nations of the earth should be blessed.

* Heb. x. 1.

159 Means used to prepare the world for the coming of Christ.

While such care was taken to prepare the descendants of Abraham for the coming of the Prince of Peace, we must not suppose that God was a respecter of persons, and that the rest of the world was totally neglected. The dispersion of the ten tribes certainly contributed to spread the knowledge of the true God among the eastern nations. The subsequent captivity of the tribes of Judah and Benjamin must have confirmed that knowledge in the great empires of Babylon and Persia; and that particular providence of God which afterwards led Ptolemy Philadelphus to have the Jewish scriptures translated into the Greek language, laid the divine oracles open to the study of every accomplished scholar. At last, when the arms of Rome had conquered the civilized world, and rendered Judea a province of the empire; when Augustus had given peace to that empire, and men were at leisure to cultivate the arts and sciences; when the different sects of philosophers had by their disputations whetted each others understandings, so that none of them was disposed to submit to an imposture; and when the police of the Roman government was such that intelligence of every thing important was quickly transmitted from the most distant provinces to the capital of the empire; "when that fulness of time was come, God sent forth his Son made of a woman, made under the law, to redeem them that were under the law, that we might receive the adoption of sons," and be restored to that inheritance of which the forfeiture introduced the several dispensations of revealed religion into the world.

SECT. V. *View of Theology more peculiarly Christian.*

MANKIND being trained by various dispensations of providence for the reception of Jesus Christ, and the time fixed by the prophets for his coming being arrived, "a messenger was sent before his face to prepare his way before him by preaching the baptism of repentance for the remission of sins." This messenger was John the Baptist, a very extraordinary man, and the greatest of all the prophets. His birth was miraculous, the scene of his ministry the wilderness, his manners austere, and his preaching upright, without respect of persons. He frankly told his audience that he was not the Messiah, that the Messiah would soon appear among them, that "he was mightier than himself, and that he would baptize them with the Holy Ghost and with fire."

160 Christ the divine word incarnate.

Mightier indeed he was; for though born of a woman the Messiah was not the son of a human father; and though living for the first thirty years of his life in obscurity and poverty, he was the lineal descendant of David, and heir to the throne of Israel. But the dignity of his human descent, great as it was, vanishes from consideration when compared with the glory which he had with his Father before the world was. The Jewish dispensation was given by the ministry of Moses, and illustrated by subsequent revelations vouchsafed to the prophets; the immediate author of the Christian religion is the λογος or the second person of the blessed Trinity, of whom St John declares, that "he was in the beginning with God, and was God; that all things were made by him; and that without him was not any thing made that was made." We have already proved that in the one Godhead there is a Trinity of persons; and that the λογος is one of the three, is apparent from these words of the apostle, and from many other passages of sacred scripture. Thus he is called *the Lord of hosts himself; the first and the last, besides whom there is no God; the most high God; God blessed for ever; the mighty God, the everlasting Father, Jehovah our righteousness;* and *the only wise God our Saviour* (B). This great Being, as the same apostle assures us, was made flesh, and dwelt among men; not that the divine nature was or could be changed into humanity, for God is immutable, the same almighty and incomprehensible Spirit,

(B) Isaiah viii. 13, 14. compared with 1 Peter ii. 7, 8.; Isaiah vi. 5. compared with John xii. 41.; Isaiah xliv. 6. compared with Revelation xxii. 13.; Psalm lxxviii. 56. compared with 1 Corinthians x. 9. Romans ix. 5. Isaiah ix. 6. Jeremiah xxiii. 6. Jude.

Theology more peculiarly Christian.

Spirit yesterday, to-day, and for ever; but the Word or second person in the godhead, assuming a human soul and body into a personal union with himself, dwelt upon earth as a man, veiling his divinity under mortal flesh. Hence he is said elsewhere to have been "manifested in the flesh," and "to have taken upon him the nature of man;" phrases of the same import with that which asserts "the WORD to have been made flesh."

161 Objections to the incarnation of the Word.

This incarnation of the Son of God is perhaps the greatest mystery of the Christian faith, and that to which ancient and modern heretics have urged the most plausible objections. The doctrine of the Trinity is indeed equally incomprehensible; but the nature of God and the mode of his subsistence, as revealed in scripture, no man, who thinks, can be surprised that he does not comprehend; for a revelation which should teach nothing mysterious on such a subject would be as incredible and as useless as another which contained nothing but *mystery*. The difficulty respecting the incarnation, which forces itself on the mind, is not how two natures so different as the divine and human can be so intimately united as to become one person; for this union in itself is not more inconceivable than that of the soul and body in one man; but that which at first is apt to stagger the faith of the reflecting Christian is the infinite distance between the two natures in Christ, and the comparatively small importance of the object, for the attainment of which the eternal Son of God is said to have taken on him our nature.

162 Obviated.

Upon mature reflection, however, much of this difficulty will vanish to him who considers the ways of Providence, and attends to the meaning of the words in which this mystery is taught. The importance of the object for which the WORD condescended to be made flesh, we cannot adequately know. The oracles of truth indeed inform us, that Christ Jesus came into the world to save sinners; but there are passages scattered through the New Testament * which indicate, not obscurely, that the influence of his sufferings extends to other worlds besides this: and if so, who can take on him to say, that the quantity of good which they may have produced was not of sufficient importance to move even to this condescension a Being who is emphatically styled LOVE?

* Eph. i. 10. Col. i. 19, 20.

But let us suppose that every thing which he did and taught and suffered was intended only for the benefit of man, we shall, in the daily administration of providence, find other instances of the divine condescension; which, though they cannot be compared with the incarnation of the second person in the blessed Trinity, are yet sufficient to reconcile our understandings to that mystery when revealed to us by the Spirit of God. That in Christ there should have dwelt on earth "all the fulness of the Godhead bodily †," is indeed a truth by which the devout mind is overwhelmed with astonishment; but it is little less astonishing that the omnipotent Creator should be intimately present at every instant of time to the meanest of his creatures, "upholding all things, the vilest reptile as well as the most glorious angel, by the word of his power ‡." Yet it is a truth self-evident, that without this constant presence of the Creator, nothing which had a beginning could continue one moment in being; that the visible universe would not only crumble into chaos, but vanish into nothing; and that the souls of men, and even the most exalted spirits of creation, would instantly lose that existence, which, as it was not of itself, and is not necessary, must depend wholly on the will of Him from whom it was originally derived. See METAPHYSICS, N° 272—276, and PROVIDENCE, N° 3.

† Col. ii.

‡ Heb. i. 3.

In what particular way God is present to his works, we cannot know. He is not diffused through the universe like the *anima mundi* of the ancient Platonists, or that modern idol termed the *substratum of space* (METAPHYSICS, N° 309, 310): but that he is in power as intimately present now to every atom of matter as when he first brought it into existence, is equally the dictate of sound philosophy and of divine revelation; for "in him we live and move and have our being;" and power without substance is inconceivable. If then the divine nature be not debased, if it cannot be debased by being constantly present with the vilest reptile on which we tread, why should our minds recoil from the idea of a still closer union between the second person of the ever blessed Trinity and the body and soul of Jesus Christ? The one union is indeed different from the other, but we are in truth equally ignorant of the nature of both. Reason and revelation assure us that God must be present to his works to preserve them in existence; and revelation informs us farther, that one of the persons in the Godhead assumed human nature into a personal union with himself, to redeem myriads of rational creatures from the miserable consequences of their own folly and wickedness. The importance of this object is such, that, for the attainment of it, we may easily conceive that he who condescends to be potentially present with the worms of the earth and the grass of the field, would condescend still farther to be personally present with the spotless soul and body of a man. Jesus Christ lived indeed a life of poverty and suffering upon earth, but his divine nature was not affected by his sufferings. At the very time when, as a man, he had not a place where to lay his head; as God, he was in heaven as well as upon earth *, dwelling in light inaccessible; and while, as a man, he was increasing in wisdom and stature, his divinity was the fulness of him who filleth all in all, and from whom nothing can be hid.

* John iii. 13.

Perhaps the very improper appellation of *mother of God*, which at an early period of the church was given to the Virgin Mary, may have been one cause of the reluctance with which the incarnation has been admitted; for as we have elsewhere observed (see NESTORIUS), such language, in the proper sense of the words, implies what those, by whom it is used, cannot possibly believe to be true; but it is not the language of scripture. We are there taught, that "Christ being in the form of God, thought it no robbery to be equal with God; but made himself of no reputation, and took upon him the form of a servant, and was made in the likeness of man †;" that "God sent forth his Son made of a woman, made under the law, to redeem them that were under the law, that we might receive the adoption of sons ‡;" and that "the WORD who was in the beginning with God, and was God, by whom all things were made, was made flesh, and dwelt among men (who beheld his glory, the glory as of the only begotten of the Father), full of grace and truth §:" but we are nowhere taught that, as God, he had a mother! It was indeed the doctrine of the primitive church ‖, that the very principle of personality and individual existence in Mary's

§ John i.

‖ Horsley's *Sermon on the Incarnation.*

Theology more peculiarly Christian.

Mary's son, was union with the uncreated Word; and this doctrine is thought to imply the miraculous conception, which is recorded in the plainest terms by two of the evangelists; for he was conceived by the Holy Ghost and born of a virgin *; but, as God, he had been begotten from all eternity of the Father, and in order of nature was prior to the Holy Ghost. This is evident from the appellation of ὁ λογος given to him by St John; for the term being used in that age, both by the Jewish rabbies and the heathen philosophers, to denote the second divine subsistence, which they considered as an eternal and necessary emanation from the first, sometimes called τ'αγαθον and sometimes το ἑν; and the apostle giving no intimation of his using the word in any uncommon sense, we must necessarily conclude, that he meant to inform us that the divinity of Christ is of eternal generation. That the term λογος was used in this sense by the later Platonists, and in all probability by Plato himself, we have sufficiently shewn in another place (see PLATONISM); and that a similar mode of expression prevailed among the Jews in the time of St John, is apparent from the Chaldee paraphrase; which, in the 110th psalm, instead of the words "the Lord said unto my Lord," has, "the Lord said unto his WORD." Again, where we are told in the Hebrew that Jehovah said to Abraham †, "I am thy shield and thy exceeding great reward," we read in the Chaldee, "my WORD is thy shield, and thy exceeding great reward." Where it is said, "your new moons and your appointed feasts my soul hateth ‡," the paraphrast hath it, "my WORD hateth;" and where it is said, that "Israel shall be saved in the Lord with an everlasting salvation §," in the same paraphrase it is, "Israel shall be saved by the WORD of the Lord with everlasting salvation." But there is a passage in the Jerusalem Targum which puts it beyond a doubt, that by the λογος the Jews understood a divine person begotten of his Father before all worlds; for commenting on Genesis iii. 22. the authors of that work thus express themselves: "The WORD of the Lord said, behold Adam, whom I created, is the only begotten upon earth, as I AM THE ONLY BEGOTTEN IN HEAVEN:" in conformity with which, Philo introduces ‖ the Logos speaking thus of himself; Και γαρ ουτε αγεννητος ως θεος ων, ουτε γεννητος ως υμεις. *I am neither unbegotten, as God, nor begotten after the same manner as you are.*

163 His divine nature begotten of the Father.

‖ *De Agricult.* lib. ii.

164 Orthodoxy of the Nicene creed.

From these quotations we may justy conclude, that the Nicene fathers expressed themselves properly when they declared that the only begotten Son of God was begotten of his father before all worlds, and is God of God; for if St John had believed the λογος or WORD to be unbegotten, contrary to the belief of all who made use of the phrase at the time when he wrote, he would surely have expressed his dissent from the generally received opinion. This however he is so far from doing, that he gives the amplest confirmation of that opinion, by declaring, that "he beheld the glory of the WORD incarnate as the glory of the only begotten of the Father;" for this declaration is true only of the divinity of Christ, his human nature not being begotten of the Father, but conceived by the Holy Ghost of the Virgin Mary. Hence our blessed Lord assures us, that "as the Father HATH life in HIMSELF, so hath he GIVEN the Son to have life in himself;" that "the Son can do nothing of *himself*, but what he seeth the Father do *;" and that "he knew the Father, because he was from him and sent by him †." We must therefore agree with Bishop Pearson (c), that "though the Father and Son are both truly God, and therefore equal in respect of nature, yet the one is greater than the other, as being the fountain of the Godhead. The Father is God, but *not of God*; Light, but *not of Light*. Christ is God, but *of* God; Light, but *of* Light. There is no difference or inequality in the nature or essence, because the same in both; but the Father of our Lord Jesus Christ hath that essence of himself, from none; Christ hath the same essence, not of himself, but from him."

* St John v. 26. 19.

† John vii. 29.

165 Purpose for which Christ was sent into the world.

The great purpose for which this divine person was sent into the world, was to bruise the head of the serpent, and restore mankind to the inheritance which had been forfeited by Adam's transgression. Every dispensation of Providence from the fall had been preparatory to this restoration. Prophets had been raised from time to time to preserve in the early ages of the world the knowledge and worship of the true God: the children of Abraham had been separated from the surrounding nations for the same purpose; and by the dispersion of the ten tribes, the captivity of the other two in Babylon, and the translation of the Hebrew scriptures into the Greek language, much of the knowledge which had been revealed to the Israelites was gradually diffused over the eastern world.

But while the Jews were thus rendered the instruments of enlightening the heathen nations of antiquity, their intercourse with those nations made them almost unavoidably acquainted with the philosophy which was cultivated among the Chaldeans, the Persians, and the Egyptian Greeks; and ingrafting many of the opinions derived from those schools upon the doctrines of Moses and the prophets, they corrupted their own religion while

(c) We beg leave to recommend to our readers this author's excellent exposition of the apostle's creed, as a work which will render them great assistance in acquiring just notions of the fundamental articles of the Christian faith. They will find it, we think, a complete antidote against the poison of modern Unitarians and modern Tritheists; of whom the former teach that Jesus Christ was a mere man, the son of Joseph as well as of Mary; while the latter, running to the other extreme, maintain, that, with respect to his divinity, he is in no sense subordinate to the Father, but might have been the Father, the Son, or the Holy Ghost, according to the good pleasure of the eternal three. We have been at some pains to prove his divinity, and likewise his eternal generation; but in such a short compend as we must give, it seems not to be worth while to prove his miraculous conception. That miracle is plainly asserted in the New Testament in words void of all ambiguity; and as it is surely as easy for God to make a man of the substance of a woman as of the dust of the earth, we cannot conceive what should have induced any person professing Christianity to call it in question. The natural generation of Christ is a groundless fancy, which can serve no purpose whatever, even to the Unitarians.

Theology more peculiarly Christian.

while they improved that of their neighbours. Hence, by the time that Christ came among them, they had made the word of God of none effect through a number of idle fancies which they inculcated on the people as the traditions of the elders; and as they had attached themselves to different masters in philosophy, their unauthorised opinions were of course different according to the different sources whence they were drawn. The peculiar tenets of the ESSENES seem to have been a species of mystic Platonism. The PHARISEES are thought to have derived their origin from a Jewish philosopher of the Peripatetic school; and the resemblance between the doctrines of the SADDUCEES and the philosophy of Epicurus has escaped no man's observation.

166 Corruption of the Jews at the time of his coming.

Though these sects maintained mutual communion in public worship, they abhorred each other's distinguishing tenets; and their wranglings had nearly banished from them every sentiment of true religion. They agreed, however, in the general expectation of the Messiah promised to their fathers; but, unhappily for themselves, expected him as a great and temporal prince. To this mistake several circumstances contributed: some of their prophets had foretold his coming in lofty terms, borrowed from the ritual law, and the splendour of earthly monarchs. The necessity of casting this veil over those living oracles we have shewn in another place (see PROPHECY, N° 17.). At the time when the predictions were made, the Mosaic system had not run out half its course, and was therefore not to be exposed to popular contempt by an information, that it was only the harsh rudiment of one more easy and perfect. To prevent, however, all mistakes in the candid and impartial, when the Messiah should arrive with the credentials of miraculous powers, other prophets had described him in the clearest terms as having no form nor comeliness, as a sheep dumb before his shearers, and as a lamb brought to the slaughter; but the Jews had suffered so much from the Chaldeans, the Greeks, and other nations by whom they had been conquered, and were then suffering so much from their masters the Romans, that they could think of no deliverance greater than that which should rescue their nation from every foreign yoke.

What men earnestly wish to be true, they readily believe. Hence that people, losing sight of the yoke under which they and the whole human race were brought by the fall of Adam, mistaking the sense of the blessing promised to all nations through the seed of Abraham, and devoting their whole attention to the most magnificent descriptions of the Messiah's kingdom, expected in him a prince who should conquer the Romans, and establish on earth a universal monarchy, of which Jerusalem was to be the metropolis.

167 The objects of his preaching.

As our Saviour came for a very different purpose, the first object of his mission was to rectify the notions of his erring countrymen, in order to fit them for the deliverance which they were to obtain through him. Accordingly, when he entered on his office as a preacher of righteousness, he embraced every opportunity of inveighing against the false doctrines taught as traditions of the elders; and by his knowledge of the secrets of all hearts, he exposed the vile hypocrisy of those who made a gain of godliness. The Jews had been led, by their separation from the rest of the world, to consider themselves as the peculiar favourites of Jehovah; and the consequence was, that, contrary to the spirit of their own law, and the explicit doctrines of some of their prophets, they looked on all other nations with abhorrence, as on people physically impure. These prejudices the blessed Jesus laboured to eradicate. Having desired a lawyer, by whom he was tempted, to read that part of the law of Moses which commanded the Israelites to love their neighbours as themselves, he compelled him, by means of a parabolical account of a compassionate Samaritan, to acknowledge, that under the denomination of neighbour the divine lawgiver had comprehended all mankind as the objects of love *. The importance in which Moses held the ritual law, and to which, as the means of preserving its votaries from the contagion of idolatry, it was justly intitled, had led the Jews to consider every ceremony of it as of intrinsic value and perpetual obligation: but Jesus brought to their recollection God's declared preference of mercy to sacrifice; shewed them that the weightier matters of the law, judgment, mercy, and faith, claimed their regard in the first place, and its ceremonial observances only in the second; and taught them, in conformity with the predictions of their own prophets †, that the hour was about to come when the worship of God should not be confined to Jerusalem, but that "true worshippers should everywhere worship the Father in spirit and in truth ‡."

* St Luke x. 25—38.

† Jeremiah xxxi. 31. &c.

‡ John iv. 25—27.

It being the design of Christ's coming into the world to break down the middle wall of partition between the Jews and Gentiles, and to introduce a new dispensation of religion which should unite all mankind as brethren in the worship of the true God, and fit them for the enjoyment of heaven; he did not content himself with merely restoring the moral part of the Mosaic law to its primitive purity, disencumbered of the corrupt glosses of the Scribes and Pharisees, but added to it many spiritual precepts, which, till they were taught by him, had never occurred either to Jew or Gentile. The Hebrew lawgiver had prohibited murder under the penalty of death; but Christ extended the prohibition to causeless anger, and to contemptuous treatment of our brethren, commanding his followers, as they valued their everlasting salvation, to forgive their enemies, and to love all mankind. Adultery was forbidden by the law of Moses as a crime of the deepest dye; but Jesus said to his disciples, "that whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart," and is of course liable to the Divine vengeance. The *lex talionis* was in force among the Jews, so that the man who had deprived his neighbour of an eye or a tooth, was to suffer the loss of an eye or a tooth himself; but this mode of punishment, which inflicted *blemish* for *blemish*, though suited to the hardness of Jewish hearts, being inconsistent with the mild spirit of Christianity, was abolished by our blessed Lord, who severely prohibited the indulgence of revenge, and commanded his followers to love even their enemies. Perjury has in every civilized nation been justly considered as a crime of the highest atrocity, and the Mosaic law doomed the false witness to bear the punishment, whatever it might be, which he intended by swearing falsely to bring on his brother; but the Author of the Christian religion forbade not only false swearing, but swearing at all, except on solemn occasions, and when an oath should be required by legal authority. See OATH.

By thus restoring the law to its original purity, and in

Theology more peculiarly Christian.

in many cases extending its sense, the blessed Jesus executed the office of a PROPHET to the lost sheep of the house of Israel; but had he not been more than an ordinary prophet, he could not have abrogated the most trivial ceremony of it, nor even extended the sense of any of its moral precepts; for their great lawgiver had told them, that "the Lord their God would raise up unto them but one Prophet, like unto him, to whom they should hearken ‡." That Prophet was by themselves understood to be the Messiah, whom they expected to tell them all things. It was necessary therefore that Jesus, as he taught some new doctrines, and plainly indicated that greater changes would soon be introduced, should vindicate his claim to that exalted character which alone could authorise him to propose innovations. This he did in the amplest manner, by fulfilling prophecies and working miracles (See MIRACLE and PROPHECY); so that the unprejudiced part of the people readily acknowledged him to be of a truth "that prophet which should come into the world—the Son of God, and the King of Israel." He did not, however, make any change in the national worship, or assume to himself the smallest civil authority. He had submitted to the rite of circumcision, and strictly performed every duty, ceremonial as well as moral, which that covenant made incumbent on other Jews; thus fulfilling all righteousness. Though the religion which he came to propagate was in many respects contrary to the ritual law, it could not be established, or that law abrogated, but in consequence of his death, which the system of sacrifices was appointed to prefigure; and as his kingdom, which was not of this world, could not commence till after his resurrection, he yielded during the whole course of his life a cheerful obedience to the civil magistrate, and wrought a miracle to obtain money to pay the tribute that was exacted of him. Being thus circumstanced, he chose from the lowest and least corrupted of the people certain followers, whom he treated with the most endearing familiarity for three years, and commissioned at his departure to promulgate such doctrines as, consistently with the order of the divine dispensations, he could not personally preach himself. With these men, during the course of his ministry on earth, he went about continually doing good, healing the sick, casting out devils, raising the dead, reproving vice, preaching righteousness, and instructing his countrymen, by the most perfect example which was ever exhibited in the world, of whatsoever things are true, or honest, or just, or pure, or lovely, or of good report. The Scribes and Pharisees, however, finding him not that conqueror whom they vainly expected, becoming envious of his reputation among the people, and being filled with rancour against him for detecting their hypocritical arts, delivered him up to the Roman governor, who, though convinced of his innocence, yielded to the popular clamour, and crucified him between two thieves, as an enemy to Cæsar.

168 In which he executed the office of a prophet.

‡ Deut. xviii. 15.

169 His strict obedience to the law.

Just before he expired, he said, It is finished, intimating that the purpose was now fulfilled for which he had come into the world, and which, as he had formerly told his disciples, "was not to be ministered unto, but to minister, and to give his life a ransom for many ||." For his blood, as he assured them at the institution of the Eucharist, "was to be shed for the remission of sins." That Christ died voluntarily for us, the just for the unjust, and that "there is none other name under heaven given among men whereby we must be saved," is the uniform doctrine of the prophets who foretold his coming, of John the Baptist who was his immediate harbinger, and of the apostles and evangelists who preached the gospel after his ascension into heaven. Thus Isaiah says of the Messiah §, that "he was wounded for our transgressions, and bruised for our iniquities; that the chastisement of our peace was upon him, and that with his stripes we are healed; that we had all like sheep gone astray, turning every one to his own way, and that the Lord laid on him the iniquity of us all; that he was cut off out of the land of the living, and stricken for the transgression of God's people; and his soul or life was made an offering for sin; and that he bore the sin of many, and made intercession for the transgressors." The Baptist, "when he saw Jesus coming unto him, said to the people, Behold the Lamb of God, which taketh away the sin of the world;" plainly intimating that his death was to be a sacrifice, since it was only as a sacrifice that the Jews could form any conception of a lamb taking away sin. The epistles of St Paul are so full of the doctrine of Christ's satisfaction, that it is needless to quote particular texts in proof of it. He tells the Romans, that Jesus Christ was set forth to be a propitiation through faith in his blood; he was delivered for our offences, and raised again for our justification; that he died for the ungodly; and that God commendeth his love towards us, in that while we were yet sinners Christ died for us." He assures the Corinthians that Christ died for all; that "they who live should not henceforth live unto themselves, but to him who died for them and rose again; and that God made him to be sin for us, who knew no sin, that we might be made the righteousness of God in him." He informs the Galatians, that Christ "gave himself for our sins, that he might deliver us from this present evil world, according to the will of God and our Father; and that he redeemed us from the curse of the law, being made a curse for us." St Peter and St John speak the very same language; the former teaching us, that "Christ suffered for us, and bare our sins in his own body on the tree †; the latter, that the blood of Jesus Christ cleanseth us from all sin, and that he is the propitiation for our sins; and not for our sins only, but also for the sins of the whole world ‡." That he came into the world for the purpose of suffering, appears from his own words: for "no man (said he §) taketh my life from me, but I lay it down of myself: I have power to lay it down, and I have power to take it again. This commandment have I received from my Father." And that he voluntarily laid it down for mankind, is evident from his calling himself the Good Shepherd, and adding, that "the Good Shepherd giveth his life for the sheep ||."

§ 1 John x. 18.

|| Ibid ver. 11.

That Christ died for the benefit of the human race, is a truth so apparent from these texts, that no man professing Christianity has hitherto called it in question. Very different opinions have been formed indeed concerning the nature and extent of that benefit, and the means by which it is applied; but that the passion and death of the blessed Jesus were essential parts of his ministry on earth, has seldom been controverted. That on the cross he made satisfaction to his Father for the sins of the world, is the general belief of Christians; but presumptuous men, aming at being wise beyond what is written, have started a thousand idle questions concerning the necessity of

171 Different opinions respecting the nature and extent of the benefit reaped from his death.

Theology more peculiarly Christian.

of such satisfaction, and the manner in which it was made. Some limiting the power and mercy of the Omnipotent, have dared to affirm that God *could not* have pardoned man without receiving full satisfaction for his offences; that nothing but the shedding of the blood of Christ could make that satisfaction; that his death was indeed sufficient to atone for a thousand worlds; that, however, he did not die for all mankind, but only for a chosen few, ordained to eternal life by a secret decree before the foundation of the world; and that the rest of the race are passed by, and doomed to eternal perdition, for the glory of God's justice. Others, convinced by every thing around them that the Creator and Governor of the universe is a being of infinite benevolence, whose only end in giving life must have been to communicate happiness, have contended, that no atonement whatever could be necessary to obtain from him the forgiveness of sin on sincere repentance; that it is contrary to all our notions of justice to punish the innocent for the guilty; and that therefore the death of Christ, though the essential part of his ministry, could not be necessary, but at the most expedient.

We enter not into these debates. The Scriptures have nowhere said what God could or could not do; and on this subject we can know nothing but what they have taught us. That "we are reconciled to God by the death of his Son," is the principal doctrine of the New Testament; and without presuming to limit the power, the mercy, or the wisdom, of him who created and sustains the universe, we shall endeavour to show that it is a doctrine worthy of all acceptation. In doing this, we shall state impartially the opinions which pious men have held respecting the form or manner in which Christ by his death made satisfaction to God for the sins of the world; and we hope that our readers will embrace that opinion which shall appear to them most consonant to the general sense of sacred Scripture.

172 Opinions of the Calvinists.

The strictest adherents to the theological system of Calvin, interpreting literally such texts of Scripture as speak of his being *made sin* for us, of his *bearing our sins in his own body on the tree*, and of the Lord's *laying on him the iniquity of us all*, contend, that the sins of the elect were lifted off from them and laid on Christ by *imputation*, much in the same way as they think the sin of Adam is imputed to his posterity. "By bearing the sins of his people (says Dr Gill†) he took them off from them, and took them upon himself, bearing or carrying them, as a man bears or carries a burden on his shoulders. There was no sin *in* him inherently, for if there had, he would not have been a fit person to make satisfaction for it; but sin was *put* upon him by his Divine Father, as the sins of the Israelites were put upon the scape-goat by Aaron. No creature (continues he) could have done this; but the LORD hath laid on him, or made to meet on him, the iniquity of us all, not a single iniquity, but a whole mass and lump of sins collected together; and laid as a common burden upon him; even the sins of all the elect of God. This phrase of laying sin on Christ is expressive of the *imputation* of it to him; for it was the will of God not to impute the transgressions of his elect to themselves, but to Christ, which was done by an act of his own; for he hath made him to be sin for us: that is, by *imputation*, in which way we are made the righteousness of God in him; that being imputed to us by him as our sins were to Christ. The sense (says our author) is, a charge of sin was brought against him as the surety of his people. He was numbered with the transgressors; for bearing the sins of many, he was reckoned as if he had been a sinner himself, sin being *imputed* to him; and he was dealt with as such. Sin being found upon him by *imputation*, a demand of satisfaction for sin was made, and he answered it to the full. All this was with his own consent. He *agreed* to have sin laid upon him, and *imputed* to him, and a charge of it brought against him, to which he engaged to be responsible; yea, he himself took the sins of his people upon him; so the evangelist Matthew has it, 'He himself took our infirmities, and bore our sicknesses ‡.' As he took the nature of men, so he took their sins, which made his flesh to have *the likeness of sinful flesh*, though it really was not sinful. What Christ bore being laid upon him, and imputed to him, were *sins* of all sorts, original and actual; sins of every kind, open and secret, of heart, lip, and life; all acts of sin committed by his people, for he has redeemed them from all their iniquities; and God, for Christ's sake, forgives all trespasses, his blood cleanses from all sin, and his righteousness justifies from all; all being imputed to him as that is to them. Bearing sin supposes it to be a burden; and indeed it is a burden too heavy to bear by a sensible sinner (E). When sin is charged home upon the conscience, and a saint groans, being burdened with it, what must that burden be, and how heavy the load which Christ bore, consisting of all the sins of all the elect from the beginning of the world to the end of it; and yet he sunk not, but stood up under it; failed not, nor was he discouraged, being the mighty God, and the Man of God's right hand, made strong for himself."

† Body of Divinity, vol. ii. book iii. chap. v. § 4.

‡ Chap. viii. 17.

173 Objected to.

To the Arminians or Remonstrants, this doctrine of the imputation of the sins of men to the Son of God appears as absurd as the similar doctrine of the imputation of the sin of Adam to his unborn posterity; and it is certainly attended with consequences which have alarmed serious Christians of other denominations.

Were it possible in the nature of things, says the Arminian, to transfer the guilt of one person to another, and to lay it upon him as a burden, it could not be done without violating those laws of equity which are established in the scripture and engraven on the human heart. But this is not possible. To talk of lifting lumps of sin, or transferring them like burdens from the guilty to the innocent, is to utter jargon, says he, which has no meaning; and we might with as much propriety speak of lifting a scarlet colour from a piece of cloth and laying it on the sound of a trumpet, as of literally lifting the sins of the elect from them and laying them on Christ. Guilt is seated on the mind; and no man can become a sinner but by an act of volition. If Christ therefore *really* took upon him the sins of his people, he must have deliberately formed a wish to have actually committed

(E) By the phrase *a sensible sinner*, the learned author means a sinner who is not past feeling, but has a conscience alive to the sense of remorse.

Theology more peculiarly Christian.

committed all these sins; but such a wish, though it would have made him inherently guilty, and therefore incapable of satisfying for sin, could not have cancelled deeds that were done before he was born, or have made those innocent who really had been sinners. A deed once done cannot be undone; a volition which has been formed cannot be annihilated. By sincere repentance, the habitual dispositions are indeed changed, and those who have been sinners become objects of mercy; but no power can recal the hours that are past, or make those actions which have been performed to have been not performed. To remove guilt from the sinner and lay it on the innocent may therefore be safely pronounced impossible even for Omnipotence itself, for it implies that a thing may be and not be at the same instant of time; and the doctrine which teaches that this removal was made from the elect to Christ, is an imagination of yesterday, which has no countenance from scripture, and is contrary to the established constitution of things. Those who imagine that guilt may be propagated from father to son, have something like an argument to urge for the imputation of Adam's sin to his numberless posterity; for all the men and women who have by ordinary generation been introduced into the world, have undoubtedly derived their nature from the primeval pair. But Christ did not derive his nature from the *elect*, that their sins should be communicated to him; nor, as he was miraculously conceived by the Holy Ghost, can we attribute to him any degree of that *taint* which is supposed to have been conveyed from Adam to all the other generations of men.

174
Texts on which they are built explained.

Nothing more, therefore, can be meant by "Christ's being made sin for us," and "bearing our sins in his own body on the tree," or by God's "laying upon him the iniquity of us all," than that by his sufferings we are freed from the punishment of our sins: it being in scripture a common figure of speech, as even Dr Gill has somewhere acknowledged, to denote by the word *sin* the *consequences* of sin. That this figure is used in those texts from which he infers that Christ took the sins of the elect on himself, is evident from the verse which he quotes from the gospel of St Matthew; in which it is said, that "himself took our infirmities and bore our sicknesses." The sicknesses and infirmities there alluded to are the leprosy, the palsy, the fever, and demoniacal possessions: but when our blessed Lord cured these diseases, surely he did not by his omnipotent word lift them off from the patients and take them on himself, so as actually to become a leper, a paralytic, and a dæmoniac, or even to be reckoned as such either by the multitude, or by the priest, whose duty it was to take cognizance of every illegal uncleanness*. And if his inveterate enemies did not *impute* to him the leprosy when he removed that plague from others, why should it be supposed that his own Father, to whom he was at all times well-pleasing, imputed to him the sins of which, by his sufferings, he removed the punishment from those who were guilty? To impute to a person any action, whether virtuous or vicious, which he did not perform, can proceed only from ignorance or malice, or partiality; but God is no respecter of persons, and from ignorance and malice he is removed to an infinite distance. It is indeed an undoubted truth, that "the Lord Jesus, by his perfect obedience and sacrifice of himself, which he through the eternal spirit once offered up unto God, hath fully satisfied the justice of his Father; and purchased not only reconciliation, but an everlasting inheritance in the kingdom of heaven for all those whom the Father hath given him †;" but that he actually took on himself the sins of mankind, or that those sins were imputed to him by God, who punished him as a person whom he considered as guilty, is a doctrine equally injurious to the justice of the Father and to the immaculate purity of the Son.

* Levit. xiii.

† *Confession of Faith*, chap. viii. § v.

175
They have probably contributed to make Socinus deny the doctrine of redemption.

The earnestness with which this doctrine was inculcated by some of the earliest reformers, and the impossibility of admitting it, which every reflecting and unprejudiced mind must feel, was probably one of the causes which drove Socinus and his followers to the other extreme of denying Christ's satisfaction altogether, and considering his death as nothing more than that of an ordinary martyr, permitted for the purpose of attesting the truth of his doctrine, and paving the way for his resurrection, to confirm the great promise of immortality. According to these men, forgiveness is freely dispensed to those who repent, by the essential goodness of God, without regard to the merit or sufferings of any other being; and the gospel is said to save from sin, because it is the most perfect lesson of righteousness. The great objection of *Crellius* to the doctrine of the satisfaction is, that it is a hinderance to piety; for if Christ has paid the whole debt, he thinks that he must have nothing to do, as nothing more can be required of us. And if it were indeed true that our sins are imputed to Christ, and his righteousness imputed to us, this objection would be insurmountable; for God could not justly exact a double punishment for the same sin, or inflict misery on those to whom he imputes perfect righteousness. But as to this imaginary transferring of virtues and vices from one person to another, the scriptures give no countenance; so they nowhere call the death of Christ a *satisfaction* for the sins of men. The term has indeed been long in use among divines, and when properly explained it may be retained without any danger; but in treating of this subject, it would perhaps be more prudent to restrict ourselves to the use of scripture language, as the word *satisfaction* carries in it the ideas of a debt paid and accepted; whereas it is said by St Paul, that "eternal life is the *gift* of God through Jesus Christ our Lord; and that we are justified *freely by his grace* through the redemption that is in Jesus Christ, whom God hath set forth to be a propitiation through faith in his blood."

176
The death of Christ restored to mankind what they had lost.

To clear up this matter, and attain adequate notions of redemption and justification, it will be necessary to look back to the fall of our first parents; for the great purpose for which Christ was promised, and for which he came into the world, was, by bruising the head of the serpent, to restore mankind to the inheritance which they had lost through the transgression of Adam. This is apparent not only from the original promise made to the woman, but also from different passages in the epistles of St Paul, who expressly calls Christ the second Adam, and says, that, "as by the offence of one, judgement came upon all men to condemnation; even so by the righteousness of one, the free gift came upon all men unto justification of life;" that "as by one man's disobedience many were made sinners, so by the obedience of one shall many be made righteous;" and that, "as in Adam all die, even so in Christ shall all be made alive."

Theology more peculiarly Christian.

alive." Hence it was that John the Baptist, when he saw Jesus coming to him, said to his disciples †, "Behold the Lamb of God which taketh away, not the *sins*, but the *sin* of the world," evidently alluding to Adam's sin and its consequences, since no other sin was ever committed of which the consequences extend to the whole world.

† Ch. i. ver. 23.

This being the case, it is undeniable, that whatever we lost in the first Adam is restored to us by the second; and therefore they who believe that the punishment denounced against eating the forbidden fruit was death *corporal*, *spiritual*, and *eternal*, must believe that we are redeemed from all these by Christ; who having "appeared once in the end of the world to put away sin by the sacrifice of himself, died for us, that whether we wake or sleep, we should live together with him *." If the image of God in which man was created was lost by the breach of the first covenant, it is more than restored to us "by the Mediator of a better covenant, which is established upon better promises;" if by the sin of Adam we were utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually, we are freed from that dreadful curse by "our Saviour Jesus Christ who gave himself for us, that he might redeem us from all iniquity, and purify to himself a peculiar people zealous of good works †;" and if for our share in the first transgression we be justly liable to all punishments in this world and in that which is to come, the apostle assures us, that "when we were enemies we were reconciled to God by the death of his Son, because that God was in Christ reconciling the world to himself, not imputing their trespasses unto them ‡." As Jesus is "the Lamb slain in the divine decree from the foundation of the world," these beneficial consequences of his death have been extended by a retrospective view to all in every age whose names are written in the book of life, though it be absurd to suppose that he literally took their sins upon him, and impious to imagine that he suffered under the imputation of sin.

* Heb. ix. 26. 1 Thess. v. 10.

† Titus ii. 14.

‡ Rom. v. 10. 2 Cor. v. 19.

177 Moderate Calvinists and Remonstrants of the same opinion.

Such is the general doctrine of redemption, as it is taught by the more moderate Calvinists and more moderate Remonstrants; for moderate Christians of all denominations, though they express themselves differently, have nearly the same views of the fundamental articles of their common faith. It must not, however, be concealed, that many divines of great learning and piety contend strenuously against the doctrine of vicarious atonement for actual transgressions of the moral law. These are the more zealous Arminians, who deny that we inherit any mortal taint or intellectual weakness from our first parents, whom they believe never to have been in a state of greater perfection than many of their posterity who are called *degenerate*. According to them, we lost nothing by the fall of Adam but our title to eternal life or perpetual existence, together with those graces of the Holy Spirit which were bestowed under the first covenant to train mankind for the society of heaven; and as eternal life and supernatural grace constituted one free gift, not due to the nature of man, or indeed of any created being, they might, when forfeited, be restored by any means or on any condition which should seem expedient to the all-wise Donor. These means, and that condition, human reason cannot indeed discover; but it seems very fit that they should be different from the means by which moral agents under the law of nature can secure to themselves the favour of their Creator, or recover it when occasionally lost. The former depends on arbitrary will and pleasure, or at least on no other principles discoverable by us; while the latter ariseth out of the established and well-known constitution of things. Thus moral virtue, comprehending piety, was the condition of that favour and protection which man, in his original state, could claim from his Maker; but obedience to a positive command was the condition of the free gift of immortality conferred on Adam on his introduction into paradise. The claim arising from the relation between the creature and the Creator is indissoluble, because that relation cannot be dissolved: so that the man who, by a transgression of the moral law has forfeited the favour of God may reasonably hope to recover it by sincere repentance and a return to his duty; and nothing but such repentance and reformation can recover it; because, in a moral agent, nothing can be agreeable to God but moral dispositions, which cannot be transferred from one person to another, and for the want of which nothing can atone. Our virtues are not required nor our vices prohibited, as if the one could profit and the other injure him who created us; for "is it any *pleasure* to the Almighty that we are righteous? or is it *gain* to him that we make our ways perfect? Will he reprove us for *fear* of us?" No? He commands us to be virtuous, and forbids us to be vicious, only because virtue is necessary to our own happiness, and vice productive of everlasting misery.

178 Doctrine of the more zealous Arminians.

Were an immoral man to be introduced into the society of angels and just men made perfect, he would not experience in that society what we are taught to expect from the joys of heaven; because to such joys his acquired dispositions would be wholly repugnant. Nor could the sufferings of any person whatever, or the *imputation* of any extrinsic righteousness, make that mind which had long been immersed in the grossest sensuality relish the intellectual and refined enjoyments of heaven; or the man who had been the habitual slave of envy, malice, and duplicity, a fit inhabitant of that place where all are actuated by mutual love. On the other hand, say the divines whose doctrine we are now detailing, it is impossible to suppose that the Father of mercies, who knows whereof we are made, should have doomed to eternal misery any moral agent who had laboured through life to serve him in sincerity and in truth; or that any atonement could be necessary to redeem from the pains of hell the man whose pious and virtuous dispositions have through penitence and prayer become suited to the society of heaven. Unsinning perfection never was nor ever could be expected in man. He is brought into the world free indeed from vice, but equally destitute of virtue; and the great business of his life is to guard his mind from being polluted by the former, and to acquire dispositions habitually leading to the practice of the latter. Till these habits be fairly formed, it seems impossible that he should not sometimes deviate from the paths of rectitude, and thereby incur a temporary forfeiture of the divine favour; but the very constitution of his mind, and the purpose for which he is placed in a state of probation, show that the divine favour thus forfeited can be recovered only by repentance and reformation.

Widely

Theology more peculiarly Christian.

Widely different, however, is the case with respect to the forfeiture and recovery of a free gift, to which man has no natural claim. When the condition is broken on which such a gift was bestowed, repentance can be of no avail; it must be either irrecoverably lost or restored by the mere good pleasure of the giver. Immortality or perpetual existence is a gift which upon certain terms was freely bestowed upon the human race, and forfeited by the transgression of their first parent violating those terms. It was restored by the free grace of God, who was pleased to ordain, that "since by man came death, by man should also come the resurrection of the dead; for as in Adam all die, even so in Christ shall all be made alive. "Hence the apostle, writing to the Romans of the benefits of being the children of God, and joint-heirs with Christ, summeth up those benefits with resurrection from the dead." For the creature, i. e. mankind, was made subject (says he §) to vanity or death, not willingly, but by reason of him who hath subjected the same in hope: because the creature itself also shall be delivered from the bondage of corruption into the glorious liberty of the children of God. For we know that the whole creation groaneth, and travaileth in pain together until now: and not only *they*, but *ourselves* also, who have the first fruits of the spirit, even we ourselves groan within ourselves, waiting for the adoption, viz. *the redemption of our body* (F). That this the redemption of our body is the consequence of the sacrifice of Christ, is taught in the most explicit terms in the epistle to the Hebrews; of which the inspired author informs us, that "forasmuch as the children are partakers of flesh and blood, he also himself likewise took part of the same; that through *death* he might destroy him that had the power of death, that is the devil; and deliver them, who through fear of death were all their lifetime subject to bondage *." A vicarious atonement made with this view, the divines, whose theory we are now considering, acknowledge to be perfectly rational and consistent with the strictest justice. "The law of nature (say they †) allows not of vicarious atonements; but ordains that the man who transgresseth shall himself bear the punishment of his iniquity; a punishment which no man deserves for the faults of another, unless he be partaker of the guilt by joining in the transgression." And in proof of this their opinion, they appeal to the words of God himself, declaring to Moses,—"Whosoever hath sinned against me, him will I blot out of my book ‡." But when the free gift of immortality was lost, it was with great wisdom, say they, that God restored it through a Mediator who should make atonement by his blood for the breach of the first covenant; since such a mediation implies that the gift restored is merely of grace, to the attainment of which man could no further co-operate than by his hopes and wishes.

179 That Christ died to redeem us from the power of the grave.

§ Rom. viii 20—24.

† *Warburton's Div. Leg.* b. ix. and *Law's Considerations on the Theory of Religion*, part iii.

‡ Exod. xxxii. 33— 34.

180 An objection.

To this view of redemption, and indeed to every view of it which we have yet taken, an objection forces itself upon the mind. Throughout the New Testament LIFE AND IMMORTALITY are considered as a *FREE gift*, and called so in express words by St Paul *. To the scheme under consideration it is essential to consider them as such; and yet we know that a large price was paid for them, as St Paul likewise acknowledges, when he twice tells the Corinthians that they were bought with a price †.

* Rom. v. 15.

† Cor. vi. 20. vii. 23.

181 Obviated.

"To clear up this matter (says Bishop Warburton), and to reconcile the apostle to himself, who certainly was not defective either in natural sense or artificial logic, let us once again remind the reader, that life and immortality bestowed on Adam in paradise was a *FREE gift*, as appears from the history of his creation. As a *free gift*, it was taken back by the Donor when Adam fell; to which resumption our original natural rights are not subject, since natural religion teacheth, that sincere repentance alone will reinstate us in the possession of those rights which our crimes had suspended. So that when this free gift, forfeited by the *first* Adam, was recovered by the *second*, its nature continuing the same, it must still remain a *free gift*—a gift to which man, by and at his creation had no claim; a gift which natural religion did not bestow. But if misled by measuring this *revealed mystery* of human redemption by the scant idea of human transactions, where a *free gift* and *purchased benefit* are commonly opposed to one another, yet even here we may be able to set ourselves right, since, with regard to man, the character of a *free gift* remains to *immortality restored*. For the price paid by forfeited man was not paid by him, but by a Redeemer of divine extraction, who was pleased, by participating of man's nature, to stand in his stead. Hence the sacred writers seeing, in this case, the perfect agreement between a *FREE GIFT* and a *PURCHASED POSSESSION*, call it sometimes by the one and sometimes by the other name ‡."

‡ *Div. Leg.* book 9. ch. 2.

182 The death of Christ an atonement only indirectly for actual sin.

A restoration to life and immortality from that state of unconsciousness or extinction, to which all mankind were doomed in consequence of the fall, is that great salvation which we have obtained through the blood of our Redeemer; and according to the theologians whose theory we are now considering, it was the only thing in the divine intention when the promise was given to the first mother that the seed of the woman should bruise the head of the serpent. But though they contend that the death of Christ does not operate, *directly* as atonement for the *actual* sins of men, they admit that it does so *indirectly* and by necessary consequence, since it gives opportunities for repentance and newness of life, which under the first covenant they did not enjoy. Had a man under that covenant transgressed any moral precept, he would have forfeited the favour of his God, and either been subjected to punishment or to a long course of repentance; but supposing the efficacy of repentance under

(F) That by the words *creature* and *creation* the apostle here means all mankind, and by *vanity* and *corruption*, death, the reader will find proved by Dr Whitby, in his note on the place, with a strength of argument which cannot be shaken; and that the whole creation, the Gentiles as well as the Jews, groaned and travailed in pain together under the apprehension of death, is apparent from the writings of Cicero, who always seems doubtful whether death be a good or an evil; and from the lamentation of Hezekiah, when desired by the prophet to set his house in order because he should die and not live.

der the law of nature to be what they suppose it to be, he might before it was perfected have lost his existence by the eating of the forbidden fruit; and thus his penitence or punishment have ended in everlasting death. This can never be the issue of things under the new covenant, which, by the death of Christ, secures immortality to man, and gives to him opportunities, as long as he shall be in a state of probation, of recovering the divine favour when forfeited, whether by a moral transgression or a temporary violation of the peculiar condition of the covenant. Hence they admit the truth of the apostle's doctrine, that we are gainers by the fall of Adam and the redemption wrought by Christ; which will appear when we come to consider their notions of justification. In the mean time it may be proper to observe, that they consider it as no small confirmation of their opinion, that it tends to put an end to the long agitated disputes concerning the *extent* of redemption, and to reconcile passages of scripture which, on the commonly received theories both of Calvinists and Arminians, seem to be at variance with each other.

183 According to the Calvinists Christ died only for the elect.

It is well known to be one of the fundamental doctrines of the Calvinistic school, that "none are *redeemed* by Christ, effectually called, justified, adopted, sanctified, and saved, but the elect only *;" and if the notions of redemption, which, in the end of the 17th century, were very generally embraced, be admitted as just, it will not be easy to overturn the arguments by which that doctrine is supported. Such of them as are connected with the great question of election and reprobation, and enter into the decision of it, we have stated in another place (see PREDESTINATION, N° 14.); but it is farther argued †, that the doctrine of *universal* redemption reflects on the wisdom, the justice, and the power of God, and robs him of his glory.

* *Confession of Faith of the Church of Scotland*, ch. iii. § 6.

† *Gill's Body of Divinity*, vol. ii. book 3. ch. 3.

The scriptures assure us that all men shall not be saved; but how can this be, if Christ died for all, and the scheme of salvation, by his death was formed by infinite wisdom? The Arminians indeed say, that those who fail of salvation, fail through their own fault in not performing the conditions required of them; but God either *knew* or knew *not* that such men would not perform those conditions. If he knew it not, his knowledge is limited; if he did know it, where was his wisdom in providing a scheme of redemption for men to whom he was aware that it would be of no benefit? "God, we are told, is righteous in all his ways, and holy in all his works;" but there is no righteousness in making Christ bear the sins of *all* men, and suffer the punishment due to them, if any one of those men shall be afterwards punished everlastingly. If Christ has already paid the debts of the whole world, it cannot be just to cast a single inhabitant of the whole world into the prison of hell, there to be detained till he shall again have paid the uttermost farthing. "The Lord's hand is not shortened that it cannot save;" for he is and always will be the same Almighty power that he was from eternity; but if by the divine decree Christ died for all men, and yet all men shall not be saved, it would appear that man is mightier than his Maker! The ultimate end of God in the redemption of man is admitted to have been his own glory; but if any individual of the human race, who was redeemed by Christ, shall not be saved, God will so far lose his end, and be deprived of his glory. For, if this were the case, where would be the glory of God the Father in forming a scheme which, with respect to multitudes, does not succeed? and where would be the glory of the Son of God, the Redeemer, in working out the redemption of men who are yet not to be saved by him? and where would be the glory of the spirit of God, if redemption were not by him effectually applied to every individual for whom it was wrought? By such arguments as these do the Calvinists oppose the scheme of universal redemption, and contend that Christ died only for the *elect*, or such as shall be placed on his right hand at the day of judgment. This notion of a limited redemption, as they think it more worthy of the sovereignty of God, they believe to be taught by our Saviour himself, when he saith *, "All that the Father *giveth* me shall come to me; and him that cometh to me, I will in nowise cast out. For I came down from heaven, not to do mine own will, but the will of him that sent me. And this is the Father's will who hath sent me, that of all which he hath *given* me I should lose nothing, but should raise it up again at the last day."

* John vi. 37—40.

184 According to the Arminians he died for all men.

The Arminians, on the other hand, contend, that it is impious to limit the effects of Christ's death to a chosen few, since it appears from scripture, that by the decree and intention of his Father he tasted death for every man, that all, without exception, might through him obtain remission of their sins. Thus our Lord himself told Nicodemus †, that "as Moses lifted up the serpent in the wilderness, even so must the Son of Man be lifted up; that *whosoever* believeth in him, should not perish; but have everlasting life. For God so loved the *world*, that he gave his only begotten Son, that whosoever believeth in him should not perish, but have everlasting life. For God sent not his Son into the world to condemn the world, but that the *world* through him might be saved." In perfect conformity with the doctrine of his divine Master, St Paul teaches ‡, that "Christ died for *all*; that God was in Christ reconciling the *world* to himself, not imputing their trespasses unto them;" that "he will have *all* men to be saved, and to come into the knowledge of the truth;" that "Christ gave himself a ransom for *all*;" and that "Jesus was made a little lower than the angels, that by the grace of God he should taste death for *every man*." The very same thing is taught by St Peter and St John, when the former says §, that "the Lord is not willing that *any* should perish, but that *all* should come to repentance;" and the latter ||, that "Jesus Christ the righteous is the propitiation for our sins; and not for our's only, but for *the whole world*."

† John iii. 14—16.

‡ 2 Cor. v. 14—20. 1 Tim. ii. 4—7. Heb. ii. 9.

§ 2 Peter iii. 9.

|| 1 John ii. 2.

On these texts, without any commentary, the Arminians are willing to rest their doctrine of universal redemption; though they think that a very strong additional argument for its truth arises from the numberless absurdities which flow from the contrary opinion. Thus, say they *, the apostles were commanded by our Saviour † to "go into *all* the world and preach the gospel to *every creature*," and all who hear it preached are required to believe it: but no man, as the Calvinists themselves confess, can believe the gospel as a Christian, without believing that Christ *died for him*; and therefore, if it be true that Christ died only for the *elect*, a great part of mankind are required to believe a lie, and a falsity is made the object of divine faith! Again, if Christ did not die for *all*, then no man can be sure that he

* *Limborch's Theologia Christiana*, Eng. Trans. book 4. ch. iii.

† St Mark xvi. 15, 16.

Theology more peculiarly Christian.

he is bound to believe in Christ when preached to him: nor can any man be justly condemned for infidelity: which is not only absurd in itself, but directly contrary to what we are taught by our blessed Lord, who assures us *, that unbelief is the cause of condemnation. Lastly, if Christ died not for *all*, then is it certain that he cannot claim dominion *over all* in *consequence* of his *death* and *resurrection*; but St Paul says expressly †, that "to *this end* Christ both *died*, and *rose*, and *revived*, that he might be the Lord of the *dead* and *living*." The Arminians acknowledge, that though Christ died for all, there are many who will not be saved; for, say they ‡, the death of Christ did not literally pay the debts incurred by sinners, but only obtained for them the gracious covenant of the gospel, by which all who believe in him, and sincerely endeavour to work out their own salvation with fear and trembling, are entitled to forgiveness of sins and eternal life.

* St John iii. 18, 19, and 36.

† Rom. xiv. 9.

‡ *Wells' Div. Laws and Covenants*, part 2. ch. 3.

185 Difficulties removed by the modern Arminians.

Such is the state of this controversy as it was agitated between the Calvinists and Arminians of the 17th century; but the present leaders of this latter school are of opinion, that it never could have been started, had not both parties mistaken the purpose for which Christ died. It is not conceivable, say they, that any thing for which the eternal Son of God took upon him human nature, and in that nature suffered a cruel and ignominious death, shall not be fully accomplished; and therefore, if in the divine intention he died to make atonement for the sins of man actual as well as original, we must of necessity conclude, that those for whom he died shall certainly be saved. Yet we learn from scripture that many shall go away into everlasting punishment, though the same scripture repeatedly assures us that Christ gave his life a ransom for *all*, and that he is the propitiation for *the whole world*. To reconcile these different passages of scripture is impossible, if we suppose that he laid down his life to atone for the *actual* transgressions of men; but if the direct purpose of the Godhead in forming this stupendous plan of redemption was, that the death of Christ should be the ransom of all from the grave or utter extinction, every difficulty is removed; for we know that all, the wicked as well as the righteous, shall through him be raised to life at the last day. That this was the purpose for which he died, they think apparent from the very words quoted by the Calvinists to prove that redemption was not universal; for he declares that it was his Father's will, "that of all which had been given him he should lose nothing." *not* that he should save it all from *future punishment*, but only that he "should raise it up at the last day." When St John calls him a propitiation for our sins, which, as we have seen, the divines whose doctrine we are now stating hold him to be indirectly, he does not add, as in our translation, for the *sins* of the whole world, but περι ὁλου του κοσμου, for the whole world, which, by his death, he redeemed from that vanity and corruption under which, according to St Paul, it had groaned from the fall till the preaching of the gospel. Hence it is that our blessed Lord calls himself "the resurrection and the life," and always promises to those who should believe in him, that though they were dead, yet should they live, and that he would raise them up at the last day.

Among these various opinions respecting the destination of the death of Christ, it belongs not to us to decide. The serious reader, divesting himself of prejudice in favour of the system in which he has been educated, will search the scriptures, and adopt the theory which he shall find most explicitly taught in that sacred volume; but as in every system it is admitted, that *one purpose* for which Christ died was to redeem mankind from the everlasting power of the grave, and bring to light life and immortality, it is of the utmost importance to know whether that purpose has been fully attained. Death we see still triumphing over all the generations of men; and as the scriptures give us no hopes of being rescued from its dominion but through the medium of a resurrection, some sensible evidence seems necessary to evince that a general resurrection shall actually take place. This we are promised as one great benefit purchased for us by the sufferings of Christ sacrificed on the cross. And since the price has been *paid*, and paid thus *visibly*, the nature of the covenant requires that the benefit should be as *visibly enjoyed* by the person whose sufferings obtained it for his brethren. "If the Redeemer himself had not been seen to enjoy the fruits of the redemption procured, what hopes could have remained for the rest of mankind? Would not the natural conclusion have been, that the expedient of *redemption*, by the death and sacrifice of Jesus, had proved ineffectual?" This is the conclusion which St Paul himself draws: "If Christ be not risen (says he *), then is our preaching vain, and your faith is also vain; ye are yet in your sins. Then they also, who are fallen asleep in Christ, are perished—απωλοντο—are lost, as if they had never existed. But now (adds he) is Christ risen from the dead, and become the first fruits of them that *slept*. For since by man came *death*, by man came also the *resurrection* of the dead: For as in Adam *all die*, even so in Christ *shall all be made alive*."—So necessarily connected, in the opinion of the apostle, is the resurrection of Christ with the very essence of Christianity †.

Theology more peculiarly Christian.

186 One purpose for which Christ died was to bring to light life and immortality.

* 1 Cor. xv. 15—23.

† *Warburton's Sermon on the Resurrection.*

We have in another place (see RESURRECTION, N° 50.) stated such arguments for the truth of this fundamental article of our common faith, as must carry conviction to every mind capable of estimating the force of evidence; we shall not here resume the subject.

Archbishop King has supposed ‡, that the human will is a faculty distinct from the understanding and the appetites; that activity is essential to it; and that previous to an election formed, it is equally indifferent to all objects. He thence infers, that a man may choose, and even take delight in, what is not naturally agreeable to any of his appetites; because when the choice is made, a relation is formed between the will and the object of choice, which, from being originally indifferent, now becomes a favourite object. But neither his Grace, nor any other asserter of human liberty, has ever affirmed or supposed, that any man or body of men could deliberately choose *evil* for its *own sake*, or enter zealously upon a tedious and difficult enterprise, from which *no good* could *possibly arise*, and from which *unmixed misery* was *clearly foreseen* as the *necessary result of every step of the progress*. Such, however, must have been the choice and the conduct of the apostles, when they resolved to preach a new religion founded on the resurrection of Jesus, if they did not certainly know that Jesus had risen from the dead. And this conduct must have been adopted, and, in opposition to every motive which can influence the human mind, have been persevered

‡ *Origin of Evil*, 4th edit. ch. v. sect. 1. subsect. 3. and 4.

Theology more peculiarly Christian.

vered in by a great number of men and women, without the smallest contradiction having ever appeared in the various testimonies, which at different times, and under the cruellest tortures, they all gave to a variety of circumstances, of which not one had its foundation in truth. He who can admit this supposition, will not surely object to the incredibility of miracles. The resurrection of a man from the dead is an event so different indeed from the common course of things, that nothing but the most complete evidence can make it an object of rational belief; but as the resurrection of Jesus has always been said to have had God for its Author, it is an effect which does not exceed the power of the cause assigned, and is therefore an event possible in itself and capable of proof. It is a deviation from the laws of nature, but it is not contradictory to any one of those laws.

That a great number of men and women should deliberately form a plan of ruin and misery to themselves, without a prospect of the smallest advantage either in this world or in the next, is as different from the common course of things as the resurrection from the dead; and therefore in itself at least as great a miracle: but that they should persist in prosecuting this plan in the midst of torments; that they should spread themselves over the whole world, and everywhere publish a number of falsehoods, without any one of them contradicting the rest; that truth should never escape them either in an unguarded moment, or when lingering on the rack, and yet that all their lies should be in perfect agreement with each other; that they should every one of them court sufferings for a person whom they knew to be an impostor; that not one of the number—not even a single woman—should have so much compassion for a fellow-creature, as to rescue him from the flames by confessing a truth which could injure nobody—not even the suffering deceivers themselves;—all this is not only different from the common course of things, but directly contrary to the most known laws of nature, and is therefore not miraculous, but may be pronounced impossible. Yet this impossibility we must admit, or acknowledge, that as Christ died for our sins, according to the Scriptures, and was buried; so he arose again the third day according to the Scriptures; that he was seen of Cephas, then of the twelve; after that of above five hundred brethren at once; after that of James; then of all the apostles; and that he was last of all seen of St Paul *, who was converted by the vision to preach the faith which till then he had persecuted.

* 1 Cor. xv. 3—9.

187

Hence we are assured of our own resurrection.

Thus we are assured, that "those who have fallen asleep in Christ are not lost, since he is risen from the dead, and become the first fruits of them that slept. For since by man came death, by man came also the resurrection of the dead. For as in Adam all die, even so in Christ shall all be made alive. But every man in his own order: Christ the first-fruits, afterwards they that are Christ's at his coming; for all that are in the graves shall hear his voice, and shall come forth; they that have done good unto the resurrection of life, and they that have done evil to the resurrection of damnation †."

† 1 Cor. xv. 20—24. and St John v. 28, 29.

Our blessed Lord having conversed familiarly with the eleven apostles for forty days after his resurrection, instructing them in the things pertaining to the kingdom of God; having extended their authority as his ministers, by giving them a commission to teach all nations, and make them his disciples, by baptizing them in the name of the Father, and of the Son, and of the Holy Ghost; and having promised them power from on high to enable them to discharge the duties of so laborious an office—led them on as far as Bethany, that they might be witnesses of his ascension into heaven. "When they therefore were come together, they asked of him, saying, Lord, wilt thou at this time restore again the kingdom to Israel? And he said, it is not for you to know the times and the seasons, which the Father hath put in his own power. But ye shall receive power after that the Holy Ghost is come upon you; and ye shall be witnesses unto me, both in Jerusalem, and in all Judea, and in Samaria, and unto the uttermost parts of the earth. But tarry ye in the city of Jerusalem, until ye be endued with power from on high; and he lift up his hands and blessed them; and it came to pass while he blessed them, he was parted from them, and a cloud received him out of their sight. And while they looked steadfastly towards heaven, as he went up, behold, two men stood by them in white apparel; who also said, Ye men of Galilee, why stand ye gazing up into heaven? This same Jesus, who is taken up from you into heaven, shall so come, in like manner as ye have seen him go into heaven. And they worshipped him, and returned to Jerusalem with great joy *."

* St Luke xxiv. 49—53. and Acts i. 6—12.

188

Proofs of Christ's ascension.

That our blessed Lord ascended into heaven, will scarcely be denied in the present age by any one who admits that he rose from the dead. The ascension was indeed the natural consequence of the resurrection; for we cannot suppose that a man would be called back from the grave to live for ever in a world where all other men fall in succession a prey to death. The purpose for which he died was to recover for the descendants of Adam every privilege which they had forfeited through his transgression; and if, as has been generally believed, mankind were by the terms of the first covenant to enjoy eternal life in heaven, some proof was necessary that Christ by his death and resurrection had opened the kingdom of heaven to all faithful observers of the terms of the second. Hence it was prophesied † of the Messiah, in whom all the nations of the earth were to be blessed, that "he should ascend on high, lead captivity captive, and sit on the right hand of God until his enemies should be made his footstool." It was therefore of the greatest importance to the apostles to have sufficient proof of their Master's exaltation to the right hand of the Majesty on high; for otherwise they could neither have looked for an entrance into heaven themselves, by a new and living way, as the author of the epistle to the Hebrews expresses it, nor have preached Jesus as the Messiah promised to their fathers, since they could not have known that in him these prophecies were fulfilled. But the proof vouchsafed them was the most complete that the nature of the thing would bear. The spectators of the ascension were many; for, according to the history of St Luke ‡, those who returned from the Mount of Olives to Jerusalem, and prepared themselves for the coming of the Holy Ghost, were in number about six score; and to such a cloud of witnesses the evangelist would not have appealed, had not the fact he was recording been very generally known. Yet these were perhaps but part of the witnesses; for since

† Ps. lxviii. 18. cx. 1. Micah ii. 13.

‡ Acts i. 12—16.

Theology more peculiarly Christian.

since Christ had told to his disciples that he was to ascend to his Father and their Father, to his God and their God, and that he was going to prepare a place for them, that where he is there they might be likewise; he can hardly doubt but that all who believed in him as the Redeemer of the world would take care to be present, not only to view their Master's triumph over all his enemies, but also to have a sight of that glory which awaited themselves. It was on this occasion probably that he was seen after his resurrection by above five hundred brethren at once, of whom the greater part were alive at the writing of St Paul's first epistle to the Corinthians.

But though such multitudes of people saw Jesus lifted up from the mount, and gradually vanish out of their sight, some other evidence seemed necessary to certify them of the place to which he had gone. Two angels therefore appear, and attest what human eyes could not see, but what was indeed the consequence of what they had seen. They attest that Christ had ascended to heaven, not to descend again till the last day; and surely, with respect to this point, the citizens of heaven were the most unexceptionable witnesses. We must therefore acknowledge and confess, against all the wild heresies of old (K), that Jesus Christ the Son of God, who died and rose again, did with the same body and soul with which he had lived upon earth ascend up "into heaven, there to appear in the presence of God for us *. Having in the outward tabernacle of this world once offered up himself a pure and perfect sacrifice for the expiation of our sins, he entered within the veil into the most holy place, there to present his blood before God himself, in order to obtain mercy for us, and restore us to the Divine favour. So that, "if any man sin, we have an advocate with the Father, Jesus Christ the righteous, who is the propitiation for our sins, and not for ours only, but also for the sins of the whole world; and he is able to save to the uttermost those that come to God by him, seeing he ever liveth to make intercession for us." "Seeing then that we have a great high-priest, who is passed into the heavens, Jesus the Son of God, we may through him come boldly unto the throne of grace, that we may obtain mercy and find grace to help him in time of need."

* Heb. ix. 24.

189 In heaven our Saviour executes the office of a priest,

190 and a king.

But it is not the office of a priest only that our Lord discharges in heaven; he is represented as sitting on the right hand of God, to denote that regal authority with which he is now vested; angels, and authorities, and powers, being made subject to him †." Hence it is, that after his resurrection, he said of himself ‡, "all power is given unto me in heaven and in earth;" for, as St Paul informs us §, "because he humbled himself and became obedient unto death, even the death of the cross, therefore God hath highly exalted him, and given him a name which is above every name: that at the name of Jesus every knee should bow, of things in heaven, and things in earth, and things under the earth." And this submission is due to him, because "God raised him from the dead, and set him at his own right hand in the heavenly places, far above all principalities and powers, and might, and dominion, and every name that is named, not only in this world, but also in that which is to come; and hath put all things under his feet, and gave him to be head over all things to the church *." As God, Christ possessed a kingdom, which, as it had not a beginning, can never have an end: but the dominion, of which the apostle is here treating, was conferred upon him as the mediator of the new covenant, and will no longer continue than till his enemies shall be subdued; for we are told, that "he must reign till he hath put all enemies under his feet; and that the last enemy which shall be destroyed is death." "He will ransom his subjects from the power of the grave; he will redeem them from death. O death, he will be thy plague; O grave, he will be thy destruction †." The trumpet shall sound, the graves shall be opened, all the sons and daughters of Adam shall return to life, and death shall be swallowed up in victory. "Then cometh the end, when the office of mediator ceasing, he shall have delivered up the kingdom to God, even the Father, when he shall have put down all rule and all authority and power. For when all things shall be subdued unto him, then shall the Son also himself be subject unto him that put all things under him, that God may be all in all ‡."

‡ 1 Cor. xv. 24—28.

191 Descent of the Holy Ghost on the apostles.

The first conspicuous proof which our blessed Lord gave of being vested with supreme power, and made head over all things to the church, was on the day of Pentecost. He had told the apostles that he would pray the Father to give them another comforter, who should abide with them for ever, even the Spirit of truth, which should teach them all things, and bring all things to their remembrance which he had said unto them. He had assured them, that it was expedient for them that he himself should go away; "for if I go not away (said he*), the Comforter will not come unto you; but if I depart, I will send him unto you." At his last interview with them, just before his ascension, he had desired them to tarry at Jerusalem till they should be endued with power from on high, before they entered upon their great work of converting the nations. These promises were amply fulfilled; for "when the day of Pentecost was fully come, they were all with one accord in one place. And suddenly there came a sound from heaven as of a rushing mighty wind, and it filled all the house where they were sitting. And there appeared unto them cloven tongues, like as of fire, and it sat upon each of them. And they were all filled with the Holy Ghost, and began to speak with other tongues, as the Spirit gave them utterance. And there were dwelling

* John xvi. 7.

(K) There was one Apelles in the primitive church, who was condemned as a heretic for teaching that Christ's body was dissolved in the air, and that he ascended to heaven without it. The opinions of this man and his followers are stated at large and confuted by Tertullian, Gregory Nazianzen, and Epiphanius; and the reader who thinks such ridiculous notions worthy his notice, will find enough said of them in the Notes to the sixth article of Pearson's Exposition of the Creed. Perhaps it may be from a hint communicated in these Notes, that our great modern corrector of the evangelists has discovered, if it be indeed true that he pretends to have discovered, that Jesus Christ is still upon earth.

Theology more peculiarly Christian.

dwelling at Jerusalem Jews, devout men, out of every nation under heaven. Now when this was noised abroad, the multitude came together, and were confounded, because that every man heard them speak in his own language. And they were all amazed, and marvelled, saying one to another, Behold, are not all these who speak Galileans? And how hear we every man in our own tongue, wherein we were born? Parthians, and Medes, and Elamites, and the dwellers in Mesopotamia, and in Judea, and Cappadocia, in Pontus and Asia, Phrygia and Pamphylia, in Egypt and in the parts of Libya about Cyrene, and strangers of Rome, Jews, and proselytes, Cretes and Arabians—we do hear them speak in our tongues the wonderful works of God. And they were all amazed, and were in doubt, saying one to another, What meaneth this *!"

* Acts ii. 1—13.

192 Certainty of that miracle.

That those who heard the apostles speak so many different languages were amazed, is what we should naturally suppose; but that a single individual among them remained unconvinced, is astonishing; for the gift of tongues on the day of Pentecost is one of the most palpable miracles that was ever wrought. It is likewise one of the best authenticated miracles; for the book entitled *the Acts of the Apostles* was written not more than 30 years after the event took place (see SCRIPTURE, N° 168.); and it is not conceivable that, within so short a period, St Luke, or any man of common sense, would have appealed for the truth of what he recorded to so many inveterate enemies of the Christian name, had he not been aware that the miraculous gift of tongues was a fact incontrovertible. We all know how desirous the Jewish rulers were to stop the progress of the faith, by whatever means; but if this miracle was not really performed, they had now an opportunity of doing it effectually by means to which truth and honour would give their approbation. Thousands must have been alive in the city of Jerusalem who were men and women at the time when the apostles were said to have been thus suddenly inspired with the tongues of the Parthians, Medes, and Elamites, &c.; and as these foreigners were themselves either Jews by descent, or at least proselytes to the Jewish religion, surely the chief-priests would have found multitudes ready, both at home and abroad, to contradict this confident appeal of St Luke's if contradiction had been possible. We read however of no objection whatever being made to this miracle. Some of the audience, indeed, when the apostles addressed people of so many nations in all their respective languages, not understanding what was said, and taking it for jargon which had no meaning, concluded, not unnaturally, that the speakers were full of new wine, and mocked them for being drunk so early in the day; but this is a circumstance which, so far from rendering the miracle doubtful, adds much to the credit of the historian, as it would hardly have occurred to the writer of a narrative wholly false, and would certainly not have been mentioned, had he known that the apostles really attempted to impose on the multitude unmeaning sounds for foreign languages.

193 The gift of tongues permanent with the apostles.

As it is thus certain that the apostles were miraculously furnished with the gift of tongues, so the elegance and propriety of that miracle to attest the real descent of the Spirit of truth, who was to teach them all things, and endue them with power from on high to convert the nations, can never be enough admired by the pious Christian; for words being the vehicle of knowledge, an ability to speak the different languages of the earth was absolutely necessary to enable those who had been originally fishermen to go into all the world and preach the gospel to every creature. Yet there have been writers *, who, though unable to call in question the reality of the gift of tongues on the day of Pentecost, have contended, that it was a gift "not lasting, but instantaneous and transitory; not bestowed upon them for the constant work of the ministry, but as an occasional sign only, that the person endowed with it was a chosen minister of the gospel; which sign, according to them, ceased and totally vanished as soon as it had served that particular purpose." The chief argument upon which this opinion is attempted to be built, is drawn from the scripture Greek, which is said to be "utterly rude and barbarous, and abounding with every fault which can possibly deform a language; whereas we should naturally expect to find an inspired language pure, clear, noble, and affecting, even beyond the force of common speech; since nothing can come from God but what is perfect in its kind. In short, we should expect, says the objecter, the purity of Plato and the eloquence of Cicero †."

* Dr Middleton and Lord Shaftesbury.

194 Objections.

† Middleton's Essay on the Gift of Tongues.

In reply to this objection, it has been well observed ‡, that it supposes what is called the purity, elegance, and sublimity, of language, to be something natural and essential to human speech, and inherent in the constitution of things. "But the matter is far otherwise. These qualities are accidental and arbitrary, and depend on custom and fashion; modes of humanity as various as the different climes of the earth; and as inconstant as the tempers, genius, and circumstances, of its inhabitants. For what is *purity*, but the use of such terms and their combinations as the caprice of a writer or speaker of authority hath preferred to their equals? what is *elegance*, but such a turn of idiom as a fashionable fancy hath brought into credit; and what is *sublimity*, but the application of such images as arbitrary and casual connections, rather than their own native grandeur, have dignified and ennobled? The consequence of this is, that the mode of composition which is a model of perfection to one nation or people, has always appeared either extravagant or mean to another. Asiatic and Indian eloquence was esteemed hyperbolical and unnatural by the Greeks and Romans, and is so esteemed by us; whilst the Greek and Roman eloquence in its turn appeared cold and insipid to the warm inhabitants of the east; and ours would appear perhaps still colder. But the New Testament was designed for the rule of life to all mankind. Such a rule required inspiration; and inspiration, say the objectors, implies the most perfect eloquence. What human model then was the Holy Ghost to follow? for a human model it must have been, because there was no other; and if there had, no other would have answered the purpose, which was to make a due impression on the mind and affections. Should the eastern eloquence have been employed? But it would have been too swelling and animated for the west. Should the western? This would have been too still and inactive for the east. Or suppose us only solicitous for what we best understand; which species of this latter genus should the sacred writers have preferred? The dissolute softness of the Asiatic Greeks, or the dry conciseness of the Spartans? The flowing exuberances

‡ Warburton's Doctrine of Grace.

195 Answered.

Theology more peculiarly Christian.

uberances of Attic eloquence, or the grave severity of the Roman?

"But are there not some general principles of eloquence in common to all the species? There are. Why then should not these have been employed to credit the apostolic inspiration? Because the end even of these (replies our author), is to mislead reason, and inflame the passions; which being abhorrent to the truth and purity of our holy religion, were very fitly rejected by the inspired penman. Besides, it might easily be known to have been the purpose of Providence, though such purpose had not been expressly declared, that the gospel should bear all possible marks of its divine original, as well in the course of its progress as in the circumstances of its promulgation. To this end, the human instruments of its conveyance were mean and illiterate, and chosen from among the lowest of the people, that when the world saw itself converted by the *foolishness of preaching*, as the only learned apostle thinks fit to call it, unbelievers might have no pretence to ascribe its success to the parts, or stations, or authority, of the preachers. Now had the language inspired into these illiterate men been the eloquence of Plato or Tully, Providence would have appeared to counteract its own measures, and to defeat the purpose best calculated to advance its glory. But God is wise, though man is a fool. The course of Providence was uniform and constant: It not only chose the weakest instruments, but carefully kept out of their hands that powerful weapon of WORDS which their adversaries might so easily have wrested to the dishonour of the gospel. Common sense tells us, that the style of an universal law should retain what is common to all languages, and neglect what is peculiar to each. It should retain nothing but CLEARNESS and PRECISION, by which the mind and sentiments of the writer are intelligibly conveyed to the reader. This quality is essential, invariably the same, and independent of custom and fashion. It is the consequence of syntax, the very thing in language which is least positive, as being formed on the principles of philosophy and logic: whereas all besides, from the very power of the elements and signification of the terms to the tropes and figures in composition, are arbitrary; and, as deviating from these principles, frequently vicious. But this quality of clearness and precision eminently distinguishes the writings of the New Testament; insomuch that it may be easily shown, that whatever difficulties occur in the sacred books do not arise from any imperfect information caused by this local or nominal barbarity of style; but either from the sublime or obscure nature of the things treated of, or from the intentional conciseness of the writers; who, in the casual mention of any thing not essential to the dispensation, always observe a studied brevity."

After much ingenious and sound reasoning on the nature of language in general, our author concludes, that the STYLE of the New Testament, even on the truth of what has been said to its discredit, is so far from proving the language not to be divinely inspired, that it bears one certain mark of that original. "Every language consists of two distinct parts, the single terms, and the phrases and idioms. Suppose now a foreign language to be instantaneously introduced into the minds of illiterate men like the apostles; the impression must be made either by fixing in the memory the terms and single words only with their signification, as, for instance, Greek words corresponding to such or such Syriac or Hebrew words; or else, together with that simple impression, by enriching the mind with all the phrases and idioms of the language so inspired. But to enrich the mind with the peculiar phrases and idiom of a foreign language, would require a previous impression to be made of the manners, notions, fashions, and opinions, of the people to whom that language is native; because the idiom and phrases arise from, and are dependent on, these manners. But this would be a waste of miracles without sufficient cause or occasion; for the Syriac or Hebrew idiom, to which the Jews were of themselves enabled to adapt the Greek or any other words, abundantly served the useful purposes of the gift of tongues, which all centered in those tongues, being so spoken and written as to be CLEARLY UNDERSTOOD. Hence it follows, that if the style of the New Testament were indeed derived from that language which was miraculously impressed upon the apostles on the day of Pentecost, it must be just such a one as in reality we find it to be; that is, it must consist of Greek words in the Syriac or Hebrew idiom."

196 Divinity of the Holy Ghost.

The immediate author of this gift, so necessary to the propagation of the gospel, was the Spirit of truth, or the Comforter, who is the Holy Ghost and the third person in the blessed Trinity. That there are three persons in the one Godhead, has been shewn at large in a former section of this article; and that the Holy Ghost is one of these three, might be safely concluded from the form of baptism instituted by Christ himself. But as more plausible objections have been urged against his divinity than any that we have met with against the divinity of Christ, it may not be improper to consider these before we proceed to give an account of the graces which he imparted to the infant church, and of the apostles preaching under his influence, By the Arians the Holy Ghost is considered as a creature; by the Socinians and modern Unitarians, as they call themselves, the words *Holy Ghost* are supposed to express, not a person or spiritual subsistence, but merely an energy or operation, a quality or power, of the Father, whom alone they acknowledge to be God. If this doctrine can be confuted, the Arian hypothesis will fall to the ground of itself; for it is not conceivable that any inspired teacher should command his followers to be baptized in the name of the self-existent God and two creatures.

197 Objections.

It is admitted by the Socinians themselves, that in the Scriptures many things are spoken of the Holy Ghost which can be properly predicated only of a person; but the inference drawn from this concession they endeavour to invalidate by observing, that in scripture there are likewise expressions in which things are predicated of abstract virtues, which can be literally true only of such persons as practise these virtues. Thus when St Paul says *, that "charity suffereth long and is kind, charity envieth not, charity vaunteth not itself, is not puffed up," &c. we cannot suppose his meaning to be, that these actions are performed by charity in the abstract, but that every charitable person, in consequence of that one Christian grace, suffereth long and is kind, envieth not, vaunteth not himself, and is not puffed up, &c. In like manner, say they, personal actions are attributed to the Holy Ghost, which itself is no

* 1 Cor. xiii. 4—8.

Theology more peculiarly Christian.

no person, but only the virtue, power, or efficacy, of God the Father; because God the Father, who is a person, performs such actions by that power, virtue, or efficacy, in himself, which is denominated the Holy Ghost. Thus when we read * that "the Spirit said unto Peter, Behold three men seek thee; arise therefore and get thee down, and go with them, doubting nothing, for I have sent them;" we must understand that God the Father was the person who spoke these words and sent the three men; but because he did so by that virtue in him which is called the *Spirit*, therefore the *Spirit* is said to have spoken the words and sent the men. Again, when "the Holy Ghost said † to those at Antioch, Separate me Barnabas and Saul for the work whereunto I have called them;" we are to conceive that it was God the Father who commanded the two apostles to be separated for the work to which he had called them; but because he had done all this by that power within him which is called the Holy Ghost, therefore his words and actions are attributed to the Holy Ghost, just as long-suffering in men is attributed to charity.

* Acts x. 19, 20.

† Acts xiii. 2.

198 Answered.

This reasoning has a plausible appearance, and would be of much force were *all* the actions which in scripture are attributed to the Holy Ghost of such a nature as that they could be supposed to have proceeded from the person of God the Father in consequence of any particular power or virtue in him; but this is far from being the case. Thus "Spirit is said ‡ to make intercession for us;" but with whom can we suppose God the Father, the fountain of divinity, to intercede? Our Saviour assured § his disciples, that the Father would, in his name, send to them the Holy Ghost, who is the Comforter; that he would himself send the Comforter unto them from the Father; that the Comforter should not speak of himself, but speak only what he should hear; and that he should receive of Christ's, and shew it unto them. But we cannot, without blasphemy and absurdity, suppose that the Father would, in the name of Christ, send himself; that the Son would send the Father from the Father; and the Father would not speak of himself, but speak only what he heard; or that either the Father in person, or a quality of the Father, should receive any thing of Christ to shew unto the apostles.

‡ Rom. viii. 26. 27.

§ St John xiv. 26. xv. 26. xvi. 13, 14, 15.

The sagacity of Socinus perceived the force of such objections as these to his notion of the Holy Ghost being nothing more than the power of the Father personified; and therefore he invented another *prosopopeia* to serve his purpose in the interpretation of those texts to which this one cannot be applied. "The Spirit of God (says he ‖) may be considered either as a property or power in God, or as the things on which that power is working. When taken in the former sense, the Spirit, where any personal attribute is given to it, means God the Father; when taken in the latter sense, it means the man on whom the power of the Father is working; who, as long as he is affected by that power, is therefore called the Spirit of God;" and he quotes, we think most absurdly, the tenth verse of the second chapter of the first epistle to the Corinthians, as a text in which by the Spirit is meant an inspired man who could search all things, yea, even THE DEEP THINGS OF GOD.

‖ *Faust. Socinus in Resp. ad Wickam*, cap. 10.

How his modern followers, who deny the plenary inspiration even of Christ, will relish such a degree of inspiration as this, which raises mere men to a temporary equality with God, we know not; but leaving them to settle the dispute with their master, we shall produce one or two passages in which personal attributes are given to the Spirit of God, when it is impossible to conceive that Spirit, either as a power inherent in the Divine Father, or as the person on whom that power is operating. We need not bring new texts into view, as some of those already quoted will serve our purpose. When our Saviour promises that the *Holy Ghost*, *the Comforter*, *the Spirit of truth*, should be sent by the Father and the Son to the apostles, we have seen, that by this Spirit he could not mean the Father or a property of the Father; neither could he possibly mean the apostles themselves, unless we are to suppose that the Father and the Son sent St Peter to St Peter, and that St Peter, so sent, came to St Peter! Again, when Christ saith of the Holy Ghost, "he shall receive of mine, and shall show it unto you," he could not, for the reason already assigned, mean by the Holy Ghost the Father or the power of the Father; and surely his meaning was not, that the apostles, under the influence of the power of the Father, should receive something and shew it each to himself! The Holy Ghost therefore is unquestionably a person; for though there are many passages of scripture in which the *gifts* of the Holy Ghost are called the *Holy Ghost*, they are so called by a very common figure of speech, in which the effect receives the name of its cause: and since this person is joined with the Father and the Son in the formula of Christian baptism; since they who lied to the Holy Ghost are said * to have lied unto God; since blasphemy against him is a more heinous offence than the same sin against even the Father or the Son †; and since it was by the operation of the Holy Ghost that Jesus Christ was conceived of the Virgin Mary, and even on that account called the ‡ Son of God—it follows that the Holy Ghost is God, of the same substance with the Father and Son.

* Acts v. 4.

† Mark iii. 28, 29.

‡ Luke i. 35.

199 The apostles miraculously instructed in the principles of religion.

It was this Divine Spirit which, on the day of Pentecost, inspired the apostles with the knowledge of different languages; and as these were given only to enable them to preach the gospel to every creature, it can admit of no doubt but that he, who so amply provided the means of preaching, would take care that the gospel should be preached in purity. Our Saviour had told his apostles, that the Comforter would guide them into all the truth (εις πασαν την αληθειαν), and bring all things to their remembrance, whatsoever he had said unto them; but if they had not comprehended the meaning of what he said, the bare remembrance of his sayings would have been of little importance. That before this miraculous shedding abroad of the Spirit they had but a very imperfect knowledge of his doctrines, and of the purpose for which he had come into the world, is apparent from that unseasonable question which they put to him when assembled to witness his glorious ascension; "Lord, wilt thou at this time restore again the kingdom to Israel?"

200 Their great need of such instruction.

Their minds still cherished with fondness the vain prospect of temporal power; but after the day of Pentecost they were directed to nobler objects. From the same Spirit they received diversities of gifts besides that of language; for we are assured by St Paul §, when speaking of the early converts to Christianity in general,

§ 1 Cor. xii. 8—12.

Theology more peculiarly Christian.

ral, that "to one was given by the Spirit the word of WISDOM; to another the word of KNOWLEDGE by the same Spirit; to another FAITH by the same Spirit; to another the gifts of HEALING by the same Spirit; to another the working of MIRACLES; to another PROPHECY; to another DISCERNING OF SPIRITS; to another DIVERS KINDS of TONGUES; to another the INTERPRETATION OF TONGUES:" and these gifts, which were severally divided either among private Christians or among the inferior orders of ministers in the church, we have reason to believe were all bestowed in a greater or less degree upon each of the apostles.

Men thus endowed were well qualified to declare unto the world all the counsel of God. By the word of *wisdom* they communicated to the Gentile nations a pure system of what is called *natural religion;* turning them from the vanity of idols to the worship of the living God: by the word of *knowledge*, they preached the great doctrines of revelation both to Jews and Gentiles, shewing them that there is none other name under heaven given unto men whereby they may be saved than the name of Jesus Christ (L); and by their gifts of *healing* and of *miracles*, &c.; they were enabled to prove unanswerably, that their doctrines were divine. They taught everywhere the unity of God, the creation of the world, the fall of man, the necessity of redemption, the divinity of the Redeemer, his sacrifice on the cross to restore mankind to their forfeited immortality, and the terms of the new covenant into which they had through him been graciously admitted by God.

Such a view as our limits would admit of we have given of all these doctrines, except that which respects the terms of the gospel covenant; but these being explicitly stated only by St Paul and St James, we could not till now investigate them, without violating the historical order into which, for the sake of perspicuity, we have digested the several parts of this short system. Our Saviour himself has indeed taught with great plainness the necessity of faith and baptism to the salvation of those who have an opportunity of hearing the gospel preached with power (see BAPTISM): and in his sermon on the mount, which is such a lecture of ethics founded on religion as the Son of God only could have delivered, we learn, that "unless our righteousness shall exceed the righteousness of the Scribes and Pharisees, we shall in no case enter into the kingdom of heaven; that not every one who saith unto Christ, Lord, Lord, shall enter into the kingdom of heaven, but he who doth the will of the Father who is in heaven: and that many will say to him at the day of judgment, Lord, Lord, have we not prophesied in thy name, and in thy name done many wonderful works?" which could not be done without faith; to whom he will, notwithstanding, say, "Depart from me, ye that work iniquity *." St Paul, however, seems to attribute our justification to the bare act of believing; for he repeatedly assures us, "that a man is justified by faith without the deeds of the law;" while St James, on the other hand, affirms, "that by works a man is justified, and not by faith only." This apparent difference in the language of the two apostles, has produced among divines opinions really different respecting the justification of Christians; and the principal of these opinions it is our duty to state.

* St Matt. v. 20. vii. 21.—24.

201
Meaning of justification.

Between *pardon* of sin and *justification* there is so close a connection, that many writers seem to consider the terms as synonymous, and to infer, that he who is pardoned is *ipso facto* justified. That every Christian, who shall be pardoned at the judgment of the great day, will likewise be justified, is indeed true; but in propriety of speech, *justification* is a word of very different import from *pardon*, and will entitle the Christian to what mere pardon could not lead him to expect. An innocent person, when falsely accused and acquitted, is *justified* but not *pardoned;* and a criminal may be *pardoned*, though he cannot be *justified* or declared innocent. A man whose sins are pardoned is free from punishment; but the justified Christian is entitled to everlasting life, happiness, and glory. If we were only pardoned through Christ, we should indeed escape the pains of hell, but could have no claim to the enjoyments of heaven; for these, being more than the most perfect human virtue can merit, must be, what in the scriptures they are always said to be, "the gift of God through Jesus Christ our Lord." Hence it is that St Paul, distinguishing, as we have done upon his authority, between mere remission of sins and justification of life, declares †, that "Jesus our Lord was *delivered* for our *offences*, and *raised* again for our *justification*."

† Romans iv. 25.

The word justification, as used both by St Paul and St James, has been very generally considered as a forensic term expressing the sentence of a judge. The most eminent reformed divines of all denominations ‡, and even many of the Romanists themselves, have strenuously contended, that this is its genuine sense, when it is distinguished from mere remission of sins, regeneration, and sanctification; and if so, it will signify God's pronouncing a person *just*, either as being perfectly blameless, or as having fulfilled certain conditions required of him in the Christian covenant. But that "there is not a just man upon earth, who doth good and sinneth not," is made known to us by the most complete evidence possible, the joint dictates of our own consciences and of divine

‡ *Limborch, Bull, Waterland, Warburton, Beveridge, Vitringa, Gill*, &c.

(L) It is not perhaps easy to determine what is here meant by the word of WISDOM and the word of KNOWLEDGE, as distinguished from each other. By the former (λογος σοφιας), Bishop Warburton understands all the great principles of natural religion. "The ancients (says he) used the word σοφια in this peculiar sense; it is used in the same sense by St Paul in Col. iv. 5.; and we can hardly give it any other in the place before us, where we see the word of wisdom distinguished from the word of knowledge (λογος γνωσεως), which evidently means all the great principles of revelation; the term γνωσις being as peculiarly applied by Christian writers to revealed religion as σοφια is by the Gentiles to the natural. St Paul uses the word in this sense in 2 Cor. xi. 6. where he says, Ει δε και ιδιωτης τω λογω αλλου τη γνωσει; and St Peter in his first epistle, chap. iii. verse 7. Hence those early heretics who so much deformed the simplicity and purity of the Christian faith by visionary pretences to superior knowledge of revelation, took from this word the name of Gnostics." See *Warburton's Sermon on the Office and Operation of the Holy Ghost*.

Theology more peculiarly Christian.

divine revelation; and therefore whosoever is pronounced just by the Judge of all the earth, must be so, either because, though not absolutely blameless, he has performed the conditions required of him in the covenant of grace, or because Christ has fulfilled all righteousness in his stead.

202 It is a forensic term.

If this be the Scripture notion of justification, it must be wholly the act of God, and cannot be the effect either of our faith or of our virtue. Accordingly, we are said by the apostle to be justified freely by his grace through the redemption that is in Jesus Christ; whom *God hath set forth* to be a propitiation through faith in his blood *. The act of justification therefore proceeds from the divine philanthropy, and cannot be performed by the instrumentality of faith; for it is not God, but man, who believes; and man is not the justifier of himself. To talk of any kind of *instrument* of justification besides the propitiation set forth by God, is indeed to make use of very improper language: "Omnis causa instrumentalis (says Bishop Bull †), suo modo in effectum influit, eique effecti productio propriè attribui potest. Jam vero, cum justificatio nihil aliud sit quam gratiosus Dei actus, quo peccata nostra nobis condonet, ac nos ad salutem acceptet, valde absurdum esset dicere, vel fidem, vel opera nostra, vel quidvis aliud, nostri aut remittere peccata nostra, aut personas nostras acceptare: quod tamen, si instrumentalis causa justificationis fides sit, planè dicendum esset."

* Rom. iii. 24, 25.

† *Harmonia Apostolica*, cap. ii. § 9.

In this sentiment of the bishop of St David's some of the most eminent divines both among the Calvinists and Arminians agree. Many, however, have chosen to treat of justification not only in the active sense, as it is the act of God, for all admit that it is he who justifies; but likewise in a passive sense, as it means our *privilege* or *possession* holden of him, when we are said to be justified by his grace. In this view of the subject they may talk with sufficient propriety, of an instrument of justification, not as the mean by which it is conveyed, but as the medium through which it is received by the true Christian. And hence it follows, that Waterland and Warburton strenuously maintain the doctrine of the Westminster Confession, "that faith receiving and resting on Christ is the alone instrument of justification; though it cannot be alone in the person justified, but must ever be accompanied with all other saving graces, and be a faith which worketh by love."

But notwithstanding this agreement between the leaders of the rival sects, they have found abundant matter of controversy respecting faith and works, in deciding the great question, "Whether, when God justifies man, he considers him as absolutely righteous on account of Christ's righteousness performed in his stead; or only as just, because he has fulfiled the conditions of the covenant of grace, which does not require of him perfect righteousness?" The former is the doctrine of the more rigid Calvinists, the latter that of the Arminians or Remonstrants.

"A notion (says Dr Gill ‡) obtained some years ago, that a relaxation of the law and the severities of it has been obtained by Christ; and a new law, a remedial law, a law of milder terms, been introduced by him, which is the gospel; the terms of which are, faith, repentance, and new obedience; and though these be imperfect, yet, being sincere, they are accepted by God in the room of perfect righteousness. But every article of this scheme (continues he) is wrong; for the law is not relaxed, nor any of its severities abated; Christ came not to destroy, but to fulfil it; and therefore it requires the same holy, just, and good things, as ever. Nor is the gospel a new law. There is nothing in it (he says) which looks like a law; for it has no commands in it, but all promises, being a pure declaration of grace and salvation by Christ; nor are faith, repentance, and a new obedience, required by it as conditions of man's acceptance with God. Faith and repentance are gospel doctrines, and parts of the gospel ministry; they are graces, and not terms required to be performed by men of themselves. Faith is the gift of God, and repentance is a grant from him. It is not true (continues our author) that God will accept of an imperfect righteousness in the room of a perfect one; nor can any thing more highly reflect upon the justice and truth of God, who is the judge of all the earth, than to suppose that he can ever account that as a righteousness which is not one."

‡ *Body of Divinity*, vol. ii. book iii. chap. 8. § 5.

203 Doctrine of the Calvinists respecting it.

Having thus proved by arguments which were almost in the same words stated long before by Bishop Beveridge *, that the gospel is no relaxation of the law, he proceeds to lay down his own notions of justification, of which (he says) "the sole matter, or that for the sake of which a sinner is justified before God, is the righteousness of Christ—that which he did and suffered on earth, in our nature, in our stead, and as our representative. This is commonly called his active and passive obedience; and when the purity and holiness of his own nature was added to it, the whole made up the δικαιωμα του νομου, *the righteousness of the law*, which was fulfilled by him as the head and representative of his people †; for whatever the law required is necessary to a sinner's justification before God, and it required of sinners more than it did of man in innocence. Man was created with a pure and holy nature, conformable to the pure and holy law of God; and it was incumbent on him to continue so, and to yield in it perfect and sinless obedience, in the failure whereof he was threatened with death. Man did fail, by which his nature was vitiated and corrupted, and his obedience became faulty and imperfect. He therefore became liable to the penalty of the law, and still perfect obedience was required him. To the justification of a sinner therefore is required the most complete obedience, active and passive; or, in other words, purity of nature, perfect obedience, and the sufferings of death; all which meet in Christ, the representative of his people, in whom they are justified. There are indeed some divines (continues our author) who exclude the active obedience of Christ from being any part of the righteousness by which men are justified. They allow it to have been a condition requisite in him as a Mediator, qualifying him for his office; but deny that it is the matter of justification, or reckoned for righteousness to man. But without the active obedience of Christ the law would not be satisfied; the language of which is, *Do and live;* and unless its precepts be obeyed, as well as its penalty endured, it cannot be satisfied; and unless it be satisfied there can be no justification. If therefore men are justified by the righteousness of Christ, it must be by his active obedience imputed and made over to them, so as to become their's, *even as David describeth the blessedness of the man unto whom God imputeth righteousness without works* ‡. That this is really the way in which men are justified, our author thinks evident,

* See his *Private Thoughts of Religion*.

† Rom. viii. 4.

‡ Rom. iv. 6.

Theology more peculiarly Christian.

evident, because they must be justified either by an inherent or by an imputed righteousness; but they cannot be justified by their own inherent righteousness, for that is imperfect, and therefore not justifying. Hence the apostle 'counts all things but dung, that he may win Christ and be found in him; not having his own righteousness, which is of the law, but that which is *through the faith of Christ*, the righteousness which is of *God by faith* *.' But by such a righteousness as this a man cannot be justified in any other way than by an imputation of it to him. Whence it follows, that '*as by one man's disobedience many were made sinners* by imputation, so *by the obedience of one shall many be made* righteous, by having that obedience placed to their own account."

* Philip. iii. 8, 9.

As this author properly considers justification as the act of God, he does not approve of the language in which faith is called the instrument either of conferring or receiving it. "Faith (says he †) is merely the evidence of justification to the person justified; for 'faith is the evidence of things not seen.' The righteousness of God, of the God-man and Mediator Jesus Christ, is revealed from faith to faith in the everlasting gospel ‡; and therefore must be before it is revealed, and before the faith to which it is revealed. Faith is that grace whereby a soul, having seen its want of righteousness, beholds in the light of the Divine Spirit a complete righteousness in Christ, renounces its own, lays hold on that, puts it on as a garment, rejoices in it, and glories of it; the Spirit of God witnessing to his spirit that he is a justified person: and so he is evidently and declaratively 'justified in the name of the Lord Jesus, and by the spirit of our God ‖'. Faith adds nothing to the *esse*, only to the *bene esse* of justification; which is a complete act in the eternal mind of God, without the being or consideration of faith, or any foresight of it. In the account of God, a man is as much justified before his faith as after it; and after he does believe, his justification depends not on his acts of faith, for though *we believe not, yet God abides faithful* to his covenant-engagements with his Son, by whose suretyship-righteousness the elect are justified; but by faith men have a comfortable sense, perception, and apprehension, of their justification, and enjoy that peace of soul which results from it. It is by that only, under the testimony of the Divine Spirit, that they know their interest in it, and can claim it, and so have the comfort of it."

† *Body of Divinity*, vol. i. book ii. § 5.

‡ Rom. i. 17.

‖ 1 Cor. vi. 11.

Though this language differs from that of the Westminster Confession, the author seems not to teach a different doctrine; for if faith be that grace by which a soul renounces its own righteousness, and lays hold of Christ's, which it puts on as a garment, it must be that very thing which the compilers of the Confession meant by their definition of faith receiving and resting on Christ and his righteousness, when they called it "the alone instrument of justification." Accordingly our author elsewhere * teaches, that "true faith in sensible sinners assents to Christ and embraces him, not merely as a Saviour of man in general, but as a special suitable Saviour for them in particular. It proceeds upon Christ's being revealed *in* them as well as *to* them, by the spirit of wisdom and revelation, in the knowledge of him as a Saviour that becomes them. It comes not merely through external teachings by the hearing of the word from men; for no man, saith our blessed Lord, can come to me except the Father draw him; but such souls as are thus drawn, having heard and learned of the Father, believe not only in the *doctrine* of Christ, but also in *himself*, trusting in him alone for everlasting life and salvation."

* *Body of Practical Divinity*, book i. chap. 6.

204 And of the more moderate Arminians.

Were it not that this author, in every thing that he writes, has an eye to the doctrine of election and reprobation, which he carries to a greater height than almost any other divine with whose works we are acquainted, he would differ little in his notions of justification from the more moderate Arminians. "Justification (says Limborch) is the merciful and gracious act of God, whereby he fully absolves from all guilt the truly penitent and believing soul, through, and for the sake of Christ apprehended by a true faith; or gratuitously remits sins upon the account of faith in Jesus Christ, and graciously imputes that faith for righteousness." Here indeed the imputation of Christ's righteousness is expressly denied; but Dr Waterland, who can hardly be considered as a Calvinist, seems to contend for the imputation of that righteousness to the sinner, as well as for faith being the instrument by which it is received.

"It cannot be for nothing (says that able writer *) that St Paul so often and so emphatically speaks of man's being justified by faith, or through faith in Christ's blood; and that he particularly notes it of Abraham, that he *believed*, and that his faith was counted to him for justification, when he might as easily have said that Abraham, to whom the gospel was preached, was justified by gospel-faith and obedience, had he thought faith and obedience equally instruments of justification. Besides, it is on all hands allowed, that though St Paul did not directly oppose faith to *evangelical works*, yet he comprehended the works of the *moral law* under those which he excluded from the office of *justifying*, in his sense of the word justification. He even used such arguments as extended to all kinds of works; for Abraham's works were excluded, though they were undoubtedly evangelical. To prove that he interprets the apostle's doctrine fairly, our author quotes, from the genuine epistle of Clemens of Rome, a passage, in which it appears beyond a doubt that this fellow-labourer of St Paul so understood the doctrine of justifying faith as to oppose it even to evangelical works, however exalted. It is true (continues our author), Clemens elsewhere, and St Paul almost everywhere, insists upon true holiness of heart and obedience of life as indispensable conditions of salvation or justification; and of that, one would think, there could be no question among men of any judgment or probity. But the question about conditions is very distinct from the other question about instruments; and therefore both parts may be true, viz. that faith and obedience are equally conditions, and equally indispensable where opportunities permit; and yet faith over and above is emphatically the instrument both of receiving and holding justification, or a title to salvation.

* *Summary View of Justification.*

205 Faith the instrument of it.

"To explain this matter more distinctly, let it be remembered, that God may be considered either as a party contracting with man on very gracious terms, or as a Judge to pronounce sentence on him. Man can enter into the covenant, supposing him adult, only by assenting to it; and accepting it, to have and to hold it on such kind of tenure as God proposes: that is to say, upon a self-denying tenure, considering himself as a guilty man standing in need of pardon, and of borrowed merits, and at length resting upon mercy. So here, the previous question is, Whether a person shall consent to hold a privilege upon this submissive kind of tenure or not?

Theology more peculiarly Christian.

not? Such assent or consent, if he comes into it, is the very thing which St Paul and St Clemens call *faith*. And this previous and general question is the question which both of them determine against any proud claimants who would hold by a more self admiring tenure.

"Or if we next consider God as sitting in judgment, and man before the tribunal going to plead his cause; here the question is, What kind of plea shall a man resolve to trust his salvation upon? Shall he stand upon his innocence, and rest upon strict law? or shall he plead guilty, and rest in an act of grace? If he chooses the former, he is proud, and sure to be cast: if he chooses the latter, he is safe so far in throwing himself upon an act of grace. Now this question also, which St Paul has decided, is previous to the question, What conditions even the act of grace itself finally insists upon? A question which St James in particular, and the general tenure of the whole Scripture, has abundantly satisfied; and which could never have been made a question by any considerate or impartial Christian. None of our works are good enough to stand by themselves before him who is of purer eyes than to behold iniquity. Christ only is pure enough for it at first hand, and they that are Christ's at second hand in and through him. Now because it is by faith that we thus interpose, as it were, Christ between God and us, in order to gain acceptance by him; therefore faith is emphatically the instrument whereby we receive the grant of justification. Obedience is equally a condition or qualification, but not an instrument, not being that act of the mind whereby we look up to God and Christ, and whereby we embrace the promises."

206
Faith and obedience its conditions.

But though our author contends that faith is the instrument of justification, he does not, like the Antinomians, teach that it will save men without works. "The covenant of grace (says he) has conditions annexed to it of great importance, for without them no instruments can avail. These are faith and obedience, as St James hath particularly maintained. St Paul had before determined the general and previous question respecting the plea by which we ought to abide; and when some libertines, as is probable, had perverted his doctrine of faith and grace, St James showed that the very faith which rests in a covenant of grace implies a cordial submission to the conditions of that covenant, otherwise it would be nothing but an empty ceremony. The perfect agreement between St Paul and St James in the article of *justification*, appears very clear and certain. St Paul declares, that in order to come at justification, it is necessary to stand upon grace, not upon merit; which St James does not deny, but rather confirms, in what he says of the perfect law of liberty (James i. 25. ii. 12.). St Paul makes faith the instrument of receiving that grace; which St James does not dispute, but approves by what he says of Abraham (ii. 23.); only he maintains also, that in the conditionate sense, justification depends equally upon faith and good works; which St Paul also teaches and inculcates in effect, or, in other words, through all his writings. If St Paul had had precisely the same question before him which St James happened to have, he would have decided just as St James did; and if St James had had precisely the same question before him which St Paul had, he would have determined just as St Paul did. Their principles were exactly the same, but the questions were diverse; and they had different adversaries to deal with, and opposite extremes to encounter, which is a common case.

"It may be noted, that that faith which is here called a *condition*, is of much wider compass than that particular kind of faith which is precisely the instrument of justification. For faith as a condition means the whole complex of Christian belief, as expressed in the creeds; while faith as an instrument means only the laying hold on grace, and resting in Christ's merits, in opposition to our own deservings: though this also, if it is a vital and operative principle (and if it is not, it is nothing worth), must of course draw after it an hearty submission to, and observance of, all the necessary conditions of that covenant of grace wherein we repose our whole trust and confidence. So that St Paul might well say, "Do we then make void the law (the moral law) through faith? God forbid, Yea, we establish the law *." We exempt no man from religious duties; which are duties still, though they do not merit nor are practicable to such a degree as to be above the need of pardon: they are necessary conditions in their measure of justification, though not sufficient in themselves to justify, nor perfect enough to stand before God or to abide trial: therefore Christ's merits must be taken to supply their defects: and so our resting in Christ's atonement by an humble self-denying faith is our last resort, our anchor of salvation both sure and steadfast, after we have otherwise done our utmost towards the fulfilling of God's sacred laws, towards the performing of all the conditions required.

* Rom. iii. 31.

"That good works, internal and external, are according as opportunities offer and circumstances permit, *conditions* properly so called, is clear from the whole tenor of Scripture, as hath been often and abundantly proved by our own divines (M), and is admitted by the most judicious among the foreign Reformed (N). Yet some have been very scrupulous as to this innocent name, even while they allow the absolute necessity of good works as indispensable qualifications for future blessedness. Why not conditions therefore as well as qualifications? Perhaps because that name might appear to strike at absolute predestination, or unconditional election; and there may lie the scruple: otherwise the difference appears to lie rather in words than in things.

"Some will have them called not conditions, but *fruits* or *consequents* of justification. If they mean by justification the same as the grace of the Holy Spirit, and the first grace of faith springing from it, they say true; and then there is nothing more in it than an improper use of the word *justification*, except that from abuse of words very frequently arises some corruption of doctrine. If they mean only, that outward acts of righteousness are fruits of inward habits or dispositions; that

(M) Bull. *Op. Latin.* p. 412, 414, 415, 430, 434, 514, 516, 544, 583, 645, 668. *Edit. ult.*—Stillingfleet's Works, vol. iii. p. 367, 380, 393, 398.—Tillotson's Posthumous Sermons, vol. ii. p. 484, 487.

(N) Vossius *de Bonis Operibus*, Thes. x. p. 370.—Op. tom. vi.—*Frid. Spanhem. fil.* Op. tom. iii. p. 141, 159.

that also is undoubtedly true: but that is no reason why internal acts, virtues, graces (good works of the mind), should not be called conditions of justification; or why the outward acts should not be justly thought conditions of preserving it. But if they mean that justification is ordinarily given to adults, without any preparative or previous conditions of faith and repentance, that indeed is very new doctrine and dangerous, and opens a wide door to carnal security and to all ungodliness."

Such is the doctrine of Christian justification as it has been taught by the followers of Calvin, and by some of the most eminent Arminians who flourished in the end of the 17th and beginning of the 18th century. They appear not, from this view of their opinions, to differ so widely as some of them have wished the world to believe. It is evident that Dr Waterland, though he rejects some of the distinguishing tenets of Calvinism, lays greater stress upon faith in his scheme of justification than Dr Gill himself; and that they both consider it as the *instrument* by which the adult Christian must

207 Objections of the more zealous Arminians to this statement of the doctrine.

receive the imputed righteousness of Christ. The greater part of modern Arminians, however, exclaim against the imputation of Christ's righteousness, as a doctrine false in itself, and fraught with the most pernicious consequences; and they would be ready to tell Dr Gill, in his own words, that of his scheme every article is wrong. It is not true (say they) that God exacts of man, or ever did exact of him, an obedience absolutely perfect; for under every dispensation man was in a state of discipline, and had habits of virtue and piety to acquire; and it is probable that his progress in piety, virtue, and wisdom, will continue for ever, as none but God is perfect and stationary, and incapable of deviating from the line of rectitude. Most of them, after Bishop Bull, dislike the use of such unscriptural phrases as *instrument of justification*, applied either to faith or to works; and think, that by considering God as the sole justifier of man, upon certain conditions, they can more precisely ascertain the distinct provinces of faith and obedience in the scheme of justification, than either their brethren of the old school of Arminius, or their rivals of the school of Calvin.

208 Their own statement of it.

By the very constitution of man, piety and virtue are duties which, if he do not sincerely perform, he must of course forfeit the favour of his Maker; but the most perfect performance of his natural duties would not entitle him to a supernatural and eternal reward. Eternal life is the *gift* of God through Jesus Christ; and it is surely reasonable that we should acknowledge it to be so, and not claim it as a debt due to our merits. The pious and virtuous man has a natural claim to more happiness than misery during the period of his existence, a claim founded on the attributes of that God who called him into being; but he has no natural claim to a future life, and still less to a perpetuity of existence. This is a truth not more clearly taught in the holy scripture than consonant to the soundest philosophy: and yet, by not attending to it, have St Paul and St James been set at variance, and the most opposite doctrines taught respecting the justification of Christians.

Because faith in Christ cannot entitle a wicked man to eternal *happiness*, one class of divines seem to infer that such faith is not necessary to Christian *justification*, and that "his faith cannot be wrong whose life is in the right." They proceed upon the supposition that man is naturally immoral; that piety and virtue are entitled to reward; and that therefore the pious and virtuous man, whatever be his belief, must undoubtedly inherit an eternal reward. But this is very fallacious reasoning. That piety and virtue are through the divine justice and benevolence entitled to reward, is indeed a truth incontrovertible; but that man who is of yesterday is naturally immortal; that a being who began to exist by the mere good will of his Maker, has in himself a principle of perpetual existence independent of that will—is a direct contradiction. Whatever began to be, can be continued in being only by the power, and according to the pleasure, of the infinite Creator; but it pleased the Creator of his free grace at first to promise mankind eternal life, on the single condition of their first father's observing one positive precept. That precept was violated, and the free gift lost: but the co-

209 Faith the sole condition of the justification peculiarly Christian;

venant was renewed in Christ, who "by his death hath abolished death, and by his resurrection hath brought to light life and immortality." The condition annexed to the gift thus restored was faith; for "being justified by faith *, we have peace with God through our Lord Jesus Christ; by whom also we have access by faith into this grace wherein we stand, and rejoice in the hope of the GLORY OF GOD." Faith therefore in the Son of God and Saviour of the world, is not only a condition, but the *sole* condition, of that justification which is peculiarly Christian; for since Christ, without any co-operation of ours, hath purchased for us the free gift of eternal life, we shall be guilty of the grossest ingratitude to our Divine Benefactor, and impiously claim an independence on God, if we look upon that gift either as a right inherent in our nature, or as a debt due to our meritorious deeds.

* Rom. v. 1, 2.

210 but not of obtaining eternal happiness.

But though faith be the condition of justification, as that implies the inheritance of *eternal life*, there are other conditions to be performed before a man can be put in possession of *eternal felicity*. By a law long prior to the promulgation of the gospel—a law interwoven with our very being—no man can enjoy the favour of his Maker, who does not make it his constant endeavour "to do justly, to love mercy, and to walk humbly with his God." This law was in force before man fell; it continues to be in force now that he is redeemed; and it will not be abrogated even at that period when faith shall give place to vision, and hope to enjoyment.

211 The different conditions of divine favour and of eternal life.

By the grace of the Christian covenant, all mankind are rendered immortal in consequence of the death and resurrection of Christ, who is the Lamb slain, in the divine decree, from the foundation of the world; but to obtain immortal *happiness*, they must observe the conditions both of nature and of revealed religion, which are repentance from dead works, and faith in Christ the Redeemer. The former is that condition upon which alone we can retain the Divine favour, and of course enjoy either present or future happiness; the latter is a most equitable acknowledgement required of us, that perpetual conscious existence is neither a right inherent in our nature, nor a debt due to our virtuous obedience, but merely the gift of God through Jesus Christ our Lord.

"To make the distinct provinces of faith and works in the business of justification clear, let us suppose (says Bishop Warburton †), that, at the publication of the gospel, all to whom the glad tidings of immortality were

† Div. Leg. book ix. chap. 3.

Theology more peculiarly Christian.

were offered on the condition of *faith in Jesus* had been moral or virtuous men, and on that account entitled (as natural religion teacheth) to the favour of God and an abundant reward; is it not self-evident that FAITH ALONE, exclusive of the condition of good works, would, in that case, have been the very thing which *justified* or entitled them to life *everlasting*? But are *good works*, therefore, of no use in the Christian system? So far from it, that those only who serve God in sincerity and in truth are capable of the justification which faith alone

212 Illustrated by a familiar example.

embraces; for, to illustrate this matter by a familiar instance, suppose a British monarch to bestow, in *free gift*, a certain portion of his own *domains*, to which immortality may well be compared, upon such of his subjects as should perform a certain service to which they were not obliged by the laws of the kingdom; it is evident that the performance of this last service ONLY would be the thing which entitled them to the *free gift*. Yet it is obvious that obedience to the laws, which gave them a claim to protection as subjects, in the enjoyment OF THEIR OWN PROPERTY (to which the reward offered by natural religion may be compared), would be a previous and necessary qualification to their enjoyment of their new possession; since it is absurd to suppose that such a *gift* could be intended for rebels and traitors, or indeed for any but good and faithful servants of their king and country." Well therefore might the apostle reprove the ignorance or licentiousness of certain of his converts at Rome, in his question—"Do we then make void the LAW through FAITH? God forbid! yea, we ESTABLISH THE LAW;" obedience to it being the previous qualification of all who are entitled to the fruits of justifying faith—LIFE AND IMMORTALITY.

Had proper attention been paid to this distinction, which St Paul everywhere makes between such duties as are common to all religions that are true, and those which are peculiar to the Christian revelation, many useless controversies might have been avoided respecting the instrument of justification and the conditions of the Christian covenant. By not attending to it, the divines of one school, who perceive that the mere belief of any truth whatever cannot entitle a man to eternal felicity, have almost dropt faith from their system of Christianity, and taught moral duties like Pagan philosophers; whilst another party, who err almost as far in their interpretations of scripture, finding eternal life represented as the *gift of God*, and faith in Christ as the instrument

213 Sum of Christianity.

or means by which that gift must be accepted, have expunged from their system the necessity of good works, forgetting surely that wicked believers, like believing devils, may be doomed to an eternity of torments. But the sum of Christianity, as we are taught by the beloved disciple, is comprehended in this one commandment of God, "that we should believe on the name of his Son Jesus Christ, and love one another as he gave us commandment." In perfect harmony with him, the great apostle of the Gentiles assures us*, that "in Christ Jesus nothing can avail to our eternal happiness but faith which WORKETH BY LOVE;" and he informs Titus†, that it "is a true saying, and what he wills to be constantly affirmed, that they who have believed in God be careful to maintain good works."

* Gal. v. 6.

† Chap. iii. 8.

Indeed no man can have complete faith in Christ who believes not the promises of the gospel; but all those promises, except the single one of resurrection from the dead to perpetual conscious existence, are made to us upon the express condition that we obey the law of the gospel; "for God will render to every man according to his deeds: to them that are contentious and do not obey the truth, but obey unrighteousness, indignation and wrath; tribulation and anguish upon every soul of man that doth evil, of the Jew first and also of the Gentile; but glory, honour, and peace to every man that worketh good, to the Jew first and also to the Gentile*."

* Rom. ii. 8, 9.

Such are the notions of justification entertained by those who in the present age have been considered as the leaders† of the sect of Arminians. How far they are just, the reader must decide for himself; but under every view of this doctrine which we have taken, the Christian covenant appears much more gracious than

† Warburton and Law, &c.

214 The Christian covenant more gracious than the paradisiacal.

that into which Adam was admitted in paradise: since it affords room for repentance, even to that man, who may be so unhappy as to be drawn for a time into apostasy from the terms of the covenant. Whether the death of Christ therefore was a *direct* atonement for the actual sins of men, or only operated as such *indirectly* by procuring for them repeated opportunities of repentance, it is an undoubted truth, that "if through the offence of one many be dead, much more the grace of God, and the gift by grace, which is by one man, Jesus Christ, hath abounded unto many. And not as it was by one that sinned, so is the gift: for the judgment was of one offence to *condemnation*, but the free gift is of many offences to *justification*‡."

‡ Rom. v. 16, 17.

Thus graciously has the divine goodness displayed itself in the restoration of our lost inheritance. But it stopt not here. The same bountiful Lord of life, for its further security, imparts to every true believer the strength and light of his holy spirit to support faith in working out our own salvation. Our blessed Saviour promised, before he left this world, to send to his followers the Holy Ghost or Comforter to abide with them for ever, to guide them into all truth, to bring all things to their remembrance whatsoever he had said unto them, and, as we learn from other passages of scripture, to "work in them both to will and to do of his good pleasure." How amply this promise was fulfilled to the apostles, we have already seen; but we are not to suppose that it was re-

215 Christians sanctified by the Holy Ghost, who

stricted to them. As man is designed for a supernatural state in heaven, he stands in need of supernatural direction to guide him to that state. "No man (says our Saviour) can come to me except the Father draw him; for as no man knoweth the things of a man save the spirit of a man which is in him, even so none knoweth the things of God but the Spirit of God." This omniscient Spirit indeed searcheth all things, yea even the deep things of God," and revealeth them to the sons of men, to enlighten their understandings and purify their hearts. The grace which he sheds abroad is either external and general, or internal and particular. The former has been extended to the whole church of God under the patriarchal, Mosaic, and Christian dispensations, in such a revelation of the divine will as was sufficient to instruct men unto eternal life, whether they had a clear view or not of that stupendous plan of redemption, by which the kingdom of heaven was opened to them after the forfeiture of the terrestrial paradise; for there have been "holy prophets ever since the world began;

Theology more peculiarly Christian.

began; and prophecy came not at any time by the will of man, but holy men of God spake as they were moved by the Holy Ghost *." Hence it is that all scripture was given by inspiration of God to teach us every thing which it is necessary for us to know and believe; and the scripture is that work of the Spirit which is extended to the universal church.

* Luke i. 70. and 2 Peter i. 21.

But the same spirit which thus generally reveals the object of faith to the church, does likewise particularly illuminate the minds of individual believers, working in them an assent to that which is taught them from the written word. It was thus that "the Lord opened the heart of Lydia †; that she attended to the things which were spoken by Paul;" it is thus that "the word preached doth not profit if it be not mixed with faith in them who hear it ‡;" and it is thus that "God deals to every man the measure of faith §;" for "by grace are we saved through faith, which is not of ourselves; it is the gift of God ||." This illumination of the Spirit was conveyed to the apostles "in a sound from heaven as of a rushing mighty wind," because it was meant to testify to the world that they were chosen ministers of the gospel; but the ordinary Christian receives it "in the still small voice," because it is conveyed to him only to "open his understanding that he may understand the scriptures."

† Acts xvi. 14.

‡ Heb. iv. 2.

§ Rom. xii. 3.

|| Eph. ii. 8.

216 Regenerates them,

Another operation of the Spirit on the minds of believers is that which in scripture is called REGENERATION; for "according to his mercy God saveth us by the washing of regeneration and renewing of the Holy Ghost *, which he sheds on us abundantly through Jesus Christ our Lord." To those who believe that we derive from Adam a corrupted nature, this particular grace must appear so absolutely necessary, that without it we could have no relish for heaven or heavenly things." "The natural man (we are told) receiveth not the things of the spirit of God; for they are foolishness to him; neither can he know them, because they are spiritually discerned." Indeed whatever be the powers of our moral faculties, when compared with those of our first father, it is so long before they be completely developed, that we should infallibly be lost, if we were not blessed by a supernatural guide, when reason is incapable of directing our conduct. Our passions and appetites are in their full strength before experience has furnished the mind with materials, by means of which motives may be weighed; and therefore it would be impossible, during the giddy period of youth, to keep them in due subjection, or to prevent vicious habits from being formed, were we not influenced by divine grace. So true is it, that "except a man be born again of water and of the Holy Ghost, he cannot enter into the kingdom of God." This change in our dispositione, from an immoderate attachment to earth to a relish for the things of heaven, is in scripture called "a renewing of our minds, a new creation, a new man;" in opposition to our natural disposition, which is called "the old man, corrupted according to the deceitful lusts." The ancient fathers of the church, as well as some very eminent modern divines †, generally speak of baptism as the instrument in God's hand of man's regeneration; and for the truth of their opinion they appeal to John iii. 3, 5. Ephes. v. 25, 26. and 1 Cor. vi. 11. in which great stress is certainly laid on the washing of water, as well as on sanctification by the word.

* Titus i. 5, 6.

† *Clarke* and *Waterland*.

217 guides them through life,

A third office of the Holy Spirit is to lead, direct, and govern us through all the periods of our lives. Without such a leader and guide, the temptations with which we are surrounded would certainly overcome us, and we should faint long before we arrive at the end of our journey. By the very constitution of our nature we are subjected in some degree to the influence of sense, of which the objects are present, whilst the enjoyments of heaven are future, and seen, as at a distance, only by the eye of faith; but "the law of the Spirit of life, in Christ Jesus, hath made us free from the law of sin and death;" for God worketh in us both to will and to do of his good pleasure; and as many as are thus led by the spirit of God, they are the sons of God; and while they walk in the Spirit, they do not fulfil the lusts of the flesh." Without the aid of the same Spirit, we could not even make our prayers acceptable; for since "our confidence in God is, that he heareth us only when we ask any thing according to his will; and since we know not what we should pray for as we ought, the Spirit itself maketh intercession for us with groanings which cannot be uttered *.

* Rom. viii. 26.

218 unites them to Christ,

A fourth operation of the Holy Ghost, as he is the sanctifier of Christians, is to join them to Christ, and make them members of that one body of which he is the head. "For by one Spirit are we all baptized into one body †; and as the body is one and hath many members, and all the members of that one body being many are one body, so also is Christ." "Hereby we know that God abideth in us, by the Spirit which he hath given us;" and as, in the ordinary course of his dealings with Christians, this Spirit is first given in baptism, so is it continued to the faithful by the instrumentality of the Lord's supper. That ordinance we have elsewhere (see *SUPPER of the Lord*) proved to be a federal rite; and surely no time can be supposed so highly sanctified for the reception of the graces of the Holy Spirit, as that in which we renew our federal union with our Lord and Master in the communion of his body and blood.

† 1 Cor. xii. 12, 13.

It is likewise the office of the Holy Ghost to give us an earnest of our everlasting inheritance, to create in us a sense of the paternal love of God, and thereby to assure us of the adoption of sons. "As many as are led by the Spirit of God, they are the SONS of God; and because we are sons, God hath sent forth the spirit of his Son into our hearts. For we have not received the spirit of bondage again to fear; but we have received the Spirit of adoption, whereby we cry Abba Father; the Spirit itself bearing witness with our spirit, that we are the children of God ‡."

‡ Gal. iv. 6. Rom. viii. 15, 16.

219 and sanctifies the administrations of the ministers of the gospel.

As the gifts of grace are generally annexed to means, to the proper use of the word and sacraments, it is a sixth office of the same Spirit to sanctify such persons as are regularly set apart for the work of the ministry, and ordained to offer up the public prayers of the people; to bless them in the name of God; to teach the doctrines of the gospel; to administer the sacraments instituted by Christ; and to perform all things necessary "for the perfecting of the saints, for the work of the ministry, for the edifying of the body of Christ §." The same Spirit which illuminated the apostles, and endowed them with power from above to perform personally their apostolic functions, fitted them also for sending others, as they were sent by their Divine Masters; and for establishing

§ Eph. iv. 12.

Theology more peculiarly Christian.

blishing such a constitution of the church as was best adapted for preserving Christians in the unity of the Spirit and bond of peace. They committed a standing power to a successive ministry to be conveyed down to the end of the world; and those who are vested with that power are obliged to "take heed unto themselves, and to all the flock over which the HOLY GHOST hath made them overseers, to feed the church of God, and to contend earnestly for the faith which was once delivered unto the saints *." See EPISCOPACY, INDEPENDENTS, PRESBYTERIANS, POPE, and QUAKERS.

* Acts xx. 18. and Jude ver. 3.

By these, and the like means, doth the Spirit of God sanctify the sons of men; and in consequence of this santification proceeding immediately from his office, he is called the HOLY Spirit and the COMFORTER. This is such a provision "for renewing us in the spirit of our minds, and enabling us to put on the new man, which, after God, is created in righteousness and true holiness," as, when made known by revelation, appears to have been expedient, may be conceived to have been even necessary, and though reason could hardly have hoped for it, is contradicted by none of our natural notions either of God or of man. Many, however, are the controversies to which it has given rise in the church of God; some contending that it is given only unto the elect, upon whom it operates with resistless efficacy; others affirming that it is offered to all, but in such a manner as that, by the abuse of their free will, it may be "resisted, grieved, and quenched;" and some few, still intoxicated with the pride of PELAGIUS, think it is not necessary, and of course is not bestowed.

220 Controversies occasioned by this doctrine.

The questions concerning *election*, the *efficacy of grace*, and the final *perseverance of the saints*, we have stated elsewhere, and given a summary view of the arguments by which the contending parties maintain their respective opinions (see PREDESTINATION); and the texts of Scripture which we have just quoted, under the different heads of sanctification, show sufficiently that the opinion of Pelagius is directly contrary to the doctrine of the apostles. It may not be improper to enquire whether it be as agreeable to reason and experience as its patrons seem to imagine.

221 discussed elsewhere.

If it be unreasonable to expect any assistance from the Spirit of God in carrying on the work of our own salvation, how came so many of the wisest and best of men in all ages to believe, that he who sincerely endeavours to discharge his duty is supported in that endeavour by assistance from heaven? That such was the popular belief of the early Greeks, is evident from the poems of Homer; in which we everywhere find some god calming the passions of the heroes, altering their determinations when improper, and inspiring them with wisdom. Nor was this the sentiment of the poets only. Socrates, it is well known, professed to believe that his own conduct was under the direction of a superior spirit, which he called a *dæmon;* and Plutarch, as we find him quoted by Wollaston, speaks of the gods assisting men, by "exciting the powers or faculties of the soul; by suggesting secret principles, imaginations, or thoughts; or, on the contrary, by diverting or stopping them." Of the same opinion must Cicero have been, when he said, "stabit illud quidem, quod locum hunc continet, de quo agimus, esse Deos, et eorum providentia mundum administrari, eosdemque consulere rebus humanis, nec solum *universis*, verum etiam SINGULIS †;" for it is not conceivable that a particular providence can be administered without the influence of the Deity on the minds of men. That the poets and philosophers of the heathen world derived these notions from primeval tradition, cannot, we think, be questioned; but if they were absurd in themselves, or apparently contradictory to the laws of nature, they would not surely have been so universally embraced; for it will scarcely be denied, that Socrates and Cicero were men of as great natural sagacity as Pelagius or any of his followers. It is indeed so far from being incredible that the Father of spirits occasionally directs the thoughts and actions of men, that we believe there are very few who have made observations on themselves and their own affairs, who have not found, on reflection, many instances in which their usual judgment and sense of things were *overruled*, they know not *how*, or *why;* and that the actions which they performed in those circumstances have had consequences very remarkable in their general history. See PROVIDENCE, N° 18, 19.

222 Opinions of the heathens concerning it.

† *De Div.* lib. i. sect. 51.

This being the case, why should the pride of Christians make them hesitate to admit, on the authority of divine revelation, what Socrates, and Plutarch, and Cicero, and all the virtuous and wise men of antiquity, admitted in effect, on no better evidence than that of oral tradition, supported by their own meditations on their own thoughts, and the principles of their own conduct? Is it that they see not such beneficial effects of Christianity as to induce them to believe the professors of that religion to be indeed "chosen to salvation through the sanctification of the Spirit ‡?" Let them study the practical precepts of the gospel, consider the consequences which they have had on the peace and happiness of society, and compare the general conduct of Christians with that of the Jews, Pagans, and Mahometans (see RELIGION), and they will doubtless find reason to alter their opinion; and let those who embrace the truth remember, that as they are the temple of God, if the Spirit of God dwell in them, "it is their indispensable duty to cleanse themselves from all filthiness of the flesh and spirit; to follow peace with all men, and holiness, without which, no man shall see the Lord; and to work out their own salvation with fear and trembling, since it is God who worketh in them both to will and and to do of his good pleasure."

‡ Thess. ii. 3.

223 The gospel the last revelation.

From this short view of the several dispensations of revealed religion, it is evident that the gospel is not only the best but the last gift of the kind which man has to expect from his Maker; that the scheme of revelation is completed; and that the pretences of Mahomet and of more modern enthusiasts to divine inspiration are not only false, but fraught with contradictions. All these men admit the divine origin of the Mosaic and Christian religions; but it appears from the scriptures, in which those religions are taught, that the system of revealed truths which constitute the Patriarchal, Mosaic, and Christian revelations, commenced with the fall of man, and that it must therefore necessarily end with his restoration to life and immortality by the sacrifice of Christ upon the cross. A new revelation therefore like that of Mahomet cannot be admitted without rejecting the whole Bible, though the impostor himself everywhere acknowledges the inspiration of Abraham, of Moses, and of Christ. Nor is greater regard due to the claims of Christian enthusiasts. Such as pretend to have

have been in heaven *, and thence to have brought spiritual discoveries to the earth, have either forgotten or never understood, that in the scriptures of the Old and New Testaments the great scene of Providence appears to be closed in the full completion of its one regular, entire, and eternal purpose; that St Paul has pronounced † a curse on any man or angel from heaven who shall preach another gospel than what has been already preached by the apostles and evangelists; that in their writings we are taught every thing which it is our duty to believe or to practise in order to our own salvation; and that we have the promise of our blessed Lord himself, that the Spirit of truth shall remain with us to guide us into all necessary truth, till that great day when he shall come again to judge the world in righteousness, and render to every man according to his works.

* Bœhmen, Swedenbourg, and others.

† Gal. i. 8.

THE

THEOPHRASTA, a genus of plants belonging to the class of pentandria. See BOTANY *Index*.

THEOPHRASTUS, the philosopher, was born about 371 years before Christ, and was successively the disciple of Plato and of Aristotle. He succeeded Aristotle in the Peripatetic school, and conducted the charge with such high reputation that he had about 2000 scholars. He is highly celebrated for his industry, learning, and eloquence; and for his generosity and public spirit. He is said to have twice freed his country from the oppression of tyrants. He contributed liberally towards defraying the expence attending the public meetings of philosophers; which were held, not for the sake of show, but for learned and ingenious conversation. In the public schools he commonly appeared, as Aristotle had done, in an elegant dress, and was very attentive to the graces of elocution. He lived to the advanced age of 85: some say of 107. Towards the close of his life, he grew exceedingly infirm, and was carried to the school on a couch. He expressed great regret on account of the shortness of life; and complained that nature had given long life to stags and crows, to whom it is of so little value, and had denied it to man, who, in a longer duration, might have been able to attain the summit of science; but now, as soon as he arrives within sight of it, is taken away. His last advice to his disciples was, that, since it is the lot of man to die as soon as he begins to live, they would take more pains to enjoy life as it passes, than to acquire posthumous fame. His funeral was attended by a large body of Athenians. He wrote many valuable works, of which all that remain are, several treatises on the Natural History of Plants and Fossils; Of Winds, Of Fire, &c. a rhetorical work entitled "Characters," and a few Metaphysical Fragments.

Enfield's History of Philosophy.

To Theophrastus we are indebted for preserving the works of Aristotle. See ARISTOTLE.

THEOPOMPUS, a celebrated Greek orator and historian, was born in the island Chios, and flourished in the reign of Alexander the Great. He was one of the most famous of all the disciples of Isocrates, and won the prize from all the panegyrists whom Artemisia invited to praise Mausolus. He wrote several works, which are lost.

THEOREM, a proposition which terminates in theory, and which considers the properties of things already made or done; or it is a speculative proposition deduced from comparing together several definitions. A theorem is something to be proved, and a problem something to be done.

THE

THEORETIC, something relating to theory, or that terminates in speculation.

THEORY, in general, denotes any doctrine which terminates in speculation, without considering the practical uses or application thereof.

THEOSOPHISTS, a sect of men who pretend to derive all their knowledge from divine illumination. They boast that, by means of this celestial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have access to the most sublime secrets of nature. They ascribe it to the singular manifestation of divine benevolence, that they are able to make such a use of the element of fire, in the chemical art, as enables them to discover the essential principles of bodies, and to disclose stupendous mysteries in the physical world. They even pretend to an acquaintance with those celestial beings which form the medium of intercourse between God and man, and to a power of obtaining from them, by the aid of magic, astrology, and other similar arts, various kinds of information and assistance.

Ibid.

To this class belonged Paracelsus, Robert Fludd, Jacob Bœhmen, Van Helmont, Peter Poiret, and the Rosicrucians. They are also called *FIRE-Philosophers*.

THERAPEUTÆ, a term applied to those that are wholly in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed, in the cure of diseases.

THERMÆ, hot baths or bagnios. Luxury and extravagance were in nothing carried to such heights as in the thermæ of the Roman emperors. Ammian complains, that they were built to such an extent as to equal whole provinces; from which Valesius would abate, by reading *piscinæ* instead of *provinciæ*. And yet after all, the remains of some still standing are sufficient testimonies for Ammian's censure; and the accounts transmitted of their ornaments and furniture, such as being laid with precious stones (Seneca), set round with seats of solid silver (Pliny), with pipes and cisterns of the same metal (Statius), add to, rather than take from, the censure. The most remarkable bagnios were those of Dioclesian and Caracalla at Rome, great part of which remains at this day; the lofty arches, stately pillars, variety of foreign marble, curious vaulting of the roofs, great number of spacious apartments, all attract the curiosity of

Thermæ, Thermometer.

of the traveller. They had also their summer and winter baths.

THERMOMETER, an instrument for measuring the degree of heat or cold in any body.

1
Invention of the thermometer.
Martine's Essays.
* *Chem.* I. p. 152, 156.
† *Life of F. Paul*, p. 158.
‡ *Vit. Galil* p. 67.
|| *Corn. in Galen.* p. 756—842.
§ *De Mot. Animal.* II. prop. 175.
* *Opera Posth.* p. 30.

The thermometer was invented about the beginning of the 17th century; but, like many other useful inventions, it has been found impossible to ascertain to whom the honour of it belongs. Boerhaave * ascribes it to Cornelius Drebbel of Alcmar, his own countryman. Fulgenzio † attributes it to his master Paul Sarpi, the great oracle of the Venetian republic; and Viviani gives the honour of it to Galileo ‡. But all these are posthumous claims. Sanctorio || claims this honour to himself; and his assertion is corroborated by Borelli § and Malpighi * of the Florentine academy, whose partiality is not to be suspected in favour of a member of the Patavinian school.

Perhaps the best way to reconcile these different claims would be, to suppose that the thermometer was really invented by different persons about the same time. We know that there are certain periods in the progress of the arts when the stream of human genius runs in the same direction, and moves towards the same object. That part of the current which reaches the object first may possess the title; but the other parts follow so rapidly and arrive so soon after, that it is impossible for a spectator to decide which is first in point of time.

2
The air-thermometer described.

The first form of this instrument for measuring the degrees of heat and cold, was the air-thermometer. It is a well known fact that air expands with heat so as to occupy more space than it does when cold, and that it is condensed by cold so as to occupy less space than when warmed, and that this expansion and condensation is greater or less according to the degree of heat or cold applied. The principle then on which the air-thermometer was constructed is very simple. The air was confined in a tube by means of some coloured liquor; the liquor rose or fell according as the air became expanded or condensed. What the first form of the tube was, cannot now perhaps be well known; but the following description of the air-thermometer will fully explain its nature.

Plate DXXXIII. fig. 1.

The air-thermometer consists of a glass tube BE, fig. 1. connected at one end with a large glass ball A, and at the other end immersed in an open vessel, or terminating in a ball DE, with a narrow orifice at D; which vessel, or ball, contains any coloured liquor that will not easily freeze. Aquafortis tinged of a fine blue colour with a solution of vitriol or copper, or spirit of wine tinged with cochineal, will answer this purpose. But the ball A must be first moderately warmed so that a part of the air contained in it may be expelled through the orifice D; and then the liquor pressed by the weight of the atmosphere will enter the ball DE, and rise, for example, to the middle of the tube at C, at a mean temperature of the weather; and in this state the liquor by its weight, and the air included in the ball A, &c. by its elasticity, will counterbalance the weight of the atmosphere. As the surrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower ball, and consequently its surface will descend; on the contrary, as the ambient air becomes colder, that in the ball is condensed, and the liquor pressed by the weight of the atmosphere will ascend; so that the liquor in the tube will ascend or descend more or less according to the state of the air contiguous to the instrument. To the tube is affixed a scale of the same length, divided upwards and downwards from the middle C into 100 equal parts, by means of which the ascent and descent of the liquor in the tube, and consequently the variations in the cold or heat of the atmosphere, may be observed.

3
Its defects.

This instrument was extremely defective; for the air in the tube was not only affected by the heat and cold of the atmosphere, but also by its weight.

4
The spirit of wine thermometer.

The air being found improper for measuring with accuracy the variations of heat and cold according to the form of the thermometer which was first adopted, another fluid was proposed about the middle of the 17th century by the Florentine academy. This fluid was spirit of wine, or alcohol, as it is now generally named. The alcohol being coloured, was inclosed in a very fine cylindrical glass tube previously exhausted of its air, having a hollow ball at one end A, fig. 2. and hermetically sealed at the other end D. The ball and tube are filled with rectified spirit of wine to a convenient height, as to C, when the weather is of a mean temperature, which may be done by inverting the tube into a vessel of stagnant coloured spirit, under a receiver of the air-pump, or in any other way. When the thermometer is properly filled, the end D is heated red hot by a lamp, and then hermetically sealed, leaving the included air of about one-third of its natural density, to prevent the air which is in the spirit from dividing it in its expansion. To the tube is applied a scale, divided from the middle, into 100 equal parts, upwards and downwards. Fig. 2.

As spirit of wine is capable of a very considerable degree of rarefaction and condensation by heat and cold, when the heat of the atmosphere increases the spirit dilates, and consequently rises in the tube; and when the heat decreases, the spirit descends, and the degree or quantity of the motion is shown by a scale.

5
Its defects.

The spirit of wine thermometer was not subject to some of the inconveniences which attended the air thermometer. In particular, it was not affected by variations in the weight of the atmosphere: accordingly it soon came into general use among philosophers. It was, at an early period, introduced into Britain by Mr Boyle. To this instrument, as then used, there are, however, many objections. The liquor was of different degrees of strength, and therefore different tubes filled with it, when exposed to the same degree of heat, would not correspond. There was also another defect: The scale which was adjusted to the thermometer did not commence at any fixed point. The highest term was adjusted to the great sunshine heats of Florence, which are too variable and undetermined; and frequently the workman formed the scale according to his own fancy. While the thermometer laboured under such disadvantages it could not be of general use. *Martine's Essays.*

6
Different fixed points proposed by philosophers.

To obtain some fixed unalterable point by which a determined scale might be discovered, to which all thermometers might be accurately adjusted, was the subject which next drew the attention of philosophers. Mr Boyle, who seems at an early period to have studied this subject with much anxiety, proposed the freezing of the essential oil of aniseeds as a convenient point for graduating thermometers; but this opinion he soon laid aside. Dr Halley next proposed that thermometers should

Thermometer.

should be graduated in a deep pit under ground, where the temperature both in winter and summer is pretty uniform; and that the point to which the spirit of wine should rise in such a subterraneous place should be the point from which the scale should commence. But this proposal was evidently attended with such inconveniences that it was soon abandoned. He made experiments on the boiling point of water, of mercury, and of spirit of wine; and he seems rather to give a preference to the spirit of wine *. He objected to the freezing of water as a fixed point, because he thought that it admitted considerable latitude.

* Phil. Trans. Abr. II. 34.

7 Sir Isaac Newton's oil thermometer.

It seems to have been reserved to the all-conquering genius of Sir Isaac Newton to determine this important point, on which the accuracy and value of the thermometer depends. He chose, as fixed, those points at which water freezes and boils; the very points which the experiments of succeeding philosophers have determined to be the most fixed and convenient. Sensible of the disadvantages of spirit of wine, he tried another liquor which was homogeneous enough, capable of a considerable rarefaction, about 15 times greater than spirit of wine. This was linseed oil. It has not been observed to freeze even in very great colds, and it bears a heat about four times that of water before it boils. With these advantages it was made use of by Sir Isaac Newton, who discovered by it the comparative degree of heat for boiling water, melting wax, boiling spirit of wine, and melting tin; beyond which it does not appear that this thermometer was applied. The method he used for adjusting the scale of this oil thermometer was as follows: Supposing the bulb, when immerged in thawing snow, to contain 10,000 parts, he found the oil expand by the heat of the human body so as to take up $\frac{1}{39}$th more space, or 10,256 such parts; and by the heat of water boiling strongly 10,725; and by the heat of melting tin 11,516. So that reckoning the freezing point as a common limit between heat and cold, he began his scale there, marking it 0, and the heat of the human body he made 12°; and consequently, the degrees of heat being proportional to the degrees of rarefaction, or 256 : 725 : : 12 : 34, this number 34 will express the heat of boiling water; and by the same rule, 72 that of melting tin †. This thermometer was constructed in 1701.

† Phil. Trans. N° 270. or Abr. vol. iv. part 2.

8 Its imperfections.

To the application of oil as a measure of heat and cold, there are insuperable objections. It is so viscid, that it adheres too strongly to the sides of the tube. On this account it ascends and descends too slowly in case of a sudden heat or cold. In a sudden cold, so great a portion remains adhering to the sides of the tube after the rest has subsided, that the surface appears lower than the corresponding temperature of the air requires. An oil thermometer is therefore not a proper measure of heat and cold.

9 Reaumur's spirit of wine thermometer.

All the thermometers hitherto proposed were liable to many inconveniences, and could not be considered as exact standards for pointing out the various degrees of temperature. This led Reaumur to attempt a new one, an account of which was published in the year 1730 in the Memoirs of the Academy of Sciences. This thermometer was made with spirit of wine. He took a large ball and tube, the dimensions and capacities of which were known; he then graduated the tube, so that the space from one division to another might contain 1000th part of the liquor; the liquor containing 1000 parts when it stood at the freezing point. He adjusted the thermometer to the freezing point by an artificial congelation of water: then putting the ball of his thermometer and part of the tube into boiling water, he observed whether it rose 80 divisions: if it exceeded these, he changed his liquor, and by adding water lowered it, till upon trial it should just rise 80 divisions; or if the liquor, being too low, fell short of 80 divisions, he raised it by adding rectified spirit to it. The liquor thus prepared suited his purpose, and served for making a thermometer of any size, whose scale would agree with his standard.

Martine's Essays on the Construction of Thermometers.

10 Its defects.

This thermometer was far from being perfect. As the bulbs were three or four inches in diameter, the surrounding ice would be melted before its temperature could be propagated to the whole spirits in the bulb, and consequently the freezing point would be marked higher than it should be. Dr Martine accordingly found, that instead of coinciding with the 32d degree of Fahrenheit, it corresponded with the 34th, or a point a little above it. Reaumur committed a mistake also respecting the boiling point; for he thought that the spirit of wine, whether weak or strong, when immerged in boiling water, received the same degree of heat with the boiling water. But it is well known that highly rectified spirit of wine cannot be heated much beyond the 175th degree of Fahrenheit, while boiling water raises the quicksilver 37 degrees higher. There is another thermometer that goes by the name of *Reaumur's*, which shall be afterwards described.

11 Mercurial thermometers.

At length a different fluid was proposed, by which thermometers could be made free from most of the defects hitherto mentioned. This fluid was mercury, and seems first to have occurred to Dr Halley in the last century; but it was not adopted by him on account of its having a smaller degree of expansibility than the other fluids used at that time *. Boerhaave says that the mercurial thermometer was first constructed by Olaus Roemer; but the honour of this invention is generally given to Fahrenheit of Amsterdam, who presented an account of it to the Royal Society of London in 1724.

* Phil. Trans. vol. xvii. or Abr. vol. ii.

That we may judge the more accurately of the propriety of employing mercury, we will compare its qualities with those of the fluids already mentioned, air, alcohol, and oil.

12 Properties of air, alcohol, and oil.

Air is the most expansible fluid, but it does not receive nor part with its heat so quickly as mercury. Alcohol does not expand much by heat. In its ordinary state it does not bear a much greater heat than 175 of Fahrenheit; but when highly rectified it can bear a greater degree of cold than any other liquor hitherto employed as a measure of temperature. At Hudson's Bay, Mr Macnab, by a mixture of vitriolic acid and snow, made it to descend to 69 below 0 of Fahrenheit. This is an inconvenience, however, attending the use of this liquor; it is not possible to get it always of the same degree of strength. As to oil, its expansion is about 15 times greater than that of alcohol; it sustains a heat of 600°, and its freezing point is so low that it has not been determined; but its viscosity renders it useless.

13 Thermometrical properties of mercury.

Mercury is superior to alcohol and oil, and is much more manageable than air. 1. As far as the experiments

Thermometer

Recherches sur les Mod. de l'Atmosphere.

ments already made can determine, it is of all the fluids hitherto employed in the construction of thermometers, that which measures most exactly equal differences of heat by equal differences of its bulk: its dilatations are in fact very nearly proportional to the augmentations of heat applied to it (A). 2. Of all liquids it is the most easily freed from air. 3. It is fitted to measure high degrees of heat and cold. It sustains a heat of 600° of Fahrenheit's scale, and does not congeal till it fall 39 or 40 degrees below 0. 4. It is the most sensible of any fluid to heat and cold, even air not excepted. Count Rumford found that mercury was heated from the freezing to the boiling point in 58 seconds, while water took two minutes 13 seconds, and common air 10 minutes and 17 seconds. 5. Mercury is a homogeneous fluid, and every portion of it is equally dilated or contracted by equal variations of heat. Any one thermometer made of pure mercury is, *cæteris paribus*, possessed of the same properties with every other thermometer made of pure mercury. Its power of expansion is indeed about six times less than that of spirit of wine, but it is great enough to answer most of the purposes for which a thermometer is wanted.

* *Phil. Trans.* for 1786.

14 Fixed points.

The fixed points which are now universally chosen for adjusting thermometers to a scale, and to one another, are the boiling and freezing points of water. The boiling water point, it is well known, is not an invariable point, but varies some degrees according to the weight and temperature of the atmosphere. In an exhausted receiver, water will boil with a heat of 98° or 100°; whereas in Papin's digester it will require a heat of 412. Hence it appears that water will boil at a lower point, according to its height in the atmosphere, or to the weight of the column of air which presses upon it. In order to ensure uniformity therefore in the construction of thermometers, it is now agreed that the bulb of the tube be plunged in the water when it boils violently, the barometer standing at 30 English inches (which is its mean height round London, and the temperature of the atmosphere 55°. A thermometer made in this way, with its boiling point at 212°, is called by Dr Horsley *Bird's Fahrenheit*, because Mr Bird was the first person who attended to the state of the barometer in constructing thermometers.

15 Rule for adjusting thermometers to these.

As artists may be often obliged to adjust thermometers under very different pressures of the atmosphere, philosophers have been at pains to discover a general rule which might be applied on all occasions. M. de Luc, in his *Recherches sur les Mod. de l'Atmosphere*, from a series of experiments, has given an equation for the allowance on account of this difference, in Paris measure, which has been verified by Sir George Shuckburgh*; also Dr Horsley, Dr Maskelyne, and Sir George Shuckburgh, have adapted the equation and rules to English measures, and have reduced the allowances into tables for the use of the artist. Dr Horsley's rule deduced from De Luc's, is this:

* *Phil. Trans.* for 1775 and 1778.

$$\frac{99}{8990000}\log. z - 92.804 = h,$$

where h denotes the height of a thermometer plunged in boiling water, above the point of melting ice, in degrees of Bird's Fahrenheit, and z the height of the barometer in 10ths of an inch. From this rule he has computed the following table, for finding the heights, to which a good Bird's Fahrenheit will rise when plunged in boiling water, in all states of the barometer, from 27 to 31 English inches; which will serve, among other uses, to direct instrument-makers in making a true allowance for the effect of the variation of the barometer, if they should be obliged to finish a thermometer at a time when the barometer is above or below 30 inches; though it is best to fix the boiling point when the barometer is at that height.

Equation

(A) We have affirmed that the expansions of the bulk of quicksilver by heat are nearly (for they are not strictly so) in a regular arithmetical progression, according to the quantity of heat it is exposed to; and such seems to be the case according to the Table published by M. de Luc, at page 309 of his first volume on the Modifications of the Atmosphere. The following extract of this table shows these variations: and the first and second differences are added, in order to render these irregularities more sensible. They are such as can hardly be conceived from the nature of any substance, without the influence of extraneous and accidental causes, which may have escaped the attention of the observer; neither have they been found exactly true by Dr Crawford. M. de Luc supposes the whole heat from melting ice to that of boiling water to be divided into 80 parts; by the fractional subdivisions of which he expresses the absolute quantities of heat, answering to each 5 or 10 degrees of Reaumur's thermometer (=22,5 of Fahrenheit's scale); so that the whole sum of these fractions amounts exactly to the assumed number 80. They are as follow:

Cronstedt's Mineralogy, vol. ii.

	Reaumur's Thermometer.	*Fahrenheit's Thermometer.*	*Quantities of heat.*	*First differences.*	*Second differences.*
Degrees	80	212			
	70	189.5	9.44		
	60	167	9.60	.16	+ .06
	50	145.5	9.70	.10	— .06
	40	122	9.86	.16	— .06
	30	99.5	10.08	.22	+ .10
	20	77	10.20	.12	— .06

Thermometer.

16
Table formed from the rule.

Equation of the Boiling Point.

Barometer.	*Equation.*	*Difference.*
31.0	+ 1.57	
30.5	+ 0.79	0.78
30.0	0.00	0.79
29.5	— 0.80	0.80
29.0	— 1.62	0.82
28.5	— 2.45	0.83
28.0	— 3.31	0.85
27.5	— 4.16	0.86
27.0	— 5.04	0.88

The numbers in the first column of this table express heights of the quicksilver in the barometer in English inches and decimal parts: the second column shows the equation to be applied, according to the sign prefixed, to 212° of Bird's Fahrenheit, to find the true boiling point for every such state of the barometer. The boiling point for all intermediate states of the barometer may be had with sufficient accuracy, by taking proportional parts, by means of the third column of differences of the equations. See Philosophical Transactions, vol. lxiv. art. 30.; also Dr Maskelyne's Paper, vol. lxiv. art. 20.

17
Sir George Shuckburgh's observations compared with De Luc's rules

In the following table we have the result of fifteen different observations made by Sir George Shuckburgh compared with the result of M. de Luc's rules.

Height of the Barometer reduced to the same temperature of 50°	Mean Boiling Point by observation.	Boiling Point by De Luc's Rules.	Height of Barometer.	Boiling Point by Observation.	Boiling Point by De Luc's Rules.

18
Observations made by a committee of the Royal Society for adjusting the fixed points.

The Royal Society, fully apprised of the importance of adjusting the fixed points of thermometers, appointed a committee of seven gentlemen to consider of the best method for this purpose; and their report is published in the Phil. Trans. vol. lxvii. part ii. art. 37.

They observed, that though the boiling point be placed so much higher on some of the thermometers now made than on others, yet this does not produce any considerable error in the observations of the weather, at least in this climate; for an error of $1\frac{1}{2}$° in the position of the boiling point, will make an error only of half a degree in the position of 92°, and of not more than a quarter of a degree in the point of 62°. It is only in nice experiments, or in trying the heat of hot liquors, that this error in the boiling point can be of much importance.

In adjusting the freezing as well as the boiling point, the quicksilver in the tube ought to be kept of the same heat as that in the ball. When the freezing point is placed at a considerable distance from the ball, the pounded ice should be piled to such a height above the ball, that the error which can arise from the quicksilver in the remaining part of the tube not being heated equally with that in the ball, shall be very small, or the observed point must be corrected on that account according to the following table:

19
Table for correcting the freezing point.

Heat of the Air.	Correction.
42°	.00087
52	.00174
62	.00261
72	.00384
82	.00435

The correction in this table is expressed in 1000th parts of the distance between the freezing point and the surface of the ice: e. gr. if the freezing point stands seven inches above the surface of the ice, and the heat of the room is 62, the point of 32° should be placed 7×00261, or .018 of an inch lower than the observed point. A diagonal scale will facilitate this correction.

Thermometer.

20 The quicksilver in the tube ought to be heated to the same degree as that in the ball.

The committee observe, that in trying the heat of liquors, care should be taken that the quicksilver in the tube of the thermometer be heated to the same degree as that in the ball; or if this cannot be done conveniently, the observed heat should be corrected on that account; for the manner of doing which, and a table calculated for this purpose, we must refer to their excellent report in the Phil. Trans. vol. lxvii. part ii. art. 37.

21 The tubes ought to be cylindrical and capillary.

With regard to the choice of tubes, they ought to be exactly cylindrical. But though the diameter should vary a little, it is easy to manage that matter in the manner proposed by the Abbé Nollet *, by making a small portion of the quicksilver, e. gr. as much as fills up an inch or half an inch, slide backward and forward in the tube; and thus to find the proportions of all its inequalities, and from thence to adjust the divisions to a scale of the most perfect equality. The capillary tubes are preferable to others, because they require smaller bulbs, and they are also more sensible, and less brittle. The most convenient size for common experiments has the internal diameter about the 40th or 50th of an inch, about nine inches long, and made of thin glass, that the rise and fall of the mercury may be better seen.

* *Leçons de Phys. Exp.* tom. iv. p. 376.

22 The number of degrees into which the scale ought to be divided.

The next thing to be considered, is of what number of degrees or divisions the scale ought to consist, and from what point it ought to commence. As the number of the divisions of the scale is an arbitrary matter, the scales which have been employed differ much from one another in this circumstance. Fahrenheit has made 180 degrees between the freezing and boiling water point. Amontons made 73, and Sir Isaac Newton only 34. There is, however, one general maxim, which ought to be observed: *That such an arithmetical number should be chosen as can easily be divided and subdivided, and that the number of divisions should be so great that there shall seldom be occasion for fractions.* The number 80 chosen by Reaumur answers extremely well in this respect, because it can be divided by several figures without leaving a remainder; but it is too small a number: the consequence of which is, that the degrees are placed at too great a distance from one another, and fractions must therefore be often employed. We think, therefore, that 160 would have been a more convenient number. Fahrenheit's number 180 is large enough, but when divided its quotient soon becomes an odd number.

23 At what point the scale ought to commence.

As to the point at which the scale ought to commence, various opinions have been entertained. If we knew the beginning or lowest degree of heat, all philosophers would agree, that the lowest point of the thermometer ought to be fixed there; but we know neither the lowest nor the highest degrees of heat; we observe only the intermediate parts. All that we can do, then, is to begin it at some invariable point, to which thermometers made in different places may easily be adjusted. If possible too, it ought to be a point at which a natural well-known body receives some remarkable change from the effects of heat or cold. Fahrenheit began his scale at the point at which snow and salt congeal. Kirwan proposes the freezing point of mercury. Sir Isaac Newton, Hales, and Reaumur adopted the freezing point of water. The objection to Fahrenheit's lowest point is, that it commences at an artificial cold never known in nature, and to which we cannot refer our feelings, for it is what few can ever experience. There would be several great advantages gained, we allow, by adopting the freezing point of mercury. It is the lowest degree of cold to which mercury can be applied as a measure; and it would render unnecessary the use of the signs plus and minus, and the extension of the scale below 0. But we object to it, that it is not a point well known; for few, comparatively speaking, who use thermometers, can have an opportunity of seeing mercury congealed. As to the other advantage to be gained by adopting the freezing point of mercury, namely, the abolition of negative numbers, we do not think it would counterbalance the advantage, to be enjoyed by using a well-known point. Besides, it may be asked, Is there not a propriety in using negative numbers to express the degree of cold, which is a negative thing? Heat and cold we can only judge of by our feelings: the point then at which the scale should commence, ought to be a point which can form to us a standard of heat and cold; a point familiar to us from being one of the most remarkable that occurs in nature, and therefore a point to which we can with most clearness and precision refer to in our minds on all occasions. This is the freezing point of water chosen by Sir Isaac Newton, which of all the general changes produced in nature by cold is the most remarkable. It is, therefore, the most convenient point, for the thermometers to be used in the temperate and frigid zones; we may say over the globe, for even in the hottest countries of the torrid zone many of the mountains are perpetually covered with snow.

24 Thermometers generally used.

The thermometers which are at present in most general use, are Fahrenheit's, De l'Isle's, Reaumur's, and Celsius's. Fahrenheit's is used in Britain, De l'Isle's in Russia, Reaumur's and the thermometre centigrade in France, and Celsius's, the same as the last named, in Sweden. They are all mercurial thermometers. For their description and the method of comparing them together, see CHEMISTRY, N° 198—201. See also Plate DXXXIV.

25 Account of self-registering thermometers.

As in meteorological observations it is necessary to attend to the greatest rise and fall of the thermometer, attempts have been made to construct a thermometer which might register the greatest degree of heat, or greatest degree of cold, which took place during the absence of the observer. In 1757 Lord Charles Cavendish presented to the Royal Society of London a thermometer in two different forms; the one contrived to mark the greatest degree of heat, and the other the greatest degree of cold.

26 Lord Charles Cavendish's thermometer.

Plate DXXXIII. fig. 3.

The first consists of a glass tube AB, fig. 3. with a cylindrical bulb B at the lower end, and capillary at the top, over which there is fixed a glass ball C. The bulb and part of the tube are filled with mercury, the top of which shows the degrees of heat as usual. The upper part of the tube above the mercury is filled with spirit of wine; the ball C is also filled with the same liquor almost to the top of the capillary tube. When the mercury rises the spirit of wine is also raised, and falls into the ball C, which is so made that the liquor cannot return into the tube when the mercury sinks; consequently the height of the spirit of wine in the ball, added to that in the tube, will give the greatest degree of heat to which the thermometer has pointed since last observation. When a new observation is to be made, the instrument must be inclined

Thermometer.

inclined till the liquor in the ball cover the end of the capillary tube.

In this thermometer it is evident that the mercury must be affected by the weight and elasticity of the spirit of wine, and therefore it will not correspond to any of the common mercurial thermometers.

Fig. 4.

The thermometer for showing the greatest degree of cold is represented in fig. 4. by the crooked tube ABCD. This instrument is filled with spirit of wine, with the addition of as much mercury as is sufficient to fill both legs of the syphon, and about a fourth or fifth part of the hollow ball C. We are not told what the proportion of mercury was to that of spirit of wine. The degrees of heat are shown by the rise or fall of the mercury in the leg AB. The thermometer marks the greatest fall by means of the hollow ball C. When the mercury in the longer leg sinks by cold, that in the shorter will rise and run over into the ball C, from which it cannot return when the mercury subsides in the shorter and rises in the longer leg. The upper part of the shorter leg will therefore be filled with a column of spirits of a length proportional to the increase of heat; the bottom or lower surface of which, by means of a proper scale, will show how much the mercury has been lower than it is; which being subtracted from the present height will give the lowest point to which the mercury has fallen. That the thermometer may be fitted for a new observation, the mercury must be made to run back from the ball into the shorter leg, by inclining the tube and heating the ball.

27
Mr Six's thermometer.
Fig. 5.

In 1782 Mr Six proposed another self-registering thermometer. It is properly a spirit of wine thermometer, though mercury is also employed for supporting an index. *a b*, fig. 5. is a thin tube of glass 16 inches long, and $\frac{5}{10}$ths of an inch caliber: *c d e* and *f g h* are smaller tubes about $\frac{1}{10}$th of an inch caliber. These three tubes are filled with highly rectified spirit of wine, except the space between *d* and *g*, which is filled with mercury. As the spirit of wine contracts or expands in the middle tube, the mercury falls or rises in the outside tubes.

Fig. 6.

An index, such as that represented in fig. 6. is placed on the surface, within each of these tubes, so light as to float upon it. *k* is a small glass tube $\frac{3}{4}$ths of an inch long, hermetically sealed at each end, and inclosing a piece of steel wire nearly of its own length. At each end *l*, *m*, of this small tube, a short tube of black glass is fixed, of such a diameter as to pass freely up and down within either of the outside tubes of the thermometer *e c* or *f h*. From the upper end of the index is drawn a spring of glass to the fineness of a hair, and about $\frac{4}{7}$ths of an inch long; which being placed a little oblique, presses lightly against the inner surface of the tube, and prevents the index from descending when the mercury descends. These indexes being inserted one into each of the outside tubes, it is easy to understand how they point out the greatest heat or cold that has happened in the observer's absence. When the spirit of wine in the middle tube expands, it presses down the mercury in the tube *h f*, and consequently raises it in the tube *e c*; consequently the index on the left hand tube is left behind and marks the greatest cold, and the index in the right hand tube rises and marks the greatest heat.

28
Rutherford's thermometer.

In 1790 a paper was given in to the Royal Society of Edinburgh, describing two thermometers, newly invented, by Dr John Rutherford of Middle Bailish; the one for registering the highest and the other for registering the lowest degree of heat to which the thermometer has risen or fallen during the absence of the observer. An account of them may be found in the third volume of the Transactions of the Society.

29
Mr Keith's thermometer.

A new self-registering thermometer has been invented by Mr Keith of Ravelstone, which we consider as the most ingenious, simple, and perfect, of any which has hitherto appeared. Its simplicity is so great, that it requires only a very short description to make it intelligible.

Fig 7.

AB, fig. 7. is a thin glass tube about 14 inches long and $\frac{3}{4}$ths of an inch caliber, close or hermetically sealed at top. To the lower end, which is open, there is joined the crooked glass tube BE, seven inches long, and $\frac{4}{10}$ths of an inch caliber, and open at top. The tube AB is filled with the strongest spirit of wine, and the tube BE with mercury. This is properly a spirit of wine thermometer, and the mercury is used merely to support a piece of ivory or glass, to which is affixed a wire for raising one index or depressing another, according as the mercury rises or falls. E is a small conical piece of ivory or glass, of such a weight as to float on the surface of the mercury. To the float is joined a wire called the *float-wire*, which reaches upwards to H, where it terminates in a knee bent at right angles. The float-wire, by means of an eye at *a*, moves easily along the small harpsichord wire GK. LL are two indexes made of thin black oiled silk, which slide upwards or downwards with a force not more than two grains. The one placed above the knee points out the greatest rise, and the one placed below it points out the greatest fall, of the thermometer.

When the instrument is to be prepared for an observation, both indexes are to be brought close to the knee H. It is evident, that when the mercury rises, the float and float-wire, which can be moved with the smallest force, will be pushed upwards till the mercury become stationary. As the knee of the float-wire moves upwards, it will carry along with it the upper index L. When the mercury again subsides, it leaves the index at the highest point at which it was raised, for it will not descend by its own weight: As the mercury falls the float-wire does the same; it therefore brings along with it the lower index L, and continues to depress it till it again becomes stationary or ascend in the tube; in which case it leaves the lower index behind it as it had formerly left the upper. The scale to which the indexes point is placed parallel to the slender harpsichord wire. It may be seen more distinctly in fig. 8. Fig. 8.
That the scale and indexes may not be injured by the wind and rain, a cylindrical glass cover, close at top, and made so as exactly to fit the part G F, is placed over it.

The ingenious inventor has another improvement in contemplation, which, if upon trial it be found to answer, will make this thermometer as perfect as can be desired, provided there do not arise some errors from the variable pressure of the atmosphere. He proposes to adapt clock-work to this thermometer, in such a way as to register with the utmost precision the degrees of heat and cold for every month, day, and minute in the year. The principles on which this clockwork is to be formed we shall forbear to describe, hoping that the author himself, after his experiment has met with the success which

which we ardently wish, will favour the world with his own account of it.

The same ingenious gentleman has invented a self-registering barometer, upon the same principles with the self registering thermometer. We have had the pleasure of seeing both; and are convinced that they will fully gratify the wishes of all who are engaged in meteorological studies. He is also in expectation of being soon able to produce an air-thermometer free from the defects of those which were formerly made, as he has found out a way of preventing it from being affected by the pressure of the atmosphere.

30 M. de Luc's supposed improvements.

M. de Luc has described the best method of constructing a thermometer, fit for determining the temperature of the air, in the mensuration of heights by the barometer. He has also shown how to divide the scale of a thermometer, so as to adapt it for astronomical purposes in the observation of refractions.

31 Mr Cavallo has proposed a thermometrical barometer.

Mr Cavallo, in 1781, proposed the construction of a thermometrical barometer, which, by means of boiling water, might indicate the various gravity of the atmosphere, or the height of the barometer. But as he does not say that the instrument has been tried with the desired success, we forbear to describe it. Those who wish to know his ideas respecting it may consult the Philosophical Transactions, vol. lxxi. p. 524.

32 The thermometers described above too limited.

The thermometers hitherto described are very limited in their extent; they indeed point out to us the lowest degrees of heat which are commonly observed even in cold climates, but they by no means reach to those degrees of heat which are very familiar to us. The mercurial thermometer extends no farther than to 600 of Fahrenheit's scale, the heat of boiling mercury; but we are sure that the heat of solid bodies, when heated to ignition, or till they emit light, far exceeds the heat of boiling mercury.

33 Sir Isaac Newton's method of extending the scale of the thermometer.

In order to remedy this defect, Sir Isaac Newton, whose genius overcame those obstacles which ordinary minds could not approach, attempted by an ingenious experiment to extend the scale to any degree required. Having heated a mass of iron red hot, and exposed it to the cold air, he observed the time which elapsed till it became cold, or of the same temperature with the air; and when the heat so far decreased that he could apply some known measure (as a thermometer) to it, he observed the degrees of heat lost in given times; and thence drew the general conclusion, that the quantities of heat lost in given small spaces are always proportional to the heat remaining in the body, reckoning the heat to be the excess by which it is warmer than the ambient air. So that taking the number of minutes which it took to cool after it came to a determined point in an arithmetical progression, the decrements of the heat of the iron would be continually proportional. Having by this proportion found out the decrements of heat in a given time after it came to a known point, it was easy, by carrying upwards the same proportion to the beginning of its cooling, to determine the greatest heat which the body had acquired. This proportion of Sir Isaac's was found by Dr Martine to be somewhat inaccurate. The heat of a cooling body does not decrease exactly in proportion to that which the body retains. As the result of many observations, he found that two kinds of proportion took place, an arithmetical as well as the geometrical proportion which Sir Isaac Newton had adopted; namely, that the decrements of heat were partly proportional to the times (that is, that quantities of heat are lost in equal times), as well as partly in proportion to the remaining heat; and that if these two are added together the rule will be sufficiently accurate. By the geometrical proportion which Sir Isaac Newton adopted he discovered the heat of metals red hot or in fusion.

Martine's Essays.

34 Mr Wedgwood's thermometer for measuring high degrees of heat

This method, so successfully pursued by Sir Isaac, was sufficient to form a scale of high degrees of heat, but was not convenient for practical purposes. Accordingly the late Mr Wedgwood invented a very simple thermometer which marks with much precision the different degrees of ignition, from a dull red heat visible in the dark to the heat of an air-furnace. It consists of two rulers fixed upon a smooth flat plate, a little farther asunder at the one end than at the other, leaving an open longitudinal space between them. Small pieces of alum and clay mixed together are made of such a size as just to enter at the wide end; and are heated along with the body whose heat we wish to determine. The earthy body contracts according to the degree of heat, so that when applied to the wide end of the gage, it will slide on towards the narrow end, less or more according to the degree of heat to which it has been exposed.

35 described. Fig. 9.

ABCD, fig. 9. is a smooth flat plate; and EF and GH two rulers or flat pieces, a quarter of an inch thick, fixed flat upon the plate, with the sides that are towards one another made perfectly true, a little farther asunder at one end EG than at the other end FH: thus they include between them a long converging canal, which is divided on one side into a number of small equal parts, and which may be considered as performing the offices both of the tube and scale of the common thermometer. It is obvious, that if a body, so adjusted as to fit exactly at the wider end of this canal, be afterwards diminished in its bulk by fire, as the thermometer pieces are, it will then pass further in the canal, and more and more so according as the diminution is greater; and conversely, that if a body, so adjusted as to pass on to the narrow end, be afterwards expanded by fire, as is the case with metals, and applied in that expanded state to the scale, it will not pass so far; and that the divisions on the side will be the measures of the expansions of the one, as of the contractions of the other, reckoning in both cases from that point to which the body was adjusted at first.

Philosophical Transactions, vol lxxiv.

I is the body whose alteration of bulk is thus to be measured. This is to be gently pushed or slid along towards the end FH, till it is stopped by the converging sides of the canal. See Chemistry, N° 1412.

A very ingenious application of Fahrenheit's thermometer has been made by Mrs Lovi, glass-blower in Edinburgh, for ascertaining the temperature of compost dunghills, for regulating the temperature of hot-beds, and observing the changes of temperature in corn and haystacks when they are put up damp. This may be called an agricultural thermometer, and has been found of great use for the above purposes.

THERMOPYLÆ, in *Ancient Geography*, a narrow pass or defile, between the Sinus Maliacus on the east, and a steep branch of Mount Oeta, covered with unpassable woods, on the west; leading from Thessaly to Locris and Bœotia. These mountains

tains divide Greece in the middle, in the same manner as the Apennine does Italy; forming one continued ridge from Leucate on the west to the sea on the east, with thickets and rocks interspersed. The valley is of small breadth, and completely occupied by a marsh, through which it is impossible for horse or foot to penetrate. Through the middle of this marsh a paved road was made by the Greeks, which still remains, and affords the only path to Greece from Thessaly. The Thermæ or hot springs, from which the place had its name, are near the narrowest part of the pass; and their temperature was found by Dr Clarke to be 111°. At the south entrance of the defile is a small eminence, on which Dr Clarke found a tumulus, with the remains of a massive pedestal of red breccia much time-worn, and evidently the tomb of the 300 Spartans, to whose immortal memories this monument was consecrated. The rising ground on which the monument stands is the spot where the Spartans fell. The remains of the wall which shut up the pass are also yet visible. For an account of the battle of Thermopylæ, see SPARTA.

THESEA, in antiquity, feasts celebrated by the Athenians in honour of Theseus, consisting of sports and games, with mirth and banquets. Such as were poor and unable to contribute to them were entertained at the public expence.

THESEUS, a famous hero of antiquity, ranked among the demigods, whose history is fabulous. He was the reputed son of Ægeus king of Athens. He threw Sciron, a cruel robber, down a precipice; fastened Procrustes tyrant of Attica to a bending pine, which being let loose tore him asunder; killed the Minotaur kept in the labyrinth by King Minos, in Crete; and by the assistance of that prince's daughter, Ariadne, who gave him a clue, escaped out of that labyrinth, and sailed with his deliverer to the isle of Naxos, where he had the ingratitude to leave her.

Theseus afterwards overcame the Centaurs, subdued the Thebans, and defeated the Amazons. He assisted his friend Pirithous in his expedition to the infernal regions to carry off Proserpine; but was imprisoned by Pluto, till he was released by Hercules. He is also said to have established the Isthmian games, in honour of Neptune; to have united the twelve cities of Attica; and to have founded a republic there, 1236 B.C. Some time after, taking a voyage into Epirus, he was seized by Aidonus king of the Molossians; meanwhile Menestheus rendered himself master of Athens. But at length Theseus being released from prison, retired to Scyros, where King Lycomedes caused him to be thrown from the top of a rock. Theseus had several wives; the first of whom was Helena the daughter of Tyndarus; the second, Hypolita queen of the Amazons; and the last, Phedra sister to Ariadne, who punished him for his infidelity to her sister, by her incestuous passion for his son Hippolitus.

THESIS, a general position which a person advances, and offers to maintain. In taking degrees in universities, the candidates are generally obliged to write a thesis, which they must afterwards defend.

THESIUM, BASE FLUELLIN; a genus of plants belonging to the class of pentandria, and order of monogynia. See BOTANY *Index*.

THESPIS, a famous Greek tragic poet, and the first representer of tragedy at Athens. He carried his troop from village to village in a waggon, from which they performed their pieces. Alcestis was the first tragedy they performed at Athens, 536 B. C. See THEATRE.

THESSALIAN CHAIR, so called from Thessaly, where chairs of this figure were most in use; it is recommended by Hippocrates* in place of a machine for reducing a recent luxation of the shoulder bone. The back of this chair is perpendicular to the seat, as Galen tells us; by which construction it is distinguished and accommodated to the operation.

* *Lib. de Art.*

THESSALY, a country of Greece, whose boundaries have been different at different periods. Properly speaking, Thessaly was bounded on the south by the southern parts of Greece, or Græcia Propria; east, by the Ægean; north, by Macedonia and Mygdonia; and west, by Illyricum and Epirus. It was generally divided into four separate provinces, Thessaliotis, Pelasgiotis, Istiæotis, and Phthiotis, to which some add Magnesia. It has been severally called *Æmonia*, *Pelasgicum*, *Argos*, *Hellas*, *Argeia*, *Dryopis*, *Pelasgia*, *Pyrrhæa*, &c. The name of Thessaly is derived from Thessalus, one of its monarchs. Thessaly is famous for a deluge which happened there in the age of Deucalion. Its mountains and cities are also celebrated, such as Olympus, Pelion, Ossa, Larissa, &c. The Argonauts were partly natives of Thessaly. The inhabitants of the country passed for a treacherous nation, so that false money was called *Thessalian coin*, and a perfidious action a *Thessalian deceit*. Thessaly was originally governed by kings, till it became subject to the Macedonian monarchs. The cavalry was universally esteemed, and the people were superstitious and addicted to the study of magic and incantations. See *Lucan*, lib. vi. ver. 438. &c.; *Dionys.* 219; *Curt.* lib. iii. cap. 2.; *Ælian*, *Var. Hist.* lib. iii. cap. 1.; *Paus.* lib. iv. cap. 36. lib. x. cap. 1.; *Mela*, lib. ii. cap. 3.; *Justin*, lib. vii. cap. 6.; *Diod.* iv. *Lempriere's Dictionary.*

Thessaly is now called *Janna*, a province of European Turkey, bounded by Macedonia on the north, by the Archipelago on the east, by Achaia or Livadia on the south, and by Epirus on the west.

THETIS, in Pagan mythology, the wife of Oceanus, and the mother of Nereus and Doris, who were married to each other; and from this marriage sprung the nymphs of the earth and sea. Among the sea nymphs there was one named *Thetis the Younger*, who excelled all the rest in beauty, and for whom Jupiter conceived such a passion, that he resolved to espouse her: but being informed by the Destinies that she would bring forth a son who would rise above his father, he married her to Peleus. To their nuptials all the gods and goddesses were invited except Discord, who, to be revenged for this contempt, threw a golden apple into the assembly, on which was engraven, *For the Fairest*. Juno, Pallas, and Venus, disputed for this apple; but Paris being chosen to decide the difference, adjudged it to Venus. From this marriage of Thetis and Peleus sprung Achilles.

THEURGY, θεουργια, a name which the ancients gave to that sacred part of magic which we sometimes call *white magic*, or the *white art*.

The word is formed from θεος, "God," and εργον, "work;" q. d. the art of doing divine things, or things which God alone can do: or the power of working extraordinary and supernatural things, by invoking the

names

names of God, saints, angels, &c. Accordingly, those who have written of magic in general, divide it into three parts: the first whereof is called *theurgy*, as operating by divine or celestial means; the second *natural magic*, performed by the powers of nature; and the third, comprehending *necromancy*, *sorcery*, and *witchcraft* or *magic*, performed by the assistance of demons or departed men. See MAGIC.

THIBET. See TIBET.

THIGH. See ANATOMY, N° 58.

THINKING, a general name for an act or operation of the mind. See METAPHYSICS.

THIRLAGE. See LAW, N° clxx. 12—18.

THIRST, an uneasy sensation arising from a deficiency of the saliva to moisten the inward parts of the mouth. Hence arises a strong desire for drink; and thirst is a symptom generally attending fevers of all kinds.—Thirst is best allayed by acids, water kept a while in the mouth, then spit out, and repeated as required; a pit of bread chewed with a little water, which latter may be gradually swallowed; if the person is very hot, brandy is the best for holding in the mouth, but should be spit out again: except in fevers, large draughts of cold water are hurtful.

Preservation against Hunger and THIRST. See HUNGER.

THISTLE, a name applied to different genera and species of plants belonging chiefly to the syngenesia class. See CARDUUS, ONOPORDUM, SERRATULA, SONCHUS, and also DIPSACUS, BOTANY *Index*.

Order of the THISTLE, or *of St Andrew*, a military order of knighthood in Scotland, the rise and institution of which is variously related by different authors. Lesley bishop of Ross reports, that the night before the battle between Athelstan king of Northumberland and Hungus king of the Picts, a bright cross, in form of that whereon St Andrew (the tutelar saint of Scotland) suffered martyrdom, appeared to Hungus; who having gained the victory, ever after bore the figure of that cross on his banners. Others assert, that Achaius king of Scotland first instituted this order, after having made the famous league offensive and defensive with Charlemagne king of France. But although the thistle had been acknowledged as the symbol of the kingdom of Scotland from the reign of Achaius, yet some refer the beginning of this order to Charles VII. of France. Others place the foundation of it as low as the year 1500.

The chief and principal ensign is a gold collar composed of thistles and sprigs of rue interlinked with amulets of gold, having pendent thereto the image of St Andrew with his cross, and the motto, NEMO ME IMPUNE LACESSET. "No body shall provoke me with impunity."

The ordinary or common ensign worn by the knights is a star of four silver points, and over them a green circle, bordered and lettered with gold, containing the said motto, and in the centre is a thistle; all which is embroidered on their left breast, and worn with the collar, with a green ribband over the left shoulder, and brought under the right arm; pendent thereto is the image of St Andrew, with his cross, in a purple robe, within an oval of gold enamelled vert, with the former motto; but sometimes they wear, encircled in the same manner, a thistle crowned.

About the time of the Reformation, this order was dropped, till James II. of Great Britain resumed it, by creating eight knights. The Revolution unsettled it again; and it lay neglected, till Queen Anne, in 1703, restored it to the primitive design, of twelve knights of St Andrew.

THLAPSI, BASTARD-CRESS, or *Mithridate-Mustard*; a genus of plants belonging to the class of tetradynamia. See BOTANY *Index*.

THOLOUSE. See TOULOUSE.

THOMÆANS, THOMISTS. See *CHRISTIANS of St Thomas*.

THOMAS AQUINAS. See AQUINAS.

St THOMAS's Day, a festival of the Christian church, observed on Dec. 21. in commemoration of St Thomas the apostle.

St THOMAS of Canterbury's Day, a festival of the Romish church, observed on Dec. 29. in memory of Thomas Becket archbishop of Canterbury, who was murdered, or as the Romanists say, martyred, in the reign of King Henry II.

THOMAS the Reymour, called also *Thomas Lermont* and *Thomas of Erceldon*, was born at Erceldon, or Earlston, a village near Melrose in Tweeddale, in what year is uncertain; but he was an old man when Edward I. was carrying on war in Scotland.

The character of Lermont as a prophet, and which was common to him with Linus, Orpheus, and other early poets in many countries, arose, if we may believe Mackenyie in his Lives of Scottish Writers, from his having conferences with Eliza, a nun and prophetess at Haddington. Lermont put her predictions into verse, and thus came in for his share of the prophetic spirit. None of these ancient prophecies now remain; but the following, which pretends to be one of them, is given from a manuscript of the time of Edward I. or II. The countess of Dunbar is the lady famous for the defence of her castle against the English. Her proper title was *Countess of March*; but it was common in these times to style a nobleman from his chief residence. Thus Gilbert Strongbow, earl of Pembroke, is called *Earl of Striguil*, from his residence at Striguil castle, near Chepstow, Monmouthshire, &c.

Pinkerton's Account of Scottish Poets.

La Countesse de Donbar demande a Thomas de Essedoune, quant la guere d'Escoce prendreit fyn. E yl la repoundy, et dyt—

When man as mad a kyng of a capped mon.
When mon is levere other mons thyng than is owen.
When londe thouys forest, and forest ys feide.
When hares kendles othe hersten.
When Wyt and Wille werres togedere.
When mon makes stables of kyrkes; and steles castles wyth styes.
When Rokesbourh nys no burgh; ant market is at Forwyleye.
When the alde is gan, and the newe is come that doue noht.
When Bambourne ys donged with dede men.
When men ledes men in ropes to buyen ant to sellen.
When a quarter of whaty whete is chaunged for a colt of ten markes.
When prude prikes, ant pees is leyd in priscun.
When a Scot ne may hym hude ase hare in forme, that the Englysh ne shall hym fynde.

When ryht ant wrong astente the togedere.
When laddes weddeth lovedies.
When Scottes flen so faste, that for faute of ship, hy
drouneth hemselve.
When shal this be ?
Nouther in thyne tyme, ne in myne.
Ah comen, ant gone,
Withinne twenty wynter ant'on.

In fact, the prophecies of Lermont appear to have been merely traditional; nay, it seems doubtful if he ever pretended to such folly, notwithstanding Mackenyie's story of Eliza. The reverence of the people for a learned and respectable character seems to have been the sole foundation of Thomas's claim to prophecy. But, in the 16th century, prophecies were made, and ascribed to him, as well as others given to Bede, Merlin, &c. (A). They were printed at Edinburgh, 1615; reprinted 1680, and 1742.

THOMISM. See Aquinas.

THOMSON, James, an excellent British poet, the son of a Scotch divine, was born in the shire of Roxburgh in 1700, and was educated in the university of Edinburgh with a view to the ministry. But his genius inclining him to the study of poetry, which he soon found would be incompatible with that of theology, or at least might prevent his being provided for in that way in his own country, he relinquished his views of engaging in the sacred function, and repaired to London in consequence of some encouragement which he had received from a lady of quality there, a friend of his mother.

The reception he met with wherever he was introduced, emboldened him to risk the publication of his excellent poem on Winter.—This piece was published in 1726; and from the universal applause it met with, Mr Thomson's acquaintance was courted by people of the first taste and fashion. But the chief advantage which it procured him was the acquaintance of Dr Rundle, afterward bishop of Derry, who introduced him to the late lord chancellor Talbot; and some years after, when the eldest son of that nobleman was to make his tour on the continent, Mr Thomson was chosen as a proper companion for him. The expectations which his Winter had raised, were fully satisfied by the successive publications of the other seasons; of Summer, in the year 1727; of Spring, in the following year; and of Autumn, in a quarto edition of his works, in 1730. Beside the Seasons, and his tragedy of Sophonisba, written and acted with applause in the year 1729, he had, in 1727, published his poem to the memory of Sir Isaac Newton, with an account of his chief discoveries; in which he was assisted by his friend Mr Gray, a gentleman well versed in the Newtonian philosophy. That same year the resentment of our merchants, for the interruption of their trade by the Spaniards in America, running very high, Mr Thomson zealously took part in it, and wrote his Britannia, to rouse the nation to revenge.

With the honourable Charles Talbot, our author visited most of the courts in Europe, and returned with his views greatly enlarged; not only of exterior nature and the works of art, but of human life and manners, and of the constitution and policy of the several states, their connections, and their religious institutions. How particular and judicious his observations were, we see in his poem of Liberty, begun soon after his return to England. We see at the same time to what a high pitch his care of his country was raised, by the comparisons he had all along been making of our happy government with those of other nations. To inspire his fellow-subjects with the like sentiments, and show them by what means the precious freedom we enjoy may be preserved, and how it may be abused or lost, he employed two years in composing that noble work, upon which he valued himself more than upon all his other writings. On his return to England with Mr Talbot (who soon after died), the chancellor made him his secretary of briefs; a place of little attendance, suiting his retired indolent way of life, and equal to all his wants. From this office he was removed, when death, not long after, deprived him of his noble patron. He then found himself reduced to a state of precarious dependence. In this situation, having created some few debts, and his creditors finding that he had no longer any certain support, became inexorable; and imagined by confinement to force that from his friends, which his modesty would not permit him to ask. One of these occasions furnished Quin, the celebrated actor, with an opportunity of displaying the natural goodness of his heart, and the disinterestedness of his friendship. Hearing that Thomson was confined in a spunging house for a debt of about 70l. he repaired to the place; and, having inquired for him, was introduced to the bard. Thomson was a good deal disconcerted at seeing Quin, as he had always taken pains to conceal his wants; and the more so, as Quin told him he was come to sup with him. His anxiety upon this head was however removed, upon Quin's informing him, that, as he supposed it would have been inconvenient to have had the supper dressed in the place they were in, he had ordered it from an adjacent tavern; and, as a prelude, half a dozen of claret was introduced. Supper being over, and the bottle circulating pretty briskly, Quin said, "It is time now we should balance accounts." This astonished Thomson, who imagined he had some demand upon him; but Quin perceiving it, continued, "Mr Thomson, the pleasure I have had in perusing your works I cannot estimate at less than a hundred pounds, and I insist upon now acquitting the debt." On saying this, he put down a note of that value, and took his leave, without waiting for a reply.

The profits arising from his works were not inconsiderable; his tragedy of Agamemnon, acted in 1738, yielded a good sum. But his chief dependence was upon the prince of Wales, who settled on him a handsome allowance, and honoured him with many marks of particular favour. Notwithstanding this, however, he was

(A) Sibilla and Banister Anglicus are mentioned in the time of Edward IV. (MSS. Cot. Dom. A. IX.). A long Latin prophecy of Bridlington is there given. Waldhave and Eltraine seem also English prophets. In the whole collection, therefore, Thomas is the only Scottish one.

Thomson. was refused a licence for his tragedy of Edward and Eleonora, which he had prepared for the stage in the year 1736, for some political reasons. Mr Thomson's next performance was the Masque of Alfred, written in the year 1740 jointly with Mr Mallet, by the command of the prince of Wales, for the entertainment of his royal highness's court at Clifden, his summer residence.

Mr Thomson's poem, entitled the Castle of Indolence, was his last work published by himself; his tragedy of Coriolanus being only prepared for the theatre, when a fatal accident robbed the world of one of the best of men and best of poets. He would commonly walk the distance between London and Richmond (where he lived) with any acquaintance that offered, with whom he might chat and rest himself, or perhaps dine by the way. One summer evening being alone in his walk from town to Hammersmith, he had over-heated himself, and in that condition imprudently took a boat to carry him to Kew; apprehending no bad consequence from the chill air on the river, which his walk to his house, towards the upper end of Kew-lane, had always hitherto prevented. But now the cold had so seized him, that the next day he was in a high fever. This, however, by the use of proper medicines, was removed, so that he was thought out of danger; till the fine weather having tempted him to expose himself once more to the evening dews, his fever returned with violence, and with such symptoms as left no hopes of a cure. His death happened on the 27th of August 1748.

Mr Thomson had improved his taste upon the finest originals, ancient and modern. The autumn was his favourite season for poetical composition, and the deep silence of the night he commonly chose for his studies. The amusement of his leisure hours were civil and natural history, voyages, and the best relations of travellers. Though he performed on no instrument, he was passionately fond of music, and would sometimes listen a full hour at his window to the nightingales in Richmond gardens; nor was his taste less exquisite in the arts of painting, sculpture, and architecture. As for the more distinguishing qualities of his mind and heart, they best appear in his writings. There his devotion to the Supreme Being, his love of mankind, of his country, and friends, shine out in every page; his tenderness of heart was so unbounded, that it took in even the brute creation. It is not known, that through his whole life he ever gave any person a moment's pain, either by his writings or otherwise. He took no part in the political squabbles of his time, and was therefore respected and left undisturbed by both sides. These amiable virtues did not fail of their due reward; the applause of the public attended all his productions, and his friends loved him with an enthusiastic ardour.

Johnson's Lives of the Poets. "As a writer (says Dr Johnson), he is entitled to one praise of the highest kind; his mode of thinking, and of expressing his thoughts, is original. His blank verse is no more the blank verse of Milton, or of any other poet, than the rhymes of Prior are the rhymes of Cowley. His numbers, his pauses, his diction, are of his own growth, without transcription, without imitation. He thinks in a peculiar train, and thinks always as a man of genius; he looks round on Nature and on life with the eye which Nature bestows only on a poet; the eye that distinguishes, in every thing represented to its view, whatever there is on which imagination can delight to be detained, and with a mind that at once comprehends the vast, and attends to the minute. The reader of the Seasons wonders that he never saw before what Thomson shews him, and that he never yet has felt what Thomson impresses."

Thomson ‖ Thornhill.

His testamentary executors were the lord Lyttelton, whose care of our poet's fortune and fame ceased not with his life; and Mr Mitchell, a gentleman equally noted for the truth and constancy of his private friendship, and for his address and spirit as a public minister. By their united interests, the orphan play of Coriolanus was brought on the stage to the best advantage; from the profits of which, and the sale of manuscripts and other effects, a handsome sum was remitted to his sisters. His remains were deposited in the church of Richmond, under a plain stone, without any inscription. A handsome monument was erected to him in Westminster abbey in the year 1762, the charge of which was defrayed by the profits arising from a splendid edition of all his works in 4to; Mr Millar the bookseller, who had purchased all Mr Thomson's copies, giving up his property on this grateful occasion. A monument has also been erected to him at the place of his birth.

THOR, the eldest and bravest of the sons of Odin and Frea, was, after his parents, the greatest god of the Saxons and Danes while they continued heathens. They believed, that Thor reigned over all the aerial regions, which composed his immense palace, consisting of 540 halls; that he launched the thunder, pointed the lightning, and directed the meteors, winds, and storms. To him they addressed their prayers for favourable winds, refreshing rains, and fruitful seasons; and to him the fifth day of the week, which still bears his name, was consecrated. *Henry's History of Great Britain, vol. ii. part iv.*

THORAX. See ANATOMY.

WHITE or *HAW* THORN. See CRATÆGUS, BOTANY *Index*.

THORN, a town of Poland, in Regal Prussia, and in the palatinate of Culm. It was formerly a Hanseatic town, but is now subject to Prussia; it is large and well fortified. Copernicus, the celebrated discoverer of the true system of the universe, was born here in 1472. It is seated on the Vistula, and contains 10,000 inhabitants. E. Long. 18. 30. N. Lat. 52. 55.

THORNBACK. See RAIA, ICHTHYOLOGY *Index*.

THORNHILL, SIR JAMES, an eminent English painter, was born in Dorsetshire in 1676, of an ancient family; but was constrained to apply to some profession by the distresses of his father, who had been reduced to the necessity of selling his family estate. His inclination directed him to the art of painting; and on his arrival at London he applied to his uncle, the famous Dr Sydenham, who enabled him to proceed in the study of the art under the direction of a painter who was not very eminent. However, the genius of Thornhill made ample amends for the insufficiency of his instructer, and by a happy application of his talents he made so great a progress, that he gradually rose to the highest reputation. *Dictionary of Painters.*

His genius was well adapted to historical and allegorical compositions; he possessed a fertile and fine invention; and he sketched his thoughts with great ease, freedom, and spirit. He excelled also equally in portrait,

trait, perspective, and architecture; shewed an excellent taste for design, and had a free and firm pencil. Had he been so fortunate as to have studied at Rome and Venice, to acquire greater correctness at the one, and a more exact knowledge of the perfection of colouring at the other, no artist among the moderns might perhaps have been his superior. Nevertheless, he was so eminent in many parts of his profession, that he must for ever be ranked among the best painters of his time; and his performances in the dome of St Paul's church at London, in the hospital at Greenwich, and at Hampton-court, are such public proofs of his merit as will convey his name to posterity with great honour.

This painter lived in general esteem; he enriched himself by the excellence of his works; was appointed state-painter to Queen Anne, from whom he received the honour of knighthood; had the singular satisfaction to repurchase his family estate; and was so much distinguished as to be elected one of the members of parliament. He died in 1732.

THOROUGH-WAX, in *Botany*. See BUPLEURUM.

THOTH, or THEUT, (called by the Phœnicians *Taaut*, by the Greeks *Hermes*, and by the Romans *Mercury*), was a Phœnician of very superior talents, and one of the civilizers of mankind. He was prime minister to Osiris, whom, after his death, he deified; and he was himself deified by his countrymen the Egyptians, for the benefits that he had rendered to the human race. See MERCURY, MYTHOLOGY, N° 34. and POLYTHEISM, N° 18.

THOUGHT, a general name for all the ideas consequent on the operations of the mind, and even on the operations themselves. See METAPHYSICS.

THOUGHT, in composition. See ORATORY, Part I. and II.

THOUINIA, a genus of plants belonging to the class of diandria, and order of monogynia. See BOTANY *Index*.

THRACE, a country very frequently mentioned by the Greek and Latin writers, deriving its name, according to Josephus, from Tiras one of the sons of Japhet. It was bounded on the north by Mount Hæmus; on the south, by the Ægean sea; on the west, by Macedon and the river Strymon; and on the east, by the Euxine sea, the Hellespont, and the Propontis.—The Thracian Chersonesus is a peninsula inclosed on the south by the Ægean sea, on the west by the gulf of Melas, and on the east by the Hellespont; being joined on the north to the continent by a neck of land about 37 furlongs broad. The inland parts of Thrace are very cold and barren, the snow lying on the mountains the greatest part of the year; but the maritime provinces are productive of all sorts of grain and necessaries for life; and withal so pleasant, that Mela compares them to the most fruitful and agreeable countries of Asia.

The ancient Thracians were deemed a brave and warlike nation, but of a cruel and savage temper; being, according to the Greek writers, strangers to all humanity and good nature. It was to the Thracians, however, that the Greeks were chiefly indebted for the polite arts that flourished among them; for Orphæus, Linus, Musæus, Thamyris, and Eumolpus, all Thracians, were the first, as Eustathius informs us, who charmed the inhabitants of Greece with their eloquence and melody, and persuaded them to exchange their fierceness for a sociable life and peaceful manners; nay, great part of Greece was anciently peopled by Thracians. Tereus, a Thracian, governed at Daulis in Phocis, where the tragical story of Philomela and Progne was acted. From thence a body of Thracians passed over to Eubœa, and possessed themselves of that island. Of the same nation were the Aones, Tembices, and Hyanthians, who made themselves masters of Bœotia; and great part of Attica itself was inhabited by Thracians, under the command of the celebrated Eumolpus. It is not, therefore, without the utmost ingratitude and injustice that the Greeks style them *Barbarians*, since to them chiefly they were indebted both for the peopling and polishing of their country.

Thrace was anciently divided into a number of petty states, which were first subdued by Philip of Macedon. On the decline of the Macedonian empire, the country fell under the power of the Romans. It continued under subjection to them till the irruption of the Turks, in whose hands it still remains.

THRASHING, in *Agriculture*, the operation by which corn is separated from the straw. This operation is performed in a variety of ways, sometimes by the feet of animals, sometimes by a flail, and sometimes by a machine.

The most ancient method of separating the corn from the straw was by the hoofs of cattle or horses. This was practised by the Israelites, as we find from the books of Moses; it was also common among the Greeks and Romans*. Flails and thrashing machines were also not uncommon among these nations†. The flail which was used by the Romans, called *baculus*, *fustis*, or *pertica*, was probably nothing more than a cudgel or pole. The thrashing machine, which was called *tribula* or *tribulum*, and sometimes *traha*, was a kind of sledge made of boards joined together, and loaded with stone or iron. Horses were yoked to this machine, and a man was seated upon it to drive them over the sheaves of corn.

* *Pliny*, xviii. 30. *Virgil.* Georg. iii. 132. *Col.* ii. 21. *Tibull.* i. 5. 21.

† Isaiah xviii. 27. *Homer*, Il. xx. 495.

Different methods are employed in different countries for separating the corn from the stalk. In the greatest part of France the flail is used; but in the southern districts it is generally performed by the feet of animals. Animals are also used for the same purpose in Spain, in Italy, in the Morea, in the Canaries, in China, and in the vicinity of Canton, where the flail is also sometimes used. It appears that in hot climates the grains do not adhere so firmly to the stalk as in cold countries, and therefore may be more easily separated. This will explain the reason why animals are so frequently employed in hot countries for treading out the corn; whereas in cold climates we know they are seldom tried, and have no reason to suppose thst they would answer the purpose. In the Isle of France in Africa, rice and wheat are thrashed with poles, and maize with sticks; for it has not been possible to teach the negroes the use of the flail.

The animals used for treading out corn are, oxen, cows, horses, mules, and even asses when the quantity is not great. The operation is performed in this manner: The sheaves, after being opened, are spread in such a manner that the ears of the corn are laid as much uppermost as possible, and a man, standing in the centre, holds the halters of the cattle, which are made to trot round as in a manege; whilst other men with forks

forks shake the straw up from time to time, and the cattle are trotted over it again and again till they have beaten out all the grain. This method is expeditious enough; but besides bruising a considerable quantity of corn, it requires a great many cattle, and injures the legs of the horses and mules, which are preferred before cows and oxen for this work.

The flail is undoubtedly a much better instrument for thrashing corn than the feet of animals, for it separates the grain from the straw and husks both more effectually and more expeditiously; yet it is liable to many objections. It is a very laborious employment, too severe indeed even for a strong man; and as it is usually the interest of the thrasher rather to thrash much than to thrash clean, a good deal of corn will generally be left upon the straw. It is therefore an object of great importance in husbandry to procure a proper machine for separating the corn from the straw.

The first thrashing machine attempted in modern times, of which we have received any account, was invented in Edinburgh by Mr Michael Menzies about the year 1732. It consisted of a number of instruments like flails, fixed in a moveable beam, and inclined to it at an angle of ten degrees. On each side of the beam in which the flails were fixed, floors or benches were placed for spreading the sheaves on. The flails were moved backwards and forwards upon the benches by means of a crank fixed on the end of an axle, which made about 30 revolutions in a minute.

The second thrashing machine was invented by Mr Michael Stirling, a farmer in the parish of Dunblane, Perthshire. Of this discovery we have received a very accurate and authentic account from his son, the reverend Mr Robert Stirling minister of Crieff.

It is an old proverb, that necessity is the mother of invention. This was verified on the present occasion. Besides his ordinary domestic servants, Mr M. Stirling had occasion sometimes to hire an additional number to thrash out his grain, and frequently found it difficult to procure so many as he needed. This naturally led him to reflect whether the operation of thrashing could not easily be performed by machinery. Accordingly, so early as the year 1753, under the pretence of joining in the amusements of his children, he formed in miniature a water mill, in which two iron springs made to rise and fall alternately, represented the motion of two flails, by which a few stalks of corn put under them might be speedily thrashed. This plan he executed on a scale sufficiently large within two years after, making the springs about ten feet long, each of which had one end firmly screwed into a solid plank, and the other terminated in a round batoon of solid iron, two feet long and above an inch in diameter. Under these the sheaves were conveyed gradually forward in a narrow channel or trough, by passing between two indented horizontal cylinders, similar to those now used in the most of the thrashing mills in that part of the country, and called *feeders*. In this manner the thrashing was executed completely, and with considerable rapidity; but as the operation was performed on a low floor, and no method contrived for carrying off the straw, the accumulation of it produced such confusion, and the removal of it was attended with such danger that this scheme was very soon entirely abandoned. The mortification arising from disappointment, and especially the scoffs of his neighbours, for what was universally accounted an absurd and ridiculous attempt, served only to stimulate the exertions of the inventor to accomplish his designs on another plan.

Laying aside therefore the iron springs with the feeders, and all the apparatus adapted to them, he retained only an outer or water wheel, with an inner or cog-wheel moving on the same axle: to this inner wheel, which had 48 teeth or cogs, he applied a vertical trundle or pinion, with seven notches, the axle of which passed through a floor above the wheel, and having its upper pivot secured in a beam six feet above that floor. At the distance of three feet three inches above the floor two straight pieces of squared wood, each four feet long, passed through the axle of the trundle at right angles, forming four arms, to be moved round horizontally. To the extremities of these arms were fixed four iron plates, each 20 inches long, and eight broad at the end next the arms, but tapering towards a point at the other end. This large horizontal fly constituting four thrashers, was inclosed within a wooden cylindrical box three feet and a half high and eight in diameter. On the top of the box was an opening or port (two or three ports were made at first, but one was found sufficient) eight inches wide, and extending from the circumferece a foot and a half towards its centre, through which the corn sheaves descended, being first opened and laid one by one on a board with two ledges gently declining towards the port; on which board they were moderately pressed down with a boy's hand, to prevent them from being too hastily drawn in by the repeated strokes of the thrashers. Within the box was an inclined plane, along which the straw and grain fell down into a wide wire riddle two feet square, placed immediately under a hole of nearly the same size. The riddle received a jerk at every revolution of the spindle from a knob placed on the side of it, and was instantly thrust backward by a small spring pressing it in the opposite direction. The short straw, with the grain and chaff which passed through the wide riddle, fell immediately into an oblong straight riddle, which hung with one end raised and the other depressed, and was moved by a contrivance equally simple as the other; and having no ledge at the lower end, the long chaff which could not pass through the riddle dropped from thence to the ground; while the grain and most of the chaff falling through the riddle into a pair of common barn-fanners that stood under it on the ground floor, the strong grain, the weak, and the chaff, were all separated with great exactness. The fanners were moved by a rope or band running circuitously in a shallow niche cut on the circumference of the cog-wheel. The straw collected gradually in the bottom of the box over the wide riddle, and through an opening two and a half feet wide, and as much in height, left in that side of the box nearest the brink of the upper floor, was drawn down to the ground with a rake by the person or persons employed to form it into sheaves or rolls.

Such was the thrashing mill invented by Mr Michael Stirling, which, after various alterations and improvements he completed in the form now described, A. D. 1758. By experiment it was found that four bolls of oats, Linlithgow measure, could be thrashed by it in 25 minutes. From that period he never used a common flail in thrashing, except for humbling or bearding barley.

THRASHING MACHINE. PLATE DXXXV.

Thrashing. ley. In every other kind of grain he performed the whole operation of thrashing with the mill; and continued always to use it till 1772, when he retired from business, and his thrashing mill became the property of his second son, who continued to use it with equal advantage and satisfaction. Several machines were constructed on the same plan, particularly one near Stirling, under Mr Stirling's direction, for Mr Moir of Leckie, in 1765, which, we undertand, has been used ever since, and gives complete satisfaction to the proprietor. There was another erected in 1778 by Mr Thomas Keir (in the parish of Muthil and county of Perth), who has contrived a method of bearding barley with it: and by the addition of a small spindle with short arms contiguous to the front of the box, and moved by a band common to it and the great spindle to which it is parallel, the straw is shaken and whirled out of the box to the ground. That this machine did not come immediately into general use, was owing partly to the smallness of the farms in that part of the country, whose crops could easily be thrashed by the few hands necessarily retained on them for other purposes; and chiefly to an apprehension that the machine could only be moved by water; an apprehension which experience proves to be entirely groundless. The machine, however, was ingenious, and did great credit to the worthy inventor, and certainly deserved a better fate than it was destined to undergo.

A third thrashing mill was invented in 1772, by two persons nearly about the same time, and upon the same principles. The inventors were, Mr Alderton who lived near Alnwick, and Mr Smart at Wark in Northumberland. The operation was performed by rubbing. The sheaves were carried round between an indented drum of about six feet diameter, and a number of indented rollers arranged round the circumference of the drum, and attached to it by means of springs; so that while the drum revolved, the fluted rollers rubbed the corn off from the straw by rubbing against the flutings of the drum. But as a considerable quantity of the grain was bruised in passing between the rollers, the machine was soon laid aside.

In 1776 an attempt was made by Mr Andrew Meikle, an ingenious millwright in the parish of Tyninghame, East Lothian, to construct a new machine upon the principles which had been adopted by Mr Menzies already mentioned. This consisted in making joints in the flails, which Mr Menzies had formed without any. But this machine, after much labour and expence, was soon laid aside, on account of the difficulty of keeping it in repair, and the small quantity of work performed, which did not exceed one boll or six Winchester bushels of barley per hour.

Some time after this, Mr Francis Kinloch, then junior of Gilmerton, having visited the machine invented in Northumberland, attempted an improvement upon it. He inclosed the drum in a fluted cover; and instead of making the drum itself fluted, he fixed upon the outside of it four fluted pieces of wood, which by means of springs could be raised a little above the circumference of the drum, so as to press against the fluted covering, and thus rub off the ears of corn as the sheaves passed round between the drum and the fluted covering. But not finding this machine to answer his expectation (for it bruised the grain in the same manner as the Northumberland machine did), he sent it to Mr Meikle, that he might, if possible, rectify its errors. Thrashing.

Mr Meikle, who had long directed his thoughts to this subject, applied himself with much ardour and perseverance to the improvement and correction of this machine; and after spending a good deal of time upon it, found it was constructed upon principles so erroneous, that to improve it was impracticable.

At length, however, Mr Meikle's own genius invented a model, different in principle from the machines which had already been constructed. This model was made in the year 1785; and in the following year the first thrashing machine on the same principles was erected in the neighbourhood of Alloa, in the county of Stirling, by Mr George Meikle the son of the inventor. This machine answered completely the wishes of Mr Stein, the gentleman for whom it was erected, who gave the most ample testimony of his satisfaction both to the inventor and to the public. The fame of this discovery soon spread over the whole country, and a great many farmers immediately applied to Mr Meikle, desiring to have thrashing-mills erected on their farms. The discovery, it appeared, would be profitable, and it was reasonable that the inventor should enjoy the profits of his invention. He accordingly applied for a patent; which, after considerable expence, arising from the opposition of some persons, who claimed a share in the discovery, was granted.—These machines are now becoming very common in many parts of Scotland, and are increasing very considerably in number every year over all the united kingdom.

We will now endeavour to describe this machine in its most improved state; which is so simple, that with the assistance of a plate, exhibiting the plan of elevation, fig. 1. the ground plan, fig. 2. and the 3d showing its essential parts in a distinct manner, we hope it will be easily understood by all our readers who have not had an opportunity of seeing it. The power employed for turning that part of the machine which separates the corn from the straw is produced by four wheels (when moved by horses), the teeth of which move in one another and turn the drum, on which four scutchers are fixed. The sheaves are introduced between two fluted rollers, which hold them firm, and draw them in gradually, while the scutchers strike off the grain from the straw as it passes through. This will suffice for a general idea of this machine. We will now be more particular. Plate DXXXV.

The large spur-wheel A, fig. 1. and 2. which has 276 cogs, is horizontal, and moves the pinion D, which has 14 teeth. The pinion B moves the crown-wheel C, which has 84 teeth; the wheel C moves a second pinion D, which has 16 teeth; and the pinion D moves the drum HIKL. The drum is a hollow cylinder three feet and a half diameter, and placed horizontally; on the outside of which the scutchers are fixed by strong screw bolts. The scutchers consist of four pieces of wood, faced on one side with a thin plate of iron, placed at an equal distance from each other, and at right angles to the axis of the drum. Fig. 1. and 2.

The sheaves are spread on an inclined board F, fig. 3. from which they are introduced between two fluted rollers GG made of cast iron, about three inches and a half in diameter, and making about 35 revolutions in a minute. As these rollers are only about three quarters of Fig. 3.

Thrashing. of an inch distant from the scutchers or leaves of the drum HIKL, they serve to hold the sheaves fast, while the scutchers *a*, *b*, *c*, *d*, moving with prodigious velocity, separate the grain completely from the straw, and at the same time throw out both grain and straw upon the concave rack M, lying horizontally with slender parallel ribs, so that the corn passes through them into a hopper N placed below. From the hopper it passes through a harp or riddle O into a pair of fanners P, from which, in the most improved machines, it comes out clean and fit for the market. The straw, after being thrown by the scutchers *a*, *b*, *c*, *d*, into the rack, is removed from it by a rake QRST into a place contiguous V. The rake consists of four thin pieces of wood or leaves; on the end of each of these leaves is ranged a row of teeth *e*, *f*, *g*, *h*, five inches long. The rake moves in a circular manner in the convave rack, while the teeth catch hold of the straw, and throw it out of the rack. These are all the essential parts of the machine; the rest may be easily understood by the references to the plate. W is the horse-course, N° 1, which is 27 feet diameter. X is the pillar for supporting the beams on which the axle of the spur-wheel is fixed. YYY are three spindles for moving the two fluted rollers, the rake, and fanners. To the description now given we have only to add, that the drum has a covering of wood Z at a small distace above it, for the purpose of keeping the sheaves close to the scutchers.

The advantages of this machine are many. As the drum makes 300 revolutions in a minute, the four scutchers together make 200 strokes in the same space of time. From such power and velocity, it is evident that much work must be performed. When the horses go at the rate of two and one-third miles per hour, from three to six bolls will be thrashed; but as the quantity thrashed will be less when the straw is long than when it is short, we shall take the average at four bolls. One gentleman, whose veracity and accuracy we can depend on, assures us, that his mill thrashed 63 bolls in a day; by which, we suppose, he meant 10 hours. To prove the superior advantage of this machine to the common method of thrashing with flails, a gentleman ordered two equal quantities of oats to be thrashed by the mill and by flails. When the corn was cleaned and measured, he obtained one-sixteenth more from the sheaves thrashed by the mill than from those thrashed by the flail. We are also informed by another gentleman who has studied this machine with much attention, and calculated its advantages with care, that, independently of having the corn much cleaner separated from the straw than is usually done by flails, there is a saving of 30 or 40 per cent. in the expence of thrashing.

The number of persons requisite for attending the mill when working is six: One person drives the horses; a second hands the sheaves to a third, who unties them, while a fourth spreads them on the inclined boards and presses them gently between the rollers; a fifth person is necessary to riddle the corn as it falls from the fanners, and a sixth to remove the straw (A).

Thrashing ‖ Throne.

This machine can be moved equally well by water, wind, or horses. Mr Meikle has made such improvements on the wind-mill as to render it much more manageable and convenient than formerly; and we are informed many windmills are now erecting in different parts of the country. As to the comparative expence of these different machines, the erection of the horse machine is least; but then the expence of employing horses must be taken into consideration. One of this kind may be erected for 70l. A water-mill will cost 10l. more on account of the expence of the water-wheel. A wind-mill will cost from 200l. to 300l. sterling.

THRAVE *of Corn*, an expression denoting 24 sheaves or four shocks of six sheaves to the shock; though in some countries they only reckon 12 sheaves to the thrave.

THRASYBULUS, a renowned Athenian general and patriot, the deliverer of his country from the yoke of the 30 tyrants, lived about 294 B. C.*

* See *Attica*, N° 99—174.

THRASYMENUS LACUS, in *Ancient Geography*, a lake of Etruria, near Perusia, and not far from the Tiber, fatal to the Romans in the Punic war. Now *Il Lago de Perugia* in the Ecclesiastical State.

THREAD, a small line made up of a number of fine fibres of any vegetable or animal substance, such as flax, cotton, or silk; from which it takes its name of linen, cotton, or silk thread.

THREATENING LETTERS. Knowingly to send any letter without a name, or with a fictitious name, demanding money, or any other valuable thing, or threatening (without any demand) to kill or fire the house of any person, is made felony without benefit of clergy. And sending letters, threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort from him any money or other valuable chattels, is punishable by statute 30 Geo. II. cap. 24. at the discretion of the court, with fine, imprisonment, pillory, whipping, or transportation for seven years.

THRESHING. See THRASHING.

THRIFT. See STATICE, BOTANY *Index*.

THRINAX, SMALL JAMAICA FAN-PALM, a genus of plants belonging to the class of palmæ. See BOTANY *Index*.

THRIPS, a genus of insects belonging to the order of hemiptera. See ENTOMOLOGY *Index*.

THROAT, the anterior part of an animal, between the head and the shoulders.

THROAT-WORT. See CAMPANULA, BOTANY *Index*.

THRONE, a royal seat or chair of state, enriched with ornaments of architecture and sculpture, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings and other sovereigns.

THROSTLE.

(A) We add, on the authority of an experienced farmer, that of the six persons necessary to attend the thrashing machine, only two can in justice be charged to the account of the machine; namely, the person who manages the horses, and the one who feeds the machine: For in the usual mode of thrashing by the flail, it requires the same number of persons as the thrashing machine does to clear an equal quantity of corn from the chaff in the same manner.

THROSTLE. See TURDUS, } ORNITHOLOGY *Index*.
THRUSH. See TURDUS, }

THRUSH, or *Aphtha*. See MEDICINE *Index*.

THRYALLIS, a genus of plants belonging to the class decandria, and order of monogynia; and in the natural system ranging under the 38th order, *Tricoccæ*. See BOTANY *Index*.

THUANUS, JACOBUS AUGUSTUS, youngest son of the president de Thou, was famous for his erudition. He was born in 1553; and having finished his studies and travels, was made president a-mortier, and took possession thereof in 1595. He was employed in several important offices of state, and in reforming the university of Paris. He wrote the history of his own time in Latin, from the year 1543 to 1608, in 138 books; a work, both for subject and style, worthy of the ancients. He also left memoirs of his own life, besides poems; and died at Paris, 1617.

THUCYDIDES, a celebrated Greek historian, was born at Athens 471 B. C. He was the son of Olorus, and grandson of Miltiades, who is thought to have been descended from Miltiades the famous Athenian general, and to have married the king of Thrace's daughter. He was educated in a manner suitable to his quality, that is, in the study of philosophy and eloquence. His master in the former was Anaxagoras, in the latter Antiphon; one, by his description in the eighth book of his History, for power of speech almost a miracle, and feared by the people on that account. Suidas and Photius relate, that when Herodotus recited his history in public, a fashion in use then and many ages after, Thucydides felt so great a sting of emulation, that it drew tears from him; insomuch that Herodotus himself took notice of it, and congratulated his father on having a son who showed so wonderful an affection to the Muses. Herodotus was then 29 years of age, Thucydides about 16.

When the Peloponnesian war began to break out, Thucydides conjectured truly, that it would prove a subject worthy of his labour; and it no sooner commenced than he began to keep a journal. This explains the reason why he has attended more to chronological order than to unity of design. During the same war he was commissioned by his countrymen to relieve Amphipolis; but the quick march of Brasidas the Lacedæmonian general defeated his operations; and Thucydides, unsuccessful in his expedition, was banished from Athens. This happened in the eighth year of this celebrated war; and in the place of his banishment the general began to write an impartial history of the important events which had happened during his administration, and which still continued to agitate the several states of Greece. This famous history is continued only to the 21st year of the war; and the remaining part of the time till the demolition of the walls of Athens was described by the pen of Theopompus and Xenophon. Thucydides wrote in the Attic dialect, as being possessed of most vigour, purity, elegance, and energy. He spared neither time nor money to procure authentic materials; and the Athenians, as well as their enemies, furnished him with many valuable communications, which contributed to throw great light on the different transactions of the war. His history has been divided into eight books; the last of which is imperfect, and supposed to have been written by his daughter.

Lempriere's Dictionary.

The historian of Halicarnassus has often been compared with the son of Olorus, but each has his peculiar excellence. Sweetness of style, grace and elegance of expression, may be called the characteristics of the former; while Thucydides stands unequalled for the fire of his descriptions, the conciseness, and at the same time the strong and energetic manner of his narratives. His relations are authentic, as he himself was interested in the events he mentions; his impartiality is indubitable, as he nowhere betrays the least resentment against his countrymen, and the factious partizans of Cleon, who had banished him from Athens. The history of Thucydides was so admired by Demosthenes, that he transcribed it eight different times, and read it with such attention, that he could almost repeat it by heart. Thucydides died at Athens, where he had been recalled from his exile about 411 years B. C.

The best edition of Thucydides is that of Oxford, published in 1696, folio, and that of Duker, published at Amsterdam in 1731, folio.

THUJA, the ARBOR VITÆ; a genus of plants belonging to the class of monadelphia, and order of monœcia; and in the natural system ranging under the 51st order, *Coniferæ*. See BOTANY *Index*.

THULE, or THYLÆ, in *Ancient Geography*, an island in the most northern parts of the German ocean. Its situation was never accurately ascertained by the ancients, hence its present name is unknown by modern historians. Some suppose that it is the island now called Iceland, or part of Greenland, and others that it was *Foula*. See FOULA.

THUMB, in *Anatomy*, one of the extremities of the hand.

THUMB-Cap, an uninhabited island in the South sea, lies about seven leagues north-west of Lagoon island; it is low, woody, of a circular form, and not much above a mile in compass.

THUMMIM. See URIM.

THUNBERGIA, a genus of plants belonging to the class of didnyamia. See BOTANY *Index*.

THUNDER, the noise occasioned by the explosion of a flash of lightning echoed back from the inequalities on the surface of the earth, in like manner as the noise of a cannon is echoed, and in particular circumstances forms a rolling lengthened sound. See ELECTRICITY.

THUNDERBOLT. When lightning acts with extraordinary violence, and breaks or shatters any thing, it is called a *thunderbolt;* which the vulgar, to fit it for such effects, suppose to be a hard body, and even a stone. But that we need not have recourse to a hard solid body to account for the effects commonly attributed to the thunderbolt, will be evident to any one who considers those of the pulvis fulminans and of gunpowder; and more especially the astonishing powers of electricity. It has been supposed that meteoric stones may have given rise to the notion of a thunderbolt.

THUNDER-House. See ELECTRICITY.

THURINGIA, a division of the circle of Upper Saxony in Germany. It is a fruitful tract, abounding in corn, especially wheat; in black cattle, sheep, and horses. It is about 73 miles in length, and as much in breadth. It contains 47 towns, 14 boroughs, betwixt 700 and 800 villages, 300 noble estates, 7 superintendencies, and 5 under consistories. Thuringia, the country of the ancient Thuringi, or Catti, a branch of the

Vandals, mentioned by Tacitus, was formerly a kingdom, afterwards a county, then a landgravate, and was governed by its own princes for many ages, till 1124, when it devolved to the marquis of Misnia, and, with that country, afterwards to the duke of Saxony. But the modern Thuringia is only a part of the ancient, nay, but a part of the ancient South Thuringia, which comprehends besides, a large share of the modern Franconia, Hesse, &c. On the extinction of the male line of the ancient landgraves in 1247, it came to the margraves of Meissen, ancestors to the present electoral family. The elector has no voice in the diet, on account of his share in the landgravate or circle of Thuringia. Erfurt is the capital.

THURSDAY, the fifth day of the Christian week, but the sixth of that of the Jews.

THUS, Frankincense, a solid brittle resin, brought to us in little globes or masses, of a brownish or yellowish colour on the outside, internally whitish or variegated with whitish specks. It is supposed to be the produce of the pine that yields the common turpentine, and to concrete upon the surface of the terebinthinate juice soon after it has issued from the tree. See Incense.

THUYA. See Thuja.

THYMUS, Thyme; a genus of plants belonging to the class of didynamia, and in the natural system ranging under the 42d order, *Verticillatæ*. See Botany *Index*.

Thymus. See Anatomy *Index*.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus, and wherewith they furnished the menades in their Bacchanalia.

Thyrsus, a mode of flowering resembling the cone of a pine. It is, says Linnæus, a panicle contracted into an oval or egg-shaped form. The lower footstalks, which are longer, extend horizontally, whilst the upper ones are shorter and mount vertically. Lilac and butter-bur furnish examples.

TIARA, an ornament or habit wherewith the ancient Persians covered their head; and with which the Armenians and kings of Pontus are represented on medals; these last, because they were descended from the Persians. Latin authors call it indifferently *tiara* and *cidaris*. Strabo says the tiara was in form of a tower; and the scholiast on Aristophanes's comedy, Αχαρνης, act i. scene 2. affirms that it was adorned with peacocks feathers.

Tiara is also the name of the pope's triple crown. The tiara and keys are the badge of the papal dignity; the tiara of his civil rank, and the keys of his jurisdiction: for as soon as the pope is dead, his arms are represented with the tiara alone, without the keys. The ancient tiara was a round high cap. John XXIII. first encompassed it with a crown. Boniface VIII. added a second crown; and Benedict XII. a third.

TIARELLA, a genus of plants, belonging to the class of decandria; and in the natural system ranging under the 13th order, *Succulentæ*. See Botany *Index*.

TIBER, a great river of Italy which runs through the pope's territories, passing by Perugia and Orvietto; and having visited Rome, falls into the Tuscan sea at Ostia, 15 miles below that city.

TIBET, called by the Tartars *Barantola, Bootan*, or *Tangoot*, and by the Chinese *Tsang*, is situated between 27° and 35° north latitude; and is reckoned to be 1350 miles from east to west, and 480 from north to south. It is bounded on the north by the country of the Mongols and the desert of Kobi; on the east by China; on the west by Hindostan, and on the south by the same country and the kingdom of Ava. In the valleys lying between the lower mountains are many tribes of Indian people; and a dispute happening between the heirs of one of the rajahs or petty princes, one party called to their assistance the Boutaners, and the other the British. The latter prevailed; and the fame of British valour being carried to the court of Tibet, the Teeshoo Lama, who ruled the state under the Delai-Lama, at that time in his minority, sent a deputation to Bengal, desiring peace for the prince who had been engaged in war with the British. This was readily granted by the governor; and Mr Bogle was sent ambassador to the court of Tibet, where he resided several months; and after an absence of a year and a quarter, returned to Calcutta. The account of this gentleman's expedition hath not been published by himself; but from Mr Stewart's letter to Sir John Pringle, published in the Philosophical Transactions, vol. lxvii. we learn the following particulars, collected from his papers.

"Mr Bogle divides the territories of the Delai-Lama into two different parts. That which lies immediately contiguous to Bengal, and which is called by the inhabitants *Doopo*, he distinguishes by the name of *Bootan;* and the other, which extends to the northward as far as the frontiers of Tartary, called by the natives *Pu*, he styles *Tibet*. Bootan is ruled by the Dah Terriah, or Deb Rajah. It is a country of steep and inaccessible mountains, whose summits are crowned with eternal snow; they are intersected with deep valleys, through which pour numberless torrents that increase in their course, and at last, gaining the plains, lose themselves in the great rivers of Bengal. These mountains are covered down their sides with forests of stately trees of various sorts; some (such as pines, &c.) which are known in Europe; others, such as are peculiar to the country and climate. The valleys and sides of the hills which admit of cultivation are not unfruitful, but produce crops of wheat, barley, and rice. The inhabitants are a stout and warlike people, of a copper complexion, in size rather above the middle European stature, hasty and quarrelsome in their temper, and addicted to the use of spirituous liquors; but honest in their dealings, robbery by violence being almost unknown among them. The chief city is Tassey Seddein, situated on the Patchoo. Tibet begins properly from the top of the great ridge of the Caucasus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to some of the dominions of the Russian empire. The woods, which everywhere cover the mountains in Boutan, are here totally unknown; and, except a few straggling trees near the villages, nothing of the sort is to be seen. The climate is extremely severe and rude. At Chamnanning, where he wintered, although it be in latitude 31° 39′, only 8° to the northward of Calcutta, he often found the thermometer in his room at 29° by Fahrenheit's scale; and in the middle of April the standing waters were all frozen, and heavy showers of snow perpetually fell. This, no doubt, must be owing to the great elevation of the country, and to the vast

Tibet.

vast frozen space over which the north wind blows uninterrupted from the pole, through the vast deserts of Siberia and Tartary, till it is stopped by this formidable wall.

"The Tibetians are of a smaller size than their southern neighbours, and of a less robust make. Their complexions are also fairer, and many of them have even a ruddiness in their countenances unknown to the other climates of the east. Those whom Mr Bogle saw at Calcutta appeared to have quite the Tartar face. They are of a mild and cheerful temper; the higher ranks are polite and entertaining in conversation, in which they never mix either strained compliments or flattery. The common people, both in Bootan and Tibet are clothed in coarse woollen stuffs of their own manufacture, lined with such skins as they can procure: but the better orders of men are dressed in European cloth, or China silk, lined with the finest Siberian furs. The use of linen is totally unknown among them. The chief food of the inhabitants is the milk of their cattle, prepared into cheese, butter, or mixed with the flour of a coarse barley or of pease, the only grain which their soil produces; and even these articles are in a scanty proportion: but they are furnished with rice and wheat from Bengal and other countries in their neighbourhood. They also are supplied with fish from the rivers in their own and the neighbouring provinces, salted and sent into the interior parts. They have no want of animal food from the cattle, sheep, and hogs, which are raised on their hills; and are not destitute of game. They have a singular method of preparing their mutton, by exposing the carcase entire, after the bowels are taken out, to the sun and bleak northern winds which blow in the months of August and September, without frost, and so dry up the juices and parch the skin, that the meat will keep uncorrupted for the year round. This they generally eat raw, without any other preparation.

"The religion and political constitution of this country, which are intimately blended together, would make a considerable chapter in its history. It suffices to say, that at present, and ever since the expulsion of the Eluth Tartars, the kingdom of Tibet is regarded as depending on the empire of China, which they call *Cathay;* and there actually reside two mandarins, with a garrison of a thousand Chinese, at Lahassa the capital, to support the government; but their power does not extend far: and in fact the Lama, whose empire is founded on the surest grounds, personal affection and religious reverence, governs every thing internally with unbounded authority. Every body knows that the Delai Lama is the great object of adoration for the various tribes of heathen Tartars, who roam through the vast tract of continent which stretches from the banks of the Volga to Correa on the sea of Japan, the most extensive religious dominion, perhaps, on the face of the globe. See LAMA.

"It is an old notion, that the religion of Tibet is a corrupted Christianity; and even Father Disederii, a Jesuit (but not of the Chinese mission) who visited the country about the beginning of this century, thinks he can resolve all their mysteries into ours; and asserts, with a truly mystical penetration, that they have certainly a good notion of the Trinity, since in their address to the Deity, they say as often *konciok-oik* in the plural as *konciok* in the singular, and with their rosaries pronounce these words *om*, *ha*, *hum*. The truth is, that the religion of Tibet, from whatever source it sprung, is pure and simple in its source, conveying very exalted notions of the Deity, with no contemptible system of morality: but in its progress it has been greatly altered and corrupted by the inventions of worldly men; a fate we can hardly regret in a system of error, since we know that that of truth has been subject to the same. Polygamy, at least in the sense we commonly receive the word, is not in practice among them; but it exists in a manner still more repugnant to European ideas; for there is a plurality of husbands, which is firmly established and highly respected there. In a country where the means of subsisting a family are not easily found, it seems not impolitic to allow a set of brothers to agree in raising one, which is to be maintained by their joint efforts. In short, it is usual in Tibet for the brothers in the family to have a wife in common, and they generally live in great harmony and comfort with her; not but sometimes little dissensions will arise (as may happen in families constituted upon different principles), an instance of which Mr Bogle mentions in the case of a modest and virtuous lady, the wife of half a dozen of the Teeshoo Lama's nephews, who complained to the uncle that the two youngest of her husbands did not furnish that share of love and benevolence to the common stock which duty and religion required of them. In short, however strange this custom may appear to us, it is an undoubted fact that it prevails in Tibet.

"The dead are exposed on the pinnacle of some neighbouring mountain, to be devoured by wild beasts and birds of prey, or wasted away by time and the vicissitudes of the weather in which they lie. The mangled carcases and bleached bones lie scattered about; and amidst this scene of horror, some miserable old wretch, man or woman, lost to all feelings but those of superstition, generally sets up an abode, to perform the dismal office of receiving the bodies, assigning each a place, and gathering up the remains when too widely dispersed."

To the account of Tibet which we have given from the communications of Mr Bogle, we may add the information which we have obtained from a later traveller, Mr Saunders * surgeon at Boglepoer in Bengal, who made a journey into Tibet in the year 1783. His observations chiefly respect the natural productions and diseases of the country.

* Paper in the *Phil. Trans.* vol. lxxix.

The plants which Mr Saunders found were almost all European plants, a great number of them being natives of Britain. From the appearance of the hills he concludes that they must contain many ores of metal and pyrites. There are inexhaustible quantities of tincal or borax, and rock-salt is plentiful; gold-dust is found in great quantities in the beds of rivers, and sometimes in large masses, lumps and irregular veins; lead, cinnabar containing a large proportion of quicksilver, copper, and iron, he thinks might easily be procured. But the inhabitants of Tibet have no better fuel than the dung of animals. A coal mine would be a valuable discovery. We are told, that in some parts of China bordering on Tibet coal is found and used as fuel.

It is remarkable that the same disease prevails at the foot

foot of the mountains of Tibet as in Switzerland at the foot of the Alps, a glandular swelling in the throat commonly called *goitre*.

The language spoken in Tibet is different from that of the Tartars. The astronomers are acquainted with the motion of the heavenly bodies, and able to calculate eclipses; but the lamas are generally ignorant; few of them can read, much less understand their antient books. See ASIA, SUPPLEMENT.

TIBULLUS, AULUS ALBIUS, a Roman knight, and a celebrated Latin poet, was born at Rome 43 B. C. He was the friend of Horace, Ovid, Macer, and other great men in the reign of Augustus. He accompanied Messala Corvinus in his expedition against the island of Corcyra: but falling sick, and being unable to support the fatigues of war on account of the weakness of his constitution, he quitted the profession of arms, and returned to Rome, where he died before the year 17; when Ovid showed his grief for his death by writing a fine elegy upon him. Tibullus wrote four books of elegies, which are still extant: they are written in a tender and agreeable style, and in very elegant Latin. Muret and Joseph Scaliger have written learned and curious commentaries on the works of this poet. The best edition of Tibullus is that of Janus Bronckhusius, published at Amsterdam in 1708, in one volume quarto. We have an English poetical version by Mr Grainger.

TIBUR, in *Ancient Geography*, a town of Latium, pleasantly situated on the Anio. Here Horace had his villa and house; and here he wished to end his days. Here Adrian built an extraordinary villa called *Tiburtina*, inscribed with the names of the provinces and of the most considerable places, (Spartian); near which Zenobia had a house called *Zenobia*, (Trebellius, Pollio). Hither Augustus often retreated on account of its salubrity, (Suetonius): for which it is greatly recommended (Martial). Anciently, when the Romans had far extended their territory, it was the utmost place of banishment, (Ovid). It had a temple of Hercules; and therefore called *Herculeum*. In the temple was a library, (A. Gellius). Now *Tivoli* in the Campagna di Roma, on the Teverone.

TICINUS, in *Ancient Geography*, a river in Insubria, rising in Mount Adula, traversing the Lacus Verbanus southwards, and falling into the Po near Ticinum. Between this river and the Po Hannibal gained his first victory over the Romans under P. Scipio. The general himself escaped with the utmost difficulty, and that by the bravery of his son the first Scipio Africanus. Now the *Tesino*, rising in Mount Godard, running south through the Lago Maggiore and Milan, by Pavia, into the Po.

TICK. See ACARUS, ENTOMOLOGY *Index*.

TICKELL, THOMAS, an excellent English poet, was the son of the Reverend Richard Tickell, and was born in 1686, at Bridekirk in Cumberland. He was educated at Queen's college, Oxford, of which he was made fellow; and while he continued at that university, he addressed to Mr Addison a complimentary copy of verses on his Opera of Rosamond, which introduced him to an acquaintance with that gentleman, who discovering his merit, became his sincere friend. On Mr Addison being made secretary of state, he appointed Mr Tickell his under-secretary; and on his being obliged to resign that office on account of his ill-health, he recommended him so effectually to Mr Craggs his successor, that he was continued in his post till that gentleman's death. In 1724, Mr Tickell was appointed secretary to the lords justices in Ireland, and enjoyed that place as long as he lived. He wrote some poems, which, when separately published, met with a favourable reception, and passed through several editions: they are now printed in the second volume of the Minor Poets. After Mr Addison's death Mr Tickell had the care of the edition of his works printed in 4 vols. 4to; to which he prefixed an account of Mr Addison's life, and a poem on his death. Mr Tickell died in the year 1740.

TICKERA, a considerable article of merchandise in Fezzan in Africa; it is valued by travellers as a portable and highly salubrious food. It is a preparation of pounded dates, and the meal of Indian corn, formed into a paste, and highly dried in an oven.

TICKSEED, SUN-FLOWER. See COREOPSIS, BOTANY *Index*.

TICUNAS. See POISON.

TIDE, is a word which expresses that rising and falling of the waters which are observed on all maritime coasts.

There is a certain depth of the waters of the ocean which would obtain if all were at rest: but observation shows that they are continually varying from this level, and that some of these variations are regular and periodical.

1*st*, It is observed, that on the shores of the ocean, and in bays, creeks, and harbours, which communicate freely with the ocean, the waters rise up above this mean height twice a-day, and as often sink below it, forming what is called a FLOOD and an EBB, a HIGH and LOW WATER. The whole interval between high and low water is called a TIDE; the water is said to FLOW and to EBB; and the rising is called the FLOOD TIDE, and the falling is called the EBB TIDE.

2*d*, It is observed, that this rise and fall of the waters is variable in quantity. At Plymouth, for instance, it is sometimes 21 feet between the greatest and least depth of the water in one day, and sometimes only 12 feet.

These different heights of tide are observed to succeed each other in a regular series, diminishing from the greatest to the least, and then increasing from the least to the greatest. The greatest is called a SPRING TIDE, and the least is called a NEAP TIDE.

3*d*, This series is completed in about 15 days. More careful observation shows that two series are completed in the exact time of a lunation. For the spring tide in any place is observed to happen precisely at a certain interval of time (generally between two and three days) after new or full moon; and the neap tide at a certain interval after half moon: or, more accurately speaking, it is observed that the spring tide always happens when the moon has got a certain number of degrees eastward of the line of conjunction and opposition, and the neap tide happens when she is a certain number of degrees from her first or last quadrature. Thus the whole series of tides appears to be regulated by the moon.

4*th*, It is observed that high water happens at new and full moon, when the moon has a certain determined position with respect to the meridian of the place of observation, preceding or following the moon's

southing

southing a certain interval of time; which is constant with respect to the place, but very different in different places.

5th, The time of high water in any place appears to be regulated by the moon; for the interval between the time of high water and the moon's southing never changes above three quarters of an hour, whereas the interval between the time of high water and noon changes six hours in the course of a fortnight.

6th, The interval between two succeeding high waters is variable. It is least of all about new and full moon, and greatest when the moon is in her quadratures. As two high waters happen every day, we may call the double of their interval a TIDE DAY, as we call the diurnal revolution of the moon a *lunar day*. The tide is shortest about new and full moon, being then about $24^h\ 37'$; about the time of the moon's quadratures it is $25^h\ 27'$. These values are taken from a mean of many observations made at Barbadoes by Dr Maskelyne.

7th, The tides in similar circumstances are greatest when the moon is at her smallest distance from the earth, or in her perigee, and, gradually diminishing, are smallest when she is in her apogee.

8th, The same remark is made with respect to the sun's distance, and the greatest tides are observed during the winter months of Europe.

9th, The tides in any part of the ocean increase as the moon, by changing her declination, approaches the zenith of that place.

10th, The tides which happen while the moon is above the horizon are greater than the tides of the same day when the moon is below the horizon.

Such are the regular phenomena of the tides. They are important to all commercial nations, and have therefore been much attended to. It is of the tides, in all probability, that the Bible speaks, when God is said to set bounds to the sea, and to say, "thus far shall it go, and no farther."

Homer is the earliest profane author who speaks of the tides. Indeed it is not very clear that it is of them that he speaks (in the 12th book of the Odyssey) when he speaks of Charybdis, which rises and retires thrice in every day. Herodotus and Diodorus Siculus speak more distinctly of the tides in the Red sea. Pytheas of Marseilles is the first who says any thing of their cause. According to Strabo he had been in Britain, where he must have observed the tides of the ocean. Plutarch says expressly that Pytheas ascribed them to the moon. It is somewhat wonderful that Aristotle says so little about the tides. The army of Alexander, his pupil, were startled at their first appearance to them near the Persian gulf; and we should have thought that Aristotle would be well informed of all that had been observed there. But there are only three passages concerning them in all Aristotle's writings, and they are very trivial. In one place he speaks of great tides observed in the north of Europe; in another, he mentions their having been ascribed by some to the moon; and in a third, he says, that the tide in a great sea exceeds that in a small one. The Greeks had little opportunity of observing the tides. The conquests and the commerce of the Romans gave them more acquaintance with them. Cæsar speaks of them in the 4th book of his Gallic War. Strabo, after Posidonius, classes the phenomena into daily, monthly, and annual. He observes, that the sea rises as the moon gets near the meridian, whether above or below the horizon, and falls again as she rises or falls; also, that the tides increase at the time of new and full moon, and are greatest at the summer solstice. Pliny explains the phenomena at some length; and says, that both the sun and moon are their cause, dragging the waters along with them (B. II. c. 97.). Seneca (*Nat. Quest.* III. 28.) speaks of the tide with correctness; and Macrobius (*Somn. Scip.* I. 6.) gives a very accurate description of their motions.

It is impossible that such phenomena should not exercise human curiosity as to their cause. Plutarch (*Plut. Phil.* III. 17.), Galileo (*Syst. Mund.* Dial. 4.), Riccioli in his *Almagest*, ii. p. 374, and Gassendi, ii. p. 27. have collected most of the notions of their predecessors on the subject; but they are of so little importance, that they do not deserve our notice. Kepler speaks more like a philosopher (*De Stella Martis*, and *Epit. Astron.* p. 555.). He says that all bodies attract each other, and that the waters of the ocean would all go to the moon were they not retained by the attraction of the earth; and then goes on to explain their elevation under the moon and on the opposite side, because the earth is less attracted by the moon than the nearer waters, but more than the waters which are more remote.

The honour of a complete explanation of the tides was reserved for Sir Isaac Newton. He laid hold of this class of phenomena as the most incontestable proof of universal gravitation, and has given a most beautiful and synoptical view of the whole subject; contenting himself, however, with merely exhibiting the chief consequences of the general principle, and applying it to the phenomena with singular address. But the wide steps taken by this great philosopher in his investigation leave ordinary readers frequently at fault: many of his assumptions require the greatest mathematical knowledge to satisfy us of their truth. The academy of Paris therefore proposed to illustrate this among other parts of the principles of natural philosophy, and published the theory of the tides as a prize problem. This produced three excellent dissertations by M'Laurin, Daniel Bernoulli, and Euler. Aided by these, and chiefly by the second, we shall here give a physical theory, and accommodate it to the purposes of navigation by giving the rules of calculation. We have demonstrated in our dissertations on the physical principles of the celestial motions, that it is an unexcepted fact, that every particle of matter in the solar system is actually deflected toward every other particle; and that the deflection of a particle of matter toward any distant sphere is proportional to the quantity of matter in that sphere directly, and to the square of the distance of the particle from the centre of that sphere inversely: and having found that the heaviness of a piece of terrestrial matter is nothing but the supposed opponent to the force which we exert in carrying this piece of matter, we conceive it as possessing a property, that is, distinguishing quality, manifested by its being *gravis* or heavy. This is heaviness, *gravitas*, gravity; and the manifestation of this quality, or the event in which it is seen, whether it be directly falling, or deflected in a parabolic curve, or stretching a coiled spring, or breaking a rope, or simply pressing on its support, is *gravitatio*, gravitation; and the body is said to gravitate. When all obstacles are removed from the body,

Tide.

body, as when we cut the string by which a stone is hung, it moves directly downwards, *tendit ad terram. Si discindatur funis tenderet lapis ad terram. Dum vero funis integer perstet, lapis terram versus niti censetur.* By some metaphysical process, which it is needless at present to trace, this *nisus ad motum* has been called a *tendency* in our language. Indeed the word has now come to signify the energy of any active quality in those cases where its simplest and most immediate manifestation is prevented by some obstacle. The stone is now said to tend towards the earth, though it does not actually approach it, being withheld by the string. The stretching the string in a direction perpendicular to the horizon is conceived as a full manifestation of this tendency. This tendency, this energy of its heaviness, is therefore named by the word which distinguishes the quality; and it is called *gravitation*, and it is said to *gravitate*.

But Sir Isaac Newton discovered that this deflection of a heavy body differs in no respect from that general deflection observed in all the bodies of the solar system. For 16 feet, which is the deflection of a stone in one second, has the very same proportion to $\frac{1}{20}$th of an inch, which is the simultaneous deflection of the moon, that the square of the moon's distance from the centre of the earth has to the square of the stone's distance from it, namely, that of 3600 to 1.

Thus we are enabled to compare all the effects of the mutual tendencies of the heavenly bodies with the tendency of gravity, whose effects and measures are familiar to us.

If the earth were a sphere covered to a great depth with water, the water would form a concentric spherical shell; for the gravitation of every particle of its surface would then be directed to the centre, and would be equal. The curvature of its surface therefore would be every where the same, that is, it would be the uniform curvature of a sphere.

Plate DXXXVI. fig. 1.

It has been demonstrated in former articles, after Sir Isaac Newton, that the gravitation of a particle C (fig. 1.) to the centre O, is to that of a particle E at the surface as CO to EO. In like manner the gravitation of o is to that of p as o to p O. If therefore EO and O p are two communicating canals, of equal lengths, the water in both would be in equilibrio, because each column would exert the same total pressure at O. But if the gravitation of each particle in p O be diminished by a certain proportion, such as $\frac{1}{100}$th of its whole weight, it is plain that the total pressure of the column p O will be $\frac{1}{100}$th part less than that of the column EO. Therefore they will no longer be in equilibrio. The weight of the column EO will prevail; and if a hollow tower P p be built at the mouth of the pit p o, the water will sink in EO and rise in O p, till both are again in equilibrio, exerting equal total pressures at O. Or we may prevent the sinking at E by pouring in more water into the tower P p. The same thing must happen in the canal fc perpendicular to EO, if the gravitation of every particle be diminished by a force acting in the direction CF, and proportional to the distance of the particle from C, and such, that when c C is equal to o O, the force acting on c is equal to the force acting on o. In order that the former equilibrium may be restored after this diminution of the gravitation of the column fC, it is plain that more water must be poured into the oblique tower f F. All this is evident when we consider the matter hydrostatically. The gravitation of the particle c may be represented by o O; but the diminution of the pressure occasioned by this at O is represented by C c.

Hence we can collect this much, that the whole diminution of pressure at C is to the whole diminution of pressure at O as the sum of all the lines c C to the sum of all the lines o O, that is, as $f\,C^2$ to PO^2. But the weight of the small quantity of water added in each tower is diminished in the same proportion; therefore the quantity added at F f must be to the quantity added at P p as fC to p O. Therefore we must have Ff: P p=fC : p O, and the points E, F, P, must be in the circumference of an ellipse, of which PO and EO are the transverse and conjugate semi-axes.

What we have here supposed concerning the diminution of gravity in these canals is a thing which really obtains in nature. It was demonstrated, when treating of the *Precession of the Equinoxes*, that if the sun or moon lie in the direction OP, at a very great distance, there results from the unequal gravitation of the different particles of the earth a diminution of the gravity of each particle; which diminution is in a direction parallel to OP, and proportional to the distance of the particle from a plane passing through the centre of the earth at right angles to the line OP.

Thus it happens that the waters of the ocean have their equilibrium disturbed by the unequal gravitation of their different particles to the sun or to the moon; and this equilibrium cannot be restored till the waters come in from all hands, and rise up around the line joining the centres of the earth and of the luminary. The spherical ocean must acquire the form of a prolate spheroid generated by the revolution of an ellipse round its transverse axis. The waters will be highest in that place which has the luminary in its zenith, and in the antipodes to that place; and they will be most depressed in all those places which have the luminary in their horizon. P and P′ will be the poles, and EOQ will be the equator of this prolate spheroid.

Mr Ferguson, in his Astronomy, assigns another cause of this arrangement, viz. the difference of the centrifugal forces of the different particles of water, while the earth is turning round the common centre of gravity of the earth and moon. This, however, is a mistake. It would be just if the earth and moon were attached to the ends of a rod, and the earth kept always the same face toward the moon.

It is evident that the accumulation at P and P′, and the depression at the equator, must augment and diminish in the same proportion with the disturbing force. It is also evident that its absolute quantity may be discovered by our knowledge of the proportion of the disturbing force to the force of gravity.—Now this proportion is known; for the proportion of the gravitation of the earth's centre to the sun or moon, to the force of gravity at the earth's surface, is known; and the proportion of the gravitation of the earth's centre to the luminary, to the difference of the gravitations of the centre and of the surface, is also known, being very nearly the proportion of the distance of the luminary to twice the radius of the earth.

Although this reasoning, by which we have ascertained the elliptical form of the watery spheroid, be sufficiently

Tide.

ciently convincing, it is very imperfect, being accommodated to one condition only of equilibrium, viz. the equilibrium of the canals fc and co. There are several other conditions equally necessary to which this lax reasoning will not apply, such as the direction of the whole remaining gravitation in any point F. This must be perpendicular to the surface, &c. &c. Nor will this mode of investigation ascertain the eccentricity of the spheroid without a most intricate process. We must therefore take the subject more generally, and show the proportion and directions of gravity in every point of the spheroid. We need not, however, again demonstrate that the gravitation of a particle placed any where without a perfect spherical shell, or a sphere consisting of concentric spherical shells, either of uniform density, or of densities varying according to some function of the radius, is the same as if the whole matter of the shell or sphere were collected in the centre. This has been demonstrated in the article ASTRONOMY. We need only remind the reader of some consequences of this theorem which are of continual use in the present investigation.

1. The gravitation to a sphere is proportional to its quantity of matter directly, and to the square of the distance of its centre from the gravitating particle inversely.

2. If the spheres be homogeneous and of the same density, the gravitations of particles placed on their surfaces, or at distances which are proportional to their diameters, are as the radii; for the quantities of matter are as the cubes of the radii, and the attractions are inversely as the squares of the radii; and therefore the whole gravitations are as $\frac{r^3}{r^2}$, or as r.

3. A particle placed within a sphere has no tendency to the matter of the shell which lies without it, because its tendency to any part is balanced by an opposite tendency to the opposite part. Therefore,

4. A particle placed any where *within* a homogeneous sphere gravitates to its centre with a force proportional to its distance from it.

It is a much more difficult problem to determine the gravitation of particles to a spheroid. To do this in general terms, and for every situation of the particle, would require a train of propositions which our limits will by no means admit; we must content ourselves with as much as is necessary for merely ascertaining the ratio of the axes. This will be obtained by knowing the ratio of the gravitation at the pole to that at the equator. Therefore,

Fig. 2. Let NmSqN (fig. 2.) be a section through the axis of an oblate homogeneous spheroid, which differs very little from a sphere. NS is the axis, mq is the equatorial diameter, O is the centre, and NMSQ is the section of the inscribed sphere. Let P be a particle situated at any distance without the sphere in its axis produced; it is required to determine the gravitation of this particle to the whole matter of the spheroid?

Draw two lines PAC, PBD, very near to each other, cutting off two small arches AB, CD; draw GAa, HBb, ICc, KDd, perpendicular to the axis; also draw OE and AL perpendicular to PAC, and OF perpendicular to PD, cutting PC in f. Join OA.

Let OA, the radius of the inscribed sphere, be r, and OP the distance of the gravitating particle be d, and Mm, the elevation of the equator of the spheroid, or the ellipticity, be e. Also make AE $= x$, and OE$=y$, $=\sqrt{r^2-x^2}$. Then AE—BF$=\dot{x}$ and F$f$$=\dot{y}$, $=-\frac{x\dot{x}}{\sqrt{r^2-x^2}}$.

Tide.

Suppose the whole figure to turn round the axis OP. The little space ABba will generate a ring of the redundant matter; so will CDdc. This ring may be considered as consisting of a number of thin rings generated by the revolution of Aa. The ring generated by Aa is equal to a parallelogram whose base is the circumference described by A, and whose height is Aa. Therefore let c be the circumference of a circle whose radius is 1. The ring will be A$a \times c \times$AG. But because maN is an arch of an ellipse, we have Mm : Aa = MO : AG$=r$: AG, and Aa=M$m \times \frac{\text{AG}}{r}$, $=\frac{e}{r}$ AG. Therefore the surface of this ring is $= c\frac{e}{r}\,\text{AG}^2$.

We have supposed the spheroid to be very nearly spherical, that is, e exceedingly small in comparison of r. This being the case, all the particles in Aa, and consequently all the particles in the ring generated by the revolution of Aa, will attract the remote particle P with the same force that A does very nearly. We may say the same thing of the whole matter of the ring generated by the revolution of ABba. This attraction is exerted in the direction PA by each individual particle. But every action of a particle A is accompanied by the action of a particle A′ in the direction PA′. These two compose an attraction in the direction PO. The whole attraction in the directions similar to PA is $= c \times \frac{e}{r} \frac{\text{AG}^2}{\text{PA}^2} \times$GH, for GH measures the number of parallel plates of which the solid ring is composed. This being decomposed in the direction PG is $= c \times \frac{e}{r} \times \frac{\text{AG}^2 \cdot \text{PG}}{\text{PA}^3} \times$GH. But $\frac{\text{AG}^2}{\text{PA}^2} = \frac{\text{OE}^2}{\text{PO}^2}$, and $\frac{\text{PG}}{\text{PA}} = \frac{\text{PE}}{\text{PO}}$. Therefore the attraction of the ring, estimated in the direction PO, is $= c \times \frac{e}{r} \times \frac{\text{OE}^2 \cdot \text{PE}}{\text{PO}^3} \times$GH.

Further, by the nature of the circle, we have HG : AB=AG : AO; also AB : BL=AO : OE. But PA : AG=PO : OE, and OE $= \frac{\text{AG} \times \text{PO}}{\text{PA}}$. Therefore

AB : BL=AO : $\frac{\text{AG . PO}}{\text{PA}}$, =AO . PA : PO . AG

Also BL : LA=EO : EA,

And LA : Ff= PA : Pf, = ultimately PA : PE.

Therefore, by equality, HG : Ff, =AG . AO . PA. EO . PA : AO . PO . AG . EA . PE.

Or HG : Ff=EO . PA² : PO . EA . PE.

and HG$=$F$f \times \frac{\text{EO . PA}^2}{\text{PO . PE . EA}}$.

Now substitute this value of HG in the formula expressing the attraction of the ring. This changes it to $c\frac{e}{r} \times \frac{\text{OE}^2\text{. PE}}{\text{PO}^3} \times \frac{\text{OE . PA}^2}{\text{PO . PE . EA}} \times$F$f$, or $c\frac{e}{r} \times \frac{\text{OE}^3\text{. PA}^2}{\text{PO}^4\text{. EA}} \times$ Ff. In like manner, the attraction of

 the

the ring generated by the revolution of CD $\dot{d}c$ is $c\frac{e}{r} \times \frac{OE^3 . PC^2}{PO^4 . EA} \times Ff$. Therefore the attraction of both is $= c\frac{e}{r} \times Ff \times \frac{OE^3}{PO^4.EA} \times \overline{PA^2 + PC^2}, = c\frac{e}{r} \times Ff \frac{y^3}{d^4 . x} \times \overline{PA^2 + PC^2}$. But $PA^2 + PC^2 = 2\,PE^2 + 2\,EA^2 = 2\,PE^2 + 2\,x^2$. Therefore the attraction is $2c\frac{e}{r\,d^4} \times Ff\frac{y^3}{x} \times \overline{PE^2 + x^2}$. But $Ff = \dot{y}, = \frac{x}{y}\dot{x}$. Therefore $Ff\frac{y^3}{x} = \frac{x}{y}\dot{x} \times \frac{y^3}{x}, = y^2\dot{x}, = \overline{r^2 - x^2}\,\dot{x}$.

Therefore the attraction of the two rings is $2c\frac{e}{r\,d^4} \times \overline{r^2 - x^2} \times \overline{PE^2 + x^2} \times \dot{x}$. But $PE^2 = PO^2 - OE^2, = d^2 - (r^2 - x^2) = d^2 - r^2 + x^2$ Therefore the attraction of the two rings is

$$2c\frac{e}{r\,d^4} \times \overline{r^2 - x^2} \times \overline{d^2 - r^2 + 2x^2}\,\dot{x}, = 2c\frac{e}{r\,d^4} \times \overline{r^2 d^2 \dot{x} - r^4\dot{x} + 2r^2x^2\dot{x} - d^2x^2\dot{x} + r^2x^2\dot{x} - 2x^4\dot{x}} = 2c\frac{e}{r\,d^4} \times \overline{r^2d^2\dot{x} + 3r^2x^2\dot{x} - r^4\dot{x} - d^2x^2\dot{x} - 2x^4\dot{x}}.$$

The attraction of the whole shell of redundant matter will be had by taking the fluent of this formula, which is

$$2c\frac{e}{rd^4} \times \left(r^2d^2x + \frac{3r^2x^3}{3} - r^4x - \frac{d^2x^3}{3} - \frac{2x^5}{5}\right),$$

and then make $x = r$. This gives $2c\frac{e}{r\,d^4}(d^2r^3 + r^5 - r^5 - \frac{1}{3}d^2r^3 - \frac{2}{5}r^5)$, which is $= 2c\frac{e}{r\,d^4}(\frac{2}{3}d^2r^3 - \frac{2}{5}r^5)$, $= \frac{4cer^2}{3d^2} - \frac{4r^2}{5d^4}$. To this add the attraction of the inscribed sphere, which is $\frac{2}{3}\frac{cr^3}{d^2}$, and we have the attraction of the whole spheroid

$$= \frac{2}{3}\frac{cr^3}{d^2} + \frac{4}{3}\frac{cer^2}{d^2} - \frac{4}{5}\frac{cer^4}{d^4}.$$

Cor. 1. If the particle P is situated precisely in N, the pole of the spheroid, the attraction of the spheroid is $\frac{2}{3}cr + \frac{8}{15}ce$.

If the spheroid is not oblate, but oblong, and if the greater semiaxis be r, and the depression at the equator be e, the analysis is the same, taking e negatively. Therefore the attraction for a particle in the pole, or the gravitation of a particle in the pole, is $\frac{2}{3}cr - \frac{8}{15}ce$.

But if the polar semiaxis be $r + e$, and the equatorial radius be r, so that this oblong spheroid has the same axis with the former oblate one, the gravitation of a particle in the pole is $\frac{2}{3}cr + \frac{2}{15}ce$.

Cor. 2. If a number of parallel planes are drawn perpendicular to the equator of an oblong spheroid, whose longer semiaxis is $r + e$, and equatorial radius r, they will divide the spheroid into a number of similar ellipses; and since the ellipse through the axis has $r + e$ and r for its two semiaxes, and the radius of a circle of equal area with this ellipse is a mean proportional between r and $r + e$, and therefore very nearly $= r + \frac{1}{2}e$, when e is very small in comparison of r, a particle on the equator of the oblong spheroid will be as much attracted by these circles of equal areas, with their corresponding ellipses, as by the ellipses. Now the attraction at the pole of an oblate spheroid was $\frac{2}{3}cr + \frac{8}{15}ce$. Therefore putting $\frac{1}{2}e$ in place of e, the attraction on the equator of the oblong spheroid will be equal to $\frac{2}{3}cr + \frac{4}{15}ce$.

Thus we have ascertained the gravitations of a particle situated in the pole, and of one situated in the equator, of a homogeneous oblong spheroid. This will enable us to solve the following problem:

If the particles of a homogeneous oblong fluid spheroid attract each other with a force inversely as the squares of their distances, and if they are attracted by a very distant body by the same law, and if the ratio of the equatorial gravity to this external force be given; to find what must be the proportion of the semiaxis, so that all may be in equilibrio, and the spheroid preserve its form?

Let r be the equatorial radius, and $r + e$ be the polar semiaxis. Then the gravitation at the pole m is $\frac{2}{3}cr + \frac{2}{15}ce$, and the gravitation at the equator is $\frac{2}{3}cr + \frac{4}{15}ce$. Now by the gravitation towards the distant body placed in the direction of the polar axis, the polar gravitation is diminished, and the equatorial gravitation is increased; and the increase of the equatorial gravitation is to the diminution of the polar gravitation as NO to 2 m O. Therefore if the whole attraction of the oblong spheroid for a particle on its equator be to the force which the distant body exerts there, as G to P, and if the spheroid is very nearly spherical, the absolute weight at the equator will be $\frac{2}{3}cr + \frac{4}{15}ce + \frac{2}{3}cr\frac{P}{G}$. And the absolute weight at the pole will be $\frac{2}{3}cr + \frac{2}{15}ce - \frac{2}{3}cr\frac{2P}{G}$. Their difference is $\frac{2}{15}ce + 2cr\frac{P}{G}$.

Now if we suppose this spheroid to be composed of similar concentric shells, all the forces will decrease in the same ratio. Therefore the weight of a particle in a column reaching from the equator to the centre will be to the weight of a similarly situated particle of a column reaching from the pole to the centre, as the weight of a particle at the equator to the weight of a particle at the pole. But the whole weights of the two columns must be equal, that they may balance each other at the centre. Their lengths must therefore be reciprocally as the weights of similarly situated particles; that is, the polar semiaxis must be to the equatorial radius, as the weight of a particle at the equator to the weight of a particle at the pole. Therefore we must have $\frac{2}{15}ce + 2cr\frac{P}{G} : \frac{2}{3}cr + \frac{2}{15}ce - \frac{4}{3}cr\frac{P}{G} = e : r$.

Hence we derive $2r\frac{P}{G} = \frac{8}{15}e$, or $4\,G : 15\,P = r : e$.

This determines the form of the fluid spheroid when the ratio of G to P is given.

It is well known that the gravitation of the moon to the earth is to the disturbing force of the sun as 178,725 to 1 very nearly. The lunar gravitation is increased as she approaches the earth in the reciprocal duplicate ratio of the distances. The disturbing force of the sun diminishes in the simple ratio of the distances; therefore the weight of a body on the surface of the earth is to the disturbing

disturbing force of the sun on the same body in a ratio compounded of the ratio of 178,725 to 1, the ratio of 3600 to 1, and the ratio of 60 to 1; that is, in the ratio of 38604600 to 1. If the mean radius of the earth be 20934500 feet, the difference of the axis, or the elevation of the pole of the watery spheroid produced by the gravitation to the sun, will be $\frac{15}{4} \times \frac{20934500}{38604600}$ feet, or very nearly $24\frac{1}{2}$ inches. This is the tide produced by the sun on a homogeneous fluid sphere.

It is plain, that if the earth consists of a solid nucleus of the same density with the water, the form of the solar tide will be the same. But if the density of the nucleus be different, the form of the tide will be different, and will depend both on the density and on the figure of the nucleus.

If the nucleus be of the same form as the surrounding fluid, the whole will still maintain its form with the same proportion of the axis. If the nucleus be spherical, its action on the surrounding fluid will be the same as if all the matter of the nucleus by which it exceeds an equal bulk of the fluid were collected at the centre. In this case, the ocean cannot maintain the same form: for the action of this central body being proportional to the square of the distance inversely, will augment the gravity of the equatorial fluid more than it augments that of the circumpolar fluid; and the ocean, which was in equilibrio (by supposition), must now become more protuberant at the poles. It may, however, be again balanced in an elliptical form, when it has acquired a just proportion of the axes. The process for determining this is tedious, but precisely similar to the preceding.

If the density of the nucleus exceed that of the fluid about $\frac{1}{5\frac{1}{2}}$, we shall have $r : e = G : 3\,P$, which is nearly the form which has been determined for the earth, by the mensuration of degrees of the meridian, and by the vibration of pendulums. The curious reader will do well to consult the excellent dissertations by Clairaut and Boscovich on the Figure of the Earth, where this curious problem is treated in the most complete manner. Mr Bernoulli, in his dissertation on the Tides, has committed a great mistake in this particular. On the other hand, if the nucleus be less dense than the waters, or if there be a great central hollow, the elevation produced by the sun will exceed $24\frac{1}{2}$ inches.

It is needless to examine this any farther. We have collected enough for explaining the chief affections of the tides.

It is known that the earth is not a sphere, but swelled out at the equator by the diurnal rotation. But the change of form is so very small in proportion to the whole bulk, that it cannot sensibly affect the change of form afterwards induced by the sun on the waters of the ocean. For the disturbing force of the sun would produce a certain protuberance on a fluid sphere; and this protuberance depends on the ratio of the disturbing force to the force of gravity at the surface of this sphere. If the gravity be changed in any proportion, the protuberance will change in the same proportion. Therefore if the body be a spheroid, the protuberance produced at any point by the sun will increase or diminish in the same proportion that the gravity at this point has been changed by the change of form. Now the change of gravity, even at the pole of the terrestrial spheroid, is extremely small in comparison with the whole gravity. Therefore the change produced on the spheroid will not sensibly differ from that produced on the sphere; and the elevations of the waters above the surface, which they would have assumed independent of the sun's action, will be the same on the spheroid as on the sphere. For the same reason, the moon will change the surface already changed by the sun, in the same manner as she would have changed the surface of the undisturbed ocean. Therefore the change produced by both these luminaries in any place will be the same when acting together as when acting separately; and it will be equal to the sum, or the difference of their separate changes, according as these would have been in the same or in opposite directions.

Let us now consider the most interesting circumstances of the form of an elliptical tide, which differs very little from a sphere.

Let T (fig. 2.) be a point in the surface of the inscribed sphere, and let Z express the angular distance TOQ from the longer axis of the surrounding spheroid S *m* N *q*. Let TR, TW be perpendicular to the equatorial diameter and to the axis, so that they are the cosine and the sine of TOQ to the radius TO or QO. Let S′ *q* N′ be a section of the circumscribed sphere. Draw OT cutting the spheroid in Z and the circumscribed sphere in *t*. Also let *s o n* be a section of a sphere which has the same capacity with the spheroid, and let it cut the radius in *r*. Then, Fig. 2.

1. The elevation TZ of the point Z of the spheroid above the inscribed sphere is $= Q\,q \times \cos.^2 Z$, and the depression t Z below the circumscribed sphere is $= Q\,q \times \sin^2 Z$. Produce RT till it meet the surface of the spheroid in V. The minute triangle VTZ may be considered as rectilineal, right-angled at Z, and therefore similar to OTR. Therefore OT : TR = TV : TZ. But in the ellipse OQ, or OT : TR = Q q : TV. Therefore $OT^2 : TR^2 = Q\,q : TZ$, and $TZ = \frac{Q\,q \cdot TR^2}{OT^2}$,

$$= Q\,q : \frac{Q\,q \times \cos.^2 Z}{1}, = Q\,q \times \cos.^2 Z.$$

And in the very same manner it may be shown, that $t\,Z = Q\,q \times \sin.^2 Z$.

2. The elevation of the point T above another point T′, whose angular distance TOT′ from the point T is 90°, is $= Q\,q \times \overline{\cos.^2 Z - \sin.^2 Z}$. Call the angle QOT′ Z′. Then $\overline{T'\,Z' = Q\,q \times}\cos.^2 Z'$, and TZ—T′, Z′, $= Q\,q \times \cos.^2 Z - \cos.^2 Z'$. But the arch QT′ is the complement of QT, and therefore $\cos.^2 Z' = \sin.^2 Z$. Therefore $TZ - T', Z' = Q\,q \times \overline{\cos.^2 Z - \sin.^2 Z}$.

3. $Q\,o = \frac{1}{3}\,Q\,q$. For the inscribed sphere is to the spheroid as OQ to O q. But the inscribed sphere is to the sphere *s o n* as OQ^3 to $O\,o^3$. Therefore because the sphere *s o n* is equal to the spheroid S q N, we have $OQ : O\,q = OQ^3 : O\,o^3$, and O o is the first of two mean proportionals between OQ and O q. But Q q is very small in comparison with OQ. Therefore Q o is very nearly $\frac{1}{3}$ of Q q.

Since *s o n* is the sphere of equal capacity, it is the form of the undisturbed ocean. The best way therefore of conceiving the changes of form produced by the sun or moon, or by both together, is to consider the elevations or depressions which they produce above or below this surface. Therefore,

4. The

Tide.

4. The elevation r Z of the point Z above the equicapacious sphere is evidently $= \mathrm{Q}q \times \cos.^2 \mathrm{Z} - \frac{1}{3}\mathrm{Q}q$. Also the depression r' Z′ of the point Z′ is $= \mathrm{Q}q \times \sin.^2 \mathrm{Z}' - \frac{2}{3}\mathrm{Q}q$.

N. B. Either of these formulæ will answer for either the elevation above, or the depression below, the natural ocean: For if $\cos.^2\mathrm{Z}$ is less than $\frac{1}{3}$, the elevation given by the formula will be negative; that is, the point is below the natural surface. In like manner, when $\sin.^2\mathrm{Z}'$ is less than $\frac{2}{3}$, the depression is negative, and the point is above the surface. But if $\cos.^2\mathrm{Z}$ be $=\frac{1}{3}$, or $\sin.^2\mathrm{Z}'$ be $=\frac{2}{3}$, the point is in the natural surface. This marks the place where the spheroid and the equal sphere intersect each other, viz. in P′, the arch P′ o being $54^\circ\ 44'$ very nearly, and $\mathrm{PS}=35^\circ\ 16'$.

Let S represent the whole elevation of the pole of the solar tide above its equator, or the difference between high and low water produced by the sun: and let M represent the whole elevation produced by the moon. Let x and y represent the zenith distances of the sun and moon with respect to any point whatever on the ocean. Then x and y will be the arches intercepted between that point and the summits of the solar and lunar tides. Then the elevation produced by both luminaries in that plane is $\mathrm{S}\cdot\cos.^2 x - \frac{1}{3}\mathrm{S} + \mathrm{M}\cdot\cos.^2 y - \frac{1}{3}\mathrm{M}$; or, more concisely, $\mathrm{S}\cdot\cos.^2 x + \mathrm{M}\cdot\cos.^2 y - \frac{1}{3}\overline{\mathrm{S}+\mathrm{M}}$, and the depression is $\mathrm{S}\cdot\sin.^2 x + \mathrm{M}\cdot\sin.^2 y - \frac{2}{3}\overline{\mathrm{S}+\mathrm{M}}$.

Let the sun and moon be in the same point of the heavens. The solar and lunar tides will have the same axis; the cosines of x and y will each be 1, and the elevation at the compound pole will be $\mathrm{S}+\mathrm{M}-\frac{1}{3}\overline{\mathrm{S}+\mathrm{M}} = \frac{2}{3}\overline{\mathrm{S}+\mathrm{M}}$. The depression at any point 90° from this pole will be $\frac{1}{3}\overline{\mathrm{S}+\mathrm{M}}$, and the whole tide is S+M.

Let the moon be in quadrature, as in a (fig. 3.). The appearance at s will be known, by considering that in this place the cosine of x is 1, and the cosine of y is 0. Therefore the elevation at $s = \mathrm{S} - \frac{1}{3}\overline{\mathrm{S}+\mathrm{M}}, = \frac{2}{3}\mathrm{S} - \frac{1}{3}\mathrm{M}$.
The depression at $a = \mathrm{S} - \frac{2}{3}\overline{\mathrm{S}+\mathrm{M}} = \frac{1}{3}\mathrm{S} - \frac{2}{3}\mathrm{M}$.
The difference or whole tide $= \overline{\mathrm{S}-\mathrm{M}}$.
In like manner, the whole elevation at a above the inscribed sphere is M—S.

Hence we see that the whole tide, when the moon is in quadrature is the difference of S and M. We also see, that if M exceeds S, the water will be higher at a than at s. Now it is a matter of observation, that in the quadratures it is high water under the moon, and low water under the sun. It is also a matter of observation, that in the free ocean, the ebb tide, or the water at s, immediately under the sun, is below the natural surface of the ocean. Hence we must conclude, that $\frac{2}{3}$ S is less than $\frac{1}{3}$ M, or that M is more than double of S. This agrees with the phenomena of nutation and precession, which seem to make $\mathrm{S}=\frac{2}{5}$ of M.

In all other positions of the sun and moon, the place of high water will be different. It is high water where the sum of the elevations produced by both luminaries above the natural ocean is greatest; and the place of low water is where the depression below the natural ocean is greatest. Therefore, in order that it may be high water, we must have $\mathrm{S}\cdot\cos.^2 x + \mathrm{M}\cdot\cos.^2 y - \frac{1}{3}\overline{\mathrm{S}+\mathrm{M}}$ a maximum; or, neglecting the constant quantity $\frac{\mathrm{S}+\mathrm{M}}{3}$, we must have $\mathrm{S}\cdot\cos.^2 x + \mathrm{M}\cdot\cos.^2 y$ a maximum.

Tide.

In like manner, to have low water in a place where the zenith distance of the sun and moon are v and w, we must have $\mathrm{S}\cdot\sin.^2 v + \mathrm{M}\cdot\sin.^2 w$ a maximum.

Lemma 1. If we consider the sines and cosines of angles as numeral fractions of the radius 1, then we have $\cos.^2\mathrm{Z} = \frac{1}{2} + \frac{1}{2}\cos.^2\mathrm{Z}$, and $\sin.^2\mathrm{Z} = \frac{1}{2} - \frac{1}{2}\cos.^2\mathrm{Z}$.

Let $a\ m\ s$ (fig. 3.) be a quadrant of a circle of which O is the centre, and O s is the radius. On O s describe the semicircle OMS, cutting O m in M. Draw s M, and produce it till it cut the quadrant in n. Also draw MC to the centre of the semicircle, and MD and $n\ d$ perpendicular to O s. Fig. 3.

It is plain that s M is perpendicular to OM; and if O s be radius, s M is the sine of the angle s OM, which we may call Z; OM is its cosine: and because O s: OM = OM : OD, and O s : OD = O s^2 : OM², and OD may represent $\cos.^2$ Z. Now OD=OC+CD. If O s=1, then OC=$\frac{1}{2}$. CD=CM · cos. MCD, = CM · cos. 2 MOD, =$\frac{1}{2}$ · cos. 2 Z. Therefore, $\cos.^2\mathrm{Z} = \frac{1}{2} + \frac{1}{2}\cos.\ 2\mathrm{Z}$.

In like manner, because O s : s M = s M : s D, s D is = $\sin.^2$Z. This is evidently $= \frac{1}{2} - \frac{1}{2}\cos.\ 2\mathrm{Z}$.

Lemma 2. $\cos.^2\mathrm{Z} - \sin.^2\mathrm{Z} = \cos.\ 2\mathrm{Z}$. For, because s M is perpendicular to OM, the arch $s\ n$ is double of the arch $s\ m$, and because MD is parallel to $n\ d$, $s\ d$ is = 2 s D, and d D= $\sin.^2$Z. Therefore O d = $\cos.^2$Z —$\sin.^2$Z. But O d is the cosine of $n\ s$, =cos. 2Z and $\cos.^2\mathrm{Z} - \sin.^2\mathrm{Z} = \cos.\ 2\mathrm{Z}$.

By the first Lemma we see, that in order that there may be high water at any place, when the zenith distances of the sun and moon are x and y, we must have $\mathrm{S}\cdot\cos.\ 2x + \mathrm{M}\cdot\cos.\ 2y$ a maximum.

That this may be the case, the fluxion of this formula must be = 0. Now we know that the fluxions of the cosines of two arches are as the sines of those arches. Therefore we must have $\mathrm{S}\cdot\sin.\ 2x + \mathrm{M}\cdot\sin.\ 2y = 0$, or $\mathrm{S}\cdot\sin.\ 2x = -\mathrm{M}\cdot\sin.\ 2y$, which gives us $\sin.\ 2x : \sin.\ 2y = \mathrm{M} : \mathrm{S}$.

In like manner, the place of low water requires $\sin.\ 2v : \sin.\ 2w = \mathrm{M} : \mathrm{S}$.

From this last circumstance we learn, that the place of low water is 0, removed 90° from the place of high water; whereas we might have expected, that the spheroid would have been most protuberant on that side on which the moon is: For the sines of $2v$ and of $2w$ have the same proportion with the sines of $2x$ and of $2y$. Now we know that the sine of the double of any arch is the same with the sine of the double of its complement. Therefore if low water be really distant 90° from high water, we shall have $\sin.\ 2x : \sin.\ 2y = \sin.\ 2v : \sin.\ 2w$. But if it is at any other place, the sines cannot have this proportion.

Now let s be the point of the earth's surface which has the sun in the zenith, and m the point which has the moon in the zenith. Let h be any other point. Draw O h cutting the semicircle OM s in H. Make OM to CS as the disturbing force of the moon to that of the sun; and draw S v parallel, and S t, M r perpendicular to HH′. Join MH and MH′. The angle HC s is double of the angle HO s, and MCH is double of MH′H, or of its equal MOH. Because HMH is a semicircle, HM is perpendicular to MO. Therefore

fore if HH' be considered as radius, HM is the sine and $H'M$ is the cosine of $MH'H$. And Cr is $= MC \cdot \cos. 2y, = M \cdot \cos. 2y$. And Ct is $SC \cdot \cos. 2x$. Therefore tr or $S'v$ is $= S \cdot \cos. 2x + M \cdot \cos. 2y$. Therefore tr or Sv will express the whole difference of elevation between h and the points that are 90 degrees from it on either side (by *Lemma* 2.); and if h be the place of high water, it will express the whole tide, because the high and low waters were shown to be 90° asunder. But when h is the place of high water, Sv is a maximum. Because the place of the moon, and therefore the point M, is given, Sv will be a maximum when it coincides with SM, and CH is parallel to SM.

This suggested to us the following new, and not inelegant, solution of the problem for determining the place of high water.

Fig. 4. and 5. Let $sQoqs$ (fig. 4. and 5.) be a section of the terraqueous globe, by a plane passing through the sun and moon, and let O be its centre. Let s be the point which is immediately under the sun, and m the place immediately under the moon. Bisect Os in C, and describe round C the circle $OMsLO$, cutting Om in M. Take Cs to represent the disturbing force of the moon, and make Cs to CS as the force of the moon to that of the sun (supposing this ratio to be known). Join MS, and draw CH parallel to it. Draw OHh, and $lOLl'$ perpendicular to it. And lastly, draw CI perpendicular to SM. Then we say that m and its opposite m' are the places of high water, l and l' are the places of low water, MS is the height of the tide, and MI, SI are the portions of this tide produced by the moon and sun.

For it is plain, that in this case the line Sv of the last proposition coincides with MS, and is a maximum. We may also observe, that $MC : CS = \sin. MSC : \sin. SMC, = \sin. HCS : \sin. MCH, = \sin\ 2hOs : \sin. 2hOm, = \sin. 2x : \sin. 2y$, or $M : S = \sin. 2x : \sin. 2y$, agreeably to what was required for the maximum.

It is also evident, that $MI = MC \cdot \cos. CMI, = M \cdot \cos. 2y$, and $SI = SC \cdot \cos. ISC, = S \cdot \cos. 2x$; and therefore MS is the difference of elevation between h and the points l and l', which are 90° from it, and is therefore the place of low water; that is, MS is the whole tide.

The elevation of every other point may be determined in the same way, and thus may the form of the spheroid be completely determined.

If we suppose the figure to represent a section through the earth's equator (which is the case when the sun and moon are in the equator), and farther suppose the two luminaries to be in conjunction, the ocean is an oblong spheroid, whose axis is in the line of the syzigies, and whose equator coincides with the six hour circle. But if the moon be in any other point of the equator, the figure of the ocean will be very complicated. It will not be any figure of revolution; because neither its equator (or most depressed part) nor its meridians are circles. The most depressed part of its equator will be in that section through the axis which is perpendicular to the plane in which the luminaries are situated. And this greatest depression, and its shortest equatorial diameter will be constant, while its other dimensions vary with the moon's place. We need not inquire more minutely into its form; and it is sufficient to know that all the sections perpendicular to the plane passing through the sun and moon are ellipses.

This construction will afford us a very simple, and, we hope, a very perspicuous explanation of the chief phenomena of the tides. The well informed reader will be pleased with observing its coincidence with the algebraic solution of the problem given by Daniel Bernoulli, in his excellent dissertation on the Tides, which shared with M'Laurin and Euler the prize given by the Academy of Sciences at Paris, and with the ease and perspicuity with which the phenomena are deducible from it, being in some sort exhibited to the eye.

In our application, we shall begin with the simplest cases, and gradually introduce the complicating circumstances which accommodate the theory to the true state of things.

We begin, therefore, by supposing the earth covered, to a proper depth, with water, forming an ocean concentric with its solid nucleus.

In the next place, we suppose that this ocean adopts in an instant the form which is consistent with the equilibrium of gravity and the disturbing forces.

Thirdly, We suppose the sun stationary, and the moon to move eastward from him above $12\frac{1}{5}$° every day.

Fourthly, We suppose that the solid nucleus turns round its proper axis to the eastward, making a rotation in 24 solar hours. Thus any place of observation will successively experience all the different depths of water.

Thus we shall obtain a certain SUCCESSION of phenomena, precisely similar to the succession observed in nature, with this sole difference, that they do not correspond to the contemporaneous situations of the sun and moon. When we shall have accounted for this difference, we shall presume to think that we have given a just theory of the tides.

We begin with the simplest case, supposing the sun and moon to be always in the equator. Let the series begin with the sun and moon in conjunction in the line Os. In this case the points s, m, and h coincide, and we have high water at 12 o'clock noon and midnight.

While the moon moves from s to Q, Om cuts the upper semicircle in M; and therefore CH, which is always parallel to MS, lies between MC and Cs. Therefore h is between m and s, and we have high water after 12 o'clock, but before the moon's southing. The same thing happens while the moon moves from o to q, during her third quarter.

But while the moon moves from her first quadrature in Q to opposition in o (as in fig, 5.), the line mO drawn from the moon's place, cuts the lower semicircle in M, and CH, parallel to SM, again lies between M and s, and therefore h lies between m and o. The place of high water is to the eastward of the moon, and we have high water after the moon's southing. The same thing happens while the moon is moving from her last quadrature in q to the next syzigy. In short, the point H is always between M and s, and the place of high water is always between the moon and the *nearest* syzigy. The place of high water overtakes the moon in each quadrature, and is overtaken by the moon in each syzigy. Therefore during the first and third quarters, the place of high water gradually falls behind the moon for some time, and then gains upon her again, so

as

as to overtake her in the next quadrature. But during the second and fourth quarters, the place of high water advances before the moon to a certain distance, and then the moon gains upon it, and overtakes it in the next syzigy.

If therefore we suppose the moon to advance uniformly along the equator, the place of high water moves unequally, slowest in the time of new and full moon, and swiftest in the time of the quadratures. There must be some intermediate situations where the place of high water neither gains nor loses upon the moon, but moves with the same velocity.

The rate of motion of the point h may be determined as follows: Draw C i, S n, making very small and equal angles with HC and MS. Draw n C, and about S, with the distance S n, describe the arch $n\,v$, which may be considered as a straight line perpendicular to n S, or to MS.

Then, because SM and S n are parallel to CH and Ci, the points n and i are contemporaneous situations of M and H, and the arches n M, i H, are in the ratio of the angular motions of m and h. Also, because $n\,v$ and n M are perpendicular to n S and n C, the angle $v\,n$ M is equal to the angle SnC, or SMC. Also, because the angles $n\,v$ M and MIC are right angles, and the angles $v\,n$ M, CMI, are also equal, the triangles $v\,n$ M, CMI, are similar. Therefore

nM : $n\,v$=MC : MI. And

$n\,v$: iH=nS : iC, or = MS : MC; therefore

nM : iH=MS : MI. Therefore the angular motion of the moon is to the angular motion of the place of high water as MS to MI.

Therefore, when M'S is perpendicular to SC, and the point I coincides with S, the motion of high water is equal to that of the moon. But when M'S is perpendicular to SC, H'C is also perpendicular to C s, and the angle h' O s is 45°, and the high water is in the octant. While the moon passes from s to m', or the high water from s to h', the point I falls between M and S, and the motion of high water is slower than that of the moon. The contrary obtains while the moon moves from m' to Q, or the high water from the octant to the quadrature.

It is evident, that the motion of h in the third quarter of the lunation, that is, in passing from o to q, is similar to its motion from s to Q. Also, that its motion from Q to o must retard by the same degrees as it accelerated in passing from s to Q, and that its motion in the last quarter from q to s is similar to its motion from Q to o.

At new and full moon the point I coincides with C, and the point M coincides with s. Therefore the motion of the high water at full and change is to the motion of the moon as s C to s S. But when the moon is in quadrature, I coincides with C, and M with o. Therefore the motion of the moon is to that of high water as OS to OC or s C. Therefore the motion of high water at full and change is to its motion in the quadratures as OS to S s, or as the difference of the disturbing forces to their sum. The motion of the tide is therefore slowest in the syzigies and swiftest in the quadratures; yet even in the syzigies it passes the sun along with the moon, but more slowly.

Let the interval between the morning tide of one day and that of the next day be called a *tide-day*. This is always greater than a solar day, or 24h 0m, because the place of high water is moving faster to the eastward than the sun. It is less than a lunar day, or 24h. 50', while the high water passes from the second to the third octant, or from the fourth to the first. It is equal to a lunar day when high water is in the octants, and it exceeds a lunar day while high water passes from the first to the second octant, or from the third to the fourth.

The difference between a solar day and a tide day is called the PRIMING or the RETARDATION of the tides. This is evidently equal to the time of the earth's describing in its rotation an angle equal to the motion of the high water in a day from the sun. The smallest of these retardations is to the greatest as the difference of the disturbing forces to their sum. Of all the phenomena of the tides, this seems liable to the fewest and most inconsiderable derangements from local and accidental circumstances. It therefore affords the best means for determining the proportion of the disturbing forces. By a comparison of a great number of observations made by Dr Maskelyne at St Helena, and at Barbadoes (places situated in the open sea), it appears that the shortest tide-day is 24h. 37', and the longest is 25h. 27'. This gives M—S : M+S=37 : 87, and S : M =2 : 4.96; which differs only 1 part in 124 from the proportion of 2 to 5, which Daniel Bernoulli collected from a variety of different observations. We shall therefore adopt the proportion of 2 to 5 as abundantly exact. It also agrees exactly with the phenomena of the nutation of the earth's axis and the precession of the equinoxes; and the astronomers affect to have deduced this proportion from these phenomena. But an intelligent reader of their writings will perceive more finesse than justice in this assertion. The nutation and precession *do not* afford phenomena of which we can assign the share to each luminary with sufficient precision for determining the proportion of their disturbing forces; and it is by means of many arbitrary combinations, and without necessity, that D'Alembert has made out this ratio. We cannot help being of opinion, that D'Alembert has accommodated his distribution of the phenomena to this ratio of 2 to 5, which Daniel Bernoulli (the best philosopher and the most candid man of that illustrious family of mathematicians) had, with so much sagacity and justness of inference, deduced from the phenomena of the tides. D'Alembert could not but see the value of this inference; but he wanted to show his own address in deducing it *proprio marte* forsooth from the nutation and precession. His procedure in this resembles that of his no less vain countryman De la Place, who affects to be highly pleased with finding that Mr Bode's discovery that Meyer had seen the Georgium Sidus in 1756, perfectly agreed with the theory of its motions which he (De la Place) had deduced from his own doctrines. Any well informed mathematician will see, that De la Place's data afforded no such precision; and the Book on the Elliptical Motions of the Planets, to which he alludes, contains no grounds for his inference. This observation we owe to the author of a paper on that subject in the Transactions of the Royal Society of Edinburgh. We hope that our readers will excuse this occasional observation, by which we wish to do justice to the merit of a modest man, and one of the greatest philosophers of his time. Our only claim in the present dissertation is the making his excellent performance

Tide. formance on the tides accessible to an Enlish reader not much versant in mathematical researches; and we are sorry that our limits do not admit any thing more than a sketch of it. But to proceed.

Assuming 2 : 5 as the ratio of SC to CM′, we have the angle CM′S=23° 34′ nearly, and $m'oh'$=11°47′; and this is the greatest difference between the moon's place and the place of high water. And when this obtains, the moon's elongation $m'os$ is 56° 47′ from the nearest syzigy. Hence it follows, that while the moon moves uniformly from 56° 47′ west elongation to 56° 47′ east, or from 123° 13′ east to 123° 13′ west, the tide day is shorter than the lunar day; and while she moves from 56° 47′ east to 123° 13′, or from 123° 13′ west to 56° 47′, the tide day is longer than the lunar day.

We see now the reason why

———The swelling tides obey the moon.

The time of high water, when the sun and moon are in the equator, is never more than 47 minutes different from that of the moon's southing (+ or — a certain fixed quantity, to be determined once for all by observation).

It is now an easy matter to determine the hour of high water corresponding to any position of the sun and moon in the equator. Suppose that on the noon of a certain day the moon's distance from the sun is ms. The construction of this problem gives us sh, and the length of the tide day. Call this T. Then say 360° : sm=T : t, and t is the hour of high water.

Or, if we choose to refer the time of high water to the moon's southing, we must find the value of mh at the time of the moon's southing, and the difference d between the tide day and the mean lunar day L, and say 360 : mh=d : ☽, the time of high water before the moon's southing in the first and third quarters, but after it in the second and fourth. The following table by Daniel Bernoulli exhibits these times for every 10th degree of the moon's elongation from the sun. The first or leading column is the moon's elongation from the sun or from the point of opposition. The second column is the minutes of time between the moon's southing and the place of high water. The marks — and + distinguish whether the high water is before or after the moon's southing. The third column is the hour and minute of high water. But we must remark that the first column exhibits the elongation, not on the noon of any day, but at the very time of high water. The two remaining columns express the heights of the tides and their daily variations.

The height of high water above the low water constitutes what is usually called the tide. This is the interesting circumstance in practice. Many circumstances render it almost impossible to say what is the elevation of high water above the natural surface of the ocean. In many places the surface at low water is above the natural surface of the ocean. This is the case in rivers at a great distance from their mouths. This may appear absurd, and is certainly very paradoxical; but it is a fact established on the most unexceptionable authority. One instance fell under our own observation. The low-water-mark at spring tide in the harbour of Alloa was found by accurate levelling to be three feet higher than the top of the stone pier at Leith, which is several feet above the high water mark of this harbour. A little attention to the motion of running waters will explain this completely. Whatever checks the motion of water in a canal must raise its surface. Water in a canal runs only in consequence of the declivity of this surface: (See RIVER). Therefore a flood tide coming to the mouth of a river checks the current of its waters, and they accumulate at the mouth. This checks the current farther up, and therefore the waters accumulate there also; and this checking of the stream, and consequent rising of the waters, is gradually communicated up the river to a great distance. The water rises everywhere, though its surface still has a slope. In the mean time, the flood tide at the mouth passes by, and an ebb succeeds. This must accelerate even the ordinary course of the river. It will more remarkably accelerate the river now raised above its ordinary level, because the declivity at the mouth will be so much greater. Therefore the waters near the mouth, by accelerating, will sink in their channel, and increase the declivity of the canal beyond them. This will accelerate the waters beyond them; and thus a stream more rapid than ordinary will be produced along the whole river,

river, and the waters will sink below their ordinary level. Thus there will be an ebb below the ordinary surface as well as a flood above it, however sloping that surface may be.

Hence it follows, that we cannot tell what is the natural surface of the ocean by any observations made in a river, even though near its mouth. Yet even in rivers we have regular tides, subjected to all the varieties deduced from this theory.

We have seen that the tide is always proportional to MS. It is greatest therefore when the moon is in conjunction or opposition, being then S s, the sum of the separate tides produced by the sun and moon. It gradually decreases as the moon approaches to quadrature; and when she is at Q or q, it is SO, or the difference of the separate tides. Supposing S s divided into 1000 equal parts, the length of MS is expressed in these parts in the fourth column of the foregoing table, and their differences are expressed in the fifth column.

We may here observe, that the variations of the tides in equal small times are proportional to the sine of twice the distance of the place of high water from the moon. For since M n is a constant quantity, on the supposition of the moon's uniform motion, M v is proportional to the variation of MS. Now M n : M v=MC : CI=1 : sin. $2y$, and M n and MC are constant quantities.

Thus we have seen with what ease the geometrical construction of this problem not only explains all the interesting circumstances of the tides, but also points them out, almost without employing the judgment, and exhibits to the eye the gradual progress of each phenomenon. In these respects it has great advantages over the very elegant algebraic analysis of Mr Bernoulli. In that process we advance almost without ideas, and obtain our solutions as detached facts, without perceiving their regular series. This is the usual pre-eminence of geometrical analysis; and we regret that Mr Bernoulli, who was eminent in this branch, did not rather employ it. We doubt not but that he would have shown still more clearly the connection and gradual progress of every particular. His aim, however, being to instruct those who were to calculate tables of the different affections of the tides, he adhered to the algebraic method. Unfortunately it did not present him with the easiest formulæ for practice. But the geometrical construction which we have given suggests several formulæ which are exceedingly simple, and afford a very ready mode of calculation.

The fundamental problems are to determine the angle s O h or m O h, having m O s given; and to determine MS.

Let the given angle m O s be called a; and, to avoid the ambiguity of algebraic signs, let it always be reckoned from the nearest syzigy, so that we may always have a equal to the sum of x and y. Also make $d^2=\frac{S^2\times\sin.^2 2a}{M^2+S^2+2M\times S\times\cos. 2a}$, which represents the $\frac{Sc^2}{SM^2}$ of fig. 4. or sin.^{2} $2y$, and make $p=\frac{S\times\sin. 2a}{M+S\times\cos. 2a}$, which is the expression of $\frac{Sc}{Mc}$ of that figure, or of tan. $2y$. Then we shall have,

1. Sin. $y=\sqrt{\frac{1-\sqrt{1-d^2}}{2}}$. For we shall have cos. $2y=\sqrt{1-d^2}$. But sin.$^2 y=\frac{1}{2}-\frac{1}{2}\cos. 2y=1-\frac{\sqrt{1-d^2}}{2}$, and sin. $y=\sqrt{\frac{1-\sqrt{1-d^2}}{2}}$.

2. Tan. $y=\frac{p}{1+\sqrt{1+p^2}}$. For because p is = tan. $2y$, $\sqrt{1+p^2}$ is the secant of $2y$, and $1+\sqrt{1+p^2}:1=p:\tan. y$.

These processes for obtaining y directly are abundantly simple. But it will be much more expeditious and easy to content ourselves with obtaining $2y$ by means of the value of its tangent, viz. $\frac{S\cdot\sin. 2a}{M+S\cdot\cos. 2a}$. Or, we may find x by means of the similar value of its tangent $\frac{Md}{Sd}$ of fig. 4.

There is still an easier method of finding both $2x$ and $2y$, as follows.

Make M+S : M—S=tan. a : tan. b. Then b is the difference of x and y, as a is their sum. For this analogy evidently gives the tangent of half the difference of the angles CSM and CMS of fig. 4. or of $2x$ and $2y$. Therefore to a, which is half the sum of $2x+2y$, add b, and we have $2x=a+b$, or $x=\frac{a+b}{2}$, and $y=\frac{a-b}{2}$.

By either of these methods a table may be readily computed of the value of x or y for every value of a.

But we must recollect that the values of S and M are by no means constant, but vary in the inverse triplicate ratio of the earth's distance from the sun and moon; and the ratio of 2 to 5 obtains only when these luminaries are at their mean distances from the earth. The forces corresponding to the perigean, medium, and apogean distances are as follow.

		Sun.	Moon.
Apogean	-	1.901	4.258
Medium	-	2.	5.
Perigean	-	2.105	5.925

Hence we see that the ratio of S to M may vary from 1.901 : 5.925 to 2.105 : 4.258, that is, nearly from 1 : 3 to 1 : 2, or from 2 : 6 to 2 : 4. The solar force does not vary much, and may be retained as constant without any great error. But the change of the moon's force has great effects on the tides both as to their time and their quantity.

I. In respect of their Time.

1. The tide day following a spring tide is 24 h. 27′ when the moon is in perigee, but 24 h. 33′ when she is in apogee.

2. The tide day following neap tide is 25 h. 15′, and 25 h. 40′ in these two situations of the moon.

3. The greatest interval of time between high water and the moon's southing is 39′ and 61′; the angle

y

y being $9^\circ 45'$ in the first case, and $15^\circ 15'$ in the second.

II. In respect of their Heights.

1. If the moon is in perigee when new or full, the spring tide will be 8 feet instead of 7, which corresponds to her mean distance. The very next spring tide happens when she is near her apogee, and will be 6 feet instead of 7. The neap tides happen when she is at her mean distance, and will therefore be 3 feet.

But if the moon be at her mean distance when new or full, the two succeeding spring tides will be regular or 7 feet, and one of the neap tides will be 4 feet and the other only 2 feet.

Mr Bernoulli has given us the following table of the time of high water for these three chief situations of the moon, namely, her perigee, mean distance, and apogee. It may be had by interpolation for all intermediate positions with as great accuracy as can be hoped for in phenomena which are subject to such a complication of disturbances. The first column contains the moon's elongation from the sun. The columns P, M, A, contain the minutes of time which elapse between the moon's southing and high water, according as she is in perigee, at her mean distance, or in apogee. The sign — indicates the priority, and + the posteriority, of high water to the moon's southing.

The reader will undoubtedly be making some comparison in his own mind of the deductions from this theory with the actual state of things. He will find some considerable resemblances; but he will also find such great differences as will make him very doubtful of its justness. In very few places does the high water happen within three-fourths of an hour of the moon's southing, as the theory leads him to expect; and in no place whatever does the spring tide fall on the day of new and full moon, nor the neap tide on the day of her quadrature. These always happen two or three days later. By comparing the difference of high water and the moon's southing in different places, he will hardly find any connecting principle. This shows evidently that the cause of this irregularity is local, and that the justness of the theory is not affected by it. By considering the phenomena in a navigable river, he will learn the real cause of the deviation. A flood tide arrives at the mouth of a river. The true theoretical tide differs in no respect from a wave. Suppose a spring tide actually formed on a fluid sphere, and the sun and moon then annihilated. The elevation must sink, pressing the under waters aside, and causing them to rise where they were depressed. The motion will not stop when the surface comes to a level; for the waters arrived at that position with a motion continually accelerated. They will therefore pass this position as a pendulum passes the perpendicular, and will rise as far on the other side, forming a high water where it was low water, and a low water where it was high water; and this would go on for ever, oscillating in a time which mathematicians can determine, if it were not for the viscidity, or something like friction, of the waters. If the sphere is not fluid to the centre, the motion of this wave will be different. The elevated waters cannot sink without diffusing themselves sidewise, and occasioning a great horizontal motion, in order to fill up the hollow at the place of low water. This motion will be greatest about half way between the places of high and low water. The shallower we suppose the ocean, the greater must this horizontal motion be. The resistance of the bottom (though perfectly smooth and even) will greatly retard it all the way to the surface. Still, however, it will move till all be level, and will even move a little farther, and produce a small flood and ebb where the ebb and flood had been. Then a contrary motion will obtain; and after a few oscillations, which can be calculated, it will be insensible. If the bottom of the ocean (which we still suppose to cover the whole earth) be uneven, with long extended valleys running in various directions, and with elevations reaching near the surface, it is evident that this must occasion great irregularities in the motion of the undermost waters, both in respect of velocity and direction, and even occasion small inequalities on the surface, as we see in a river with a rugged bottom and rapid current. The deviations of the under currents will drag with them the contiguous incumbent waters, and thus occasion greater superficial irregularities.

Now a flood arriving at the mouth of a river, must act precisely as this great wave does. It must be propagated up the river (or along it, even though perfectly level) in a certain time, and we shall have high water at all the different places in succession. This is distinctly seen in all rivers. It is high water at the mouth of the Thames at three o'clock, and later as we go up the river, till at London bridge we have not high water till three o'clock in the morning, at which time it is again high water at the Nore. But, in the mean time, there has been low water at the Nore, and high water about half way to London; and while the high water is proceeding to London, it is ebbing at this intermediate place, and is low water there when it is high water at London and at the Nore. Did the tide extend as far beyond London as London is from the Nore, we should

Tide. should have three high waters with two low waters interposed. The most remarkable instance of this kind is the Maragnon or Amazon river in South America. It appears by the observations of Condamine and others, that between Para, at the mouth of the river, and the conflux of the Madera and Maragnon, there are seven coexistent high waters, with six low waters between them. Nothing can more evidently show that the tides in these places are nothing but the propagation of a wave. The velocity of its superficial motion, and the distance to which it will sensibly go, must depend on many circumstances. A deep channel and gentle acclivity will allow it to proceed much farther up the river, and the distance between the successive summits will be greater than when the channel is shallow and steep. If we apply the ingenious theory of Chevalier Buat delivered in the article River, we may tell both the velocity of the motion and the interval of the successive high waters. It may be imitated in artificial canals, and experiments of this kind would be very instructive. We have said enough at present for our purpose of explaining the irregularity of the times of high water in different places, with respect to the moon's southing. For we now see clearly that something of the same kind must happen in all great arms of the sea which are of an oblong shape, and communicate by one end with the open ocean. The general tide in this ocean must proceed along this channel, and the high water will happen on its shores in succession. This also is distinctly seen. The tide in the Atlantic ocean produces high water at new and full moon at a later and later hour along the south coast of Great Britain in proportion as we proceed from Scilly islands to Dover. In the same manner it is later and later as we come along the east coast from Orkney to Dover. Yet even in this progress there are considerable irregularities, owing to the sinuosities of the shores, deep indented bays, prominent capes, and extensive ridges and valleys in the channel. A similar progress is observed along the coasts of Spain and France, the tide advancing gradually from the south, turning round Cape Finisterre, ranging along the north coast of Spain, and along the west and north coasts of France.

The attentive consideration of these facts will not only satisfy us with respect to this difficulty, but will enable us to trace a principle of connection amidst all the irregularities that we observe.

We now add, that if we note the difference between the time of high water of spring tide, as given by theory, for any place, and the *observed time* of high water, we shall find this interval to be very nearly constant through the whole series of tides during a lunation. Suppose this interval to be 40 hours. We shall find every other phenomenon succeed after the same interval. And if we suppose the moon to be in the place where she was 40 hours before, the observation will agree pretty well with the theory, as to the succession of tides, the length of tide day, the retardations of the tides, and their gradual diminution from spring to neap tide. We say pretty well; for there still remain several small irregularities, different in different places, and not following any observable law. These are therefore local, and owing to local causes. Some of these we shall afterwards point out. There is also a general deviation of the theory from the real series of tides. The neap tides, and those adjoining, happen a little earlier than the corrected theory points out. Thus at Brest (where more numerous and accurate observations have been made than at any other place in Europe), when the moon changes precisely at noon, it is high water at 3 h 28′. When the moon enters her second quarter at noon, it is high water at 8 h. 40′, instead of 9 h. 48′, which theory assigns.

Something similar, and within a very few minutes equal, to this is observed in *every* place on the sea-coast. This is therefore something general, and indicates a real defect in the theory.

But this arises from the same cause with the other general deviation, viz. that the greatest and least tides do not happen on the days of full and half moon, but a certain time after. We shall attempt to explain this.

We set out with the supposition, that the water acquired in an instant the elevation competent to its equilibrium. But this is not true. No motion is instantaneous, however great the force; and every motion and change of motion produced by a sensible or finite force increases from nothing to a sensible quantity by infinitely small degrees. Time elapses before the body can acquire any sensible velocity; and in order to acquire the same sensible velocity by the action of different forces acting similarly, a time must elapse inversely proportional to the force. An infinitely small force requires a finite time for communicating even an infinitely small velocity; and a finite force, in an infinitely small time, communicates only an infinitely small velocity; and if there be any kind of motion which changes by insensible degrees, it requires a finite force to prevent this change. Thus a bucket of water, hanging by a cord lapped round a light and easily moveable cylinder, will run down with a motion uniformly accelerated; but this motion will be prevented by hanging an equal bucket on the other side, so as to act with a finite force. This force prevents only infinitely small accelerations.

Now let ALKF (fig. 6.) be the solid nucleus of the earth, surrounded by the spherical ocean $bhdg$. Let this be raised to a spheroid BHDG by the action of the moon at M, or in the direction of the axis CM. If all be at rest, this spheroid may have the form precisely competent to its equilibrium. But let the nucleus, with its spheroidal ocean, have a motion round C in the direction AFKL from west to east. When the line of water BA is carried into the situation sq infinitely near to BA, it is no longer in equilibrio; for s is too elevated, and the part now come to B is too much depressed. There is a force tending to depress the waters at s, and to raise those now at B; but this force is infinitely small. It cannot therefore restore the shape competent to equilibrium till a sensible time has elapsed; therefore the disturbing force of the moon cannot keep the summit of the ocean in the line MC. The force must be of a certain determinate magnitude before it can in an instant undo the instantaneous effect of the rotation of the waters and keep the summit of the ocean in the same place. But this effect is possible; for the depression at s necessary for this purpose is nearly as the distance from B, being a depression, not from a straight line, but from a circle described with the radius CB. It is therefore an infinitesimal of the first order, and may be restored in an instant, or the continuation of the depression Fig. 6.

pression prevented by a certain finite force. Therefore there is some distance, such as By, where the disturbing force of the moon may have the necessary intensity. Therefore the spherical ocean, instead of being kept continually accumulated at B and D, as the waters turn round, will be kept accumulated at y and y', but at a height somewhat smaller. It is much in this way that we keep melted pitch or other clammy matter from running off from a brush, by continually turning it round, and it hangs protuberant, not from the lowest point, but from a point beyond it, in the direction of its motion. The facts are very similar. The following experiment will illustrate this completely, and is quite a parallel fact. Conceive GDH, the lower half of the ellipse, to be a supple heavy rope or chain hanging from a roller with a handle. The weight of the rope makes it hang in an oblong curve, just as the force of the moon raises the waters of the ocean. Turn the roller very slowly, and the rope, unwinding at one side and winding up on the other side of the roller, will continue to form the same curve: but turn the roller very briskly in the direction FKL, and the rope will now hang like the curve $u\,y'\,v$, considerably advanced from the perpendicular, so far, to wit, that the force of gravity may be able in an instant to undo the infinitely small elevation produced by the turning.

We are very anxious to have this circumstance clearly conceived, and its truth firmly established; because we have observed it to puzzle many persons not unaccustomed to such discussions: we therefore hope that our readers, who have got over the difficulty, will indulge us while we give yet another view of this matter, which leads us to the same conclusion.

It is certain that the interval between high and low water is not sufficient for producing all the accumulation necessary for equilibrium in an ocean so very shallow. The horizontal motion necessary for gathering together so much water along a shallow sea would be prodigious. Therefore it never attains its full height; and when the waters, already raised to a certain degree, have passed the situation immediately under the moon, they are still under the action of accumulating forces, although these forces are now diminished. They will continue rising, till they have so far past the moon, that their situation subjects them to depressing forces. If they have acquired this situation with an accelerated motion, they will rise still farther by their inherent motion, till the depressing forces have destroyed all their acceleration, and then they will begin to sink again. It is in this way that the nutation of the earth's axis produces the greatest inclination, not when the inclining forces are greatest, but three months after. It is thus that the warmest time of the day is a considerable while after noon, and that the warmest season is considerably after midsummer. The warmth increases till the momentary waste of heat exceeds the momentary supply. We conclude by saying, that it may be demonstrated, that, in a sphere fluid to the centre, the time of high water cannot be less, and may be more, than three lunar hours after the moon's southing. As the depth of the ocean diminishes, this interval also diminishes.

It is perhaps impossible to assign the distance By at which the summit of the ocean may be kept while the earth turns round its axis. We can only see, that it must be less when the accumulating force is greater, and therefore less in spring tides than in neap tides; but the difference may be insensible. All this depends on circumstances which we are little acquainted with; many of these circumstances are local; and the situation of the summit of the ocean, with respect to the moon, may be different in different places.

Nor have we been able to determine theoretically what will be the height of the summit. It will certainly be less than the height necessary for perfect equilibrium. Daniel Bernoulli says, that, after very attentive consideration, he is convinced that the height at new or full moon will be to the theoretical height as the cosine of the angle BCy to radius, or that the height at y will be $\mathrm{B}b \times \frac{\mathrm{C}n}{\mathrm{C}b}$.

The result of all this reasoning is, that we must always suppose the summit of the tide is at a certain distance eastward from the place assigned by the theory. Mr Bernoulli concludes, from a very copious comparison of observations at different places, that the place of high water is about 20 degrees to the eastward of the place assigned by the theory. Therefore the table formerly given will correspond with observation, if the leading column of the moon's elongation from the sun be altered accordingly. We have inserted it again in this place, with this alteration, and added three columns for the times of high water. Thus changed it will be of great use.

We have now an explanation of the acceleration of the neap tides, which should happen 6 hours later than the spring tides. They are in fact tides corresponding to positions of the moon, which are 20° more, and not the real spring and neap tides. These do not happen till two days after; and if the really greatest and least tides be observed, the least will be found 6 hours later than the first.

This table is general, and exhibits the time of high water, Tide. water, and their difference from those of the moon's southing, in the open sea, from all local obstructions. If therefore the time of high water in any place on the earth's equator (for we have hitherto considered no other) be different from this table (supposed correct), we must attribute the difference to the distinguishing circumstances of the situation. Thus every place on the equator should have high water on the day that the moon, situated at her mean distance, changes precisely at noon, at 22 minutes past noon; because the moon passes the meridian along with the sun by supposition. Therefore, to make use of this table, we must take the difference between the first number of the column, intitled time of high water, from the time of high water at full and change peculiar to any place, and add this to all the numbers of that column. This adapts the table to the given place. Thus, to know the time of high water at Leith, when the moon is 50° east of the sun, at her mean distance from the earth, take 22′ from 4h. 30′, there remains 4.08. Add this to 2h. 48′ and we have 6° 56′ for the hour of high water. The hour of high water at new and full moon for Edinburgh is marked 4h. 30′ in Maskelyne's tables, but we do not pretend to give it as the exact determination. This would require a series of accurate observations.

It is by no means an easy matter to ascertain the time of high water with precision. It changes so very slowly, that we may easily mistake the exact minute. The best method is to have a pipe with a small hole near its bottom, and a float with a long graduated rod. The water gets in by the small hole, and raises the float, and the smallness of the hole prevents the sudden and irregular starts which waves would occasion. Instead of observing the moment of high water, observe the height of the rod about half an hour before, and wait after high water till the rod comes again to that height. Take the middle between them. The water rises sensibly half an hour before the top of the tide, and quickly changes the height of the rod, so that we cannot make a great mistake in the time.

Mr Bernoulli has made a very careful comparison of the theory thus corrected, with the great collection of observations preserved in the *Depot de la Marine* at Brest and Rochfort *; and finds the coincidence very great, and far exceeding any rule which we had ever seen. Indeed we have no rules but what are purely empirical, or which suppose a uniform progression of the tides.

* See Mr Cassini, *Mem. Acad. Par.* 1734.

The heights of the tides are much more affected by local circumstances than the regular series of their times. The regular spring tide should be to the neap tide in the same proportion in all places; but nothing is more different than this proportion. In some places the spring tide is not double of the neap tide, and in other places it is more than quadruple. This prevented Bernoulli from attempting to fix the proportion of M to S by means of the heights of the tides. Newton had, however, done it by the tides at Bristol, and made the lunar force almost five times greater than the solar force. But this was very ill-founded, for the reason now given.

Yet Bernoulli saw, that in all places the tides gradually decreased from the syzigies to the quadratures. He therefore presumed, that they decreased by a similar law with the theoretical tides, and has given a very ingenious method of accommodating the theory to any tides which may be observed. Let A be the spring tide, and B the neap tide in any place. Then form an M and an S from these, by making $M=\frac{A+B}{2}$, and $S=\frac{A-B}{2}$; so that $M+S$ may be $=A$, and $M-S=B$ agreeable to the theory. Then with this M and S compose the general tide T, agreeable to the construction of the problem. We may be persuaded that the result cannot be far from the truth. The following table is calculated for the three chief distances of the moon from the earth.

Elong. ☽ & ☉.	Height of the Tide.		
	Moon in Perigee.	Moon in M Dist.	Moon in Apogee.
0	0.99A+0.15B	0.88A+0.12B	0.79A+0.08B

100	0.03A+1.24B	0.03A+0.97B	0.03A+0.68B
110	0.00A+1.28B	0.00A+0.00B	0.00A+0.70B
120	0.03A+1.24B	0.03A+0.97B	0.03A+0.68B
130	0.13A+1.13B	0.12A+0.88B	0.11A+0.62B
140	0.28A+0.96B	0.25A+0.75B	0.23A+0.53B
150	0.46A+0.75B	0.41A+0.59B	0.37A+0.41B
160	0.67A+0.53B	0.59A+0.41B	0.53A+0.29B
170	0.85A+0.32B	0.75A+0.25B	0.68A+0.18B
180	0.99A+0.15B	0.88A+0.12B	0.79A+0.08B

Observe that this table is corrected for the retardation arising from the inertia of the waters. Thus when the moon is 20 degrees from the sun, the mean distance tide is 1.00A+0.00B, which is the theoretical tide corresponding to conjunction or opposition.

We have now given in sufficient detail the phenomena of the tides along the equator, when the sun and moon are both in the equator, shewing both their times and their magnitude. When we recollect that all the sections of an oblong spheroid by a plane passing through an equatorial diameter are ellipses, and that the compound tide is a combination of two such spheroids, we perceive that every section of it through the centre, and perpendicular to the plane in which the sun and moon are situated, is also an ellipse, whose shorter axis is the equatorial diameter of a spring tide. This is the greatest depression in all situations of the luminaries; and the points of greatest depression are the lower poles of every compound tide. When the luminaries are in the equator, these lower poles coincide with the poles of the earth. The equator, therefore, of every compound tide is also an ellipse: the whole circumference of which is lower than any other section of this tide, and gives the place of low water in every part of the earth. In like manner, the section through the four poles, upper and lower, gives the place of high water. These two sections are terrestrial meridians or hour circles, when the luminaries are in the equator.

4

Hence

Hence it follows, that all we have already said as to the times of high and low water may be applied to every place on the surface of the earth, when the sun and moon are in the equator. But the heights of tide will diminish as we recede from the equator. The heights must be reduced in the proportion of radius to the cosine of the latitude of the place. But in every other situation of the sun and moon all the circumstances vary exceedingly. It is very true, that the determination of the elevation of the waters in any place whatever is equally easy. The difficulty is, to exhibit for that place a connected view of the whole tide, with the hours of flood and ebb, and the difference between high and low water. This is not indeed difficult; but the process by the ordinary rules of spherical trigonometry is tedious. When the sun and moon are not near conjunction or opposition, the shape of the ocean resembles a turnip, which is flat and not round in its broadest part. Before we can determine with precision the different phenomena in connection, we must ascertain the position or attitude of this turnip; marking on the surface of the earth both its elliptical equators. One of these is the plane passing through the sun and moon, and the other is perpendicular to it, and marks the place of low water. And we must mark in like manner its first meridian, which passes through all the four poles, and marks on the surface of the earth the place of high water. The position of the greatest section of this compound spheroid is frequently much inclined to the earth's equator; nay sometimes it is at right angles to it, when the moon has the same right ascension with the sun, but a different declination. In these cases the ebb tide on the equator is the greatest possible; for the lower poles of the compound spheroid are in the equator. Such situations occasion a very complicated calculus. We must therefore content ourselves with a good approximation.

And first, with respect to the times of high water. It will be sufficient to conceive the sun and moon as always in one plane, viz. the ecliptic. The orbits of the sun and moon are never more inclined than $5\frac{1}{2}$ degrees. This will make very little difference; for when the luminaries are so situated that the great circle through them is much inclined to the equator, they are then very near to each other, and the form of the spheroid is little different from what it would be if they were really in conjunction or opposition. It will therefore be sufficient to consider the moon in three different situations.

1. In the equator. The point of highest water is never farther from the moon than 15°, when she is in apogee, and the sun in perigee. Therefore if a meridian be drawn through the point of highest water to the equator, the arch *m h* of fig. 4. will be represented on the equator by another arch about $\frac{92}{100}$ of this by reason of the inclination of the equator and ecliptic. Therefore to have the time of high water, multiply the numbers of the columns which express the difference of high water and the moon's southing by $\frac{92}{100}$, and the products give the real difference.

2. Let the moon be in her greatest declination. The arch of right ascension corresponding to *m h* will be had by multiplying *m h*, or the time corresponding to it in the table, by $\frac{102}{91}$.

3. When the moon is in a middle situation between these two extremes, the numbers of the table will give the right ascension corresponding to *m h* without any correction, the distance from the equator compensating for the obliquity of the ecliptic arch *m h*.

The time of low water is not so easily found; and we must either go through the whole trigonometrical process, or content ourselves with a less perfect approximation. The trigonometrical process is not indeed difficult: we must find the position of the plane through the sun and moon. A great circle through the moon perpendicular to this is the line of high water; and another perpendicular circle cutting this at right angles is the circle of low water.

But it will be abundantly exact to consider the tide as accompanying the moon only.

Let NQSE (fig. 7.) be a section of the terraqueous globe, of which N and S are the north and south poles and EOQ the equator. Let the moon be in the direction OM, having the declination BQ. Let D be any place on the earth's surface. Draw the parallel LDC of latitude. Let B'F *b'f* be the ocean, formed into a spheroid, of which B *b* is the axis and *f*E the equator. Fig. 7.

As the place D is carried along the parallel CDL by the rotation of the earth, it will pass in succession through different depths of the watery spheroid. It will have high water when at C and L, and low water when it crosses the circle *f*OF. Draw the meridian N *d* G, and the great circle B *d b*. The arch GQ, when converted into lunar hours (each about 62 minutes), gives the duration of the flood *d c* and of the subsequent ebb *c d*, which happen while the moon is above the horizon: and the arch EG will give the durations of the flood and of the ebb which happen when the moon is below the horizon. It is evident, that these two floods and two ebbs have unequal durations. When D is at C it has high water, and the height of the tide is CC'. For, the spheroid is supposed to touch the sphere on the equator *f* OF, so that of CC' is the difference between high and low water. At L the height of the tide is LL'; and if we describe the circle LN *q*, C *q* is the difference of these high waters, or of these tides.

Hence it appears, that the two tides of one lunar day may be considerably different, and it is proper to distinguish them by different names. We shall call that a *superior tide* which happens when the moon is above the horizon during high water. The other may be called the *inferior tide*. The duration of the superior tide is measured by 2GQ, and that of the inferior tide by 2EG; and 4GO measures the difference between the whole duration of a superior and of an inferior tide.

From this construction we may learn in general,

1. When the moon has no declination, the durations and also the heights of the superior and inferior tides are equal in all parts of the world. For in this case the tide equator *f*F coincides with the meridian NOS, and the poles B'*b'* of the watery spheroid are on the earth's equator.

2. When the moon has declination, the duration and also the height of a superior tide at any place is greater than that of the inferior; or is less than it, according as the moon's declination and the latitude of the place are of the same or opposite names.

This is an important circumstance. It frequently happens that the inferior tide is found the greatest when it should be the least; which is particularly the case at the Nore. This shows, without further reasoning, that the tide at the Nore is only a branch of the regular tide.

Tide.

tide. The regular tide comes in between Scotland and the continent; and after travelling along the coast reaches the Thames, while the regular tide is just coming in again between Scotland and the continent.

3. If the moon's declination is equal to the colatitude of the place, or exceeds it, there will be only one tide in a lunar day. It will be a superior or an inferior tide, according as the declination of the moon and the latitude of the place are of the same or opposite kinds. For the equator of the tide cuts the meridian in f and F. Therefore a place which moves in the parallel cf has high water when at c, and 12 lunar hours afterwards has low water when at f. And any place k which is still nearer to the pole N has high water when at k, and 12 lunar hours afterwards has low water at m. Therefore, as the moon's declination extends to 30°, all places farther north or south than the latitude 60° will sometimes have only one tide in a lunar day.

4. The sine of the arch GO, which measures ¼th of the difference between the duration of a superior and inferior tide, is = tan. lat. × tan. decl. For in the spherical triangle dOG

Rad. : cotan. dOG = tan. dG : sin. GO, and
Sin. GO = tan. dOQ × tan. dG, = tan. decl. × tan. lat.

Hence we see, that the difference of the durations of the superior and inferior tides of the same day increase both with the moon's declination and with the latitude of the place.

The different situations of the moon and of the place of observation affect the heights of the tides no less remarkably. When the point D comes under the meridian NBQ in which the moon is situated, there is a superior high water, and the height of the tide above the low water of that day is CC'. When D is at L, the height of the inferior tide is LL'. The elevation above the inscribed sphere is $M \times \cos.^2 y$, y being the zenith distance of the moon at the place of observation. Therefore at high water, which by the theory is in the place directly under the moon, the height of the tide is as the square of the cosine of the moon's zenith or nadir distance.

Hence we derive a construction which solves all questions relating to the height of the tides with great facility, free from all the intricacy and ambiguities of the algebraic analysis employed by Bernoulli.

Fig. 8. With the radius CQ=M (the elevation produced by the moon above the inscribed sphere) describe the circle pQPE (fig. 8.) to represent a meridian, of which P and p are the poles, and EQ the equator. Bisect CP in O; and round O describe the circle PBCD. Let M be the place over which the moon is vertical, and Z be the place of observation. MQ is the moon's declination, and ZQ is the latitude of the place. Draw MCm, ZCN, cutting the small circle in A and B. Draw AGI perpendicular to CP, and draw CIμ, which will cut off an arch Eμ=QM. MZ and μ N are the moon's zenith and nadir distances. Draw the diameter BD, and the perpendiculars IK, GH, and AF. Also draw OA, PA, AB, ID.

Then DF is the superior tide, DK is the inferior tide, and DH is the arithmetical mean tide.

For the angles BCA, BDA, standing on BA, are equal. Also the angles IDB, μCN, are equal, being supplements of the angle ICB. Therefore, if BD be made radius, DA and DI are the sines of the zenith and nadir distances of the moon.

But BD : DA = DA : DF. Therefore DF = $M \times \cos.^2 y$, = the height Zz of the superior tide. Also DK=M · $\cos.^2 y'$, = the height nn' of the inferior tide.

Also, because IA is bisected in G, KF is bisected in H, and $DH = \frac{DK+DF}{2}$, = the medium tide.

Let us trace the relation of the consequences of the various positions of Z and M, as we formerly considered the results of the various situations of the sun and moon.

First, then, let Z retain its place, and let M gradually approach it from the equator. When M is in the equator, A and I coincide with C, and the three points F, K, and H, coincide in i.

As M approaches to Z, A and I approach to B and D; DF increases, and DK diminishes. The superior or inferior time is greatest when the moon is in M or in N; and DF is then = M. As the moon passes to to the northward of the place, the superior and inferior tides both diminish till I comes to D; at which time MQ is equal to ZP, and there is no inferior tide. This however cannot happen if z P is greater than 30°, because the moon never goes farther from the equator. M still going north, we have again a perpendicular from I on BD, but below I, indicating that the inferior tide, now measured by DK, belongs to the hemispheroid next the moon. Also, as M advances from the equator northward, DH diminishes continually. First, while H lies between O and B, because G approaches O; and afterwards, when G is above O and H lies between O and D. It is otherwise, however, if ZQ is greater than 45"; for then DB is inclined to EQ the other way, and DH increases as the point G rises.

In the next place, let M retain its position, and Z proceed along the meridian.

Let us begin at the equator, or suppose Q the place of observation. BD then coincides with CP, and the three lines DF, DK, and DH, all coincide with PG, denoting the two equal tides Qq and Ee and their medium, equal to either. As Z goes northward from Q, BOD detaches itself from COP; the line DF increases, while DK and DH diminish. When Z has come to M, F and B coincide with A, and DK and DH are still more diminished. When Z passes M, all the three lines DF, DK, and DH, continue to diminish. When Z comes to latitude 45°, DB is parallel to IA and EQ, and the point H coincides with O. This situation of Z has the peculiar property that DH (now DO) is the same, whatever be the declination of the moon. For IA being always parallel to DB, OK and OF will be equal, and DO will be half of DK and DF, however they may vary. When Z gets so far north that ZP is = MQ, the diameter bd falls on I; so that dk vanishes, and we have only df. And when Z goes still farther north, dk appears on the other side of I. When Z arrives at the pole, BD again coincides with PC, D with C, and DF, DK, and DH, coincide with CG.

These variations of the points F, K, and H, indicate the following phenomena.

1. The

Fig. 1.

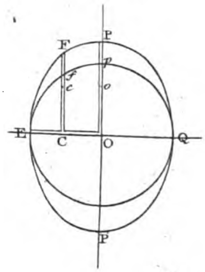

Fig. 2.

W. Train Sculp.

Tide.

1. The greatest tides happen when the moon is in the zenith or nadir of the place of observation; for then the point B coincides with A, and DF becomes DB; that is, $=$ M, indicating the full tide BB'.

2. When the moon is in the equator, the superior and inferior tides have equal heights, $= M \cdot \cos.^2$ lat. For then A and I coincide with C, and the points F and K coincide in i, and D i is $= DB \cdot \cos.^2 BDC, = M \cdot \cos.^2$ lat.

3. If the place of observation is in the equator, the inferior and superior tides are again equal, whatever is the moon's declination: For then B coincides with C, and the points F, K, and H, coincide with G; and PG $\times PC \cdot \cos.^2 APG, = M \cdot \cos.^2$ decl. moon.

4. The superior tides are greater or less than the inferior tides according as the latitude and declination are of the same or of opposite names. For by making Qζ $=$ QZ, and drawing ζ C n, cutting the small circle in β, we see that the figure is reversed. The difference between the superior and inferior tides is KF, or IA $\times$ cosin. of the angle formed by IA and DB; that is, of the angle BDδ, which is the complement of twice ZQ; because BOC $=$ 2 ZCQ. Now IA is 2 GA, $=$ 2 OA $\cdot$ sin. 2 MQ $=$ PC $\cdot$ sin. 2 MQ, $=$ M. $\cdot$ sin. 2 decl. Therefore the difference of the superior and inferior tides is M $\cdot$ sin. 2 declin. sin. 2 lat.

5. If the colatitude be equal to the declination, or less than it, there will be no inferior tide, or no superior tide, according as the latitude of the place and declination of the moon are of the same or opposite names.

For when PZ $=$ MQ, D coincide with I, and IK vanishes. When PZ is less than MQ, the point D is between C and I, and the point Z never passes through the equator of the watery spheroid; and the low water of its only tide is really the summit of the inferior tide.

6. At the pole there is no daily tide: but there are two monthly tides $= M \cdot \sin.^2$ declin. and it is low water when the moon is in the equator.

7. The medium tide, respresented by DH, is $= M \times \frac{1 + \cos.\ 2\,\text{lat.} \times \cos.\ 2\,\text{declin.}}{2}$. For DH $=$ DO $+$ OH. Now OH is equal to OG $\times$ cos. GOH $=$ OG $\cdot$ cos. 2ZQ. And OG $=$ OA $\cdot$ cos. GOA, $=$ OA $\cdot$ cos. 2MQ. Therefore OH $=$ OA $\cdot$ cos. 2ZQ $\cdot$ cos. 2MQ, Therefore DH $=$ OA $+$ OA $\cdot$ cos. 2ZQ $\cdot$ cos. 2MQ $=$

$$M \times \frac{1 + \cos.\ 2ZQ \cdot \cos.\ 2MQ}{2}.$$

Let this for the future be called m.

N. B. The moon's declination never exceeds 30°. Therefore cos. 2MQ is always a positive quantity, and never less than $\frac{1}{2}$, which is the cosine of 60°. While the latitude is less than 45°, cos. 2 lat. is also a positive quantity. When it is precisely 45°, the cosine of its double is *o*; and when it is greater than 45°, the cosine of its double is negative. Hence we see,

1. That the medium tides are equally affected by the northern and southern declinations of the moon.

2. If the latitude of the place is 45°, the medium tide is always $\frac{1}{2}$ M. This is the reason why the tides along the coasts of France and Spain are so little affected by the declination of the moon.

3. If the latitude is less than 45°, the mean tides increase as the moon's declination diminishes. The contrary happens if ZQ is greater than 45°. For DH increases or diminishes while the point G separates from C according as the angle COD is greater or less than COB; that is, according as PCZ is greater or less than ZCQ.

4. When Z is in the equator, H coincides with G, and the effect of the moon's declination on the height of the tides is the most sensible. The mean tide is then $= M \frac{1 + \cos.\ 2\,MQ}{2}$.

All that we have now said may be said of the solar tide, putting S in place of M.

Also the same things hold true of spring tides, putting M$+$S in place of M.

But in order to ascertain the effects of declination and latitude on other tides, we must make a much more complicated construction, even though we suppose both luminaries in the ecliptic. For in this case the two depressed poles of the watery spheroid are not in the poles of the earth; and therefore the sections of the ocean, made by meridians, are by means ellipses.

In a neap tide, the moon is vertical at B (fig. 7. or 8.), and the sun at some point of fF, 90° from B. If O be this point, the construction for the heights of the tides may be made by adding to both the superior and inferior tides for any point D, the quantity $\overline{M + S - DF}$ or DK $\times \sin.^2 d\,O, = \overline{M + S - \text{tide}} \times \frac{\sin.^2 2Q}{\cos.^2 MQ}$, as is evident. Fig. 7. or 8.

But if the sun be vertical at d, d will be the highest part of the circle fOF, and no correction is necessary. But in this case the circle of high water will be inclined to the meridian in an angle equal to dBO (fig. 7.), and neither the times nor elevations of high water will be properly ascertained, and the error in time may be considerable in high latitudes.

The inaccuracies are not so great in intermediate tides, and respect chiefly the time of high water and the height of low water.

The exact computation is very tedious and peculiar, so that it is hardly possible to give any account of a regular progress of phenomena; and all we can do is, to ascertain the precise heights of detached points. For which reasons, we must content ourselves with the construction already given. It is the exact geometrical expression of Bernoulli's analysis, and its consequences now related contain all that he has investigated. We may accommodate it very nearly to the real state of things, by supposing PC equal, not to CO of fig. 4. but to MS, exhibiting the whole compound tide. And the point B, instead of representing the moon's place, must represent the place of high water.

Thus have we obtained a general, though not very accurate, view of the phenomena which must take place in different latitudes and in different declinations of the sun and moon, provided that the physical theory which determines the form and position of the watery spheroid be just. We have only to compute, by a very simple process of spherical trigonometry, the place of the pole of this spheroid. The second construction, in fig. 8. shows us all the circumstances of the time and height of high water at any point. It will be recollected, that in computing this place of the pole, the anticipation of 20 degrees, arising from the inertia of the waters, must be attended to.

Were we to institute a comparison of this theory with observation, without farther consideration, we should still find it unfavourable, partly in respect of the heights of the tides, and more remarkably in respect of the time of low water. We must again consider the effects of the inertia of the waters, and recollect, that a regular theoretical tide differs very little in its progress from the motion of a wave. Even along the free ocean, its motion much resembles that of any other wave. All waves are propagated by an oscillatory motion of the waters, precisely similar to that of a pendulum. It is well known, that if a pendulum receive a small impulse in the time of every descent, its vibrations may be increased to infinity. Did the successive actions of the sun or moon just keep time with the natural propagation of the tides, or the natural oscillations of the waters, the tides would also augment to infinity: But there is an infinite odds against this exact adjustment. It is much more probable that the action of to-day interrupts or checks the oscillation produced by yesterday's action, and that the motion which we perceive in this day's tide is what remains, and is compounded with the action of to-day. This being the case, we should expect that the nature of any tide will depend much on the nature of the preceding tide. Therefore we should expect that the superior and inferior tides of the same day will be more nearly equal than the theory determines. The whole course of observation confirms this. In latitude 45°, the superior and inferior tides of one day may differ in the proportion of $2\frac{1}{2}$ to 1, and the tides corresponding to the greatest and least declinations of the moon may differ nearly as much. But the difference of the superior and inferior tides, as they occur in the list of Observations at Rochefort, is not the third part of this, and the changes made by the moon's declination is not above one-half. Therefore we shall come much nearer the true measure of a spring tide, by taking the arithmetical mean, than by taking either the superior or inferior.

We should expect less deviation from the theory in the gradual diminution of the tides from spring tide to neap tide, and in the gradual changes of the medium tide by the declination of the moon; because the successive changes are very small; and when they change in kind, that is, diminish after having for some time augmented, the change is by insensible degrees. This is most accurately confirmed by observation. The vast collection made by Cassini of the observations at Brest being examined by Bernoulli, and the medium of the two tides in one day being taken for the tide of that day, he found such an agreement between the progression of these medium tides and the progression of the lines MS of fig. 4. that the one seemed to be calculated by the other. He found no less agreement in the changes of the medium tide by the moon's declination.

In like manner, the changes produced by the different distances of the moon from the earth, were found abundantly conformable to the theory, although not so exact as the other. This difference or inferiority is easily accounted for: When the moon changes in her mean distance, one of the neap tides is uncommonly small, and therefore the successive diminutions are very great, and one tide sensibly affects another. The same circumstance operates when she changes in apogee, by reason of a very large spring tide. And the changes corresponding both to the sun's distance from the earth and his declination agreed almost exactly.

All these things considered together, we have abundant reason to conclude, that not only the theory itself is just in principle (a thing which no intelligent naturalist can doubt), but also that the data which are assumed in the application are properly chosen; that is, that the proportion of two to five is very nearly the true proportion of the mean solar and lunar forces. If we now compute the medium tide for any place in succession, from spring tide to neap tide, and still more, if we compute the series of times of their occurrence, we shall find as great an agreement as can be desired. Not but that there are many irregularities; but these are evidently so anomalous, that we can ascribe them to nothing but circumstances which are purely local.

This general rule of computation must be formed in the following manner:

The spring tide, according to theory, being called A, and the neap tide B, recollect that the spring tide, according to the regular theory, is measured by M + S. Recollect also, that when the lunar tide only is considered the superior spring tide is $M \times \sin.^2, ZM$ (fig. 8.). But when we consider the action of two adjoining tides on each other, we find it safer to take the medium of the superior and inferior tides for the measure; and this is $M \times \frac{1 + \cos.^2 2ZQ \times \cos. 2MQ}{2}$. Let this be called m. This being totally the effect of M as modified by latitude and declination, may be taken as its proper measure, by which we are to calculate the other tides of the monthly series from spring tide to neap tide.

In like manner, we must compute a value for S, as modified by declination and latitude; call this s. Then say,

$$M+S : A = m+s : A \times \frac{m+s}{M+S}.$$

This fourth proportional will give the spring tide as modified for the given declination of the luminaries, and the latitude of the place.

Now recollect, that the medium tide, when the luminaries are in the equator, is $A \times \cos.^2$ lat. Therefore let F be the spring tide *observed* at any place when the luminaries are in the equator; and let this be the medium of a great many observations made in these circumstances. This gives $A \cdot \cos.^2$ lat. (as modified by the peculiar circumstances of the place) = F. Therefore the fourth proportional now given changes to $F \times \frac{m+s}{\overline{M+S} \cdot \cos.^2 \text{lat.}}$. And a similar substitute for B is $G + \frac{m-s}{\overline{M-S} \cdot \cos.^2 \text{lat.}}$.

Lastly, To accommodate our formulæ to every distance of the earth from the sun and moon, let D and Δ be the mean distances of the sun and moon, and d and δ their distances at the given time; and then the two substitutes become

$$\frac{\Delta^3 d^3 M + \delta^3 D^3 S}{d^3 \delta^3 (M+S)} \times F \times \frac{m+s}{(M+S) \cos.^2 \text{lat.}}$$

$$\frac{\Delta^3 d^3 M - \delta^3 D^3 S}{d^3 \delta^3 (M-S)} \times G \times \frac{m+s}{(M-S) \cos.^2 \text{lat.}}.$$

The

Tide.

The half sum of these two quantities will be the MC, and their half difference will be the SC, of fig. 4. with which we may now operate, in order to find the tide for any other day of the menstrual series, by means of the elongation a of the moon from the sun; that is, we must say $MC+CS : MC-CS = \tan. a : \tan. b$; then $x = \frac{a+b}{2}$, and $y = \frac{a-b}{2}$. And MS, the height of the tide, is $MC \times \cos. 2y + CS \times \cos. 2x$.

SUCH is the general theory of the tides, deduced from the principle of universal gravitation, and adjusted to that proportion of the solar and lunar forces which is most consistent with other celestial phenomena. The comparison of the greatest and least daily retardations of the tides was with great judgment preferred to the proportion of spring and neap tides, selected by Sir Isaac Newton for this purpose. This proportion must depend on many local circumstances. When a wave or tide comes to the mouths of two rivers, and sends a tide up each, and another tide of half the magnitude comes a fortnight after; the proportion of tides sent up to any given places of these rivers may be extremely different. Nay, the proportion of tides sent up to two distant places of the same river can hardly be the same; nor are they the same in any river that we know. It can be demonstrated, in the strictest manner, that the farther we go up the river, where the declivity is greater, the neap tide will be smaller in proportion to the spring tide. But it does not appear that the time of succession of the different tides will be much affected by loyal circumstances. The tide of the second day of the moon being very little less than that of the first, will be nearly as much retarded, and the intervals between their arrivals cannot be very different from the real intervals of the undisturbed tides; accordingly, the succession of the highest to the highest but one is found to be the same in all places, when not disturbed by *different* winds. In like manner the succession of the lowest and the lowest but one is found equally invariable; and the highest and the lowest tides observed in any place *must* be accounted the spring and neap tides of that place, whether they happen on the day of full and half moon or not. Nay, we can see here the explanation of a general deviation of the theory which we formerly noticed. A low tide, being less able to overcome obstructions, will be sooner stopped, and the neap tides should happen a little earlier than by the undisturbed theory.

With all these corrections, the theory now delivered will be found to correspond with observation, with all the exactness that we can reasonably expect. We had an opportunity of comparing it with the phenomena in a place where they are very singular, viz. in the harbour of Bissestedt in Iceland. The equator of the watery spheroid frequently passes through the neighbourhood of this place, in a variety of positions with respect to its parallel of diurnal revolution, and the differences of superior and inferior tides are most remarkable and various. We found a wonderful conformity to the most diversified circumstances of the theory.

There is a period of 18 years, respecting the tides in Iceland, taken notice of by the ancient Saxons; but it is not distinctly described. Now this is the period of the moon's nodes, and of the greatest and least inclination of her orbit to the equator. It is therefore the period of the positions of the equator of the tides which ranges round this island, and very sensibly affects them.

Hitherto we have supposed the tides to be formed on an ocean completely covering the earth. Let us see how those may be determined which happen in a small and confined sea, such as the Caspian or the Black sea. The determination in this case is very simple. As no supply of water is supposed to come into the bason, it is susceptible of a tide only by sinking at one end and rising at the other. This may be illustrated by fig. 6. where C s, C y, are two perpendicular planes bounding a small portion of the natural ocean. The water will sink at z and rise at x, and form a surface $o\,t\,r$ parallel to the equilibrated surface $y\,s$. It is evident that there will be high water, or the greatest possible rise, at r, when the bason comes to that position where the tangent is most of all inclined to the diameter. This will be when the angle t CB is 45° nearly, and therefore three lunar hours after the moon's southing; at the same time, it will be low water at the other end. It is plain that the rise and fall must be exceedingly small, and that there will be no change in the middle. The tides of this kind in the Caspian sea, in latitude 45°, whose extent in longitude, does not exceed eight degrees are not above seven inches; a quantity so small, that a slight breeze of wind is sufficient to check it, and even to produce a rise of the waters in the opposite direction. We have not met with any accounts of a tide being observed in this sea.

It should be much greater, though still very small, in the Mediterranean sea. Accordingly, tides are observed there, but still more remarkably in the Adriatic, for a reason which will be given by and by. We do not know that tides have been observed in the great lakes of North America. These tides, though small, should be very regular.

Should there be another great bason in the neighbourhood of $z\,x$, lying east or west of it, we should observe a curious phenomenon. It would be low water on one side of the shore z when it is high water on the other side of this partition. If the tides in the Euxine and Caspian seas, or in the American lakes which are near each other could be observed, this phenomenon should appear, and would be one of the prettiest examples of universal gravitation that can be conceived. Something like it is to be seen at Gibraltar. It is high water on the east side of the rock about 10 o'clock at full and change, and it is high water on the west side not a mile distant, at 12. This difference is perhaps the chief cause of the singular current which is observed in the straits mouth. There are three currents observed at the same time which change their directions every 12 hours. The small tide of the Mediterranean proceeds along the Barbary shore, which is very uniform all the way from Egypt, with tolerable regularity, But along the northern side, where it is greatly obstructed by Italy, the islands, and the east coast of Spain, it sets very irregularly; and the perceptible high water on the Spanish coast differs four hours from that of the southern coast. Thus it happens, that one tide ranges round Europa point, and another along the shore near Ceuta, and there is a third current in the middle different from both. Its general direction is from the

Tide.

Atlantic ocean into the Mediterranean sea, but it sometimes comes out when the ebb tide in the Atlantic is considerable.

Suppose the moon over the middle of the Mediterranean. The surface of the sea will be level, and it will be half tide at both ends, and therefore within the Straits of Gibraltar. But without the Straits it is within half an hour of high water. Therefore there will be a current setting *in* from the Atlantic. About three and a half hours after, it is high water within and half ebb without. The current now sets out from the Mediterranean. Three hours later, it is low water without the Straits and half ebb within; therefore the current has been setting out all this while. Three hours later, it is half flood without the Straits and low water within, and the current is again setting in, &c.

Were the earth fluid to the centre, the only sensible motion of the waters would be up and down, like the waves on the open ocean, which are not brushed along by strong gales. But the shallowness of the channel makes a horizontal motion necessary, that water may be supplied to form the accumulation of the tide. When this is formed on a flat shelving coast, the water must flow in and out, on the flats and sands, while it rises and falls. These horizontal motions must be greatly modified by the channel or bed along which they move. When the channel contracts along the line of flowing water, the wave, as it moves up the channel, and is checked by the narrowing shores, must be reflected back, and keep a-top of the waters still flowing in underneath. Thus it may rise higher in these narrow seas than in the open ocean. This may serve to explain a little the great tides which happen on some coasts, such as the coast of Normandy. At St Malo the flood frequently rises 50 feet. But we cannot give any thing like a full or satisfactory account of these singularities. In the bay of Fundy, and particularly at Annapolis Royal, the water sometimes rises above 100 feet. This seems quite inexplicable by any force of the sun and moon, which cannot raise the waters of the free ocean more than eight feet. These great floods are unquestionably owing to the proper timing of certain oscillations or currents adjoining, by which they unite, and form one of great force. Such violent motions of water are frequently seen on a small scale in the motions of brooks and rivers; but we are too little acquainted with hydraulics to explain them with any precision.

We have seen that there is an oscillation of waters formed under the sun and moon; and that in consequence of the rotation of the earth, the inertia and the want of perfect fluidity of the waters, and obstructions in the channel, this accumulation never reaches the place where it would finally settle if the earth did not turn round its axis. The consequence of this must be a general current of the waters from east to west. This may be seen in another way. The moon in her orbit round the earth has her gravity to the earth diminished by the sun's disturbing force, and therefore moves in an orbit less incurvated than she would describe independent of the sun's action. She therefore employs a longer time. If the moon were so near the earth as almost to touch it, the same thing would happen. Therefore suppose the moon turning round the earth, almost in contact with the equator, with her natural undisturbed periodic time, and that the earth is revolving round its axis in the same time, the moon would remain continually above the same spot of the earth's surface (suppose the city of Quito), and a spectator in another planet would see the moon always covering the same spot. Now let the sun act. This will not affect the rotation of the earth, because the action on one part is exactly balanced by the action on another. But it will affect the moon. It will move more slowly round the earth's centre, and at a greater distance. It will be left behind by the city of Quito, which it formerly covered. And as the earth moves round from west to east, the moon, moving more slowly, will have a motion to the west with respect to Quito. In like manner, every particle of water has its gravity diminished, and its diurnal motion retarded; and hence arises a general motion or current from east to west. This is very distinctly perceived in the Atlantic and Pacific oceans. It comes round the Cape of Good Hope, ranges along the coast of Africa, and then sets directly over to America, where it meets a similar stream which comes in by the north of Europe. Meeting the shores of America, it is deflected both to the south along the coast of Brazil, and to the north along the North American shores, where it forms what is called the *Gulf Stream*, because it comes from the gulf of Mexico. This motion is indeed very slow, this being sufficient for the accumulation of seven or eight feet on the deep ocean; but it is not altogether insensible.

We may expect differences in the appearances on the western shores of Europe and Africa, and on the western shore of America, from the appearances on the eastern coasts of America and of Asia, for the general current obstructs the waters from the western shores, and sends them to the eastern shores. Also when we compare the wide opening of the northern extremity of the Atlantic ocean with the narrow opening between Kamtschatka and America, we should expect differences between the appearances on the west coasts of Europe and of America. The observations made during the circumnavigations of Captain Cook and others show a remarkable difference. All along the west coast of North America the inferior tide is very trifling, and frequently is not perceived.

In the very same manner, the disturbing forces of the sun and moon form a tide in the fluid air which surrounds this globe, consisting of an elevation and depression, which moves gradually from east to west. Neither does this tide ever attain that position with respect to the disturbing planets which it would do were the earth at rest on its axis. Hence arises a motion of the whole air from east to west; and this is the principal cause of the trade-winds. They are a little accelerated by being heated, and therefore expanding. They expand more to the westward than in the opposite direction, because the air expands on that side into air which is now cooling and contracting. These winds very evidently follow the sun's motion, tending more to the south or north as he goes south or north. Were this motion considerably affected by the expansion of heated air, we should find the air rather coming northward and southward from the torrid zone, in consequence of its expansion in that climate. We repeat it, it is almost solely produced by the aerial tide, and is necessary for the very formation of this tide. We cannot perceive the accumulation. It cannot affect the barometer, as many

many think, because, though the air becomes deeper, it becomes deeper only when it is made lighter by the gravitation to the sun. Instead of pressing more on the cistern of the barometer, we imagine that it presses less; because, like the ocean, it never attains the height to which it tends. It remains always too low for equilibrium, and therefore it should press with less force on the cistern of a barometer.

There is an appearance precisely similar to this in the planet Jupiter. He is surrounded by an atmosphere which is arranged in zones or belts, probably owing to climate differences of the different latitudes, by which each seems to have a different kind of sky. Something like this will appear to a spectator in the moon looking at this earth. The general weather and appearance of the sky is considerably different in the torrid and temperate zones. Jupiter's belts are not of a constant shape and colour; but there often appear large spots or tracts of cloud, which retain their shape during several revolutions of Jupiter round his axis. To judge of his rotation by one of these, we should say that he turns round in 9.55. There is also a brighter spot which is frequently seen, occupying one certain situation on the body of Jupiter. This is surely adherent to his body, and is either a bright-coloured country, or perhaps a tract of clouds hovering over some volcano. This spot turns round in $9.51\frac{1}{2}$. And thus there is a general current in his atmosphere from east to west.

Both the motion of the air and of the water tend to diminish the rotation of the earth round its axis; for they move slower than the earth, because they are retarded by the luminaries. They must communicate this retardation to the earth, and must take from it a quantity of motion precisely equal to what they want, in order to make up the equilibrated tide. In all probability this retardation is compensated by other causes; for no retardation can be observed. This would have altered the length of the year since the time of Hipparchus, giving it a smaller number of days. We see causes of compensation. The continual washing down of soil from the elevated parts of the earth must produce this effect, by communicating to the valley on which it is brought to rest the excess of diurnal velocity which it had on the mountain top.

While we were employed on this article, a book was put into our hands called *Studies of Nature*, by a Mr Saint Pierre. This author scouts the Newtonian theory of the tides, as erroneous in principle, and as quite insufficient for explaining the phenomena; and he ascribes all phenomena of the tides to the liquefaction of the ices and snows of the circumpolar regions, and the greater length of the polar than of the equatorial axis of the earth. He is a man of whom we wish to speak with respect, for his constant attention to final causes, and the proof thence resulting of the wisdom and goodness of God. For this he is entitled to the greater praise, that it required no small degree of fortitude to resist the influence of national example, and to retain his piety in the midst of a people who have drunk the very dregs of the atheism of ancient Greece. This is a species of merit rarely to be met with in a Frenchman of the present day; but as a philosopher, M. de St Pierre can lay claim to no other merit except that of having collected many important facts. The argument which he employs to prove that the earth is a prolate spheroid, is a direct demonstration of the truth of the contrary opinion; and the melting of the ice and snows at the poles cannot produce the smallest motion in the waters. Were there even ten times more ice and snow floating on the northern sea than there is, and were it all to melt in one minute, there would be no flux from it; for it would only fill up the space which it formerly occupied in the water. Of this any person will be convinced, who shall put a handful of snow squeezed hard into a jar of water, and note the exact height of the water. Let the snow melt, and he will find the water of the same height as before.

Tide-Waiters, or *Tidesmen*, are inferior officers belonging to the customhouse, whose employment is to watch or attend upon ships until the customs be paid: they get this name from their going on board ships on their arrival in the mouth of the Thames or other ports, and so come up with the tide.

TIEND in *Scots Law*. See TEIND.

TIERCE, or TEIRCE, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or 42 gallons.

TIERCED, in *Heraldry*, denotes the shield to be divided by any part of the partition lines, as party, coupy, tranchy, or tailly, into three equal parts of different colours or metals.

TIGER. See FELIS, MAMMALIA *Index*.

TIGER-Wolf, the name of the hyæna at the Cape of Good Hope. See CANIS, MAMMALIA *Index*.

TIGRIS, a river of Asia, which has its source near that of the Euphrates in the mountain Tchildir in Turkomania: afterwards it separates Diarbeck from Erzerum, and Khusistan from Irac-Arabia; and uniting with the Euphrates at Gorno, it falls into the gulf of Bassorah, under the name of *Schat el-Arab*. This river passes by Diarbekir, Gezira, Mousul, Bagdad, Gorno, and Bassorah.

TILIA, LIME or LINDEN TREE, a genus of plants belonging to the class of polyandria; and in the natural system ranging under the *Columniferæ*. See BOTANY *Index*.

TILLEMONT, SEBASTIAN LE NAIN DE. See NAIN.

TILLER *of a Ship*, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the *helm*.

TILLOEA, a genus of plants belonging to the class of tetrandria; and in the natural system ranging under the 13th order, *Succulentæ*. See BOTANY *Index*.

TILLOTSON, JOHN, a celebrated archbishop of Canterbury, was the son of Robert Tillotson of Sowerby, in the parish of Halifax in Yorkshire, clothier; and was born there in the year 1630. He studied in Clare-hall, Cambridge; and in 1656 left this college, in order to become tutor to the son of Edmund Prideaux, Esq. of Ford abbey in Devonshire. He was afterwards curate to Dr Hacket, vicar of Cheshunt, in Hertfordshire. In 1663 he was presented by Sir Thomas Barnardiston to the rectory of Ketton or Keddington in the county of Suffolk; but was the next year chosen preacher to Lincoln's Inn, when he procured Ketton to be bestowed on his curate. He was greatly admired in London for his sermons; and in the same year was chosen Tuesday-lecturer at St Lawrence's church, London, where his lectures were frequented by all

all the divines of the city, and by many persons of quality and distinction. In 1666, he took the degree of Doctor of Divinity at Cambridge; in 1669, was made prebendary of Canterbury; in 1672, was admitted dean of that cathedral; and three years after, was made a prebendary of St Paul's cathedral, London. In 1679, he became acquainted with Charles earl of Shrewsbury, whom he converted from Popery; and the next year refused to sign the clergy of London's address of thanks to King Charles II. for not agreeing to the bill of exclusion of the duke of York. In 1683, he visited the unfortunate Lord Russel when under condemnation; and attended him in his last moments on the scaffold. In 1689, he was installed dean of St Paul's; made clerk of the closet to King William and Queen Mary; and appointed one of the commissioners to prepare matters to be laid before the convocation, in order to a comprehension of all Protestants, as well dissenters as churchmen; but this attempt was frustrated by the zeal of those members of that body, who refused to admit of any alteration in things confessedly indifferent. In 1691, Dr Tillotson was, notwithstanding the warmest remonstrances and intreaties on his part, consecrated archbishop of Canterbury, and four days after was sworn one of the privy council; their majesties always reposing an entire confidence in his prudence, moderation, and integrity. In 1694, he was seized with a palsy, of which he died in the 65th year of his age. He was interred in the church of St Lawrence Jewry, London, where a handsome monument is erected to his memory. This learned and pious divine, while living, was greatly inveighed against by the enemies of the revolution. After his death there was found a bundle of bitter libels which had been published against him, on which he had written with his own hand, "I forgive the authors of these books, and pray God that he may also forgive them." It is remarkable, that while this truly great man was in a private station, he always laid aside two-tenths of his income for charitable uses. One volume in folio of Dr Tillotson's sermons was published in his life-time, and corrected by his own hand; they were translated into French by Barbeyrac. Those which came abroad after his death, from his chaplain Dr Barker, made two volumes in folio, the copy of which was sold for 2500l. This was the only legacy he left to his family, his extensive charity having consumed his yearly revenues as constantly as they came to his hands. King William, however, gave two grants to his widow; the first of which was an annuity of 400l. during the term of her natural life, and the second of 200l. as an addition to the former annuity. Dr Tillotson wrote some other works besides his Sermons; and also published Dr Barrow's works, and Dr Wilkin's Treatise of the Principles and Duties of Natural Religion, and a volume of that divine's Sermons.

TIMBER, wood fit for building, &c. See TREE, and *STRENGTH of Materials*.

TIMBERS, the ribs of a ship, or the incurvated pieces of wood, branching outward from the keel in a vertical direction, so as to give strength, figure, and solidity, to the whole fabric. See SHIP-BUILDING, book i. chap. ii.

TIME, a succession of phenomena in the universe, or a mode of duration marked by certain periods or

measures, chiefly by the motion and revolution of the sun.

The general idea which time gives in every thing to which it is applied, is that of limited duration. Thus we cannot say of the Deity, that he exists in time; because eternity, which he inhabits, is absolutely uniform, neither admitting limitation nor succession. See METAPHYSICS, N° 209.

TIME, in *Music*, is an affection of sound, by which it is said to be long or short, with regard to its continuance in the same tone or degree of tune.

Musical time is distinguished into *common* or *duple* time, and *triple* time.

Double, *duple*, or *common* time, is when the notes are in a duple duration of each other, viz. a semibreve equal to two minims, a minim to two crotchets, a crotchet to two quavers, &c.

Common or double time is of two kinds. The first when every bar or measure is equal to a semibreve, or its value in any combination of notes of a less quantity. The second is where every bar is equal to a minim, or its value in less notes. The movements of this kind of measure are various, but there are three common distinctions; the first *slow*, denoted at the beginning of the line by the mark C; the second *brisk*, marked thus $\overline{\mathrm{C}}$; and the third *very brisk*, thus marked 𝄵.

Triple time is when the durations of the notes are triple of each other, that is, when the semibreve is equal to three minims, the minim to three crotchets, &c. and it is marked T.

TIME-Keepers, or *Instruments for measuring Time*. See CLOCK, DIAL, WATCH, &c.

Harrison's TIME-Keeper. See HARRISON and LONGITUDE.

TIMOLEON, a celebrated Corinthian general, who restored the Syracusans to their liberty, and drove the Carthaginians out of Sicily. See SYRACUSE, N° 50—54.

TIMON the *Sceptic*, who is not to be confounded with Timon the *Misanthrope*, was a Phliasian, a disciple of Pyrrho, and lived in the time of Ptolemy Philadelphus. He took so little pains to invite disciples to his school, that it has been said of him, that as the Scythians shot flying, Timon gained pupils by running from them. He was fond of rural retirement; and was so much addicted to wine, that he had a successful contest with several celebrated champions in drinking. Like Lucian, he wrote with sarcastic humour against the whole body of philosophers. The fragments of his satirical poem *Silli*, often quoted by the ancients, have been carefully collected by Henry Stephens in his *Poesis Philosophica*. Timon lived to the age of 90 years.

TIMON, surnamed *Misanthropos*, or the *Man-hater*, a famous Athenian, who lived about 420 B. C. He was one day asked, why he loved the young Alcibiades while he detested all the rest of the human race? on which he replied, "It is because I foresee that he will be the ruin of the Athenians." He carefully avoided all sorts of company; yet went one day to an assembly of the people, and cried with a loud voice, "That he had a fig-tree on which several persons had hanged themselves;

themselves; but as he intended to cut it down, in order to build a house on the place where it stood, he gave them notice of it, that if any of them had a mind to hang themselves, they must make haste and do it speedily." He had an epitaph engraved on his tomb, filled with imprecations against those who read it. Shakespeare has formed a tragedy on his story.

TIMOR, an island of Asia, in the East Indian sea, to the south of the Moluccas, and to the east of the island of Java, being 150 miles in length, and 37 in breadth. It abounds in sandal-wood, wax and honey; and the Dutch have a fort here. The inhabitants are Pagans, and are little better than savages; and some pretend they had not the use of fire many years ago.

TIMOTHEUS, one of the most celebrated poet-musicians of antiquity, was born at Miletus, an Ionian city of Caria, 446 years B. C. He was contemporary with Philip of Macedon and Euripides; and not only excelled in lyric and dithyrambic poetry, but in his performance upon the cithara. According to Pausanias, he perfected that instrument by the addition of four new strings to the seven which it had before; though Suidas says it had nine before, and that Timotheus only added two, the 10th and 11th, to that number. See Lyre.

With respect to the number of strings upon the lyre of Timotheus: The account of Pausanias and Suidas is confirmed in the famous senatus-consultum against him, still extant, preserved at full length in Boethius. Mr Stillingfleet has given an extract from it, in proof of the simplicity of the ancient Spartan music. The fact is mentioned in Athenæus; and Casaubon, in his notes upon that author, has inserted the whole original text from Boethius, with corrections. The following is a faithful translation of this extraordinary Spartan act of parliament. "Whereas Timotheus the Milesian, coming to our city, has dishonoured our ancient music, and, despising the lyre of seven strings, has, by the introduction of a greater variety of notes, corrupted the ears of our youth; and by the number of his strings, and the novelty of his melody, has given to our music an effeminate and artificial dress, instead of the plain and orderly one in which it has hitherto appeared; rendering melody infamous, by composing in the chromatic instead of the enharmonic:——————The kings and the ephori have therefore resolved to pass censure upon Timotheus for these things: and, farther, to oblige him to cut all the superfluous strings of his eleven, leaving only the seven tones; and to banish him from our city; that men may be warned for the future not to introduce into Sparta any unbecoming custom."———

The same story, as related in Athenæus, has this additional circumstance, That when the public executioner was on the point of fulfilling the sentence, by cutting off the new strings, Timotheus, perceiving a little statue in the same place, with a lyre in his hand of as many strings as that which had given the offence, and showing it to the judges, was acquitted.

It appears from Suidas, that the poetical and musical compositions of Timotheus were very numerous, and of various kinds. He attributes to him 19 nomes, or canticles, in hexameters; 36 proems, or preludes; 18 dithyrambics; 21 hymns; the poem in praise of Diana; one panegyric; three tragedies, the Persians, Phinidas, and Laertes; to which must be added a fourth, mentioned by several ancient authors, called *Niobe*, without forgetting the poem on the birth of Bacchus. Stephen of Byzantium makes him author of 18 books of nomes, or airs, for the cithara, to 8000 verses; and of 1000 Προνομια, or preludes, for the nomes of the flutes.

Timotheus died in Macedonia, according to Suidas, at the age of 97; though the Marbles, much better authority, say at 90; and Stephen of Byzantium fixes his death in the fourth year of the 105th Olympiad, two years before the birth of Alexander the Great; whence it appears, that this Timotheus was not the famous player on the flute so much esteemed by that prince, who was animated to such a degree by his performance as to seize his arms; and who employed him, as Athenæus informs us, together with the other great musicians of his time, at his nuptials. However, by an inattention to dates, and by forgetting that of these two musicians of the same name the one was a Milesian and the other a Theban, they have been hitherto often confounded.

TIMUR-beck. See Tamerlane.

TIN, a metallic substance. See Chemistry and Mineralogy *Index* for an account of its qualities and ores; and for the method of reducing its ores, see Ores, *Reduction of*.

TINCAL, the name by which crude or impure borax is sometimes known. See Borax, Chemistry *Index*.

TINCTURE, in *Pharmacy*. See Materia Medica *Index*.

TINDAL, Dr Matthew, a famous English writer, was the son of the reverend Mr John Tindal of Beer-Ferres in Devonshire, and was born about the year 1657. He studied at Lincoln college in Oxford, whence he removed to Exeter, and was afterwards elected fellow of All Souls. In 1685 he took the degree of doctor of law, and in the reign of James II. declared himself a Roman Catholic; but soon renounced that religion. After the revolution he published several pamphlets in favour of government, the liberty of the press, &c. His "Rights of the Christian Church asserted," occasioned his having a violent contest with the high-church clergy; and his treatise "Christianity as old as the Creation," published in 1730, made much noise, and was answered by several writers, particularly by Dr Conybeare, Mr Foster, and Dr Leland. Dr Tindal died at London in August 1733. He left in manuscript a second volume of his "Christianity as old as the Creation;" the preface to which has been published. Mr Pope has satirized Dr Tindal in his Dunciad.

TINDALE, William. See Tyndale.

TINNING, the covering or lining any thing with melted tin, or tin reduced to a very fine leaf. Looking-glasses are foliated or tinned with plates of beaten tin, the whole bigness of the glass, applied or fastened thereto by means of quicksilver. See *Foliating of Looking-Glasses*.

TINNITUS aurium, a noise in the ears like the continued sound of bells, very common in many disorders, particularly in nervous fevers.

TIPPERARY, a county of the province of Munster in Ireland, bounded on the west by those of Limerick and Clare, on the east by the county of Kilkenny and Queen's county, on the south by the county of Waterford, Tipperary ‖ Tirol.

Gough's edit. of Camden's Britannia.

ford, and on the north and north-east by King's-county and the territory of the ancient O'Carols. It extends about 52 miles in length, and 27 in breadth, containing 599,500 acres, divided into 12 baronies, containing 169,000 inhabitants. It sends three members to parliament, viz. two for the county, and one for Clonmell. The north part of it is mountainous and cold; but in the south the air is milder, and the soil much more fertile, producing plenty of corn, and good pasture for the numerous herds of cattle and flocks of sheep with which it abounds. The north part is called *Ormond*, and for a long time gave the title of *earl*, and afterwards of *marquis* and *duke*, to the noble family of Butler, descended from a sister of Thomas à Becket archbishop of Canterbury, till, at the accession of George I. the last duke was attainted of high-treason, and died abroad. In that part of the county, the family had great prerogatives and privileges granted them by Edward III. Another district in this county was anciently called the *County of the Holy Cross of Tipperary*, from a famous abbey in it styled *Holy Cross*, on account of a piece of Christ's cross that was said to be preserved there. The remains of the abbey, or rather the spot where it stood, are still held in great veneration. See TIPPERARY, SUPPLEMENT.

TIPSTAFF, an officer who attends the judges with a kind of staff tipped with silver, aud takes into his charge all prisoners who are committed or turned over at a judge's chambers.

TIPULA, the CRANE-FLY; a genus of insects belonging to the order of *diptera*. See ENTOMOLOGY *Index*.

TIRE, in the sea language, is a row of cannon placed along a ship's side, either above upon deck, or below, distinguished by the epithets of *upper* and *lower tires*.

TIREE, or TIREY, one of the Western islands of Scotland, 10 miles long and from one to two in breadth, contains above 2000 inhabitants, and produces sheep and black cattle, with some grain and kelp. W. Long. 6. 48. N. Lat. 56. 32.

TIROL, or TYROL, a county of Germany in the circle of Austria, under which may be included the territories belonging to the bishops of Brixen, Trent, and Chur, the Teutonic Order, and the prince of Deitrichstein, the Austrian seigniories before the Arlberg, and the Austrian districts in Swabia. It is 150 miles in length, and 120 in breadth, and contains 28 large towns.

The face of the country is very mountainous. Of these mountains some have their tops always buried in snow; others are covered with woods abounding with game. Of the lower, some yield plenty of corn, others wine, and woods of chesnut trees. The valleys are exceeding fertile also, and pleasant. In some places considerable quantities of flax are raised, in others there is a good breed of horses and horned cattle; and, among the mountains, abundance of chamois and wild goats. In this country are also found garnets, rubies, amethysts, agates, carnelians, calcedonies, malachites, &c.; nor is it without hot baths, acid waters, salt pits, mines of silver, copper, and lead. The principal river of Tirol is the Inn, which, after traversing the country, and receiving a number of lesser streams into it, enters Bavaria, in which, at Passau, it falls into the Danube. The men here are very tall, robust, and vigorous; the women also are stout, and generally fair; and both sexes have a mixture of the Italian and German in their tempers and characters. As there is little trade or manufacture in the country, except what is occasioned by the mines and salt works, many of the common people are obliged to seek a subsistence elsewhere. A particular kind of salutation is used all over Tirol. When a person comes into a house, he says, "Hail! Jesus Christ:" the answer is, "May Christ be raised, and the Holy Virgin his mother." Then the master of the house takes the visitor by the hand. This salutation is fixed up in print at all the doors, with an advertisement tacked to it, importing that Pope Clement XI. granted 100 days indulgence, and a plenary absolution, to those who should pronounce the salutation and answer, as often as they did it. The emperor has forts and citadels so advantageously situated on rocks and mountains all over the country, that they command all the valleys, avenues, and passes that lead unto it. The inhabitants, however, to keep them in good humour, are more gently treated, and not so highly taxed as those of the other hereditary countries. As to the states, they are much the same in this country as in the other Austrian territories, except that the peasants here send deputies to the diets. Tirol came to the house of Austria in the year 1363, when Margaret, countess thereof, bequeathed it to her uncles the dukes of Austria. Besides the governor, here are three sovereign colleges, subordinate to the court at Vienna, which sit at Inspruck, and have their different departments. Towards the expences of the military establishment of this country, the proportion is 100,000 florins yearly; but no more than one regiment of foot is generally quartered in it.

Tirol, Titan.

Tirol is divided into six quarters, as they are called; namely, those of the Lower and Upper Innthal, Vintsgow, Etch, Eisack, and Pusterthal. At the peace of Presburg in 1805, Austria was compelled to cede the Tirol. The brave inhabitants however took arms, and under Andrew Hofer an innkeeper, made an obstinate resistance. Deputies came to London to seek pecuniary supplies, and considerable sums were raised. But the French at last succeeded in subduing the country. The greater part of the Tirol was annexed to Bavaria, in whose possession it continued till 1815, when it was restored to Austria. Its population in 1815 amounted to 802,000 including Trent and Brixen.

TITAN, in fabulous history, the son of Cœlus and Terra, and the elder brother of Saturn, suffered the latter to enjoy the crown, on condition that he should bring up none of his male issue, by which means the crown should at length revert to him; but Jupiter being spared by the address of Rhea, Saturn's wife, Titan and his children were so enraged at seeing their hopes frustrated, that they took up arms to revenge the injury; and not only defeated Saturn, but kept him and his wife prisoners till he was delivered by Jupiter, who defeated the Titans; when from the blood of these Titans slain in the battle, proceeded serpents, scorpions, and all venomous reptiles. See SATURN.

Such is the account given by the poets of this family of Grecian and Roman gods. From the fragments of Sanchoniatho, however, and other ancient writers, many learned men have inferred that the Titans were an early race of ambitious heroes, who laid the foundation of that idolatry which quickly overspread the world, and that

Titan. that by assuming the names of the luminaries of heaven they contrived to get themselves every where adored as the *Dii majorum gentium*. That the word *Titan* signifies the sun, there can indeed be very little doubt. Every one knows that such was its signification in the Æolic dialect; and as it is evidently compounded of *Ti*, which, in some oriental tongues, signifies *bright* or *clear*, and *Tan*, which signifies a *country* or the *earth*, it may be safely concluded that *Titan* was the name of the sun before the word was imported into Greece. But the great question among antiquarians is, of what country was that race which, assuming to themselves the names of the heavenly bodies, introduced into the world that species of idolatry which is known by the appellation of *Hero-worship*?

M. Pezron, in a work published many years ago, and entitled *The Antiquities of Nations*, maintains that the Titans were a family of Sacæ or Scythians, who made their first appearance beyond Media and Mount Imaus, in the upper regions of Asia; that they were the descendants of Gomer the son of Japheth and grandson of Noah; and that after conquering a great part of the world, upon entering Upper Phrygia, they quitted their ancient name of Gomerians or Cimmerians, and assumed that of Titans. All this, he says, happened before the birth of Abraham and the foundation of the Assyrian monarchy; and he makes Uranus, their second prince in the order of succession, to have conquered Thrace, Greece, the island of Crete, and a great part of Europe. Uranus was succeeded by Saturn, and Saturn by Jupiter, who flourished, he says, 300 years before Moses, and divided his vast empire between himself, his brother Pluto, and his cousin-german Atlas, who was called *Telamon*. For the truth of this genealogy of the Titans M. Pezron appeals to the most approved Greek historians; but unluckily for his hypothesis, these writers have not a single sentence by which it can be fairly supported. It supposes not only the great antiquity of the Scythians, but likewise their early progress in arts and sciences, contrary to what we have proved in other articles of this work. See SCULPTURE, N° 4 and 5. and SCYTHIA.

Others, taking the fragment of Sanchoniatho's Phenician history for their guide, have supposed the Titans to have been the descendants of Ham. Of this opinion was Bishop Cumberland; and our learned friend Dr Doig, to whom we have been indebted for greater favours, indulged us with the perusal of a manuscript, in which, with erudition and ingenuity struggling for the pre-eminence, he traces that impious family from the profane son of Noah, and shows by what means they spread the idolatrous worship of themselves over the greater part of the ancient world. Cronus, of whose exploits some account has been given elsewhere (see SANCHONIATHO), he holds to be Ham; and tracing the progress of the family from Phœnicia to Cyprus, from Cyprus to Rhodes, thence to Crete, and from Crete to Samothrace, he finds reason to conclude that the branch called *Titans* or *Titanides* flourished about the era of Abraham, with whom, or with his son Isaac, he thinks the Cretan Jupiter must have been contemporary. As they proceeded from countries which were the original seat of civilization to others in which mankind had sunk into the grossest barbarism, it was easy for them to persuade the ignorant inhabitants that they derived the arts of civil life from their parent the sun, and in consequence of their relation to him to assume to themselves divine honours. To ask how they came to think of such gross impiety, is a question as foolish as it would be to ask how Ham their ancestor became so wicked as to entail the curse of God upon himself and his posterity. The origin of evil is involved in difficulties; but leaving all inquiries into it to be prosecuted by the metaphysician and moralist, it is surely more probable that the worship of dead men originated among the descendants of Ham than among those of Shem and Japheth; and that the fragment of Sanchoniatho, when giving an account of the origin of the Titans, the undoubted authors of that worship, is more deserving of credit than the fabulous and comparatively late writers of Greece and Rome. Titan, Tithes.

TITHES, in ecclesiastical law, are defined to be the tenth part of the increase, yearly arising and renewing from the profits of lands, the stock upon lands, and the personal industry of the inhabitants: the first species being usually called *predial*, as of corn, grass, hops and wood; the second *mixed*, as of wool, milk, pigs, &c. consisting of natural products, but nurtured and preserved in part by the care of man; and of these the tenth must be paid in gross; the third *personal*, as of manual occupations, trades, fisheries, and the like; and of these only the tenth-part of the clear gains and profits is due.

We shall, in this article, consider, 1. The original of the right of tithes. 2. In whom that right at present subsists. 3. Who may be discharged, either totally or in part, from paying them.

1. As to their original, we will not put the title of the clergy to tithes upon any divine right; though such a right certainly commenced, and we believe as certainly ceased, with the Jewish theocracy. Yet an honourable and competent maintenance for the ministers of the gospel is undoubtedly *jure divino*, whatever the particular mode of that maintenance may be. For, besides the positive precepts of the New Testament, natural reason will tell us, that an order of men who are separated from the world, and excluded from other lucrative professions for the sake of the rest of mankind, have a right to be furnished with the necessaries, conveniences, and moderate enjoyments of life, at their expence; for whose benefit they forego the usual means of providing them. Accordingly all municipal laws have provided a liberal and decent maintenance for their national priests or clergy; ours, in particular, have established this of tithes, probably in imitation of the Jewish law: and perhaps, considering the degenerate state of the world in general, it may be more beneficial to the English clergy to found their title on the law of the land, than upon any divine right whatsoever, unacknowledged and unsupported by temporal sanctions. *Blackst. Comment.*

We cannot precisely ascertain the time when tithes were first introduced into this country. Possibly they were contemporary with the planting of Christianity among the Saxons by Augustin the monk, about the end of the sixth century. But the first mention of them which we have met with in any written English law, is a constitutional decree, made in a synod held A. D. 786, wherein the payment of tithes in general is strongly enjoined. This canon or decree, which at first bound not the laity, was effectually confirmed by two kingdoms

Tithes. kingdoms of the heptarchy, in their parliamentary conventions of estates, respectively consisting of the kings of Mercia and Northumberland, the bishops, dukes, senators, and people. Which was a few years later than the time that Charlemagne established the payment of them in France, and made that famous division of them into four parts; one to maintain the edifice of the church, the second to support the poor, the third the bishop, and the fourth the parochial clergy.

The next authentic mention of them is in the *fœdus Edwardi et Guthruni*; or the laws agreed upon between King Guthrun the Dane, and Alfred and his son Edward the Elder, successive kings of England, about the year 900. This was a kind of treaty between those monarchs, which may be found at large in the Anglo-Saxon laws: wherein it was necessary, as Guthrun was a Pagan, to provide for the subsistence of the Christian clergy under his dominion; and accordingly, we find the payment of tithes not only enjoined, but a penalty added upon non-observance: which law is seconded by the laws of Athelstan, about the year 930. And this is as much as can certainly be traced out with regard to their legal original.

2. We are next to consider the persons to whom tithes are due. Upon their first introduction, though every man was obliged to pay tithes in general, yet he might give them to what priests he pleased; which were called *arbitrary consecrations of tithes*; or he might pay them into the hands of the bishop, who distributed among his diocesan clergy the revenues of the church, which were then in common. But when dioceses were divided into parishes, the tithes of each parish were allotted to its own particular minister; first by common consent or the appointments of lords of manors, and afterwards by the written law of the land.

Arbitrary consecrations of tithes took place again afterwards, and were in general use till the time of King John. This was probably owing to the intrigues of the regular clergy, or monks of the Benedictine and other orders, under Archbishop Dunstan and his successors; who endeavoured to wean the people from paying their dues to the secular or parochial clergy (a much more valuable set of men than themselves), and were then in hopes to have drawn, by sanctimonious pretences to extraordinary purity of life, all ecclesiastical profits to the coffers of their own societies. And this will naturally enough account for the number and riches of the monasteries and religious houses which were founded in those days, and which were frequently endowed with tithes. For a layman, who was obliged to pay his tithes somewhere, might think it good policy to erect an abbey, and there pay them to his own monks, or grant them to some abbey already erected; since for this donation, which really cost the patron little or nothing, he might, according to the superstition of the times, have masses for ever sung for his soul. But in process of years, the income of the poor laborious parish-priests being scandalously reduced by these arbitrary consecrations of tithes, it was remedied by Pope Innocent III. about the year 1200, in a decretal epistle sent to the archbishop of Canterbury, and dated from the palace of Lateran: which has occasioned Sir Henry Hobart and others to mistake it for a decree of the council of Lateran, held A. D. 1179, which only prohibited what was called the *infeodation of tithes*, or their being granted to mere laymen; whereas this letter of Pope Innocent to the archbishop enjoined the payment of tithes to the parsons of the respective parishes where every man inhabited, agreeable to what was afterwards directed by the same pope in other countries. This epistle, says Sir Edward Coke, bound not the lay subjects of this realm; but being reasonable and just, it was allowed of, and so became *lex terræ*. This put an effectual stop to all the arbitrary consecrations of tithes; except some footsteps which still continue in those portion of tithes which the parson of one parish hath, though rarely, a right to claim in another: for it is now universally held, that tithes are due, of common right, to the parson of the parish, unless there be a special exemption. This parson of the parish, may be either the actual incumbent, or else the appropriator of the benefice; appropriations being a method of endowing monasteries, which seems to have been devised by the regular clergy, by way of substitution to arbitrary consecrations of tithes.

3. We observed that tithes are due of common right to the parson, unless by special exemption; let us therefore see, *thirdly*, who may be exempted from the payment of tithes, and how lands and their occupiers may be exempted or discharged from the payment of tithes, either in a part or totally; first, by a real composition; or, secondly, by custom or prescription.

First, A real composition is when an agreement is made between the owner of the lands and the parson or vicar, with the consent of the ordinary and the patron, that such lands shall for the future be discharged from payment of tithes, by reason of some land or other real recompense given to the parson in lieu and satisfaction thereof. This was permitted by law, because it was supposed that the clergy would be no losers by such composition; since the consent of the ordinary, whose duty it is to take care of the church in general, and of the patron, whose interest it is to protect that particular church, were both made necessary to render the composition effectual: and hence have arisen all such compositions as exist at this day by force of the common law. But experience showing that even this caution was ineffectual, and the possessions of the church being by this and other means every day diminished, the disabling statute 13 Eliz. c. 10. was made; which prevents among other spiritual persons, all parsons and vicars from making any conveyances of the estates of their churches, other than for three lives of 21 years. So that now, by virtue of this statute, no real composition made since the 13 Eliz. is good for any longer term than three lives or 21 years, though made by consent of the patron and ordinary: which has indeed effectually demolished this kind of traffic; such compositions being now rarely heard of, unless by authority of parliament.

Secondly, a discharge by custom or prescription, is where time out of mind such persons or such lands have been either partially or totally discharged from the payment of tithes. And this immemorial usage is binding upon all parties; as it is in its nature an evidence of universal consent and acquiescence, and with reason supposes a real composition to have been formerly made. This custom or prescription is either *de modo decimandi*, or *de non decimando*.

A *modus decimandi*, commonly called by the simple name of a *modus* only, is where there is by custom a particular

Tithes.

particular manner of tithing allowed, different from the general law of taking tithes in kind, which are the actual tenth-part of the annual increase. This is sometimes a pecuniary compensation, as twopence an acre for the tithe of land: sometimes it is a compensation in work and labour, as that the parson shall have only the twelfth cock of hay, and not the tenth, in consideration of the owner's making it for him: sometimes, in lieu of a large quantity of crude or imperfect tithe, the parson shall have a less quantity when arrived at greater maturity, as a couple of fowls in lieu of tithe-eggs, and the like. Any means, in short, whereby the general law of tithing is altered, and a new method of taking them is introduced, is called a *modus decimandi*, or special manner of tithing.

A prescription *de non decimando* is a claim to be entirely discharged of tithes, and to pay no compensation in lieu of them. Thus the king by his prerogative is discharged from all tithes. So a vicar shall pay no tithes to the rector, nor the rector to the vicar, for *ecclesia decimas non solvit ecclesiæ*. But these personal privileges (not arising from or being annexed to the land) are personally confined to both the king and the clergy; for their tenant or lessee shall pay tithes, though in their own occupation their lands are not generally tithable. And, generally speaking, it is an established rule, that in lay hands, *modus de non decimando non valet*. But spiritual persons or corporations, as monasteries, abbots, bishops, and the like, were always capable of having their lands totally discharged of tithes by various ways: as, 1. By real composition. 2. By the pope's bull of exemption. 3. By unity of possession; as when the rectory of a parish, and lands in the same parish, both belonged to a religious house, those lands were discharged of tithes by this unity of possession. 4. By prescription; having never been liable to tithes, by being always in spiritual hands. 5. By virtue of their order; as the Knights Templars, Cistercians, and others, whose lands were privileged by the pope with a discharge of tithes. Though, upon the dissolution of abbeys by Henry VIII. most of these exemptions from tithes would have fallen with them, and the lands become tithable again, had they not been supported and upheld by the statute 31 Henry VIII. c. 13. which enacts, that all persons who should come to the possession of the lands of any abbey then dissolved, should hold them free and discharged of tithes, in as large and ample a manner as the abbeys themselves formerly held them. And from this original have sprung all the lands which being in lay hands, do at present claim to be tithe-free: for if a man can show his lands to have been such abbey-lands, and also immemorially discharged of tithes by any of the means before mentioned, this is now a good prescription *de non decimando*. But he must show both these requisites: for abbey-lands, without a special ground of discharge, are not discharged of course; neither will any prescription *de non decimando* avail in total discharge of tithes, unless it relates to such abbey-lands.

It is universally acknowledged that the payment of tithes in kind is a great discouragement to agriculture. They are inconvenient and vexatious to the husbandman, and operate as an impolitic tax upon industry. The clergyman, too, frequently finds them troublesome and precarious; his expences in collecting are a considerable drawback from their value, and his just rights are with difficulty secured: he is too often obliged to submit to imposition, or is embroiled with his parishioners in disputes and litigations, no less irksome to his feelings than prejudicial to his interest, and tending to prevent those good effects which his precepts should produce. It is therefore of the utmost importance to parochial tranquillity, and even to religion, that some just and reasonable standard of composition could be fixed. Land has been proposed, but in the present state of the division of property this is impossible: and as money is continually changing in its value, it would also be a very improper standard, unless some plan could be formed by which the composition could be increased as the value of money diminishes. A plan of this kind has been published in the Transactions of the Society instituted at Bath, vol. iv. which those who are interested in this subject may consult for farther information.

Tithes ‖ Titian.

TITHING, (*Tithinga*, from the Sax. *Theothunge*, i. e. *Decuriam*), a number or company of ten men, with their families, knit together in a kind of society, and all bound to the king, for the peaceable behaviour of each other. Anciently no man was suffered to abide in England above forty days, unless he were enrolled in some tithing.—One of the principal inhabitants of the tithing was annually appointed to preside over the rest, being called the *tithing-man*, the head-borough, and in some countries the borseholder, or borough's ealder, being supposed the discreetest man in the borough, town, or tithing. The distribution of England into tithings and hundreds is owing to King Alfred. See BORSEHOLDER.

TITIANO VECELLI, or TITIAN, the most universal genius for painting of all the Lombard-school, the best colourist of all the moderns, and the most eminent for histories, portraits, and landscapes, was born at Cadore, in the province of Friuli, in the state of Venice, in 1477, or in 1480 according to Vasari and Sandrart. His parents sent him at ten years of age to one of his uncles at Venice, who finding that he had an inclination to painting, put him to the school of Giovanni Bellino.

Pilkington's Dictionary of Painters.

But as soon as Titian had seen the works of Giorgione, whose manner appeared to him abundantly more elegant, and less constrained than that of Bellino, he determined to quit the style to which he had so long been accustomed, and to pursue the other that recommended itself to him, by having more force, more relief, more nature, and more truth. Some authors affirm, that he placed himself as a disciple with Giorgione; yet others only say, that he cultivated an intimacy with him; but it is undoubtedly certain that he studied with that great master; that he learned his method of blending and uniting the colours; and practised his manner so effectually, that several of the paintings of Titian were taken for the performances of Giorgione; and then his success inspired that artist with an invincible jealousy of Titian, which broke off their connection for ever after.

The reputation of Titian rose continually; every new work contributed to extend his fame through all Europe; and he was considered as the principal ornament of the age in which he flourished. And yet, Sandrart observes that amidst all his applause and constant employment at Venice, his income and fortune were inconsiderable; and

and he was more remarkable for the extensiveness of his talents, than for the affluence of his circumstances. But when his merit was made known to the emperor Chas. V. that monarch knew how to set a just value on his superior abilities; he enriched him by repeated bounties, allowed him a considerable pension, conferred on him the honour of knighthood, and, what was still more, honoured him with his friendship. He painted the portrait of that benefactor several times; and it is recorded by Sandrart, that one day, while the emperor was sitting for his picture, a pencil happening to drop from the painter, he stooped, took it up, and returned it; obligingly answering to the modest apology of the artist (who blushed at the condescension of so great a monarch), that the merit of a Titian was worthy of the attendance of an emperor.

The excellence of Titian was not so remarkably apparent in the historical compositions which he painted as in his portraits and landscapes, which seem to be superior to all competition; and even to this day, many of them preserve their original beauty, being as much the admiration of the present age as they have deservedly been of the ages past.—It is observed of Titian by most writers, that in the different periods of his life he had four different manners; one resembling his first instructor Bellino, which was somewhat stiff; another, in imitation of Giorgione, more bold, and full of force; his third manner was the result of experience, knowledge, and judgment, beautifully natural, and finished with exquisite care, which manner was peculiarly his own; and in those pictures which he painted between the years of approaching old age and his death may be noticed his fourth manner. His portraits were very differently finished in his early, and in his latter time, according to the testimony of Sandrart. At first he laboured his pictures highly, and gave them a polished beauty and lustre, so as to produce their effect full as well when they were examined closely as when viewed at a distance; but afterwards, he so managed his penciling, that their greatest force and beauty appeared at a more remote view, and they pleased less when they were beheld more nearly. So that many of those artists who studied to imitate him, being misled by appearances which they did not sufficiently consider, have imagined that Titian executed his work with readiness and a masterly rapidity; and concluded that they should imitate his manner most effectually by a freedom of hand and a bold pencil: Whereas in reality, Titian took abundance of pains to work up his pictures to so high a degree of perfection; and the freedom that appears in the handling was entirely effected by a skilful combination of labour and judgment.

It cannot be truly affirmed, that Titian equalled the great masters of the Roman school in design; but he always took care to dispose his figures in such attitudes as showed the most beautiful parts of the body. His taste in designing men was not generally so correct or elegant as it appeared in his boys and female figures; but his colouring had all the look of real flesh, his figures breathe. He was not so bold as Giorgione, but in tenderness and delicacy he proved himself much superior to him and all other artists. The expression of the passions was not his excellence, though even in that respect many of his figures merited the justest commendation; but he always gave his figures an air of ease and dignity. His landscapes are universally allowed to be unequalled, whether we consider the forms of his trees, the grand ideas of nature which appear in his scenery, or his distances which agreeably delude and delight the eye of every observer; and they are executed with a light, tender, and mellow pencil. He learned from nature the harmony of colours, and his tints seem astonishing, not only for their force, but their sweetness; and in that respect his colouring is accounted the standard of excellence to all professors of the art.

It would prove almost an endless task to enumerate the variety of works executed by this illustrious artist, at Rome, Venice, Bologna, and Florence, as well as those which are to be seen in other cities of Italy, in England, Spain, Germany, and France; but there are two, which are mentioned as being truly admirable. One is, a Last Supper, preserved in the refectory at the Escurial in Spain, which is inimitably fine; the other is at Milan, representing Christ crowned with thorns. The principal figure in the latter has an attitude full of grace and dignity more than mortal, and the countenance shows a benevolence and humility, combined with dignity and pain, which no pencil but that of Titian could so feelingly have described. It is admirably coloured, and tenderly and delicately penciled; the heads are wonderfully beautiful, the composition excellent, and the whole has a charming effect by the chiaro-scuro.

He was of so happy a constitution, that he was never ill till the year 1576, when he died of the plague, at 99 years of age. His disciples were Paulo Veronese, Giacomo Tintoret, Giacomo de Porte Bassano, and his sons.

TITLARK. See ALAUDA, ORNITHOLOGY *Index*.

TITLE, an appellation of dignity or rank given to princes and persons of distinction.

Titles were not so common among the ancient Greeks or Romans as they are in modern times. Till the reign of Constantine the title of *Illustrious* was never given except to those who were distinguished in arms or letters: But at length it became hereditary in the families of princes, and every son of a prince was illustrious. The title of *Highness* was formerly given only to kings. The kings of England before the reign of Henry VIII. were addressed by the title of *your Grace*. That monarch first assumed the title of *Highness*, and afterwards that of *Majesty*. The title of majesty was first given him by Francis I. in their interview in 1520. Charles V. was the first king of Spain who assumed the same title.

Princes, nobles, and clergy, generally have one title derived from their territories and estates, and another derived from their rank or from some other remarkable circumstance. The pope is called the *Bishop of Rome*, and has the title of *Holiness*. A cardinal has his name generally from some church, and is saluted by the name of *Eminent*, or *most Eminent*. An archbishop, besides being named from his diocese, is called *his Grace* and *most Reverend*: a bishop is also distinguished by the name of his diocese, and has the title of *his Lordship* and *right Reverend*. Inferior clergymen are denominated *Reverend*.

The titles of crowned heads derived from their dominions it is unnecessary to mention. It will be sufficient to mention those by which they are addressed. To an emperor

emperor is given the title of *Imperial Majesty*; to kings, that of *Majesty*; to the princes of Great Britain, *Royal Highness*; to those of Spain, *Infant*; to electors, *Electoral Highness*; to the grand duke of Tuscany, *Most Serene Highness*; to the other princes of Italy and Germany, *Highness*; to the doge of Venice, *Most Serene Prince*; to the grand-master of Malta, *Eminence*; to nuncios and ambassadors of crowned heads, *Excellency*; to dukes, *Grace*; to marquises, earls, and barons, *Lordship*.

The emperor of China, among his titles, takes that of *Tien Su*, "Son of Heaven." The Orientals, it is observed, are exceedingly fond of titles; the simple governor of Schiras, for instance, after a pompous enumeration of qualities, lordships, &c. adds the titles of *Flower of Courtesy*, *Nutmeg of Consolation*, and *Rose of Delight*.

TITLE, in *Law*, denotes any right which a person has to the possession of a thing, or an authentic instrument whereby he can prove his right. See the articles RIGHT, PROPERTY, &c.

TITLE to the Crown in the British Constitution. See SUCCESSION.

TITMOUSE. See PARUS, ORNITHOLOGY *Index*.

TITULAR, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he performs the functions thereof or not.

TITUS VESPASIANUS, the Roman emperor, the son of Vespasian; of whom it is related, that not being able to recollect any remarkable good action he had done on a certain day, he exclaimed, "I have lost a day!" He might truly be called the *father of his people*; and though Rome laboured under various public calamities during his reign, such was his equitable and mild administration, that he constantly preserved his popularity. He was a great lover of learning, and composed several poems. He reigned but two years; and it is thought Domitian his brother poisoned him, A. D. 81. aged 41. See (*History of*) ROME.

TIVIOT HILLS. See CHEVIOT.

TIVOLI, the modern name of TIBUR.

TOAD. See RANA, ERPETOLOGY *Index*.

TOAD-Fish. See LOPHIUS, ICHTHYOLOGY *Index*.

TOAD-Flax. See ANTIRRHINUM, BOTANY *Index*.

TOAD-Stone, an argillaceous stone. See GEOLOGY.

TOBACCO. See NICOTIANA, BOTANY *Index*, and SNUFF.

TOBACCO-Pipe-Fish. See FISTULARIA, ICHTHYOLOGY *Index*.

TOBACCO-Pipes, *Manufacture of*. The art of making tobacco-pipes, or, as it is commonly called, *pipe-making*, though one of the simplest species of pottery, is sufficiently curious to merit description in a dictionary of arts and sciences.

The process of pipe-making may be divided into six stages; viz. 1. Beating or preparing the clay; 2. Rolling; 3. Moulding; 4. Trimming; 5. Drying; and, 6. Burning.

Preparation of the Clay.—The fine white clay employed by the pipe-makers, is dug from the quarries in masses of about a cubic foot each. Before it can be used in the manufacture of tobacco-pipes, it must be reduced to the consistence of a tough paste. To effect this, after its outer surface has been cleared from dirt or dust, it is broken into small pieces about as large as a goose's egg, and thrown into a tub with such a quantity of soft water as experience has shown to be sufficient to bring it to the proper consistence. After lying till it has soaked up all the water, which usually requires from 12 to 24 hours, it is taken from the tub and laid on a thick strong wooden bench. Here it is beaten by a heavy four-square iron instrument, in such a manner as to cut it from one end to the other into very thin slices. It requires considerable address to perform this operation, and it is surprising how thin the workmen will sometimes cut the slices, and how equally they will thus divide the clay. This beating is continued, alternately folding up the clay and slicing it, till the whole is perfectly smooth. It is then ready for rolling.

Rolling.—The operation of rolling reduces the clay into pieces of a proper size and length for making pipes, and almost to the proper form. The roller sits at a bench with a smooth board before him, and holds in his hand another smooth board about 18 inches long, four broad, and about half an inch thick, having one end rounded off on one side, so as to produce a corresponding hollow in the clay. He now takes a piece of the beaten clay, and rolls it out, first with his hands, and then with the board, till it acquire the form of a long slender cylinder, with one end considerably larger than the rest. This large end is to form the bole, and the cylinder the shank of the future pipe. The pieces of clay thus formed are laid beside each other on a flat board, and are now ready for moulding.

Moulding.—This is the most complex operation, and requires the greatest number of instruments. The principal of these is the mould, which is composed of two long pieces of iron, formed so as to join together, and having their corresponding sides cut into the shape of half a tobacco pipe, each piece being hollowed so as to form half a slender cylinder, with a larger cavity at the upper end, and at such an angle as it is intended the bole of the pipe shall make with the shank. Just above that part of each side of the mould which stands beyond what is intended to form the bole, there is a notch for admitting a knife to cut off the superfluous clay. To receive the united mould there is a vice, having at one end two upright posts, between which moves a long lever, and to this lever, near the posts, there is loosely attached a piece of iron ending below in a smooth conical head, capable of entering the large opening of the mould, but rather smaller than the opening, so as that when forced down into it, a sufficient thickness of clay may be left between the cone and the sides of the mould, to form the bole of the pipe. One side of this vice is fixed, and the other moveable, towards the former. The moveable side has attached to it an iron screw with a very long lever as its handle, so that by turning the screw one way or the other, the moveable side of the vice may be forced nearer the fixed side, or suffered to return to its original position.

Besides these principal instruments, the moulder requires a slender steel wire, fixed in a handle at one end, and having its other extremity formed into a very small head; a saucer containing wool well impregnated with oil, and a small woollen or cotton brush.

When about to mould his pipes, he lays hold of the shank of one of the rolled pieces, and with great dexterity, which practice alone can teach, he passes up the oiled

Tobacco. oiled wire through its whole length, till he finds it arrived at the commencement of the larger extremity of the clay. This extremity he then bends to the proper angle, and having oiled the inside of each part of his mould, he lays the piece of clay with the wire in it, into one part of the mould, and covers it with the other. He now puts the mould containing the clay into the vice, and with the left hand turning round the handle of the screw, so as to fix the mould firmly within the vice, he, with the right hand, presses down the lever with its conical head, and thus forms the cavity of the bole. He now withdraws the mould, cuts off with his knife the superfluous clay from the bole, opens the mould, takes out the pipe, and now only withdraws the wire. He then lays the moulded pipe on a flat board, in the same manner as the rolled pieces before described. The pipes thus moulded require to be trimmed, that is, to have the prominences arising from the joining of the mould, and other superfluous pieces of clay taken off, so as to render the surface smooth and round.

Trimming.—The operation of trimming is generally performed by boys and girls, as it requires very little skill. The trimmer has before him a smooth block of wood, about the length of the pipe, and of considerable thickness, elevated a little at the remote end. He has also a thick piece of smooth iron, one edge of which has across it two or more semicylindrical grooves, capable of receiving half the shank of a pipe. Taking one of the rough moulded pipes, the trimmer carefully passes up the hollow of the shank, a wire similar to that employed in moulding, and holding the pipe by the bole, while the shank lies before him on the wooden block, he pares off with a blunt knife all the excrescences of clay, both from the shank and bole, and rubs the former, while lying on the block, with the grooved part of his iron, so as to render it as smooth as possible. He now cuts off the ragged piece at the extremity of the shank, withdraws the wire, and lays the pipe on the drying frame. One great object of the trimmer is, to see that the pipe is completely perforated, which he discovers by blowing through it; and if he finds the hole choked up, he must open it by pushing the wire as far as possible. If this does not succeed, he breaks the pipe as useless.

Drying.—The pipe has now received all the work that can be bestowed on it by the maker, previous to its being burned; but as the exposing of it to heat, while soft and pliable, would make it crack, it is necessary that it be properly dried. For this purpose, a frame is prepared, composed of three or four long pieces of wood, fastened to two end pieces in such a manner, as that the middle of the frame shall be the lowest, to give the shanks of the pipes that curve which they generally possess. After being trimmed, the pipes are laid beside each other in this concave frame, with their boles hanging down over the edges of the frame, and their shanks bending within its hollow. In this position they are exposed to the air till they are dry and firm. They are then ready for burning or baking.

Burning.—For burning or baking the pipes, there is to be prepared a kiln of a simple but peculiar construction. It is built in the form of a cylinder, close at the bottom and on the sides, and open at the top. Below the bottom is a grate for receiving the fuel, and round the sides are constructed vertical or spiral flues, opening at the top, and communicating below with the grate. The sides of the furnace on its interior are pretty thin, and are formed of a cement composed of clay mixed with fresh cow dung. In the middle of the cavity is placed a pedestal composed of the same materials, for the pipes to lean against. When the pipes are sufficiently dried, they are arranged round this pedestal, resting against it, and against each other, with their boles next the bottom of the furnace. They are thus placed in successive layers, till the furnace be sufficiently full, when the open space at top is filled up with bricks placed over each other, so as to leave interstices for the free circulation of the air, and of the smoke and flame which issue through the flues. In these interstices are laid several pieces of broken dried pipes, to serve as pyrometers for ascertaining the state of the included pipes during the burning. The fire is now lighted, and kept up, till, on examining the pieces of clay laid in the interstices of the bricks, it is concluded that the pipes within the furnace are sufficiently baked. The fire is then suffered to go out, and the whole to cool till the next day, when the bricks are taken down, the pipes removed, and packed in barrels for sale.

After being burnt, the pipes are sometimes glazed, which is done by rubbing them, while warm, with flannel and a little white flax. In some places the extremities of the shanks are rendered smooth by dipping them before burning in the ordinary potters glazing, which prevents that adhesion to the lips so unpleasant in new unglazed pipes.

Tobacco, Tobago. TOBAGO, one of the Caribbee islands, ceded to Great Britain by the treaty of Paris in 1763, taken by the French in 1781, and retaken by the British in 1793. It lies in the latitude of 11 degrees 10 minutes north, and 59 degrees 40 minutes longitude west from London, about 40 leagues south-by-west from Barbadoes, 35 south-east from St Vincents, 20 south-east from Grenada, 12 north-east from the Spanish island of Trinidada, and between 30 and 40 north-east from the Spanish main. According to the latest accounts, it is somewhat more than 30 miles in length from north-east to south-west, between 8 and 9 in breadth, and from 23 to 25 leagues in circumference. The English visited this island very early, Sir Robert Dudley being there in the reign of Queen Elizabeth. In that of Charles I. William earl of Pembroke procured a grant of this, with two other small islands; but died before he was able to carry into execution his design of settling them. In A. D. 1632 some merchants of Zealand sent over a small colony thither, and gave it the name of *New Walcheren;* but before they were able thoroughly to establish themselves, they were destroyed by the Indians assisted by the Spaniards. Ten years after, James duke of Courland sent a colony thither, who settled themselves upon Great Courland bay, and made a considerable progress in planting. A. D. 1654, Messieurs Adrian and Cornelius Lampsius, two opulent merchants of Flushing, sent a considerable number of people thither, who settled on the other side of the island, and lived in amity with the Courlanders, until they learned that the king of Sweden had seized the person of their duke and dispossessed him of his dominions, when they attacked and forced his subjects to submit. The duke being afterwards restored, he obtained from Charles II. a grant of this island, dated the 17th of November 1664.

1664. In the second Dutch war the count d'Estrees, by order of his master, totally ruined it at the close of the year 1677; and from that time it continued waste till Britain took possession of it after the treaty of Paris. The climate, notwithstanding its vicinity to the line, is so tempered by the breezes from the sea, as to be very supportable even to Europeans; and has the same advantages with that of Grenada, in having regular seasons, and also in being exempt from the hurricanes. There are throughout the island many rising grounds, though, except at the north-east extremity, there is no part of it that can be styled mountainous; and even there the country is far from being rugged or impassable. The soil, if we may credit either Dutch or French writers, is as fertile and luxuriant as any of the islands, and very finely diversified. Ground provisions of all sorts have been raised in great plenty, a vast variety of vegetables, excellent in their kind, some for food, some for physic. Almost every species of useful timber is to be found here, and some of an enormous size; amongst others, the true cinnamon and nutmeg tree, as the Dutch confess, and of which none could be better judges; whole groves of sassafras, and of trees that bear the true gum copal, with other odoriferous plants that render the air wholesome and pleasant. It is as well watered as can be wished, by rivers that fall into the sea on both sides, many smaller streams, and fine fresh springs in almost every part of the island. The sea-cost is indented by 10 or 12 fair and spacious bays, and there are amongst these one or two ports capable of receiving as large ships as ever visited those seas. There are wild hogs in great plenty, abundance of fowls of different kinds, and a vast variety of sea and river fish. At the north-east extremity lies little Tobago, which is two miles long, and about half a mile broad, very capable of improvement.

TOBOLSK, the capital of a province of the same name in Asiatic Russia, comprehending the greater part of the country known by the name of Siberia, is situated at the confluence of the rivers Tobol and Irtish, in N. Lat. 58° 12′, E. Long. 68° 18.′ The city stands upon the ascent of a high hill, the lower part of which is inhabited by Mahometan Tartars, who carry on a considerable traffic upon the river Irtish, and convey their merchandise quite across Great Tartary, as far as China. The river Irtish joins the Tobol, and both fall into the Oby. By means of these two rivers, there is a constant flow of merchandise into the city during the summer season. Tobolsk is therefore a great mart for the commodities of Muscovy, Tartary, and other countries: and here is a great concourse of merchants. All sorts of provisions are plentiful and cheap. An hundred weight of rice is sold for 16 copecs, equal to about eightpence sterling; a sturgeon weighing 40 pounds, for half that money; an ox for two rix-dollars, and every other article in proportion. The adjacent country abounds with game in great variety. The supreme court of judicature for all Siberia is held in this city, which is also the seat of a metropolitan, sent hither from Moscow to exercise spiritual jurisdiction over the whole kingdom. Tobolsk is well fortified, and defended by a strong garrison, under the command of the governor, who resides in the place, and takes charge of the fur tribute, which is here deposited in proper magazines. This governor enjoys a very extensive command, and can occasionally bring into the field 9000 men besides a strong body of Tartars on horseback, to make head against the Kalmucks and Cossacks, in their repeated incursions. A sufficient number of Russians, called *Jemskoiks*, are kept in continual pay by the government, on the banks of the Irtish, to supply travellers on the czar's account with men, boats, or carriages, to convey them as far as Surgut on the Oby, a voyage of 200 leagues by water. This is the common method of travelling in the summer; but in winter the journey by land is not half so long, being performed in sleds over the ice and snow, with which the country is covered. These sleds are moved by a pair of dogs, which will draw a load of 300 pounds with surprising expedition. They are hired at easy rates, and during one half of the year may be seen flying over the snow in great numbers. The city is supposed to contain 15,000 inhabitants. It is 900 miles east from Moscow, and 1200 from Petersburgh.

TODDA Panna. See Cycas, Botany *Index*.

TODDY, a name given to the juice of the cocoa-nut tree. See Arack.—Tody is also a name given to a mixture of spirits, water, and sugar.

Toddy-Bird. See Loxia, Ornithology *Index*.

TODUS, the Tody; a genus of birds belonging to the order of picæ. See Ornithology *Index*.

TOGA, in Roman antiquity, a wide woollen gown or mantle, which seems to have been of a semicircular form, without sleeves; differing both in richness and largeness, according to the circumstances of the wearer, and used only upon occasion of appearing in public.

Every body knows that the toga was the distinguished mark of a Roman: hence the *jus togæ*, or privilege of a Roman citizen; i. e. the right of wearing a Roman habit, and of taking as they explain it, fire and water through the Roman empire.

TOKAY wine, derives its name from a town of Hungary, where it is produced. There are four sorts of wine made from the same grapes, distinguished at Tokay by the names of *essence*, *auspruch*, *masluch*, and the *common wine*. The essence is made by picking out the half-dried and shrivelled grapes, and putting them into a perforated vessel, where they remain as long as any juice runs off by the mere pressure of their own weight. This is put into small casks. The auspruch is made by pouring the expressed juice of the grapes from which the former had been picked on those that yielded the essence, and treading them with the feet. The liquor thus obtained stands for a day or two to ferment, and then is poured into small casks, which are kept in the air for about a month, and afterwards put into casks. The same process is again repeated by the addition of more juice to the grapes which have already undergone the two former pressures, and they are now wrung with the hands; and thus is had the maslach. The fourth kind is made by taking all the kinds together at first, and submitting them to the greatest pressure: this is chiefly prepared by the peasants. The essence is thick, and very sweet and lucious: it is chiefly used to mix with the other kinds. The auspruch is the wine commonly exported, and which is known in foreign countries by the name of *Tokay*.

The goodness of it is determined by the following rules. The colour should neither be reddish nor very pale, but a light silver: in trying it, the palate and tip of

Tokay Wine ‖ Toledo.

of the tongue should be wetted without swallowing it, and if it manifest any acrimony to the tongue it is not good; but the taste ought to be soft and mild: when poured out, it should form globules in the glass, and have an oily appearance: when genuine, the strongest is always of the best quality: when swallowed, it should have an earthy astringent taste in the mouth, which is called the taste of the root. All tokay wine has an aromatic taste, which distinguishes it from every other species of wine. It keeps to any age, and improves by time: but is never good till about three years old. It is the best way to transport it in casks; for when it is on the seas, it ferments three times every season, and thus refines itself. When in bottles, there must be an empty space left between the wine and the cork, otherwise it would burst the bottle. A little oil is put upon the surface, and a piece of bladder tied over the cork. The bottles are always laid on their sides in sand. Phil. Trans. vol. lxiii. part ii. p. 292, &c.

TOKENS. See *Tradesmens Tokens*.

TOISE, or Fathom, a French measure containing six of their feet, equal to 6,3945 English feet.

TOLAND, John, a famous writer, was born near Londonderry in Ireland in 1670, and educated in the Popish religion; but at 16 years of age embraced the principles of the Protestants. He studied three years at the university of Glasgow; was created master of arts in the university of Edinburgh; and afterwards completed his studies at Leyden, where he resided two years. He then went to Oxford, where, having the advantage of the public library, he collected materials upon various subjects, and composed some pieces; among which was, A Dissertation to prove the received history of the tragical death of Atilius Regulus, the Roman consul, to be a fable. He began likewise a work of greater consequence, in which he undertook to show that there are no mysteries in the Christian religion. He published it in 1696 at London, under the title of *Christianity not mysterious*. This book gave great offence, and was attacked by several writers. He afterward wrote in favour of the Hanoverian succession, and many other pieces. In 1707 he went into Germany, where he visited several courts; and in 1710 he was introduced to Prince Eugene, who gave him several marks of his generosity. Upon his return to England he was for some time supported by the liberality of the earl of Oxford lord-treasurer, and kept a country house at Epsom; but soon losing his lordship's favour, he published several pamphlets against that minister's measures. In the last four years of his life he lived at Putney, but used to spend most part of the winter in London. Mr Toland died at London in 1722. He was a man of uncommon abilities, published a number of curious tracts, and was perhaps the most learned of all the infidel writers; but his private character was far from being an amiable one; for he was extremely vain, and wanted those social virtues which are the chief ornaments as well as duties of life. His posthumous works, two volumes octavo, were published in 1726, with an account of his life and writings, by Mr Des Maizeaux.

TOLEDO, an ancient and trading city of Spain in New Castile, of which it was formerly the capital. About two centuries ago it is said to have contained more than 200,000 inhabitants; but they are now diminished to 20,000, or at most to 30,000. It is advantageously seated on the river Tajo, which surrounds it on two sides; and on the land side, it has an ancient wall built by a Gothic king, and flanked with 100 towers. It is seated on a mountain, which renders the streets uneven, and which are narrow; but the houses are fine, and there are a great number of superb structures, besides 17 public squares, where the markets are kept. The finest buildings are the royal castle and the cathedral church; which last is the richest and most considerable in Spain. It is seated in the middle of the city, joining to a handsome street, with a fine square before it. Several of the gates are very large, and of bronze. There is also a superb steeple, extremely high, from whence there is a very distant prospect. The Sagrariro, or principal chapel, is a real treasury, in which are 15 large cabinets let into the wall, full of prodigious quantities of gold and silver vessels, and other works. There are two mitres of silver gilt, set all over with pearls and precious stones, with three collars of massy gold, enriched in like manner. There are two bracelets and an imperial crown of the Virgin Mary, consisting of large diamonds and other jewels. The weight of the gold in the crown is 15 pounds. The vessel which contains the consecrated wafer is of silver gilt, as high as a man, and so heavy, that it requires 30 men to carry it; within it is another of pure gold enriched with jewels. Here are 39 religious houses, most of which are worthy a traveller's notice, with many other sacred buildings, besides seventy churches belonging to 27 parishes, and fifteen hospitals. Without the town are the remains of an amphitheatre, and other antiquities.

Bourgoanne's Travels in Spain, vol. ii.

Toledo ‖ Toleration.

Toledo is an archbishop's see, who is primate of Spain, and perhaps the richest prelate in Europe. His revenue is said to amount to 125,000l. sterling, but there are large deductions to be made from it. He pays 15,000 ducats to the monks of the Escurial, besides several other pensions. Toledo has also a university. It was formerly celebrated for the exquisite temper of the sword blades made there. It is situated in E. Long. 3. 15. N. Lat. 39. 50. and is 37 miles south from Madrid.

Swinburne and Laborde's Travels in Spain.

TOLERATION, in matters of religion, is either civil or ecclesiastical. Civil toleration is an impunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace: and ecclesiastical toleration is the allowance which the church grants to its members to differ in certain opinions, not reputed fundamental.

As the gods of Paganism were almost all local and tutelary, and as it was a maxim universally received that it was the duty of every man to worship, together with his own deities, the tutelary gods of the country in which he might chance to reside, there was no room for persecution in the Heathen world, on account of different sentiments in religion, or of the different rites with which the various deities were worshipped. Had the primitive Christians joined their fellow-citizens in the worship of Jupiter, Juno, and the rest of the rabble of Roman divinities, they would have been suffered to worship, without molestation, the Creator of the world and the Redeemer of mankind; for in that case the God of the Christians would have been looked upon as a Being of the same kind with the gods of the empire; and the great principle of intercommunity would have remained unviolated. But the true God had expressly prohibited

Toleration. prohibited both Jews and Christians from worshipping any other god besides Himself; and it was their refusal to break that precept of their religion which made their Heathen masters look upon them as Atheists, and persecute them as a people inimical to the state. Utility, and not truth, was the object for which the Heathen legislatures supported the national religion. They well knew that the stories told by their poets of their different divinities, of the rewards of Elysium, and of the punishments of Tartarus, were a collection of senseless fables; but they had nothing better to propose to the vulgar, and they were not such strangers to the human heart, as to suppose that mankind could live together in society without being influenced in their conduct by some religion.

Widely different from the genius of Paganism was the spirit of the Jewish dispensation. Truth, which is in fact always coincident with general utility, was the great object of the Mosaic law. The children of Israel were separated from the rest of the world, to preserve the knowledge and worship of the true God, at a time when all the other nations on earth, forgetting the Lord that made them, were falling prostrate to stocks and stones, and worshipping devils and impure spirits. Such was the contagion of idolatry, and so strong the propensity of the Israelites to the customs and manners of the Egyptians, and other polytheistic nations around them, that the purpose of their separation could not have been served, had not Jehovah condescended to become not only their tutelary God, but even their supreme civil Magistrate (see THEOLOGY, N° 151.); so that under the Mosaic economy, idolatry was the crime of high treason, and as such justly punished by the laws of the state. Among the Jews, the church and state were not indeed different societies. They were so thoroughly incorporated, that what was a sin in the one was a crime in the other; and the forfeiture of ecclesiastical privileges was the forfeiture of the rights of citizens.

In many respects the Christian religion is directly opposite to the ritual law of Moses. It is calculated for all nations, and intended to be propagated among all. Instead of separating one people from another, one of its principal objects is to disseminate universal benevolence, and to inculcate upon the whole human race, that mutual love which naturally springs from the knowledge that all men are brethren. Its ultimate end being to train its votaries for heaven, it concerns itself no farther with the affairs of earth than to enforce by eternal sanctions the laws of morality; and the kingdom of its Founder not being of this world, it leaves every nation at liberty to fabricate its own municipal laws, so as best to serve its own interest in the various circumstances in which it may be placed; and denounces a curse upon all who pay not to those laws the fullest obedience, when they are not obviously inconsistent with the laws of piety and virtue, which are of prior obligation. The Christian church therefore must always remain a distinct society from the state; and though, till the present age of hazardous innovations, it has been deemed expedient in every country, where the truth of the gospel is admitted, to give to the religion of Christ a legal establishment, and to confer immunities on its ministers, this measure has been adopted, not to secure the purity of the faith, which appeals to the private judgment of each individual, but merely to preserve the peace of society, and to put a restraint upon those actions of which human laws cannot take cognizance. With religion, Christian governments have no farther concern than as it tends to promote the practice of virtue. The early Christians, however, not understanding the principle upon which penal laws were employed to preserve the purity of the Jewish religion; and, as our blessed Lord observed to two of his apostles, not knowing what spirit they were of—hastily concluded that they had a right to enforce the doctrines and worship of the New Testament, by the same means which had been used to preserve the Israelites steady to the doctrines and worship of the Old. Hence, though they had suffered the cruellest persecutions themselves (see PERSECUTION), they no sooner got the power of the state in their hands, than they persecuted the Pagans for their idolatry; and afterwards, when heresies arose in the church, persecuted one another for expressing in different phrases metaphysical propositions, of such a nature as no human mind can fully comprehend. The apostle had forewarned them that there must be heresies in the church, that they who are approved may be made manifest; but it did not occur to them that persecution for opinion is the worst of all heresies, as it violates at once truth and charity.

Hitherto these unhallowed means of bringing Christians to uniformity of faith and practice, had been only occasionally employed, from their not accurately distinguishing between the spirit of the gospel and that of the law; but as soon as the bishops of Rome had brought the inhabitants of Europe to recognize their infallibility in explaining articles of faith and deciding points of controversy, persecution became a regular and permanent instrument of ecclesiastical discipline. To doubt or to deny any doctrine to which these unerring instructors had given the sanction of their approbation, was held to be not only a resisting of the truth, but an act of rebellion against their sacred authority; and the secular power, of which, by various arts, they had acquired the absolute direction, was instantly employed to avenge both.

Robertson's History of Charles V.

"Thus Europe had been accustomed, during many centuries, to see speculative opinions propagated or defended by force; the charity and mutual forbearance, which Christianity recommends with so much warmth, were forgotten; the sacred rights of conscience and of private judgment were unheard of; and not only the idea of toleration, but even the word itself, in the sense now affixed to it, was unknown. A right to extirpate error by force, was universally allowed to be the prerogative of those who possessed the knowledge of truth; and though the first reformers did not arrogate to themselves in direct terms that infallibility which they had refused to the church of Rome, they were not less confident of the truth of their own doctrines, and required with equal ardour the princes of their party to check such as presumed to impugn or to oppose them. To this request too many of these princes lent a willing ear. It flattered at once their piety and their pride, to be considered as possessing all the rights of Jewish princes; and Henry the VIII. of England, after labouring to make his divines declare that all authority ecclesiastical as well as civil flows from the crown, persecuted alternately the Papists and Protestants. Many of his successors, whose characters were much better than his, thought themselves duly authorized

authorized, in virtue of their acknowledged supremacy over all states and conditions of men, to enforce by means of penal laws a uniformity of faith and worship among their subjects: and it was not till the revolution that any sect in England seems to have fully understood, that all men have an unalienable right to worship God in the manner which to them may seem most suitable to his nature, and the relation in which they stand to him; or that it is impossible to produce uniformity of opinion by any other means than candid disquisition and sound reasoning. That the civil magistrate has a right to check the propagation of opinions which tend only to sap the foundations of virtue, and to disturb the peace of society, cannot, we think, be questioned; but that he has no right to restrain mankind from publicly professing any system of faith, which comprehends the being and providence of God, the great laws of morality, and a future state of rewards and punishments, is as evident as that it is the object of religion to fit mankind for heaven, and the whole duty of the magistrates to maintain peace, liberty, and property, upon earth. We have elsewhere observed (see TEST), that among a number of different sects of Christians, it is not the superior purity of the system of faith professed by one of them, that gives it a right to the immunities of an establishment in preference to all its rivals; but though the legislature is authorized, in certain circumstances, to make a less pure system the religion of the state, it would be the height of absurdity to suppose that any man, or body of men, can have authority to prevent a purer system from being acknowledged as the religion of individuals. For propagating opinions and pursuing practices which necessarily create civil disturbance, every man is answerable to the laws of his country; but for the soundness of his faith, and the purity of his worship, he is answerable to no tribunal but that which can search the heart.

When churches are established, and creeds drawn up as guides to the preaching of the national clergy, it is obvious that every clergyman who teaches any thing directly contrary to the doctrine of such creeds, violates the condition on which he holds his living, and may be justly deprived of that living, whether his obnoxious opinion be in itself true or false, important or unimportant; but his punishment should be extended no farther. To expel a Christian from private communion for teaching any doctrine which is neither injurious to the state nor contrary to the few simple articles which comprise the sum of the Christian faith, is the grossest tyranny; and the governors of that church which is guilty of it, usurp the prerogative of the blessed Lord, who commanded the apostles themselves not to be called masters in this sense; for one (says he) is your master (υμων ὁ καθηγητης), even Christ. It is indeed a hardship to deprive a man of his living for conscientiously illustrating what he believes to be a truth of the gospel, only because his illustration may be different from that which had formerly been given by men fallible like himself; but if the establishment of human compilations of faith be necessary, this hardship cannot be removed, but by making such compilations as simple as possible, and drawing them up in scripture language. Such a reformation, could it be effected peaceably, would serve other good purposes; for while it would sufficiently guard the purity of the faith, it would withdraw that temptation which too many establishments throw in the way of men, to subscribe to the truth of what they do not really believe; and it would effectually banish from the Christian church every thing which can be called by the name of *persecution*. See NONCONFORMISTS.

TOLL, a tax or custom paid for liberty to vend goods in a market or fair, or for keeping roads in proper repair. The first appointment of a toll on highways of which we read, took place in 1346. See ROAD.

TOLOUSE. See TOULOUSE.

TOLU, a town of South America in Terra Firma, and in the government of Carthagena; famous for the fine balsam of Tolu, brought into Europe from thence, and produced from a tree like a pine. It is seated on a bay of the Carribbean sea, 60 miles south of Carthagena. W. Long. 75. 25. N. Lat. 9. 45.

TOLUIFERA, the BALSAM-of-TOLU TREE; a genus of plants belonging to the class of decandria. See BOTANY, p. 182. and CHEMISTRY, N° 2483.

TOMATOES. See SOLANUM, BOTANY *Index*.

TOMB, includes both the grave or sepulchre wherein a defunct is interred, and the monument erected to preserve his memory. The word is formed from the Greek τυμβος, *tumulus*, "sepulchre;" or, according to Menage, from the Latin *tumba*, which signifies the same.

In many nations it has been customary to burn the bodies of the dead, and to collect the ashes with pious care into an urn, which was deposited in a tomb or sepulchre. See BURNING. Among many nations it has also been the practice to lay the dead body in a tomb, without consuming it, after having wrapped it up decently, and sometimes placing it in a coffin. See COFFIN.

The tombs of the Jews were generally hollow places hewn out of a rock. Abraham buried Sarah in a cave. Such was the place too in which the kings of Judah and Israel were interred: and such was the place in which the body of our Saviour was deposited by Joseph of Arimathea. But it is probable that the common people buried their dead in graves; for our Saviour compares the Pharisees to "graves which appear not, and the men that walk over them are not aware of them." Over the tombs, perhaps only of people of distinction, a stone or monument was erected, to intimate to passengers that they were burying places, that they might not pollute themselves by touching them. With the same intention, as Lightfoot informs us, they whitened them every year on the 15th of February.

The Egyptians also buried their dead in caves, called *catacombs*. See CATACOMB. The pyramids, as some think, were also employed for the same purpose. Sometimes also, after embalming their dead, they placed them in niches in some magnificent apartment in their houses.

The Greeks and Romans burned their dead, and deposited their ashes in a tomb. The Greeks interred the ashes without the cities, by the sides of their highways. Sometimes indeed, by way of particular honour, they were buried in an elevated part of the town; and the Lacedæmonians were allowed by Lycurgus to bury in the city and round their temples: But this was forbidden among the Romans by the law of the twelve tables, *In urbe ne sepelito, neve urito;* yet Valerius Publicola, Posthumus Tubertius, and the family of the Claudii, were buried in the Capitol. To bury by the sides of public

Tomb. public roads was common among the Romans also; hence their epitaphs frequently began with *Siste viator*. Highways were made choice of probably for two reasons: 1. That the dead might not be offensive or injure the health of the living, which they certainly would if buried in towns or populous places; and, 2dly, That they might hold out to travellers a lesson of mortality, and teach the rustic moralist to die.

As it would swell this article to too great a size, to describe all the different kinds of tombs which have been used by different nations and ages, we must content ourselves with shortly describing the tombs of a few nations, and adding a few concomitant circumstances.

The tombs of the Parsees are singular. The deceased, after lying a proper time in his own house, for the purposes of mourning, is carried, followed by his relations and friends, the females chanting a requiem, and deposited in a tomb of the following construction: It is a circular building, open at top, about 55 feet diameter, and 25 feet in height, filled to within 5 feet of the top, excepting a well of 15 feet diameter in the centre. The part so filled is terraced, with a slight declivity toward the well. Two circular grooves three inches deep are raised round the well; the first at the distance of four, the second at ten, feet from the well. Grooves of the like depth or height, and four feet distance from each other at the outer part of the outer circle, are carried straight from the wall to the well, communicating with the circular ones, for the purpose of carrying off the water, &c. The tomb, by this means, is divided into three circles of partitions: the outer, about seven feet by four: the middle six by three: the inner, four by two: the outer for the men, the middle for the women, the inner for the children; in which the bodies are respectively placed, wrapped loosely in a piece of cloth, and left to be devoured by the vultures; which is very soon done, as numbers of those animals are always seen hovering and watching about these charnel houses, in expectation of their prey. The friends of the deceased, or the persons who have charge of the tomb, come, at the proper time, and throw the bones into their receptacle, the well in the centre; for which purpose, iron rakes and tongs are deposited in the tomb. The entrance is closed by an iron door, four feet square, on the eastern side, as high up as the terrace, to which a road is raised. Upon the wall, above the door, an additional wall is raised, to prevent people from looking into the tomb, which the Parsees are particularly careful to prevent. A Persian inscription is on a stone inserted over the door, which we once copied, but have forgotten its tenor. From the bottom of the wall subterraneous passages lead to receive the bones, &c. and prevent the well from filling.

Of the ancient sepulchres found in Russia and Siberia, some are perfect tumuli, raised to an enormous height, while others are almost level with the ground. Some of them are encompassed with a square wall of large quarry stones placed in an erect position; others are covered only with a small heap of stones, or they are tumuli adorned with stones at top. Some are walled with brick within, and vaulted over; others are no more than pits or common graves. In some the earth is excavated several fathoms deep; others, and especially those which are topped by a lofty tumulus, are only dug of a sufficient depth for covering the carcase. In many of these sepulchres the bones of men, and frequently of horses, are found, and in a condition that renders it probable the bodies were not burnt before they were inhumed. Other bones show clearly that they have been previously burnt; because a part of them is unconsumed, and because they lie in a disordered manner, and some of them are wanting. Urns, in which other nations of antiquity have deposited the ashes of their dead, are never met with here. But sometimes what remained of their bodies after the combustion, and even whole carcases, are found wrapped up in thin plates of gold. Many dead bodies are frequently seen deposited together in one tomb; a certain indication that either a battle had been fought in the neighbourhood of the place, or that some families buried their relations in an hereditary tomb.

Archæologia, vol. vii.

The Moors, like all other Mahometans, hold it contrary to the spirit of religion to bury their dead in mosques, and to profane the temple of the Most High by the putrefaction of dead bodies. In the infancy of the church the Christians had the like respect for their temples. The burial grounds of the Mahometans are without the city; the emperors have their sepulchres distinct and distant from the mosque, in sanctuaries, built by themselves: their tombs are exceedingly simple.

Chenier's Morocco, vol. i.

All Mahometans inter the dead at the hour set apart for prayer. The defunct is not kept in the house, except he expires after sunset; but the body is transported to the mosque, whither it is carried by those who are going to prayer. Each, from a spirit of devotion, is desirous to carry in his turn. The Moors sing at their burial service; which usage perhaps they have imitated after the Christians of Spain. They have no particular colour appropriated to mourning. Women regularly go on the Friday to weep over and pray at the sepulchres of the dead, whose memory they hold dear.

Among the northern nations it was customary to bury their dead under heaps of stones called *cairns*, or under barrows: (See the articles CAIRNS and BARROW.) The inhabitants of Tibet, it is said, neither bury nor burn their dead; but expose them on the tops of mountains. See TIBET.

Tomb ‖ Tone.

TOMBUCTOO, a city of Africa, and capital of a rich and populous country, situated near the Niger, in E. Long. 1. 30. and N. Lat. 16. 30. Some manufactures, particularly that of cotton cloth, are carried on in Tombuctoo; and it has a considerable trade with the caravans. Many fruitless attempts have recently been made by European travellers to reach this city, which is supposed to be one of the most considerable in the interior of Africa. See AFFRICA, SUPPLEMENT.

TOMPION, a sort of bung or cork used to stop the mouth of a cannon. At sea this is carefully encircled with tallow or putty, to prevent the penetration of the water into the bore, whereby the powder contained in the chamber might be damaged or rendered incapable of service.

TON, a measure or weight. See TUN.

TONE, or TUNE, in *Music*, a property of sound, whereby it comes under the relation of *grave* and *acute*; or

Tone ‖ Tonnage.

or the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of the sonorous body.

The variety of tones in human voices arises partly from the dimensions of the windpipe, which, like a flute, the longer and narrower it is, the sharper the tone it gives; but principally from the head of the larynx or knot of the throat: the tone of the voice being more or less grave as the rima or cleft thereof is more or less open.

The word *tone* is taken in four different senses among the ancients: 1. For any sound; 2. For a certain interval, as when it is said the difference between the diapente and diatessaron is a tone; 3. For a certain locus or compass of the voice, in which sense they used the Dorian, Phrygian, Lydian tones; 4. For tension, as when they speak of an acute, grave, or a middle tone.

TONE is more particularly used, in music, for a certain degree or interval of tune, whereby a sound may be either raised or lowered from one extreme of a concord to the other, so as still to produce true melody.

TONGUE. See ANATOMY, N° 102.

TONIC, in *Music*, signifies a certain degree of tension, or the sound produced by a vocal string in a given degree of tension, or by any sonorous body when put in vibration.

Tonic, says Rousseau, is likewise the name given by Aristoxenus to one of the three kinds of chromatic music, whose divisions he explains, and which was the ordinary chromatic of the Greeks, proceeding by two semitones in succession, and afterwards a third minor.

TONIC Dominant. See DOMINANT.

TONNAGE *and* POUNDAGE, an ancient duty on wine and other goods, the origin of which seems to have been this: About the 21st of Edward III. complaint was made that merchants were robbed and murdered on the seas. The king thereupon, with the consent of the peers, levied a duty of 2s. on every ton of wine, and 12d. in the pound on all goods imported; which was treated as illegal by the commons. About 25 years after, the king, when the knights of shires were returned home, obtained a like grant from the citizens and burgesses, and the year after it was regularly granted in parliament. These duties were diminished sometimes, and sometimes increased; at length they seem to have been fixed at 3s. tonnage and 1s. poundage. They were at first usually granted only for a stated term of years, as, for two years in 5 Ric. II.; but in Henry VI.'s time they were granted him for life by a statute in the 31st year of his reign; and again to Edward IV. for the term of his life also: since which time they were regularly granted to all his successors for life, sometimes at the first, sometimes at other subsequent parliaments, till the reign of Charles I.; when, as the noble historian expresses it, his ministers were not sufficiently solicitous for a renewal of his legal grant. And yet these imposts were imprudently and unconstitutionally levied and taken, without consent of parliament, for 15 years together; which was one of the causes of those unhappy discontents, justifiable at first in too many instances, but which degenerated at last into causeless rebellion and murder. For, as in every other, so in this particular case, the king (previous to the commencement of hostilities) gave the nation ample satisfaction for the errors of his former conduct, by passing an act, whereby he renounced all power in the crown of levying the duty of tonnage and poundage, without the express consent of parliament; and also all power of imposition upon any merchandises whatever. Upon the restoration, this duty was granted to King Charles II. for life, and so it was to his two immediate successors; but now, by three several statutes, 9 Ann. c. 6. 1 Geo. I. c. 12. and 3 Geo. I. c. 7. it is made perpetual, and mortgaged for the debt of the public.

Blackst. Comment. vol. i.

Tonnage, Tonquin.

TONQUIN, a kingdom of Asia, in the East Indies, beyond the Ganges; bounded on the north by the province of Yunnan in China, on the east by the province of Canton and the bay of Tonquin, on the south by Cochin China, and on the west by the kingdom of Laos. It is about 1200 miles in length and 500 in breadth; and is one of the finest and most considerable kingdoms of the East, as well on account of the number of inhabitants as the riches it contains and the trade it carries on. The country is thick set with villages; and the natives in general are of a middle stature and clean limbed, with a tawney complexion. Their faces are oval and flattish, and their noses and lips well proportioned. Their hair is black, long, lank, and coarse; and they let it hang down their shoulders. They are generally dexterous, nimble, active, and ingenious in mechanic arts. They weave a multitude of fine silks, and make curious lacker-works, which are transported to other countries. There is such a number of people, that many want employment; for they seldom go to work but when foreign ships arrive. The money and goods brought hither by the English and Dutch put them in action; for they have not money of their own sufficient to employ themselves; and therefore one-third at least must be advanced beforehand by the merchants: and the ships must stay here till the goods are finished, which is generally five or six months. They are so addicted to gaming, that when every thing else is lost, they will stake their wives and children. The garments of the Tonquinese are made either of silk or cotton; but the poor people and soldiers wear only cotton of a dark tawney colour. Their houses are small and low; and the walls either of mud, or hurdles daubed over with clay. They have only a ground floor, with two or three partitions; and each room has a square hole to let in the light. The villages consist of 30 or 40 houses, surrounded with trees; and in some places there are banks to keep the water from overflowing their gardens, where they have oranges, betels, melons, and salad-herbs. In the rainy season they cannot pass from one house to another without wading through the water; they sometimes have boats. In the capital city called *Cacho* there are about 20,000 houses with mud-walls, and covered with thatch; a few are built with brick, and roofed with pan-tiles. In each yard is a small arched building like an oven, about six feet high, made of brick, which serves to secure their goods in case of fire. The principal streets are very wide, and paved with small stones. The king of Tonquin has three palaces in it, such as they are; and near them are stables for his horses and elephants. The house of the English factory is seated at the north end of the city, fronting the river, and is the best in the city. The people in general are courteous, and civil to strangers; but the great men are proud, haughty, and ambitious; the soldiers insolent, and the poor thievish. They buy all

their

their wives, of which the great men have several; but the poor are stinted for want of money. In hard times the men will sell both their wives and children to buy rice to maintain themselves. The women offer themselves to strangers as wives while they stay, and agree with them for a certain price. Even the great men will offer their daughters to the merchants and officers who are likely to stay six months in the country. They are not afraid of being with child; for if they are girls they can sell them well when they are young, because they are fairer than the other inhabitants. These women are said to be very faithful; and are trusted with money and goods by the Europeans during their absence, and will make great advantage with them. The first new moon in the year that happens after the middle of January, is a great festival; when they rejoice for 10 or 12 days together, and spend their time in all manner of sports. Their common drink is tea, but they make themselves merry with arrack. The language is spoken very much in the throat; and some of the words are pronounced through the teeth, and has a great resemblance to the Chinese. They have several mechanic arts or trades; such as smiths, carpenters, joiners, turners, weavers, tailors, potters, painters, money-changers, paper-makers, workers in lacker, and bell-founders.—Their commodities are gold, musk, silks, calicoes, drugs of many sorts, woods for dyeing, lacquered wares, earthen wares, salt, aniseeds, and worm-seeds. The lacquered ware is not inferior to that of Japan, which is accounted the best in the world. The chief trade is carried on by the Chinese, English, and Dutch. Tonquin anciently formed part of the Chinese empire, but established its independence about 1553. From that period it was governed by its own princes till the year 1800, when after a long struggle it was finally conquered by the sovereign of Cochin China.

TONSILS. See ANATOMY, N° 102.

TONSURE, in *Ecclesiastical History*, a particular manner of shaving or clipping the hair of ecclesiastics or monks. The ancient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity: and the same observation is true with respect to the tonsure of the ancient monks. But the Romans have carried the affair of tonsure much farther; the candidate for it kneeling before the bishop, who cuts the hair in five different parts of the head, viz. before, behind, on each side, and on the crown.

TONTINE, a loan given for life annuities with benefit of survivorship; so called from the inventor Laurence Tonti, a Neapolitan. He proposed his scheme in 1653 to reconcile the people to Cardinal Mazazine's government, by amusing them with the hope of becoming suddenly rich. He obtained the consent of the court, but the parliament would not register the edict. He made attempts afterwards, but without success.

It was not till Louis XIV. was distressed by the league of Augsburg, and by his own immense expences, that he had recourse to the plans of Tonti, which, though long laid aside, were not forgotten. By an edict in 1689 he created a Tontine royale of 1,400,000 livres annual rent, divided into 14 classes. The actions were 300 livres a piece, and the proprietors were to receive 10l. per cent. with benefit of survivorship in every class. This scheme was executed but very imperfectly; for none of the classes rose to above 25,000 livres, instead of 100,000, according to the original institution; though the annuities were very regularly paid. A few years after, the people seeming in better humour for projects of this kind, another tontine was erected upon nearly the same terms, but this was never above half full. They both subsisted in the year 1726, when the French king united the 13th class of the first tontine with the 14th of the second; all the actions of which were possessed by Charlotte Bonneymay, widow of Louis Barbier, a surgeon of Paris, who died at the age of 96. This gentlewoman had ventured 300 livres in each tontine; and in the last year of her life she had for her annuity 73,500 livres, or about 3600l. a-year, for about 30l.

The nature of the tontine is this; there is an annuity, after a certain rate of interest, granted to a number of people; divided into classes, according to their respective ages; so that annually the whole fund of each class is divided among the survivors of that class; till at last it falls to one, and upon the extinction of that life, reverts to the power by which the tontine was erected, and which becomes thereby security for the due payment of the annuities.

TOOL, among mechanics, denotes in general any instrument used for making other complex instruments and machines, or in other operations of the mechanic arts.

TOOTH, for a description of, see ANATOMY, N° 27.

TOOTHACH. See MEDICINE, N° 210, and SURGERY *Index*.

TOOTHACH-Tree. See ZANTHOXYLUM, } BOTANY *Index*.
TOOTHWORT. See PLUMBAGO, }

TOP, a sort of platform, surrounding the lower masthead, from which it projects on all sides like a scaffold.

The principal intention of the top is to extend the topmast shrouds, so as to form a greater angle with the mast, and thereby give additional support to the latter. It is sustained by certain timbers fixed across the hounds or shoulders of the masts, and called the *trestle-trees* and *cross-trees*.

Besides the use above mentioned, the top is otherwise extremely convenient to contain the materials necessary for extending the small sails, and for fixing or repairing the rigging and machinery with more facility and expedition. In ships of war it is used as a kind of redoubt, and is accordingly fortified for attack or defence; being furnished with swivels, musketry, and other fire-arms, and guarded by a thick fence of corded hammocks. Finally, it is employed as a place for looking out, either in the day or night.

TOP-Mast, the second division of a mast, or that part which stands between the upper and lower pieces. See the article MAST.

TOP-Sails, certain large sails extended across the topmasts by the top-sail yard above, and by the yard attached to the lower mast beneath; being fastened to the former by robands, and to the later by means of two great blocks fixed on its extremities, through which the topsail-sheets are inserted, passing from thence to two other blocks fixed on the inner part of the yard close

close by the mast; and from these latter the sheets lead downwards to the deck, where they may be slackened or extended at pleasure. See the article SAIL.

TOPAZ, a gem or precious stone. See MINERALOGY *Index*.

TOPE, a species of SQUALUS. See ICHTHYOLOGY *Index*.

TOPHET. See HINNOM and MOLOCH.

TOPHUS, in *Medicine*, denotes a chalky or stony concretion in any part of the body; as the bladder, kidney, &c. but especially in the joints.

TOPIC, a general head or subject of discourse.

TOPICS, in *Oratory*. See ORATORY, N° 10—13.

TOPICS, or *Topical Medicines*, are the same with external remedies, or those applied outwardly to some diseased and painful part: such are plasters, cataplasms, unguents, &c.

TOPOGRAPHY, a description or draught of some particular place, or small tract of land, as that of a city or town, manor, or tenement, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TOPSHAM, a town in Devonshire, in England, seated on the river Exmouth, five miles south-east of Exeter, to which place the river was formerly navigable; but in time of war was choaked up designedly, so that ships are now obliged to load and unload at Topsham. W. Long. 3. 26. N. Lat. 50. 30.

TORBAY, a fine bay of the English channel, on the coast of Devonshire, a little to the east of Dartmouth, formed by two capes, called *Bury Points*, and *Bob's Nose*.

TORDA, or RASOR-BILL. See ALCA, ORNITHOLOGY *Index*.

TORDYLIUM, HART-WORT, a genus of plants belonging to the class of pentandria, and in the natural system arranged under the 45th order, *Umbellatæ*. See BOTANY *Index*.

TORIES, a political faction in Britain, opposed to the Whigs.

The name of *Tories* was given to a sort of banditti in Ireland, and was thence transferred to the adherents of Charles I. by his enemies, under the pretence that he favoured the rebels in Ireland. His partisans, to be even with the republicans, gave them the name of *Whigs*, from a word which signifies *whey*, in derision of their poor fare. The Tories, or *cavaliers*, as they were also called, had then principally in view the political interest of the king, the crown, and the church of England; and the round-heads, or Whigs, proposed chiefly the maintaining of the rights and interests of the people, and of Protestantism. This is the most popular account; and yet it is certain the names *Whig* and *Tory* were but little known till about the middle of the reign of King Charles II. M de Cize relates, that it was in the year 1678 that the whole nation was first observed to be divided into Whigs and Tories; and that on occasion of the famous deposition of Titus Oates, who accused the Catholics of having conspired against the king and the state, the appellation of *Whig* was given to such as believed the plot real; and *Tory* to those who held it fictitious.

These parties may be considered either with regard to the state or to religion. The state Tories are either violent or moderate: the first would have the king to be absolute, and therefore plead for passive obedience, non-resistance, and the hereditary right of the house of Stuart. The moderate Tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state Whigs are either strong republicans or moderate ones. The first (says Rapin) are the remains of the party of the long parliament, who attempted to change monarchy to a commonwealth: but these make so slender a figure, that they only served to strengthen the party of other Whigs. The Tories would persuade the world, that all the Whigs are of this kind; as the Whigs would make us believe that all the Tories are violent. The moderate state Whigs are much in the same sentiments with the moderate Tories, and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old Whigs were always jealous of the encroachments of the royal prerogative, and watchful over the preservation of the liberties and properties of the people.

TORMENTILLA, TORMENTIL, a genus of plants belonging to the class of icosandria, and in the natural system ranging under the 35th order, *Senticosæ*. See BOTANY *Index*.

TORNADO, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guinea.

TORPEDO, the CRAMP-FISH. See RAJA, ICHTHYOLOGY *Index*.

TORPOR, a numbness, or defect of feeling and motion. Galen says it is a sort of intermediate disorder between palsy and health.

TORREFACTION, in *Chemistry*, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation. Sulphur is thus discharged from an ore before it can be wrought to advantage.

TORRENT, denotes a temporary stream of water falling suddenly from mountains, whereon there have been great rains or an extraordinary thaw of snow.

TORRICELLI, EVANGELISTE, an illustrious Italian mathematician and philosopher, born at Faenza in 1608. He was trained in Latin literature by his uncle a monk; and after cultivating mathematical knowledge for some time without a master, he studied it under Father Benedict Castelli, professor of mathematics at Rome. Having read Galileo's dialogues, he composed a treatise on motion, on his principles, which brought him acquainted with Galileo, who took him home as an assistant: but Galileo died in three months after. He became professor of mathematics at Florence, and greatly improved the art of making telescopes and microscopes: but he is best known for finding out a method of ascertaining the weight of the atmosphere by quicksilver; the barometer being called, from him, the *Torricellian tube*. He published *Opera Geometrica*, 4to, 1644; and died in 1647.

TORRICELLIAN EXPERIMENT, a famous experiment made by Torricelli, by which he demonstrated the pressure of the atmosphere in opposition to the doctrines of suction, &c. finding that pressure able to support only a a certain length of mercury, or any other fluid, in an inverted glass tube. See BAROMETER.

TORSK, or TUSK. See GADUS, ICHTHYOLOGY *Index*.

TORTOISE. See TESTUDO, ERPETOLOGY *Index*.

Phil. Trans. N° 435. p. 117. *TORTOISE shell*, the shell, or rather scales, of the testaceous animal called a *tortoise;* used in inlaying, and in various other works, as for snuff-boxes, combs, &c. Mr Catesby observes, that the hard strong covering which incloses all sorts of tortoises, is very improperly called a *shell;* being of a perfect bony contexture; but covered on the outside with scales, or rather plates, of a horny substance; which are what the workmen call *tortoise-shell*.

There are two general kinds of tortoises, viz. the *land* and *sea tortoise*, *testudo terrestris* and *marina*. The sea-tortoise, again, is of several kinds; but it is the caret, or testudo imbricata of Linnæus, alone which furnishes that beautiful shell so much admired in Europe.

The shell of the caretta, or hawksbill tortoise, is thick; and consists of two parts, the upper, which covers the back, and the lower the belly: the two are joined together at the sides by strong ligaments, which yet allow of a little motion. In the fore-part is an aperture for the head and fore-legs, and behind for the hind-legs and tail. It is the under shell alone that is used: to separate it, they make a little fire beneath it, and as soon as ever it is warm, the under shell becomes easily separable with a point of a knife, and is taken off in laminæ or leaves.

The whole spoils of the caret consist in 13 leaves or scales, eight of them flat, and five a little bent. Of the flat ones, there are four large ones, sometimes a foot long, and seven inches broad. The best tortoise-shell is thick, clear, transparent, of the colour of antimony, sprinkled with brown and white. When used in marquetry, &c. the workmen give it what colour they please by means of coloured leaves, which they put underneath it.

Working and joining of TORTOISE-shell.—Tortoise-shell and horn become soft in a moderate heat, as that of boiling water, so as to be pressed, in a mould, into any form, the shell or horn being previously cut into plates of a proper size. Plumier informs us, in his *Art de Turner*, that two plates are likewise united into one by heating and pressing them; the edges being thoroughly cleaned, and made to sit close to one another. The tortoise-shell is conveniently heated for this purpose by applying a hot iron above and beneath the juncture, with the interposition of a wet cloth to prevent the shell from being scorched by the irons: these irons should be pretty thick, that they may not lose their heat before the union is effected. Both tortoise-shell and horns may be stained of a variety of colours, by means of the colouring drugs commonly used in dyeing, and by certain metallic solutions.

TORTURE, a violent pain inflicted on persons to force them to confess the crimes laid to their charge, or as a punishment for crimes committed.

Torture was never permitted among the Romans except in the examination of slaves: it would therefore appear, that it was a general opinion among them, that a slave had such a tendency to falsehood, that the truth could only be extorted from him. To the disgrace of the professors of Christianity, torture was long practised by those who called themselves Catholics, against those whom they termed *heretics;* that is, those who differed in opinion from themselves. Finding that they could not bring over others to adopt their sentiments by the force of argument, they judged it proper to compel them by the force of punishment. This practice was very general among orthodox Christians, but especially among Roman Catholics. See INQUISITION.

By the law of England, torture was at one period employed to compel those criminals who stood obstinately mute when brought to trial, and refused either to plead guilty or not guilty; but it is now abolished (see ARRAIGNMENT, and RACK). A history of the machines which have been invented to torture men, and an account of the instances in which they have been employed, would exhibit a dismal picture of the human character.

TORUS, in *Architecture*, a large round moulding used in the bases of columns. See ARCHITECTURE.

TOUCAN. See RHAMPHASTOS, ORNITHOLOGY *Index*.

TOUCH-NEEDLE, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together, in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone with those of the bars.

The metals usually tried by the touchstone are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions, by fusion. In order to find out the purity or quantity of baser metal in these various admixtures, when they are to be examined they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ or plates, one-twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half-long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it. The black rough marbles, the basaltes, or the softer kinds of black pebbles, are the most proper for touchstones.

The method of using the needles and stone is thus: The piece of metal to be tried ought first to be wiped well with a clean towel or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person, will in some degree, judge beforehand what the principal metal is, and how and with what debased.

Then choose a convenient, not over large, part of the surface of the metal, and rub it several times very hardly and strongly against the touchstone, that in case a deceitful coat or crust should have been laid upon it, it may be worn off by that fricton: this, however, is more readily done by a grindstone or small file. Then wipe a flat and very clear part of the touchstone, and rub against it, over and over, the just-mentioned part of the surface of the piece of metal, till you have, on the flat surface of the stone, a thin metallic crust, an inch long, and about an eighth of an inch broad: this done, look out the needle that seems most like to the metal under trial, wipe the lower part of this needle

very

Touch-Needle ‖ Toulon.

very clean, and then rub it against the touchstone, as you did the metal, by the side of the other line, and in a direction parallel to it.

When this is done, if you find no difference between the colours of the two marks made by your needle and the metal under trial, you may with great probability pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraved on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, choose out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touchstone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

Touchstone, a black, smooth, glossy stone, used to examine the purity of metals. The ancients called it *lapis Lydius*, the Lydian stone, from the name of the country whence it was originally brought.

Any piece of peeble or black flint will answer the purposes of the best lapis Lydius of Asia. Even a piece of glass made rough with emery is used with success, to distinguish true gold from such as is counterfeit; both by the metallic colour and the test of aquafortis. The true touchstone is of a black colour, and is not uncommon in many parts of the world.

TOUCHWOOD. See Boletus, Botany *Index*.

TOULON, a celebrated city and seaport of France, in that part of the late province of Provence which is now denominated the department of the *Var*. It is a very ancient place, having been founded, according to the common opinion, by a Roman general. It is the chief town of the department, and before the great revolution in 1789 was an episcopal see. The inhabitants were computed at 29,000 in 1817. It is divided into the Old Quarter and the New Quarter. The first, which is very ill built, has nothing remarkable in it but the *Rue aux Arbres*, the Tree-Street, which is a kind of course or mall, and the town-house; the gate of this is surrounded by a balcony, which is supported by two termini, the masterpieces of the famous Pujet. The New Quarter, which forms as it were a second city, contains, beside the magnificent works constructed in the reign of Louis XIV. many fine houses (among which that of the late seminary merits beyond comparison the preference) and a grand oblong square, lined with trees, and serving as a parade.

The Merchants Haven, along which extends a noble quay, on which stands the town-house, is protected by two moles, begun by Henry IV. The New Haven was constructed by Louis XIV. as were the fortifications of the city. In the front of this haven is an arsenal, containing all the places necessary for the construction and fitting out of vessels: the first object that appears is a rope-walk, entirely arched, extending as far as the eye can reach, and built after the designs of Vauban: here cables are made, and above is a place for the preparation of hemp. Here likewise is the armoury for muskets, pistols, halberds, &c. In the park of artillery are cannons placed in piles, bombs, grenades, mortars, and balls of vurious kinds, ranged in wonderful order. The long-sail-room, the foundery for cannon, the dockyards, the basons, &c. are all worthy of observation.

Toulon, Toulouse.

Both the Old and New Port have an outlet into the spacious outer road or harbour, which is surrounded by hills, and formed by nature almost circular. Its circuit is of very great extent, and the entrance is defended on both sides by a fort with strong batteries. In a word, the basons, docks, and arsenal, at Toulon, warranted the remark of a foreigner that visited them in the late reign, that "the king of France was greater there than at Versailles." Toulon is the on y mart in the Mediterranean for the re-exportation of the products of the East Indies.

This place was destroyed toward the end of the tenth century, and pillaged by the African pirates almost as soon as rebuilt. The constable of Bourbon, at the head of the Imperial troops, obtained possession of it in 1524, as did Charles V. in 1536; but in the next century Charles Emanuel duke of Savoy could not enter it, and Prince Eugene in 1707 ineffectually laid siege to it. This city was surrendered by the inhabitants in September 1793 to the British admiral Lord Hood, as a condition and means of enabling them to effect the re-establishment of monarchy in France, according to the constitution of 1789. Lord Hood accordingly, in conjunction with the Spanish land and naval forces, took possion of the harbour and forts in trust for Louis XVII. It was garrisoned for some time by the British troops, and their allies the Spaniards, Neapolitans, and Sardinians; but the French having laid seige to it, the garrison was obliged to evacuate the place in the month of December following, after having destroyed the grand arsenal, two ships of 84 guns, eight of 74, and two frigates; and carried off the Commerce de Marseilles, a ship of 120 guns, with an 80 and 74 gun ship. This exploit was most gallantly performed, after it was found impossible to defend the town, or to carry off the ships. Lord Hood entrusted the management of the affair to Sir Sydney Smith, so distinguished for his intrepidity. Captain Hare commanded the fireship which was towed into the grand arsenal; and so eager was he to execute his orders, that instead of setting fire to the train in the usual cautious manner, he fired a pistol loaded with powder into the bowl of the train, composed of 36 pounds of powder and other combustibles. The consequence was, he was blown into the water with such violence, as to knock a lieutenant of the Victory's boat overboard, and narrowly escaped with his life. A Spanish captain was appointed to set fire to the small arsenal, but cowardice prevented him from executing his orders; and this is the reason why the whole French ships were not destroyed. We have been favoured with this account by an officer of the British fleet.

Toulon is seated on a bay of the Mediterranean, 17 leagues south-east of Aix, 15 south-east of Marseilles, and 217 south-east of Paris. E. Long. 5. 56. N. Lat. 43. 7.

TOULOUSE, a very ancient city of France, in the department of Upper Garonne, and late province of Languedoc, with an archbishop's see. It is one of the most considerable cities in the south of France, although its population bears no proportion to its extent. In 1817 it was estir ed to contain 48,000 inhabitants. The streets are ver hand-some,

some, and the walls of the city, as well as the houses, are built with bricks. The town-house, a modern structure, forms a perfect square, 324 feet long and 66 high. The principal front occupies an entire side of the grand square, lately called the *Place Royale*. In the great hall, called the *Hall of Illustrious Men*, is the statue of the Chevalier Isaure, and the busts of all the great men to whom Toulouse has given birth. Communicating with the ocean on one side by the river Garonne, and with the Mediterranean on the other by the canal of Languedoc, Toulouse might have been a great commercial city; but the taste of the inhabitants has been directed to the sciences and belles-lettres. Of course, there are two colleges, two public libraries, and three academies. The little commerce of Toulouse consists in leather, drapery, blankets, mignionets, oil, iron, mercery, hardware, and books. The bridge over the Garonne is at least equal to those of Tours and Orleans; it forms the communication between the suburb of St Cyprian and the city. A bloody battle was fought at Toulouse on the 10th April 1814, between the British army under Lord Wellington, and the French army under Soult, in which the latter was defeated with great loss. Toulouse is 37 miles east of Auch, 125 south-east of Bourdeaux, and 350 south-by-west of Paris. E. Long. 1. 32. N. Lat. 43. 36.

TOUR, Henry de la, Viscount Turenne, a celebrated French general, was the second son of Henry de la Tour duke of Bouillon, and was born at Sedan in 1611. He made his first campaigns in Holland, under Maurice and Frederic Henry princes of Orange; who were his uncles by the mother's side; and even then distinguished himself by his bravery. In 1634 he marched with his regiment into Lorraine; and having contributed to the taking of La Mothe, was, though very young, made mareschal de camp. In 1636 he took Saverne, and the year following the castles of Hirson and Sole; on which occasion he performed an action like that of Scipio's, with respect to a very beautiful woman whom he sent back to her husband. The viscount Turenne continued to distinguish himself in several sieges and battles, and in 1644 was made marshal of France; but had the misfortune to be defeated at the battle of Mariendal in 1645. However, he gained the battle of Nortlingen three months after; restored the elector of Treves to his dominions; and the following year made the famous junction of the French army with that of Sweden commanded by General Wrangel, which obliged the duke of Bavaria to demand a peace. Afterwards that duke breaking the treaty he had concluded with France, he was defeated by the viscount Turenne at the battle of Zumarshausen, and in 1648 driven entirely out of his dominions. During the civil wars in France, he sided with the princes, and was defeated at the battle of Rhetel in 1650; but soon after was restored to the favour of the king, who in 1652 gave him the command of his army. He acquired great honour at the battles of Jergeau, Gren, and the suburbs of St Anthony, and by the retreat he made before the army commanded by the princes at Ville Neuve St George. In 1654 he made the Spaniards raise the siege of Arras: the next year he took Conde, St Guilian, and several other places; gained the famous battle of Dunes; and made himself master of Dunkirk, Oudenarde, and almost all Flanders: this obliged the Spaniards to conclude the peace of the Pyrenees in 1660. These important services occasioned his being made marshal-general of the king's camps and armies. The war being renewed with Spain in 1667, Turenne commanded in Flanders; and took so many places, that in 1668 the Spaniards were obliged to sue for peace. He commanded the French army in the war against the Dutch in 1672; took 40 towns in 22 days; pursued the elector of Brandenburg even to Berlin; gained the battles of Slintsheim, Ladenburg, Ensheim, Mulhausen, and Turkeim; and obliged the Imperial army, which consisted of 70,000 men, to repass the Rhine. By this campaign the viscount Turenne acquired immortal honour. He passed the Rhine to give battle to General Montecuculi, whom he followed as far as Saspach; but mounting upon an eminence to discover the enemy's camp, he was killed by a cannon-ball in 1675. All France regretted the loss of this great man, who, by his military exploits, had raised the admiration of Europe.

TOURAINE, a province of France, bounded on the north by Maine, on the east by Orleanois, on the south by Berris, and on the west by Anjou and Poitou. It is about 58 miles in length, and 55 in breadth where it is broadest. This country is watered by 17 rivers, besides many brooks, which not only render it delightful, but keep up a communication with the neighbouring provinces. The air is temperate, and the soil is so fruitful that it is called the *garden of France*. It now forms the department of Indre and Loire, of which Tours is the capital.

TOURMALINE, a species of mineral belonging to the siliceous genus. See Mineralogy *Index*.

TOURNAMENT, a martial sport or exercise which the ancient cavaliers used to perform, to show their bravery and address. It is derived from the French word *tourner*, i. e. "to turn round," because to be expert in these exercises, much agility both of horse and man was requisite, they riding round a ring in imitation of the ancient Circi.

The first tournaments were only courses on horseback, wherein the cavaliers tilted at each other with canes in manner of lances; and were distinguished from justs, which were courses or careers, accompanied with attacks and combats, with blunted lances and swords. See Just.

The prince who published the tournament, used to send a king at arms, with a safe-conduct, and a sword, to all the princes, knights, &c. signifying that he intended a tournament and clashing of swords, in the presence of ladies and damsels; which was the usual formula of invitation.

They first engaged man against man, and then troop against troop; and, after the combat, the judges allotted the prize to the best cavalier, and the best striker of swords; who was accordingly conducted in pomp to the lady of the tournament; where, after thanking her very reverently, he saluted her and likewise her two attendants.

These tournaments made the principal diversion of the 13th and 14th centuries. Munster says, it was Henry the Fowler, duke of Saxony, and afterwards emperor, who died in 936, that first introduced them; but it appears from the chronicle of Tours, that the true inventor of this famous sport, at least in France, was one Geoffrey, lord of Preuilli, about the year 1066.

Instances of them occur among the English in the reign of King Stephen, about the year 1140; but they were not much in use till Richard's time, towards the year 1149. After which period these diversions were performed with extraordinary magnificence in the Tilt-yard near St James's, Smithfield, and other places.

The following is the account of a tournament, from Maitland. King Richard II. designing to hold a tournament at London on the Sunday after Michaelmas, sent divers heralds to make proclamation of it in all the principal courts of Europe; and accordingly not a few princes, and great numbers of the prime nobility, resorted hither from France, Germany, the Netherlands, &c. This solemnity began on Sunday afternoon, from the Tower of London, with a pompous cavalcade of 60 ladies, each leading an armed knight by a silver chain, being attended by their 'squires of honour, and, passing through Cheapside, rode to Smithfield, where the justs and tournaments continued several days with magnificent variety of entertainments; on which occasion the king kept open house at the bishop of London's palace for all persons of distinction, and every night concluded with a ball.

At last, however, they were found to be productive of bad effects, and the occasions of several fatal misfortunes—as in the instance of Henry II. of France, and of the tilt exhibited at Chalons, which, from the numbers killed on both sides, was called the *little war of Chalons*. These and other inconveniencies, resulting from those dangerous pastimes, gave the popes occasion to forbid them, and the princes of Europe gradually concurred in discouraging and suppressing them.

TOURNAY, a town of the Netherlands in Flanders, and capital of a district called *Tournaysis*, with a bishop's see. It is divided into two parts by the river Scheldt, is well built, and contained 21,300 inhabitants in 1800. It carries on a great trade in woollen stuffs and stockings. The cathedral is a very handsome structure, and contains a great many chapels, and several magnificent tombs of marble and brass. The town was taken by the allies in 1709; but was ceded to the house of Austria by the treaty of Utrecht, though the Dutch had a right to put in a garrison. It was taken by the French in June 1745, who demolished the fortifications. In 1781 the emperor Joseph II. obliged the Dutch to withdraw their garrison. It was taken by the French in 1791, abandoned in 1793, again conquered by them in 1794, and finally united to the kingdom of the Netherlands in 1814. It is 14 miles south-east of Lisle, and 135 north-by-east from Paris. E. Long. 3. 25. N. Lat. 50. 35.

TOURNEFORT, Joseph Pitton de, a famous French botanist, was born at Aix in Provence in 1656. He had a passion for plants from his childhood, which overcame his father's views in putting him to study philosophy and divinity; therefore on his death he quitted theology, and gave himself up entirely to physic, natural history, and botany. He wandered over the mountains of Dauphiny, Savoy, Catalonia, the Pyrenees, and the Alps, in search of new species of plants, which he acquired with much fatigue and danger. His fame in 1683 procured him the employment of botanic professor, in the king's garden; and by the king's order, he travelled into Spain, Portugal, Holland, and England, where he made prodigious collections of plants. In 1700, Mr Tournefort, in obedience to another order, simpled over all the isles of the Archipelago, upon the coasts of the Black sea, in Bithynia, Pontus, Cappadocia, Armenia, and Georgia; making observations on natural history at large, ancient and modern geography, religion, manners, and commerce. He spent three years in this learned voyage; and then resuming his profession, was made professor of physic in the college-royal. He died in consequence of an accidental crush of his breast by a cart-wheel, which brought on a spitting of blood and hydrothorax, that carried him off in 1708. He wrote Elements of Botany, both in French and Latin; A relation of his Voyage into the Levant; with other pieces of less consideration.

TOURNIQUET, in *Surgery*, an instrument formed with screws, for compressing any part with rollers, &c for the stopping of hæmorrhagies. See Surgery *Index*.

TOWER, a tall building consisting of several stories, usually of a round form, though some are square or polygonal. Towers are built for fortresses, &c. as the Tower of London. See London, N° 46.

TOWN, a place inhabited by a considerable number of people, being of a middle size between a city and a village.

TOXICODENDRON. See Rhus, Botany *Index*.

TRAAS. See Terras.

TRACHEA. See Anatomy, N° 119.

TRACHINUS, the Weever, a genus of fishes belonging to the order of jugulares. See Ichthyology *Index*.

TRACT, in *Geography*, an extent of ground, or a portion of the earth's surface.

Tract, in matters of literature, denotes a small treatise or written discourse upon any subject.

TRADE, in general, denotes the same with commerce, consisting in buying, selling, and exchanging of commodities, bills, money, &c. See Commerce, Coin, Money, Company, &c.

Trade-Winds, denote certain regular winds at sea, blowing either constantly the same way, or alternately this way and that; thus called from their use in navigation, and the Indian commerce. See Meteorology.

TRADESMEN's tokens, a term synonymous among medalists with provincial coins.

This is a subject curious enough to deserve attention, though we will not go so far as Mr Pinkerton does, who says that it is a subject in which the perpetual glory of the nation is interested. Since the year 1789 provincial halfpence have been made and circulated in considerable quantity. As ancient medals and coins have been frequently of use to historians, it is to be regretted that many of these provincial halfpence are rendered useless in this respect by unmeaning figures and puerile devices. Utility and elegance ought to be studied: for this view it has been proposed by a gentleman of taste on this subject, that all coins should be distinguished by one of the following five characteristics. 1. Fac similes of magnificent beautiful buildings. 2. Representations of great and useful undertakings. 3. Emblems of the industry and commerce of the age. 4. The illustrious men, &c. to whom the nation has given birth. 5. Important historical events.

TRADITION, something handed down from one generation to another without being written. Thus the Jews

Jews pretended, that besides their written law contained in the Old Testament, Moses had delivered an oral law which had been conveyed down from father to son; and thus the Roman Catholics are said to value particular doctrines supposed to have descended from the apostolic times by tradition.

TRAGACANTH. See ASTRAGALUS, MATERIA MEDICA *Index*.

TRAGEDY, a dramatic poem, representing some signal action performed by illustrious persons, and which has frequently a fatal issue or end. See POETRY, Part II. sect. I.

TRAGI-COMEDY; a dramatic piece, partaking both of the nature of tragedy and comedy; in which a mixture of merry and serious events is admitted.

TRAGOPOGON, GOAT'S-BEARD; a genus of plants belonging to the class of syngenesia; and in the natural system ranging under the 49th order *Compositæ*. See BOTANY *Index*.

TRAJAN, MARCUS ULPIUS, a celebrated Roman emperor, who gained many victories over the Parthians and Germans, pushing the empire to its utmost extent on the east and north sides. He died at Silinunte, a city of Cilicia, which from him was called *Trajanopolis*, in the year 117.

TRAJAN's Column, a famous historical column erected in Rome, in honour of the emperor Trajan. It is of the Tuscan order, though somewhat irregular: its height is eight diameters, and its pedestal Corinthian: it was built in a large square called *Forum Romanum*. Its base consists of 12 stones of an enormous size, and is raised on a socle, or foot, of eight steps: within side is a staircase illuminated with 44 windows. It is 140 feet high, which is 35 feet short of the Antonine column, but the workmanship of the former is much more valued. It is adorned from top to bottom with basso relievos, representing the great actions of the emperor against the Dacians.

TRAIN, a line of gunpowder laid to give fire to a quantity thereof, in order to do execution by blowing up earth, works, buildings, &c.

TRAIN of Artillery, includes the great guns and other pieces of ordnance belonging to an army in the field.

TRAIN-Oil, the oil procured from the blubber of a whale by boiling.

TRALLIAN, ALEXANDER, a Greek writer on physic, a native of Tralles in Lydia, who lived about the middle of the sixth century. His works are divided into 12 books; in which he treats of distempers as they occur from head to foot. He was the first who opened the jugular vein, and that used cantharides as a blister for the gout. Dr Freind, in his History of Physic, styles him one of the most valuable authors since the time of Hippocrates. Though he appears on the whole to have been a rational physician, yet there are things in his writings that savour of enthusiasm and superstition.

TRA-LOS-MONTES, a province of Portugal, called in Latin *Transmontana*, because situated on the east side of a chain of hills that separate it from Entre Ducro-e-Minho. It is bounded on the north by Galicia; on the south by the provinces of Beira and Leon; by the last of which it is bounded also to the east. Its length from north to south is upwards of 120 miles, and its breadth about 80. It is full of mountains, and produces little corn, but plenty of wine, fruits of several sorts, and abundance of game.

TRANSACTIONS, a name generally given to a collection of the papers read before literary or philosophical societies. The name of *Philosophical Transactions* was first adopted by the Royal Society of London.

The Philosophical Transactions to the end of the year 1700 were abridged in three volumes by Mr John Lowthorp: those from the year 1700 to 1720 were abridged in two volumes by Mr Henry Jones: those from 1719 to 1733 were abridged in two volumes by Mr John Eames and Mr John Martyn; Mr Martyn continued the abridgement of those from 1732 to 1744 in two volumes, and of those from 1743 to 1750 in two volumes.

They were for many years published in numbers, and the printing of them was always, from time to time, the single act of the respective secretaries, till the year 1752, when the society thought fit that a committee should be appointed to reconsider the papers read before them, and to select out of them such as they should judge most proper for publication in the future Transactions. They are published annually in two parts at the expence of the society, and each fellow is entitled to receive one copy *gratis* of every volume published after his admission into the society.

They were first set on foot in 1665, by Mr Oldenburg, secretary of the society, and were continued by him till the year 1677. Upon his death, they were discontinued till January 1678, when Dr Grew resumed the publication of them, and continued it for the months of December 1678, and January and February 1679, after which they were intermitted till January 1683. During this last interval they were supplied in some measure by Dr Hooke's Philosophical Collections. They were also interrupted for three years, from December 1687 to January 1691, beside other smaller interruptions, amounting to near one year and a half more, before October 1695, since which time the Transactions have been regularly carried on.

TRANSCENDENTAL, or TRANSCENDENT, something elevated, or raised above other things; which passes and transcends the nature of other inferior things.

TRANSCRIPT, a copy of any original writing, particularly that of an act or instrument inserted in the body of another.

TRANSFER, in commerce, an act whereby a person surrenders his right, interest, or property, in any thing moveable or immoveable, to another.

TRANSFORMATION, in general, denotes a change of form, or the assuming a new form different from a former one.

TRANSFUSION, the act of pouring a liquor out of one vessel into another.

TRANSFUSION of Blood, an operation by which it was some time ago imagined that the age of animals would be renewed, and immortality, or the next thing to it, conferred on those who had undergone it.

The method of transfusing Dr Lower gives us to the following effect: take up the carotid artery of the dog, or other animal, whose blood is to be transfused into another of the same, or a different kind: separate it from the nerve of the eighth pair, and lay it bare above an inch. Make a strong ligature on the upper part of the artery; and an inch nearer the heart another ligature with a running knot, to be loosened and fastened as occasion requires. Draw two threads between the two ligatures, open the artery, put in a quill, and tie up the artery again upon the quill by the two threads, and stop the quill by a stick.

Then make bare the jugular vein of the other animal for about an inch and a half in length, and at each end make a ligature with a running knot; and in the space between the two knots draw under the veins two threads, as in the other. Open the vein, and put into it two quills, one into the descending part of the vein, to receive the blood from the other dog, and carry it to the heart; the other quill put into the other part of the jugular, towards the head, through which the second animal's own blood is to run into dishes. The quills thus tied fast, stop them up with sticks till there be occasion to open them.

Things thus disposed, fasten the dogs on their sides towards one another, in such a manner as that the quills may go into each other; then unstop the quill that goes down into the second dog's jugular vein, as also that coming out of the other dog's artery; and by the help of two or three other quills put into each other, as there shall be occasion, insert them into one another. Then slip the running knots, and immediately the blood runs through the quills as through an artery, very impetuously. As the blood runs into the dog, unstop the quill in the upper part of his jugular, for his own blood to run out at, though not constantly, but as you perceive him able to bear it, till the other dog begins to cry and faint, and at last die. *Lastly*, Take both quills out of the jugular, tie the running knot fast, and cut the vein asunder, and sew up the skin: the dog, thus dismissed, will run away as if nothing ailed him.

In the Philosophical Transactions we have accounts of the success of various transfusions practised at London, Paris, in Italy, &c. Sir Edmund King transfused forty-nine ounces of blood out of a calf into a sheep; the sheep, after the operation, appearing as well and as strong as before.

M. Denis transfused the blood of three calves into three dogs, which all continued brisk, and ate as well as before. The same person transfused the blood of four wethers into a horse twenty-six years old, which thence received much strength, and a more than ordinary appetite.

Soon after this operation was introduced at Paris, viz. in 1667 and 1668, M. Denis performed it on five human subjects, two of whom recovered of disorders under which they laboured; one being in perfect health suffered no inconvenience from it; and two persons who were ill, and submitted to the operation, died; in consequence of which the magistrates issued a sentence, prohibiting the transfusion on human bodies under pain of imprisonment.

Mr John Hunter, we are told, made many ingenious experiments to determine the effects of transfusing blood, some of which are sufficient to attract attention. But whether such experiments can ever be made with safety on the human body, is a point not easily determined. They might be allowed in desperate cases proceeding from a corruption of the blood, from poison, &c. as in hydrophobia.

TRANSIT, from *transit*, "it passes over," signifies the passage of any planet over the sun, moon, or stars.

TRANSITION, the passage of any thing from one place to another.

TRANSITION, in *Oratory*. See ORATORY, N° 39.

TRANSITIVE, in *Grammar*, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it. Under the head of verbs transitive come what we usually call *verbs active* and *passive*; other verbs, whose action does not pass out of themselves, are called *neuters*.

TRANSLATION, the act of transferring or removing a thing from one place to another; as we say, the translation of a bishop's see, a council, a seat of justice, &c.

TRANSLATION is also used for the version of a book or writing out of one language into another.

The principles of translation have been clearly and accurately laid down by Dr Campbell of Aberdeen in his invaluable Preliminary Dissertations to his excellent translations of the gospels. The fundamental rules which he establishes are three: 1. That the translation should give a complete transcript of the ideas of the original. 2. That the style and manner of the original should be preserved in the translation. 3. That the translation should have all the ease of original composition. The rules deducible from these general laws are explained and illustrated with much judgment and taste, in an Essay on the Principles of Translation, by Mr Tytler, judge-advocate of Scotland.

TRANSMARINE, something that comes from or belongs to the parts beyond sea.

TRANSMIGRATION, the removal or translation of a whole people into another country, by the power of a conqueror.

TRANSMIGRATION is particularly used for the passage of the soul out of one body into another. See METEMPSYCHOSIS.

TRANSMUTATION, the act of changing one substance into another.

Nature, says Sir Isaac Newton, is delighted with transmutation: water, which is a fluid, volatile, tasteless salt, is, by heat, transmuted into vapour, which is a kind of air; and by cold into ice, which is a cold, transparent, brittle stone, easily dissolvable; and this stone is convertible again into water by heat, as vapour is by cold.—Earth, by heat, becomes fire, and, by cold, is turned into earth again: dense bodies, by fermentation, are rarefied into various kinds of air; and that air, by fermentation also, and sometimes without it, reverts into gross bodies. All bodies, beasts, fishes, insects, plants, &c. with all their various parts, grow and increase out of water and aqueous and saline tinctures; and, by putrefaction, all of them revert into water, or an aqueous liquor again.

TRANSMUTATION, in alchemy, denotes the act of changing imperfect metals into gold or silver. This is also called the *grand operation*; and, they say, it is to be effected with the philosopher's stone.

The trick of transmuting cinnabar into silver is thus: the cinnabar, being bruised grossly, is stratified in a crucible with granulated silver, and the crucible placed in a great fire; and, after due time for calcination, taken off; then the matter, being poured out, is found to be cinnabar

cinnabar turned into real silver, though the silver grains appear in the same number and form as when they were put into the crucible; but the mischief is, coming to handle the grains of silver, you find them nothing but light friable bladders which will crumble to pieces between the fingers.

The transmutability of water into earth seems to have been believed by Mr Boyle; and Bishop Watson thinks that it has not yet been disproved. See his *Chemical Essays*.

Transmutation of Acids, or *of Metals*, is the change of one acid or of one metal into another.

TRANSOM, among builders, denotes the piece that is framed across a double-light window.

TRANSOMS, in a ship, certain beams or timbers extended across the sternpost of a ship, to fortify her afterpart, and give it the figure most suitable to the service for which she is calculated.

TRANSPARENCY, in *Physics*, a quality in certain bodies, whereby they give passage to the rays of light: in contradistinction to opacity, or that quality of bodies which renders them impervious to the rays of light.

It has been generally supposed by philosophers, that transparent bodies have their pores disposed in straight lines, by which means the rays of light have an opportunity of penetrating them in all directions; but some experiments in electricity have made it apparent, that by the action of this fluid the most opaque bodies, such as sulphur, pitch, and sealing-wax, may be rendered transparent as glass, while yet we cannot suppose the direction of their pores to be any way altered from what it originally was (see Electricity). There is a curious instance of an increase of transparency in rubbing a piece of white paper over one that has been written upon or printed: while the white paper is at rest, the writing or print will perhaps scarce appear through it; but when in motion, will be very easily legible, and continue so till the motion is discontinued.

TRANSPOSITION, in *Grammar*, a disturbing or dislocating the words of a discourse, or a changing their natural order of construction, to please the ear by rendering the contexture more smooth, easy, and harmonious.

TRANSUBSTANTIATION, in *Theology*, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ; which the Romish church suppose to be wrought by the consecration of the priest. See *Supper of the Lord*, N° 5.

TRANSVERSALIS, in *Anatomy*, a name given to several muscles. See Anatomy, Part II.

TRANSVERSE, something that goes across another from corner to corner: thus bends and bars in heraldry are transverse pieces or bearings; the diagonals of a parallelogram or a square are transverse lines.

TRANSYLVANIA, a province of Europe, annexed to Hungary, and bounded on the north by Upper Hungary and Galicia, on the east by Moldavia and Walachia, on the south by Walachia, and on the west by Upper and Lower Hungary. It is surrounded on all parts by high mountains, and covers an area of 21,000 square English miles. The inhabitants have abundance of corn and wine; and there are rich mines of gold, silver, lead, copper, quicksilver, and alum. It has undergone various revolutions; but it now belongs to the house of Austria. The inhabitants are of several sorts of religions; as Papists, Lutherans, Calvinists, Socinians, Photinians, Arians, Greeks, and Mahometans. It is about 162 miles in length, and 150 in breadth. The administration of affairs is conducted by twelve persons; namely, three Roman Catholics, three Lutherans, three Calvinists, and three Socinians. The militia is commanded by the governor, whose commission is the more important, as Transylvania is the bulwark of Christendom. It is divided into several small districts, called *palatinates* and *counties*; and its inhabitants, who consist of Saxons, Silesians, and Hungarians, amounted to 1,655,400 in 1805. Hermanstadt is the capital town.

TRAPEZIUM, in *Geometry*, a plane figure contained under four unequal right lines.

TRAPEZIUS, a muscle. See Anatomy, Part II.

TRAPP, a compound rock. See Geology.

TRAVELLERS joy. See Clematis, Botany *Index*.

TRAVERSE, or Transverse, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.

Traverse, in *Navigation*, implies a compound course, or an assemblage of various courses, lying at different angles with the meridian. See Navigation.

Traverse Board, a thin circular piece of board, marked with all the points of the compass, and having eight holes bored in each, and eight small pegs hanging from the centre of the board. It is used to determine the different courses run by a ship during the period of the watch, and to ascertain the distance of each course.

TRAVESTY, a name given to a humorous translation of any author. The word is derived from the French *travester*, "to disguise."

TREACLE, or Melasses. See Sugar.

Treacle Beer. See Spruce.

Treacle Mustard. See Clypeola, Botany *Index*.

TREASON, a general appellation, made use of by the law, to denote not only offences against the king and government, but also that accumulation of guilt which arises whenever a superior reposes a confidence in a subject or inferior, between whom and himself there subsists a natural, a civil, or even a spiritual relation; and the inferior so abuses that confidence, so forgets the obligations of duty, subjection, and allegiance, as to destroy the life of any such superior or lord. Hence treason is of two kinds, *high* and *petty*.

High Treason, or *Treason Paramount* (which is equivalent to the *crimen læsæ majestatis* of the Romans, as Glanvil denominates it also in our English law), is an offence committed against the security of the king or kingdom, whether by imagination, word, or deed. In order to prevent the inconveniences which arose in England from a multitude of constructive treasons, the statute 25 Edw. III. c. 2. was made; which defines what offences only for the future should be held to be treason; and this statute comprehends all kinds of high-treason under seven distinct branches.

"1. When a man doth compass or imagine the death of our lord the king, of our lady his queen, or of their eldest son and heir." Under this description it is held that a queen-regnant (such as Queen Elizabeth and

Treason. Queen Anne) is within the words of the act, being invested with royal power, and intitled to the allegiance of her subjects: but the husband of such a queen is not comprised within these words; and therefore no treason can be committed against him.

Let us next see what is a *compassing* or *imagining* the death of the king, &c. These are synonymous terms: the word *compass* signifying the purpose or design of the mind or will; and not, as in common speech, the carrying such design to effect. And therefore an accidental stroke, which may mortally wound the sovereign, *per infortunium*, without any traitorous intent, is no treason: as was the case of Sir Walter Tyrrel, who, by the command of King William Rufus, shooting at a hart, the arrow glanced against a tree, and killed the king upon the spot. But as this compassing or imagination is an act of the mind, it cannot possibly fall under any judicial cognizance, unless it be demonstrated by some open or overt act. The statute expressly requires, that the accused "be thereof upon sufficient proof attainted of some open act by men of his own condition." Thus, to provide weapons or ammunition for the purpose of killing the king, is held to be a palpable overt act of treason in imagining his death. To conspire to imprison the king by force, and move towards it by assembling company, is an overt act of compassing the king's death; for all force used to the person of the king, in its consequence may tend to his death, and is a strong presumption of something worse intended than the present force, by such as have so far thrown off their bounden duty to their sovereign: it being an old observation, that there is generally but a short interval between the prisons and the graves of princes. It seems clearly to be agreed, that by the common law and the statute of Edw. III. words spoken amount only to a high misdemeanor, and no treason. For they may be spoken in heat, without any intention; or be mistaken, perverted, or misremembered by the hearers; their meaning depends always on their connection with other words and things; they may signify differently even according to the tone of voice with which they are delivered; and sometimes silence itself is more expressive than any discourse. As therefore there can be nothing more equivocal and ambiguous than words, it would indeed be unreasonable to make them amount to high treason. And accordingly, in 4 Car. I. on a reference to all the judges, concerning some very atrocious words spoken by one Pyne, they certified to the king, "that though the words were as wicked as might be, yet they were no treason; for unless it be by some particular statute, no words will be treason." If the words be set down in writing, it argues more deliberate intention; and it has been held, that writing is an overt act of treason; for *scribere est agere*. But even in this case the bare words are not the treason, but the deliberate act of writing them.

2. The second species of treason is, "if a man do violate the king's companion, or the king's eldest daughter unmarried, or the wife of the king's eldest son and heir." By the king's companion is meant his wife; and by violation is understood carnal knowledge, as well without force as with it: and this is high treason in both parties if both be consenting; as some of the wives of Henry VIII. by fatal experience evinced.

3. The third species of treason is, "if a man do levy war against our lord the king in his realm." And this may be done by taking arms, not only to dethrone the king, but under pretence to reform religion, or the laws, or to remove evil counsellors, or other grievances whether real or pretended. For the law does not, neither can it permit any private man, or set of men, to interfere forcibly in matters of such high importance; especially as it has established a sufficient power for these purposes in the high court of parliament: neither does the constitution justify any private or particular resistance for private or particular grievances; though, in cases of national oppression, the nation has very justifiably risen as one man, to vindicate the original contract subsisting between the king and his people.

4. "If a man be adherent to the king's enemies in his realm, giving to them aid and comfort in the realm or elsewhere," he is also declared guilty of high-treason. This must likewise be proved by some overt act; as by giving them intelligence, by sending them provisions, by selling them arms, by treacherously surrendering a fortress, or the like.

5. "If a man counterfeit the king's great or privy seal," this is also high-treason. But if a man takes wax bearing the impression of the great seal off from one patent, and fixes it to another, this is held to be only an abuse of the seal, and not a counterfeiting of it: as was the case of a certain chaplain, who in such a manner framed a dispensation for non-residence. But the knavish artifice of a lawyer much exceeded this of the divine. One of the clerks in chancery glued together two pieces of parchment; on the uppermost of which he wrote a patent, to which he regularly obtained the great seal, the label going through both the skins. He then dissolved the cement, and taking off the written patent, on the blank skin, wrote a fresh patent of a different import from the former, and published it as true. This was held no counterfeiting of the great seal, but only a great misprison; and Sir Edward Coke mentions it with some indignation that the party was living at that day.

6. The sixth species of treason under this statute is, "if a man counterfeit the king's money; and if a man bring false money into the realm counterfeit to the money of England, knowing the money to be false, to merchandise and make payment withal." As to the first branch, counterfeiting the king's money; this is treason, whether the false money be uttered in payment or not. Also if the king's own minters alter the standard or alloy established by law, it is treason. But gold and silver money only are held to be within this statute. With regard likewise to the second branch, importing foreign counterfeit money in order to utter it here; it is held that uttering it, without importing it, is not within the statute.

7. The last species of treason ascertained by this statute is, "if a man slay the chancellor, treasurer, or the king's justices of the one bench or the other, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places doing their offices." These high magistrates, as they represent the king's majesty during the execution of their offices, are therefore for the time equally regarded by the law. But this statute extends only to the actual killing of them; and not to wounding, or a bare attempt to kill them. It extends also only to the officers therein specified; and therefore the barons of the exchequer, as such, are not within

within the protection of this act; but the lord keeper or commissioners of the great seal now seem to be within it, by virtue of the statutes 5 Eliz. c. 18. and 1 W. and M. c. 21.

The new treasons, created since the statute 1 M. c. 1. and not comprehended under the description of statute 25 Edw. III. may be comprised under three heads. The first species relates to Papists; the second to falsifying the coin or other royal signatures, as falsely forging the sign manual, privy signet, or privy seal, which shall be deemed high treason (1 M. stat. ii. c. 6.). The third new species of high treason is such as was created for the security of the Protestant succession in the house of Hanover. For this purpose, after the act of settlement was made, it was enacted by statute 13 and 14 W. III. c. 3. that the pretended prince of Wales, assuming the title of King James III. should be attainted of high treason; and it was made high-treason for any of the king's subjects to hold correspondence with him or any person employed by him, or to remit money for his use. And by 17 Geo. II. c. 39. it is enacted, that if any of the sons of the pretender shall land or attempt to land in this kingdom, or be found in the kingdom or any of its dominions, he shall be adjudged attainted of high-treason; and corresponding with them or remitting money to their use is made high-treason. By 1 Ann. stat. 2. c. 17. the offence of hindering the next in succession from succeeding to the crown is high-treason: and by 6 Ann. c. 7. if any person shall maliciously, advisedly, and directly, by writing or printing, maintain, that any other person hath any right to the crown of this realm, otherwise than according to the act of settlement, or that the kings of this realm with the authority of parliament are not able to make laws to bind the crown and its descent; such person shall be guilty of high-treason.

The punishment of high treason in general is very solemn and terrible. 1. That the offender be drawn to the gallows, and not be carried or walk; though usually (by connivance, at length ripened by humanity into law) a sledge or hurdle is allowed, to preserve the offender from the extreme torment of being dragged on the ground or pavement. 2. That he be hanged by the neck, and then cut down alive. 3. That his entrails be taken out, and burned while he is yet alive. 4. That his head be cut off. 5. That his body be divided into four parts. 6. That his head and quarters be at the king's disposal.

The king may, and often doth, discharge all the punishment except beheading, especially where any of noble blood are attainted. For beheading being part of the judgment, that may be executed, though all the rest be omitted by the king's command. But where beheading is no part of the judgment, as in murder or other felonies, it hath been said that the king cannot change the judgment, although at the request of the party, from one species of death to another.

In the case of coining, which is a treason of a different complexion from the rest, the punishment is milder for male offenders; being only to be drawn and hanged by the neck till dead. But in treasons of every kind the punishment of women is the same, and different from that of men. For as the natural modesty of the sex forbids the exposing and publicly mangling their bodies, their sentence (which is to the full as terrible to sense as the other) is to be drawn to the gallows, and there to be burned alive.

For the consequences of this judgment, see ATTAINDER, FORFEITURE, and *CORRUPTION of Blood*.

Petty or *Petit Treason*, according to the statute 25 Edward III. c. 2. may happen three ways: by a servant killing his master, a wife her husband, or an ecclesiastical person (either secular or regular) his superior, to whom he owes faith and obedience. A servant who kills his master whom he has left, upon a grudge conceived against him during his service, is guilty of petty treason: for the traitorous intention was hatched while the relation subsisted between them, and this is only an execution of that intention. So if a wife be divorced *a mensa et thoro*, still the *vinculum matrimonii* subsists; and if she kills such divorced husband, she is a traitress. And a clergyman is understood to owe canonical obedience to the bishop who ordained him, to him in whose diocese he is beneficed, and also to the metropolitan of such suffragan or diocesan bishop; and therefore to kill any of these is petit treason. As to the rest, whatever has been said with respect to wilful MURDER, is also applicable to the crime of petit treason, which is no other than murder in its most odious degree; except that the trial shall be as in cases of high treason, before the improvements therein made by the statutes of William III. But a person indicted of petit treason may be acquitted thereof, and found guilty of manslaughter or murder: and in such case it should seem that two witnesses are not necessary, as in cases of petit treason they are. Which crime is also distinguished from murder in its punishment.

The punishment of petit treason in a man, is to be drawn and hanged, and in a woman to be drawn and burned: the idea of which latter punishment seems to have been handed down to us from the laws of the ancient Druids, which condemned a woman to be burned for murdering her husband; and it is now the usual punishment for all sorts of treasons committed by those of the female sex. Persons guilty of petit treason were first debarred the benefit of clergy by statute 12 Henry VII. c. 7. which has since been extended to their aiders, abettors, and counsellors, by statutes 23 Henry VIII. c. 1, 4, and 5 P. and M. c. 4.

TREASURE, in general, denotes a store or stock of money in reserve.

TREASURE-Trove, in *Law*, derived from the French word *trover*, "to find," called in Latin *thesaurus inventus*, is where any money or coin, gold, silver, plate, or bullion, is found hidden in the earth or other private place, the owner thereof being unknown; in which case the treasure belongs to the king: but if he that had hid it be known, or afterwards found out, the owner and not the king is intitled to it.

TREASURER, an officer to whom the treasure of a prince or corporation is committed to be kept and duly disposed of, in payment of officers and other expences. See TREASURY.

Of these there is great variety. His majesty of Great Britain, in quality of elector of Hanover, is arch-treasurer of the Roman empire. In England, the principal officers under this denomination are, the lord high-treasurer, the treasurer of the household, treasurer of the navy, of the king's chamber, &c.

The lord high-treasurer of Great Britain, or first commissioner

missioner of the treasury, when in commission, has under his charge and government all the king's revenue which is kept in the exchequer. He holds his place during the king's pleasure; being instituted by the delivery of a white staff to him. He has the check of all the officers employed in collecting the customs and royal revenues: and in his gift and disposition are all the offices of the customs in the several ports of the kingdom; escheators in every county are nominated by him; he also makes leases of the lands belonging to the crown.

The office of lord-treasurer is now in commission. The number of lords-commissioners is five; one of whom is the first lord, whose annual salary was formerly 383l. but is now 4000l.; and who, unless he be a peer, is also chancellor of the exchequer, and prime minister in the government of this country; the other lords commissioners have an annual salary of 1600l. each.

Treasurer of the Household, is an officer who, in the absence of the lord-steward, has power, with the comptroller and other officers of the green-cloth and the steward of the Marshalsea, to hear and determine treasons, felonies, and other crimes committed within the king's palace. See Household.

There is also a treasurer belonging to the establishment of her majesty's household, &c.

Treasurer of the Navy, is an officer who receives money out of the exchequer, by warrant from the lord high-treasurer, or the lords commissioners executing that place; and pays all charges of the navy, by warrant from the principal officers of the navy.

Treasurer of the County, he that keeps the county stock. There are two of them in each county, chosen by the major part of the justices of the peace, &c. at their general quarter session; under previous security given for the money entrusted with them, and the faithful execution of the trusts reposed in them.

TREASURY, the place wherein the revenues of a prince are received, preserved and disbursed. In England the treasury is a part of the exchequer; by some called the *lower exchequer*. The officers of his majesty's treasury, or the lower exchequer, are the lords commissioners, one of whom is chancellor, two joint secretaries, private secretary to the first lord, two chamberlains, an auditor, four tellers, a clerk of the pells, ushers of the receipt, a tally-cutter, &c. See each officer under his proper article, Chancellor, Teller, Tally, &c.

Lords of the Treasury. In lieu of one single director and administrator of his majesty's revenues under the title of *lord high treasurer*, it is at present thought proper to put that office in commission, i. e. to appoint several persons to discharge it with equal authority, under the title of *lords commissioners of the treasury*.

TREATISE, a set discourse in writing on any subject.

TREATY, a covenant between two or more nations; or the several articles or conditions stipulated and agreed upon by two sovereign powers.

TREBLE, in *Music*, the highest or most acute of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

TREBUCHET, Trebucket, *Tribuch* (*Terbichelum*), a tumbrel or cucking stool. Also a great engine to cast stones to batter walls.

TREE, a large vegetable, rising with one woody stem to a considerable height.

Trees may be divided into two classes, *timber* and *fruit-trees*; the first including all those trees which are used in machinery, ship-building, &c. or, in general, for purposes of utility; and the second comprehending those trees valued only, or chiefly, for their fruit. It is not necessary to form a third class to include trees used for fuel, as timber is used for this purpose where it is abundant; and where it is not abundant the branches of the timber trees, or such of them as are dwarfish, unhealthy, or too small for mechanical purposes, are used as fuel.

The anatomy and physiology of trees have already been given under the generic name Plant and Sap.

Certain trees, it is well known, are natives of particular districts; but many of them have been transplanted from their native soil, and now flourish luxuriantly in distant countries, so that it becomes a matter of very considerable difficulty to ascertain their original soil. The following rules are given for this purpose by the Honourable Daines Barrington.

1. They must grow in large masses, and cover considerable tracts of ground, the woods not ending abruptly, by a change to other trees, except the situation and strata become totally different. 2. They must grow kindly in copses, and shoot from the stool, so as to continue for ever, if not very carefully grubbed up. 3. The seed must ripen kindly; nature never plants but where a succession in the greatest profusion will continue. Lastly, trees that give names to many places are probably indigenous.

The growth of trees is a curious and interesting subject; yet few experiments have been made to determine what the additions are which a tree receives annually in different periods of its age. The only observations which we have seen on this subject worth repeating were made by the ingenious Mr Barker, to whom the Philosophical Transactions are much indebted for papers containing an accurate register of the weather, which he has kept for many years. He has drawn up a table to point out the growth of three kinds of trees, oaks, ashes, and elms; which may be seen in the Philosophical Transactions for 1788. We shall give his conclusions.

"I find (says he) the growth of oak and ash to be nearly the same. I have some of both sorts planted at the same time, and in the same hedges, of which the oaks are the largest; but there is no certain rule as to that. The common growth of an oak or an ash is about an inch in girth in a year; some thriving ones will grow an inch and a half; the unthriving ones not so much. Great trees grow more timber in a year than small ones; for if the annual growth be an inch, a coat of one-sixth of an inch is laid on all round, and the timber added to the body every year is its length multiplied into the thickness of the coat and into the girth, and therefore the thicker the tree is, the more timber is added."

We will present our readers with a table, showing the growth of 17 kinds of trees for two years. The trees grew at Cavenham in Suffolk.

N°	July 1755. F.	In.	July 1786. F.	In.	July 1787. F.	In.

Trees sometimes attain a very great size: this must depend in a great measure on the richness of soil, but no less on the degree of heat. Indeed heat is so essential to the growth of trees, that as we go from the place within the polar circles where vegetation begins, and advance to the equator, we find the trees increase in size. Greenland, Iceland, and other places in the same latitude, yield no trees at all; and the shrubs which they produce are dwarfish; whereas, in warm climates, they often grow to an immense size. Mr Marsham saw spruce and silver firs in the dock-yard in Venice above 40 yards long, and one of 39 yards was 18 inches diameter at the small end. He was informed that they came from Switzerland.

The largest tree in Europe, mentioned by travellers, is the chesnut tree on Mount Etna, already described under the article ETNA, N° 18. It is a certain fact that trees acquire a very great size in volcanic countries. Beside the multitude of fine groves in the neighbourhood of Albano in Italy, there are many detached oaks 20 feet in circumference, and many elms of the same size, especially in the romantic way to Eastello, called the *Galleria*. In travelling by the side of the lake of Bolsena, the road leads through an immense number of oaks, spread upon beautiful hills. Where the lava has been sufficiently softened, they are clean and straight, and of a considerable size; but where the lava has not been converted into a soil proper for strong vegetation, they are round-headed, and of less size; however, taken all together, they make a magnificent appearance; and the spot itself ought to be ranked among the fine parts of Italy. The same may be observed of the small lake of Vico, encompassed with gentle risings, that are all clothed with forest-trees.

Some yews have been found in Britain 60 feet round. Palms in Jamaica attain the height of 200 feet; and some of the pines in Norfolk island are 280 feet high.

Of all the different kinds known in Europe, oak is best for building; and even when it lies exposed to air and water, there is none equal to it. Fir timber is the next in degree of goodness for building, especially in England, where they build upon leases. It differs from oak in this, that it requires not much seasoning, and therefore no great stock is required before-hand. Fir is used for flooring, wainscoting, and the ornamental parts of building within doors. Elm is the next in use, especially in England and France: it is very tough and pliable, and therefore easily worked: it does not readily split; and it bears driving of bolts and nails better than any other wood; for which reason it is chiefly used by wheel-wrights and coach-makers, for shafts, naves, &c. Beech is also used for many purposes: it is very tough and white when young, and of great strength; but liable to warp very much when exposed to the weather, and to be worm eaten when used within doors; its greatest use is for planks, bedsteads, chairs, and other household goods. Ash is likewise a very useful wood, but very scarce in most parts of Europe; it serves in buildings, or for any other use, when screened from the weather; handspikes and oars are chiefly made of it. Wild chesnut timber is by many esteemed to be as good as oak, and seems to have been much used in old buildings; but whether these trees are more scarce at present than formerly, or have been found not to answer so well as was imagined, it is certain that this timber is now but little used. Walnut-tree is excellent for the joiner's use, it being of a more curious brown colour than beech, and not so subject to the worms. The poplar, abele, and aspen trees, which are very little different from each other, are much used instead of fir; they look well, and are tougher and harder.

The goodness of timber not only depends on the soil and situation in which it stands, but likewise on the season wherein it is felled. In this people disagree very much; some are for having it felled as soon as its fruit is ripe, others in the spring, and many in the autumn. But as the sap and moisture of timber is certainly the cause that it perishes much sooner than it otherwise would do, it seems evident, that timber should be felled when there is the least sap in it, viz. from the time that the leaves begin to fall till the trees begin to bud. This work usually commences about the end of April in England, because the bark then rises most freely; for where a quantity of timber is to be felled, the statute requires it to be done then, for the advantage of tanning. The ancients chiefly regarded the age of the moon in felling their timber; their rule was to fell it in the wane, or four days after the new moon, or sometimes in the last quarter. Pliny advises it to be in the very instant of the change: which happening to be in the last day of the winter solstice, the timber, says he, will be incorruptible.

Timber should likewise be cut when of a proper age; for when it is either too young or too old, it will not be so durable as when cut at a proper age. It is said that oak should not be cut under 60 years old, nor above 200. Timber, however, should be cut in its prime, when almost fully grown, and before it begins to decay; and this will be sooner or later according to the dryness and moistness of the soil where the timber grows, as also according to the bigness of the trees; for there are no fixed rules in felling of timber, experience and judgment must direct here as in most other cases.

Great attention is necessary in the seasoning of tim-

Tree. ber. Some advise the planks of timber to be laid for a few days in some pool or running stream, in order to extract the sap, and afterwards to dry them in the sun or air. By this means, it is said, they will be prevented from either chopping, casting, or cleaving; but against shrinking there is no remedy. Some again are for burying them in the earth, others in a heat; and some for scorching and seasoning them in fire, especially piles, posts, &c. which are to stand in water or earth. The Venetians first found out the method of seasoning by fire; which is done after this manner: They put the piece to be seasoned into a strong and violent flame; in this they continually turn it round by means of an engine, and take it out when it is everywhere covered with a black coaly crust; the internal part of the wood is thereby so hardened, that neither earth nor water can damage it for a long time afterwards.

Dr Plott says, it is found by long experience, that the trunk or body of the trees, when barked in the spring, and left standing naked all the summer exposed to the sun and wind, are so dried and hardened, that the sappy part in a manner becomes as firm and durable as the heart itself. This is confirmed by M. Buffon, who, in 1738, presented to the Royal Academy of Sciences at Paris a memoir entitled, "An easy method of increasing the solidity, strength, and duration of timber;" for which purpose he observes, "nothing more is necessary than to strip the tree entirely of its bark during the season of the rising of the sap, and to leave it to dry completely before it be cut down."

By many experiments, particularly described in that essay, it appears, that the tree should not be felled till the third year after it has been stripped of the bark; that it is then perfectly dry, and the sap become almost as strong as the rest of the timber, and stronger than the heart of any other oak tree which has not been so stripped; and the whole of the timber stronger, heavier, and harder; from which he thinks it fair to conclude, that it is also more durable. "It would no longer (he adds) be necessary, if this method were practised, to cut off the sap; the whole of the tree might be used as timber; one of 40 years growth would serve all the purposes for which one of 60 years is now required; and this practice would have the double advantage of increasing the quantity, as well as the strength and solidity, of the timber."

The navy board, in answer to the inquiries of the commissioners of the land revenue, in May 1789, informed them, that they had then standing some trees stripped of their bark two years before, in order to try the experiment of building one half of a sloop of war with that timber, and the other half with timber felled and stripped in the common way. This very judicious mode of making the experiment, if it be properly executed, will undoubtedly go far to ascertain the effects of this practice. We are sorry that we are not able to inform our readers what was the result of the experiment.

After the planks of timber have been well seasoned and fixed in their places, care is to be taken to defend or preserve them; to which the smearing them with linseed oil, tar, or the like oleaginous matter, contributes much. The ancients, particularly Hesiod and Virgil, advise the smoke-drying of all instruments made of wood, by hanging them up in the chimneys where wood fires are used. The Dutch preserve their gates, portcullices, drawbridges, sluices, &c. by coating them over with a mixture of pitch and tar, whereon they strew small pieces of cockle and other shells, beaten almost to powder, and mixed with sea-sand, which incrusts and arms them wonderfully against all assaults of wind and weather. When timber is felled before the sap is perfectly at rest, it is very subject to worms; but to prevent and cure this, Mr Evelyn recommends the following remedy as the most approved: Put common sulphur into a cucurbit, with as much aquafortis as will cover it three fingers deep; distil it to dryness, which is performed by two or three rectifications. Lay the sulphur that remains at bottom, being of a blackish or sand-red colour, on a marble, or put it in a glass, and it will dissolve into an oil; with this oil anoint the timber which is infected with worms. This, he says, will not only prevent worms, but preserve all kinds of woods, and many other things, as ropes, nets, and masts, from putrefaction, either in water, air, or snow.

An experiment to determine the comparative durability of different kinds of timber, when exposed to the weather, was made by a nobleman in Norfolk; of which an account is given by Sir Thomas Beevor. This nobleman, in the year 1774, ordered three posts, forming two sides of a quadrangle, to be fixed in the earth on a rising ground in his park. Into these posts were mortised planks, an inch and a half thick, cut out of trees from 30 to 45 years growth. These, after standing 10 years, were examined, and found in the following state and condition: Annals of Agriculture, vol. ii. p. 156.

The cedar was perfectly sound; larch, the heart sound, but the sap quite decayed; spruce fir, sound; silver fir, in decay; Scotch fir, much decayed; pinaster, quite rotten; chesnut, perfectly sound; abele, sound; beech, sound; walnut, in decay; sycamore, much decayed; birch, quite rotten. Sir Thomas Beevor justly remarks, that the trees ought to have been of the same age; and Mr Arthur Young adds, they ought to have been cut out of the same plantation.

The immense quantity of timber consumed of late years in ship-building and other purposes has diminished in a very great degree the quantity produced in this country. On this account, many gentlemen who wish well to their country, alarmed with the fear of a scarcity, have strongly recommended it to government to pay some attention to the cultivation and preservation of timber.

We find, on the best authority, that of Mr Irving inspector general of imports and exports, that the shipping of England in 1760 amounted to 6107 in number, the tonnage being 433,922; and the shipping in Scotland amounted to 976 in number, the tonnage being 52,818. In 1788 the whole shipping of Britain and Ireland and their colonies amounted to 13,800, being 1,359,752 tons burden, and employing 107,925 men. The tonnage of the royal navy in the same year was 413,667. We are informed also, on what we consider as the best authority (the report of the commissioners of the land revenue), that the quantity of oak timber, of English growth, delivered into the dockyards from 1760 to 1788 was no less than 768,676 loads, and that the quantity used in the merchants yards in the same time was 516,630 loads; in all 1,285,306 loads. The foreign oak used in the same period was only 137,766 loads. Eleventh Report.

Tree. loads. So that, after deducting the quantity remaining in the dock-yards in 1760 and 1788, and the foreign oak, there will remain about 1,054,284 loads of English oak, consumed in 28 years, which is at an average 37,653 loads per annum, besides from 8300 to 10,000 loads expended annually by the East India Company within the same period (A).

The price of wood has risen in proportion to the demand and to its diminution. At the conquest, woods were valued, not by the quantity of timber which they contained, but the number of swine which the acorns could support. In 1608, oak in the forests was sold at 10s. per load, and fir-wood for 2s. per load. In 1663 or 1665, in navy contracts from 2l. to 2l. 15s. 6d. per load was given. In 1756 it rose to 4l. 5s. per load, and 3s. in addition, because no tops are received. Plank four inch sold in 1769 for 7l. a load, three inch 6l.; which prices were the same in 1792.

So great an expenditure of valuable timber within so short a period, gives reason to fear that the forests of this country will soon be entirely dismantled, unless some hing is done to raise fresh supplies. The building of a 70 gun ship, it is said, would take 40 acres of timber. This calculation is indeed so excessive, that it is scarcely credible. This, however, is no exaggeration. According to the prevailing opinion of experienced surveyors, it will require a good soil and good management to produce 40 trees on an acre, which, in a hundred years, may, at an average, be computed at two loads each. Reckoning, therefore, two loads at 8l. 16s. one acre will be worth 350l. and consequently 40 acres will only be worth 14,200l. Now a 70 gun ship is generally supposed to cost 70,000l.; and as ships do not last a great many years, the navy continually requires new ships, so that the forests must be stripped in a century or two, unless young trees are planted to supply their place.

Many plans have been proposed for recruiting the forests. Premiums have been held forth to individuals; and it has been proposed that the crown-lands should be set apart for the special purpose of raising timber. With respect to individuals, as they must generally be disposed to sow or plant their lands with those vegetables which will best reward their labours, it is not to be expected that they will set apart their fields for planting trees unless they have a greater return from them than other crops. But bad must that land be which will not yield much more than 350l. produce in 100 years. But though it be evident that good land will produce crops much more lucrative to the proprietor than timber, yet still there are lands or pieces of land which might be applied with very great advantage to the production of wood. Uneven ground, or the sides of fields where corn cannot be cultivated, might very properly be set apart for this purpose; barren lands, or such as cannot be cultivated without great labour and expence, might also be planted. Hedge-rows and clumps of trees, and little woods scattered up and down, would shelter and defend the fields from destructive winds, would beautify the face of the country, render the climate warmer, improve barren lands, and furnish wood for the arts and manufactures.

But to cultivate forest timber has also been thought of such national importance, that it has been deemed worthy of the attention of government. It has been proposed to appropriate such part of the crown lands as are fit for the purpose solely of producing timber for the navy. This appears a very proper scheme in speculation; but it has been objected, that for government to attempt the farming of forests would be really to establish groups of officers to pocket salaries for doing what, it is well known, will never be done at all. But to this objection we reply, that such an agreement might be made with the inspectors of forests, as to make it their own interest to cultivate trees with as much care as possible. Their salary might be fixed very low, and raised in proportion to the number of trees which they could furnish of such a size in a certain number of years. After all, we must acknowledge that we must depend greatly on Russia, Sweden, Norway, and America, for supplying us with timber; and while these countries take our manufactures in exchange, we have no reason to complain. Still, however, we ought surely not to neglect the cultivation of what is of so much importance to our existence as a nation, for it may often be impossible in time of war to obtain timber from foreign countries.

In the beginning of this article we mentioned the general division of trees into timber or forest-trees and fruit trees. We have already said all that our limits will permit respecting the former: we will now, therefore, say something of the latter. Our observations shall be confined to the methods of preserving fruit trees in blossom from the effects of frost, and from other diseases to which they are liable.

The Chevalier de Dienenberg of Prague, we are told, has discovered a method of effectually preserving trees in blossom from the fatal effects of those frosts which sometimes in the spring destroy the most promising hopes of a plentiful crop of fruit. His method is extremely simple. He surrounds the trunk of the tree in blossom with a wisp of straw or hemp. The end of this he sinks, by means of a stone tied to it, in a vessel of spring water, at a little distance from the tree. One vessel will conveniently serve two trees: or the cord may be lengthened so as to surround several, before its end is plunged into the water. It is necessary that the vessel be placed in an open situation, and by no means shaded by the branches of the neighbouring trees, that the frost may produce all its effect on the water, by means of the cord communicating with it.—This precaution is particularly necessary for those trees the flowers of which appear nearly at the same time as the leaves; which trees are peculiarly exposed to the ravages of the frost. The proofs of its efficacy, which he had an opportunity of observing in the spring

European Magazine, March 1791.

(A) A writer in the Bath Transactions says, that the aggregate of oaks felled in England and Wales for 30 years past has amounted to 320,000 loads a year; and affirms that he has documents in his possession founded on indisputable facts. The difference between this account, and that which we have given in the text from the report of the commissioners, we leave to be reconciled by those who have proper opportunities. We give the facts merely on the authority of others.

Tree.

spring of 1787, were remarkably striking. Seven apricot espaliers in his garden began to blossom in the month of March. Fearing that they would suffer from the late frosts, he surrounded them with cords as above directed. In effect, pretty sharp frosts took place six or eight nights: the apricot-trees in the neighbouring gardens were all frozen, and none of them produced any fruit, whilst each of the chevalier's produced fruit in abundance, which came to the greatest perfection.

The following is the method proposed by Mr William Forsyth for curing injuries and defects in trees; for which a reward was given to him by his majesty, on condition that he should make it public. It is equally applicable to forest as to fruit trees (B).

Take one bushel of fresh cow-dung; half a bushel of lime rubbish of old buildings (that from the ceilings of rooms is preferable); half a bushel of wood ashes; and a sixteenth part of a bushel of pit or river sand. The three last articles are to be sifted fine before they are mixed; then work them well together with a spade, and afterwards with a wooden beater, until the stuff is very smooth, like fine plaster used for the ceilings of rooms. The composition being thus made, care must be taken to prepare the tree properly for its application, by cutting away all the dead, decayed, and injured parts, till you come to the fresh sound wood, leaving the surface of the wood very smooth, and rounding off the edges of the bark with a draw-knife, or other instrument, perfectly smooth, which must be particularly attended to. Then lay on the plaster about one-eighth of an inch thick all over the part where the wood or bark has been so cut away, finishing off the edges as thin as possible. Then take a quantity of dry powder of wood ashes, mixed with a sixth part of the same quantity of the ashes of burnt bones; put it into a tin box, with holes in the top, and shake the powder on the surface of the plaster, till the whole is covered over with it, letting it remain for half an hour to absorb the moisture: then apply more powder, rubbing it on gently with the hand, and repeating the application of the powder, till the whole plaster becomes a dry smooth surface.

All trees cut down near the ground should have the surface made quite smooth, rounding it off in a small degree, as before mentioned; and the dry powder directed to be used afterwards should have an equal quantity of powder of alabaster mixed with it, in order the better to resist the dripping of trees and heavy rains. If any of the composition be left for a future occasion, it should be kept in a tub or other vessel, and urine of any kind poured on it, so as to cover the surface; otherwise the atmosphere will greatly hurt the efficacy of the application. Where lime rubbish of old buildings cannot be easily got, take powdered chalk, or common lime, after having been slaked a month at least. As the growth of the tree will gradually affect the plaster, by raising up its edges next the bark, care should be taken, where that happens, to rub it over with the finger when occasion may require (which is best done when moistened by rain), that the plaster may be kept whole, to prevent the air and wet from penetrating into the wound.

Tree || Trent.

Forsyth's Observations on the Diseases of Trees.

By this process, some old worn-out pear trees, that bore only a few small, hard fruit, of a kernelly texture, were made to produce pears of the best quality and finest flavour the second summer after the operation; and in four or five years they bore such plenteous crops, as a young healthy tree would not have produced in four times that period.

By this process, too, some large ancient elms, in a most decayed state, having all their upper parts broken, and a small portion only of the bark remaining, shot out stems from their tops, above thirty feet in height, in six or seven years from the first application of the composition.

Thus may valuable trees be renovated; and forest trees, which are useful or ornamental from their particular situation, be preserved in a flourishing state. But what is far more interesting, a perfect cure has been made, and sound timber produced, in oak trees, which had received very considerable damage from blows, bruises, cutting of deep letters, the rubbing off the bark by the ends of rollers, or wheels of carts, or from the breaking of branches by storms.

TREFOIL. See Trifolium, Botany *Index*.

TREMELLA, a genus of plants belonging to the class of cryptogamia. See Botany *Index*.

TREMOR, an involuntary shaking, chiefly of the hands and head, sometimes of the feet, and sometimes of the tongue and heart.—Tremors arising from a too free use of spirituous liquors require the same treatment as palsies.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach the more securely to the place attacked, whence they are also called *lines of approach*.

TRENT, Bishopric of, a province of Germany, in the circle of Austria, near the frontiers of Italy; is bounded on the north by Tirol; on the east by the Feltrino and Bellunese; on the south, by Vincentino, the Veronese, Bresciano, and the lake de Garda; and on the west, by the Bresciano, and the lake de Garda. The soil is said to be very fruitful, and to abound in wine and oil. It is subject to Austria.

Trent, a city of Germany, and capital of the bishopric of that name, is a very ancient place, and stands in a fertile and pleasant plain, in the midst of the high mountains of the Alps. The river Adige washes its walls, and creeping for some time among the hills, runs swiftly into Italy. Trent has three considerable churches, the principal of which is the cathedral: this is a very regular piece of architecture. The church of St Maria Major is all of red and white marble; and is remarkable for being the place where the famous council of Trent

(B) A paste for covering the wounds of trees, and the place where grafts are inserted, was discovered long ago. It is recommended in a Treatise on Fruit Trees, published by Thomas Hitt in 1755; a third edition of which, with additions, was published in 1768. It consists of a mixture of clay and cow's dung diluted with water. This paste he directs to be laid on the wound with a brush; it adheres firmly, he says, without cracking, till the wound heals. We are informed by a gentleman, to whose opinion and experience we pay great respect, that this paste answers every purpose which Mr Forsyth's can serve.

Trent was held, whose decisions are now the standing rule of the Romish church. E. Long. 11. 5. N. Lat. 46.

TRENT, one of the largest rivers in England, which rises in the moorland of Staffordshire, and runs southwest by Newcastle-under-Line; and afterwards dividing the county into two parts, runs to Burton, then to Nottingham and Newark; and so continuing its course due north to Gainsborough on the confines of Lincolnshire, it joins several rivers, and falls into the Humber.

TRENT, *Council of*, in *Ecclesiastical History*, denotes the council assembled by Paul III. in 1545, and continued by 25 sessions till the year 1563, under Julius III. and Pius IV. in order to correct, illustrate, and fix with perspicuity, the doctrine of the church, to restore the vigour of its discipline, and to reform the lives of its ministers. The decrees of this council, together with the creed of Pope Pius IV. contain a summary of the doctrines of the Roman Catholics. These decrees were subscribed by 255 clergy, consisting of four legates, 2 other cardinals, 3 patriarchs, 25 archbishops, 168 bishops, besides inferior clergy. Of these 150 came from Italy, of course the council was entirely under the influence of the pope. For a more particular account of the council of Trent, see Mosheim's Church History, the Modern Universal History, vol. xxiii. and Father Paul's History of the Council of Trent.

TRENTON. See *New Jersey*.

TREPANNING. See SURGERY *Index*.

TRES TABERNÆ, in *Ancient Geography*, a place in Latium, lying on the Via Appia, on the left or south side of the river Astura, to the north of the Paludes Pomptinæ. Its ruins are now seen near Cisterna, a village in the Campagna di Roma, 21 miles from Rome, whence the Christians went out to meet St Paul.

TRESPASS, in *Law*, signifies any transgression of the law, under treason, felony, or misprision of either: but it is commonly used for any wrong or damage that is done by one private person to another, or to the king in his forest.

TRESSLE TREES, in *Ship-Building*, two strong bars of timber fixed horizontally on the opposite sides of the lower mast head, to support the frame of the top and the weight of the top-mast.

TRESSURE, in *Heraldry*, a diminutive of an orle, usually held to be half the breadth thereof.

TRET, in *Commerce*, an allowance made for the waste or the dirt that may be mixed with any commodity; which is commonly four pounds in every 104 pounds weight.

TREVERI, or TREVIRI, in *Ancient Geography*, an ancient and a powerful people, both in horse and foot, according to Cæsar; extending far and wide between the Meuse and the Rhine. Their chief town was called *Treveris*. Now *Triers* or *Treves*.

TREVES, or TRIERS (in Latin *Trevere*, *Trevers*, *Treviris*, or *Augusta Trevirorum*), the capital of the German archbishopric of the same name, stands 60 miles west of Mentz, 52 south of Cologne, and 82 north of Strasburg. This city vies with most in Europe for antiquity, having been a large and noted town before Augustus settled a colony in it. It was free and imperial till the year 1560, when it was surprised and subjected by its archbishop James III. It stands on the Moselle, over which it has a fair stone bridge. The cathedral is a large building; and near it stands the elector's palace. Here are three collegiate and five parish churches, an university founded in 1472, with some remains of the ancient Roman theatre. Roman coins and medals are often found in the ruins of the old city. The private houses here are mean; and the city is neither well fortified nor inhabited. Four-fifths of this archbishopric were seized by France in 1794 and united to her territories; and the remaining parts were secularised and distributed among certain princes in 1802. In 1814 the part which France held was given to Prussia. E. Long. 6. 41. N. Lat. 49. 45.

TRIAL, in *Law*, the examination of a cause according to the laws of the land before a proper judge; or it is the manner and order observed in the hearing and determining of causes.

Trials are either civil or criminal.

I. *Civil Trials.* The species of trials in civil cases are seven: By *record;* by *inspection* or examination; by *certificate;* by *witnesses;* by wager of *battel;* by wager of *law;* and by *jury*. The first six are only had in certain special or eccentrical cases, where the trial by jury would not be so proper or effectual: (See them explained under their respective titles). The nature of the last, that principal criterion of truth in the law of England, shall be explained in this article.

As trial by jury is esteemed one of the most important privileges which members of society can enjoy, and the bulwark of the British constitution, every man of reflection must be stimulated by the desire of inquiring into its origin and history, as well as to be acquainted with the forms and advantages by which it is accompanied. We will therefore begin with tracing it to its origin. Its institution has been ascribed to our Saxon ancestors by Sir William Blackstone.

"Some authors (says that illustrious lawyer) have endeavoured to trace the original of juries up as high as the Britons themselves, the first inhabitants of our island; but certain it is that they were in use among the earliest Saxon colonies, their institution being ascribed by Bishop Nicholson to Woden himself, their great legislator and captain. Hence it is, that we may find traces of juries in the laws of all those nations which adopted the feodal system, as in Germany, France, and Italy; who had all of them a tribunal composed of twelve good men and true, *boni homines*, usually the vassals or tenants of the lord, being the equals or peers of the parties litigant; and, as the lord's vassals judged each other in the lord's courts, so the king's vassals, or the lords themselves, judged each other in the king's court. In England we find actual mention of them so early as the laws of King Ethelred, and that not as a new invention. Stiernhook ascribes the invention of the jury, which in the Teutonic language is denominated *nembda*, to Regner king of Sweden and Denmark, who was contemporary with our King Egbert. Just as we are apt to impute the invention of this, and some other pieces of juridical polity, to the superior genius of Alfred the Great; to whom, on account of his having done much, it is usual to attribute every thing: and as the tradition of ancient Greece placed to the account of their own Hercules whatever achievement was performed superior to the ordinary prowess of mankind. Whereas the truth seems to be, that this tribunal was universally established among all the northern nations, and so interwoven in their very constitution,

Blackst. Comment. vol. iii. p. 349.

constitution, that the earliest accounts of the one give us also some traces of the other."

This opinion has been controverted with much learning and ingenuity by Dr Pettingal in his Inquiry into the Use and Practice of Juries among the Greeks and Romans, who deduces the origin of juries from these ancient nations.

He begins with determining the meaning of the word δικαςαι in the Greek, and *judices* in the Roman, writers. "The common acceptation of these words (says he), and the idea generally annexed to them, is that of *presidents of courts*, or, as we call them, *judges;* as such they are understood by commentators, and rendered by critics. Dr Middleton, in his life of Cicero, expressly calls the judices, *judges of the bench;* and Archbishop Potter, and in short all modern writers upon the Greek or Roman orators, or authors in general, express δικαςαι and *judices* by such terms as convey the idea of *presidents in courts of justice.* The propriety of this is doubted of, and hath given occasion for this inquiry; in which is shown, from the best Greek and Roman authorities, that neither the δικαςαι of the Greeks, or the *judices* of the Romans, ever signified *presidents in courts of judicature*, or *judges of the bench;* but, on the contrary, they were distinguished from each other, and the difference of their duty and function was carefully and clearly pointed out by the orators in their pleadings, who were the best authorities in those cases, where the question related to forms of law, and methods of proceeding in judicial affairs and criminal process.

The presidents of the courts in criminal trials at Athens were the nine archons, or chief magistrates, of which whoever presided was called ηγεμων δικαςηριε, or president of the court. These nine presided in different causes peculiar to each jurisdiction. The archon, properly so called, had belonging to his department all pupillary and heritable cases; the βασιλευς or *rex sacrorum*, the chief priest, all cases where religion was concerned; the polemarchus, or general, the affairs of the army and all military matters; and the six thesmothetæ, the other ordinary suits.

Wherever then the ανδρες δικαςαι, or judicial men, are addressed by the Greek orators in their speeches, they are not to be understood to be the presiding magistrates, but another class of men, who were to inquire into the state of the cause before them, by witnesses and other methods of coming at truth; and after inquiry made and witnesses heard, to report their opinion and verdict to the president, who was to declare it.

The several steps and circumstances attending this judicial proceeding are so similar to the forms observed by our jury, that the learned reader, for such I must suppose him, cannot doubt but that the nature, intent, and proceedings of the δικαςηριοι among the Greeks were the same with the English jury; namely, for the protection of the lower people from the power and oppression of the great, by administering equal law and justice to all ranks; and therefore when the Greek orators directed their speeches to the ανδρες δικαςαι, as we see in Demosthenes, Æschines, and Lysias, we are to understand it in the same sense as when our lawyers at the bar say, *Gentlemen of the jury.*

So likewise among the Romans, the *judices*, in their pleadings at the bar, never signified judges of the bench, or presidents of the court, but a body or order of men, whose office in the courts of judicature was distinct from that of the prætor or *judex questionis*, which answered to our judge of the bench, and was the same with the archon, or ηγεμων δικαςηριε, of the Greeks: whereas the duty of the judices consisted in being impannelled, as we call it, challenged, and swore to try uprightly the case before them; and when they had agreed upon their opinion or verdict, to deliver it to the president who was to pronounce it. This kind of judicial process was first introduced into the Athenian polity by Solon, and thence copied into the Roman republic, as probable means of procuring just judgment, and protecting the lower people from the oppression or arbitrary decisions of their superiors.

When the Romans were settled in Britain as a province, they carried with them their *jura* and *instituta*, their laws and customs, which was a practice essential to all colonies; hence the Britons, and other countries of Germany and Gaul, learned from them the Roman laws and customs; and upon the irruption of the northern nations into the southern kingdoms of Europe, the laws and institutions of the Romans remained, when the power that introduced them was withdrawn: and Montesquieu tells us, that under the first race of kings in France, about the fifth century, the Romans that remained, and the Burgundians their new masters, lived together under the same Roman laws and police, and particularly the same forms of judicature. How reasonable then is it to conclude, that in the Roman courts of judicature continued among the Burgundians, the form of a jury remained in the same state it was used at Rome. It is certain, Montesquieu, speaking of those times, mentions the *paires* or *hommes de fief*, homagers or peers, which in the same chapter he calls *juges, judges* or *jurymen:* so that we hence see how at that times the *hommes de fief*, or "men of the fief," were called *peers*, and those peers were *juges* or jurymen. These were the same as are called in the laws of the Confessor *pers de la tenure*, the "peers of the tenure, or homagers," out of whom the jury of peers were chosen, to try a matter in dispute between the lord and his tenant, or any other point of controversy in the manor. So likewise in all other parts of Europe, where the Roman colonies had been, the Goths succeeding them, continued to make use of the same laws and institutions, which they found to be established there by the first conquerors. This is a much more natural way of accounting for the origin of a jury in Europe, than having recourse to the fabulous story of Woden and his savage Scythian companions, as the first introducers of so humane and beneficent an institution."

Trials by jury in civil causes are of two kinds; *extraordinary* and *ordinary.*

1. The first species of *extraordinary* trial by jury is that of the grand assize, which was instituted by King Henry II. in parliament, by way of alternative offered to the choice of the tenant or defendant in a writ of right, instead of the barbarous and unchristian custom of duelling. For this purpose a writ *de magna assisa eligenda* is directed to the sheriff, to return four knights, who are to elect and choose 12 others to be joined with them; and these all together form the grand assize, or great jury, which is to try the matter of right, and must now consist of 16 jurors. Another species of extraordinary juries is the jury to try an attaint; which is a process commenced against a former jury for bringing a false verdict. See the article ATTAINT.

Trial.

2. With regard to the *ordinary* trial by jury in civil cases, the most clear and perspicuous way of treating it will be by following the order and course of the proceedings themselves.

Blackst Comment.

When therefore an issue is joined by these words, "And this the said A prays may be inquired of by the country;" or, "And of this he puts himself upon the country, and the said B does the like;" the court awards a writ of *venire facias* upon the roll or record, commanding the sheriff "that he cause to come here, on such a day, twelve free and lawful men, *liberes et legales homines*, of the body of his country, by whom the truth of the matter may be better known, and who are neither of kin to the aforesaid A nor the aforesaid B, to recognise the truth of the issue between the said parties." And such writ is accordingly issued to the sheriff. It is made returnable on the last return of the same term wherein issue is joined, viz. hilary or trinity terms; which, from the making up of the issues therein, are usually called *issuable terms*. And he returns the names of the jurors in a panel (a little pane or oblong piece of parchment) annexed to the writ. This jury is not summoned, and therefore not appearing at the day must unavoidably make default. For which reason a compulsive process is now awarded against the jurors, called in the common pleas a writ of *habeas corpora juratorum*, and in the King's Bench *distringas*, commanding the sheriff to have their bodies, or to distrain them by their lands and goods, that they may appear upon the day appointed. The entry therefore on the roll of record is, "That the jury is respited, through defect of the jurors, till the first day of the next term, then to appear at Westminster; unless before that time, viz. on Wednesday the fourth of March, the justices of our lord the king appointed to take assizes in that county shall have come to Oxford, that is, to the place assigned for holding the assizes. Therefore the sheriff is commanded to have their bodies at Westminster on the said first day of next term, or before the said justice of assize, if before that time they come to Oxford, viz. on the fourth of March aforesaid." And as the judges are sure to come and open the circuit commissions on the day mentioned in the writ, the sheriff returns and summons this jury to appear at the assizes: and there the trial is had before the justices of assize and *nisi prius:* among whom (as hath been said*) are usually two of the judges of the courts at Westminster, the whole kingdom being divided into six circuits for this purpose. And thus we may observe, that the trial of common issues, at *nisi prius*, was in its original only a collateral incident to the original business of the justices of assize; though now, by the various revolutions of practice, it is become their principal civil employment; hardly any thing remaining in use of the real assizes but the name.

* See the article *Assize*.

If the sheriff be not an indifferent person, as if he be a party in the suit, or be related by either blood or affinity to either of the parties, he is not then trusted to return the jury; but the *venire* shall be directed to the coroners, who in this, as in many other instances, are the substitutes of the sheriff to execute process when he is deemed an improper person. If any exception lies to the coroners, the *venire* shall be directed to two clerks of the court, or two persons of the county named by the court, and sworn. And these two, who are called *elisors*, or electors, shall indifferently name the jury, and their return is final; no challenge being allowed to their array.

Let us now pause a while, and observe (with Sir Matthew Hale*), in these first preparatory stages of the trial, how admirably this constitution is adapted and framed for the investigation of truth beyond any other method of trial in the world. For, first, the person returning the jurors is a man of some fortune and consequence; that so he may be not only the less tempted to commit wilful errors, but likewise be responsible for the faults of either himself or his officers; and he is also bound by the obligation of an oath faithfully to execute his duty. Next, as to the time of their return: the panel is returned to the court upon the original *venire*, and the jurors are to be summoned and brought in many weeks afterwards to the trial, whereby the parties may have notice of the jurors, and of their sufficiency or insufficiency, characters, connections, and relations, that so they may be challenged upon just cause; while, at the same time, by means of the compulsory process (of *distringas*, or *habeas corpora*) the cause is not liketo be retarded through defect of jurors. Thirdly, As to the place of their appearance: which in causes of weight and consequence is at the bar of the court; but in ordinary cases at the assizes, held in the county where the cause of action arises, and the witnesses and jurors live: a provision most excellently calculated for the saving of expence to the parties. For though the preparation of the causes in point of pleading is transacted at Westminster, whereby the order and uniformity of proceeding is preserved throughout the kingdom, and multiplicity of forms is prevented; yet this is no great charge or trouble, one attorney being able to transact the business of 40 clients. But the troublesome and most expensive attendance is that of jurors and witnesses at the trial; which therefore is brought home to them, in the county where most of them inhabit. Fourthly, The persons before whom they are to appear, and before whom the trial is to be held, are the judges of the superior court, if it be a trial at bar; or the judges of assize, delegated from the courts at Westminster by the king, if the trial be held in the country: persons, whose learning and dignity secure their jurisdiction from contempt, and the novelty and very parade of whose appearance have no small influence upon the multitude. The very point of their being strangers in the county is of infinite service, in preventing those factions and parties which would intrude in every cause of moment, were it tried only before persons resident on the spot, as justices of the peace, and the like. And the better to remove all suspicion of partiality, it was wisely provided by the statutes 4 Edw. III. c. 2. 8 Ric. II. c. 2. and 33 Hen. VIII. c. 24. that no judge of assize should hold pleas in any county wherein he was born or inhabits. And as this institution prevents party and faction from intermingling in the trial of right, so it keeps both the rule and the administration of the laws uniform. These justices, though thus varied and shifted at every assizes, are all sworn to the same laws, have had the same education, have pursued the same studies, converse and consult together, communicate their decisions and resolutions, and preside in those courts which are mutually connected, and their judgments blended together, as they are interchangeably courts of appeal or advice to each other. And hence their administration of justice, and conduct

* *Hist. C. L.* c. 12.

Trial. conduct of trials, are consonant and uniform; whereby that confusion and contrariety are avoided, which would naturally arise from a variety of uncommunicating judges, or from any provincial establishment. But let us now return to the assizes.

When the general day of trial is fixed, the plaintiff or his attorney must bring down the record to the assizes, and enter it with the proper officer, in order to its being called on in course.

These steps being taken, and the cause called on in court, the record is then handed to the judge, to peruse and observe the pleadings, and what issues the parties are to maintain and prove, while the jury is called and sworn. To this end the sheriff returns his compulsive process, the writ of *habeas corpora* or *distringas*, with the panel of jurors annexed, to the judge's officer in court.

The jurors contained in the panel are either special or common jurors. Special juries were originally introduced in trials at bar, when the causes were of too great nicety for the discussion of ordinary freeholders; or where the sheriff was suspected of partiality, though not upon such apparent cause as to warrant an exception to him. He is in such cases, upon motion in court, and a rule granted thereupon, to attend the prothonotary or other proper officer with his freeholder's book; and the officer is to take indifferently 48 of the principal freeholders in the presence of the attorneys on both sides: who are each of them to strike off 12, and the remaining 24 are returned upon the panel. By the statute 3 Geo. II. c. 25. either party is entitled upon motion to have a special jury struck upon the trial of any issue, as well at the assizes as at bar, he paying the extraordinary expence, unless the judge will certify (in pursuance of the statute 24 Geo. II. c. 18.) that the cause required such special jury.

A common jury is one returned by the sheriff according to the directions of the statute 3 Geo. II. c 25. which appoints that the sheriff or officer shall not return a separate panel for every separate cause, as formerly; but one and the same panel for every cause to be tried at the same assizes, containing not less than 48, nor more than 72, jurors: and that their names being written on tickets, shall be put into a box of glass; and when each cause is called, 12 of these persons, whose names shall be first drawn out of the box, shall be sworn upon the jury, unless absent, challenged, or excused; or unless a previous view of the messuages, lands, or place in question, shall have been thought necessary by the court; in which case, six or more of the jurors returned, to be agreed on by the parties, or named by a judge or other proper officer of the court, shall be appointed by special writ of *habeas corpora* or *distringas*, to have the matters in question shown to them by two persons named in the writ; and then such of the jury as have had the view, or so many of them as appear, shall be sworn on the inquest previous to any other jurors. These acts are well calculated to restrain any suspicion of partiality in the sheriff, or any tampering with the jurors when returned.

As the jurors appear when called, they shall be sworn unless challenged by either party. See the article CHALLENGE.

If by means of challenges or other cause, a sufficient number of unexceptionable jurors doth not appear at the trial, either party may pray a *tales*.

5

A *tales* is a supply of such men as are summoned upon the first panel, in order to make up the deficiency. For this purpose a writ of *decem tales*, *octo tales*, and the like, was wont to be issued to the sheriff at common law, and must be still so done at a trial at bar, if the jurors make default. But at the assizes, or *nisi prius*, by virtue of the statute 35 Hen. VIII. c. 6. and other subsequent statutes, the judge is empowered at the prayer of either party to award a *tales de circumstantibus* of persons present in court, to be joined to the other jurors to try the cause; who are liable, however, to the same challenges as the principal jurors. This is usually done till the legal number of 12 be completed; in which patriarchal and apostolical number Sir Edward Coke hath discovered abundance of mystery.

When a sufficient number of persons impannelled, or talesmen appear, they are then separately sworn, well and truly to try the issue between the parties, and a true verdict to give according to the evidence; and hence they are denominated "the jury," *jurata*, and "jurors," *sc. juratores*.

The jury are now ready to hear the merits; and to fix their attention the closer to the facts which they are impannelled and sworn to try, the pleadings are opened to them by counsel on that side which holds the affirmative of the question in issue. For the issue is said to lie, and proof is always first required upon that side which affirms the matter in question: in which our law agrees with the civil, *ei incumbit probatio qui dicit, non qui negat; cum per rerum naturam factum negantis probatio nulla sit.* The opening counsel briefly informs them what has been transacted in the court above; the parties, the nature of the action, the declaration, the plea, replication, and other proceedings; and lastly, upon what point the issue is joined, which is there sent down to be determined. Instead of which, formerly the whole record and process of the pleadings were read to them in English by the court, and the matter of issue clearly explained to their capacities. The nature of the case, and the evidence intended to be produced, are next laid before them by counsel also on the same side; and when their evidence is gone through, the advocate on the other side opens the adverse case, and supports it by evidence; and then the party which began is heard by way of reply. See PLEADINGS.

Evidence in the trial by jury is of two kinds; either that which is given in proof, or that which the jury may receive by their own private knowledge. The former, or *proofs*, (to which in common speech the name of evidence is usually confined) are either written or parol; that is, by word of mouth. Written proofs, or evidence, are, 1. Records; and, 2. Ancient deeds of 30 years standing, which prove themselves: but, 3. Modern deeds; and, 4. Other writings, must be attested and verified by parol evidence of witnesses. With regard to parol evidence or witnesses; it must first be remembered that there is a process to bring them in by writ of *subpœna ad testificandum;* which commands them, laying aside all pretences and excuses, to appear at the trial on pain of 100l. to be forfeited to the king; to which the statute 5 Eliz. c. 9. has added a penalty of 10l. to the party aggrieved, and damages equivalent to the loss sustained by want of his evidence. But no witness, unless his reasonable expences be tendered him is bound to appear at all; nor, if he appear, is he bound to to give evidence till such charges are actually paid him; except he resides within the bills of mortality, and is summoned to give evidence within the same. This compulsory process, to bring in unwilling witnesses, and the additional terrors of an attachment in case of disobedience, are of excellent use in the thorough investigation of truth: and, upon the same principle, in the Athenian courts, the witnesses who were summoned to attend the trial had their choice of three things: either to swear to the truth of the fact in question, to deny or abjure it, or else to pay a fine of 1000 drachmas.

All witnesses, of whatever religion or country, that have the use of their reason, are to be received and examined, except such as are infamous, or such as are interested in the event of the cause. All others are competent witnesses; though the jury from other circumstances will judge of their credibility. Infamous persons are such as may be challenged as jurors, *propter delictum:* and therefore never shall be admitted to give evidence to inform that jury, with whom they were too scandalous to associate. Interested witnesses may be examined upon a *voir dire,* if suspected to be secretly concerned in the event; or their interest may be proved in court. Which last is the only method of supporting an objection to the former class; for no man is to be examined to prove his own infamy. And no counsel, attorney, or other person, intrusted with the secrets of the cause by the party himself, shall be compelled, or perhaps allowed, to give evidence of such conversation or matters of privacy as came to his knowledge by virtue of such trust and confidence: but he may be examined as to mere matters of fact, as the execution of a deed or the like, which might have come to his knowledge without being intrusted in the cause.

One witness (if credible) is sufficient evidence to a jury of any single fact: though undoubtedly the concurrence of two or more corroborates the proof. Yet our law considers that there are many transactions to which only one person is privy; and therefore does not always demand the testimony of two. Positive proof is always required, where, from the nature of the case, it appears it might possibly have been had. But, next to positive proof, circumstantial evidence, or the doctrine of presumptions, must take place: for when the fact itself cannot be demonstratively evinced, that which comes nearest to the proof of the fact is the proof of such circumstances which either necessarily or usually attend such facts; and these are called *presumptions,* which are only to be relied upon till the contrary be actually proved.

The oath administered to the witness is not only that what he deposes shall be true, but that he shall also depose the whole truth: so that he is not to conceal any part of what he knows, whether interrogated particularly to that point or not. And all this evidence is to be given in open court, in the presence of the parties, their attorneys, the counsel, and all bystanders: and before the judge and jury: each party having liberty to except to its competency, which exceptions are publicly stated, and by the judge are openly and publicly allowed or disallowed, in the face of the country: which must curb any secret bias or partiality that might arise in his own breast.

When the evidence is gone through on both sides, the judge, in the presence of the parties, the counsel, and all others, sums up the whole to the jury; omitting all superfluous circumstances, observing wherein the main question and principal issue lies, stating what evidence has been given to support it, with such remarks as he thinks necessary for their direction, and giving them his opinion in matters of law arising upon that evidence.

The jury, after the proofs are summed up, unless the case be very clear, withdraw from the bar to consider of their verdict; and in order to avoid intemperance, and causeless delay, are to be kept without meat, drink, fire, or candle, unless by permission of the judge, till they are unanimously agreed. A method of accelerating unanimity not wholly unknown in other constitutions of Europe, and in matters of greater concern. For by the golden bull of the empire, if, after the congress is opened, the electors delay the election of a king of the Romans for 30 days, they shall be fed only with bread and water till the same is accomplished. But if our juries eat or drink at all, or have any eatables about them, without consent of the court, and before verdict, it is finable; and if they do so at his charge for whom they afterwards find, it will set aside the verdict. Also, if they speak with either of the parties or their agents after they are gone from the bar, or if they receive any fresh evidence in private, or if, to prevent disputes, they cast lots for whom they shall find, any of these circumstances will entirely vitiate the verdict. And it has been held, that if the jurors do not agree in their verdict before the judges are about to leave the town, though they are not to be threatened or imprisoned, the judges are not bound to wait for them, but may carry them round the circuit from town to town in a cart. This necessity of a total unanimity seems to be peculiar to our own constitution; or at least, in the *nembda* or jury of the ancient Goths, there was required (even in criminal cases) only the consent of the major part; and in case of an equality, the defendant was held to be acquitted.

When they are all unanimously agreed, the jury return back to the bar; and before they deliver their verdict, the plaintiff is bound to appear in court, by himself, attorney, or counsel, in order to answer the amercement to which by the old law he is liable, in case he fails in his suit, as a punishment for his false claim. To be amerced, or *a mercie,* is to be at the king's mercy with regard to the fine to be imposed; in *misericordia domini regis pro falso clamore suo.* The amercement is disused, but the form still continues; and if the plaintiff does not appear, no verdict can be given; but the plaintiff is said to be nonsuit, *non sequitur clamorem suum.* Therefore it is usual for a plaintiff, when he or his counsel perceives that he has not given evidence sufficient to maintain his issue, to be voluntarily nonsuited, or withdraw himself: whereupon the crier is ordered to call the plaintiff; and if neither he, nor any body for him, appears, he is nonsuited, the jurors are discharged, the action is at an end, and the defendant shall recover his costs. The reason of this practice is, that a nonsuit is more eligible for the plaintiff than a verdict against him: for after a nonsuit, which is only a default, he may commence the same suit again for the same cause of action; but after a verdict had, and judgment consequent thereupon, he is for ever barred from attacking the

Trial.

the defendant upon the same ground of complaint. But in case the plaintiff appears, the jury by their foreman deliver in their verdict.

A verdict, *vere dictum*, is either privy or public. A privy verdict is when the judge hath left or adjourned the court: and the jury, being agreed, in order to be delivered from their confinement, obtain leave to give their verdict privily to the judge out of court: which privy verdict is of no force, unless afterwards affirmed by a public verdict given openly in court; wherein the jury may, if they please, vary from their privy verdict. So that the privy verdict is indeed a mere nullity; and yet it is a dangerous practice, allowing time for the parties to tamper with the jury, and therefore very seldom indulged. But the only effectual and legal verdict is the public verdict: in which they openly declare to have found the issue for the plaintiff, or for the defendant; and if for the plaintiff, they assess the damages also sustained by the plaintiff, in consequence of the injury upon which the action is brought.

When the jury have delivered in their verdict, and it is recorded in court, they are then discharged; and so ends the trial by jury: a trial which ever has been, and it is hoped ever will be, looked upon as the glory of the English law. It is certainly the most transcendant privilege which any subject can enjoy or wish for, that he cannot be affected either in his property, his liberty, or his person, but by the unanimous consent of 12 of his neighbours and equals. A constitution that we may venture to affirm has, under providence, secured the just liberties of this nation for a long succession of ages. And therefore a celebrated French writer *, who concludes, that because Rome, Sparta, and Carthage, have lost their liberties, therefore those of England in time must perish, should have recollected that Rome, Sparta, and Carthage, at the time when their liberties were lost, were strangers to the trial by jury.

* *Montesquieu, Spir. L.* xi. 6.

Great as this eulogium may seem, it is no more than this admirable constitution, when traced to its principles, will be found in sober reason to deserve.

The impartial administration of justice, which secures both our persons and our properties, is the great end of civil society. But if that be entirely entrusted to the magistracy, a select body of men, and those generally selected by the prince or such as enjoy the highest offices in the state, their decisions, in spite of their own natural integrity, will have frequently an involuntary bias towards those of their own rank and dignity: it is not to be expected from human nature, that the few should be always attentive to the interests and good of the many. On the other hand, if the power of judicature were placed at random in the hands of the multitude, their decisions would be wild and capricious, and a new rule of action would be every day established in our courts. It is wisely therefore ordered, that the principles and axioms of law, which are general propositions flowing from abstracted reason, and not accommodated to times or to men, should be deposited in the breasts of the judges, to be occasionally applied to such facts as come properly ascertained before them. For here partiality can have little scope; the law is well known, and is the same for all ranks and degrees: it follows as a regular conclusion from the premises of fact pre-established. But in settling and adjusting a question of fact, when intrusted to any single magistrate, partiality and injustice have an ample field to range in, either by boldly asserting that to be proved which is not so, or more artfully by suppressing some circumstances, stretching and warping others, and distinguishing away the remainder. Here therefore a competent number of sensible and upright jurymen, chosen by lot from among those of the middle rank, will be found the best investigators of truth, and the surest guardians of public justice. For the most powerful individual in the state will be cautious of committing any flagrant invasion of another's right, when he knows that the fact of his oppression must be examined and decided by 12 indifferent men not appointed till the hour of trial; and that when once the fact is ascertained, the law must of course redress it. This therefore preserves in the hands of the people that share which they ought to have in the administration of public justice, and prevents the encroachments of the more powerful and wealthy citizens.

Criminal TRIALS. The regular and ordinary method of proceeding in the courts of criminal jurisdiction may be distributed under 12 general heads, following each other in a progressive order: viz. 1. Arrest; 2. Commitment and bail; 3. Prosecution; 4. Process; 5. Arraignment, and its incidents; 6. Plea, and issue; 7. Trial, and conviction; 8. Clergy; 9. Judgment, and its consequences; 10. Reversal of judgment; 11. Reprieve, or pardon; 12. Execution. See ARREST, COMMITMENT, PRESENTMENT, INDICTMENT, INFORMATION, APPEAL, *PROCESS upon an Indictment*, ARRAIGNMENT, and PLEA; in which articles all the forms which precede the trial are described, and are here enumerated in the proper order.

The several methods of trial and conviction of offenders, established by the laws of England, were formerly more numerous than at present, through the superstition of our Saxon ancestors; who, like other northern nations, were extremely addicted to divination; a character which Tacitus observes of the ancient Germans. They therefore invented a considerable number of methods of purgation or trial, to preserve innocence from the danger of false witnesses, and in consequence of a notion that God would always interpose miraculously to vindicate the guiltless; as, 1. By ORDEAL; 2. By CORSNED; 3. By BATTEL. See these articles.

4. A fourth method is that by the *peers of Great Britain*, in the *Court of* PARLIAMENT; or the *Court of the Lord High* STEWARD, when a peer is capitally indicted; for in case of an appeal, a peer shall be tried by jury. This differs little from the trial *per patriam*, or by jury; except that the peers need not all agree in their verdict; and except also, that no special verdict can be given in the trial of a peer; because the lords of parliament, or the lord high steward (if the trial be had in his court), are judges sufficiently competent of the law that may arise from the fact; but the greater number, consisting of 12 at the least, will conclude, and bind the minority.

The trial by jury, or the country, *per patriam*, is also that trial by the peers of every Briton, which, as the great bulwark of his liberties, is secured to him by the great charter: *nullus liber homo capiatur, vel imprisonetur, aut exulet, aut aliquo alio modo destruatur, nisi per legale judicium parium suorum, vel per legem terræ.*

When therefore a prisoner on his ARRAIGNMENT has pleaded not guilty, and for his trial hath put himself upon

Trial.

upon the country, which country the jury are, the sheriff of the county must return a panel of jurors, *liberos et legales homines, de vicineto*; that is, freeholders without just exception, and of the *visne* or neighbourhood; which is interpreted to be of the county where the fact is committed. If the proceedings are before the court of king's bench, there is time allowed between the arraignment and the trial, for a jury to be impanelled by writ of *venire facias* to the sheriff, as in civil causes; and the trial in case of a misdemeanor is had at *nisi prius*, unless it be of such consequence as to merit a trial at bar; which is always invariably had when the prisoner is tried for any capital offence. But, before commissioners of oyer and terminer and gaol-delivery, the sheriff, by virtue of a general precept directed to him beforehand, returns to the court a panel of 48 jurors, to try all felons that may be called upon their trial at that session; and therefore it is there usual to try all felons immediately or soon after their arraignment. But it is not customary, nor agreeable to the general course of proceedings, unless by consent of parties, to try persons indicted of smaller misdemeanors at the same court in which they have pleaded not guilty, or traversed the indictment. But they usually give security to the court to appear at the next assizes or session, and then and there to try the traverse, giving notice to the prosecutor of the same.

In cases of high-treason, whereby corruption of blood may ensue (except treason in counterfeiting the king's coin or seals), or misprision of such treason, it is enacted by statute 7 W. III. c. 3. first, that no person shall be tried for any such treason, except an attempt to assassinate the king, unless the indictment be found within three years after the offence committed: next, that the prisoner shall have a copy of the indictment (which includes the caption), but not the names of the witnesses, five days at least before the trial, that is, upon the true construction of the act, before his arraignment; for then is his time to take any exceptions thereto, by way of plea or demurrer; thirdly, that he shall also have a copy of the panel of jurors two days before his trial: and, lastly, that he shall have the same compulsive process to bring in his witnesses for him, as was usual to compel their appearance against him. And by statute 7 Ann. c. 21. (which did not take place till after the decease of the late pretender) all persons indicted for high-treason, or misprisions thereof, shall have not only a copy of the indictment, but a list of all the witnesses to be produced, and of the jurors impanelled, with their professions and places of abode, delivered to him ten days before the trial, and in the presence of two witnesses, the better to prepare him to make his challenges and defence. And no person indicted for felony is, or (as the law stands) ever can be, entitled to such copies before the time of his trial.

When the trial is called on, the jurors are to be sworn as they appear, to the number of 12, unless they are challenged by the party.

Challenges may here be made, either on the part of the king, or on that of the prisoner; and either to the whole array, or to the separate polls, for the very same reasons that they may be made in civil causes. But in criminal causes, or at least in capital ones, there is, *in favorem vitæ*, allowed to the prisoner an arbitrary and capricious species of challenge, to a certain number of jurors, without showing any cause at all; which is called a *peremptory* challenge; a provision full of that tenderness and humanity to prisoners for which our English laws are justly famous. This is grounded on two reasons. 1. As every one must be sensible what sudden impressions and unaccountable prejudices we are apt to conceive upon the bare looks and gestures of another; and how necessary it is that a prisoner) when put to defend his life) should have a good opinion of his jury, the want of which might totally disconcert him; the law wills not that he should be tried by any one man against whom he has conceived a prejudice, even without being able to assign a reason for such his dislike. 2. Because, upon challenges for cause shown, if the reason assigned prove insufficient to set aside the juror, perhaps the bare questioning his indifference may sometimes provoke a resentment; to prevent all ill consequences from which, the prisoner is still at liberty, if he pleases, peremptorily to set him aside.

The peremptory challenges of the prisoner must, however, have some reasonable boundary; otherwise he might never be tried. This reasonable boundary is settled by the common law to be the number of 35; that is, one under the number of three full juries.

If by reason of challenges or the default of the jurors, a sufficient number cannot be had of the original panel, a tales may be awarded as in civil causes, till the number of 12 is sworn, "well and truly to try, and true deliverance make, between our sovereign lord the king and the prisoner whom they have in charge; and a true verdict to give, according to their evidence."

When the jury is sworn, if it be a cause of any consequence, the INDICTMENT is usually opened, and the evidence marshalled, examined, and enforced by the counsel for the crown or prosecution. But it is a settled rule at common law, that no counsel shall be allowed a prisoner upon his trial upon the general issue, in any capital crime, unless some point of law shall arise proper to be debated. A rule which (however it may be palliated under cover of that noble declaration of the law, when rightly understood, that the judge shall be counsel for the prisoner; that is, shall see that the proceedings against him are legal and strictly regular) seems to be not at all of a piece with the rest of the humane treatment of prisoners by the English law. For upon what face of reason can that assistance be denied to save the life of a man, which yet is allowed him in prosecutions for every petty trespass? Nor indeed is it, strictly speaking, a part of our ancient law; for the Mirrour, having observed the necessity of counsel in civil suits, "who know how to forward and defend the cause by the rules of law, and customs of the realm," immediately afterwards subjoins, "and more necessary are they for defence upon indictments and appeals of felony, than upon other venial causes." And, to say the truth, the judges themselves are so sensible of this defect in our modern practice, that they seldom scruple to allow a prisoner counsel to stand by him at the bar, and to instruct him what questions to ask, or even to ask questions for him, with regard to matters of fact; for as to matters of law arising on the trial, they are entitled to the assistance of counsel. But still this is a matter of too much importance to be left to the good pleasure of any judge, and is worthy the interposition of the legislature; which has shown its inclination to indulge prisoners with this reasonable assistance, by enacting, in statute 7 W. III. c. 3. that persons indicted for such high-treason as works a corruption of the blood or misprisonment thereof (except treason in counterfeiting the king's coins or seals), may make their full defence by counsel, not exceeding two, to be named by the prisoner, and assigned by the court or judge; and this indulgence, by statute 20 Geo. II. c. 30. is extended to parliamentary impeachments for high-treason, which were excepted in the former act.

When the evidence on both sides is closed, the jury cannot be discharged (unless in cases of evident necessity) till they have given in their VERDICT. If they find the prisoner not guilty, he is then for ever quit and discharged of the accusation, except he be appealed of felony within the time limited by law. And upon such his acquittal, or discharge for want of prosecution, he shall be immediately set at large without payment of any fee to the gaoler. But if the jury find him guilty, he is then said to be convicted of the crime whereof he stands indicted. See the article CONVICTION; and subsequent thereto, the article JUDGMENT, ATTAINDER, FORFEITURE, EXECUTION, also *Benefit of* CLERGY, REPRIEVE, PARDON.

TRIAL, in *Scotland*. See *Scots* LAW.

TRIANDRIA, (from τρεις, "three," and ανηρ, "a man or husband)," the name of the third class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, which have three stamina or male organs.

TRIANGLE, in *Geometry*, a figure of three sides and three angles.

TRIBE, in antiquity, a certain quantity or number of persons, when a division was made of a city or people into quarters or districts.

TRIBRACHYS, in *Ancient Poetry*, a foot consisting of three syllables, and these all short; as, *melius*.

TRIBUNAL, in general, denotes the seat of a judge, called in our courts *bench*.

TRIBUNE, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 259. The first design of their creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number at first was but two; but the next year, under the consulate of A. Posthumius Aruncius and Cassius Viscellinus, there were three more added; and this number of five was afterwards increased by L. Trebonius to ten.

Military TRIBUNE, an officer in the Roman army, commander in chief over a body of forces, particularly the division of a legion; much the same with our colonel, or the French maitre de camp.

TRIBUTARY, one who pays tribute to another in order to live in peace with or share in his protection.

TRIBUTE, a tax or impost which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

TRICEPS, in *Anatomy*. See there, *Tables of the Muscles*.

TRICHECUS, WALRUS; a genus of aquatic animals belonging to the class of *mammalia*, and order of *bruta*. See MAMMALIA *Index*.

TRICHOMANES, a genus of plants belonging to the class of *cryptogamia*, and order of *filices*. See BOTANY *Index*.

TRICOCCEÆ, (τρεις, "three," and κοκκος, "a grain"), the name of the 38th order in Linnæus's Fragments of a Natural Method, consisting of plants with a single three-cornered capsule, having three cells, or internal divisions, each containing a single seed. See BOTANY.

TRICOSANTHES, a genus of plants belonging to the class of *monœcia*, and in the natural system ranging under the 34th order, *Cucurbitaceæ*. See BOTANY *Index*.

TRIDENT, an attribute of Neptune, being a kind of sceptre which the painters and poets put into the hands of that god, in form of a spear or fork with three teeth; whence the word.

TRIENNIAL, an epithet applied chiefly to offices or employments which last for three years.

TRIENS, in antiquity, a copper money of the value of one third of an *as*, which on one side bore a Janus's head, and on the other a water rat.

TRIENTALIS, CHICKWEED WINTER-GREEN, a genus of plants belonging to the class of *heptandria*, and in the natural system ranging under the 20th order, *Rotaceæ*. See BOTANY *Index*

TRIERS, or TREVES. See TREVES.

TRIFOLIUM, TREFOIL, or *Clover*, a genus of plants belonging to the class of *diadelphia*, and in the natural system ranging under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

TRIGA, in antiquity, denotes a kind of car or chariot drawn by three horses; whence the name.

TRIGLA, a genus of fishes belonging to the order of thoracici. See ICHTHYOLOGY *Index*.

TRIGLOCHIN, a genus of plants belonging to the class of *hexandria*, and in the natural system ranging under the fifth order, *Tripetaloideæ*. See BOTANY *Index*.

TRIGLYPHS, in *Architecture*, a sort of ornament repeated at equal intervals, in the Doric freeze.

Dialing TRIGON. See DIALING.

TRIGONALIS. See PILA.

TRIGONELLA, FENUGREEK, a genus of plants belonging to the class of *diadelphia*, and in the natural system arranged under the 32 order, *Papilionaceæ*. See BOTANY *Index*.

TRIGONOMETRY.

Nature and Construction of Trigonometrical Tables.

TRIGONOMETRY is the application of arithmetic to geometry. It consists of two principal parts, viz. PLANE TRIGONOMETRY and SPHERICAL TRIGONOMETRY.

Plane trigonometry treats of the application of numbers to determine the relations of the sides and angles of a plane triangle to one another.

Spherical trigonometry treats of the application of numbers in like manner to spherical triangles; the nature of these will be explained in the course of this article.

Both branches of the subject depend essentially upon certain numerical tables, the nature and construction of which we shall now proceed to explain.

SECTION I.

NATURE AND CONSTRUCTION OF TRIGONOMETRICAL TABLES.

IT has been demonstrated in GEOMETRY (Theor. 31. Sect. IV). that any angles at the centre of a circle have to one another the same proportion as the arches intercepted between the lines which contain the angles. Hence it is easy to infer, that an angle at the centre of a circle has the same ratio to four right angles, that the arch intercepted between the lines which contain the angle has to the whole circumference. It also follows that we may employ arches of a circle as *measures* of angles, and thus the comparison of angles is reduced to the comparison of arches of a circle. From this principle we infer the consistency of the first of the following series of definitions.

DEFINITIONS.

I. If two straight lines intersect one another in the centre of a circle, the arch of the circumference intercepted between them is called the *Measure* of the angle which they contain. Thus, (Plate DXXXVII. fig. 1.) the arch AB is the measure of the angle contained by the lines CA and CH.

Plate DXXXVII. fig. 1.

II. If the circumference of a circle be divided into 360 equal parts, each of these is called a *Degree;* and if a degree be divided into 60 equal parts, each of these is called a *Minute;* and if a minute be divided into 60 equal parts, each of these is called a *Second*, and so on; and as many degrees, minutes, seconds, &c. as are in any arch, so many degrees, minutes, seconds, &c. are said to be in the angle measured by that arch.

COR. 1. Any arch is to the whole circumference of which it is a part, as the number of degrees and parts of a degree in it is to the number 360. And any angle is to four right angles as the number of degrees, &c. in the arch which is the measure of the angle to 360.

COR. 2. Hence also it appears that the arches which measure the same angle, whatever be the radii with which they are described, contain the same number of degrees and parts of a degree.

Nature and Construction of Trigonometrical Tables.

The degrees, minutes, seconds, &c. contained in an arch or angle are commonly written thus, $23^\circ\ 29'\ 32''\ 20'''$, which expression means 23 degrees 29 minutes 32 seconds, and 20 thirds.

III. Two angles which make together two right angles, also two arches which make together a semicircle, are called the *Supplements* of one another.

IV. A straight line BG drawn through B, one of the extremities of the arch AB, perpendicular to the diameter passing through the other extremity A, is called the *Sine* of the arch AC, or of the angle ACB, having the arch AB for its measure.

COR. 1. The sine of a quadrant or of a right angle is equal to the radius.

COR. 2. The sine of an arch is half the chord of twice the arch.

V. The segment AG of the diameter intercepted between its extremity and the sine BG is called the *Versed Sine* of the arch AB, or of the angle ACB.

VI. A straight line AH touching the circle at A one extremity of the arch AB, and meeting the diameter CB which passes through B the other extremity, is called the *Tangent* of the arch AB, or of the angle ACB.

COR. The tangent of half a right angle is equal to the radius.

VII. The straight line CH between the centre and the extremity of the tangent AH is called the *Secant* of the arch AB or of the angle ACB.

COR. to Def. 4, 6, 7. The sine, tangent, and secant of any angle ACB, are also the sine, tangent, and secant of its supplement BCE. For by the definition, BG is the sine of the angle BCE; and if BC be produced to meet the circle in I, then AH is the tangent and CH the secant of the angle ACI or BCE.

COR. to Def. 4, 5, 6, 7. The sine, versed sine, tangent, and secant of an arch which is the measure of the angle ACB is to the sine, versed sine, and secant of any other arch which is the measure of the same angle, as the radius of the first arch is to the radius of the second.

Let BG, fig. 2. be the sine, AG the versed sine, AH the tangent, and CH the secant of the arch AB to the radius CA; and bg, ag, ah, ch the same things to the radius Ca. From similar triangles BG : bg :: BC : bC; and because CG : Cg (:: CB : Cb) :: CA : Ca; therefore, by division AG : ag :: CA : Ca. Also AH : ah :: CH : Ch :: CA : Ca.

Hence it appears that if tables be constructed exhibiting in numbers the sines, tangents, and versed sines of certain angles to a given radius, they will exhibit the ratios of the sines, tangents, and versed sines of the same angles to any radius whatever. In such tables, which are called trigonometrical tables, the radius is either supposed 1, or some number in the series 10, 100, 1000, &c.

Nature and Construction of Trigonometrical Tables.

&c. The construction and use of these tables we shall presently explain.

VIII. The difference between any angle and a right angle, or between any arch and a quadrant, is called the *Complement* of that angle, or of that arch. Thus, if the angle ACD, fig. 1. be a right angle, and consequently the arch AD, which is its measure, a quadrant, the angle BCD is the complement of the angle BCA, and the arch BD is the complement of the arch AB. Also the complement of the obtuse angle BCE is BCD, its excess above a right angle; and the complement of the arch BDE is the arch BD.

Fig. 1.

IX. The sine, tangent, or secant of the complement of any angle is called the cosine, cotangent, or cosecant of that angle. Thus, supposing the angle ACD to be a right angle, then BF=CG, the sine of the angle BCD, is the cosine of the angle BCA; DK, the tangent of the angle BCD, is the cotangent of the angle BCA, and CK, the secant of the angle BCD, is the cosecant of the angle BCA.

The following properties of the lines which have been defined flow immediately from their position.

1. The sum of the squares of the sine and cosine of any angle is equal to the square of the radius. For, in the right-angled triangle BGC, $BC^2=BG^2+GC^2$, (GEOMETRY, Sect. IV. theor. 13.). Now BG is the sine, and CG=BF is the cosine of the angle BCA.

2. The radius is a mean proportional between the tangent of any angle and its cotangent, or $\tan. ACB \times \cot. ACB = \text{rad.}^2$. For since DK, CA are parallel, the angles DKC, HCA are equal; now CDK, CAH are right angles, therefore the triangles CDK, HCA are similar, and therefore AH : AC :: CD or AC : DK, and $AC^2=AH\times DK$.

3. The radius is a mean proportional between the cosine and secant of any angle. Or $\cos. ACB \times \sec. ACB = \text{rad.}^2$. For the triangles CGB, CAH are similar; therefore CG : CB or CA :: CA : CH.

4. The tangent of an arch is a fourth proportional to its cosine, its sign and the radius, or $\tan. ACB = \frac{\sin. ACB}{\cos. ACB}\times \text{rad.}$ For, from similar triangles CG : GB :: CA : AH.

Trigonometrical tables usually exhibit the sines, tangents, and secants of all angles which can be expressed by an exact number of degrees and minutes from 1 minute to 90 degrees, or a right angle. These may be computed in various ways, the most elementary is to caculate them by the help of principles deducible immediately from the elements of geometry.

It has been demonstrated in GEOMETRY, (Sect. V. prob. 22.) that the chord of one-sixth of the circumference, or an arch of 60°, is equal to the radius; therefore, if BD be an arch of 30°, its sine BF will be half the radius (cor. 2. def. 4.). Let us suppose the radius to be expressed by unity, or 1, then $\sin. 30° = \frac{1}{2}$; now since a being put for any arch, $\cos.^2 a + \sin.^2 a = \text{rad.}^2$ (where by $\cos.^2 a$ is meant the square of the number expressing the cosine of the arch a, &c.) and as $\sin.^2 30° = \frac{1}{4}$, therefore $\cos.^2 30° = 1 - \frac{1}{4} = \frac{3}{4}$, &c. $\cos. 30° = \frac{1}{2}\sqrt{3} = .8660254038$.

It has been demonstrated in the arithmetic of sines (ALGEBRA, § 356.) that $2\cos.^2 a = 1 + \cos. 2a$; hence we have the following formula for finding the cosine of an arch, having given the cosine of its double; $\cos. a = \sqrt{\frac{1+\cos. 2a}{2}}$. By this formula from the cosine of 30° we may find that of 15°, and again from cos. 15° we may find cos. 7° 30′, and proceeding in this way we may find the cosines of 3° 45′, 1° 52′ 30″, and so on, till after 11 bisections the cosine of 52″ 44‴ 3^{iv} 45^{v} is found; we may then find the sine of this arch by the formula $\sin. a = \sqrt{(1 - \cos.^2 a)}$. Now, as from the nature of a circle the ratio of an arch to its sine approaches continually to that of equality, when the arch is continually diminished, it follows that the sines of very small arches will be very nearly to one another as the arches themselves: Therefore, as 52″ 44‴ 3^{iv} 45^{v} to 1′ so is the sine of the former arch to the sine of the latter. By performing all the calculations which we have here indicated, it will be found that the sine of 1′ is .0002908882.

It has been shewn in the arithmetic of sines (ALGEBRA, § 355.) that a and b being put for any two arches, $\sin. (a+b) = 2\cos. b \sin. a - \sin. (a-b)$, hence putting 1′ for b, and 1′, 2′, 3′, &c. successively for a, we have,

$$\sin. 2' = 2\cos. 1' \times \sin. 1',$$
$$\sin. 3' = 2\cos. 1' \times \sin. 2' - \sin. 1',$$
$$\sin. 4' = 2\cos. 1' \times \sin. 3' - \sin. 2',$$
&c.

In this way the sines for every minute of the quadrant may be computed, and as the multiplier cos. 1′ remains always the same, the calculation is easy. If instead of 1′, the common difference of the series of arches were any other angle, the very same formula would apply.

The sines, and consequently the cosines of any number of arches being supposed found, their tangents may be found by considering that $\tan. a = \frac{\sin. a}{\cos. a}$; and their secants from the formula $\sec. a = \frac{1}{\cos. a}$.

We have here very briefly indicated the manner of constructing the trigonometrical *canon*, as it is sometimes called. There are, however, various properties of sines, tangents, &c. which greatly facilitate the actual calculation of the numbers: these the reader will find detailed in ALGEBRA, Sect. XXV. which treats expressly of the *Arithmetic of Sines*.

The most expeditious mode of computing the sine or cosine of a single angle is by means of infinite series: The investigation of these is given in FLUXIONS, § 70.; and it is there shewn that if a denote any arch, then, the radius being expressed by 1,

$$\sin. a = a - \frac{a^3}{1\cdot 2\cdot 3} + \frac{a^5}{1\cdot 2\cdot 3\cdot 4\cdot 5} - \text{\&c.}$$
$$\cos. a = 1 - \frac{a^2}{1\cdot 2} + \frac{a^4}{1\cdot 2\cdot 3\cdot 4} - \text{\&c.}$$

To apply these we must have the arch expressed in parts of the radius, which requires that we know the proportion of the diameter of the circle to its circumference, We have investigated this proportion in GEOMETRY. Prop. 6. Sect. vi.; also in FLUXIONS, § 137.; and subsequently in the article entitled SQUARING THE CIRCLE.

From these series others may be found which shall express the tangent and secant. Thus because tan. $a=$

Nature and Construction of Trigonometrical Tables.

$a = \frac{\sin. a}{\cos. a}$, we get, after dividing the series for the sine by that for the consine,

$$\tan. a = a + \frac{a^3}{3} + \frac{2a^5}{15} + \frac{17a^7}{315} + \&c.$$

And in like manner, dividing unity by the series for $\cos. a$, because $\sec. a = \frac{1}{\cos. a}$, we get

$$\sec. a = 1 + \frac{a^2}{2} + \frac{5a^4}{24} + \frac{61a^6}{720} + \&c.$$

We shall conclude what we proposed to say on the construction of the tables, by referring such of our readers as wish for more extensive information on this subject to Dr Hutton's Introduction to his excellent Mathematical Tables; also to the treatises which treat expressly of trigonometry, among which are those of *Emerson*, *Simpson*, *Bonnycastle*, *Cagnoli*, *Mauduit*, *Lacroix*, *Legendre*. In particular we refer to an excellent treatise on the subject by *Mr R. Woodhouse* of Caius college, Cambridge.

Description of the Table of Logarithmic Sines, &c.

That trigonometrical tables may be extensively useful, they ought to contain not only the sine, tangent, and secant to every minute of the quadrant, but also the logarithms of these numbers; and these are given in Dr Hutton's Mathematical Tables, a work which we have already mentioned; as, however, the sines, &c. or the *natural* sines, &c. as they are called, are much less frequently wanted than their logarithms, we have only given a table of the latter. See LOGARITHMS.

This table contains the logarithms of the sines and tangents, or the *logarithmic sines* and *tangents*, to every minute of the quadrant, the degrees at top and minutes descending down the left-hand side, as far as 45°, and from thence returning with the degrees at the bottom and the minutes ascending by the right-hand side to 90°, in such a manner that any arch on the one side is in the same line with its complement on the other, the respective sines, cosines, tangents, and cotangents, being in the same line with the minutes, and on the columns figured with their respective names at top when the degrees are at top, but at the bottom when the degrees are at the bottom. The differences of the sines and cosines are placed in columns to the right-hand, marked D; and the differences of the tangents and cotangents are placed in a column between them, each difference belonging equally to the columns on both sides of it. Also each differential number is set opposite the space between the numbers whose difference it is. All this will be evident by inspecting the table itself.

There are no logarithmic secants in the table, but these are easily had from the cosines; for since $\sec. a = \frac{\text{rad.}^2}{\cos. a}$, therefore, log. sec. $a = 2$ log. rad.—log. cos. a; now log. rad. $= 10$, therefore the log. secant of any arch is had by subtracting its log. cosine from 20.

The log. sine, log. tangent, or log. secant of any angle is expressed by the same numbers as the log. sine, log. tangent, or log. secant of its supplement; therefore, when an angle exceeds 90°, subtract it from 180° and take the log. sine, &c. of the remainder for that of the angle.

To find the log. sine of any angle expressed by degrees and minutes. If the angle be less than 45°, look for the number of degrees at the top, and opposite to the minutes on the left hand will be found the sine required; thus the log. sine of 8° 10′ is 9.15245. But if the angle be 45° or more than 45°, look for the degrees at the bottom and the minutes on the right hand, and opposite will be found the log. sine required. Thus the log. sine of 58° 12′ is 9.92936. The very same directions apply for the cosine, tangent, and cotangent; and from what has been said, the manner of finding the angle to degrees and minutes, having given its sine, &c. must be obvious.

If the angle consists of degrees, minutes, and seconds, find the sine or tangents to the degrees and minutes, and add to this a proportional part of the difference given in the column of differences for the seconds, observing that the whole difference corresponds to 1′ or 60″. Thus to find the log. sine of 30° 23′ 28″; first the sine of 30° 23′ is 9.70396. The difference is 21. As 60″ : 28″ :: 21 : $\frac{28 \times 21}{60} = 10$ nearly, the part of the difference to be added, therefore the sine of 30° 23′ 28″ is 9.70406.

On the contrary, let it be required to find the angle corresponding to the tangent 10.14152.

The next less tangent in the table is 10.14140, which corresponds to 54° 10′; the difference between the proposed tangent and next less is 12; and the difference between the next less and next greater, as given in the table, is 26; therefore, 26 : 12 :: 60″ : $\frac{12 \times 60}{26}$: 28″ nearly, hence the angle corresponding to the proposed log. tangent is 34° 10′ 28″.

SECTION II.

PLANE TRIGONOMETRY.

THE following propositions express as many of the properties of plane triangles as are essentially necessary in plane trigonometry.

THEOR. I.

In a right-angled plane triangle, as the hypothenuse is to either of the sides, so is the radius to the sine of the angle opposite to that side; and as either of the sides to the other side, so is the radius to the tangent of the angle opposite to that side.

Let ABC be a right-angled plane triangle (fig. 3.), of which AC is the hypothenuse. On A as a centre with any radius, describe the arch DE; draw EG at right angles to AB, and draw DF touching the circle at D, and meeting AC in F. Then EG is the sine of the angle A to the radius AD or AE, and DF is its tangent. Fig. 3.

The triangles AGE, ADF are manifestly similar to the triangle ABC. Therefore AC : CB :: AE : EG; that is, AC : CB :: rad. : sin. A.

Again

Again, AB : BC :: AD : DF; that is AB : BC :: rad. : tan. A.

Cor. In a right-angled triangle, as the hypothenuse to either of the sides, so is the secant of the acute angle adjacent to that side to the radius. For AF is the secant of the angle A to the radius AD; and AC : AB :: AF : AD, that is, AC : AB :: sec. A : rad.

Note. This proposition is most easily remembered when stated thus. *If in a right-angled triangle the hypothenuse be made the radius, the sides become the sines of the opposite angles; and if one of the sides be made the radius, the other side becomes the tangent of the opposite angle, and the hypothenuse its secant.*

Theor. II.

The sides of a plane triangle are to one another as the sines of the opposite angles.

Fig. 4. From B any angle of the triangle ABC (fig. 4.) draw BD perpendicular to AC. Then, by last theorem,

AB : BD :: rad. : sin. A,
also BD : BC :: sin. C : rad.

therefore *ex æquo* inversely (Geometry, Sect. III. Theor. 7.), AB : BC :: sin. C : sin. A.

Theor. III.

The sum of any two sides of a triangle is to their difference as the tangent of half the sum of the angle opposite to these sides to the tangent of half their difference.

Fig. 5. Let ABC, fig. 5. be a triangle; AB + BC : AB — BC :: tan. $\frac{1}{2}$ ($\angle$BCA + $\angle$BAC) : tan. $\frac{1}{2}$ ($\angle$BCA — $\angle$BAC).

In AB produced take BE = BC, and on B as a centre with BC or BE as a radius, describe the semicircle ECF meeting AC in D; join BD, CF, and CE, and from F draw FG parallel to AC, meeting CE in G.

Because the angles CFE, CBE, stand on the same arch CE, and the former is at the circumference of the circle, and the latter at the centre; therefore, the angle CFE is half the angle CBE (Geometry, Sect. II. Theor. XIV.); but the angle CBE is the sum of the angles BAC, BCA (Geometry, Sect. I. Theor. XXIII.); therefore the angle CFE is half the sum of the angles BCA, BAC.

Because the angle BDC is the sum of the angles BAC, ABD, therefore the angle ABD is the difference between the angles BDC, BAD; but since BD = BC, the angle BDC is equal to BCD or BCA, therefore ABD is the difference of the angles BCA, BAC; but ABD, or FBD, being an angle at the centre of the circle, is double the angle FCD at the circumference, which last is equal to the alternate angle CFG; therefore the angle CFG is half the difference of the angles BCA, BAC.

Because CE is manifestly the tangent of the angle CFE to the radius CF, and CG the tangent of the angle CFG to the same radius; therefore CE : CG :: tan. CFE : tan. CFG, that is, CE : CG :: tan. $\frac{1}{2}$ (BCA + BAC) : tan. $\frac{1}{2}$ (BCA — BAC); but because FG is parallel to AC, CE : CG :: AE : AF, that is, CE : CG :: AB + BC : AB — BC, therefore AB + BC : AB — BC : tan. $\frac{1}{2}$ (BCA + BAC) tan. $\frac{1}{2}$ (BCA — BAC).

Theor. IV.

If a perpendicular be drawn from any angle of a triangle to the opposite side or base; the sum of the segments of the base is to the sum of the other two sides of the difference of these sides to the difference of the segments of the base.

Let ABC be a triangle (fig. 6.), and BD a perpendicular drawn to the base from the opposite angle; AD + DC : AB + BC :: AB — BC : AD — DB. Fig. 6

On, B as a centre with the radius BC, describe a circle meeting AC in E, and AB in G, and the same line produced in F. Then AC : AF :: AG : AE; now AF = AB + BC, and AG = AB — BC, and because ED = DC, AE (or AD — DE) = AD — DC, therefore AC : AB + BC :: AB — BC : AD — DC.

Problem.

Having given the sum of any two quantities and also their difference, to find each of the quantities.

Solution. To half the sum add half the difference of the quantities, and it will give the greater; and from half the sum subtract half the difference, and it will give the less.

For let the greater of the two quantities be expressed by the line AB, and the less by BC; bisect AC in D, and take DE equal to DB, then AE = BC, and AB — BC = AB — AE = EB, and $\frac{1}{2}$ (AB — BC) = DB; also $\frac{1}{2}$ (AB + BC) = AD; now AB = AD + DB and BC = AD — DB, therefore the truth of the solution is evident.

In a plane triangle there are five distinct parts, which are so connected with one another, that any three of them being given, the remaining two may be found; these are, the three sides and any two of the three angles; as to the remaining angle, that depends entirely upon the other two, and may be found from them independent of the sides.

If one of the angles be a right angle, then the number of parts is reduced to four, and of these, any two being given, the remaining two may be found.

Solution of the Cases of Right-angled Plane Triangles.

In right-angled triangles there are four cases which may be resolved by the first theorem.

Case 1. The hypothenuse AC (fig. 7.) and an angle A being given, to find the sides AB, BC about the right angle. Fig. 7.

Solution. $\begin{cases} \text{Rad. : sin. A :: AC : BC,} \\ \text{Rad. : cos. A :: AC : AB.} \end{cases}$

Example. In the triangle ABC, let the hypothenuse AC be 144, and the angle A 39° 22′. Required the sides AB and BC.

To find AB.	Logarithms.	To find BC.	Log.
Rad. - -	10.00000	Rad. -	10.00000
Sin. A 39° 22′	9.80228	Cos. A 39° 22′	9.88824
AC 144 -	2.15836	AC 144	2.15836
BC = 91.3	1.96064	AB = 111.3	2.04660

Here

Here the logarithms of the second and third terms are added, and the logarithm of the first term subtracted or rejected from the sum.

CASE 2. A side AB, and an acute angle A (and consequently the other angle C) being given, to find the hypothenuse AC, and remaining side BC.

SOLUTION. $\begin{cases} \text{Cos. A : rad.} \quad :: \text{AB : AC,} \\ \text{Rad.} \quad \text{: tan. A :: AB : BC.} \end{cases}$

Example. In the triangle ABC are given AB 208, and the angle A 35° 16′, to find AC and BC.

To find AC.		To find BC.	
Cos. A 35° 16′	9.91194	Rad. - - -	10.00000
Rad. - - -	10.00000	Tan. A 35° 16′	9.84952
AB 208 -	2.31806	AB 208 -	2.31806
	12.31806	BC=147.1	2.16758
AC=254.7	2.40612		

CASE 3. The hypothenuse AC and a side AB being given, to find the angle A (and consequently C) and the side BC.

SOLUTION. $\begin{cases} \text{AC : AB} \quad \text{:: rad. : cos. A,} \\ \text{Rad. : sin. A :: AC : BC.} \end{cases}$

Example. Let the hypothenuse AC be 272, and the side AB 232. Required the angle A and the side BC.

To find A.		To find BC.	
AC 272 -	2.43457	Rad. - -	10.00000
AB 232 -	2.36549	Sin. A 31° 28′	9.71767
Rad. - -	10.00000	AC 272 - -	2.43457
	12.36549	BC 142 - -	2.15224
Cos. A=31° 28′	9.93092		

CASE 4. The sides AB and BC about the right angle being given, to find the angle A (and thence C) and the hypothenuse AC.

SOLUTION. $\begin{cases} \text{AB : BC : rad. : tan. A,} \\ \text{Cos. A : rad. : AB : AC.} \end{cases}$

Example. Let the side AB be 186, the side BC 152. Required the angle A, and the hypothenuse AC.

To find A.		To find AC.	
AB 186 -	2.26951	Cos. A 39° 15′	9.88896
BC 152 -	2.18184	Rad. - -	10.00000
Rad. - -	10.00000	AB 186 -	2.26951
	12.18184		12.26951
Tan. A=39° 15′	9.91233	AC=240.2	2.38055

Solution of the Cases of Oblique-angled Triangles.

In oblique-angled triangles there are also four cases, which, with their solutions, are as follows.

Fig. 8. CASE 1. Two angles A and B, and a side AB, being given, to find the other sides AC, BC.

SOLUTION. [illegible] B from 180°, and [illegible] AC and BC [illegible]

Sin. C [illegible]

Sin. C [illegible]

The truth of this [illegible]

Example. In the triangle [illegible] AB=266, the angle A [illegible] to find the sides AC and BC.

First, A+B=11[illegible], and [illegible] 4′=C.

Sin. C 69° 4′	9.97035	Sin. C [illegible]	[illegible]
Sin. B 72° 16′	9.97886	Sin. A [illegible]	[illegible]
AB 266 -	2.42488	AB 266 -	[illegible]
	12.40374		[illegible]
AC=271.3	2.43339	BC=177.9	[illegible]

CASE. 2. Two sides AC, CB (fig. 9.) and the angle A opposite to one of them, being given; to find the other angles B, C, and also the other side AB.

SOLUTION. The angle B is found by this proportion.

CB : AC :: sin. A : sin. B.

When CB is less than CA, the angle B admits of two values, one of which is the supplement of the other; because, corresponding to the same value of the side AC, and the angle A, the side BC may evidently have two distinct positions, viz. CB, C*b*. The angle CBA and its supplement C*b*A being found, the angle ACB, also the angle AC*b* may be found, by subtracting the sum of the two known angles from 180°, and then AB and A*b* may be found by these proportions.

Sin. A : Sin. ACB :: CB : AB,
Sin. A : Sin. AC*b* :: CB or C*b* : A*b*.

This is called the *ambiguous* case, on account of the angle B and the side AB having sometimes two values.

This solution, like the last, is deduced from Theorem II.

Example. Suppose AC 225, BC 180, and the angle A 42° 20′; to find the remaining parts.

CB 180 - -	2.25527
AC 225 - -	2.35218
Sin. A 42° 20′ -	9.82830
	12.18048
Sin. ABC=57° 20′ Or sin. A*b*C=122.40	9.92521

In the triangle ACB we have now the side AC and the angles CAB, CBA, therefore the remaining angle ACB and side AB may be found by Case 1.; and the same is true of the triangle AC*b*.

CASE

Plane Trigonometry.

CASE 3. Two sides CA, CB and the included angle C being given, to find the remaining angles B, A, and side AB.

SOLUTION. Find AC+CB, the sum of the sides, and AC—CB their difference; also find the sum of the angles A and B (that sum is the supplement of C), and half that sum; then half the difference of the angles will be got from this proportion. (See Theor. III.).

$AC+CB : AC-CB :: \tan.\frac{1}{2}(B+A) : \tan.\frac{1}{2}(B-A)$.

Having now the sum and difference of the angles B and A, the angles will be found by the rule given in the problem following Theor. IV.

The remaining side may be found by either of these proportions.

Sin. B : sin. C :: AC : AB; or sin. A : sin. C :: BC : AB.

Example. Let AC be 128, CB 90, and the angle C 48° 2′. Required the remaining parts of the triangle.

AC+CB 218	-	2.33846
AC—CB 38	-	1.57978
tan. $\frac{1}{2}$ (B+A) 65° 54′	-	10.34938
		11.92916
tan. $\frac{1}{2}$ (B—A) 21° 17′	-	9.59070

Hence by the given rule in the above-mentioned problem, B=87° 11′, A=43° 37′. As we now know all the angles and two sides, the remaining side may be found by Case 1.

Fig. 10. CASE 4. The three sides AB, BC and AC (fig. 10.) being given, to find the three angles A, B, C.

SOLUTION. Let fall a perpendicular CD upon the greatest of the three sides from the opposite angle. Then find the difference between AD and DB by this proportion.

$AB : AC+CB :: AC-CB : AD-DB$.

The segments AD, DB may now be found severally by the rule given for finding each of the quantities whose sum and difference is given, and then the angles A and B may be found by the following proportions.

CA : AD :: rad. : cos. A,
CB : BD :: rad. : cos. B.

The angles A, B being found, C of course is known. The first part of this solution follows from Theor. IV. the latter part from Theor. I.

Example. Let AB be 125, AC 105, and BC 95. Required the angles.

In this case AC+BC=200, AC—BC=10, therefore we have

$$125 : 200 :: 10 : AD-DB=\frac{200\times 10}{125}=16.$$

Now AD+DB=125, therefore AD=70.5 DB=54.5.

To find A.			To find B.		
AC 105	-	2.02119	BC 95	-	1.97772
AD 70.5	-	1.84819	BD 54.5	-	1.73640
Rad.	-	10.00000	Rad.	-	10.00000
		11.84819			11.73640
Cos. A 47° 49′		9.82700	Cos. B 55°	-	9.75868

Spherical Trigonometry.

For the application of plane trigonometry, see MENSURATION, Sect. I.

SECTION III.

SPHERICAL TRIGONOMETRY.

THEOR. I.

If a sphere be cut by a plane through the centre, the section is a circle.

THE truth of this proposition is evident from the definition of a sphere. See GEOMETRY, Sect. IX. Def. 3.

DEFINITIONS.

I. Any circle which is a section of a sphere by a plane passing through its centre, is called a *great circle* of the sphere.

COR. All great circles of a sphere are equal, and the centre of the sphere is their common centre, and any two of them bisect one another.

II. The *pole* of a great circle of the sphere is a point in the superficies of the sphere from which all straight lines drawn to the circumference of the circle are equal.

III. A *spherical angle* is that which on the superficies of a sphere is contained by two arches of great circles, and is the same with the inclination of the planes of these great circles.

IV. A *spherical triangle* is a figure upon the superficies of a sphere comprehended by three arches of three great circles, each of which is less than a semicircle.

THEOR. II.

The arch of a great circle between the pole and the circumference of another circle is a quadrant.

Let ABC be a great circle (fig. 11.), and D its pole; let the great circle ADC pass through D, and let AEC be the common section of the planes of the two circles, which will pass through E the centre of the circle, join DA, DC. Because the chord DA is equal to the chord DC, (Def. 2.) the arch DA is equal to the arch DC; now ADC is a semicircle, therefore the arches AD and DC are quadrants. Fig. 11.

COR. 1. If DE be drawn, the angle AED is a right angle, and DE being therefore at right angles to every line it meets with in the plane of the circle ABC, is at right angles to that plane. Therefore the straight line drawn from the pole of any great circle to the centre of the sphere is at right angles to the plane of that circle.

COR. 2. The circle has two poles D, D′, one on each

each side of its plane, which are the extremities of a diameter of the sphere perpendicular to the plane ABC.

Theor. III.

A spherical angle is measured by the arch of a great circle intercepted between the great circles containing the angle, and having the angular point for its pole.

Fig. 12. Let AB, AC be two arches of great circles containing the spherical angle BAC; let BC be an arch of a great circle intercepted between them, and having A for its pole, and let BD, CD, AD be drawn to D the centre of the sphere. The arches AB, AC are quadrants, (Theor. II.), and therefore the angles ADB, ADC right angles; therefore (Geometry, Sect. VII. Def. 4.) the angle BDC (which is measured by the arch BC) is the inclination of the planes of the circles BDA, CDA, and is equal to the spherical angle BAC (Def. 3.).

Cor. If AB, AC two arches of great circles meet in A, then A shall be the pole of a great circle passing through B and C.

Theor. IV.

Two great circles whose planes are perpendicular pass through each others poles.

Fig. 13. Let ACBD, AEBF be two great circles, the planes of which are at right angles to one another; from G the centre of a sphere, draw GC in the plane ABCD perpendicular to AB, then GC is also perpendicular to the plane AEBF, (Geometry, Sect. VII. Theor. 12.); therefore C is the pole of the circle AEBF, and if CG be produced to D, D is the other pole of the circle AEBF.

In the same manner, by drawing GE in the plane AEBF perpendicular to AB, and producing it to F, it is shewn that E and F are the poles of the circle ABCD.

Cor. 1. If two great circles pass through each others poles, their planes are perpendicular to one another.

Cor. 2. If of two great circles the first passes through the poles of the second, the second also passes through the poles of the first.

Theor. V.

If the angular points of any spherical triangle be made the poles of three great circles, another triangle will be formed by their intersections, such, that the sides of the one triangle will be respectively the supplements of the measures of the angles opposite to them in the other.

Fig. 14. Let the angular points of the triangle ABC be the poles of three great circles; which by their intersections form the three lunary surfaces DQ, FR, and EO; A being the pole of EF, B the pole of DF, and C the pole of ED. Then the triangle DEF, which is common to three lunary surfaces, will be in every respect supplemental to the triangle ABC.

For let each side of ABC be produced to meet the sides that contain the angle opposite to it, in the triangle DEF; then, because BC passes through the poles of ED, DF, ED, DF must also pass through the poles of BC. (Theor. II. Cor. 2.). Therefore the points D, Q are the poles of BC. In like manner R, F are the poles of AB, and E, O the poles of AC. Hence EL, FK are quadrants, (Theor. II.); and therefore EF is the supplement of KL, but since A is the pole of EF, KL is the measure of the angle at A; thus EF is the supplement of the measure of the angle at A. In like manner FD is the supplement of the measure of the angle at B, and DE the supplement of the measure of the angle at C.

Further, it will appear in the same manner that BC is the supplement of HM, the measure of the angle at D; that AB is the supplement of NK the measure of the angle at F; and that AC is the supplement of GL, the measure of the angle at E.

Theor. VI.

If from any point E, which is not the pole of the great circle ABC, there be drawn arches of great circles EA, EK, EB, &c. the greatest of these is EGA, which passes through G the pole of ABC, and EC the remainder of the semicircle is the least, and of the other, EK, EB, &c. EK which is nearer to EA is greater than EB, which is more remote.

Let AC be the common section of the planes of the great circles AEC, ABC; draw EH perpendicular to AC, which will be perpendicular to the plane of the circle ABC (Geometry, Sect. VII. Theor. XII.), and join AE, KE, BE, KH, BH. Then of all the straight lines drawn from H to the circumference, HA is the greatest, HC the least, and HK greater than HB: Therefore in the right-angled triangles EHA, EHK, EHB, EHC, which have the side EH common, EA is the greatest hypothenuse, EC the least, and EK greater than EB, consequently the arch EGA is the greatest, EC the least, and EK greater than EB. Fig. 15.

Theor. VII.

Any two sides of a spherical triangle are together greater than the third, and all the three sides are together less than a circle.

Let ABC be a spherical triangle, let D be the centre of the sphere, join DA, DB, DC. The solid angle at D is contained by three plane angles ADB, BDC, ADC, any two of which are greater than the third, (Geometry, Sect. VII. Theor. XV.); and therefore any two of the arches AB, BC, AC which measure these angles must be greater than the third arch. Fig 16.

To prove the second part of the proposition, produce the sides AB, AC until they meet again in E; then ECA and EBA are semicircles; now CB is less than CE+EB, therefore CB+CA+BA is less than CE+EB+CA+BA, but these four arches make up two semicircles; therefore CB+CA+BA is less than a circle.

Theor. VIII.

If two sides of a spherical triangle be equal, the angles opposite to them are equal, and conversely.

Fig. 17. In the triangle ABC, if the sides AB, AC be equal, the angles ABC, ACB are also equal. If AB, AC be quadrants, ABC, ACB are right angles. If not, let the tangent to the side AB at B meet EA the line of common section of the planes AB, AC in F, and let the tangents to the base BC at its extremities meet each other in G; also, let FC, FG, EC, and EB be joined. Then the triangles FEB, FEC have FE common, EB=EC, and the angle AEB=AEC, therefore FB =FC, and the angle FCE=FBE a right angle: hence FC is a tangent, and the triangles FGB, GCF are mutually equilateral, therefore the angle FBG=FCG, and consequently the spherical angle ABC=ACB.

Again, if the angles ABC, ACB be equal, the side AB=AC. For, if in fig. 14. the angle ABC be equal to ACB, the side DF of the supplemental triangle DEF will be equal to the side DE (Theor. V.); therefore the angle DEF=DFE, and consequently in the triangle ABC, the side AC=AB by Theorem V.

Cor. In any triangle the greater angle is subtended by the greater side; and conversely. For if the angle

Fig. 18. ACB be greater than ABC (fig. 18.) let BCD=ABC, then BD=DC, and AB=AD+DC, which is greater than AC (Theor. VII.). The converse is demonstrated in the same manner as the like property of plane triangles, (Geometry, Sect. I. Theor. XIII.).

Theor. IX.

All the angles of a spherical triangle are together greater than two, and less than six right angles.

Fig. 14. In the triangle ABC (fig. 14.) the three angles are altogether less than six right angles, because when added to the three exterior angles they only make six; and they are greater than two right angles, because their measures GH, KL, MN, added to DE, EF, FD, are equal to three semicircles; and DE, EF, FD being less than two semicircles (Theor. VII.) GH, KL, MN must be greater than one.

Theor. X.

Any two angles of a spherical triangle are together greater, equal, or less than two right angles, according as the sum of the opposite side is greater, equal, or less than a semicircle; and conversely.

Fig. 19. Let the sides AB, AC (fig. 19.) of the spherical triangle ABC be produced to meet in D; then it is evident, that according as the sum of AB, BC is greater, equal, or less than the semicircle ABD, the side BC will be greater, equal, or less than BD; the angle D or A will be greater, equal, or less than BCD, and the sum of the angle BAC, BCA greater, equal, or less than the sum of BCA, BCD, which is two right angles.

Cor. According as half the sum of any two sides of a spherical triangle is greater, equal, or less than a quadrant, half the sum of the opposite angles will be greater, equal, or less than a right angle.

Theor. XI.

In a right-angled triangle, according as either of the sides about the right angles is greater, equal, or less than a quadrant, its opposite angle is greater, equal, or less than a right angle; and conversely.

Let ABC (fig. 20.) be a triangle right-angled at B, Fig. 20. and let the sides AB, BC be produced to meet in D; then, because they pass through each others poles, E the middle point of BAD will be the pole of BCD; let a great circle pass through the points CE. The arch EC is a quadrant, and the angle ECB a right angle. Now it is plain, that according as AB is greater, equal, or less than the quadrant EB, the opposite angle ACB will be greater, equal, or less than the right angle ECB, and conversely.

Cor. 1. If the two sides be both greater, or both less than quadrants, the hypothenuse will be less than a quadrant; but if the one be greater and the other less, the hypothenuse will be greater than a quadrant, and conversely.

For in the triangles ABC, ADC, right-angled at B, D, in which the sides AB, BC are less, and consequently AD, DC greater than quadrants, the hypothenuse AC is less than a quadrant, because it is nearer to CB than the quadrant CE. But in the triangle *a* BC, of which the side *a* B is greater, and BC less than a quadrant, the hypothenuse *a* C is greater than a quadrant, because it is further from CB than CE is.

Cor. 2. In every spherical triangle, of which the two sides are not both quadrants, if the perpendicular from the vertex fall within, the angles at the base will be both acute, or both obtuse; but if it fall without, the one will be obtuse, and the other acute, and conversely.

Theor. XII.

In any right-angled spherical triangle, as radius is to the sine of the hypothenuse, so is the sine of one of the oblique angles to the sine of its opposite side.

Let ABC (fig. 21.) be a spherical triangle, having Fig. 21. a right angle at B; and let AD, BD, CD be drawn to the centre of the sphere. From C, in the plane DCA, let CE be drawn perpendicular to DA, and from E, in the plane DBA, draw EF perpendicular to the same line, and let CF be joined. Then because DA is perpendicular to the two lines CE, EF, it is perpendicular to the plane CEF, and consequently the plane CEF is perpendicular to the plane DBA; but the plane DCB is also perpendicular to DBA; therefore their line of common section CF is perpendicular to the same: Hence CFD, CFE are right angles. Now in the right-angled triangle CFE, rad. : CE :: sin. E : CF; but the angle CEF, being the inclination of the planes DCA, DBA, is the same with the spherical angle CAB, CE is the sine of AC, and CF the sine of BC; therefore rad. : sin. AC :: sin. A : sin. BC.

Cor.

Cor. 1. As radius to the cosine of either of the sides, so is the cosine of the other to the cosine of the hypothenuse.

Fig. 22. For let the great circle of which A is the pole, meet the three sides in D, E, F; then F is the pole of AD; and applying this proposition to the complemental triangle FCE, rad. : sin. FC :: sin. F : sin. CE; that is, rad. : cos. BC :: cos. AB : cos. AC.

Cor. 2. As radius to the cosine of one of the sides, so is the sine of its adjacent angle to the cosine of the other angle.

Theor. XIII.

In any right-angled triangle, as radius to the sine of one of the sides, so is the tangent of the adjacent angle to the tangent of the other side.

Fig. 23. From B let BE be drawn perpendicular to DA, and from E, EF also perpendicular to DA, in the plane DCA, to meet DC in F, and let BF be joined. It may be shown as in the preceding proposition, that FB is perpendicular to the plane DBA; hence FB is the tangent of BC, and FBE is a right-angled triangle; therefore rad. : EB :: tan. E : FB; that is rad. : sin. AB :: tan. A : tan. BC.

Cor. 1. As radius to the cosine of the hypothenuse, so is the tangent of one of the angles to the cotangent of the other. For, in the complemental triangle FCE, (fig. 22.) rad. : sin. CE :: tan. C : tan. FE, that is, rad. : cos. AC :: tan. C : cot. A, or, rad. : cos. AC :: tan. A : cot. C.

Cor. 2. As radius is to the cosine of one of the angles, so is the tangent of the hypothenuse to the tangent of the side adjacent to that angle.

For rad. : sin. FE :: tan. F : tan. CE; that is, rad. : cos. A :: cot. AB : cot. AC, or rad. : cos. A :: tan. AC : tan. AB.

Napier's Rule for Circular Parts.

Let the hypothenuse, the two angles, and the complements of the two sides of any right-angled spherical triangle be called the *five circular parts* of the triangle. Any one of these being considered as the *middle* part, let the two which are next to it be called the *adjacent* parts, and the remaining two the *opposite* parts. Then the two preceding theorems, with their corollaries, may be all expressed in one proposition adapted to practice, as follows.

In any right-angled spherical triangle, the rectangle under radius, and the cosine of the middle part, is equal to the rectangle under the cotangents of the adjacent parts, or to the rectangle under the sines of the opposite parts.

Fig. 24. Case 1. Let the hypothenuse AC be the middle part.

Then, rad. : cos. AC :: tan. C : cot. A (Theor. 13. Cor. 1.).

Therefore (rad. : tan. C ::) cot. C : rad. :: cos. AC : cot. A.

And rad. : cos. AB :: cos. BC : cos. AC (Theor. 12. Cor. 1.).

Case 2. Let the angle A be the middle part.

Then (Theor. 13. Cor. 2.) rad. : cos. A :: tan. AC : tan. AB.

Therefore, (rad. : tan. AC ::) cot. AC : rad. :: cos. A : tan. AB.

And (Theor. 12. Cor. 2.) rad. : cos. BC :: sin. C : cos. A.

Case 3. Let the complement of the side AB be the middle part.

Then (Theor. 13.) rad. : sin. AB :: tan. A : tan. BC.

Therefore (rad. : tan. A ::) cot. A : rad. :: sin. AB : tan. BC.

And (Theor. 12.) rad. : sin. AC :: sin. C : sin. AB.

We are indebted for the foregoing rule to Napier, the celebrated inventor of logarithms. It comprehends all the propositions which are necessary for the resolution of right-angled triangles, and being easily remembered, is perhaps one of the happiest instances of artificial memory that is known.

Theor. XIV.

In any spherical triangle, the sines of the sides are proportional to the sines of the opposite angle.

This proposition has been demonstrated in the case of right-angled triangles. Let ABC be any oblique-angled triangle, divided into two right-angled triangles, ABD, CBD, by the perpendicular BD, falling from the vertex upon the base AC. In the former, the complement of BD being the middle part, rad. $\times$ sin. BD $=$ sin. AB $\times$ sin. A, (Napier's Rule). In the latter, the complement of BD being the middle part, rad. $\times$ sin. BD $=$ sin. BC $\times$ sin. C. Hence sin. AB $\times$ sin. A $=$ sin. BC $\times$ sin. C, and sin. AB : sin. BC :: sin. C : sin. A. Fig. 25.

Cor. 1. The cosines of the two sides are to one another directly as the cosines of the segments of the base. This is proved by making AB, BC the middle part.

Cor. 2. The tangents of the two sides are to one another inversely as the cosines of the vertical angles. This will follow from making the angles ABD, CBD the middle parts.

Lemma 1. *The sum of the tangents of two arches is to their difference, as the rectangle under the sine and cosine of half their sum to the rectangle under the sine and cosine of half their difference.*

For, putting a and b for any two arches, by the arithmetic of sines (Algebra, § 353.),

$$\text{Sin. } a \cos. b + \cos. a \sin. b = \sin. (a+b).$$

Let each side of this equation be divided by cos. a cos. b, and we get

$$\frac{\sin. a}{\cos. a} + \frac{\sin. b}{\cos. b} = \frac{\sin (a+b)}{\sin. a \cos. b}$$

that is, $\tan. a + \tan. b = \dfrac{\sin. (a+b)}{\sin. a \cos. b}$.

In like manner, from the formula $\sin. (a-b) = \sin. a \cos. b - \cos. a \sin. b$, we get

$$\tan. a - \tan. b = \frac{\sin. (a-b)}{\sin. a \cos. b};$$

therefore tan. a + tan. b : tan. a — tan. b : sin. $(a+b)$: sin. $(a-b)$, and remarking that sin. $(a+b) = 2$ sin. $\frac{1}{2}(a+b)$,

$\frac{1}{2}(a+b)$ cos. $\frac{1}{2}(a+b)$, and sin. $(a-b) = 2$ sin. $\frac{1}{2}(a-b)$ cos. $\frac{1}{2}(a-b)$, (ALGEBRA, § 358.) it follows that tan. a + tan. b : tan. a — tan. b :: sin. $\frac{1}{2}(a+b)$ cos. $\frac{1}{2}(a+b)$: sin. $\frac{1}{2}(a-b)$ cos. $\frac{1}{2}(a-b)$.

2. LEMMA. *The sum of thesines of two arches is to their difference, as the rectangle under the sine of half the sum and cosine of half the difference of these arches is to the rectangle under the sine of half the difference and cosine of half the sum.*

For it has been shown in the arithmetic of sines (ALGEBRA, § 355), that

$$\text{Sin. }(p+q) + \text{sin. }(p-q) = 2 \text{ sin. } p \text{ cos. } q,$$
$$\text{Sin. }(p+q) - \text{sin. }(p-q) = 2 \text{ cos. } p \text{ sin. } q.$$

Let $p = \frac{1}{2}a + \frac{1}{2}b$, and $q = \frac{1}{2}a - \frac{1}{2}b$, so that $p+q = a$ and $p-q = b$, then these formulas become

$$\text{Sin. } a + \text{sin. } b = 2 \text{ sin. } \tfrac{1}{2}(a+b) \text{ cos. } \tfrac{1}{2}(a-b)$$
$$\text{Sin. } a - \text{sin. } b = 2 \text{ cos. } \tfrac{1}{2}(a+b) \text{ sin. } \tfrac{1}{2}(a-b).$$

Therefore, sin. a+sin. b : sin. a—sin. b :: sin. $\frac{1}{2}(a+b)$ cos. $\frac{1}{2}(a-b)$: cos. $\frac{1}{2}(a+b)$ sin. $\frac{1}{2}(a-b)$.

LEMMA 3. *The sum of the sines of two arches is to their difference, as the tangent of half the sum of these arches is to the tangent of half their difference.*

For, dividing the latter antecedent and consequent of the proportion in the foregoing lemma by cos. $\frac{1}{2}(a+b) \times$ cos. $\frac{1}{2}(a-b)$, we have sin. a+sin. b : sin. a—sin. b :: $\frac{\text{sin. }\frac{1}{2}(a+b)}{\text{cos. }\frac{1}{2}(a+b)} : \frac{\text{sin. }\frac{1}{2}(a-b)}{\text{cos. }\frac{1}{2}(a-b)}$, that is, because $\frac{\text{sin.}}{\text{cos.}} =$ tan. sin. a + sin. b : sin. a — sin. b :: tan. $\frac{1}{2}(a+b)$: tan. $\frac{1}{2}(a-b)$.

LEMMA 4. *The sum of the cosines of two arches is to their difference, as the cotangent of half the sum of these arches is to the tangent of half their difference.*

By Arithmetic of sines (ALGEBRA, § 355.),

$$\text{cos. }(p-q) + \text{cos. }(p+q) = 2 \text{ cos. } p \text{ cos. } q,$$
$$\text{cos. }(p-q) - \text{cos. }(p+q) = 2 \text{ sin. } p \text{ sin. } q.$$

Let $p = \frac{1}{2}(b+a)$ and $q = \frac{1}{2}(b-a)$, then $p-q = a$ and $p+q = b$, and the two formulas become

$$\text{cos. } a + \text{cos. } b = 2 \text{ cos. } \tfrac{1}{2}(b+a) \text{ cos. } \tfrac{1}{2}(b-a),$$
$$\text{cos. } a - \text{cos. } b = 2 \text{ sin. } \tfrac{1}{2}(b+a) \text{ sin. } \tfrac{1}{2}(b-a);$$

Hence, cos. a+cos. b : cos. a—cos. b :: cos. $\frac{1}{2}(b+a)$ cos. $\frac{1}{2}(b-a)$: sin. $\frac{1}{2}(b+a)$ sin. $\frac{1}{2}(b-a)$;

and dividing the latter antecedent and consequent by sin. $\frac{1}{2}(b+a)$ cos. $\frac{1}{2}(b-a)$,

$$\text{cos. } a + \text{cos. } b : \text{cos. } a - \text{cos. } b :: \frac{\text{cos. }\frac{1}{2}(b+a)}{\text{sin. }\frac{1}{2}(b+a)} : \frac{\text{sin. }\frac{1}{2}(b-a)}{\text{cos. }\frac{1}{2}(b-a)},$$ that is, because $\frac{\text{cos.}}{\text{sin.}} =$ cot. and $\frac{\text{sin.}}{\text{cos.}} =$ tan. we have cos. a + cos. b : cos. a — cos. b :: cot. $\frac{1}{2}(b+a)$: tan. $\frac{1}{2}(b-a)$.

Fig. 26. IN the demonstration of the remaining theorems, we shall put A, B for the angles A and B at the base of the spherical triangle ACB (fig. 26.) a and b for the sides opposite to these angles, p and q for the segments of the base BD, AD made by the perpendicular arch CD, P and Q for the vertical angles BCD, ACD; we shall also put s for $\frac{1}{2}(a+b)$, d' for $\frac{1}{2}(a-b)$, s' for $\frac{1}{2}(p+q)$, d' for $\frac{1}{2}(p-q)$, S for $\frac{1}{2}$(A+B), D for $\frac{1}{2}$(A—B), S′ for $\frac{1}{2}$(P+Q), and D′ for $\frac{1}{2}$(P—Q).

THEOR. XV.

In any spherical triangle, the tangent of half the sum of the segments of the base is to the tangent of half the sum of the two sides, as the tangent of half their difference to the tangent of half the difference of the segments of the base.

For by Theor. XIV. Cor. 1. cos. a : cos. b :: cos. p : cos. q; therefore, cos. a + cos. b : cos. a — cos. b :: cos. p + cos. q : cos. p — cos. q, hence (Lemma 4.) cot. s : tan. d' :: cot. s' : tan. d', or cot. s : cot. s' :: tan. d : tan d'; but cot. s : cot. s' :: tan. s' : tan. s, therefore, tan s' : tan. s :: tan. d : tan. d'. This proposition expressed in words at length is the theorem to be demonstrated.

THEOR. XVI.

The cotangent of half the sum of the vertical angles and the tangent of half their difference, or the cotangent of half their difference and the tangent of half their sum, according as the perpendiculars fall within or without, are reciprocally proportional to the tangents of half the sum and half the difference of the angles at the base.

For, taking the case in which the perpendicular CD (fig. 27.) falls within, let EFG be the supplemental triangle, let the arches GE, GF meet again in L, and produce CA, CB to meet EF in H and K. Because G and L are the poles of AB, the perpendicular CD, if produced, will pass through G and L; let it meet EF in I; then, because C is the pole of EF, the arch GCI is perpendicular to EF, and since E is the pole of BC, KE=a quadrant=FH, and EH=KF, and IF—IE=IK—IH. In the triangle LEF, by the preceding proposition, tan. $\frac{1}{2}$(FI+IE) : tan. $\frac{1}{2}$(FL+LE) :: tan. $\frac{1}{2}$(FL—LE) : tan. $\frac{1}{2}$(FI—IE) or tan. $\frac{1}{2}$(KI—IH). Now FI+IE, or FE, being the supplement of C, (Theor. 5.), tan. $\frac{1}{2}$ FE=cot. $\frac{1}{2}$C; and FL, LE being the supplements of FG and GE, FL and LE are the measures of the angles A, B; moreover, IK, IH are the measures of the angles BCD, ACD, therefore, cot. $\frac{1}{2}$ C, or cot. $\frac{1}{2}$(P+Q) : tan. $\frac{1}{2}$(A+B) : tan. $\frac{1}{2}$(A—B) : tan. $\frac{1}{2}$(P—Q). In the very same way it may be proved, when the perpendicular falls without the triangle, that cot. $\frac{1}{2}$(P—Q) : tan. $\frac{1}{2}$(A+B) :: tan. $\frac{1}{2}$(A—B) : tan. $\frac{1}{2}$(P+Q). Fig. 27.

THEOR. XVII.

In any spherical triangle, the sine of half the sum of the sides is to the sine of half their difference, as the cotangent of half the vertical angle to the tangent of half the difference of the angles at the base.

For since tan. a : tan. b :: cos. Q : cos. P, therefore, tan.

tan. a+tan. b : tan. a—tan. b :: cos. Q+cos. P : cos. Q—cos. P; hence, by Lemma 2. and 4.

sin. s. cos. s : sin. d cos. d :: cot. S′ : tan. D′ . . . (1).

Again, because (by Theor. XIV.) sin. a : sin. b :: sin. A : sin. B, therefore, sin. a+sin. b : sin. a—sin. b :: sin. A+sin. B : sin. A—sin. B; hence, (by Lemma 2. and 3.)

sin. s cos. d : sin. d cos. s :: tan. S : tan. D . . . (2).

Taking now the product of the corresponding terms of the proportions (1) and (2), and rejecting the factor cos. s cos. d, which is common to the first antecedent and consequent of the resulting proportion, we have,

sin.^{2} s : sin.^{2} d :: cot. S′ tan. S : tan. D′ tan. D.

But since by Theor. XVI. tan. S : tan. D′ :: cot. S′ : tan. D, therefore cot. S′ tan. S : tan. D′ tan. D :: cot.^{2} S′ : tan.^{2} D; therefore, sin.^{2} s : sin.^{2} d :: cot.^{2} S′ : tan.^{2} D, and sin. s : sin. d :: cot. S′ : tan. D, this proportion when expressed in words is the proportion to be demonstrated.

Theor. XVIII.

In any spherical triangle, the cosine of half the sum of the two sides is to the cosine of half their difference, as the cotagent of half the vertical angle to the tangent of half the sum of the angles at the base.

For it has been proved in last theorem that

sin. s cos. s : sin. d cos. d :: cot. S′ : tan. D′
sin. s cos. d : sin. d cos. s :: tan. S : tan. D;

therefore, dividing the terms of the first of these two proportions by the corresponding terms of the second, we get

$$\frac{\text{cos. } s}{\text{cos. } d} : \frac{\text{cos. } d}{\text{cos. } s} :: \frac{\text{cot. S}'}{\text{tan. S}} : \frac{\text{tan. D}'}{\text{tan. D}}.$$

Hence, multiplying the first and second terms by cos. s × cos. d, and the third and fourth by tan. S tan. D, we have

cos.^{2} s : cos.^{2} d :: cot. S′ tan. D : tan. S tan. D′.

But since by Theor. XVI. tan. D : tan. D′ :: cot. S′ : tan. S, therefore, cot. S′ tan. D : tan. S tan. D′ :: cot.^{2} S′ : tan.^{2} S; therefore, cos.^{2} s : cos.^{2} d :: cot.^{2} S′ : tan.^{2} S, and cos. s : cos. d :: cot. S′ : tan. S.

Theor. XIX.

In any spherical triangle, the sine of half the sum of the angles at the base is to the sine of half their difference, as the tangent of half the base to the tangent of half the difference of the two sides.

For the same construction being made as in Theor. XVI. in the triangle ELF (fig. 27.) sin. $\frac{1}{2}$ (FL+LE) : sin. $\frac{1}{2}$ (FL—LE) :: cot. $\frac{1}{2}$ L : tan. $\frac{1}{2}$ (E—F) (Theor. XVII.); but EFG being the supplemental triangle of ABC, LF and LE are the measures of A and B, L is the supplement of AB, and LFE, LEF are the measures of the sides AC, BC (Theor. V.); therefore sin. $\frac{1}{2}$ (A+B) : sin. $\frac{1}{2}$ (A—B) :: tan. $\frac{1}{2}$ AB : tan. $\frac{1}{2}$ (BC—AC). Fig. 27.

Theor. XX.

In any spherical triangle, the cosine of half the sum of the angles at the base is to the cosine of half their differences as the tangent of half the base to the tangent of half the sum of the two sides.

For in the triangle ELF, cos. $\frac{1}{2}$ (LF+LE) : cos. $\frac{1}{2}$ (LF—LE) :: cot. $\frac{1}{2}$ L : tan. $\frac{1}{2}$ (E+F) (Th. XVIII.) that is, because of the relation of the triangle FLE to ABC, as expressed in last theorem, cos. $\frac{1}{2}$ (A+B) : cos. $\frac{1}{2}$ (A—B) :: tan. $\frac{1}{2}$ AB : tan. $\frac{1}{2}$ (BC+AC). Fig. 27.

Scholium.

Let one of the six parts of any spherical triangle be neglected; let the one opposite to it, or its supplement, if an angle, be called the *middle part*, the two next to it the *adjacent parts*, and the remaining two the *opposite parts*. Then the four preceding propositions, which are called *Napier's Analogies*, because first invented by him, may be included in one, as follows.

In any spherical triangle, the sine or cosine of half the sum of the adjacent parts, is to the sine or cosine of half their difference, as the tangent of half the middle part to the tangent of half the difference or half the sum of the opposite parts, that is,

Sin. $\frac{1}{2}$ (A+a) : sin. $\frac{1}{2}$ (A—a) :: tan. $\frac{1}{2}$ M : tan. $\frac{1}{2}$ (O—o).

Cos. $\frac{1}{2}$ (A+a) : cos. $\frac{1}{2}$ (A—a) :: tan. $\frac{1}{2}$ M : tan. $\frac{1}{2}$ (O+o).

When A, a and M are given, by the first proportion, $\frac{1}{2}$ (O—o) is found, and by the second $\frac{1}{2}$ (O+o); thence O and o may be had immediately by the problem following Theor. IV. Plane Trigonometry.

The Cases of Right-angled Spherical Triangles.

In a right-angled triangle, let c denote the side opposite the right angle, a, b the sides containing it, and A, B the opposite angles, A being opposite to a, and B to b. Then, combining these quantities two by two, there will be found to be six distinct combinations, or cases. Fig. 28.

Case 1. When c, A, the hypothenuse and one of the angles are given; to find a, b, B.

a is found by Theor. XII.; b by Theor. XIII. Cor. 2. and B by Theor. XIII. Cor. 1.

Case 2. Given a, B, a side and its adjacent angle. Sought, A, b, c.

A is found by Theor. XII. Cor. 2.; b by Theor. XIII.; c by Theor. XIII. Cor. 2.

Case 3. Given a, A, a side and its opposite angle; to find b B, c.

b is found by Theor. XIII.; B by Theor. XII. Cor. 2.; c by Theor. XII.

Case 4. Given c, a, the hypothenuse, and one of the sides; to find A, b, B.

A is found by Theor. XII.; b by Theor. XII. Cor. 1.; B by Theor. XIII. Cor. 2.

Spherical Trigonometry.

Case 5. Given a, b, the two sides. Sought A, B, c.
A is found by Theor. XIII.; B by the same; c by Theor. XII. Cor. 1.

CASE 6. Given A, B, the two angles. Sought a, b, c.
a and b are found by Theor. XII. Cor. 2.; c by Theor. XIII. Cor. 1.

THE case may be all resolved also by *Napier's Rule*, observing to make each of the things given the middle part; then two of the required parts will be found, and the remaining part is found by making it the middle part.

By Theor. II. and Cor. 1. each of the unknown parts is, in every case except the third, limited to one value.

The cases of Oblique-angled Spherical Triangles.

In any spherical triangle let the sides be denoted by a, b, c, and the opposite angles by A, B, C respectively.

Let p, q denote the segments into which a side is divided by a perpendicular from the opposite angle, and P, Q the parts into which it divides the angle. Combining the six quantities a, b, c, A, B, C, three by three, there are found six distinct combinations or cases.

CASE 1. Given a, A, b, two sides and an angle opposite to one of them. Sought c, B, C.
B is found by Theor. XIV.; c by either Theor. XIX. or Theor. XX.; C by Theor. XVII. or Theor. XVIII.

CASE 2. Given A, a, B, two angles and a side opposite to one of them. Sought b, c, C.
b is found by Theor. XIV.; c and C as in Case 1.

CASE 3. Given a, C, b, two sides and the included angle. Sought A, B, c.

Find $\frac{1}{2}$ (A—B) by Theor. XVII. and $\frac{1}{2}$ (A+B) by Theor. XVIII. and thence A and B by the rule SECT. II. for finding each of two quantities whose sum and difference are given. All the angles being known, also two sides, c is found by Theor. XIV.

CASE 4. Given A, c, B, two angles and a side between them. Sought a, C, b.

Find $\frac{1}{2}$ $(a—b)$ by Theor. XIX. and $\frac{1}{2}$ $(a+b)$ by Theor. XX. and thence a, b. All the sides and two angles being now known, C is found by Theor. XIV.

CASE 5. Given a, b, c, the three sides. Sought A, B, C.

Draw a perpendicular from any one of the angles, dividing the opposite side into the segments p, q. Find $\frac{1}{2}$ $(p—q)$ by Theor. XV. and then, from $\frac{1}{2}$ $(p+q)$ and $\frac{1}{2}$ $(p—q)$, find p, q. The triangle being now resolved into two right-angled triangles, the angles may be found by Case 4. of right-angled triangles.

CASE 6. Given A, B, C, the three angles. Sought a, b, c.

Draw a perpendicular, dividing any one of the angles into the parts P, Q. Find $\frac{1}{2}$ (P—Q) by Theor. XVI. and then P, Q. The triangle being now resolved into two right-angled triangles, the sides may be found by Case 6. of right-angled triangles.

By Theor. X. XI. and Cor. each of the unknown parts is limited to one value in all the cases, except in some of the subcases of the first and second.

As every oblique-angled triangle may be resolved into two right-angles, all these cases may be resolved by means of *Napier's Rule*, and the 15th proposition only. And the cases may be reduced to three, by using the supplemental triangle.

T R I

Trihilatæ ‖ Tringa.

TRIHILATÆ, from *tres*, "three," and *hilum*, "an external mark on the seed;" the name of the 23d class in Linnæus's Fragments of a Natural Method; consisting of plants with three seeds, which are marked with an external cicatrix or scar, where they are fastened within the fruit. See BOTANY.

TRIM, implies in general the state or disposition by which a ship is best calculated for the several purposes of navigation.

Thus the trim of the hold denotes the most convenient and proper arrangement of the various materials contained therein relatively to the ship's motion or stability at sea. The trim of the masts and sails is also their most apposite situation with regard to the construction of the ship and the effort of the wind upon her sails. See SEAMANSHIP.

TRINGA, SANDPIPER; a genus of birds belonging to the order of grallæ. See ORNITHOLOGY *Index*.

Tringa ‖ Trinitarians.

TRINIDAD, an island in the gulf of Mexico, separated from New Andalusia, in Terra Firma, by a strait about three miles over. The soil is fruitful, producing sugar, cotton, Indian corn, fine tobacco, and fruits. It was taken by Sir Walter Raleigh in 1595, and by the French in 1676, who plundered the island and then left it. It is about 62 miles in length, and 45 in breadth; and was discovered by Christopher Columbus in 1498. It is now in the possession of Britain. What was called a bituminous lake in this island, appears, from the experiments of Mr Hatchet, to be a porous stone from which the mineral pitch exudes.

TRINITARIANS, those who believe in the Trinity; those who do not believe therein being called *Antitrinitarians*.

TRINITY, in *Theology*, the ineffable mystery of three persons in one God; Father, Son, and Holy Spirit. See THEOLOGY.

TRINITY-House. See LONDON, N° 49.

TRINITY-Sunday, a festival observed on the Sunday next after Whitsunday, in honour of the holy Trinity. The observation of this festival was first enjoined in the council of Arles, anno 1260.

TRINOBANTES, in *Ancient Geography*, a people of Britain, supposed to have occupied Middlesex and Essex.

TRIO, in *Music*, a part of a concert wherein three persons sing; or, more properly, a musical composition consisting of three parts.

TRIPHTHONG, in *Grammar*, an assemblage or concourse of three vowels in one syllable; as *quæ*.

TRIPLE, in *Music*, is one of the species of measure or time. See MUSIC.

TRIPOD, in antiquity, a famed sacred seat or stool, supported by three feet, whereon the priest and sibyls were placed to render oracles. It was on the tripod that the gods were said to inspire the Pythias with that divine fury and enthusiasm wherewith they were seized at the delivery of their predictions.

TRIPOLI, a country of Africa, in Barbary; bounded on the north by the Mediterranean sea; on the south, by the country of the Beriberies: on the west, by the kingdom of Tunis and Biledulgerid; and on the east, by Egypt. It is about 925 miles along the sea coast; but the breadth is various. Some parts of it are pretty fruitful; but that towards Egypt is a sandy desert. It had the title of a *kingdom*; but is governed by a dey. Early in the last century Tripoli shook off its dependence on the grand Turk. In other respects the government is not essentially changed. It is still a military despotism of the most ferocious description. Its piracies are now confined to Naples, Sardinia, and other states which have no efficient navy. See BARBARY STATES, SUPPLEMENT.

TRIPOLI, a considerable town of Africa, and capital of a state of the same name in Barbary, with a castle and a fort. It is pretty large, and the inhabitants are noted pirates. It was taken by Charles V. who settled the knights of Malta there; but they were driven away by the Turks in 1551. It was formerly very flourishing; and has now some trade in stuffs, saffron, corn, oil, wool, dates, ostrich feathers, and skins: but they make more of the Christian slaves which they take at sea; for they either set high ransoms upon them, or make them perform all sorts of work. It is seated on the coast of the Mediterranean, in a sandy soil, and surrounded by a wall, strengthened by other fortifications. E. Long. 13. 12. N. Lat. 32. 34.

TRIPOLI, called *Tripolis* of *Syria*, to distinguish it from Tripoli in *Barbary*, received its name from its being anciently formed of three cities at a small distance from each other, one of which belonged to the Aradians, or ancient kingdom of Arad, the second to the Sidonians, and the third to the Tyrians, perhaps as a common mart to those maritime powers. The present town of Tripoli is built at the distance of a mile and a half from the other, upon the declivity of a hill facing the sea, in 34° 20′ north latitude, and in 35° 50′ east longitude from Greenwich. It is surrounded with walls, fortified with seven high strong towers, and a castle, all of Gothic architecture; but the streets are narrow, and the houses low. The city contains about 8000 houses, and near 60,000 inhabitants, consisting of Turks, Christians, and Jews. The basha, or pasha, who resides in the castle, where there is a garrison of 200 janizaries, governs the adjacent territory, in which there is plenty of fruit, and a great number of mulberry trees, which enable the inhabitants to carry on a silk manufacture, from which they draw considerable profit.

All the environs of Tripoli are laid out in orchards, where the nopal grows spontaneously, and the white mulberry is cultivated for the silk-worm; the pomegranate, orange, and lemon trees for their fruit, which is here very fine. The country, though delightful to the eye, is unhealthy; from July to September, epidemic fevers, like those of Scanderoon and Cyprus, prevail, and are principally caused by the artificial inundations made for the purpose of watering the mulberry trees, to enable them to throw out their second leaves, and from a want of free circulation of air, the city being open only to the westward.

TRIPOLI, a species of argillaceous earth, much used in the polishing of metals. See MINERALOGY *Index*.

TRIPTOLEMUS, LAWS OF. See MYSTERIES, N° 74.

TRIQUETROUS, among botanists, denotes a fruit or leaf that has three flat sides or faces.

TRIREMIS, in antiquity, a galley with three ranks of oars on a side.

TRISMEGISTUS, an epithet or surname given to one of the two Hermeses. See THOTH.

TRISMUS, the LOCKED JAW. See MEDICINE, N° 280.

TRISYLLABLE, in *Grammar*, a word consisting of three syllables.

TRITICUM, WHEAT; a genus of plants belonging to the class of triandria; and in the natural system ranging under the 4th order, *Gramina*. See BOTANY and AGRICULTURE *Index*.

TRITON, a sea demigod, held by the ancients to be an officer or trumpeter of Neptune, attending on him, and carrying his orders from sea to sea.

TRITURATION, the act of reducing a solid body into a subtile powder; called also *pulverisation* and *levigation*.

TRIUMPH, in Roman antiquity, a public and solemn honour conferred by the Romans on a victorious general, by allowing him a magnificent entry into the city.

The greater triumph, called also *curulis*, or simply the *triumph*, was decreed by the senate to a general, upon the conquering of a province or gaining a signal victory. The day appointed for the ceremony being arrived, scaffolds were erected in the forum and circus, and all the other parts of the city where they could best behold the pomp: the senate went to meet the conqueror without the gate called *Capena* or *Triumphalis*, and marched back in order to the Capitol; the ways being cleared and cleansed by a number of officers and tipstaffs, who drove away such as thronged the passage or straggled up and down. The general was clad in a rich purple robe, interwoven with figures of gold, setting forth his great exploits; his buskins were beset with pearl; and he wore a crown, which at first was only laurel, but afterwards gold; in one hand he bore a a branch of laurel, and in the other a truncheon. He was carried in a magnificent chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa, by elephants; that of Mark Antony by lions; that of Heliogabalus by tygers; that of Aurelian by deer, &c. His children were at his feet, and sometimes on the chariot-horses. The procession was led by the musicians, who played triumphal pieces in praise of the general: these were followed by young men, who led the victims to the sacrifice, with their horns gilded, and their heads adorned with ribbauds and garlands; next came the carts and waggons, loaded with all the spoils taken from the enemy, with their horses, chariots, &c.; these were followed by the kings, princes, and generals, who had been taken captives, loaded with chains; after these appeared the triumphal chariot, before which, as it passed, they all along strewed flowers, and the people with loud acclamations called out *Io triumphe!* The chariot was followed by the senate, clad in white robes; and the senate by such citizens as had been set at liberty or ransomed; and the procession was closed by the priests and their officers and utensils, with a white ox led along for the chief victim. In this order they proceeded through the triumphal gate, along the Via Sacra, to the Capitol, where the victims were slain. In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared everywhere.

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state. It is chiefly applied to the Roman government: Cæsar, Pompey, and Crassus, were the first triumvirs who divided the government among them. There were also other officers so called; as the triumviri or tresviri capitales, who were the keepers of the public gaol: they had the office of punishing malefactors; for which purpose they kept eight lictors under them.

TROAS, a country of Phrygia in Asia Minor, of which Troy was the capital. When Troas is taken for the whole kingdom of Priam, it may be said to contain Mysia and Phrygia Minor: but if only applied to that part of the country where Troy was situated, its extent is confined within very narrow limits. Troas was anciently called Dardania. See TROJA.

TROCHÆUS, in prosody, a foot consisting of a long and short syllable.

TROCHANTER, in *Anatomy*. See there, N° 58.

TROCHE, in *Pharmacy*, a sort of medicine made of glutinous substances into little cakes, and afterwards exsiccated. See MATERIA MEDICA *Index*.

TROCHILUS, HUMMING BIRD, a genus of birds belonging to the order of picæ. See ORNITHOLOGY *Index*.

TROGLODYTES, in the *Ancient Geography*, a people of Ethiopia, said to have lived in caves under ground. Pomponius Melo gives a strange account of the Troglodytes: he says they did not so properly speak as shriek; and that they lived on serpents.

TROGUS POMPEIUS, a Latin universal historian to the time of Augustus Cæsar, of whom we have only an abridgement by Justin, flourished about 41 B. C.

TROJA, the capital city of Troas, or, according to others, a country of which Ilium was the capital. It was built on a small eminence near Mount Ida, and the promontory of Sigæum, at the distance of about four miles from the sea-shore. Dardanus the first king of the country built it, and called it *Dardania*, and from Tros one of his successors it was called *Troja*, and from Ilus *Ilion*. This city has been celebrated by Homer and Virgil.

A description of the plain of Troy has been published in French in the 3d volume of the Philosophical Transactions of The Royal Society of Edinburgh, by M. Chevalier. The city of Troy, according to him, stood on the present site of the modern village of Bounarbachi, which is situated four leagues from the sea, on the side of an eminence, at the termination of a spacious plain, the soil of which is rich and of a blackish colour. Close to the village is to be seen a marsh covered with tall reeds; and the situation is impregnable on all sides except at Erin (Homer's ερινεος), the *hill of wild fig-trees*, which extended between the Scæan gate and the sources of the Scamander. In the plain there are several conical mounds or barrows, some of them 100 feet in diameter at the base; and which the author maintains to be the identical tombs raised over the ashes of the heroes of the Trojan war.

Since Chevalier's dissertation appeared, this plain has been investigated by Mr Morritt, Mr Gell, Dr Clarke, Mr Hobhouse, and several other travellers. Dr Clarke traversed the ground in different directions seventeen times. He rejects the hypothesis of Chevalier, and reasoning from the authority of Strabo, and from the scite of New Ilium, which he ascertained by inscriptions found among ruins, he fixes the situation of Troy four or five miles to the northward of Bournabachi, near a sluggish rivulet, called Califat Osmack, which he considers to be the Simois. The name of the Scamander is still preserved in the Mender, the most considerable stream in the district, rising in Mount Ida, as described by Homer; and the Thymbrius is still preserved in the Thymbrek. Dr Clarke also finds objects corresponding to the Calicolone, the tomb of Ilus, and the Throsmos or mound of the plain. But very strong objections have been stated to Dr Clarke's opinions by Mr Hobhouse and others; and, upon the whole, the more the subject is investigated, the more insuperable difficulties seem to present themselves to any attempt to identify the places and objects alluded to by the poet. See Clarke's Travels, vol. 3d, 8vo. and Edinburgh Review, vol. 6th, p. 257.

TROLLIUS, GLOBE-FLOWER, or *Lucken Gowan*, a genus of plants belonging to the class of polyandria; and in the natural system ranging under the 26th order, *Multisiliquæ*. See BOTANY *Index*.

TROMP, MARTIN HAPPERTZ VAN, a celebrated Dutch admiral, was born at the Baille, in Holland. He raised himself by his merit, after having distinguished himself on many occasions, especially at the famous engagement near Gibraltar in 1607. He passed for one of the greatest seamen that had till that time appeared in the world; and was declared admiral of Holland, even by the advice of the prince of Orange. He in that character defeated a large Spanish fleet in 1630, and gained 32 other victories at sea; but was killed when under deck, in an engagement with the English in 1653. The states-general caused medals to be struck to his honour, and lamented him as one of the greatest heroes of their republic. Van Tromp, in the midst

midst of the greatest glory, constantly discovered a remarkable modesty; for he never assumed a higher character than that of a burgher, and that of being the father of the sailors.

TRONAGE, an ancient customary duty or toll, for weighing of wool. According to Fleta, *trona* is a beam to weigh with, mentioned in the stat. Westm. 2. cap. 25. And tronage was used for the weighing wool in a staple or public mart, by a common trona or beam; which for the tronage of wool in London, was fixed at Leaden-Hall. The mayor and commonalty of London are ordained keepers of the beams and weights for weighing merchants commodities, with power to assign clerks and porters, &c. of the great beam and balance; which weighing of goods and wares is called *tronage*; and no stranger shall buy any goods in London before they are weighed at the king's beam, on pain of forfeiture.

TRONE-WEIGHT, the most ancient of the different weights used in Scotland; and, though now forbidden by several statutes, is still used by many for home commodities, and that in a very irregular manner; for the pound varies in different places, and for different purposes, from 20 to 24 Dutch ounces. The common allowance is 21½ ounces for wool, 20⅝ for butter and cheese, 20 for tallow, lint, hemp, and hay. It is divided into 16 of its own ounces, and 16 pounds make a stone.

TROOP, a small body of horse or dragoons, about 50 or 60, sometimes more, sometimes less, commanded by a captain, lieutenant, cornet, quarter-master, and three corporals, who are the lowest officers of a troop.

TROPE. See ORATORY, N° 52—66.

TROPHONIUS's CAVE, or *Oracle*, in *Ancient Geography*, a cave near Lebadia in Bœotia, between Helicon and Chæronea (Strabo): so called from Trophonius, an enthusiastic diviner; who, descending into this cave, pretended to give answers and pronounce oracles; and was hence called *Jupiter Trophonius*. Such as went down to this cave never after smiled; hence the proverbial saying of a man who has lost his mirth, That he is come out of Trophonius's cave. Though Pausanias affirms that persons came out of the cave affected indeed with a stupor, but that they soon after recovered themselves. Dr Clarke found the cave choaked up with stones. See ORACLE.

TROPHY (*Tropæum*), among the ancients, a monument of victory.

TROPIC-BIRD. See PHAETON, ORNITHOLOGY *Index*.

TROPICS. See GEOGRAPHY.

TROUBADOURS, poets that flourished in Provence during the 12th century.

They wrote poems on love and gallantry; on the illustrious characters and remarkable events of the times; satires which were chiefly directed against the clergy and monks; and a few didactic pieces. The troubadours were great favourites in different courts, diffused a taste for their language and for poetry over Europe, which was about that time sunk in ignorance and rudeness; they disappeared in the 14th century. A history of the troubadours in 3 vols. 12mo, was begun by M. de Sainte Palaie, and finished by the abbé Millot. See MUSIC.

TROUGH, GALVANIC. See GALVANISM. For later discoveries in galvanic electricity, see ZINC.

TROVER, in *Law*, an action that a man hath against one that, having found any of his goods, refuseth to deliver them upon demand.

TROUT. See SALMO, ICHTHYOLOGY *Index*.

TROY. See TROJA.

TROY-Weight, one of the most ancient of the different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades into Europe, and first adopted in *Troyes*, a city of Champagne; whence the name.

The pound *English* Troy contains 12 ounces, or 5760 grains. It was formerly used for every purpose; and is still retained for weighing gold, silver, and jewels; for compounding medicines; for experiments in natural philosophy; and for comparing different weights with each other.

Scots TROY-Weight was established by James VI. in the year 1618, who enacted that only one weight should be used in Scotland, viz. the French Troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7600 grains, and is equal to 17 oz. 6 dr. avoirdupois. The cwt. or 112 lb. avoirdupois, contains only 103 lb. 2½ oz. of this weight, though generally reckoned equal to 104 lb. This weight is nearly, if not exactly, the same as that of Paris and Amsterdam; and is generally known by the name of *Dutch weight*. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butcher-meat, unwrought pewter and lead, and some other articles.

TRUE-LOVE. See PARIS, BOTANY.

TRUFFLES. See LYCOPERDON, BOTANY *Index*.

TRUMPET, a musical instrument, the most noble of all portable ones of the wind kind; used chiefly in war, among the cavalry, to direct them in the service. Each troop of cavalry has one. The cords of the trumpets are of crimson, mixed with the colours of the facings of the regiments.

As to the invention of the trumpet, some Greek historians ascribe it to the Tyrrhenians; but others, with greater probability, to the Egyptians; from whom it might have been transmitted to the Israelites. The trumpet was not in use among the Greeks at the time of the Trojan war; though it was in common use in the time of Homer. According to Potter (*Arch. Græc.* vol. ii. cap. 9.), before the invention of trumpets, the first signals of battles in primitive wars were lighted torches; to these succeeded shells of fishes, which were sounded like trumpets. And when the trumpet became common in military use, it may well be imagined to have served at first only as a rough and noisy signal of battle, like that at present in Abyssinia and New Zealand, and perhaps with only one sound. But even when more notes were produced from it, so noisy an instrument must have been an unfit accompanyment for the voice and poetry; so that it is probable the trumpet was the first solo instrument in use among the ancients.

TRUMPET, Articulate, comprehends both the *speaking* and the *hearing* trumpet, is by much the most valuable instrument, and has, in one of its forms, been used by people among whom we should hardly have expected to find such improvements.

That the *speaking trumpet*, of which the object is to increase the force of articulate sounds, should have been known to the ancient Greeks, can excite no wonder; and

Trumpet.

and therefore we easily admit the accounts which we read of the horn or trumpet, with which Alexander addressed his army, as well as of the whispering caverns of the Syracusan tyrant. But that the natives of Peru were acquainted with this instrument, will probably surprise many of our readers. The fact, however, seems incontrovertible.

In the History of the Order of Jesuits, published at Naples in 1601 by Beritaria, it is said, that in the year 1595 a small convent of that order in Peru, situated in a remote corner, was in danger of immediate destruction by famine. One evening the superior Father Samaniac implored the help of the cacique; next morning, on opening the gate of the monastery, he found it surrounded by a number of women each of whom carried a small basket of provisions. He returned thanks to heaven for having miraculously interposed, by inspiring the good people with pity for the distress of his friars. But when he expressed to them his wonder how they came all to be moved as if by mutual agreement with these benevolent sentiments, they told him it was no such thing; that they looked upon him and his countrymen as a pack of infernal magicians, who by their sorceries had enslaved the country, and had bewitched their good cacique, who hitherto had treated them with kindness and attention, as became a true worshipper of the sun; but that the preceding evening at sunset he had ordered the inhabitants of such and such villages, about six miles off, to come that morning with provisions to this nest of wizzards.

The superior asked them in what manner the governor had warned so many of them in so short a time, at such a distance from his own residence? They told him that it was by the trumpet; and that every person heard at their own door the distinct terms of the order. The father had heard nothing; but they told him that none heard the trumpet but the inhabitants of the villages to which it was directed. This is a piece of very curious information; but, after allowing a good deal to the exaggeration of the reverend Jesuits, it cannot, we think, be doubted but that the Peruvians actually possessed this stentorophonic art. For we may observe that the effect described in this narration resembles what *we now know* to be the effect of speaking trumpets, while it is unlike what the inventor of such a tale would naturally and ignorantly say. Till speaking trumpets were really known, we should expect the sound to be equally diffused on all sides, which is not the case; for it is much stronger in the line of the trumpet than in any direction very oblique to it.

About the middle of the 17th century, Athanasius Kircher turned his attention to the philosophy of sound, and in different works threw out many useful and scientific hints on the construction of speaking trumpets (see ACOUSTICS and KIRCHER); but his mathematical illustrations were so vague, and his own character of inattention and credulity so notorious, that for some time these works did not attract the notice to which they were well entitled.

About the year 1670, Sir Samuel Morland, a gentleman of great ingenuity, science, and order, took up the subject, and proposed as a question to the Royal Society of London, What is the best form for a speaking trumpet? which he called a stentorophonic horn. He accompanied his demand with an account of his own notions on the subject (which he acknowledged to be very vague and conjectural), and an exhibition of some instruments constructed according to his views. They were in general very large conical tubes, suddenly spreading at the very mouth to a greater width. Their effect was really wonderful. They were tried in St James's park; and his majesty K. Charles II. speaking in his ordinary colloquial pitch of voice through a trumpet only $5\frac{1}{2}$ feet long, was clearly and most distinctly heard at the distance of a thousand yards. Another person, selected we suppose for the loudness and distinctness of his voice, was perfectly understood at the distance of four miles and a half. The fame of this soon spread; Sir Samuel Morland's principles were refined, considering the novelty of the thing, and differ considerably from Father Kircher's. The aerial undulations, (for he speaks very accurately concerning the nature of sound) endeavour to diffuse themselves in spheres, but are stopped by the tube, and therefore reundulate towards the axis like waves from a bank, and meeting in the axis, they form a strong undulation a little farther advanced along the tube, which again spreads, is again reflected, and so on, till it arrives at the mouth of the tube greatly magnified, and then it is diffused through the open air in the same manner, as if all proceeded from a very sonorous point in the centre of the wide end of the trumpet. The author distinguishes with great judgement between the prodigious reinforcement of sound in a speaking trumpet and that in the musical trumpet, bugle-horn, conch-shell, &c.; and shows that the difference consists only in the violence of the first sonorous agitation, which can be produced by us only on a very small extent of surface. The mouth-piece diameter, therefore, of the musical trumpet must be very small, and the force of blast very considerable. Thus one strong but simple undulation will be excited, which must be subjected to the modifications of harmony, and will be augmented by using a conical tube (A). But a speaking trumpet must make no change on the nature of the first undulations; and each point of the mouth-piece must be equally considered as the centre of sonorous undulations, all of which must be reinforced in the same degree, otherwise all distinctness of articulation will be lost. The mouth-piece must therefore take in the whole of the mouth of the speaker.

When Sir Samuel Morland's trumpet came to be generally known on the continent, it was soon discovered that the speaker could be heard at a great distance only in the line of the trumpet; and this circumstance was by a Mr Cassegrain (*Journ. des Sçavans*, 1672, p. 131.) attributed to a defect in the principle of its construction, which he said was not according to the laws of sonorous undulations. He proposed a conoid formed by the revolution of a hyperbola round its assymptote as the best form. A Mr Hase of Wirtemberg, on the other hand, proposed a parabolic conoid, having the mouth of the speaker

(A) Accordingly the sound of the bugle horn, of the musical trumpet, or the French horn, is prodigiously loud, when we consider the small passage through which the moderate blast is sent by the trumpeter.

Trumpet speaker placed in the focus. In this construction he plainly went on the principle of a reflection similar to that of the rays of light; but this is by no means the case. The effect of the parabola will be to give one reflection, and in this all the circular undulations will be converted into plane waves, which are at right angles to the axis of the trumpet. But nothing hinders their subsequent diffusion; for it does not appear that the sound will be enforced, because the agitation of the particles on each wave is not augmented.

The subject is exceedingly difficult. We do not fully comprehend on what circumstance the affection or agitation of our organ, or simply of the membrana tympani, depends. A more violent agitation of the same air, that is, a wider oscillation of its particles, cannot fail to increase the impulse on this membrane. The point therefore is to find what concourse of feeble undulations will produce or be equivalent to a great one. The reasonings of all these restorers of the speaking trumpet are almost equally specious, and each point out some phenomenon which should characterise the principle of construction, and thus enable us to say which is most agreeable to the procedure of nature. Yet there is hardly any difference in the performance of trumpets of equal dimensions made after these different methods.

The propagation of light and of elastic undulations seem to require very different methods of management. Yet the ordinary phenomena of echoes are perfectly explicable by the acknowledged laws either of optics or acoustics; still however there are some phenomena of sound which are very unlike the genuine results of elastic undulations. If sounds are propagated spherically, then what comes into a room by a small hole should diffuse itself from that hole as round a centre, and it should be heard equally well at twelve feet distance from the hole in every direction. Yet it is very sensibly louder when the hearer is in the straight line drawn from the sonorous body through the hole. A person can judge of the direction of the sounding body with tolerable exactness. Cannon discharged from the different sides of a ship are very easily distinguished, which should not be the case by the Newtonian theory; for in this the two pulses on the ear should have no sensible difference.

The most important fact for our purpose is this: An echo from a small plane surface in the midst of an open field is not heard, unless we stand in such a situation that the angle of reflected sound may be equal to that of incidence. But by the usual theory of undulations, this small surface should become the centre of a new undulation, which should spread in all directions. If we make an analogous experiment on watery undulations, by placing a small flat surface so as to project a little above the water, and then drop in a small pebble at a distance, so as to raise one circular wave, we shall observe, that when this wave arrives at the projecting plane, it is disturbed by it, and this disturbance spreads from it on all sides. It is indeed sensibly stronger in that line which is drawn from it at equal angles with the line drawn to the place where the pebble was dropped. But in the case of sound, it is a fact, that if we go to a very small distance on either side of the line of reflection, we shall hear nothing.

Here then is a fact, that whatever may be the nature of the elastic undulations, sounds are reflected from a small plane in the same manner as light. We may avail ourselves of this fact as a mean for enforcing sound, though we cannot explain it in a satisfactory manner. We should expect from it an effect similar to the hearing of the original sound along with another original sound coming from the place from which this reflected sound diverges. If therefore the reflected sound or echo arrives at the ear in the same instant with the original sound, the effect will be doubled; or at least it will be the same with two simultaneous original sounds. Now we know that this is in some sense equivalent to a stronger sound. For it is a fact, that a number of voices uttering the same or equal sounds are heard at a much greater distance than a single voice. We cannot perhaps explain how this happens by mechanical laws, nor assign the exact proportion in which 10 voices exceed the effect of one voice; nor the proportion of the distances at which they seem equally loud. We may therefore, for the present, suppose that two equal voices at the same distance are twice as loud, three voices three times as loud, &c. Therefore, if by means of a speaking trumpet, we can make 10 equal echoes arrive at the ear at the same moment, we may suppose its effect to be to increase the audibility 10 times; and we may express this shortly, by calling the sound 10 times louder or more intense.

Trumpet.

But we cannot do this precisely. We cannot by any contrivance make the sound of a momentary snap, and those of its echoes, arrive at the ear in the same moment, because they come from different distances. But if the original noise be a continued sound, a man's voice, for example, uttering a continued uniform tone, the first echo may reach the ear at the same moment with the second vibration of the larynx; the second echo along with the third vibration, and so on. It is evident, that this will produce the same effect. The only difference will be, that the articulations of the voice will be made indistinct, if the echoes come from very different distances. Thus if a man pronounce the syllable *taw*, and the 10 successive echoes are made from places which are 10 feet farther off, the 10th part of a second (nearly) will intervene between hearing the first and the last. This will give it the sound of the syllable *thaw*, or perhaps *raw*, because *r* is the repetition of *t*. Something like this occurs when, standing at one end of a long line of soldiers, we hear the muskets of the whole line discharged in one instant. It seems to us the sound of a running fire.

The aim therefore in the construction of a speaking trumpet may be, to cause as many echoes as possible to reach a distant ear without any perceptible interval of time. This will give distinctness, and something equivalent to loudness. *Pure* loudness arises from the violence of the single aerial undulation. To increase this may be the aim in the construction of a trumpet; but we are not sufficiently acquainted with the mechanism of these undulations to bring this about with certainty and precision; whereas we can procure this accumulation of echoes without much trouble, since we know that echoes are, *in fact*, reflected like light. We can form a trumpet so that many of these lines of reflected sound shall pass through the place of the hearer. We are indebted to Mr Lambert of Berlin for this simple and popular view of the subject; and shall here give an abstract of his most ingenious Dissertation on Acoustic Instruments published in the Berlin Memoirs for 1763.

Sound

Trumpet.

Sound naturally spreads in all directions; but we know that echoes or reflected sounds proceed almost strictly in certain limited directions. If therefore we contrive a trumpet in such a way that the lines of echo shall be confined within a certain space, it is reasonable to suppose that the sound will become more audible in proportion as this diffusion is prevented. Therefore, if we can oblige a sound which, in the open air, would have diffused itself over a hemisphere, to keep within a cone of 120 degrees, we should expect it to be twice as audible within this cone. This will be accomplished, by making the reflections such that the lines of reflected sound shall be confined within this cone. *N. B.* We here suppose that nothing is lost in the reflection. Let us examine the effect of a cylindrical trumpet.

Plate DXXXIX. fig. 1.

Let the trumpet be a cylinder ABED, (fig. 1.), and let C be a sounding point in the axis. It is evident that all the sound in the cone BCE will go forward without any reflection. Let CM be any other line of sound, which we may for brevity's sake, call a *sonorous* or *phonic line*. Being reflected in the points M, N, O, P, it is evident that it will at last escape from the trumpet in a direction PQ, equally diverging from the axis with the line CM. The same must be true of every other sonorous line. Therefore the echoes will all diverge from the mouth of the trumpet in the same manner as they would have proceeded from C without any trumpet. Even supposing, therefore, that the echoes are as strong as the original sound, no advantage is gained by such a trumpet, but that of bringing the sound forward from C to *c*. This is quite trifling when the hearer is at a distance. Yet we see that sounds may be heard at a very great distance, at the end of long, narrow, cylindrical, or prismatical galleries. It is known that a voice may be distinctly heard at the distance of several hundred feet in the Roman aqueducts, whose sides are perfectly straight and smooth, being plastered with stucco. The smooth surface of the still water greatly contributes to this effect. Cylindrical or prismatical trumpets must therefore be rejected.

Let the trumpet be a cone BCA (fig. 2.), of which CN is the axis, DK a line perpendicular to the axis, and DFHI the path of a reflected sound in the plane of the axis. The last angle of reflection IHA is equal to the last angle of incidence FHC. The angle BFH, or its equal CFD, is equal to the angles FHD and FCH; that is, the angle of incidence CFD exceeds the next angle of incidence FHC by the angle FCD; that is, by the angle of the cone. In like manner, FDH exceeds CFD by the same angle FCD. Thus every succeeding angle, either of incidence or reflection, exceeds the next by the angle of the cone. Call the angle of the cone a, and let b be the first angle of incidence PDC. The second, or DFC, is $b-a$. The third, or FHC, is $b-2a$, &c.: and the nth angle of incidence or reflection is $b-na$, after n reflections. Since the angle diminishes by equal quantities at each subsequent reflection, it is plain, that whatever be the first angle of incidence, it may be exhausted by this diminution; namely, when n times a exceeds or is equal to b. Therefore to know how many reflections of a sound, whose first incidence has the inclination b, can be made in an infinitely extended cone, whose angle is a, divide b by a; the quotient will give the number n of reflections, and the remainder, if any, will be the last angle of incidence or reflection less than a. It is very plain, that when an angle of reflection IHA is equal to or less than the angle BCA of the cone, the reflected line HI will no more meet with the other side CB of the cone.

Trumpet.

We may here observe, that the greatest angle of incidence is a right angle, or 90°. This sound would be reflected back in the same line, and would be incident on the opposite side in an angle $=90^\circ-a$, &c.

Thus we see that a conical trumpet is well suited for confining the sound: for by prolonging it sufficiently, we can keep the lines of reflected sound wholly within the cone. And when it is not carried to such a length as to do this, when it allows the sounding line GH, for example, to escape without farther reflection, the divergency from the axis is less than the last angle of reflection BGH by half the angle BCA of the cone. Let us see what is the connection between the length and the angle of ultimate reflection.

We have sin. $\overline{b-a}$: sin. b = CD : CF, and CF $=$ CD $\times \frac{\text{sin. } b}{\text{sin. } \overline{b-a}}$, and sin. $\overline{b-2a}$: sin. $\overline{b-a}$ = CF : CH, and CH $=$ CF $\times \frac{\text{sin. } \overline{b-a}}{\text{sin. } \overline{b-2a}} =$ CD $\times \frac{\text{sin. } b}{\text{sin. } \overline{b-a}} \times \frac{\text{sin. } \overline{b-a}}{\text{sin. } \overline{b-2a}}, =$ CD $\times \frac{\text{sin. } b}{\text{sin. } \overline{b-2a}}$, &c.

Therefore if we suppose X to be the length which will give us n reflections, we shall have X $=$ CD $\times \frac{\text{sin. } b}{\text{sin. } \overline{b-na}}$. Hence we see that the length increases as the angle $\overline{b-na}$ diminishes; but is not infinite, unless na is equal to b. In this case, the immediately preceding angle of reflection must be a, because these angles have the common difference a. Therefore the last reflected sound was moving parallel to the opposite side of the cone, and cannot again meet it. But though we cannot assign the length which will give the nth reflection, we can give the length which will give the one immediately preceding, whose angle with the side of the cone is a. Let Y be this length. We have Y $=$ CD $\times \frac{\text{sin. } b}{\text{sin. } a}$. This length will allow every line of sound to be reflected as often, saving once, as if the tube were infinitely long. For suppose a sonorous line to be traced backwards, as if a sound entered the tube in the direction $i\,h$, and were reflected in the points h, f, d, d, D, the angles will be continually augmented by the constant angle a. But this augmentation can never go farther than $90^\circ+\frac{1}{2}a$. For if it reaches that value at D, for instance, the reflected line DK will be perpendicular to the axis CN; and the angle ADK will be equal to the angle DKB, and the sound will come out again. This remark is of importance on another account.

Now suppose the cone to be cut off at D by a plane perpendicular to the axis, KD will be the diameter of its mouth-piece; and if we suppose a mouth completely occupying this circle, and every point of the circle to be sonorous, the reflected sounds will proceed from it in the same manner as light would from a flame which completely occupies its area, and is reflected by the inside of the cone. The angle FDA will have the greatest possible sine when it is a right angle, and it never can be greater than ADK, which is $=90+\frac{1}{2}a$. And since between $90^\circ+\frac{1}{2}a$, and $90-\frac{1}{2}a$, there must fall some multiple of a; call this multiple b. Then, in order that every sound may be reflected as often as possible, saving once, we must make the length of it $X = CD \times \frac{S,b}{S,a}$.

Now since the angle of the cone is never made very great, never exceeding 10 or 12 degrees, b can never differ from 90 above a degree or two, and its sine cannot differ much from unity. Therefore X will be very nearly equal to $\frac{CD,}{S,a}$, which is also very nearly equal to $\frac{CD}{2S,\frac{1}{2}a}$; because a is small, and the sines of small arches are nearly equal and proportional to the arches themselves. There is even a small compensation of errors in this formula. For as the sine of 90° is somewhat too large, which would give X too great, $2S,\frac{1}{2}a$ is also larger than the sine of a. Thus let a be 12°: then the nearest multiple of a is 84 or 96°, both of which are as far removed as possible from 90°, and the error is as great as possible, and is nearly $\frac{1}{160}$th of the whole.

This approximation gives us a very simple construction. Let CM be the required length of the trumpet, and draw ML perpendicular to the axis in O. It is evident that S, MCO : rad. = MO : CM, and CM; or $X=\frac{MO}{S,\frac{1}{2}a}=\frac{LM}{2S,\frac{1}{2}a}$, but $X=\frac{CD}{2S,\frac{1}{2}a}$, and therefore LM is equal to CD.

If therefore the cone be of such a length, that its diameter at the mouth is equal to the length of the part cut off, every line of sound will have at least as many reflections, save one, as if the cone were infinitely long; and the last reflected line will either be parallel to the opposite side of the cone, or lie nearer the axis than this parallel; consequently such a cone will confine all the reflected sounds within a cone whose angle is $2a$, and will augment the sound in the proportion of the spherical base of this cone to a complete hemispherical surface. Describe the circle DKT round C, and making DT an arch of 90, draw the chord DT. Then since the circles described with the radii DK, DT, are equal to the spherical surfaces generated by the revolution of the arches DK and DKT round the axis CD, the sound will be condensed in the proportion of DK^2 to DT^2.

This appears to be the best general rule for constructing the instrument; for, to procure another reflection, the tube must be prodigiously lengthened, and we cannot suppose that one reflection more will add greatly to its power.

It appears, too, that the length depends chiefly on the angle of the cone; for the mouth-piece may be considered as nearly a fixed quantity. It must be of a size to admit the mouth when speaking with force and without constraint. About an inch and a half may be fixed on for its diameter. When therefore we propose to confine the sound to a cone of twice the angle of the trumpet, the whole is determined by that angle. For since in this case LM is equal to CD, we have DK : CD = LM (or CD) : CM and $CM=\frac{CD^2}{DK}$.

$$\begin{array}{lll} \text{But} & 2S,\tfrac{1}{2}a : 1 = DK : CD, \\ \text{and} & 2S,\tfrac{1}{2}a : 1 = CD : CM ; \\ \text{therefore} & 4S,^2\tfrac{1}{2}a : 1 = DK : CM, \end{array}$$

$$\text{And} \quad CM=\frac{DK}{4S,^2\frac{1}{2}a}, =\frac{DK}{S,^2a} \text{ very nearly.}$$

And since DK is an inch and a half, we get the length in inches, counted from the apex of the cone $=\frac{1\frac{1}{2}}{S,^2a}$, or $\frac{3}{2S,^2a}$. From this we must cut off the part CD, which is $=\frac{DK}{S,\frac{1}{2}a}$, or very nearly $\frac{DK}{S,a}$, or $\frac{3}{2S,a}$, measured in inches, and we must make the mouth of the same width $\frac{3}{2S,a}$.

On the other hand, if the length of the trumpet is fixed on, we can determine the angle of the cone. For let the length (reckoned from C) be L; we have $2S,^2a=\frac{3}{L}$, or $S,^2a=\frac{3}{2L}$, and $S,a=\sqrt{\frac{3}{2L}}$.

Thus let 6 feet or 72 inches be chosen for the length of the cone, we have $S,a=\sqrt{\frac{3}{144}}=\sqrt{\frac{1}{48}}$, $=014434$ $=$ sin. $8^\circ 17'$ for the angle of the cone; and the width at the mouth is $\frac{3}{2,S,a}=10{,}4$ inches. This being taken from 72, leaves 61,6 inches for the length of the trumpet.

And since this trumpet confines the reflected sounds to a cone of $16^\circ 34'$, we have its magnifying power $=\frac{DT^2}{DK^2}$, $=\frac{\frac{1}{2}DT^2}{\frac{1}{2}DK^2}=\frac{S,^2 45^\circ}{S,^2 4^\circ 8'\frac{1}{2}}=96$ nearly. It therefore condenses the sound about 96 times; and if the distribution were uniform, it would be heard $\sqrt{96}$, or nearly 10 times farther off. For the loudness of sounds is supposed to be inversely as the square of the distance from the centre of undulation.

But before we can pronounce with precision on the performance of a speaking trumpet, we must examine into the manner in which the reflected sounds are distributed over the space in which they are all confined.

Let BKDA (fig. 3.) be the section of a conical trumpet by a plane through the axis; let C be the vertex of the cone, and CW its axis; let TKV be the section of a sphere, having its centre in the vertex of the cone; and let P be a sonorous point on the surface of the sphere, and P *a f e l* the path of a line of sound lying in the plane of the section. Fig. 3.

In the great circle of the sphere take KQ=KP, DR =DQ, and KS=KR. Draw QB *h*; also draw Q *d n* parallel to DA; and draw PB, P *d*, PA.

1. Then it is evident that all the lines drawn from P, within the cone APB, proceed without reflection, and are diffused as if no trumpet had been used.

2. All

Trumpet.

2. All the sonorous lines which fall from P on KB are reflected from it as if they had come from Q.

3. All the sonorous lines between BP and *d* P have suffered but one reflection; for *d n* will no more meet DAA′ so as to be reflected again.

4. All the lines which have been reflected from KB, and afterwards from DA, proceed as if they had come from R. For the lines reflected from KB proceed as if they had come from Q; and lines coming from Q and reflected by DA, proceed as if they had come from R. Therefore draw RA *o*, and also draw R*g m* parallel to KB, and draw Q *c* A *q*, Q *b g*, P *c*, and P *b*. Then,

5. All the lines between *b* P and *c* P have been twice reflected.

Again, draw SB *p*, B *r* R, *r u* Q, S *x* A, R*y x*, Q*z y*.

6. All the lines between *u* P and *z* P have suffered three reflections.

Draw the tangents TA *t*, VB *v*, crossing the axis in W.

7. The whole sounds will be propagated within the cone *v* W *t*. For to every sonorous point in the line KD there corresponds a point similar to Q, regulating the first reflection from KB; and a point similar to R, regulating the second reflection from DA; and a point S regulating the third reflection from KB, &c. And similar points will be found regulating the first reflection from DA, the second from KB, and the third from DA, &c.; and lines drawn from all these through A and B must lie within the tangents TA and VB.

8. Thus the centres of reflection of all the sonorous lines which lie in planes passing through the axis, will be found in the surface of this sphere; and it may be considered as a sonorous sphere, whose sounds first concentrate in W, and are then diffused in the cone *v* W *t*.

It may be demonstrated nearly in the same manner, that the sonorous lines which proceed from P, but not in the plane passing through the axis, also proceed, after various reflections, as if they had come from points in the surface of the same sphere. The only difference in the demonstration is, that the centres Q, R, S of the successive reflections are not in one plane, but in a spiral line winding round the surface of the sphere according to fixed laws. The foregoing conclusions are therefore general for all the sounds which come in all directions from every point in the area of the mouth piece.

Thus it appears, that a conical trumpet is well fitted for increasing the force of sounds by diminishing their final divergence. For had the speaker's mouth been in the open air, the sounds which are now confined within the cone *v* W *t* would have been diffused over a hemisphere: and we see that prolonging the trumpet must confine the sounds still more, because this will make the angle BWA still smaller; a longer tube must also occasion more reflections, and consequently send more sonorous undulations to the ear at a distance placed within the cone *v* W *t*.

We have now obtained a very connected view of the whole effect of a conical trumpet. It is the same as if the whole segment TKDV were sounding, every part of it with an intensity proportional to the density of the points Q, R, S, &c. corresponding to the different points P of the mouth-piece. It is easy to see that this cannot be uniform, but must be much rarer towards the margin of the segment. It would require a good deal of discussion to show the density of these fictitious sounding points; and we shall content ourselves with giving a very palpable view of the distribution of the sonorous rays, or the density (so to speak) of the echoes, in the different situations in which a hearer may be placed.

Trumpet.

We may observe, in the mean time, that this substitution of a sounding sphere for the sounding mouth-piece has an exact parallel in OPTICS, by which it will be greatly illustrated. Suppose the cone BKDA (fig. 3.) to be a tube polished in the inside, fixed in a wall B *a*, perforated in BA, and that the mouth-piece DK is occupied completely by a flat flame. The effect of this on a spectator will be the same, if he is properly placed in the axis, as if he were looking at a flame as big as the whole sphere. This is very evident. Fig. 3.

It is easy to see that the line *l e* S is equal to the line *l e f a* P; therefore the reflected sounds also come to the ear in the same moments as if they had come from their respective points on the surface of the substituted sphere. Unless, therefore, this sphere be enormously large, the distinctness of articulation will not be sensibly affected, because the interval between the arrival of the different echoes of the same snap will be insensible.

Our limits oblige us to content ourselves with exhibiting this evident similarity of the progress of echo from the surface of this phonic sphere, to the progress of light from the same luminous sphere shining through a hole of which the diameter is AB. The direct investigation of the intensity of the sound in different directions and distances would take up much room, and give no clearer conception of the thing. The intensity of the sound in any point is precisely similar to the intensity of the illumination of the same point; and this is proportional to the portion of the luminous surface seen from this point through the hole directly, and to the square of the distance inversely. The intelligent reader will acquire a distinct conception of this matter from fig. 4. which represents the distribution of the sonorous lines, and by consequence the degree of loudness which may be expected in the different situations of the hearer.

As we have already observed, the effect of the cone of the trumpet is perfectly analogous to the reflection of light from a polished concave, conical mirror. Such an instrument would be equally fitted for illuminating a distant object. We imagine that these would be much more powerful than the spherical or even parabolic mirrors commonly used for this purpose. These last, having the candle in the focus, also send forward a cylinder of light of equal width with the mirror. But it is well known, that oblique reflections are prodigiously more vivid than those made at greater angles. Where the inclination of the reflected light to the plane of the mirror does not exceed eight or ten degrees, it reflects about three-fourths of the light which falls on it. But when the inclination is 80, it does not reflect one-fourth part.

We may also observe, that the density of the reflected sounds by the conical trumpet ABC (fig. 4.) is precisely similar to that of the illumination produced by a luminous sphere TDV, shining through a hole AB. There will be a space circumscribed by the cone formed by the lines TB *t* and VA *v*, which is uniformly illuminated by the whole sphere (or rather by the segment TDV), and on each side there is a space illuminated by a Fig. 4.

Fig. 1.

Trumpet.

a part of it only, and the illumination gradually decreases towards the borders. A spectator placed much out of the axis, and looking through the hole AB, may not see the whole sphere. In like manner, he will not hear the whole sounding sphere: He may be so far from the axis as neither to see nor hear any part of it.

Assisting our imagination by this comparison, we perceive that beyond the point w' there is no place where *all* the reflected sounds are heard. Therefore, in order to preserve the magnifying power of the trumpet at any distance, it is necessary to make the mouth as wide as the sonorous sphere. Nay, even this would be an imperfect instrument, because its power would be confined to a very narrow space; and if it be not accurately pointed to the person listening, its power will be greatly diminished. And we may observe, by the way, that we derive from this circumstance a strong confirmation of the justness of Mr Lambert's principles; for the effects of speaking trumpets are really observed to be limited in the way here described.—Parabolic trumpets have been made, and they fortify the sound not only in the cylindrical space in the direction of the axis, but also on each side of it, which should not have been the case had their effect depended only on the undulations formed by the parabola in planes perpendicular to the axis. But to proceed.

Fig. 5. Let BCA (fig. 5.) be the cone, ED the mouth-piece, TEDV the equivalent sonorous sphere, and TBAV the circumscribed cylinder. Then CA or CB is the length of cone that is necessary for maintaining the magnifying power at all distances. We have two conditions to be fulfilled. The diameter ED of the mouth-piece must be of a certain fixed magnitude, and the diameter AB of the outer end must be equal to that of the equivalent sonorous sphere. These conditions determine all the dimensions of the trumpet and its magnifying power. And, first, with respect to the dimensions of the trumpet.

The similarity of the triangles ECG and BCF gives $CG : ED = CF : AB$; but $CG = BF, = \frac{1}{2} AB$, and $CF = CG + GF, = GF + \frac{1}{2} AB$; therefore $\frac{1}{2} AB : ED = GF + \frac{1}{2} AB : AB$, and $AB : ED = 2\,GF + AB : AB$; therefore $2\,GF \times ED + AB \times ED = AB^2$, and $2\,GF \times ED = AB^2, - AB \times ED, = AB \times \overline{AB - ED}$,

and $GF = \dfrac{AB \times \overline{AB - ED}}{2\,ED}$. And, on the other hand, because $AB^2 - EB \times AD = 2\,GF \times ED$, we have $AB^2 - AB \times ED + \frac{1}{4} ED^2 = 2\,GF \times ED + \frac{1}{4} ED^2$, or $\overline{AB - \frac{1}{2} ED}^2 = 2\,GF \times ED + \frac{1}{4} ED^2$, and $AB = \sqrt{2\,GF \times ED + \frac{1}{4} ED^2} + \frac{1}{2} ED$.

Let x represent the length of the trumpet, y the diameter at the great end, and m the diameter of the mouth-piece. Then $x = \dfrac{y \times \overline{y - m}}{2\,m}$, and $y = \sqrt{2xm + \frac{1}{4} m^2} + \frac{1}{2} m$.

Thus the length and the great diameter may be had reciprocally. The useful case in practice is to find the diameter for a proposed length, which is gotten by the last equation.

Now if we take all the dimensions in inches, and fix m at an inch and a half, we have $2\,x\,m = 3\,x$, and $\frac{1}{4} m^2 = 0{,}5625$, and $\frac{1}{2} m = 0{,}75$; so that our equation becomes $y = \sqrt{3x + 0{,}5625} + 0{,}75$. The following table gives the dimensions of a sufficient variety of trumpets. The first column is the length of the trumpet in feet; the second column is the diameter of the mouth in inches; the third column is the number of times that it magnifies the sound; and the fourth column is the number of times that it increases the distance at which a man may be distinctly heard by its means; the fifth contains the angle of the cone.

GF feet.	AB. Inches.	Magnifying.	Extending.	ACB.
				° ′
1	6.8	42.6	6.5	24.53
2	9.3	77.8	8.8	18.23
3	11.2	112.4	10.6	15.18
4	12.8	146.6	12.1	13.24
5	14.2	180.4	13.4	12.04
6	15.5	214.2	14.6	11.05
7	16.6	247.7	15.7	10.18
8	17.7	281.3	16.8	9.40
9	18.8	314.6	17.7	9.08
10	19.8	347.7	18.6	8.42
11	20.7	380.9	19.5	8.18
12	21.5	414.6	20.4	7.58
15	24.	513.6	22.7	7.09
18	26.2	612.3	24.7	6.33
21	28.3	711.2	26.6	6.05
24	30.2	810.1	28.5	5.42
ED in all is = 1.5				

The two last columns are constructed on the following considerations: We conceive the hearer placed within the cylindrical space whose diameter is BA. In this situation he receives an echo coming apparently from the whole surface TGV; and we account the effect of the trumpet as equivalent to the united voices of as many mouths as would cover this surface. Therefore the quotient obtained by dividing the surface of the hemisphere by that of the mouth-piece will express the magnifying power of the trumpet. If the chords g E, g T, be drawn, we know that the spherical surfaces T g V, E g D, are respectively equal to the circles described with the radii T g, E g, and are therefore as T g^2 and E g^2. Therefore the audibility of the trumpet, when compared with a single voice, may be expressed by $\dfrac{T\,g^2}{E\,g^2}$. Now the ratio of T g^2 to E g^2 is easily obtained. For if E f be drawn parallel to the axis, it is plain that $B\,f = \dfrac{BA - ED}{2}$, and that E f is to f B as radius to the tangent of BCF; which angle we may call a. Therefore $\tan.\ a = \dfrac{y - m}{2\,x}$, and thus we obtain the angle a. But if the radius CE be accounted 1, T g is $= \sqrt{2}$, and E g is $= 2 \sin. \frac{a}{2}$. Therefore $\dfrac{T\,g}{E\,g} = \dfrac{\sqrt{2}}{2 \sin. \frac{a}{2}}$, and the magnifying power of the trumpet is $= \dfrac{2}{4 \sin.^2 \frac{a}{2}}$, Trumpet. $= \frac{1}{2 \sin.^2 \frac{a}{2}}$. The numbers, therefore, in the third column of the table are each $= \frac{1}{2 \sin.^2 \frac{a}{2}}$.

But the more usual way of conceiving the power of the trumpet is, by considering how much farther it will enable us to hear a voice equally well. Now we suppose that the audibility of sounds varies in the inverse duplicate ratio of the distance. Therefore if the distance d, at which a man may be distinctly heard, be increased to z, in the proportion of EG to Tg, the sound will be less audible, in the proportion of Tg^2 to EG^2. Therefore the trumpet will be as well heard at the distance z as the simple voice is heard at the distance d. Therefore $\frac{z}{d}$ will express the *extending power* of the trumpet, which is therefore $= \frac{\sqrt{2}}{2 \sin. \frac{a}{2}}$. In this manner were the numbers computed for the fourth column of the table.

When the angle BCA is small, which is always the case in speaking trumpets, we may, without any sensible error, consider EG as $= \frac{ED}{2}, = \frac{m}{2}$. And TG=TC $\times \sqrt{2}, = \frac{AB}{2}\sqrt{2} = \frac{AB}{\sqrt{2}} = \frac{y}{\sqrt{2}}$. This gives a very easy computation of the extending and magnifying powers of the trumpet.

The extending power is $= \sqrt{2}\,\frac{y}{m}$.

The magnifying power is $= 2\,\frac{y^2}{m^2}$.

We may also easily deduce from the premises, that if the mouth-piece be an inch and a half in diameter, and the length x be measured in inches, the extending power is very nearly $= \sqrt{\frac{8}{5}x}$ and the magnifying power $= \frac{8}{5}x$.

An inconvenience still attends the trumpet of this construction. Its complete audibility is confined to the cylindrical space in the direction of the axis, and it is more faintly heard on each side of it. This obliges us to direct the trumpet very exactly to the spot where we wish it to be heard. This is confirmed by all the accounts we have of the performance of great speaking trumpets. It is evident, that by lengthening the trumpet, and therefore enlarging its mouth, we make the lines TB t and VA v expand (fig. 4.); and therefore it will not be so difficult to direct the trumpet.

Fig. 4.

But even this is confined within the limits of a few degrees. Even if the trumpet were continued without end, the sounds cannot be reinforced in a wider space than the cone of the trumpet. But it is always advantageous to increase its length; for this makes the extreme tangents embrace a greater portion of the sonorous sphere, and thus increases the sound in the space where it is all reflected. And the limiting tangents TB, VA, expand still more, and thus the space of full effect is increased. But either of these augmentations is very small in comparison of the augmentation of size. If the trumpet of fig. 5. were made an hundred times longer, its power would not be increased one half.

Trumpet.

We need not therefore aim at much more than to produce a cylindrical space of full effect; and this will always be done by the preceding rules, or table of constructions. We may give the trumpet a third or a fourth part more length, in order to spread a little the space of its full effect, and thereby make it more easily directed to the intended object. But in doing this we must be careful to increase the diameter of the mouth as much as we increase the length; otherwise we produce the very opposite effect, and make the trumpet greatly inferior to a shorter one, at all distances beyond a certain point. For by increasing the length while the part CG remains the same, we cause the tangents TB and VA to meet on some distant point, beyond which the sound diffuses prodigiously. The construction of a speaking trumpet is therefore a problem of some nicety; and as the trials are always made at some considerable distance, it may frequently happen that a trumpet which is not heard at a mile's distance, may be made very audible two miles off by cutting off a piece at its wide end.

After this minute consideration of the conical trumpet, we might proceed to consider those of other forms. In particular, the hyperbolic, proposed by Cassegrain, and the parabolic, proposed by Haase, seem to merit consideration. But if we examine them merely as reflectors of echoes, we shall find them inferior to the conical.

With respect to the hyperbolic trumpet, its inaptitude is evident at first sight. For it must dissipate the echoes more than a conical trumpet. Indeed Mr Cassegrain proceeds on quite different principles, depending on the mechanism of the aerial undulations: his aim was to increase the agitation in each pulse, so that it may make a more forcible impulse on the ear. But we are too imperfectly acquainted with this subject to decide *à priori*; and experience shows that the hyperbola is not a good form.

With respect to the parabolic trumpet, it is certain that if the mouth-piece were but a point, it would produce the most favourable reflection of all the sounds; for they would all proceed parallel to the axis. But every point of an open mouth must be considered as a centre of sound, and none of it must be kept out of the trumpet. If this be all admitted, it will be found that a conical trumpet, made by the preceding rules, will dissipate the reflected sounds much less than the parabolic.

Thus far have we proceeded on the fair consequences of the well known fact, that echoes are reflected in the same manner as light, without engaging in the intricate investigation of aerial undulations. Whoever considers the Newtonian theory of the propagation of sound with intelligence and attention, will see that it is demonstrated solely in the case of a single row of particles; and that all the general corollaries respecting the lateral diffusion of the elastic undulations are little more than sagacious guesses, every way worthy of the illustrious author, and beautifully confirmed by what we can most distinctly and accurately observe in the circular waves on the surface of still water. But they are by no means fit for becoming the foundation of any doctrine which lays the smallest claim to the title of accurate science. We really know

Trumpet. know exceedingly little of the theory of aerial undulations; and the conformity of the phenomena of sound to these guesses of Sir Isaac Newton has always been a matter of wonder to every eminent and candid mathematician: and no other should pretend to judge of the matter. This wonder has always been acknowledged by Daniel Bernoulli; and he is the only person who has made any addition to the science of sounds that is worth mentioning. For such we must always esteem his doctrine of the secondary undulations of musical cords, and the secondary pulses of air in pipes. Nothing therefore is more unwarrantable, or more plainly shows the precipitant presumption of modern sciolists, than the familiar use of the general theory of aerial undulations in their attempts to explain the abstruse phenomena of nature (such as the communication of sensation from the organ to the sensorium by the vibrations of a nervous fluid, the reciprocal communication of the volitions from the sensorium to the muscle, nay, the whole phenomena of mind), by vibrations and vibratiunculæ.

Such attempts equally betray ignorance, presumption, and meanness of soul. Ignorance of the extent to which the Newtonian theory may be logically carried, is the necessary consequence of ignorance of the theory itself. It is presumption to apply it to the phenomena of the intellectual world; and surely he has an abject soul who hugs and cherishes the humble thought, that his mind is an undulating fluid, and that its all-grasping comprehension, and all its delightful emotions, are nothing more than an etherial tune.—"Pol me occidistis amentes." This whim is older than Hartley: It may be found in Robinet's *Systeme de la Nature*. This by the bye made its first appearance as a discourse delivered by Brother Orateur in the lodge of the grand Orient at Lyons; from which source have proceeded all the cosmopolitical societies in Europe, and that illumination by which reason is to triumph over revelation, and liberty and equality over civil government. We crave pardon of our readers for this ebullition of spleen; and we hope for it from all those who can read Newton, and who esteem his modesty.

Those who have endeavoured to improve the speaking trumpet on mechanical principles, have generally aimed at increasing the violence of the elastic undulations, that that they may make a more forcible impulse on the ear. This is the object in view in the parabolic trumpet. All the undulations are converted into others which are in planes perpendicular to the axis of the instrument; so that the same little mass of air is agitated again and again in the same direction. From this it is obvious to conclude, that the total agitation will be more violent. But, in the first place, these violent agitations must diffuse themselves laterally as soon as they get out of the trumpet, and thus be weakened, in a proportion that is perhaps impossible for the most expert analyst to determine. But, moreover, we are not sufficiently acquainted with the mechanism of the very first agitations, to be able to perceive what conformation of the trumpet will cause the reflected undulations to increase the first undulations, or to check them. For it must happen, during the production of a continued sound in a trumpet, that a parcel of air, which is in a state of progressive agitation, as it makes a pulse of one sound, may be in a state of retrograde agitation, as it is part of a pulse of air producing another sound. We cannot (at least no mathematician has yet done it) discriminate, and then combine these agitations, with the intelligence and precision that are necessary for enabling us to say what is the ultimate accumulated effect. Mr Lambert therefore did wisely in abstaining from this intricate investigation; and we are highly obliged to him for deducing such a body of demonstrable doctrine from the acknowledged, but ill understood, fact of the reflection of echoes. Trumpet.

We know that two sounds actually cross each other without any mutual disturbance; for we can hear either of them distinctly, provided the other is not so loud as to stun our ears, in the same manner as the glare of the sun dazzles our eyes. We may therefore depend on all the consequences which are legitimately deduced from this fact, in the same manner as we depend on the science of catoptrics, which is all deduced from a fact perfectly similar and as little understood.

But the preceding propositions by no means explain or comprehend all the reinforcement of sound which is really obtained by means of a speaking trumpet. In the first place, although we cannot tell in what degree the aerial undulations are increased, we cannot doubt that the reflections which are made in directions which do not greatly deviate from the axis, do really increase the agitation of the particles of air. We see a thing perfectly similar to this in the waves on water. Take a long slip of lead, about two inches broad, and having bent it into the form of a parabola, set it into a large flat trough, in which the water is about an inch deep. Let a quick succession of small drops of water fall precisely on the focus of the parabola. We shall see the circular waves proceeding from the focus all converted into waves perpendicular to the axis, and we shall frequently see these straight waves considerably augmented in their height and force. We say generally, for we have sometimes observed that these reflected waves were not sensibly stronger than the circular or original waves. We do not exactly know to what this difference must be ascribed: we are disposed to attribute it to the frequency of the drops. This may be such, that the interval of time between each drop is precisely equal, or at least commensurable, to the time in which the waves run over their own breadth. This is a pretty experiment; and the ingenious mechanician may make others of the same kind which will greatly illustrate several difficult points in the science of sounds. We may conclude in general that the reflection of sounds, in a trumpet of the usual shapes, is accompanied by a real increase of the aerial agitations; and in some particular cases we find the sounds prodigiously increased. Thus, when we blow through a musical trumpet, and allow the air to take that uniform undulation which can be best maintained in it, namely, that which produces its musical tone, where the whole tube contains but one or two undulations, the agitation of a particle must then be very great, and it must describe a very considerable line in its oscillations. When we suit our blast in such a manner as to continue this note, that is, this undulation, we are certain that the subsequent agitations conspire with the preceding agitation, and augment it. And accordingly we find that the sound is increased to a prodigious degree. A cor de chasse, or a bugle horn, when properly winded, will almost deafen the ear; and yet the exertion is a mere nothing in comparison with what we make when bellowing with all

Trumpet.

our force, but with not the tenth part of the noise. We also know, that if we speak through a speaking trumpet in the key which corresponds with its dimensions, it is much more audible than when we speak in a different pitch. These observations show, that the loudness of a speaking trumpet arises from something more than the sole reflection of echoes considered by Mr Lambert—the very echoes are rendered louder.

In the next place, the sounds are increased by the vibrations of the trumpet itself. The elastic matter of the trumpet is thrown into tremors by the undulations which proceed from the mouth-piece. These tremors produce pulses in the contiguous air, both in the inside of the trumpet and on that which surrounds it. These undulations within the trumpet produce original sounds, which are added to the reflected sounds: for the tremor continues for some little time, perhaps the time of three or four or more pulses. This must increase the loudness of the subsequent pulses. We cannot say to what degree, because we do not know the force of the tremor which the part of the trumpet acquires: but we know that these sounds will not be magnified by the trumpet to the same degree as if they had come from the mouth-piece; for they are reflected as if they had come from the surface of a sphere which passes through the agitated point of the trumpet. In short, they are magnified only by that part of the trumpet which lies without them. The whole sounds of this kind, therefore, proceed as if they came from a number of concentric spherical surfaces, or from a solid sphere, whose diameter is twice the length of the trumpet cone.

All these agitations arising from the tremors of the trumpet tend greatly to hurt the distinctness of articulation; because, coming from different points of a large sphere, they arrive at the ear in a sensible succession; and thus change a momentary articulation to a lengthened sound, and give the appearance of a number of voices uttering the same words in succession. It is in this way, that, when we clap our hands together near a long rail, we get an echo from each post, which produces a chirping sound of some continuance. For these reasons it is found advantageous to check all tremors of the trumpet by wrapping it up in woollen lists. This is also necessary in the musical trumpet.

With respect to the undulations produced by the tremors of the trumpet in the air contiguous to its outside, they also hurt the articulation. At any rate, this is so much of the sonorous momentum uselessly employed; because they are diffused like common sounds, and receive no augmentation from the trumpet.

Hearing trumpet.

It is evident, that this instrument may be used (and accordingly was so) for aiding the hearing; for the sonorous lines are reflected in either direction. We know that all tapering cavities greatly increase external noises; and we observe the brutes prick up their ears when they want to hear uncertain or faint sounds. They turn them in such directions as are best suited for the reflection of the sound from the quarter whence the animal imagines that it comes.

Let us apply Mr Lambert's principle to this very interesting case, and examine whether it be possible to assist dull hearing in like manner as the optician has assisted imperfect sight.

The subject is greatly simplified by the circumstances of the case; for the sounds to which we listen generally come in nearly one direction, and all that we have to do is to produce a constipation of them. And we may conclude, that the audibility will be proportional to this constipation.

Therefore let ACB, fig. 6. be the cone, and CD its axis. The sound may be conceived as coming in the direction RA, parallel to the axis, and to be reflected in the points A, *b*, *c*, *d*, *e*, till the angle of incidence increases to 90°; after which the subsequent reflections send the sound out again. We must therefore cut off a part of the cone; and, because the lines increase their angle of incidence at each reflection, it will be proper to make the angle of the cone an aliquot part of 90°, that the least incidence may amount precisely to that quantity. What part of the cone should be cut off may be determined by the former principles. Call the angle ACD, a. We have $Ce = \frac{CA \cdot \sin.\, a}{\sin.\, (2n+1)\, a}$, when the sound gets the last useful reflection. Then we have the diameter of the mouth $AB = 2\, CA \cdot \sin.\, a$, and that of the other end $ef = Ce \cdot 2 \sin.\, a$. Therefore the sounds will be constipated in the ratio of CA^2 to Ce^2, and the trumpet will bring the speaker nearer in the ratio of CA to C*e*.

Fig. 6.

When the lines of reflected sound are thus brought together, they may be received into a small pipe perfectly cylindrical, which may be inserted into the external ear. This will not change their angles of inclination to the axis nor their density. It may be convenient to make the internal diameter of this pipe $\frac{1}{3}$ of an inch. Therefore $Ce \cdot \sin.\, a$ is $= \frac{1}{6}$ of an inch. This circumstance, in conjunction with the magnifying power proposed, determines the other dimensions of the hearing trumpet. For $Ce = \frac{1}{6 \sin.\, a} = \frac{CA \cdot \sin.\, a}{\sin.\, (2n+1)\, a}$, and $CA = \frac{\sin.\, (2n+1\, a)}{6 \sin.^2\, a}$.

Thus the relation of the angle of the cone and the length of the instrument is ascertained, and the sound is brought nearer in the ratio of CA to C*e*, or of sin. $(2n+1)\, a$ to sin. a. And seeing that we found it proper to make $(2n+1)\, a = 90°$, we obtain this very simple analogy, $1 : \sin.\, a = CA : Ce$. And the sine of $\frac{1}{2}$ the angle of the cone is to radius as 1 to the approximating power of the instrument.

Thus let it be required that the sound may be as audible as if the voice were 12 times nearer. This gives $\frac{CA}{Ce} = 12$. This gives $\sin.\, a = \frac{1}{12}$, and $a = 4°\, 47'$, and the angle of the cone $= 9.34$. Then $CA = \frac{1}{6 \sin.^2\, a} = \frac{1}{6 \frac{1}{144}} = \frac{144}{6}, = 24$. Therefore the length of the cone is 24 inches. From this take $Ce = \frac{CA}{12} = 2$, and the length of the trumpet is 22 inches. The diameter at the mouth is $2\, Ce, = 4$ inches. With this instrument one voice should be as loud as 144.

If it were required to approximate the sound only four times, making it 16 times stronger than the natural voice

Trumpet. voice at the same distance, the angle ACB must be 29°; A e must be 2 inches, AB must be $1\frac{1}{3}$d inches, and ef must be $\frac{1}{3}$d of an inch.

It is easy to see, that when the size of the ear-end is the same in all, the diameters at the outer end are proportional to the approximating powers, and the lengths of the cones are proportional to the magnifying powers.

We shall find the parabolic conoid the preferable shape for an acoustic trumpet; because as the sounds come into the instrument in a direction parallel to the axis, they are reflected so as to pass through the focus. The parabolic conoid must therefore be cut off through the focus, that the sounds may not go out again by the subsequent reflections; and they must be received into a cylindrical pipe of one-third of an inch in diameter. Therefore the parameter of this parabola is one-sixth of an inch, and the focus is one-twelfth of an inch from the vertex. This determines the whole instrument; for they are all portions of one parabolic conoid. Suppose that the instrument is required to approximate the sound 12 times, as in the example of the conical instrument. The ordinate at the mouth must be 12 times the 6th of an inch, or 2 inches; and the mouth diameter is four inches, as in the conical instrument. Then, for the length, observe, that DC in fig. 7. is $\frac{1}{6}$th of an inch, and MP is 2 inches, and AC is $\frac{1}{12}$th of an inch, and $DC^2 : MP^2 = AC : AP$. This will give $AP = 12$ inches, and $CP = 11\frac{11}{12}$ths; whereas in the conical tube it was 22. In like manner an instrument which approximates the sounds four times, is only $1\frac{1}{3}$d inches long, and $1\frac{1}{3}$d inches diameter at the big end. Such small instruments may be very exactly made in the parabolic form, and are certainly preferable to the conical. But since even these are of a very moderate size when intended to approximate the sound only a few times, and as they can be accurately made by any tinman, they may be of more general use. One of 12 inches long, and 3 inches wide at the big end, should approximate the sound at least 9 times.

Fig. 7.

A general rule for making them.—Let m express the approximating power intended for the instrument. The length of the instrument in inches is $\frac{m \times \overline{m-1}}{6}$, and the diameter at the mouth is $\frac{m}{3}$. The diameter at the small end is always one-third of an inch.

In trumpets for assisting the hearing, all reverbation of the trumpet must be avoided. It must be made thick, of the least elastic materials, and covered with cloth externally. For all reverbation lasts for a short time, and produces new sounds which mix with those that are coming in.

We must also observe, that no acoustic trumpet can separate those sounds to which we listen from others that are made in the same direction. All are received by it, and magnified in the same proportion. This is frequently a very great inconvenience.

There is also another imperfection, which we imagine cannot be removed, namely, an odd confusion, which cannot be called indistinctness, but a feeling as if we were in the midst of an echoing room. The cause seems to be this: Hearing gives us some perception of the direction of the sounding object, not indeed very precise, but sufficiently so for most purposes. In all instruments which we have described for constipating sounds, the last reflections are made in directions very much inclined to the axis, and inclined in many different degrees. Therefore they have the appearance of coming from different quarters; and instead of the perception of a single speaker, we have that of a sounding surface of great extent. We do not know any method of preventing this, and at the same time increasing the sound.

Trumpet.

There is an observation which it is of importance to make on this theory of acoustic instruments. Their performance does not seem to correspond to the computations founded on the theory. When they are tried, we cannot think that they magnify so much: Indeed it is not easy to find a measure by which we can estimate the degrees of audibility. When a man speaks to us at the distance of a yard, and then at the distance of two yards, we can hardly think that there is any difference in the loudness; though theory says, that it is four times less in the last of the two experiments; and we cannot but adhere to the theory in this very simple case, and must attribute the difference to the impossibility of measuring the loudness of sounds with precision. And because we are familiarly acquainted with the sound, we can no more think it four times less at twice the distance, than we can think the visible appearance of a man four times less when he is at quadruple distance. Yet we can completely convince ourselves of this, by observing that he covers the appearance of four men at that distance. We cannot easily make the same experiment with voices.

But, besides this, we have compared two hearing trumpets, one of which should have made a sound as audible at the distance of 40 feet as the other did at 10 feet distance; but we thought them equal at the distance of 40 and 18. The result was the same in many trials made by different persons, and in different circumstances. This leads us to suspect some mistake in Mr Lambert's principle of calculation; and we think him mistaken in the manner of estimating the intensity of the reflected sounds. He conceives the proportion of intensity of the simple voice and of the trumpet to be the same with that of the surface of the mouth-piece to the surface of the sonorous hemisphere, which he has so ingeniously substituted for the trumpet. But this seems to suppose, that the whole surface, generated by the revolution of the quadrantal arch TEG round the axis CG (fig. 4.), is equally sonorous. We are assured that it is not: For even if we should suppose that each of the points Q, R, and S (fig. 3.), are equally sonorous with the point P, these points of reflection do not stand so dense on the surface of the sphere as on the surface of the mouth-piece. Suppose them arranged at equal distances all over the mouth-piece, they will be at equal distances also on the sphere, only in the direction of the arches of great circles which pass through the centre of the mouth-piece. But in the direction perpendicular to this, in the circumference of small circles, having the centre of the mouth-piece for their pole, they must be rarer in the proportion of the sine of their distance from this pole. This is certainly the case with respect to all such sounds as have been reflected in the planes which pass through the axis of the trumpet; and we do not see (for we have not examined this point) that any compensation is made by the reflection which is not in planes.

planes passing through the axis. We therefore imagine, that the trumpet does not increase the sound in the proportion of $g\,E^2$ to $g\,T^2$ (fig. 5.), but in that of $\frac{g\,E^2}{GE}$ to $\frac{g\,T^2}{CT}$.

Mr Lambert seems aware of some error in his calculation, and proposes another, which leads nearly to this conclusion, but founded on a principle which we do not think in the least applicable to the case of sounds.

Trumpet, Marine, is a musical instrument consisting of three tables, which form its triangular body. It has a very long neck with one single string, very thick, mounted on a bridge, which is firm on one side, but tremulous on the other. It is struck by a bow with one hand, and with the other the string is pressed or stopped on the neck by the thumb.

It is the trembling of the bridge, when struck, that makes it imitate the sound of a trumpet, which it does to that perfection, that it is scarcely possible to distinguish the one from the other. And this is what has given it the denomination of trumpet-marine, though, in propriety, it be a kind of monochord. Of the six divisions marked on the neck of the instrument, the first makes a fifth with the open chord, the second an octave, and so on for the rest, corresponding with the intervals of the military trumpet.

Trumpet-Flower. See Bignonia, Botany *Index*.

TRUMPETER. See Psophia, Ornithology *Index*.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off: thus, we say, a truncated cone, pyramid, leaf, &c.

TRUNCHEON, a short staff or baton used by kings, generals, and great officers, as a mark of their command.

TRUNDLE, a sort of carriage with low wheels, whereon heavy and cumbersome burdens are drawn.

TRUNK, among botanists, that part of the herb which arises immediately from the root, and is terminated by fructification; the leaves, buds, and auxiliary parts of the herb not entering in its description.

TRUNNIONS, or Trunions, of a piece of ordnance, are those knobs or bunches of metal which bear her up on the cheeks of the carriage.

TRUSS, a bundle, or certain quantity of hay, straw, &c. A truss of hay contains 56 pounds, or half an hundred weight: 36 trusses make a load.

Truss, is also used for a sort of bandage or ligature made of steel, or the like matter, wherewith to keep up the parts in those who have hernias or ruptures.

Truss, in a ship, a machine employed to pull a yard home to its respective mast, and retain it firmly in that position.

TRUSTEE, one who has an estate, or money, put or trusted in his hands for the use of another.

TRUTH, a term used in opposition to falsehood, and applied to propositions which answer or accord to the nature and reality of the thing whereof something is affirmed or denied.

TRYPHIODORUS, an ancient Greek poet, who lived some time between the reigns of Severus and Anastasius. His writings were very numerous; yet none of them have come down to us, except an epic poem, on which Mr Addison has made some entertaining remarks in the Spectator, N° 63.

The first edition of this extraordinary work was published by Aldus at Venice, with Quintus Calaber's Paralipomena, and Coluthus's poem on the rape of Helen. It has been since reprinted at several places, particularly at Francfort in 1580 by Frischlinus; who not only corrected many corrupt passages, but added two Latin versions, one in verse and the other in prose. That in verse was reprinted in 1742, with the Greek, at Oxford, in 8vo, with an English translation in verse, and Notes, by Mr Merrick.

TUAM, a town of Ireland, in the province of Connaught, and county of Galway, with an archbishop's see. It was once a famous city, though now it is reduced to a village; but it still retains the title of a city, as being an archiepiscopal see. W. Long. 8. 46. N. Lat. 53. 33.

TUB, in commerce, denotes an indetermined quantity or measure: thus, a tub of tea contains about 60 pounds; and a tub of camphor from 56 to 86 pounds.

TUBE, in general, a pipe, conduit, or canal; a cylinder, hollow within-side, either of lead, iron, glass, wood, or other matter, for the air or some other matter to have a free conveyance through it.

Auricular Tube, or instrument to facilitate hearing. See *Articulate Trumpet*.

TUBERCLES, among physicians, denote little tumors which suppurate and discharge pus; and are often found in the lungs, especially of consumptive persons.

TUCUMAN, a province of Paraguay, in South America, bounded on the north by the provinces of Los-Chicas and Choco; on the east by Choco and Rio-de-la-Plata, on the south by the country of Chicuitos and Pampes, and on the west by Chili. The air is hot, and the soil sandy; however, some places are fruitful enough. It now forms part of the republic of Buenos Ayres. See Buenos Ayres, Supplement.

TUFA, a stone consisting of volcanic ashes concreted together with various other species of stone. It is of various colours, blackish gray, bluish gray, and yellow; every colour having a different mixture and solidity: but all of them have the bad quality of mouldering down on long exposure to the weather; notwithstanding which, they have been used in buildings both ancient and modern. The yellow kind resists the air less than any other.

TULIPA, Tulip; a genus of plants belonging to the class of hexandria; and in the natural system ranging under the 10th order, *Coronariæ*. See Botany *Index*; and for the culture of the tulip, see Gardening.

Tulip-Tree. See Liriodendron, Botany *Index*.

TULL, Jethro, an Oxfordshire gentleman who farmed his own land, and introduced a new method of culture, to raise repeated crops of wheat from the same land without the necessity of manure: the principles of which he published about 30 years since, in a Treatise on Horse-hoeing Husbandry.

TUMBRELL, Tumbrellum, or *Turbichetum*, is an engine of punishment, formerly employed for the correction of scolds and unquiet women.

TUMEFACTION, the act of swelling or rising into a tumor.

TUMOR,

TUMOR, in *Medicine* and *Surgery*, a preternatural rising or eminence in any part of the body.

TUMORS, in *Farriery*. See FARRIERY *Index*.

TUN, a large vessel or cask, of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandise for convenience of carriage; as brandy, oil, sugar, skins, hats, &c.

TUN is also the name of a measure. A tun of wine is four hogsheads; of timber, a square of 40 solid feet; and of coals 20 cwt.

TUN is also a certain weight whereby the burden of ships, &c. is estimated.

TUNBRIDGE, a town of Kent in England, situated on a branch of the river Medway, over which there is a bridge. It is a large well built place, noted for the mineral waters four or five miles south of the town. E. Long. 0. 20. N. Lat. 51. 14.

TUNE. See MUSIC and TONE.

TUNGSTEN, one of the metals. See CHEMISTRY and MINERALOGY *Index*.

TUNICA, a kind of waistcoat or under garment, in use among the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics; whence Horace calls them *populus tunicatus*.

TUNICA, in *Anatomy*, is applied to the membranes which invest the vessels, and divers others of the less solid parts of the body; thus the intestines are formed of five tunics or coats.

TUNIS, a large and celebrated town of Barbary, in Africa, and capital of a kingdom of the same name. It is seated on the point of the gulf of Goletta, about eight miles from the place where the city of Carthage stood. It is in the form of a long square, and is about four miles in circumference, with ten large streets, five gates, and 35 mosques. The houses are all built with stone, though but one story high; but the walls are very lofty, and flanked with several strong towers. It has neither ditches nor bastions, but a good citadel, built on an eminence on the west side of the city. Its population is estimated by Mr M'Gill at 100,000, and Mr Blaquiere at 130,000. The divan, or council of state, assembles in an old palace; and the dey is the chief of the republic, who resides there. The harbour of Tunis has a very narrow entrance, through a small canal. In the city they have no water but what is kept in cisterns, except one well kept for the bashaw's use. It is a place of great trade, and is 10 miles from the sea. E. Long. 16. 10. N. Lat. 36. 42.

See Observ. on the City of Tunis by Mr Stanley, in the Edin. Mag. vol. iv. p. 28.

TUNIS, a country of Africa, bounded on the north and east by the Mediterranean sea and the kingdom of Tripoli, on the south by several tribes of the Arabs, and on the west by the kingdom of Algiers and the country of Esab; being 300 miles in length from east to west, and 250 in breadth from north to south. This country was formerly a monarchy; but a difference arising between a king and his son, one of whom was for the protection of the Christians, and the other for that of the Turks, in 1574 the inhabitants shook off the yoke of both. From this time it became a republic under the protection of the Turks, but within the last forty years, it has been almost entirely independent. The air in general is healthy; but the soil in the eastern parts is indifferent for want of water. Towards the middle the mountains and valleys abound in fruits; but the western part is the most fertile, because it is watered with rivers. The environs of Tunis are very dry, upon which account corn is generally dear. The inroads of the Arabs oblige the inhabitants to sow their barley and rye in the suburbs, and to inclose their gardens with walls. However, there are plenty of citrons, lemons, oranges, dates, grapes, and other fruits. There are also olive trees, roses, and odoriferous plants. In the woods and mountains there are lions, wild beeves, ostriches, monkeys, cameleons, roebucks, hares, pheasants, partridges, and other sorts of birds and beasts. The most remarkable rivers are the Guadilcarbar, Magrida, Magerada, and Caps. The form of government is by a council, whose president is the dey. The members of the divan or council are chosen by the dey, and he in his turn is elected by the divan; which is composed of soldiers, who have more than once taken off the dey's head. The bashaw who was formerly a Turk, remitted tribute to Constantinople; but since Hamooda Bey ascended the throne in 1787, Tunis has cast off all subjection to the Porte. The common revenues are only 400,000 crowns a-year, because the people are very poor; nor can they send above 40,000 men into the field; nor more than 12 men of war of the line to sea, even upon the most extraordinary occasions. There are generally about 12,000 Christian slaves in this country; and the inhabitants carry on a great trade in linen and woollen cloth. In the city of Tunis alone there are about 3000 clothiers and weavers. They also have a trade in horses, olives, oil, soap, ostriches eggs and feathers. The Mahometans of this city have nine colleges for students, and 86 petty schools. The principal religion is Mahometanism; but the inhabitants consist of Moors, Turks, Arabs, Jews, and Christian slaves. However the Turks, though fewest in number, domineer over the Moors, and treat them little better than slaves. See BARBARY STATES, SUPPLEMENT.

TUNKERS, a religious sect of Baptists in Pennsylvania, so called from the word *tunker*, to put a morsel in sauce. They are also called *tumblers*, because in performing baptism they plunge the person into the water with the head first. As the Germans sound the letters *t* and *b* like *d* and *p*, the words *tunkers* and *tumblers*, have been sometimes written *dunkers* and *dumplers*. Their church government and discipline are the same with those of the English Baptists, except that every brother is allowed to speak in the congregation, and the best speaker is usually ordained to be their minister. They are a harmless, well-meaning people.

TUNNAGE. See TONNAGE.

TUNNY. See SCOMBER, ICHTHYOLOGY *Index*.

TUNNY-FISHING. See FISHERY.

TURBAN, the head-dress of most of the eastern nations. It consists of two parts, a cap and sash of fine linen or taffety, artfully wound in divers plaits about the cap. The cap has no brim, is pretty flat, though roundish at top, and quilted with cotton; but does not cover the ears. There is a good deal of art in giving the turban a fine air; and the making of them is a particular trade. The sash of the Turk's turban is white linen; that of the Persians red woollen. These are the distinguishing marks of their different religions. Sophi king of Persia, being of the sect of Ali, was the first who assumed the

the red colour, to distinguish himself from the Turks, who are of the sect of Omar, and whom the Persians esteem heretics.

TURBINATED, is a term applied by naturalists to shells which are spiral, or wreathed conically from a larger basis to a kind of apex.

TURBITH or TURPETH MINERAL. See MERCURY, N° 1720 and 1728 CHEMISTRY.

TURBO, the WREATH, a genus of shell-fish. See CONCHOLOGY *Index*.

TURBOT. See PLEURONECTES, ICHTHYOLOGY *Index*.

TURCÆ or TURCI, (Mela); supposed to be the *Tusci* of Ptolemy; whom he places between Caucasus and the Montes Ceraunii. The name is said to denote, "to desolate, or lay waste." Herodotus places them among the wild or barbarous nations of the north. There is a very rapid river called *Turk*, running into the Caspian sea, from which some suppose the Turks to take their name. They made no figure in the world till towards the 7th century; about the beginning of which they sallied forth from the Portæ Caspiæ, laid waste Persia, and joined the Romans against Chosroes king of Persia. In 1402 they subdued the Persians, in whose pay they served, and from whom they derived the Mahometan religion; and afterwards pouring forth, overran Syria, Cappadocia, and the other countries of the Hither Asia, under distinct heads or princes, whom Ottoman subduing, united the whole power in himself, which to this day continues in his family, and who fixed his seat of empire at Prusa in Bithynia. His successors subdued all Greece, and at length took Constantinople in 1453; which put a period to the Roman empire in the East, under Constantine the last emperor. It is a standing tradition or prophecy among the Turks, that their empire will at length be overturned by the Franks or Christians; which seems now to be drawing on apace towards accomplishment.

TURCOISE. See TURQUOISE.

TURCOMANIA, a province of Asiatic Turkey, answering to the ancient kingdom of Armenia.

TURDUS, the THRUSH; a genus of birds belonging to the order of *Passeres*. See ORNITHOLOGY *Index*.

TURENNE, VISCOUNT. See TOUR.

TURF, *peat*, a blackish earth used in several parts of the world as fuel. Turf, as distinguished from peat, consists of mould interwoven with the roots of vegetables.

TURGESCENCE, among physicians, denotes a swelling or growing bloated.

TURGOT, ANNE ROBERT JAMES, a celebrated French financier, was born at Paris in 1727, of a very ancient Norman family. His father was a long time provost of the corporation of merchants; during which he was the object of general admiration, on account of his prudent administration. M. Turgot was the youngest of three brothers, and was destined for the church. He had scarcely attained the age at which reflection commences, when he resolved to sacrifice all temporal advantages to liberty and conscience, and to pursue his ecclesiastical studies without declaring his repugnance to their proposed object. At the age of 23 years he took his degree, and was elected prior of the Sorbonne.

The time when it was necessary for him to declare that he would not be an ecclesiastic was now arrived. He announced this resolution to his father by letter, showing the motives which induced him to decline the clerical order. His father consented, and he was appointed master of requests. M. Turgot prepared himself for this office by particular application to those parts of science which are most connected with its functions and duties, viz. natural philosophy, agriculture, manufactures, commerce, &c. About this period he wrote some articles for the *Encyclopédie*, of which the principal are Etymology, Existence, Expansibility, Fair, and Foundation. He had prepared several others, but the persecution against the *Encyclopédie* induced him to decline farther contributions.

In 1761 M. Turgot was appointed intendant of Limoges, when he gave activity to the society of agriculture; opened a mode of public instruction for female professors of midwifery; procured for the people the attendance of able physicians during the raging of epidemic diseases; established houses of industry, supported by charity (the only species of alms-giving which does not encourage idleness); introduced the cultivation of potatoes into his province, &c. &c. While M. Turgot proceeded with unremitting activity and zeal, in promoting the good of the people over whom he was placed, he meditated projects of a more extensive nature, such as an equal distribution of the taxes, the construction of the roads, the regulation of the militia, the prevention of a scarcity of provision, and the protection of commerce.

At the death of Louis XV. the public voice called M. Turgot to the first offices of government, as a man who united the experience resulting from habits of business to all the improvement which study can procure. After being at the head of the marine department only a short time, he was, Aug. 24, 1774, appointed comptroller general of the finances. During his discharge of this important office, the operations he carried on are astonishing. He suppressed 23 kinds of duties on necessary occupations, useful contracts, or merited compensations. He abolished the corvée, or the labour required from the public for the highways, saving the nation thirty millions of livres annually.—He set aside another kind of corvée, which respected the carriage of military stores and baggage.—He abated the rigour in the administration of indirect impositions, to the great profit of the contributors, the king, and the financiers; beside many other essential improvements in political economy.

At length, however, by the artifices of the courtiers, he was deprived of his offices; and in retirement he devoted himself to the sciences and the belles lettres, which he had cultivated in his youth. Natural philosophy and chemistry were his favourite pursuits; sometimes he indulged in poetry. He composed, it is said, only one Latin verse, intended for a picture of Dr Franklin.

Eripuit cœlo fulmen, mox sceptra tyrannis.

He died in 1781.

TURIN, an ancient and populous city of Italy, and capital of Piedmont, where the sovereign resides, with an archbishop's see, a strong citadel, and an university. It is seated on a vast plain, at the confluence of the rivers Doria and Po. But the air is unhealthy in the autumn

tumn and winter on account of the thick fogs. One half of this place is lately built; and the streets are straight and clean, being washed by an aqueduct. It contains many elegant buildings. When the plague reigned at Marseilles in 1720, a great number of artificers withdrew to Turin; insomuch that there are now above 87,000 inhabitants, and 48 churches and convents. Turin is very well fortified, and extremely strong; as the French found by experience in 1706, who then besieged it a long while to no purpose. The citadel, which is flanked with five bastions, is without doubt a masterpiece of architecture. There are fine walks on the ramparts, and fine gardens on the side of the river Po; and the house commonly called *La Charité* is remarkable, as there is room for 3000 poor people. The college of the academy is very large and well built, and has a great number of ancient inscriptions. In the royal library are 19,000 manuscripts, besides 30,000 printed books. In December 1798, it was taken possession of by the French, who in June following were driven out of it by the Austrians. But with the rest of Italy it is now under the dominion of the French. It is charmingly seated at the foot of a mountain, 62 miles north-east of Genoa, 72 south-west of Milan, and 280 north-west of Rome. E. Long. 7. 45. N. Lat. 44. 50.

1 Situation and extent

TURKEY, an extensive empire, situated partly in Europe, and partly in Asia. It is bounded on the north by the empire of Russia, Hungary, and the Black sea; on the west by the gulf of Venice and the Mediterranean; on the south by the Mediterranean and Arabia; and on the east by Persia. In its present state, we may compute it as extending from the river Unna, in east longitude about 17°, to the mountains which separate it from Persia, in about 50° of east longitude from Greenwich, or about 33° from west to east; while from the most southerly point, a little above Bassora, in north latitude 31°, to the confines of European Russia, in north latitude 47°, it occupies a range of 16° of latitude. In British miles its extent is estimated at 1750 in length, by a medial breadth of about 1000, and its area at 652,960 square miles.

2 Divisions

Turkey is naturally divided into European and Asiatic, separated from each other by the Black sea, the Archipelago, and the straits by which these are connected. European Turkey is subdivided into 11 provinces, viz. MOLDAVIA, BESSARABIA, WALACHIA, BOSNIA, SERVIA (partially), BULGARIA, ROMELIA (including *Macedonia* and *Thrace*), DALMATIA, ALBANIA (including *Epirus*), CROATIA (partially), and the MOREA, or ancient Greece; while Asiatic Turkey is subdivided into seven provinces, viz. NATOLIA (*Asia Minor*), DIARBEC (*Mesopotamia*), SYRIA (including *Judæa*), GEORGIA (*Iberia*), TURCOMANIA (*Armenia*), IRAC-ARABIA, and KURDISTAN (*Assyria*). See each of these articles in the general alphabet.

3 Islands.

The islands belonging to Turkey are extremely numerous; comprising those of the Archipelago, or the Grecian islands, and several in the Levant. The most important are LEMNOS, LESBOS or *Mytilene*, SCIO, SAMOS, COS, RHODES, CYPRUS, CANDIA, PAROS, DELOS, NAXIA, SANCTORINI, PATMOS, NEGROPONT, ANDRO *, COLTERI or *Salamis* *, EGINA, ZANTE *, CEPHALONIA, LEUCADIA, CORFU, and CERIGO or *Cytherea*, which see under their proper heads.

* See Venice.

4 Face of the country.

Both European and Asiatic Turkey abound in mountainous tracts, interspersed with numerous plains and valleys, and here and there a desert of considerable extent. The plains are watered by numerous large rivers, and, in the Asiatic part, consist chiefly of pasture grounds.

5 Mountains.

Among the mountains of European Turkey may be noticed the Carpathian chain, which divides it from the Austrian territories; the celebrated mountains of Hæmus; the Acroceraunian mountains; and the classical hills of Pindus, Ossa, Pelion, and Athos. The most important mountains of Asiatic Turkey are, Mount Caucasus, dividing it from Russia; Mount Taurus, now called Thuron; Olympus; Ida; the mountains of Elivend, and perhaps Mount Ararat, the resting-place of the Ark, dividing it from Persia; and Mount Lebanon, celebrated in scripture for its cedars.

6 Rivers.

The principal river of European Turkey is the Danube, with its tributary streams, the Save, the Morava, the Bosna, and the Pruth; but we may also notice the Marissa or Hebrus, and the Vardan or Axius. In Asiatic Turkey are seen the Kisil-Irmak or Halys, the Saccaria, the Sarabat or Hermus, the Minder or Meander, the Araxes, the Orontes, the Jordan, and the Euphrates.

7 Lakes.

The lakes of European Turkey are of little importance, and in the Asiatic part there are only three that merit notice. These are the Dead sea and the sea of Galilee in Palestine, and the Van in Armenia.

8 Climate and seasons.

The climate in the greater part of the Turkish empire is delightful, and the seasons mild and genial. The heats of the summer, except in the deserts of Syria, and on the shores of the Black sea, are tempered by the keen winds that blow from the higher regions, and the winter is in general extremely mild. The unhealthiness of the large towns on the coast of Asiatic Turkey, is owing much more to the indolent and dirty habits of the people, than to any insalubrity of the climate.

9 Natural history.

Turkey affords a most ample field to the naturalist, whether his taste lead him to explore the animal, the vegetable, or the mineral kingdom. In the first of these he will find the lion, a variety of the tiger, the hyena, the jackall, the ibex, the goat and cat of Angora, and many other quadrupeds common in Europe. Among the birds, one of the most numerous and most useful is the stork; partridges of a large size, quails, woodcocks, cranes, and several birds of prey, are also very common. The Black sea and the Archipelago abound with excellent fish, and contain great variety of curious mollusca, and other marine animals. Among the insects, that destructive animal the locust is a frequent visitant; and Sonnini particularises the tarantula, and a monstrous species of spider, which he calls *galeode arancoide*, or the scorpion spider. Of the domestic animals, the Turks abound in excellent horses, asses of a large size, and that most useful beast of burden, the camel.

To enumerate the vegetable productions of Turkey, would far exceed our scanty limits. The forests of European Turkey, though far less extensive than in ancient times, furnish abundance of the finest timber, especially oak, cedar, larch, walnut, chesnut, and beech, while the olive, the date, the almond, the peech, the mulberry, the cherry, the lemon, and the orange, are the natural productions of Asiatic Turkey. Many of the most valuable drugs employed in medicine, are also the produce of this empire, especially opium, rhubarb, myrrh, asafœtida and other fetid gums, scammony, senna, galls, and coloquintida.

Turkey.

Both gold and silver mines are found in Turkey, but from the indolence of the natives they are scarcely ever worked. Many of the islands abound in mineral treasures, especially Cyprus, where are found mines of gold, copper, vitriol, and iron; and where rock crystal, jasper, and several precious stones, are occasionally procured. The chief mineral production of Turkey, however, is its marble, of which it furnishes several of the most rare and beautiful varieties. That from the Grecian island Paros, is proverbially excellent.

10 Outline of the Turkish history.

The people whom we now call Turks, and who form the great mass of population of the Turkish empire, are generally believed to be the descendants of the ancient Scythians. These are supposed to have migrated from the Altai mountains in Tartary, about the middle of the sixth century, and to have gradually diffused themselves towards the west, till they reached the lake Mæotis, the modern sea of Azof, near which they settled in Armenia Minor or Turcomania. At this time the Roman empire in the east was sufficiently strong to prevent the invaders from extending beyond the river Oxus, on the banks of which they established themselves, and soon became a formidable foe to the emperors of Constantinople.

11 Foundation of the Ottoman empire. A. D. 1300.

There is little certain or interesting in the history of these barbarians till the reign of the caliph Othman, or Osman, who in the end of the 13th century established what from him has been called the Ottoman empire. He first took the title of sultan, and fixed the seat of his government at Prusa, the capital of Bithynia. His successor Orkan was a restless, ambitious, and cruel prince, who greatly extended the limits of the empire, took possession of Gallipoli, and penetrated into Thrace. Amurath the grandson of Osman, in 1362, established the famous military bands called *janizaries*, which still form the chief engines and chief moderators of Turkish despotism. These were first composed of young Christian slaves that had been taken in war, and educated in the Mohammedan religion. They were inured to obedience by severe discipline, and trained to warlike exercise; and as every sentiment which enthusiasm can inspire, and every mark of honour which the favour of the prince could confer, were employed to animate them with martial ardour, and excite in them a sense of their own importance, these janizaries, (or new soldiers) soon became the chief strength and pride of the Ottoman arms. On the assassination of Amurath in 1389, he was succeeded by his son Bajazet, surnamed Ilderim, or the Thunderbolt, whose reign forms one of the most splendid epochs in the Turkish history.

12 Establishment of the Janizaries, 1362.

13 Reign of Bajazet. An. 1389.

Early in this reign, viz. in 1396, the Hungarians were defeated at Nicopoli in Bulgaria, and in 1402, was fought the famous battle between Bajazet and Timur or Tamerlane, the chief of the Moguls, between Cesarea and Ancyra, which ended in the captivity of Bajazet, and the temporary humiliation of the Turks. See MOGULS, N° 19. and 20.

On the death of Bajazet, his son Mousa became sultan, and in 1412 defeated the emperor Sigismund with great slaughter. Mousa was succeeded by his brother Mohammed I. by whom he had been assassinated. The reign of Amurath II. successor of Mohammed, contributed greatly to increase the splendour of the Turkish empire. In this reign Constantinople was attacked, but for the present escaped pillage. Amurath was successfully opposed in his hostilities against the Christian princes, by the Albanian chief George Castriota, whom the Turks call Scanderbeg *.

Amurath was succeeded by Mohammed II. and soon after his accession, viz. in 1453, the city of Constantinople was taken by the Turks, and has ever since remained the capital of their empire. The events of which we have thus drawn the faint outline, are related at some length in the article CONSTANTINOPOLITAN HISTORY, N° 111—168.

14 Taking of Constantinople, An. 1453.

15 Other successes of Mohammed II.

Three years after the taking of Constantinople, Mohammed laid siege to Belgrade, from which, after an obstinate resistance, he was at length repulsed with considerable loss. Abandoning his attempt on Hungary, the sultan made preparations for an expedition into Greece, where the princes Thomas and Demetrius, brothers of the emperor, still continued to maintain their authority. Alarmed at the progress of the Turkish arms, these princes resolved on retiring into Italy, on which the peninsula was seized by the Albanians. This tribe sent a deputation to Mohammed, offering to give up to him the Grecian cities and fortresses, provided they should be allowed to keep the open country; but this offer was rejected by the sultan, who under the appearance of assisting the Greeks, entered the country with a formidable army, defeated the Albanians, took several cities, and carried off great numbers of the inhabitants.

16 Bajazet II. An. 1481.

Mohammed was succeeded by his second son Bajazet II. in 1481, preferred by the janizaries to his elder brother Zizan, who fled for protection to Pope Alexander VI. by whom he is said to have been poisoned, at the instigation of Bajazet, and for the reward of 300,000 ducats. Selim, his youngest son and successor, was a successful prince. He conquered Egypt, Aleppo, Antioch, Tripoli, Damascus, and Gaza, and defeated the Persians. Solyman, surnamed the Magnificent, one of the most accomplished, enterprising, and warlike, of the Turkish princes, ascended the Ottoman throne in consequence of the death of Selim. An. 1512.

17 Solyman I. An. 1520.

Having quelled some insurrections in Asia, he commenced hostilities against the European princes, and entering Hungary, made himself master of Belgrade, then reckoned the chief barrier of that kingdom against the Turkish power. He next turned his victorious arms against the island of Rhodes, then the seat of the knights of St John of Jerusalem. After incredible efforts of courage and military conduct, the knights obtained an honourable capitulation, and retired to the small island of Malta, where they fixed their residence. See MALTA. He afterwards annexed Hungary to the Ottoman empire. His dominions extended from Algiers to the river Euphrates, and from the farther end of the Black sea to the extremity of Greece and Epirus. During the siege of Sigeth, a city of Hungary, before which the Turks lost above 30,000 men, Solyman expired in the 74th year of his age, and 41st of his reign.

18 Selim II. An. 1566.

His son and successor, Selim II. besieged and took Cyprus; but in the famous sea fight at Lepanto, in 1571, the Turkish fleet was utterly destroyed by Don John of Austria. He afterwards invested and took Tunis by storm, putting the garrison to the sword.

19 Amurath III. An. 1575.

On his death, Amurath III. ascended the Ottoman throne, and extended his dominions on both sides by the addition of Raab in Hungary and Tigris in Persia. His son, Mohammed III. has no claim to notice

except

* See Scanderbeg.

Turkey. except on account of his barbarity. He began his reign by strangling 19 of his brothers, and ordering 12 of his
20 father's wives, whom he suspected to be pregnant, to be
Mohammed III. drowned. This monster of cruelty had, however, a successful reign of nine years duration. During the govern-
21 Achmet I. An. 1603. ment of his son, Achmet I. the affairs of Turkey underwent a material change for the worse *. On his death, the janizaries and the divan elected his brother Mustapha, whom in two months they declared incapable of reigning, and threw him into prison; after this they proclaimed his young nephew, Osman, the son of Achmet, emperor. This prince formed a design of curbing the power of the janizaries, for which he was deposed and murdered; and Mustapha was again called from his prison to the imperial throne, but was soon after
22 strangled.

* See *Achmet I.*

Amurath IV. An. 1622. Under Amurath, or Morad IV. surnamed Gasi, the Intrepid, every thing again assumed a new appearance. He was successful in his wars, and took Bagdat from the Persians. A debauch of wine put an end to his life, and dishonoured his memory. His son Ibrahim, who succeeded him, had every vice; he was a weak prince, and wholly destitute of courage. He was strangled by four mutes.

23 Mohammed IV. An. 1649. After a long interval of inactivity, the Turks again became formidable to Europe, under Mohammed IV. who succeeded him. His grand visier Kupuli, who at once directed the councils and conducted the armies of the Porte, took Candia from the Venetians. After carrying on many wars against the Germans, the Poles, the Russians, and other European powers, he was compelled to resign the turban to Solyman II. in 1687, a
An. 1687. prince happy in his domestic government, but unsuccessful in his wars. His brother, Achmet II. was likewise unfortunate in his wars. In his reign the Turks were driven out of Hungary and Transylvania†. The acces-
24 Mustapha II. An. 1695. sion of his nephew, Mustapha II. to the Ottoman throne, gave a new turn to the affairs of the Porte. Possessed of more vigour than his predecessor, he resolved to command his troops in person. He accordingly took the field, passed the Danube, stormed Lippa, seized Itul, and falling suddenly on a body of Imperialists, under Veterani, he killed that officer, dispersed his forces, and closed with success the campaign. He was afterwards defeated by Prince Eugene in an uncommonly bloody battle at Zenta, a small village on the western bank of the Thuyse, in the kingdom of Hungary. About 20,000 Turks were left dead on the field, and 10,000 were drowned in the river, endeavouring to avoid the fury of the sword. The magnificent pavilion of the sultan, and all the stores, fell into the hands of Prince Eugene, and soon after this misfortune the haughty Mustapha was dethroned.

† See *Achmet II.*

25 Achmet III. His brother and successor, Achmet III. gave an asylum to Charles XII. king of Sweden, at Bender, a Turkish town in Moldavia, after his defeat at the battle of Pultava. (See Russia, N° 118. and Sweden, N° 140.). Being unsuccessful in his war against Kouli Khan and the Persians (see Persia), he was deposed,
26 and succeeded by Mohammed V.

Mustapha III. An. 1754. From the deposition of Achmet III. till the accession of Mostapha III. in 1754, nothing of importance occurs in the history of the Turkish empire. During the reign of this latter sultan was begun and terminated that destructive war with Russia, of which the principal events have been enumerated in the article Russia, N° 143 and 144. Turkey.

27 Appearance of a new prophet in Asia. In this reign an extraordinary alarm was excited in Turkey by the sudden appearance of a new prophet in Upper Asia. This man, whose name was *Shiek Mansour*, pretended that he was predoomed by the eternal immutable decrees of heaven to fill up the measure of divine revelation to mankind; and that, as he was to be the last, so he was the greatest of the prophets. The scene of his ministry was in the wide and desolate regions on the borders of the Caspian sea; and though the first rumour of his proceedings represented him as at the head of a multitude of armed enthusiasts, ready to overturn the established government, and the religion of Mohammed, it was soon discovered that all the military fury of his zeal was directed against the Christians. 28

A rebellion in Egypt. About the same time a formidable rebellion broke out in Egypt, which, though it has never properly formed a part of the Turkish empire, may be considered as tributary to the Turks, and as constituting the granary of that empire. This rebellion which has been sufficiently noticed under the article Egypt, N° 125, was suppressed chiefly by the wise conduct and intrepid bravery of Hossan Bey, the captain pacha, who at the age of 70, fought with all the ardour of youth, and all the skill of the most consummate general. That veteran, however, was recalled before he was able to carry all his patriotic designs into execution, that he might aid the divan with his counsel, in the critical situation into which the empire was brought by the arrogant claims of the court of Russia. The result of the deliberations was a precipitate declaration of war against that court, contrary to the better judgment of the old pacha. The war commenced in autumn 1787, and the hordes of Tartars which were first brought into the field, headed by the new prophet, were everywhere defeated by the superior discipline of the Russian troops commanded by Prince Potemkin. Some enterprises which were undertaken by the Turks against the island of Taman and the Krimea were attended with as little success as the attempts of the Tartars; while the emperor Joseph declared to the Porte, that he would assist his ally the empress of Russia with an army of 80,000 men. Four Austrian armies were accordingly assembled; one at Carlstadt in Croatia, under the command of General de Vins; another at Peterwaradin in Hungary, commanded by General Langlois; a third on the borders of Lithuania, under General Febris; and the fourth in the Buccowine, under the orders of the prince of Saxe-Cobourg. Two other generals, 10 lieutenant-generals, and 30 major-generals, were all ordered to prepare for active service in the frontier armies.

The war between the Turks and Austrians was carried on with various success. At first the advantage was evidently on the side of the Ottomans, and the imperial Joseph acquired no warlike renown. His declared purpose was to get possession of Belgrade; from which, however, he was repulsed with disgrace. The prince of Saxe-Cobourg in his department of the war displayed indeed prodigies of valour; but being opposed to a superior force, he was long obliged to act only on the defensive. At length being joined by a body of Russian forces under General Soltikoff, preparations were made for commencing in form the siege of Choczim, which was surrendered to the allied armies on Michael-

 mas

Turkey. mas day 1788, after a defence which would have done honour to the ablest general in Europe. Still, however, success seemed to lean to the Turks. The grand visier made a sudden incursion into the Bannat, and spread consternation and dismay to the very gates of Vienna. The Austrian affairs seemed approaching to a very alarming crisis; not only the splendid views of conquest which were beheld in the imagined partition of a tottering empire had totally disappeared, but had left in their place the sad and gloomy reverse of a discontented and impoverished people, an exhausted treasury, and an army thinned by pestilence and desertion. The first campaign of an invasive war had already produced an impression on the territory of the invader.

In this situation of affairs Marshal Laudohn was with some difficulty drawn from his retirement to take the command of the army in Croatia; and under his auspices fortune began to smile on the Austrian arms. He quickly reduced Dubicza and Nevi, though they were both defended by the most obstinate bravery. He then sat down before Turkish Gradisca; but the autumnal rains coming on with such violence, that the Save overflowed its banks, he was compelled to raise the siege. During this period the war in the Bannat raged with the utmost violence; torrents of blood were shed on both sides; much desperate valour displayed on the one side, and many brave actions performed on the other; while a very great part of that fine but unfortunate country suffered all the desolation and ruin that fire and sword, under the dominion of vengeance and animosity, could inflict. The inhabitants were objects of commiseration; but the injustice with which the emperor had commenced the war, made his personal losses be considered as nothing more than the due reward of his conduct.

29 Accession of Selim III. An. 1789.

In the midst of these military operations Achmet IV. was deposed, and succeeded by Selim III. the late sultan. The new emperor did not want either courage or prudence, and he continued the war with Russia and Austria, with great spirit and resolution. Those events of this war in which the Russians were more immediately concerned, have been already noticed under the article RUSSIA, N° 156, 158, 160 and 161; so that we have merely to relate the remaining operations of the Austrians.

30 Marshal Laudohn takes Gradisca and Belgrade.

Marshal Laudohn renewed his attempts upon Gradisca as soon as the season would permit, and after a brave defence it fell into his hands. This, with some other successes, roused the emperor from his inactivity, and made him seriously determine on the attack which he had long meditated on Belgrade. The enterprise was intrusted to Laudohn, who, with that good fortune which seemed constantly to attend him, made himself master of the place in less than a month. The rest of the campaign was little else than a series of the most important successes. While one detachment of General Laudohn's forces took possession of Czernitz in Walachia, another made itself master of Cladova in Servia. Bucharest, the capital of the former of these provinces, fell without opposition into the hands of Prince Cobourg; while Akerman on the Black sea was reduced by the Russians; and Bender surrendered to Prince Potemkin, not without suspicion of sinister practices, on the 15th of November.

31 Peace with Austria, An. 1790.

Soon after this, the emperor Joseph died, and his successor Leopold shewed a desire for peace. After the reduction of Orsova, therefore, which happened on the 16th of April 1790, the war was carried on with languor on the part of Austria; and in the month of June a conference was agreed on at Reichenbach, at which the ministers of Prussia, Austria, Britain, and the United Provinces, assisted, and at which also an envoy from Poland was occasionally present. After a negociation, which continued till the 17th of August, it was agreed that a peace should be concluded between the king of Hungary and the Ottoman Porte; that the basis of this treaty should be a general surrender of all the conquests made by the former, retaining only Choczim as a security till the Porte should accede to the terms of the agreement, when it also was to be restored.

32 and with Russia.

In the following year the Porte was compelled to conclude a peace with the empress of Russia, and from that period till the deposition of Selim in 1807, no event of consequence has occurred. The Porte has alternately been at war with Britain and with France, but in neither contest has she acquired either honour or territory. As the very confined limits to which we are now reduced forbid us to dwell on these minor transactions, we shall hasten to conclude this historical outline with an account of the revolution which placed Mustapha IV. on the Ottoman empire.

In the spring 1807, the spirit of insurrection had shown itself among the janizaries belonging to the garrisons of the Dardanelles, and in the camp of the grand vizier. In the afternoon of the 25th of May, the garrisons of the castles of the Dardanelles were in a state of tumult, on account of the European uniform, the new tactics, &c. Hali Aga, the commandant of Madschiaburna, on the Asiatic shore, was murdered. Indsche Bey, commandant of the entrance of the Black sea, only escaped the same fate by flight. The reis effendi happening to come to inspect that post just at the same time, the military immediately rose upon him as one of the introducers of the nizam geded. He endeavoured to save himself in a bark, by passing over to Buyukdere, but 100 pistol shots laid him and his attendants dead. It seems that the rage of the janizaries had been embittered against him by the recollection of a promise he made to raise their pay, on condition they would adopt the new discipline, and which promise he never performed. 33 Deposition of Selim and accession of Mustapha IV.

Another circumstance increased the spirit of opposition; the sultan had given notice that the janizaries were no longer to attend him as usual to the mosque, but that this duty was to devolve upon the troops disciplined after the European manner. Thousands of janizaries were now marching to Constantinople, and arrived in the suburb of Pera on the evening of the 28th. They swore to each other to conduct the revolution with the best order. Any person who should in the least injure any Frank was to suffer death. One individual janizary only met with his fate, for taking bread from a Greek (a baker), without paying for it. Behind the janizaries barracks, in the well-known place called Eimeldan, the janizaries planted their colours, and took with them their camp kettles; an infallible signal of insurrection. For a time, the sultan thought of defending himself; and troops, powder, and cannon, were brought to the seraglio. Soon after the mufti, the seimen basche, the kaimakan, and the two kazcakars of Romelia and Natolia, joined the janizaries.

zaries. A council was held in form, and it was proposed as a preliminary, to request the grand seignior to abolish the new discipline by a fettiva from the mufti. The grand seignior, however, thought he should be able to put a stop to the insurrection before the step could be taken, in consequence of his sending the heads of Mahmud, Tersana Emin, Hagi Ibrahim, and the kiaga Mehmesch Effendi, to the Eimeldan. This measure completely failed; the janizaries were more enraged than ever; they did not require the heads of the universally esteemed Mahmud Effendi, but that of the Reis Effendi, then in the camp of the grand vizier.

The janizaries continued to search every place for those ministers, who had promoted the adoption of the European discipline, and publicly avowed themselves as its patrons, namely, Fransisto, Ibrahim, Jussuf Aga, Hadschi Ibrahim, and Achmet Bey, captains of the grand seignior's guard, Hassan Aga, Achmet Effendi, and others, 12 in number, who were all taken, dragged to the Eimeldan, and there cut to pieces. At this juncture the grand seignior sent a hatti scheriff, a letter written in his own hand, in which he for ever abolished the nizam geded, and pronounced an execration on it. But the hatti scheriff was not now accepted; the deposition of the grand seignior was resolved on. The whole force of the janizaries now proceeded to the seraglio. The mufti and the ullemas alone entered the haram, while the rest of the ministers, the agas, the janizaries, and the people, surrounded the palace.

Mustapha IV. born on the 7th of September 1799, the eldest son of the sultan Achmet IV. set aside in 1789, was raised to the Turkish throne, And according to ancient custom, Selim, the former sultan, threw himself at the feet of Mustapha, kissed the border of his garment, and immediately repaired to that department of the seraglio occupied by the princes of the Ottoman blood who no longer reign.

In 1811 the Turks were involved in hostilities again with Russia. After losing several battles, the main body of the Turkish army surrendered prisoners of war to the Russians on the 6th December 1811. The Russians now found scarcely any obstacle to their progress, and continued to advance through the country, along the western shores of the Black Sea; when the invasion of Russia by the French in 1812, saved the Porte from disasters that otherwise seemed inevitable. Peace was obtained with the sacrifice of Bessarabia, and a part of Moldavia, early in 1812.

34 Population of Turkey.

The population of the whole Turkish empire is estimated at 21,000,000. Of these 14,000,000 have been allotted to Asiatic Turkey, and the remaining 7,000,000 to Turkey in Europe. A considerable part of this population consists of Jews and mercantile Christians, from different parts of Europe, who are distinguished by the name of Franks.

35 Government.

The government of Turkey is despotic, but the power of the sultan is by no means so absolute as we are generally led to suppose. Besides, being strictly subject to the laws of the Koran, and thus to the national religion, such obstructions to his absolute will are raised by the power of the mufti, or chief priest and judge, by the frequent insurrections of the janizaries, and the ambition of the pachas, or governors of provinces, that many Christian sovereigns are much more despotic. The principal title of the sultans is, as we have seen, grand seignior, and the court of Constantinople is usually styled the Porte, or Ottoman Porte, either from the large gate at the entrance of the seraglio, or, what is more probable, from the palace of the vizier, where all the affairs of state are transacted. The principal ministers of the Porte are the grand vizier or prime minister, the mufti, the reis effendi or chief secretary of state, the kislar-aga or chief of the black eunuchs, and the aga of the janizaries.

36 Revenues.

The revenue of the whole Turkish empire is not accurately known, but has been estimated at 3,000,000l. sterling. It is partly derived from the capitation tax on unbelievers and from the customs, but principally from the tax on land.

37 Military strength.

The military strength of Turkey is but inconsiderable for so large an empire. The whole of the land forces are supposed never to exceed 150,000 men, and these are ill disciplined, and now dispirited by successive disastrous wars. The navy is estimated at 30 sail of the line; but the ships are ill built, badly manned, and wretchedly navigated.

38 Religion and laws.

The established religion of Turkey is Mahometanism, the tenets of which have been already explained under the articles MAHOMETANISM and ALCORAN. The laws of the empire are entirely founded on the Koran; but in particular cases the judges are guided by certain commentaries on that work, which have acquired the force of laws. The chief of these are the commentaries of Abou-Hanife.

The mufti, or Mohammedan pontiff, resides at Constantinople, but his power has seldom interfered with the civil government. Next to him in rank are the moulahs, who, though esteemed dignitaries of the church, are in fact rather doctors of the law, while the Koran is also a code of civil observance. From the moulahs are selected the inferior muftis or judges throughout the empire, and the cadelesquiers, or chief justices. The next class of divines includes the imaums, or parish priests, who perform the service of the mosques, while the cadis are judges annually appointed to administer justice in the towns and villages, and being regarded as churchmen, like the moulahs, have directed their chief attention to the judicial part of the Koran. From this brief view it will be observed, that the ecclesiastical orders of muftis and imaums somewhat resemble the Christian bishops and parochial clergy; while the other distinctions arise from the singularity of both religion and laws being united in the Koran, so that a lawyer or judge must be at the same time a skilful divine. The Turks have also their monks, styled dervishes, of four various orders and institutions, dedicated by solemn vows to religious offices, public prayer, and preaching. The Greeks, along with their faith, retain their priests, bishops, archbishops, and patriarchs; but their church is in the last state of degradation, and its dignities openly sold by the Turks; this abomination, however, it must be confessed, partly arises from the miserable ambition and avarice of the Greek ecclesiastics, who think they can atone by idle ceremonies for the neglect of all the invaluable morality of the gospel.

39 Language and literature.

The Turkish language is of far inferior reputation to the Persian or Arabic, being a mixture of several dialects, and possessing neither the force, elegance, nor purity

Turkey. rity of these two celebrated oriental tongues. Literature, however, is not wholly neglected, and it has been repeatedly attempted to establish a printing-press at Constantinople; but the design failed from the interest of the copyists, who inferred that this art would deprive them of their bread. A late traveller informs us that there are in this capital several *buttuk-chans*, or public libraries, among which are those of St Sophia, and the Solimanie Jamasy; but none are so elegant as that founded by the grand vizier Raghid, which is wholly built of marble in the midst of a square court, and is filled with books chiefly theological. A librarian constantly attends, and there are convenient seats with carpets and cushions. In the neighbourhood is a school founded by the same vizier, in which about 1000 boys are taught to read and write. The market for books is extensive, containing many shops well supplied with oriental manuscripts. The Turks have their ancient poets, historians, and divines; but of little reputation when compared with those of Persia and Arabia. The state of education among the Turks may be conceived to be very low, and ignorance is indeed a chief part of the national character. The only profession which requires a shadow of learning is that of the law, which is intimately connected with their theology. The celebrated doctors have disciples, who are trained up to that department; but there seems nothing that can deserve the name of college or university.

40 Of commerce.

The Turks cannot be regarded as a commercial people, though they admit of an extensive commercial intercourse with the states of Europe, through the medium of Frank and Greek merchants. The chief ports are Smyrna and Constantinople, the former of which is the great centre of the Levant trade, while the latter is concerned chiefly in the trade with Russia, by the Black sea. At both these ports, and indeed throughout the Turkish empire, the trade is nominally carried on by factors from the different European states; but it is managed more immediately by Jew or Armenian brokers, who take numerous advantages of the ignorance of the factors, and seldom fail to enrich themselves at the expence of their employers. The commodities exported from Turkey, chiefly to Britain, Germany, Italy, Holland, and France, consist for the most part of bees wax, boxwood, silk, cotton yarn, walnut planks, sponges, opium, and other drugs enumerated in N° 9. madder root, and other dye stuffs, and various dried fruits, such as figs, raisins, and currants. The imports are chiefly tin and tin plates, sugar, shalloons, cotton yarn and cotton goods, muslins, clocks and watches, cutlery and glass ware, indigo, gunpowder, pistols and military stores, logwood, rum, coffee, and various spices, especially pepper, ginger, and cinnamon. The exports are principally from Smyrna, where the trade is carried on almost entirely by way of exchange, while at Constantinople the imports are generally paid for by cash or bills. The exchange is commonly against the Turks.

The Turkish money usually employed in commerce is the piastre, which, according to the exchange or agio, is rated at from 13 to 17 in the English pound sterling, so that the average value of the piastre is about 1s. 6d. Each piastre is divided into 40 paras, and each para into three aspers. The principal weight employed is the kintal, equal to about one cwt. English, divided into 44 oke, and each oke into 400 drahen.

41 Character of the Turks.

From their jealousy with respect to strangers, it is extremely difficult to form a true estimate of the national character of the Turks. An intelligent writer, who seems well qualified to direct our judgment in this respect, has thus delineated the Turkish character. "The Turks are in general a sagacious, thinking people; in the pursuit of their own interest, or fortune, their attention is fixed on one object, and they persevere with great steadiness until they attain their purpose. They are in common life seemingly obliging and humane, not without appearances of gratitude: perhaps all or either of these, when extended towards Christians, are practised with a view of some advantage. Interest is their supreme good; where that becomes an object of competition, all attachment of friendship, all ties of consanguinity, are dissolved; they become desperate, no barrier can stop their pursuit, or abate their rancour towards their competitors. In their demeanour they are rather hypochondriac, grave, sedate, and passive; but when agitated by passion, furious, raging, ungovernable; big with dissimulation; jealous, suspicious, and vindictive beyond conception; perpetuating revenge from generation to generation. In matters of religion, tenacious, supercilious, and morose *".

* Potter's Observations on the Religion, Manners, &c. of the Turks, vol. i. p. 4.

42 Manners and customs.

The manners and customs of the Turks are distinguished by the peculiarity of their religion from those of other European nations. On the birth of a child the father himself gives the name, putting at the same time a grain of salt into its mouth. The circumcision is not performed till the age of 12 or 14. Marriage is only a civil contract, which either party may break, and is managed by female mediation, the youth seldom seeing his bride till after the ceremony. The dead are perfumed with incense, and buried in a cloth, open at top and bottom, that the deceased may be able to sit up and answer the questions of the angels of death. The burial-grounds are near the highways, and stones are often placed at the heads of the graves, with carved turbans denoting the sex. As they never intrench upon a former grave, the cemeteries are very extensive. In diet the Turks are extremely moderate, and their meals are dispatched with great haste. Rice is the favourite food, and is dressed in three ways. In boiling, the meat is cut into small pieces, and in roasting still smaller, a bit of meat and an onion being placed alternately on a very long spit. The fish of the Archipelago are excellent, and the beef tolerable, except that of the buffalo, which is very hard. The hares, patridges, and other game, are of superior flavour. The meal is usually spread on a low wooden table, and the master of the house pronounces a short prayer. The frugal repast is followed by fruits and cold water, which are succeeded by hot coffee and pipes with tobacco. The houses of the Turks are seldom expensive; the chief furniture is the carpet which covers the floor, and a low sofa on one side of the room. In regard to dress, Tournefort observes that the use of the turban is unhealthy. The shirt is of callico, and the loose robe is fastened by a girdle, in which is stuck a dagger, while the tobacco box, pocket-book, &c. are worn in the bosom. The robe is generally of European broad cloth, trimmed with various furs. The shoes or slippers are slight, and unfit for much exercise. The dress of the women differs little from that of the men, the chief distinction being the head-dress; that of the fair sex consisting of a bonnet like

like an inverted basket, formed of pasteboard covered with cloth of gold, with a veil extending to the eye-brows, while a fine handkerchief conceals the under part of the face. The personal cleanliness of both sexes is highly laudable; but the European eye is not pleased with the female custom of staining the nails with a red tincture. The amusements of the Turks partake of their indolent apathy, if we except hunting, and those of a military description. To recline on an elegant carpet, or in a hot season by the side of a stream, and smoke the delicate tobacco of Syria, may be regarded as their chief amusement. Chess and draughts are favourite games; but those of chance are considered as incompatible with strict morals. The coffee-houses and baths furnish other sources of amusement; and the bairam, or festival which follows their long lent, is a season of universal dissipation *.

* *Pinkerton's Geography.*

It appears to be a mistaken notion, that the practice of eating opium, to procure intoxication, is general among the Turks. We are assured by a late traveller, that this practice is confined to a few individuals, who are regarded by the majority of their countrymen with as much contempt as drunkards are in the more polished societies of Europe.

TURNING, the art of forming hard bodies, as wood, ivory, iron, into a round or oval shape, by means of a machine called a *lathe.*

This art was well known to the ancients, and seems to have been carried by them to a very great degree of perfection; at least, if we believe the testimony of Pliny and several other authors, who tell us, that those precious vases enriched with figures in *half relief,* which still adorn our cabinets, were turned on the lathe.

The art of turning is of considerable importance, as it contributes essentially to the perfection of many other arts. The architect uses it for many ornaments, both within and without highly finished houses. The mathematician, the astronomer, and the natural philosopher, have recourse to it, not only to embellish their instruments, but also to give them the necessary dimension and precision. In short, it is an art absolutely necessary to the goldsmith, the watchmaker, the joiner, the smith.

Turning is performed by the lathe, of which there are various kinds, and several instruments, as gouges, chisels, drills, formers, screw tales, used for cutting what is to be turned into its proper form as the lathe turns round. The following is a simple kind of lathe (fig. 1.). in which *a* is the footstool, *b* the cord, *c* the frame of the lathe, *d d* thep uppets, *e e* the points, *f* the spanging-tree.

Plate DXL. fig. 1.

The lathe should be fixed in a place very well lighted; it should be immoveable, and neither too high nor too low. The puppets should neither be so low as to oblige the workman to stoop in order to see his work properly, nor so high that the little chips, which he is continually driving off, should come into his eyes.

The piece to be turned should be rounded (if it be wood) before it be put on the lathe, either with a small hatchet made for the purpose, or with a plane, or with a file, fixing it in a vice, and shaving it down till it is everywhere almost of an equal thickness, and leaving it a little bigger than it is intended to be when finished off. Before putting it on the lathe, it is also necessary to find the centres of its two end surfaces, and that they should be exactly opposite to each other, that when the *points* of the puppets are applied to them, and the piece is turned round, no side may belly out more than another. To find these two centres, lay the piece of wood to be turned upon a plank; open a pair of compasses to almost half the thickness of the piece; fix one of the legs in the plank, and let the point of the other touch one of the ends of the piece, brought into the same plane with the plank on which the compasses is fixed and very near the fixed leg. Describe four arches on that end at equal distances from each other at the circumference of the end, but intersecting one another within; the point of intersection is the centre of the end. In the same manner must the centre in the other end be found. After finding the two centres, make a small hole at each of them, into which insert the points of the puppets, and fix the piece so firmly as not to be shaken out, and yet loose enough to turn round without difficulty.

The piece being thus fixed, it is necessary in the next place to adjust the cord, by making it pass twice round the piece, and in such a manner that the two ends of the cord, both that which is fixed to the *spang* and to the *foot-board,* come off on the side on which the turner stands, that the piece may move against the edge of the cutting-tool and be turned. If the lathe be moved by a wheel, the manner of adjusting the cord needs no directions.

If the workman does not choose to be at the trouble to find the two centres of the piece in the manner described above, let him lay, as nearly as he can, the centre of one end upon the *point* of the left hand *puppet,* and then let him push forward the right hand puppet, striking it with a mallet till its point is as near as he can in the centre of the other end of the piece; and then fixing the right hand puppet by a gentle blow of the mallet on the key, let him turn round the piece to see by the eye if the centres have been properly found. If any part of it bellies out, let him strike that part gently with the mallet till it goes properly; then let him strike one of the puppets pretty smartly to drive the points into the piece, and afterwards fix the puppet by striking the key. If the workman cannot judge by the eye whether the piece be turning properly round its centres or not, he should apply gently the point of an instrument called a *triangular graver,* leaning it on the *rest,* and it will mark by a line the place where the piece is out of its centre; and by striking upon this line with a mallet, the piece can easily be placed properly. The *rest,* of which we have just spoken, ought to be placed upon the two arms of the lathe, and fixed with screws as near the piece as the workman pleases.

The piece being fixed between the two points of the puppets (or, as they are called in Scotland, the *heads*), the cord adjusted, and the *rest* fixed as near the work as possible without touching it; the workman is now to take a *gouge* (fig. 2. in which *a* is the mouth and *b* the handle) of a proper size in his left hand, and hold it by the handle a little inclined, keeping the back of the hand

Fig. 2.

Turning. hand lowermost. With his right hand, the back of which is to be turned upwards, he is to grasp it as near the end as possible on this side of the *rest;* then leaning the gouge on the *rest*, he is to present the edge of it a little higher than the horizontal diameter of the piece, so as to form a kind of tangent to its circumference; then putting the right foot on the foot-board, and turning round the wheel, and holding the gouge firmly on the *rest*, the piece will be cut neatly. In the same manner are the chisels, formers, and other instruments to be used, taking care that the wood be cut equally, and that the instrument be not pushed improperly, sometimes stronger than at others; and taking care also that the instrument used do not follow the work, but that it be kept firmly in the hand without yielding.

The young turner ought to endeavour to acquire the management of the gouge and the chisel, which are the instruments by far the most frequently used, and the most necessary in this art: by them, almost entirely, are the soft woods *turned;* but as for hard woods and other things, as box, ebony, horn, ivory, and the metals, they are hardly ever turned except by *shaving off*. In that case gravers are to be used with square, round, or triangular mouths (fig. 3, 4, 5.). They should be held horizontally while applied to the wood, and not obliquely as directed for the gouge and the chisel.

Fig. 3, 4, and 5.

After the work is completely turned, it is next to be polished; and this cannot be done with the instruments hitherto mentioned. Soft woods, as pear-tree, hazel, maple, ought to be polished with shark-skin or Dutch rushes. There are different species of sharks; some of which have a grayish, others a reddish skin. Shark-skin is always the better to be a good deal used: at first it is too rough for polishing. The *Dutch-rush (equisetum hyemale)*, which grows in moist places among mountains, and is a native of Scotland. The oldest plants are the best. Before using them they should be moistened a little, otherwise they break in pieces almost immediately, and render it exceedingly difficult to polish with them. They are particularly proper for smoothing the hard woods, as box, lignum vitæ, ebony, &c. After having cleaned up the piece well, it should be rubbed gently either with wax or olive-oil, then wiped clean and rubbed with its own raspings or with a cloth a little worn. Ivory, horn, silver, and brass, are polished with pumice-stone finely pounded and put upon leather or a linen cloth a little moistened: with this the piece is rubbed as it turns round in the lathe; and to prevent any dirt from adhering to any part of it, every now and then it is rubbed gently with a small brush dipt in water. To polish very finely, the workmen make use of tripoli, a particular kind of earth, and afterwards of putty or calx of tin. Iron and steel are polished with very fine powder of emery; this is mixed with oil, and put between two pieces of very tender wood, and then the iron is rubbed with it. Tin and silver are polished with a burnisher and that kind of red stone called in France *sanguine dune*. They may be polished also with putty, putting it dry into shamoy-skin, or with the palm of the hand.

To succeed in turning iron, it is necessary to have a *lathe* exceedingly strong in all its parts, and exceedingly well fixed. The puppets should be short, and the *rest* well fixed very near the work: the back of the *rest* should be two or three lines lower than the iron to be turned.

Turning.

The lathe and other instruments being prepared, it is necessary to determine the length and thickness of the iron to be turned according to the design which is to be executed, and to make a model of it in wood a little thicker than it ought to be: Then one exactly like this is to be forged of the best iron that can be procured; that is to say, it must not be new, but well prepared and well beaten with hammers; it must have no flaws, nor cracks, nor pimples. New iron, which has not been well beaten, often contains round drops of cast iron, called by the workmen *grains*, which blunt the edges of the gouges, chisels, and other instruments used for cutting, break them, or make them slide. The iron being forged according to the model, it should be annealed, that is, heated red hot and allowed to cool slowly on the coals till the fire go out of itself. Some people, to soften the iron, cover it over with clay and allow it to cool. The iron cylinder being thus made, it is next to be put upon the lathe, finding the centres as formerly directed, and boring a small hole in them that the iron may not escape from the points.

The points should be oiled from time to time to prevent their being excessively heated and spoiled while the iron is turning. A *crotchet* is then to be applied to the iron to be turned, a little above its centre, pretty gently, and by this means the inequalities of the cylinder will be taken off. Other instruments are then to be applied to mould the iron according to the model; and whenever any of them grow hot, they are to be plunged into a bason of water lying beside the workman. If the iron, after being properly turned, is to be bored like a gun-barrel, one of the puppets is to be removed and another substituted in its place, having a square hole through it, into which the collar of the iron is to be fixed firmly, so as not to shake; then borers are to be applied, like those which locksmiths use to bore keys; and beginning with a small one, and afterwards taking larger ones, the hole is to be made as wide and deep as necessary; great care must be taken to hold the borers firm on the *rest*, otherwise there is danger of not boring the hole straight. The borer must be withdrawn from time to time to oil it and to clean the hole. Since it is difficult to make a hole quite round with borers alone, it is necessary to have also an instrument a good deal smaller than the hole, one of the sides of which is sharp, very well tempered, and a little hollow in the middle. This instrument being fixed in a pretty long handle, is to be applied with steadiness to the inner surface of the hole, and it will entirely remove every inequality that may have been there before its application.

To cut a screw upon the cylinder, some persons use an instrument consisting principally of a female screw; but this is rather an improper instrument; for if one presses too violently, or inclines it ever so little to the right or left, he runs the greatest risk of spoiling the screw. To avoid this danger, some use it only to trace out the lines of the screw, and afterwards finish it with a file. But the following is a much better way. Take a tap for making a female screw, the threads of which have been cut very accurately, and exactly of the size of the screw which you want; and having put it in the opening which you have traced in the collar of the axis

TURNING. PLATE DXL.

Turning.

axis on which the screw is to be cut, solder it with tin, sal-ammoniac, and rosin, as exactly corresponding to the axis as possible. Take then a puppet with a hole cut into a corresponding female screw, into which the male screw is to be put. The axis on which the screw is to be cut must be placed exactly horizontally between the two puppets. The *rest* is then to be brought as near as possible to the place where the screw is to be cut, and a small hollow should be cut in that part of it which is exactly opposite to the place where the screw is to be cut, to hold your instrument firmly and prevent it from shaking. The instrument with which the screw is to be cut should be very sharp, and its point should make an angle of 60° with the screw to be cut; and if you wish the screw to be cut very deep, it should make an angle a little larger. The lathe being now put in motion, the tap fixed at the end of the axis will move gradually through the female screw in the puppet; and your instrument in the mean time will trace a similar male screw on the axis fixed in the lathe. Many persons, after having in this manner drawn the outlines of the screw, finish it with a screw-tale of three teeth corresponding exactly to the size of the screw, or with a triangular file; but this last method is rather improper.

For turning ovals, a lathe of somewhat a different construction is used. The axis or spindle, having on it the pulley over which the band-cord passes for turning the lathe, is fixed between the two puppets so as to turn round easily: one end of it passes through one of the puppets, and to it is firmly fixed a circular plate of brass, so that it turns round along with the spindle. Upon this plate two brazen segments of circles are fastened, the circumferences of which correspond to the circumference of the plate: their chords are parallel, and equally distant from the centre of the plate, so that they leave a distance between them. They have a groove in each of them: in these grooves another plate is placed which exactly fills up the space between the two grooves, but is shorter than the diameter of the large circular plate on which it is laid. This plate is made to slide in the grooves. To its centre is fixed a short spindle, on which the piece of wood to be turned is fixed. When the lathe is set a going, the circular plate moves round, and carries the piece along with it; the plate of brass on which the piece is fixed being fixed loosely in the grooves already described, slides down a little every time that the grooves become perpendicular to the floor (and there are particular contrivances to prevent it from sliding down too far); and by these two motions combined, the circular one of the large plate, and the straight one of the small, the circumference of the piece of wood to be turned necessarily describes an oval; and gouges or other tools being applied in the usual manner supported on the *rest*, it is cut into an oval accordingly. The small plate may be made to slide either more or less in the grooves; and by this contrivance the transverse diameter of the oval, or rather ellipse, may be made longer or shorter at pleasure.

1. *The method of moulding boxes of shell and horn.*—In the first place, form a proper mould, which must consist of two pieces, viz. of a circle about half an inch thick, which should slope a little in order to draw out the moulded shell the more easily; and a ring fitted to the outside of the circle, so that both together make the shape of a box. These two pieces being adjusted, it is necessary to round the shell to be moulded of such a size that when moulded, it will be a little higher than the ring of the mould, that there may be no deficiency. The mould is then to be put into a press on a plate of iron, exactly under the screw of the press; put then the shell upon the circle of the mould, so that its centre also is exactly opposite to the screw of the press: then take a piece of wood formed into a truncated cone, and not so thick as the diameter of the circle of the mould, nor so deep as the ring: then put a plate of iron above the cone, and screw down the press gently and cautiously till the whole is well fixed: then plunge the whole into a cauldron of boiling water placed above a fire. In 8 or 10 minutes the shell or horn will begin to soften; screw the press a little firmer that the wooden cone may sink into the softened shell: repeat this from time to time till the cone is quite sunk in the mould; then take out the press and plunge it into cold water. When it is cold, take the box now formed out of the mould, and put into the inside of it a new mould of tin exactly of the form you wish the inside of the box to be; do the same with the outside, put it again into the press and plunge it into boiling water; screw the press gradually till the box receive the desired form.

2. *Method of preparing green wood so that it will not split in the turning.*—Cut the wood into pieces of a proper size, put them into a vessel full of potash ley. Boil them about an hour; take the cauldron from the fire, allow the ley to cool; and take out the wood and dry it in the shade.

3. *Method of giving an ebony-black to hard and fine woods.*—After forming the wood into the destined figure, rub it with aquafortis a little diluted. Small threads of wood will rise in the drying, which you will rub off with pumice-stone. Repeat this process again, and then rub the wood with the following composition: Put into a glazed earthen vessel a pint of strong vinegar, two ounces of fine iron filings, and half a pound of pounded galls, and allow them to infuse for three or four hours on hot cinders. At the end of this time augment the fire, and pour into the vessel four ounces of copperas, and a chopin of water having half an ounce of borax and as much indigo dissolved in it; and make the whole boil till a froth rises. Rub several layers of this upon the wood; and when it is dry, polish it with leather, on which you have put a little tripoli.

4. *Method of giving to plum-tree the colour of brazil wood.*—Slake lime with urine, and bedaub the wood over with it while it is hot: allow it to dry; then take off the coat of lime, and rub it with shamoy skin well oiled. Or, steep the wood in water, having a quantity of alum dissolved in it: then, having allowed brazil wood to dissolve in water five or six hours, steep the wood in it, kept lukewarm during a night; and when it is dry, rub it, as before directed, with shamoy skin well oiled.

5. *Method of giving a fine black colour to wood.*—Steep the wood for two or three days in lukewarm water in which a little alum has been dissolved; then put a handful of logwood, cut small, into a pint of water, and boil it down to less than half a pint. If you then add a little indigo, the colour will be more beautiful. Spread a layer of this liquor quite hot on the wood with a pencil, which will give it a violet colour. When

When it is dry, spread on another layer; dry it again and give it a third: then boil verdegrise at discretion in its own vinegar, and spread a layer of it on the wood: when it is dry, rub it with a brush, and then with oiled shamoy skin. This gives a fine black, and imitates perfectly the colour of ebony.

6. *Method of cleaning and whitening bones before using them.*—Having taken off with a saw the useless ends of the bones, make a strong ley of ashes and quicklime, and into a pailful of this ley put four ounces of alum, and boil the bones in it for an hour; then take the vessel containing the ley off the fire, and let it cool; then take out the bones and dry them in the shade.

7. *Method of soldering shells.*—Clean the two sides of the shells which you wish to join together; then, having joined them, wrap them up in linen folded double and well moistened; then heat two plates of iron pretty hot, that they may keep their heat for some time; and putting the shells rolled up between them under a press, which you must screw very tight, leave them there till the whole is cold, and they will be soldered. If you do not succeed the first time, repeat the process.

8. *Method of moulding shells.*—Put six pints of water into a kettle; add to it an ounce of olive or other oil; make the water boil; then put in your shell, and it will grow soft. Take it out and put it into a mould under a press, and it will take the figure you want. This must be done quickly; for if the shell cool ever so little, the process will fail. It will not require much pressure.

9. *Method of tinging bones and ivory red.*—Boil shavings of scarlet in water. When it begins to boil, throw in a quarter of a pound of ashes made from the dregs of wine, which will extract the colour: then throw in a little rock alum to clear it, and pass the water through a linen cloth. Steep the ivory or bone in aquafortis, and put it into the water. If you wish to leave white spots, cover the places destined for them with wax.

10. *To tinge ivory black.*—Steep the ivory during five or six days in water of galls with ashes made with dried dregs of wine and arsenic; then give it two or three layers of the same black with which plum-tree is blackened, in order to imitate ebony. Or, dissolve silver in aquafortis, and put into it a little rose-water. Rub the ivory with this, and allow it to dry in the sun.

11. *Method of hardening wood to make pulleys.*—After finishing the pulley, boil it seven or eight minutes in olive oil, and it will become as hard as copper.

12. *To make Chinese varnish.*—Take of gum lac in grains four ounces; put it into a strong bottle with a pound of good spirit of wine, and add about the bulk of a hazel nut of camphor. Allow them to mix in summer in the sun, or in winter on hot embers for 24 hours, shaking the bottle from time to time. Pass the whole through a fine cloth, and throw away what remains upon it. Then let it settle for 24 hours, and you will find a clear part in the upper part of the bottle, which you must separate gently, and put into another vial, and the remains will serve for the first layers.

TURNSTONE. See TRINGA, ORNITHOLOGY *Index*.

TUSCAN ORDER, in *Architecture*. See ARCHITECTURE, N° 42.

TUSCAN Earth, a yellowish kind of bole found in many parts of Italy, and particularly about Florence, where there is a stratum eight or ten feet thick, at the depth of five or six feet from the surface. It is supposed to have an astringent property.

TUSCANY, a duchy of Italy, which makes part of the ancient Hetruria, and, excepting some detached parts, is encompassed by a part of the Mediterranean, called the *Tuscan sea;* the ecclesiastical state; the duchy of Modena; and the republic of Lucca; its extent from north to south being about 116 English miles, and from east to west about 80; its area 8400; and in 1815 it was estimated to contain 1,195,000 inhabitants.

Though some parts of it are mountainous, yet both the hills and dales are covered with vines, olives, citron, lemon, and orange trees, &c. The mountains yield also copper, iron, alum, &c. and some of the finest marble. Here is also plenty of corn, rice, saffron, honey, wax, wool, flax, hemp, with mineral waters, rich pasture, salt-pits, sulphur, alabaster, calcedony, lapis lazuli, borax, amethysts, carnelians, and jaspers. In some places the elms and ashes yield manna.

The principal river in Tuscany is the Arno, which has its source in the Apennine mountains, and falls into the sea below Pisa. There are some other smaller rivers.

This duchy fell under the dominion of the Romans about 455 years before Christ. The Ostrogoths possessed themselves of it in the fifth century, and after them the Lombards, who were expelled by Charlemagne anno 800; in consequence of which it became subject to the German emperors, who appointed governors over it. At last the cities of Florence, Pisa, Sienna, and some others, during the contentions between the pope and the emperor, and their respective adherents, the Guelphs and Gibbelines, withdrew themselves from the dominion of both, and erected themselves into separate commonwealths. In that of Florence, John de Medicis, a popular nobleman, so insinuated himself into the favour of his countrymen, that they invested him with sovereign power. Pope Pius V. conferred the title of *grand duke* on Cosmo de Medicis anno 1570, in whose family the duchy continued until the death of Gaston de Medicis, who died anno 1737. The duchy was then transferred to the duke of Lorrain, afterwards the emperor.

peror Francis I. in lieu of the duchy of Lorrain, which, by the peace of 1736, was given to King Stanislaus during his life, and then was to be annexed to France. The Austrian family lost this duchy in 1797. After undergoing various changes, it was united to France in 1806, and continued in her possession till the events of 1814 restored its independence. Its prince, who is of the royal family of Spain, is now a minor. The grand duke's annual revenues are computed at about 500,000l. sterling, arising chiefly from the tenths of all estates that are sold or alienated, and the ground rents of the houses in Leghorn, and the duties on almost all manner of provisions.

TUSK, or TORSK. See GADUS, ICHTHYOLOGY *Index*.

TUSSILAGO, COLT'S-FOOT; a genus of plants, belonging to the class of syngenesia; and in the natural system ranging under the 49th order, *Compositæ*. See BOTANY *Index*.

TUTENAG, an alloy of zinc. See CHEMISTRY *Index*.

TUTOR, in the civil law, is one chosen to look to the persons and estates of children left by their fathers and mothers in their minority. The different kinds of *tutory* established among the Romans, and the powers and duties of tutors, are described in *Inst. leg.* 1. tom. xiii. sect. 1. and 2. to which the reader is referred. See also the article GUARDIAN.—For the nature and effects of tutory in the Scotch law, which is founded on that of the Romans. See *Scots LAW*, Part III. Sect. 7.

TUTOR is also used in the English universities for a member of some college or hall, who takes on him the instruction of young students in the arts and faculties.

TUTTY, an impure ore of zinc, employed as an unguent and absorbent. See MATERIA MEDICA *Index*.

TWEED, a river of Scotland, which rises on the confines of Clydesdale, and running eastward through Tweedale, and dividing the shire of Merse from Teviotdale and Northumberland, falls into the German sea at Berwick. It abounds with salmon. See BERWICK.

TWEEDALE, or PEEBLES, a county in the south of Scotland. See PEEBLES-SHIRE.

TWELFTH-DAY, the festival of the Epiphany, or the manifestation of Christ to the Gentiles; so called, as being the twelfth day, exclusive, from the nativity or Christmas-day.

TWILIGHT, that light, whether in the morning before sunrise, or in the evening after sunset, supposed to begin and end when the least stars that can be seen by the naked eye cease or begin to appear.

TWINKLING *of the STARS*. See OPTICS, N° 21.

TWINS, two young ones delivered at a birth, by an animal which ordinarily brings forth but one.

TWITE. See FRINGILLA, ORNITHOLOGY *Index*.

TYGER, or TIGER. See FELIS, MAMMALIA *Index*.

TYLE, or TILE, in building, a thin laminated brick used on the roofs of houses.

TYMPAN, among printers, a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off. See *PRINTING-Press*.

TYMPANUM, in *Mechanics*, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves for the more easily turning the axis in order to raise a weight required.

TYMPANUM, in *Anatomy*. See ANATOMY, N° 141.

TYMPANY, or TYMPANITES, in *Medicine*. See MEDICINE, N° 337, and SURGERY *Index*.

TYNDALE, WILLIAM, a zealous English reformer, and memorable for having made the first English version of the Bible, was born on the borders of Wales some time before 1500. He was of Magdalene-hall in Oxford, where he distinguished himself by imbibing early the doctrines of Luther, and by as zealously propagating them. Afterwards he removed to Cambridge, and from thence went to live with a gentleman in Gloucestershire in the capacity of tutor to his children.—While he continued there, he showed himself so furious for Luther, and so inveterate to the pope, that he was forced, merely for the security of his person, to leave the place. He next endeavoured to get into the service of Tonstall bishop of Durham, but did not succeed. His zeal for Lutheranism made him desirous to translate the New Testament into English; and as this could not safely be done in England, he went into Germany, where, setting about the work, he finished it in 1527: He then began with the Old Testament, and finished the five books of Moses, prefixing discourses to each book, as he had done to those of the New Testament. At his first going over into Germany, he went into Saxony, and had much conference with Luther; and then returning to the Netherlands, made his abode chiefly at Antwerp. During his peregrinations from one country to another, he suffered shipwreck upon the coast of Holland, and lost all his books and papers. His translations of the Scriptures being in the mean time sent to England, made a great noise there; and, in the opinion of the clergy, did so much mischief, that a royal proclamation was issued, prohibiting the buying or reading them. But the clergy were not satisfied with this, they knew Tyndale capable of doing infinite harm, and therefore thought of nothing less than removing him out of the way. For this purpose one Philips was sent over to Antwerp, who insinuated himself into his company, and under the pretext of friendship betrayed him into custody. He was sent to the castle of Filford, about 18 miles from Antwerp; and though the English merchants at Antwerp did what they could to procure his release, and letters were also sent from Lord Cromwell and others out of England, yet Philips bestirred himself so heartily, that he was tried and condemned to die. He was first strangled by the hands of the common hangman, and then burned near Filford castle, in 1536. While he was tying to the stake, he cried with a fervent and loud voice, "Lord, open the king of England's eyes."

TYPE (τυπος), an impression, image, or representation of some model, which is termed the *antitype*. In this sense the word occurs often in the writings of divines, who employ it to denote that prefiguration of the great events of man's redemption which they have found or fancied in the principal transactions recorded in the Old Testament.

TYPE, among letter-founders and printers, the same with letter.

TYPE is also used to denote the order observed in the intension and remission of fevers, pulses, &c.

TYPHA, CAT'S-TAIL; a genus of plants belonging to the class of monœcia, and in the natural system ranging under the 3d order, *Calamariæ*. See BOTANY *Index*.

TYPHON. See WHIRLWIND.

TYPHON, the devil of the ancient Egyptians. See POLYTHEISM, N° 29.

TYPOGRAPHY, the art of printing. See PRINTING.

TYRANT, among the ancients, denoted simply a king or monarch; but the ill use which several persons invested with that sacred character made of it, has altered the import of the word; and tyrant now conveys the idea of an unjust or cruel prince, who rules in a more despotic manner than the laws allow.

TYRE, formerly a celebrated city of Asia, on the coast of Syria, situated under the 54th degree of east longitude, and 32d of north latitude. It was built, according to some writers, 2760 years before the Christian era. There were two cities of that name; the one called *Palætyrus*, situated on the continent; and the other the city of *Tyre*, built on an island about half a mile from the shore. It was about 19 miles in circumference, including Palætyrus; the town on the island was about four miles round. The buildings of Tyre were very magnificent; the walls were 150 feet high, and broad in proportion. The city was at one period the most famous commercial city in the world. Of its commercial transactions, the most particular account that is to be found in any ancient writer has been given by the prophet Ezekiel, which at the same time conveys a magnificent idea of the extensive power of that state. It resisted Nebuchadnezzar king of Babylon for 13 years; at the end of which, wearied with fruitless efforts, the inhabitants resolved to place the sea between them and their enemy, and passed accordingly into the island. The new city stood out against Alexander the Great for seven months; and before he could take it, he was obliged to fill up the strait which separated the island from the continent. It was repaired afterwards by Adrian, and became the metropolis of the province. It afterwards fell into the hands of the Arabs; and after being taken by Baldwin II. king of Jerusalem, it was destroyed by the sultan of Egypt in 1289, and abandoned. An excellent account of its modern state may be found in Volney's Travels, vol. ii. It now consists of a small village, composed of fishermen's huts, and containing about 50 or 60 poor families.

TYRIAN DYE. See MUREX, CONCHOLOGY *Index*.

TYRONE, a county of Ireland, in the province of Ulster, 46 miles in length and 37 in breadth; bounded on the north by Londonderry, on the east by Armagh and Lough-Neagh, on the south by Fermanagh, and on the west by Donnegal. It is a rough and rugged country, but tolerably fruitful; contains 12,683 houses, 30 parishes, 4 baronies, 4 boroughs, and formerly sent 10 members to the Irish parliament. The principal town is Dungannon.

U, V.

U, or u, the 20th letter and 5th vowel of our alphabet, is formed in the voice by a round configuration of the lips, and a greater extrusion of the under one than in forming the letter o, and the tongue is also more cannulated. The sound is short in *curst, must, tun, tub;* but is lengthened by a final *e*, as in *tune, tube*, &c. In some words it is rather acute than long; as in *brute, flute, lute*, &c. It is mostly long in polysyllables; as in *union, curious*, &c.; but in some words it is obscure, as in *nature, venture*, &c. This letter in the form of V or v, is properly a consonant, and as such is placed before all the vowels; as in *vacant, venal, vibrate*, &c. Though the letters v and u had always two sounds, they had only the form v till the beginning of the fourth century, when the other form was introduced, the inconvenience of expressing two different sounds by the same letter having been observed long before. In numerals V stands for five; and with a dash added at top, thus $\bar{V}$, it signifies 5000.

In abbreviations, amongst the Romans, V. A. stood for *veterani assignati;* V. B. *viro bono;* V. B. A. *viri boni arbitratu;* V. B. F. *vir bonæ fidei;* V. C. *vir consularis;* V. C. C. F. *vale, conjux charissime, feliciter;* V. D. D. *voto dedicatur;* V. G. *verbi gratia;* Vir. Ve. *virgo vestalis;* VL. *videlicet;* V. N. *quinto nonarum*.

VACCINIUM, the WHORTLE-BERRY, or *Bilberry*, a genus of plants belonging to the class octandria, and arranged in the natural system under the 18th order, *Bicornes*. See BOTANY *Index*.

VACUUM, in *Philosophy*, denotes a space devoid of all matter or body.

It has been greatly disputed whether there be in nature a perfect vacuum, or space void of all matter; but if bodies consist of material solid atoms, it is evident that there must be vacuities, or motion would be impossible (See METAPHYSICS, N° 193.). We can even produce something very near a vacuum in the receiver of an air-pump and in the Torricellian tube (see PNEUMATICS, *passim*).

VADIUM, a pledge in law, is either *vivum* or *mortuum*.

VADIUM *Vivum*, or *Living Pledge*, is when a man borrows a sum (suppose 200l.) of another; and grants him an estate, as of 20l. per annum, to hold till the rents and profits shall repay the sum so borrowed. This is an estate conditioned to be void as soon as such sum is raised. And in this case the land or pledge is said to be living: it subsists, and survives the debts; and, immediately on the discharge of that, reverts to the borrower.

Vadium Mortuum, or *Dead Pledge*. See Mortgage.

VAGABOND, or Vagrant, one who wanders illegally, without a settled habitation. Such persons are cognizable by the laws. See Idleness.

VAGINA, properly signifies a sheath or scabbard; and the term *vagina* is used in architecture for the part of a terminus, because resembling a sheath out of which the statue seems to issue.

Vagina. See Anatomy *Index*.

VAILLANT, John Foy, a physician and great medalist, to whom, according to Voltaire, France was indebted for the science of medals, and Louis XIV. for one half of his cabinet, was born at Beauvais in 1632. Through the means of the minister Colbert he travelled into Italy, Greece, Egypt, and Persia, to collect medals for the royal cabinet; and returned with so many as made the king's cabinet superior to any in Europe. In one of his voyages the ship was taken by an Algerine corsair. After a captivity of near five months he was permitted to return to France, and received at the same time 20 gold medals which had been taken from him. He embarked in a vessel bound for Marseilles, and was carried on with a favourable wind for two days, when another corsair appeared, which, in spite of all the sail they could make, bore down upon them within the reach of cannon shot. Mr Vaillant, dreading the miseries of a fresh slavery, resolved, however, to secure the medals which he had received at Algiers, and therefore swallowed them. But a sudden turn of the wind freed them from this adversary, and cast them upon the coast of Catalonia, where, after expecting to run aground every moment, they at length fell among the sands at the mouth of the Rhone. Mr Vaillant got to shore in a skiff, but felt himself extremely incommoded with the medals he had swallowed, which might weigh altogether five or six ounces, and therefore did not pass like Scarborough waters. He had recourse to a couple of physicians; who were a little puzzled with the singularity of his case; however, nature relieved him from time to time, and he found himself in possession of the greatest part of his treasure when he got to Lyons. Among his collection was an Otho, valuable for its rarity.—He was much caressed on his return; and when Louis XIV. gave a new form to the academy of inscriptions in 1701, Mr Vaillant was first made associate, and then pensionary. He wrote several works relating to ancient coins, and died in 1706.

VAIR, or Vairé, a kind of fur, formerly used for lining the garments of great men and knights of renown. It is represented in engraving by the figures of little bells reversed, ranged in a line. See Heraldry, Chap. II. Sect. 2.

VAIRY, in *Heraldry*, expresses a coat, or the bearings of a coat, when charged or chequered with vairs.

VALAIS, a valley in Swisserland, which extends from the source of the river Rhone to the lake of Geneva. It is near 100 miles in length, but of unequal breadth. It is bounded on the north by the Alps, which separate it from the cantons of Berne and Uri, on the east by the mountains of Forche, on the south by the duchy of Milan and the Val d'Aoste, and on the west by Savoy and the republic of Geneva. The inhabitants profess the Roman Catholic religion, and are subject to the swelling of the throat called *bronchocele*; and idiots are said to abound among them more than in any other place of the globe. They are naturally hardy, enterprising, and good-natured. Valais is surrounded on all sides by very high mountains, most of which are covered with perpetual snow. The soil is fertile in corn, wine, and fruits. The muscat-wine, which is produced here is excellent, and well known all over Europe. This country comprehends 55 large parishes, with one bishop. The religion is the Roman Catholic.

VALANTIA, a genus of plants belonging to the class polygamia, and in the natural system arranged under the 41st order, *Asperifoliæ*. See Botany *Index*.

VALENCIA, a province of Spain, which has the title of a kingdom; and is bounded on the east and south by the Mediterranean sea, on the north by Catalonia and Arragon, and on the west by New Castile and the kingdom of Murcia. It is about 165 miles in length, and 63 in breadth, and in 1788 contained 783,000 inhabitants. It is one of the most agreeable parts of Spain, enjoying almost a perpetual spring. The great number of rivers wherewith it is watered renders it extremely fertile. There are very rugged mountains in it, which contain mines of alum and other minerals.

Valencia, a city of Spain, and capital of the kingdom of the same name. It contains, according to Laborde, 20,000 houses, and 100,000 inhabitants. It has an university, and an archbishop's see; and was taken from the Moors by the Christians in the 13th century. The town is handsome, and adorned with very fine structures. It is not very strong, though there are some bastions along the sides of the walls. They have manufactures in wool and silk, which bring in great sums to the inhabitants. It is seated on the river Guadalaviar, over which there five handsome bridges; and it is about three miles from the sea, where there is a harbour, 110 miles north of Murcia, and 165 east by south of Madrid. This city surrendered to the earl of Peterborough in the year 1705; and suffered dreadfully when taken by Marshal Suchet in 1811. W. Long. 0. 10. N. Lat. 39. 27.

VALENCIENNES, an ancient, strong, and considerable city of France, in the department of the North, containing about 17,000 inhabitants in 1800. The Scheldt divides it into two parts. It is a very important place: the citadel and fortifications, the work of Vauban, were constructed by order of Louis XIV. who took this town from the Spaniards. It was confirmed to him by the treaty of Nimeguen, in 1678. In 1793, it surrendered to the allies after a severe siege; but was afterwards abandoned; and is now in possession of the French. Besides lace, this city is noted for manufactories of woollen stuffs and very fine linens. It is 20 miles west-south-west of Mons, 17 north-east of Cambray, and 120 north-east by north of Paris. E. Long. 3. 37. N. Lat. 50. 21.

VALENS, Flavius, emperor of the East, a great patron of the Arians. Killed by the Goths in the year 379. See Constantinople, N° 76.

VALENTINIAN I. emperor of the West, a renowned warrior, but a tyrant over his subjects. See Rome, N° 523.

Valentinian II. emperor of the West, a prince celebrated for his virtues, and above all for his moderation; yet a conspiracy was formed against him by Arbogastes, Variation. the explanations that have been offered to account for this phenomenon.

About the time that the polarity of the magnet was first observed in Europe, the magnetic direction, both in Europe and in China, was nearly in the plane of the meridian. It was therefore an inestimable present to the mariner, giving him a sure direction in his course through the pathless ocean. But by the time that the European navigators had engaged in their adventurous voyages to far distant shores, the deviation of the needle from the meridian was very sensible even in Europe. The son of Columbus positively says, that it was observed by his father in his first voyage to America, and made his companions so anxious lest they should not find the way back again to their own country, that they mutinied and refused to proceed. It is certain that Gonzales Oviedo and Sebastian Cabot observed it in their voyages. Indeed it could not possibly escape them; for in some parts of their several tracks the needle deviated above 25° from the meridian; and the rudest dead reckoning, made on the supposition of the needle pointing due north and south, must have thrown the navigators into the utmost confusion. We know that spherical trigonometry was at that time abundantly familiar to the mathematicians of Europe, and that no person pretended to take the command of a ship bound to a distant port that was not much more informed in this science than most masters of ships are at present. The deviation of the compass, however, was not generally allowed by mathematicians, who had not yet become sensible of the necessity of quitting the Aristotelian trammels, and investigating nature by experiments. They chose rather to charge the navigators with inaccuracy in their observations than the schoolmen with errors in principles. Pedro de Medina at Valladolid, in his *Arte de Naviggar*, published in 1545, denies the variation of the compass. But the concurring reports of the commanders of ships on distant voyages, in a few years, obliged the landsmen in their closets to give up the point; and Martin Cortez, in a treatise of navigation, printed at Seville before 1556, treats it as a thing completely established, and gives rules and instruments for discovering its quantity. About the year 1580 Norman published his discovery of the *dip* of the needle, and speaks largely of the horizontal deviation from the plane of the meridian, and attributes it to the attraction of a point, not in the heavens, but in the earth, and describes methods by which he hoped to find its place. To the third, and all the subsequent editions of Norman's book (called the *New Attractive*), was subjoined a dissertation by Mr Borroughs, comptroller of the navy, on the variation of the compass, in which is recorded the quantity of this deviation in many places; and he laments the obstacle which it causes to navigation by its total uncertainty previous to observation. The author indeed offers a rule for computing it *à priori*, founded on some conjecture as to its cause; but, with the modesty and candour of a gentleman, acknowledges that this is but a guess, and intreats all navigators to be assiduous in their observations, and ready in communicating them to the public. Accordingly observations were liberally contributed from time to time, and were published in the subsequent treatises on navigation.

But in 1635 the mariners were thrown into a new and great perplexity, by the publication of a *Discourse Mathematical on the Variation of the Magnetical Needle*, by Mr Henry Gillebrand, Gresham professor of astronomy. He had compared the variations observed at London by Burroughs, Gunter, and himself, and found that the north end of the mariner's needle was gradually drawing more to the westward. For Norman and Burroughs had observed it to point about $11\frac{1}{4}$ degrees to the east of north in 1580; Gunter found its deviation only $6\frac{1}{4}$ in 1622, and he himself had observed only 4° in 1634; and it has been found to deviate more and more to the westward ever since, as may be seen from the tables given under MAGNETISM.

Mr Bond, teacher of mathematics in London, and employed to edit and improve the impressions of the popular treatises of navigation, about 1650, declared, in a work called the "Seaman's Kalendar," that he had discovered the true progress of the deviation of the compass; and published in another work, called "the Longitude Found," a table of the variation for 50 years. This was, however, a gratuitous prognostication, not founded on any well-grounded principles; and though it agreed very well with the observations made in London, which showed a gradual motion to the westward at the rate of —.12′ annually, by no means agreed with the observations made in other places. See Phil. Trans. 1668.

But this news soon lost its credit: for the inconsistency with observation appeared more and more every day, and all were anxious to discover some general rule, by which a near guess at least might be made as to the direction of the needle in the most frequented seas. Halley recommended the matter in the most earnest manner to the attention of government; and, after much unwearied solicitation, obtained a ship to be sent on a voyage of discovery for this purpose. He got the command of this ship, in which he repeatedly traversed the Atlantic ocean, and went as far as the 50th degree of southern latitude. See his very curious speculations on this subject in the Phil. Trans. 1683 and 1692.

After he had collected a prodigious number of observations made by others, and compared them with his own, he published in 1700 a synoptical account of them in a very ingenious form of a sea chart, where the ocean was crossed by a number of lines passing through those planes where the compass had the same deviation. Thus, in every point of one line there was no variation in 1700; in every point of another line the compass had 20° of east variation; and in every point of a third line it had 20° of west variation. These lines have since been called *Halleyan lines*, or curves. This chart was received with universal applause, and was undoubtedly one of the most valuable presents that science has made to the arts.

The polarity of the magnetic needle, and a general though intricate connection between its positions in all parts of the world, naturally makes the philosopher speculate about its cause. We see that Cortez ascribed it to the attraction of an eccentric point, and that Bond thought that this point was placed not in the heavens, but in the earth. This notion made the basis of the famous Theory of Magnetism of Dr Gilbert of Colchester. See MAGNETISM, N° 71.

Gilbert's theory may be understood from the following general proposition. Plate DXL. fig 1.

Let NS (fig. 1.) be a magnet, of which N is the north

Variation.

north and S the south pole: Let $n\,s$ be any oblong piece of iron, poised on a point c like a compass needle. It will arrange itself in a position $n\,c\,s$ precisely the same with that which would be assumed by a compass needle of the same size and shape, having n for its north and s its south pole. And while the piece of iron remains in this position, it will be in all respects a magnet similar to the real compass needle. The pole n will attract the south pole of a small magnetised needle, and repel its north pole. If a paper be held over $n\,s$, and fine iron-filings be strewed on it, they will arrange themselves into curves issuing from one of its ends and terminating at the other, in the same manner as they will do when strewed on a paper held over a real compass needle. But this magnetism is quite temporary; for if the piece of iron $n\,s$ be turned the other way, placing n where s now is, it will remain there, and will exhibit the same phenomena. We may here add, that if $n\,s$ be almost infinitely small in comparison of NS, the line $n\,s$ will be in such a position that if $s\,a$, $s\,b$, be drawn parallel to N c, S c, we shall have $s\,a$ to $s\,b$, as the force of the pole N to the force of the pole S. And this is the true cause of that curious disposition of iron-filings when strewed round a magnet. Each fragment becomes a momentary magnet, and arranges itself in the true magnetic direction, and when so arranged, attracts the two adjoining fragments, and co-operates with the forces, which also arrange them. We throw this out to the ingenious mechanician as the foundation of a *complete* theory of the magnetical phenomena. When the filings are infinitely fine, the curves NcS have this property, that, drawing the tangent $n\,c\,s$, we always have $s\,a : s\,b =$ force of N : force of S; and thus we may approximate at pleasure to the law of magnetic attraction and repulsion. The theory, of which an outline is given under MAGNETISM, is founded on this principle, and applies with success to every phenomenon yet observed.

Now, to apply this theory to the point in hand.—Let $n\,s$ (fig. 2.) be a small compass needle, of which n is the north and s the south pole: let this needle be poised horizontally on the pin $c\,d$; and let $n'\,s'$ be the position of the *dipping needle*. Take any long bar of common iron, and hold it upright, or nearly so, as represented by AB. The lower end B will repel the pole n and will attract the pole s, thus exhibiting the properties of a north pole of the bar AB. Keeping B in its place, turn the bar round B′ as a centre, till it come into the position A′ B′ nearly parallel to $n'\,s'$. You will observe the compass needle $n\,s$ attract the end B′ with either pole n or s, when B′ A′ is in the position B′ a perpendicular to the direction $n'\,s'$ of the dipping needle: and when the bar has come into the position B′ A′, the upper end B′ will show itself to be a south pole by attracting n and repelling s. This beautiful experiment was exhibited to the Royal Society in 1673 by Mrs Hindshaw.

From this it appears, that the great magnet in the earth induces a momentary magnetism on soft iron precisely as a common magnet would do. Therefore (says Dr Gilbert) it induces permanent magnetism on magnetisable ores of iron, such as loadstones, in the same manner as a great loadstone would do; and it affects the magnetism already imparted to a piece of tempered steel precisely as any other great magnet would.

Therefore the needle of the mariner's compass in every part of the world arranges itself in the magnetic direction, so that if poised as a dipping needle should be, it will be a tangent to one of the curves NcS of fig. 1. The horizontal needle being so poised as to be capable of playing only in a horizontal plane, will only arrange itself *in the plane* of the triangle NcS. That end of it which has the same magnetism with the south pole S of the great magnet included in the earth will be turned towards its north pole N. Therefore what we call the north pole of a needle or magnet really has the magnetism of the south pole of the great primitive magnet. If the line NS be called the axis, and N and S the poles of this great magnet, the plane of any one of these curves NcS will cut the earth's surface in the circumference of a circle, great or small according as the plane does or does not pass through the centre of the earth.

Dr Halley's first thought was, that the north pole of the great magnet or loadstone which was included in the bowels of the earth was not far from Baffin's bay, and its south pole in the Indian ocean south-west from New Zealand. But he could not find any positions of these two poles which would give the needle that particular position which it was observed to assume in different parts of the world; and he concluded that the great terrestrial loadstone had four irregular poles (a thing not unfrequent in natural loadstones, and easily producible at pleasure), two of which are stronger and two weaker. When the compass is at a great distance from the two north poles, it is affected so as to be directed nearly in a plane passing through the strongest. But if we make it approach much more to the weakest, the greater vicinity will compensate for the smaller absolute force of the weak pole, and occasion considerable irregularities. The appearances are favourable to this opinion. If this be the real constitution of the great magnet, it is almost a desperate task to ascertain by computation what will be the position of the needle. Halley seems to have despaired: for he was both an elegant and a most expert mathematician, and it would have cost *him* little trouble to ascertain the places of two poles only, and the direction which these would have given to the needle. But to say what would be its position when acted on by four poles, it was necessary to know the law by which the magnetic action varied by a variation of distance; and even then, the computation would have been exceedingly difficult.

In order to account for the change of variation, Dr Halley supposes this internal magnet not to adhere to the external shell which we inhabit, but to form a nucleus or kernel detached from it on all sides, and to be so poised as to revolve freely round an axis, the position of which he hopes to discover by observation of the compass. Dr Halley imagined that the nucleus revolved from east to west round the same axis with the earth. Thus the poles of the magnet would change their positions relatively to the earth's surface, and this would change the direction of the compass needle.

The great Euler, whose delight it was always to engage in the most difficult mathematical researches and computations, undertook to ascertain the position of the needle in every part of the earth. His dissertation on this subject is to be seen in the 13th volume of the Memoirs of the Royal Academy of Berlin, and is exceedingly ing beautiful, abounding in those analytical *tours d'adresse* in which he surpassed all the world. He has reduced the computation to a wonderful simplicity.

He found, however, that four poles would engage him in an analysis which would be excessively intricate, and has contented himself with computing for two only; observing that this supposition agrees so well with observation, that it is highly probable that this is the real constitution of the terrestrial magnet, and that the coincidence would have been perfect if he had hit on the due positions of the two poles. He places one of them in lat. 76° north, and long. 96° west from Teneriffe. The south pole is placed in lat. 58° south, and long. 158° west from Teneriffe. These are their situations for 1757.—Mr Euler has annexed to his dissertation a chart of Halleyan curves suited to these assumptions, and fitted to the year 1757.

It must be acknowledged, that the *general* course of the variations according to this theory greatly resembles the real state of things; and we cannot but own ourselves highly indebted to this great mathematician for having made so fine a first attempt. He has improved it very considerably in another dissertation in the 22d volume of these memoirs. But there are still such great differences, that the theory is of no use to the navigator, and it only serves as an excellent model for a farther prosecution of the subject. Since that time another large variation chart has been published, fitted to a late period; but the public has not sufficient information of the authorities or observations on which it is founded.

The great object in all these charts is to facilitate the discovery of a ship's longitude at sea. For the lines of variation being drawn on the chart, and the variation and the latitude being observed at sea, we have only to look on the chart for the intersection of the parallel of observed latitude and the Halleyan curve of observed variation. This intersection must be the place of the ship. This being the purpose, the Halleyan lines are of great service; but they do not give us a ready conception of the direction of the needle. We have always to *imagine* a line drawn through the point, cutting the meridian in the angle corresponding to the Halleyan line. We should learn the general magnetic affections of the globe much better if a number of magnetic meridians were drawn. These are the intersections of the earth's surface with planes passing through the magnetical axis, cutting one another in angles of 5° or 10°. This would both show us the places of the magnetic poles much more clearly, and would, in every place, show us at once the direction of the needle. In all those places where these magnetic curves touch the meridians, there is no variation; and the variation in every other place is the angle contained between these magnetic meridians and the true ones.

The program of a work of this kind has been published by a Mr Churchman, who appears to have engaged in the investigation with great zeal and considerable opportunities. It is pretty certain that the north magnetic pole (or point, as Mr Churchman calls it) is not far removed from the stations given it by Halley and Euler; and there seems no doubt but that in the countries between Hudson's bay and the western coasts of North America the needle will have every position with respect to the terrestrial meridian, so that the north end of a compass needle will even point due south in several places. Almost every thing that can be desired in this inquiry would be obtained by a few *well-chosen* observations made in those regions. It would be of immense advantage to have the *dips* ascertained with great precision. These would enable us to judge at what depth under the surface the pole is situated; for the well-informed mechanician, who will study seriously what we have said about the magnetical curves, will see that a compass needle, when compared with the great terrestrial magnet, is but as a particle of iron-filings compared to a very large artificial magnet. Therefore, from the position of the dipping needle, we may infer the place of the pole, if the law of magnetic action be given; and this law may be found by means of other experiments, which we could point out. See MAGNETISM, N° 80, *et seq.*

Mr Churchman has adopted the opinion of only two poles. According to him, the north pole was (in 1800) in Lat. 58° N. and Long. 134° W. from Greenwich, very near Cape Fairweather; and the south pole lies in Lat. 58° S. and Long. 165° E. from Greenwich. He also imagines that the north pole has moved to the eastward, on a parallel of latitude, about 65 since the beginning of the 19th century (from 1600), and concludes that it makes a revolution in 1096 years. The southern pole has moved less, and completes its revolution in 2289 years. This motion he ascribes to some influences which he calls *magnetic tides*, and which he seems to consider as celestial. This he infers from the changes of variation. He announces a physical theory on this subject, which, he says, enables him to compute the variation with precision for any time past or to come; and he even gives the process of trigonometrical computation illustrated by examples. But as this publication (entitled *The Magnetic Atlas*), published for the author, by Darton and Harvey, 1794, is only a program, he expresses himself obscurely, and somewhat enigmatically, respecting his theory. He speaks of the influence of one pole being greater than that of the other; and says, that in this case the magnetic equator, where the needle will be parallel to the axis, will not be in the middle between the poles. This is true of a common magnet. He must therefore abide by this supposition in its other consequences. The magnetic meridians must be planes passing through this axis, and therefore must be circles on the surface of the earth. This is incompatible with the observations; nay, his charts are so in many places, particularly in the Pacific ocean, where the variations by his chart are three times greater than what has been observed.—His parallels of dip are still more different from observation, and are incompatible with any phenomena that could be produced by a magnet having but two poles. His rules of computation are exceedingly exceptionable. He has in fact but one example, and that so particular, that the mode of computation will not apply to any other. This circumstance is not taken notice of in the enunciation of his first problem; and the reader is made to imagine that he has got a rule for computing the variation, whereas all the rules of calculation are only running in a circle. The variation computed for the port of St Peter and Paul in Kamtschatka, by the rule, is ten times greater than the truth.

For our own part, we have little hopes of this problem ever being subjected to accurate calculation. We believe, Variation.

believe, indeed, that there is a cosmical change going on in the earth which will produce a progressive change in the variation of the needle; and we see none more likely than Dr Halley's motion. There is nothing repugnant to our knowledge of the universe in the supposition of a magnetic nucleus revolving within this earth; and it is very easy to conceive a very simple motion of revolution, which shall produce the very motion of the sensible poles for which Mr Churchman contends. We need only suppose that the magnetical axis of this nucleus is not its axis of revolution. It may not even bisect that axis; and this circumstance will cause the two poles to have different degrees of motion in relation to the shell which surrounds it.

But this regular progress of the magnet within the earth may produce very irregular motions of the compass needle, by the intervention of a third body susceptible of magnetism. The theory of which we have just given a hint comes here to our assistance. Suppose NS (fig. 3.) to represent the primitive magnet in the earth, and *n s* to be a stratum of iron ore susceptible of magnetism. Also let *n' s'* be another small mass of a similar ore; and let their situations and magnitudes be such as is exhibited in the figure. The fact will be that *n* will be the north pole and *s* the south pole of the great stratum, and *n'* and *s'* will be the north and south poles of the small mass or loadstone. Any person may remove all doubts as to this, by making the experiment with a magnet NS, a piece of iron or soft tempered steel *n s*, and another piece *n' s'*. The well-informed and attentive reader will easily see, that by such interventions every conceivable anomaly may be produced. While the great magnet makes a revolution in any direction, the needle will change its position gradually, and with a certain regularity; but it will depend entirely on the size, shape, and situation, of these intervening masses of magnetisable iron ore, whether the change of variation of the compass shall be such as the primitive magnet alone would have produced, or whether it shall be of a kind wholly different.

Now, that such intervening disturbances *may* exist, is past contradiction. We know that even on the film of earth which we inhabit, and with which only we are acquainted, there are extensive strata or otherwise disposed masses of iron ores in a state susceptible of magnetism; and experiments made on bars of hard tempered steel, and on bits of such ores, assure us that the magnetism is not induced on such bodies in a moment, but propagated gradually along the mass.—That such disturbances do actually exist, we have many relations. There are many instances on record of very extensive magnetic rocks, which affect the needle to very considerable distances. The island of Elba in the Mediterranean is a very remarkable instance of this. The island of Cannay also, on the west of Scotland, has rocks which affect the needle at a great distance.

A similar effect is observed near the Feroe islands in the North sea; the compass has no determined direction when brought on shore. *Journ. des Sçavans*, 1679, p. 174.

In Hudson's straits, in latitude 63°, the needle has hardly any polarity. *Ellis's Voyage to Hudson's Bay.*

Bouguer observed the same thing in Peru. Nay, we believe that almost all rocks, especially of whin or trappe stone, contain iron in a proper state.

All this refers only to the thin crust through which the human eye has occasionally penetrated. Of what may be below we are ignorant; but when we see appearances which tally so remarkably with what would be the effects of great masses of magnetical bodies, modifying the general and regularly progressive action of a primitive magnet, whose existence and motion is inconsistent with nothing that we know of this globe, this manner of accounting for the observed change of variation has all the probability that we can desire. Nay, we apprehend that very considerable changes may be produced in the direction of the compass needle, even without the supposition of any internal motion. If the great magnet resembles many loadstones we are acquainted with, having more than two poles, we know that these poles will act on each other, and gradually change each other's force, and consequently the direction of the compass. This process, to be sure, tends to a state of things which will change no more.—But the period of human history, or of the history of the race of Adam, may make but a small part of the history of this globe; and therefore this objection is of little force.

There can be no doubt of the operation of the general terrestrial magnetism on every thing susceptible of magnetic properties; and we cannot hesitate to explain in this way many changes of magnetic direction which have been observed. Thus, in Italy, Father de la Torré observed, that during a great eruption of Vesuvius the variation was 16° in the morning, at noon it was 14°, and in the evening it was 10°, and that it continued in that state till the lava grew so dark as no longer to be visible in the night; after which it slowly increased to 13½, where it remained. Daniel Bernoulli found the needle changed its position 45′ by an earthquake. Professor Muller at Manheim observed that the declination of the needle in that place was greatly affected by the earthquake in Calabria. Such streams of lava as flowed from Hecla in the last dreadful eruption must have made a transference of magnetic matter that would considerably affect the needle. But no observations seem to have been made on the occasion; for we know that common ironstone, which has no effect on the needle, will, by mere cementation with any inflammable substance, become magnetic. In this way Dr Knight sometimes made artificial loadstones.—But these are partial things, and not connected with the general change of variation now under consideration.

We have said so much on this subject, chiefly with the view of cautioning our readers against too sanguine expectations from any pretensions to the solution of this great problem. We may certainly gather from these observations, that even although the theory of the variation should be completed, we must expect (by what we already know of magnetism in general) that the disturbances of the needle, by local causes intervening between it and the great influence by which it is chiefly directed, may be so considerable as to affect the position of the compass needle in a very sensible manner: for we know that the metallic substances in the bowels of the earth are in a state of continual change, and this to an extent altogether unknown.

There is another irregularity of the mariner's needle that we have noticed under MAGNETISM, page 365, namely, the daily variation. This was first observed by by Mr George Graham in 1722 (Philosophical Transactions, N° 383.), and reported to the Royal Society of London. It usually moves (at least in Europe) to the westward from 8 morning till 2 P. M. and then gradually returns to its former situation. The diurnal variations are seldom less than 0° 5′, and often much greater. Mr Graham mentions (Philosophical Transactions, N° 428.) some observations by a Captain Hume, in a voyage to America, where he found the variation greatest in the afternoon. This being a general phenomenon, has also attracted the attention of philosophers. The most detailed accounts of it to be met with are those of Mr Canton (see MAGNETISM), in Philosophical Transactions, vol. li. part 1. p. 399, and those of Van Swinden, in his Treatise on Electricity and Magnetism.

Mr Canton attempts to account for these changes of position, by observing that the force of a magnet is weakened by heat. A small magnet being placed near a compass needle, ENE from it, so as to make it deflect 45° from the natural position, the magnet was covered with a brass vessel, into which hot water was poured. The needle gradually receded from the magnet 45′, and returned gradually to its place as the water cooled. This is confirmed by uniform experience.

The parts of the earth to the eastward are first heated in the morning, and therefore the force of the earth is weakened, and the needle is made to move to the westward. But as the sun warms the western side of the earth in the afternoon, the motion of the needle must take the contrary direction. This explanation, however, does not account for the prodigious diversity in the diurnal variation at different places, and is besides exposed to other very weighty objections.

But, besides this regular diurnal variation, there is another, which is subjected to no rule. The aurora borealis is observed (in Europe) to disturb the needle exceedingly, sometimes drawing it several degrees from its position. It is always observed to increase its deviation from the meridian, that is, an aurora borealis makes the needle point more westerly. This disturbance sometimes amounts to six or seven degrees, and is generally observed to be greatest when the aurora borealis is most remarkable.

The observation of the connection of the polarity of the needle with the aurora borealis occurred to the late Professor Robinson in 1759, when a midshipman on board the Royal William in the river St Lawrence. The point of the heavens to which all the rays of light converged was precisely that which was opposite to the south end of the dipping needle.

This is a very curious phenomenon, and we have not been able to find any connection between this meteor and the position of a magnetic needle. It is to be observed, that a needle of copper or wood, or any substance except iron, is not affected. We long thought it an electric phenomenon, and that the needle was affected as any other body balanced in the same manner would be; but a copper needle would then be affected.

We see the needle frequently disturbed both from its general annual position, and from the change made on it by the diurnal variation. This is probably the effect of auroræ boreales which are invisible, either on account of thick weather or daylight. Van Swinden says, he seldom or never failed to observe auroræ boreales immediately after any anomalous motion of the needle; and concluded that there had been one at the time, though he could not see it. Since no needle but a magnetic one is affected by the aurora borealis, we may conclude that there is some natural connection between this meteor and magnetism. This should farther incite us to observe the circumstance above mentioned, viz. that the south end of the dipping needle points to that part of the heavens where the rays of the aurora appear to converge. We wish that this were diligently observed in places which have very different variation and dip of the mariner's needle.

Another species of variation of great importance has lately been discovered. This arises from the action of the mass of the ship on the needle, and is found in some cases to amount to five degrees, so that when bearings are taken with the ship's head first on one side of the magnetic meridian, and then on the other, a difference will be found of ten degrees. Anomalies arising from this source had been often observed, and had greatly perplexed nautical men: they were often attributed to the defects of the compass. Captain Flinders seems to have been the first who detected the true cause of these irregularities, by ascertaining that the mean variation taken with five different compasses at the binnacle, was 4° 37′ greater than at the booms. This subject, however, was first fully investigated and explained by Mr William Bain, a nautical gentleman, in a small tract published at Edinburgh in 1817. Mr Bain having detected the effects of the local attraction of the ship by his own observations in 1811, has, by means of this principle, satisfactorily explained many facts recorded by former navigators, which appeared hitherto inexplicable. He shows, that in the short course from Plymouth to Cape Finisterre, by neglecting this local attraction, an error of 12 miles may be committed in latitude, and of 35 in longitude. In the course from St John's Newfoundland to England, the error from the same cause may amount to 64 miles in latitude, and 198 in longitude. He observes also, that in beating to windward, and tacking pretty often, all seamen have remarked, that every time the ship was put about, the wind *came round* some points with the ship. This change in the wind, however, is merely apparent, and is simply the effect of the attraction of the ship upon the needle. When the head is westerly, the north end of the needle is drawn half the difference westward; when the head is easterly, it is drawn half the difference eastward. He has also shewn, that many of the irregularities ascribed to currents are truly owing to this cause. The amount of the local variation caused by the ship must depend on her construction, and in a merchant vessel on her cargo. It will therefore most probably vary in different ships, and in the same ship, at different times. Mr Bain thinks that it would be advisable for every merchant vessel before she leaves the port, to ascertain by observations made on some fixed object at a distance, the precise amount of this local attraction; and when this is once known, she may steer her course with much greater confidence and security. For farther particulars the reader may consult Mr Bain's excellent little work, entitled, "An Essay on the Variation of the Compass."

Compass." Edinburgh, 1817. The discovery of this species of variation well deserves to be regarded as an important step in the improvement of navigation.

For the diurnal and this irregular variaion, consult the Dissertations of Celsius and of Hiorter, in the Memoirs of Stockholm; Wargentin, Philosophical Transactions, vol. xlviii.; Braun (*Comment. Petropol. Novi*, tom. v. vii. ix.); Graham and Canton as above.

VARIETY, a change, succession or difference, in the appearance or nature of things; in opposition to *uniformity*.

VARIETY, in *Botany*, is a change in some less essential part or quality; as colour, size, pubescence or age. —Externally; by the plaiting or interweaving of the branches—by bundling or uniting of several stalks into one broad flat one; by the greater breadth or narrowness, or curling of leaves—by becoming awnless, or smooth, or hirsute. Internally; by becoming mutilated in the corolla; or having one larger than ordinary —by luxuriancy, multiplication, or fulness—by becoming proliferous, or crested—by bearing bulbs instead of seeds—or being viviparous.

The usual causes of variation are, climate, soil, exposure, heat, cold, winds, culture.

VARIOLA, the SMALLPOX. See MEDICINE, N° 222—224.

VARIX, in *Medicine*, the dilatation of a vein, arising from the too great abundance or thickness of the blood.

VARNISH, a clear limpid fluid, capable of hardening without losing its transparency, used by painters, gilders, &c. to give a lustre to their works, to preserve them and defend them from the air.

A coat of varnish ought to possess the following properties: 1. It must exclude the action of the air; because wood and metals are varnished to defend them from decay and rust. 2. It must resist water; for otherwise the effect of the varnish could not be permanent. 3. It ought not to alter such colours as are intended to be preserved by this means. It is necessary therefore that a varnish should be easily extended or spread over the surface, without leaving pores or cavities; that it should not crack or scale; and that it should resist water. Now resins are the only bodies that possess these properties. Resins consequently must be used as the bases of varnish. The question which of course presents itself must then be, how to dispose them for this use? and for this purpose they must be dissolved, as minutely divided as possible, and combined in such a manner that the imperfections of those which might be disposed to scale may be corrected by others.

Resins may be dissolved by three agents. 1. By fixed oil. 2. By volatile oil. 3. By alcohol. And accordingly we have three kinds of varnish; the fat or oily varnish, essential varnish, and spirit varnish. Before a resin is dissolved in a fixed oil, it is necessary to render the oil drying. For this purpose the oil is boiled with metallic oxides; in which operation the mucilage of the oil combines with the metal, while the oil itself unites with the oxygen of the oxide. To accelerate the drying of this varnish, it is necessary to add oil of turpentine. The essential varnishes consist of a solution of resin in oil of turpentine. The varnish being applied, the essential oil flies off, and leaves the resin. This is used only for paintings. When resins are dissolved in alcohol, the varnish dries very speedily, and is subject to crack; but this fault is corrected by adding a small quantity of turpentine to the mixture, which renders it brighter, and less brittle when dry.

We shall now give the method of preparing a number of varnishes for different purposes.

A Varnish for Toilet-boxes, Cases, Fans, &c.—Dissolve two ounces of gum mastich and eight ounces of gum sandarach in a quart of alcohol; then add four ounces of Venice turpentine.

A Varnish for Wainscots, Cane-chairs, Iron-chairs, Grates.—Dissolve in a quart of alcohol eight ounces of gum sandarach, two ounces of seed lac, four ounces of rosin; then add six ounces of Venice turpentine. If the varnish is wished to produce a red colour, more of the lac and less of sandarach should be used, and a little *dragon's blood* should be added. This varnish is so thick that two layers of it are equal to four or five of another.

A Varnish for Fiddles, and other Musical Instruments. —Put four ounces of gum sandarach, two ounces of lac, two ounces of gum mastich, an ounce of gum elemi, into a quart of alcohol, and hang them over a slow fire till they are dissolved; then add two ounces of turpentine.

Varnish in order to employ Vermilion for painting Equipages.—Dissolve in a quart of alcohol six ounces of sandarach, three ounces of gum lac, and four ounces of rosin; afterwards add six ounces of the cheapest kind of turpentine; mix with it a proper quantity of vermilion when it is to be used.

Gold-coloured Varnish.—Pound separately four ounces of stick lac, four ounces of gamboge, four ounces of dragon's blood, four ounces of anotta, and one ounce of saffron: put each of them separately into a quart of alcohol, and expose them for five days in a narrow-mouthed bottle to the sun, or keep them during that time in a very warm room, shaking them every now and then to hasten the solution. When they are all melted, mix them together. More or less of each of these ingredients will give the different tints of gold according as they are combined. In order to make silver imitate gold exactly when covered with this varnish, the quantity of ingredients must be somewhat greater. The method of gilding silver-leaf, &c. with this varnish is as follows: The silver-leaf being fixed on the subject, in the same manner as gold-leaf, by the interposition of proper glutinous matters, the varnish is spread upon the piece with a brush or pencil. The first coat being dry, the piece is again and again washed over with the varnish till the colour appears sufficiently deep. What is called *gilt leather*, and many picture frames, have no other than this counterfeit gilding. Washing them with a little rectified spirit of wine affords a proof of this; the spirit dissolving the varnish, and leaving the silver-leaf of its own whiteness. For plain frames, thick tinfoil may be used instead of silver. The tin-leaf, fixed on the piece with glue, is to be burnished, then polished with emery and a fine linen cloth, and afterwards with putty applied in the same manner: being then lacquered over with the varnish five or six times, it looks very nearly like burnished gold. The same varnish, made with a less proportion of the colouring materials, is applied also on works of brass; both for heightening the colour of the metal to a resemblance with that of gold, and

Varnish. and for preserving it from being tarnished or corroded by the air.

Oil Varnishes.—Gum copal and amber are the substances principally employed in oil varnishes; they possess the properties necessary for varnishes, solidity and transparency.—The copal being whitest, is used for varnishing light, the amber for dark colours. It is best to dissolve them before mixing them with the oil, because by this means they are in less danger of being scorched, and at the same time the varnish is more beautiful. They should be melted in a pot on the fire; they are in a proper state for receiving the oil when they give no resistance to the iron spatula, and when they run off from it drop by drop. The oil employed should be a drying oil, and perfectly free from grease. It should be poured into the copal or amber by little and little, constantly stirring the ingredients at the same time with the spatula. When the oil is well mixed with the copal or amber, take it off the fire; and when it is pretty cool, pour in a greater quantity of the essence of turpentine than the oil that was used. After the varnish is made, it should be passed through a linen cloth. Oil varnishes become thick by keeping; but when they are to be used, it is only necessary to pour in a little essence of turpentine, and to put them for a little on the fire. The turpentine is necessary in oil varnishes to make them dry properly; generally twice as much of it is used as of oil. Less is necessary in summer than in winter. Too much oil binders the varnish from drying; but when too little is used, it cracks and does not spread properly. We shall subjoin the most useful oil varnishes:

White Copal Varnish.—On 16 ounces of melted copal pour four, six, or eight ounces of linseed oil, boiled and quite free from grease. When they are well mixed, take them off the fire (not forgetting to stir them properly); and when pretty cool, pour in 16 ounces of the essence of Venice turpentine. Pass the varnish through a cloth.—Amber varnish is made in the same way.

Black Varnish for Coaches and Iron Work.—This varnish is composed of bitumen of Palestine, rosin, and amber, melted separately, and afterwards mixed: the oil is then added, and afterwards the turpentine, as directed above. The usual proportions are, 12 ounces of amber, two ounces of rosin, two ounces of bitumen, six of oil, and 12 of the essence of turpentine.—Golden-coloured varnish may be made also by substituting linseed oil for alcohol.

Essential Oil Varnishes.—The only essential oil varnishes used are for pictures. Picture varnishes should be white, light, and quite transparent, which will preserve the colours without giving them any disagreeable tint; and it should be possible to take them off the picture without injuring it. They are usually made of gum mastich and turpentine dissolved together in some essential oil. The varnish is passed through a cloth, and allowed to clarify. It is applied cold to the picture.

Varnish for Glass in order to preserve it from the Rays of the Sun.—Pulverise a quantity of gum adragant, and let it dissolve for 24 hours in the white of eggs well beat up; then rub it gently on the glass with a brush.

Varnishes before they are used should be carefully kept from dust, which would spoil them; and they should be kept in a vessel quite clean and dry. When used, they should be lifted lightly with a brush, and spread upon a ground altogether free from dirt and moisture. The substance, after being varnished, should be exposed to the heat of the sun, or placed in a warm room covered with a glass case, to keep out all filth. Oil varnishes require more heat than alcohol varnishes. The varnish should be put on very quickly, making great strokes with the pencil or brush, taking care that these strokes never cross one another; it should be spread equally, and never thicker than a leaf of paper; a second coat should never be put on till the first is quite dry. If the varnish, after being put on, becomes dull and uneven, it must be taken off entirely, and new varnish put on.

When wainscot is to be varnished, it is first painted of a wooden colour. This colour is made by infusing in water either red or yellow ochre (according to the colour wished for), terra ombria (a kind of ochre) and white lead; into this as much as necessary is put of *parchment paste*. Two thin coats of this are to be put on, and, after they are quite dry, the varnish.

Varnishes are polished with pumice-stone and tripoli earth. The pumice-stone must be reduced to an impalpable powder, and put upon a piece of serge moistened with water; with this the varnished substance is to be rubbed lightly and equally. The tripoli must also be reduced to a very fine powder, and put upon a clean woollen cloth moistened with olive oil, with which the polishing is to be performed. The varnish is then to be wiped with soft linen, and, when quite dry, cleaned with starch or Spanish white, and rubbed with the palm of the hand or with a linen cloth.

To recover colours or varnish, and to take off the dirt and filth which may adhere to them, a ley is used made of potash and the ashes of lees of wine. Take 48 ounces of potash, and 16 of the above-mentioned ashes, and put them into six quarts of water, and the ley is made: instead of the ashes an equal quantity of potash would probably do as well. To clean dirty colours, dilute some of this ley with four times its quantity of water, and rub the picture with it; then wash it with river water; and when dry, give it a coat or two of varnish. In order to take off a varnish, wash it with the above-mentioned ley, then with water, and then lift it off the substance on which it was with any iron instrument.—We shall finish this article with a description of the famous Chinese varnish.

The Chinese varnish is not a composition, but a resin which exudes from a tree called in China *tsi-chu*, "varnish tree." This tree grows in several provinces of the southern parts of China. The Chinese take the following method of propagating this treee: In spring they choose a vigorous shoot about a foot in length, which proceeds immediately from the trunk; and coat over the lower part, by which it adheres to the tree, with a kind of yellow earth, at least three inches in thickness. This coat is carefully covered with a mat, to defend it from rain and the injuries of the air. Towards the autumnal equinox they detach a little of the earth, to observe in what condition the small roots are, which begin to spring forth from the shoot. If they find that the filaments which compose them are of a reddish colour, they judge it is time to make an amputation; but they defer it if the roots are white, because this colour shows that

that they are yet too tender: they then close up the coat again, and wait till the spring following. When the shoot is separated from the trunk of the tree, it is put into the earth; but in whatever season it is planted, whether in spring or autumn, great care must be taken to put plenty of cinders into the hole prepared for it; without this precaution the ants would destroy the yet tender roots, or at least deprive them of all their moisture, and cause them to decay.

The Chinese do not procure varnish from the tsi-chu until its trunk is nearly five inches in diameter, which size it seldom attains to before seven or eight years. Varnish extracted from a tree smaller or of less age would not have the same body and splendour. This liquor distils only in the night time, and during the summer season. To cause the gum to flow, they make several rows of incisions round the trunk, the number of which is proportioned to the vigour of the tree. The first row is seven inches from the earth, and the rest are at the same distance one from the other, and continue to the top of the trunk, and even sometimes on the boughs which are of sufficient strength and size. The Chinese use a crooked iron for making these incisions, which must run a little obliquely, and be equal in depth to the thickness of the bark; they make them with one hand, and with the other hold a shell, the edges of which they insert into the opening, where it remains without any support. These incisions are made towards evening, and next morning they collect the varnish which has fallen into the shells; the following evening they are again inserted, and this operation is continued until the end of summer. A thousand trees yield almost in one night 20 pounds of varnish.

While the varnish distils, it exhales a malignant vapour, the bad effects of which can only be prevented by preservatives and great precaution. The merchant who employs the workmen is obliged to keep by him a large vase filled with rape-oil, in which a certain quantity of those fleshy filaments have been boiled that are found in hog's lard, and which do not melt. When the workmen are going to fix the shells to the trees, they carry some of this oil along with them, and rub their face and hands with it, which they do with greater care when they collect in the morning the varnish that has distilled during night. After eating, they wash their whole bodies with warm water, in which the bark of the chesnut tree, fir wood, crystallized saltpetre, and some other drugs, have been boiled. When they are at work near the trees, they put upon their heads a small cloth bag in which there are two holes, and cover the fore part of their bodies with a kind of apron made of doe-skin, which is suspended from their necks with strings, and tied round them with a girdle. They also wear boots, and have coverings on their arms, made of the same kind of skin. The labourer who should attempt to collect varnish without using this precaution, would soon be punished for his rashness, and the most dreadful effects would ensue. The disorder shows itself by tetters, which become of a bright red colour, and spread in a very short time; the body afterwards swells, and the skin bursts and appears covered with an universal leprosy. The unhappy wretch could not long endure the excruciating pain which he feels, did he not find a speedy remedy in those preservatives which are used against the malignant and noxious exhalations of the varnish.

The season of collecting varnish being ended, the merchants put it into small casks closely stopped. A pound of it newly made costs him about one shilling and eight pence sterling; but he gains cent. per cent. upon it, and sometimes more, according to the distance of the place to which he transports it.

Besides the lustre and beauty which that varnish gives to many of the Chinese manufactures, it has also the property of preserving the wood upon which it is laid, especially if no other matter be mixed with it. It prevents it from being hurt either by dampness or worms.

Every workman has a particular art and method of using the varnish. This work requires not only much skill and dexterity, but also great attention, to observe the proper degree of fluidity which the gum ought to have, as it must be neither too thick nor too liquid when it is laid on. Patience above all is necessary in those who wish to succeed. To be properly varnished, a work must be done at leisure; and the whole summer is scarcely sufficient to bring it to perfection. It is therefore rare to see any of those cabinets which are imported to us from Canton so beautiful and durable as those manufactured in Japan, Tong-king, and Nang-king, the capital of the province of Kiang-nan: not that the artists do not employ the same varnish; but as they work for Europeans, who are more easily pleased, they do not take the trouble of giving the pieces which come from their hands all the polish they are capable of receiving.

There are two methods of laying on the varnish; the simplest is, when it is immediately laid on the wood. The work is first polished, and then daubed over with a kind of oil which the Chinese call *tong-yeou*. When this oil is dry, it receives two or three coats of varnish; which remain so transparent, that all the shades and veins of the wood may be seen through them. If the artist is desirous of entirely concealing the substance on which they are laid, nothing is necessary but to add a few more coats; these give the work a shining surface, the smoothness of which equals that of the most beautiful ice. When the work is dry, various figures are painted upon it in gold and silver, such as flowers, birds, trees, temples, dragons, &c. A new coat of varnish is then sometimes laid over these figures, which preserves them, and adds much to their splendour. The second method requires more preparation. The Chinese workmen fix to the wood by means of glue a kind of pasteboard, composed of paper, hemp, lime, and other ingredients, well beaten that the varnish may incorporate with them. Of this they make a ground perfectly smooth and solid, over which the varnish is laid in thin coats, that are left to dry one after the other.

It often happens, that the lustre of varnished tables and other pieces of furniture is insensibly destroyed by tea and warm liquors. "The secret of restoring to varnish its shining black colour (says a Chinese author) is to expose it for one night to a white hoar-frost, or to cover it some time with snow." For a method of imitating *Chinese varnish*, see TURNING.

VARNISH also signifies a sort of shining coat, wherewith potters-ware, delft-ware, china-ware, &c. are covered, which gives them a smoothness and lustre. Melted lead is generally used for the first, and smalt for the second. See GLAZING.

VARNISH, among medalists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to counterfeit, enhances the value of them: that is, the colour which certain soils in which they have a long time lain tinges the metals withal: some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermilion colour; others with a certain shining polished brown, vastly finer than Brasil figures. The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metals. No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar or lemon juice.

Falsifiers of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance or air of being antique. But this may be discovered by its softness.

VARRO, MARCUS TERENTIUS, the most learned of all the Romans, was born 28 years B. C. He was a senator of the first distinction, both for birth and merit; and bore many great offices. He was an intimate friend of Cicero; and this friendship was confirmed and immortalized by a mutual dedication of their learned works to each other. Thus Cicero dedicated his Academic Questions to Varro; and Varro dedicated his treatise on the Latin tongue to Cicero. In the civil wars he was zealously attached to Pompey; but after his defeat soon submitted to Cæsar, who was reconciled to him. Afterwards he applied his whole time to letters, and had the charge of the Greek and Latin libraries at Rome. He was above 70 when Antony proscribed him; however, he found means to escape and save his life, though he could not save some of his works and his library from being plundered by the soldiers. After this storm was over, he pursued his studies as usual; and Pliny relates, that he continued to study and to write when he was 88 years of age. He was 80 when he wrote his three books *De re Rustica*, which are still extant. Five of his books *De lingua Latina*, which he addressed to Cicero, are all extant. There remain, too, divers fragments of his works, particularly of his Menippean Satires, which are medleys of prose and verse; and Scaliger has collected some of his epigrams from among the *Catalecta Virgilii*. His books *De lingua Latina*, and *De re Rustica*, were printed with the notes of Joseph Scaliger, Turnebus, and Victorius, by Henry Stephens at Paris, 1573, in 8vo, and have been published separately since among the *Auctores de lingua Latina*, and the *Auctores de re Rustica*.

There was another Varro of antiquity called *Atacinus*, a poet, who was born about 10 years after the first, at a small town near Narbonne. His chief works were, A poem on the war with the Sequani, a people of Gaul; and the Astronomics, that went under the name of Planciades the grammarian. But the *Argonautics*, in four books, was what gained him the greatest reputation: and though indeed nothing but a translation of Apollonius Rhodius, yet was so well done as to be commended by Quintilian.

VARRONIA, a genus of plants belonging to the class pentandria, and arranged in the natural system under the 41st order, *Asperifoliæ*. See BOTANY *Index*.

VASCULAR, something consisting of divers vessels, as arteries, veins, &c.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious. In architecture, the appellation *vase* is also given to those ornaments placed on corniches, focles, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice, as incense-pots, flower-pots, &c. See PORTLAND-*Vase*.

VASSAL, in our ancient customs, signified a tenant or feudatory; or person who vowed fidelity and homage to a lord, on account of some land, &c. held of him in fee; also a slave or servant, and especially a domestic of a prince.—*Vassallus* is said to be *quasi inferior socius;* as he is inferior to his master, and must serve him; and yet he is in a manner his companion, because each of them is obliged to the other. See FEODAL *System*.

VATICAN, a magnificent palace of the pope in Rome, which is said to consist of several thousand rooms: but the parts of it most admired are the grand staircase, the pope's apartment, and especially the library, which is one of the richest in the world, both in printed books and manuscripts.

VAUBAN, SEBASTIAN LE PRESTRE, SEIGNEUR DE, marshal of France, and the greatest engineer that country ever produced, was born in 1633. He displayed his knowledge of fortification in the course of many sieges, and his services were rewarded with the first military honours. He was made governor of Lisle in 1668, commissary general of the fortifications of France in 1678, governor of the maritime parts of Flanders in 1689, and a marshal of France in 1703. He died in 1707, after having brought the arts of attacking and defending fortified places to a degree of perfection unknown before. His writings on these subjects are in great esteem.

VAUCLUSE, a department in the south-east of France, lying between the eastern side of the Rhone, and the branches of the Alps. The soil is various, in the north chiefly calcareous, in the west sandy, and in other parts covered with flinty pebbles. Agriculture is in a very rude state, the corn raised is not sufficient for internal consumption, and leguminous plants do not thrive here. The climate admits of the vine, the olive, and the mulberry, but none of them are cultivated with any degree of spirit. There are mines of coal, but of a kind extremely sulphurous. The manufactures are trifling. The extent of this department is 234,560 hectares, and the population in 1817 was 205,832. Avignon is the chief town.

VAUDOIS, VALDENSES, or *Waldenses*, in ecclesiastical history, a name given to a sect of reformers, who made their first appearance about the year 1160.

The origin of this famous sect, according to Mosheim, was as follows: Peter, an opulent merchant of Lyons, surnamed *Valdensis*, or *Validisius* from Vaux or Waldum, a town in the marquisate of Lyons, being extremely zealous for the advancement of true piety and Christian knowledge, employed a certain priest called *Stephanus de Evisa*, about the year 1160, in translating from Latin into French the four Gospels, with other books of Holy Scripture, and the most remarkable sentences of the ancient doctors, which were so highly esteemed

esteemed in this century. But no sooner had he perused these sacred books with a proper degree of attention, than he perceived that the religion which was now taught in the Roman church, differed totally from that which was originally inculcated by Christ and his apostles. Struck with this glaring contradiction between the doctrines of the pontiffs and the truths of the Gospel, and animated with zeal, he abandoned his mercantile vocation, distributed his riches among the poor (whence the Waldenses were called *poor men of Lyons*), and forming an association with other pious men, who had adopted his sentiments and turn of devotion, he began in the year 1180 to assume the quality of a public teacher, and to instruct the multitude in the doctrines and precepts of Christianity.

Soon after Peter had assumed the exercise of his ministry, the archbishop of Lyons, and the other rulers of the church in that province, vigorously opposed him. However, their opposition was unsuccessful; for the purity and simplicity of that religion which these good men taught, the spotless innocence that shone forth in their lives and actions, and the noble contempt of riches and honours, which was conspicuous in the whole of their conduct and conversation, appeared so engaging to all such as had any sense of true piety, that the number of their followers daily increased.—They accordingly formed religious assemblies, first in France, and afterwards in Lombardy, from whence they propagated their sect throughout the other provinces of Europe with incredible rapidity, and with such invincible fortitude, that neither fire, nor sword, nor the most cruel inventions of merciless persecution, could damp their zeal, or entirely ruin their cause.

VAULT, in *Architecture*, an arched roof, so contrived that the stones which form it sustain each other.

Vaults are on many occasions to be preferred to soffits or flat ceilings, as they give a greater height and elevation, and are besides more firm and durable.

VAYER. See MOTHE.

VAYVODE, or VAIVODE. See WAYWODE.

UBES, ST, a sea-port town of Portugal, in the province of Estremadura, seated on a bay of the Atlantic ocean, 21 miles south of Lisbon. It stands on an eminence, with a very strong castle built on a rock. The soil around is fertile in corn, wine, and fruits; and it is furnished with good fish from the sea, and a small lake in the neighbourhood. Here great quantities of fine salt are made, which is carried to the American plantations. E. Long. 8. 54. N. Lat. 38. 22.

UBIQUITARIANS, formed from *ubique*, "everywhere," in ecclesiastical history, a sect of Lutherans which rose and spread itself in Germany; and whose distinguishing doctrine was, that the body of Jesus Christ is everywhere, or in every place.

Brentius, one of the earliest reformers, is said to have first broached this error, in 1560. Luther himself, in his controversy with Zuinglius, had thrown out some unguarded expressions, that seemed to imply a belief of the omnipresence of the body of Christ; but he became sensible afterwards, that this opinion was attended with great difficulties, and particularly that it ought not to be made use of as a proof of Christ's corporal presence in the eucharist. However, after the death of Luther, this absurd hypothesis was renewed, and dressed up in a specious and plausible form by Brentius, Chemnitius, and Andræas, who maintained the communication of the properties of Christ's divinity to his human nature. It is indeed obvious, that every Lutheran who believes the doctrine of consubstantiation (see SUPPER *of the Lord*), whatever he may pretend, must be an Ubiquitarian.

UBIQUITY, OMNIPRESENCE; an attribute of the Deity, whereby he is always intimately present to all things; gives the *esse* to all things; knows, preserves, and does all in all things.

UDDER, in comparative anatomy, that part in brutes wherein the milk is prepared, answering to the mammæ or breasts in women. See ANATOMY, COMPARATIVE.

VEDAS, the sacred books of the Hindoos, believed to be revealed by God, and called *immortal*. They are considered as the fountain of all knowledge human and divine, and are four in number; of which we have the following account in the first volume of the Asiatic Researches: the *Rigveda* consists of five sections; the *Yajurveda* of eighty-six: the *Samaveda* of a thousand; and the *At'harvaveda* of nine; with eleven hundred *sac'ha's*, or branches, in various divisions and subdivisions. The *Vedas* in truth are infinite; but have been long reduced to this number and order; the principal part of them is that which explains the duties of man in a methodical arrangement; and in the fourth is a system of divine ordinances.

From these are reduced the four *Upavedas*, the first of which was delivered to mankind by BRAHMA, INDRA, DHANWANTARI, and five other deities; and comprises the theory of disorders and medicines, with the practical methods of curing diseases.

The second consists of music, invented for the purpose of raising the mind by devotion to the felicity of the Divine nature; the third treats of the fabrication and use of arms; and the fourth of *sixty-four* mechanical arts. Of however little value we may esteem the mechanical arts of the Hindoos, and however despicable their theological system may really be, the *Upaveda*, which treats of diseases and the method of curing them, surely deserves to be studied by every European physician practising in India. There are indeed a great number of medical books in the Shanscrit language worthy of attention; for though the theories of their authors may be groundless and whimsical, they contain the names and descriptions of many Indian plants and minerals, with their uses, discovered by *experience*, in the cure of diseases.

VEDETTE, in *War*, a centinel on horseback, with his horse's head towards the place whence any danger is to be feared, and his carabine advanced, with the butt-end against his right thigh. When the army has encamped, there are vedettes posted at all the avenues, and on all the rising grounds, to watch for its security.

To VEER *and* HAUL, to pull a rope tight, by drawing it in and slackening it alternately, till the body to which it is applied acquires an additional motion, like the increased vibrations of a pendulum, so that the rope is straitened to a greater tension with more facility and dispatch. This method is particularly used in bauling the bowlines.

The wind is said to veer and baul when it alters its direction, and becomes more or less fair. Thus it is said to veer aft and to haul forward.

VEER, *Ter-Veer*, anciently *Camp-Veer*, a town of Zealand in the United Provinces, standing at the mouth of the East Schelde, about four miles from Middleburgh, and eight from Flushing. Veer, in Dutch, signifies a passage or ferry over an arm of the sea or a river; and as there was once a ferry here over the Schelde to the village of Compen, on the island of North Beveland, the town thereby got the name of *Veer*, *Camp-Veer*, and *Ter-Veer*. It is well fortified, and formerly enjoyed a good trade, especially to Scotland; the natives enjoying particular privileges here. The harbour is very good, and the arsenal the best furnished in the world. Hence the Veres, anciently earls of Oxford, are said to have derived both their origin and name.

VEERING, or WEARING, the operation by which a ship, in changing her course from one board to the other, turns her stern to windward. Hence it is used in opposition to TACKING, wherein the head is turned to the wind and the stern to leeward. See SEAMANSHIP.

VEGA, LOPEZ DE, a celebrated Spanish poet. He was the son of Felix de Vega and Francisca Fernandez, who were both descended from honourable families, and lived in the neighbourhood of Madrid. Our poet was born in that city on the 25th of November 1562. He was, according to his own expression, a poet from his cradle; and beginning to make verses before he had learned to write, he used to bribe his elder school-fellows with part of his breakfast, to commit to paper the lines he had composed. Having lost his father while he was yet still a child, he engaged in a frolic very natural to a lively boy, and wandered with another lad to various parts of Spain, till, having spent their money, and being conducted before a magistrate at Segovia for offering to sell a few trinkets, they were sent home again to Madrid. Soon after this adventure, our young poet was taken under the protection of Geronimo Manrique, bishop of Avila, and began to distinguish himself by his dramatic compositions, which were received with great applause by the public, though their author had not yet completed his education: for, after this period, he became a member of the university of Alcala, where he devoted himself for four years to the study of philosophy. He was then engaged as secretary to the duke of Alva, and wrote his Arcadia in compliment to that patron: who is frequently mentioned in his occasional poems. He quitted that employment on his marriage with Isabel de Urbina, a lady (says his friend and biographer Perez de Montalvan) beautiful without artifice, and virtuous without affectation. His domestic happiness was soon interrupted by a painful incident: Having written some lively verses in ridicule of a person who had taken some injurious freedom with his character, he received a challenge in consequence of his wit; and happening, in the duel which ensued, to give his adversary a dangerous wound, he was obliged to fly from his family, and shelter himself in Valencia. He resided there a considerable time; but connubial affection recalled him to Madrid. His wife died in the year of his return. His affliction at this event led him to relinquish his favourite studies, and embark on board the Armada which was then preparing for the invasion of England. He had a brother who served in that fleet as a lieutenant; and being shot in an engagement with some Dutch vessels, his virtues were celebrated by our afflicted poet, whose heart was peculiarly alive to every generous affection. After the ill success of the Armada, the disconsolate Lopez de Vega returned to Madrid, and became secretary to the marquis of Malpica, to whom he has addressed a grateful sonnet. From the service of this patron he passed into the household of the count of Lemos, whom he celebrates as an inimitable poet. He was once more induced to quit his attendance on the great, for the more inviting comforts of a married life. His second choice was Juana de Guardio, of noble birth and singular beauty. By this lady he had two children, a son who died in his infancy, and a daughter named *Feliciana*, who survived her father. The death of his little boy is said to have hastened that of his wife, whom he had the misfortune to lose in about seven years after his marriage. Having now experienced the precariousness of all human enjoyments, he devoted himself to a religious life, and fulfilled all the duties of it with the most exemplary piety: still continuing to produce an astonishing variety of poetical compositions. His talents and virtues procured him many unsolicited honours. Pope Urban VIII. sent him the cross of Malta, with the title of Doctor in Divinity, and appointed him to a place of profit in the Apostolic Chamber: favours for which he expressed his gratitude by dedicating his *Corona Tragica* (a long poem on the fate of Mary queen of Scots) to that liberal pontiff. In his 73d year he felt the approaches of death, and prepared himself for it with the utmost composure and devotion. His last hours were attended by many of his intimate friends, and particularly his chief patron the duke of Sessa, whom he had made his executor; leaving him the care of his daughter Feliciana, and of his various manuscripts. The manner in which he took leave of those he loved was most tender and affecting. He said to his disciple and biographer Montalvan, That true fame consisted in being good: and that he would willingly exchange all the applauses he had received to add a single deed of virtue to the actions of his life. Having given his dying benediction to his daughter, and performed the last ceremonies of his religion, he expired on the 25th of August 1635.

VEGETABLE PHYSIOLOGY.—Under the article BOTANY, and also under PLANT, we have already delivered some of the commonly received doctrines on this subject. But as some late investigations seem to lead to new views with regard to the structure and nature of vegetables, we have thought it necessary to resume the subject, and to give as full a detail of the experiments and observations to which we allude as our limits will permit; we shall first treat of the structure, and secondly of the physiology of plants.

I. STRUCTURE OF PLANTS.—In considering the stucture or anatomy of plants, we shall treat, 1st, of the root; 2d, of the stem and branches; 3d, of the leaves; and 4th, of the flowers; in the order in which they are now enumerated.

1. *The Root.*—The root is that organ belonging to vegetables by which they are supplied with nourishment, and by which they are fixed to a commodious situation.

It was formerly supposed to be composed of outer and inner bark, of wood, and of pith; but Mrs Ibbetson, who has lately communicated * to the public the results of an elaborate

* Nich. Jour. xiii. 161. and 334.

elaborate series of experiments on this subject, thinks that it is wholly composed of the rind much thickened, with perhaps a very little of the outer bark, but no inner bark; of a quantity of wood, hardly any pith, and no spiral vessels. Mrs Ibbetson searched in vain for the larger vessels of the inner bark, till it occurred to her that the want of this bark accounted for there being no leaves on the root. Mrs Ibbetson had often been assured that roots were found bearing leaves, but on dissection of these supposed roots, she found that they were branches which crossed the root.

The root consists of the caudex, stock or main body, and of the radiculæ or fibres which arise from the caudex, and are the organs by which the moisture is immediately imbibed.

In botanical terminology, we generally consider all that part of a plant which is under ground as the root; but Linné comprehends under his definition, what we term the body or trunk of the plant; and he went so far as to call the stems of trees "*roots above ground;*" but as Dr Smith justly remarks, this seems paradoxical and scarcely correct. Dr Smith adds, that perhaps it would be more accurate to call the caudex a *subterraneous stem*; although he is rather inclined to think that it has functions distinct from the stem, analogous to digestion; for there is evidently a great difference in many cases, between the fluids of the root, at least the secreted ones, and those of the rest of the plant.

In botanical physiology, by the term *root*, is often understood the parts only which serve to keep the plants firm in the ground: thus the bulbous and fleshy roots as they are called, are, strictly speaking, not roots; the radiculæ or fibres being the real roots. The duration of roots is various; they are either annual, biennial, or perennial.

2. *The Stems and Branches.*—Linné long ago divided the stems of trees into four parts; the rind, the bark, the wood and the pith: and nearly a similar division has been adopted by most vegetable physiologists till the present time.

Mrs Ibbetson (aided by a powerful solar microscope), however, thinks that nature points out a more regular division, a division marked not only by the form, but by the difference of the *juices*, with which the parts are swelled.

Mrs Ibbetson divides the stem of trees into six parts; 1. The rind; 2. The bark and inner bark; 3. The wood; 4. The spiral nerves; 5. The nerves or circle of life (corona of Hill); and, 6. The pith.

Of the rind.—Mrs Ibbetson conceives the rind to be merely an outward covering to the tree, which prevents its juices from being evaporated by the influence of the sun's heat. The rind is continued under ground: but it may be as useful there to prevent the entrance of the dust and earth, the pressure of stones, or the injury of insects.

The rind is composed of two rows of cylinders, with a single line to divide them. The cylinders are filled with a pellucid liquor. There are seldom more than four or five layers of vessels in the rind; but it is in general so covered with parasitic plants, as powdery lichens, &c. that its thickness is often more than doubled.

The rind does not appear to be necessary to plants in general, as there are many in which the bark serves as a covering in its stead; but it seems to form an essential part of trees.

2. *Of the bark and inner bark.*—These parts, though certainly different as to *form*, contain the same kind of juice; and being so nearly allied, may be treated of as one. From the bark and inner bark the leaves take their origin, as will be shown when we come to treat of the formation of the leaf-bud. Mrs Ibbetson conceives that the juice of the bark is the blood of the tree.

In the bark alone are produced the gums, the resins, the oil, the milk, &c.; in short all that belongs to the tree; gives taste to it; all that makes one plant differ from another, and all its virtues, if the expression may be used. The bark is generally green; the inner bark white, yellow, or green. The former consists of vessels crossing each other; the latter of bundles of vessels of two sizes. The large vessels consist of broad cylinders, having a bottom with a hole in it, through which the liquid passes, though not with perfect ease.

Mrs Ibbetson says that on exposing several pieces of the inner bark to the solar microscope, the moment she turned the light on the specimen, the juice, which had before proceeded up the pipes rather slowly, was suddenly propelled forward with a force truly astonishing.

When the heat and light were increased by causing the focus of the rays to fall on the vessels, the side divisions of the vessels were broken through, thus inundating the specimen; but when a proper degree of light and heat was kept up, it was curious to observe the liquid passing from pipe to pipe, in one regular and easy flow, making only a short stop as it issued through the straitened apertures at the bottom of the vessels. Mrs Ibbetson has often stood for more than an hour watching the current, (which passes, however, much slower than the sap does), nor could she perceive while the heat and light were on it, that it required any additional expedient to hasten its momentum; but during the cold and darkness of night, she supposes that the pressure of the bastard grain mentioned by Mr Knight, may very likely assist its flow, as it is at night that the bastard grain is pressed against the cylinders.

The bastard grain is found however only in the wood; but the contraction at the bottom of the large vessels of the inner bark, may probably serve the same purpose, the impetus of the current being increased by the lessening of the apertures of the vessels.

The vessels of the inner bark are very thick in proportion to their size, and there is placed in them a peculiar circular body, which resembles a cullender full of holes so small that no liquid could pass them. In viewing the thick juice which runs through these pipes, Mrs Ibbetson observed many bubbles of air, the size of which was increased or diminished according to the temperature; and as their size varied, so was the flow of the liquid accelerated or retarded. To see these vessels well, the specimens may be placed in a basket which is to be fastened in a running stream for some time, or boiled thoroughly, and then thrown into green wax perfectly melted.

Mirbel says that "some plants have the same juices in every part of them:" but Mrs Ibbetson does not coincide with his idea, for she did not find it to be so; though the potent smell of the liquid belonging to the bark often extends to other parts of the plant, yet it generally vanishes if kept separate for a day, or becomes so faint

faint in comparison with the real liquid of the bark as to prove that it does not form an ingredient of these parts. Mirbel says that the cylinders of the inner bark are merely vacancies of the ordinary vessels; but Mrs Ibbetson states that they are exactly the same as these vessels, and occupy the same place.

They have a peculiar shape, being unlike any other vessels of the tree, and they perform a particular office.

The vessels of the bark are smaller, and more simple than those of the inner bark, and are divided by a line or two, running longitudinally between them.

3. *Of the Wood.*—This is a very obvious part. Place the stem of any plant in a coloured liquid, and every vessel which conveys the sap from the earth to the top of the tree will be tinged.

The sap is a thin watery liquor, probably medicated from the earth, in order to become suitable for the life of vegetables.

Mrs Ibbetson supposes that the sap may vary with the soil, though on trial she has never found that change which might have been suspected.

If we make a transverse section of the stem of a tree, two different kinds of layers present themselves in the wood; some running in a circular manner, which timber merchants call the *silver grain;* and others from the circumference to the centre, which they denominate the *bastard grain.* Linné long ago believed that one of the circular layers was added to the tree each year. This opinion has often been controverted, and among others by Duhamel and Mirbel; but Mrs Ibbetson has had an opportunity of verifying the accuracy of Linné's opinion. She also observed that the layer was large or small according to the exposure of the tree, and the favourableness of the season: thus in exposed situations, the circles taken as a whole, were much narrower than in trees not exposed. In some trees she noticed only half a circular layer.

Mrs Ibbetson thinks the bastard stripe consists of two lines or strings with a little scale between them; and they appear, from their extreme susceptibility, to be formed of the same leather-like substance as the spiral vessels, which we are immediately to notice.

Mr Knight merely calls them *scales;* but as he mentions their pressing close (which they certainly do) to the cylinders at night, and during cold weather, it is obvious (whichever of the opinions we adopt) that the bastard grains are capable of supplying the place of the sun's rays, by their pressure.

The wood-vessels are far more simple in structure than those of the bark; they are very narrow cylinders, and the two rows next to the corona are covered by the spiral vessels.

It is indeed difficult to determine the exact extent of the spiral vessels even with the assistance of the solar microscope, for it is by *unwinding* them alone that they can be known; and their extreme fineness confuses, in consequence of which they have been taken for sap vessels. Neither Mr Knight nor Mirbel was led into this mistake, and Mrs Ibbetson thinks that there can be no doubt that these vessels (formerly so called) are solid strings which hold no liquid.

The vessels of the wood may be best seen in slices of the stems of young trees; and if not very visible when recently cut, they will soon become so if the slices are kept in a dry place.

If the wood-vessels are cut longitudinally and observed with a high magnifier, as soon as the light is permitted to come on the glass, the flow of sap will be accelerated, and with perfect ease will run up vessels so diminutive that to measure them is almost impossible.

A few of the wood-vessels are separated and run with the spiral vessels to each leaf, in order to nourish it, as will be more particularly noticed, when we come to treat of the leaf-bud.

But little of the sap, however, passes off in this way from the principal current, which flows on; its chief purpose being to form the stamen and the pollen appertaining to it, and afterwards to lend its principal aid to the formation of the fruit and seed.

4. *The spiral vessels* are a quantity of solid strings coiled up into a spiral form. Mrs Ibbetson supposes them to be formed of a leather-like substance, and, as already mentioned, to be rolled round the wood. In this spiral manner they run up the stems of trees and plants of every kind (with a few exceptions), and from thence into every leaf and flower. These spiral cords are singly too small to be observed by the naked eye. They run into every fibre of the leaf, and are fastened to its edges, thus crossing among the vessels in every direction like a spider's web; by which disposition they can draw the leaves in any way that is necessary for them.

The larger of the interior wood-vessels are each supplied with sets of ten or twelve spiral cords, but the smaller of these have only three or four to each.

In the cabbage leaf and in the burdock, the spiral cords may be found in bundles almost as thick as a packthread, but in smaller leaves they are properly proportioned. These spiral cords, Mrs Ibbetson thinks, are the cause of the motions of plants. See PLANT, p. 601, where these cords are called *air-vessels.*

5. *Of the corona or circle of life.*—The next part to be noticed is the small circle of vessels situated between the wood and the pith, the importance of which, in the formation of the seed, will be noticed under *Impregnation of the Seed;* where are also related strong proofs to show that a plant cannot exist a day without the corona, and that if a young plant be deprived of this part, it will not grow again, though it will certainly do so if the plant be somewhat old. It is very curious that almost every botanical anatomist should have figured this part, without giving it a name, or noticing it particularly; and that these anatomists should have attributed all its powers to the pith, which, from the short term of its existence, and its being perpetually impeded in its progress to make way for the flower-bud, can evidently have but little influence. The circle of life, however, has not escaped the notice of Hill, who termed it the corona.

The circle of life consists of rows of little cylinders which have their own peculiar juice, generally of an austere quality. From the corona all branches take their rise, and from it all wood threads grow. The cylinders of which it is composed run up into all flower-buds, but never approach the leaf-bud as is represented by fig. 1. and 2.; when these cylinders enter the flower-bud, they make their way distinctly to each separate flower, Plate DXLI. fig. 1, 2.

flower, forming the pistil, and after depositing in each side the *line*, which is the first origin of life, they are afterwards impregnated, or acquire the power of giving life by the juice of the stamen, which runs through the same string into the seed.

That the principal *vitality* of the plant resides in the corona, we think is proved by the experiments and observations of Mrs Ibbetson under *Impregnation of seed*, and seems to be farther confirmed by the following remarks.

When a branch is cut from a tree, or a tree is torn up, the corona or circle of life is the first part that dies; and if, after a sudden frost, we examine the flowers of a fruit tree, we shall find that neither the calyx, the corolla, the stamina, nor the seeds are hurt, but that the pistilla are destroyed. And if we now observe the pistils with care, we shall see that it is the *line of life* which is decayed, and that this is the first part in which mortification commences. The peculiar liquor of the pistil acquires a blood-red colour, and the vessels which run up to the stigma become black, instead of their natural yellow colour.

If in wood, this line is injured (either by the decay of the bark or other means) the circle will undulate into a thousand forms, for the purpose of regaining a healthy situation in which it may pursue its course.

Mrs Ibbetson, to prove the power of the circle of life, relates the following observations respecting the *poa reptans*.

She had often measured in winter, seven or eight yards of this grass, which appeared perfectly dead; and yet in May or June, she perceived life in it at the most distant end from the stalk. Next spring she took up two of these creeping branches which were much alike; and on dissecting one of them through its whole length, she found in it a collection of little vessels not thicker than a very fine thread.

This collection of vessels had run about half way the length of the branch, which was about three yards.

Mrs Ibbetson having merely opened the cover of the grass, laid it down again, and the little vessels continued increasing till they reached the end of the branch, when they made a stop, and it was perceived that the grass began to thicken; and at the end nearest the roots, the dead part became inflated with juice, lost by degrees its dead appearance, thickened about the joints within, and at last shot forth fresh leaves and fresh roots from every joint.

Mrs Ibbetson has since watched with the greatest care, and found that the fine thread which runs through the grass protected by the dead scale, was the circle of life. When this thread is stopped by the covers decaying, it waits till the season permits the rest of the plant to grow. From what has been said, it is evident that the dead matter may be inflated with a living juice, and live itself again, provided the life near the stem of the plant be not extinguished. Mrs Ibbetson has observed this to happen in many plants, as in hydrangea, in which the stalks apparently lie down and are inflated again, or at least a part of them.

6. *Pith.*— Linné considered the pith of plants as of equal importance with the spinal marrow of animals; but Mrs Ibbetson thinks this part of but little consequence, and transfers this importance to the circle of life, which she compares to the brain and spinal marrow. She conceives that the pith forms merely a source of moisture for the plant when required. The pith stops with every flower-bud, and begins again to grow as soon as the bud is past; it decreases as the strength and size of the tree increase; it is the only part of the tree which is devoid of vessels; it is merely a net, not a bundle of cylinders, and is commonly of a remarkably splendid or silver white colour.

It has been said that the pith assumes a variety of figures, but Mrs Ibbetson thinks this is a mistake, though she admits a few different sorts.

All young trees and shrubs are provided with pith; but in the progress of their growth they need it no longer, the wood being a good substitute. On the same account, in general, we find no pith in water plants, which have a hollow stem, and rarely suffer from draught.

Linné thought that the pith was the seat of life and the source of vegetation; or in a word, the primary part of the plant. Duhamel considered it as of but little importance at all. Wildenow and Knight concur with Mrs Ibbetson in regarding it as a reservoir of moisture for the young plants; and Dr Smith holds a medium opinion between that of Linné and the other authors just named.

He says "there is in certain respects an analogy between the medulla of plants, and the nervous system of animals; it is no less assiduously protected than the spinal marrow; it is branched off and diffused through the plant, as nerves through the animal. Hence it is not absurd to presume that it may in like manner give life and vigour to the whole, though by no means, any more than nerves, the organ or source of nourishment *"

* See Fig. 3. 4, and 5.

We were somewhat surprised to find that Mrs Ibbetson had not particularly noticed the cellular tissue as a distinct part to be seen in the stems of trees, as it has been long known; we shall therefore subjoin a description of it. It is a succulent cellular substance, generally of a green colour, at least in the leaves and branches. Duhamel long ago called it *envellope cellulaire*, and Mirbel, more lately, *tissue herbacé*.

Duhamel supposed that the cellular tissue formed the cuticle, or epidermis; but this is not very probable, as his own experiments show that when the cuticle is removed, the cellular integument exfoliates, at least in trees, or is thrown off in consequence of the injury, and a new cuticle, covering a new layer of the cellular tissue, is formed under the old one. This substance is very universal, even in mosses and ferns. Leaves consist almost entirely of a plate of this substance, covered on each side by the cuticle. The stems and branches both of annual and perennial plants are invested with it; but in woody plants it is dried up, and reproduced almost continually, such parts only having that reproductive power. The old layers remain, are pushed outward by the new ones, and form at length the rugged dry dead covering of the old trunks of trees. The cellular integument is a part of plants of the greatest importance; for in it the juices of plants are operated on by light, air, &c.

With regard to the branches of trees it has been already noticed, that they derive their origin from the corona; and they are composed exactly of the same parts as the trunks from which they arise.

3. *The Leaves.*—Mrs Ibbetson has, with the assistance

Vegetable Physiology. ance of the solar microscope, and by great attention to this natural process, being enabled to give some new and interesting views on this subject. Her opinion respecting the formation of the leaf-bud is, "That leaves are formed or woven by the vessels or cotton that is generally supposed by botanists (to be) placed there to defend the bud from the severities of winter; that these vessels (or cotton) are a continuation of those of the bark and inner bark in the stem of the plant; that these vessels compose the various interlacing branches of the leaf, which are soon filled up by the concentrated and thickened juices of the inner bark, which form the pabulum of the leaf."

Mrs Ibbetson says the truth of her assertion may be easily seen by dissecting early buds, in which, except two or three, nothing but the cotton-like vessels will be found. She asks then what could be the use of these vessels? and answers, that to put them within the bud to keep the outside warm is against nature, for it is contrary to nature. The leaf-bud in its first state consists of two or three scales, inclosing a parcel of vessels, which appear like very moist coarse cotton, but when drawn out and placed in the solar microscope, they shew themselves to be merely the vessels of the bark and inner bark elongated and curled up in various forms.

These vessels are of three kinds like the bark, &c. First, Three or four short thick ones which appear to grow from the larger vessels of the inner bark, and through which the thickened juice flows, but with this difference, that the holes are not there.

Then there are two smaller sized vessels, which exactly resemble the smaller vessels of the bark.

Mrs Ibbetson has always found the short thick kind of vessels to form the mid-rib of the leaves, and the smaller-sized vessels to compose the interlacing fibres (or vessels) of the other parts of the leaves; and from often comparing the full-grown leaf with the leaf of the bud, she feels the most thorough conviction that the latter takes its origin as above noticed. The pabulum of the leaf which lies between the vessels, is composed of that thick juice which runs in the bark or inner bark of the tree, and which does not exist in any other part of it. The pabulum differs essentially from the sap, and may be called the blood of the tree, as it possesses peculiar properties in different trees; thus it is of a gummy nature in one, of a resinous in a second, and of an oily nature in a third, &c.

Mrs Ibbetson is not certain whether the pabulum both flows forwards and in a retrograde direction; but she is convinced that the greatest part of it is taken up in forming the leaves. The pabulum of the leaf, after the vessels are arranged and crossed, grows over in bladders, making alternate layers with the smaller pipes (vessels), and with the branches of the leaf.

Mrs Ibbetson states, that she does not know any tree which gives a more convincing proof of the formation of the leaves in the bud, than may be seen in the horse chesnut (*æsculus hippocastanum*) about the month of November or December.

Several different mid-ribs may be taken out at once from the same leaf-bud, which have an innumerable number of extremely fine silken vessels fastened to or growing up from each side of them. When these vessels have become sufficiently interlaced with each other, the pabulum will begin to grow over them, in form of small bladders full of a watery juice; and then larger vessels will cross over them, which will soon be followed by another row of bladders; and a similar process will go on until the leaf has attained its proper thickness. The leaves thus formed are very small, but when once their shape is completed every part of them continues to increase in size. Fig. 6. represents the leaf-bud of the horse-chesnut, as it was examined by Mrs Ibbetson about the month of January. Fig. 6.

Mrs Ibbetson next notices the arrangement of the leaves in the buds of different trees; but we shall consider them by and bye.

The rolling, folding, or plaiting, &c. of the leaf-bud, it is observed, does not merely take place at once; but to complete the process of budding, it appears that this arrangement of the leaves is repeated several times. During this arrangement the bud-leaves are immersed in the glutinous liquor which runs in the bark (and forms the pabulum); and the pressure of the leaves is very great. By this pressure and the rolling, &c. the leaves are completed; for if a leaf be taken from the bud before this process commences, it may be compared to a piece of cloth before it is dressed; for its back will be obscured by the ends of vessels, which, had it remained *in situ*, would have been all rubbed off, except the hairs which remain on many plants.

We come now to the formation of the edge of the leaf, a curious and beautiful process.

The bud if opened will appear full of the glutinous liquor which forms the pabulum, and the leaves arranged in the manner proper to the particular tree from which the bud is taken. If one of the leaves be taken out, the edges (in whatever manner folded) will exhibit a perfect double row of bubbles, following the scollop of the edge of the leaf; and it will appear as if it were set with brilliants.

Things being in this state, all that is wanting for the completion of the leaf is the formation of the pores, now to be mentioned. Mrs Ibbetson states that in many hundred *forming leaves* which she exposed to the solar microscope, she had never once been able to see the pores; which she has often observed after the leaves have completely quitted the bud; and she is uncertain whether this is owing to the greater thickness of the young leaf, and its being covered with more hairs than it is afterwards, which obscure or conceal the pores; or whether it be caused by the upper net-work of the leaf growing last. While the upper and under cuticles of the leaf are growing, the edge of it is completing; for the bubbles generally divide, and partly dry up, leaving horny points in their stead. When the edges of the leaves are completely formed, they burst from the bud and assume a different aspect.

The vessels of the leaves (those confined within the mid ribs and side ribs of the leaves) are of two sorts, the spiral, and the nourishing. The spiral vessels are those corkscrew-like wires which surround the two last rows of the sap vessels. The nourishing vessels are the only parts formed of the wood. They convey the sap necessary for the support of the leaves, and run on each side of the spiral vessels.

To prove that she has given a fair and accurate account of the formation of the leaf, Mrs Ibbetson

Vegetable Physiology.

son adds the following remarks. The colour of leaves, she observes, is not to be found in their substance, but in the liquid with which it is filled. The darkest green leaf that can be procured, has both its upper and under cuticles of a perfect white colour. In the cuticle the pores are to be found.

A leaf has rather a thicker net below than it has above: but this does not sufficiently account for the varieties of tints in different leaves.

The under net (or cuticle) does not lie so close to the pabulum of the leaf as the upper one; which may account for the colour not piercing so much through. When the two nets (or cuticles) are taken off, then the pabulum of the leaf appears.

The pabulum is formed of little bladders, filled with a dark-green liquid, and interlaced with vessels. When the pabulum is removed, a bed of large vessels presents itself; then a collection of bladders; which is followed by the larger lines (or veins) of the leaf. We next meet with another bed of bladders, which is covered by the under cuticle. Though the bladders differ in size and colour as well as in thickness in different leaves, yet the general arrangement is the same in most plants; but there are exceptions, as the firs, grasses, or those grassy leaves of early spring, which we have in the iris, crocus, snow-drop, &c. for their leaves are of a different nature.

But we shall now refer to the figures, which will serve to illustrate the mode of formation, &c. of the leaf-bud.

Fig. 7. 8. 9. Fig. 7. 8. 9. exhibit the commencement of the formation and growth of leaves; *a, a, a, a*, the mid rib; *b, b, b*, the young vessels appearing like cotton; *c, c*, the spiral nerves; *d*, the smaller vessels crossing each other. Fig. 10. Fig. 10. shews the formation of the pabulum; *e, e*, the fine vessels growing up each side of the mid rib; *f*, the pabulum. Fig. 11. Fig. 11. bud of the lime-tree (*tilia Europea*).

4. *Of the* FLOWERS, *including the calyx, corolla, stamina, and pistillum.*—Linné long ago expressed his opinion that each of these parts was formed from a particular part of the stem; thus the calyx was formed by the bark, the corolla by the inner bark, the stamina by the wood, and the pistilla by the pith. Linné also reckoned the pith of a plant (which he considered to be of equal importance with the spinal marrow of animals), as the sole formative organ of the whole vegetable kingdom.

Linné's idea respecting the formation of the calyx, corolla, &c. has been often refuted; but Mrs Ibbetson comes forward to defend the opinion of the illustrious author with a little modification. She does not, as already noticed, consider the pith as of great importance; she therefore says, that the corona or circle of life forms the pistil, not the pith; and thinks that each part of the stem has, when it arrives near the flower stalk, its peculiar juice.

Mrs Ibbetson, as a strong proof that the circle of life forms the pistil, says that it is to be found in all these leaves that bear the flower either on the middle or on their side; but in no other leaves.

She first observed this in the butcher's broom, where this circle leads directly up to the flower; then in scolopendrums, and afterwards in xylophyllos.

The leaves of such plants are more woody than any others, as every one may know on breaking them. In such plants also the circle of life may be traced as leading from one flower to another.

Mrs Ibbetson also thinks that all those parts which concur in forming the flower also join in forming the fruit and seed.

Mrs Ibbetson then adverts to the opinion of Wildenow, when he says, "we find in the springing flower, elongations of air-vessels, but we never see the elongations from each particular part, one forming the future calyx, another the corolla, and so forth." "For instance, in the common sun-flower (*helianthus annuus*), where in an immense large receptacle, numerous small flowers are placed, how should these elongations be able to unfold themselves into florets from the bark, inner bark, &c. through such a receptacle? There would arise a confusion amongst these small parts which is never met with."

"How should, besides, the stamina be formed in herbs, which are not ligneous, or the pistil in plants which have no pith? Every one may thus easily conceive that all these opinions are mere hypotheses, which may be refuted, even without the aid of anatomical dissection.

Mrs Ibbetson attacks Wildenow's opinion, and says that he adduces the syngenesian class to prove the accuracy of it, the class which contains the very plants that would have proved the mistake of his argument, had he dissected them.

Mrs Ibbetson then proposes the following questions to Wildenow. Why, if the nourishment of each part of the stem be not confined to each different part of the flower, does the whole arrangement of the parts *alter*, the moment it gets to the flower-stalk?

Why are there particular vessels to confine and carry the juice to each peculiar part, if it were not of consequence that this juice should touch no other places? For what purpose is the curious and artificial management in the bottom and top of a seed-vessel, which enables the dissector to say, that "there are five divisions of little vessels proceeding from the wood; I know, therefore (though I do not see it), that this must be a pentandrian flower; here is but one middle vessel proceeding from the circle of life (for the pith stops), it is therefore of the order monogynia; here are five divisions of little vessels proceeding from the inner bark, it must therefore have five petals?" Mrs Ibbetson wishes others to be convinced of these facts as well as herself. If a cut be made above or below the seed-vessel of a lily, a violet, or a tulip, she thinks conviction of her accuracy will follow. Why in cutting above or below the seed-vessel of a syngenesian flower can you directly tell, whether it belong to the order superflua, æqualis, or segregata? Look at the bottom of the seed-vessel of the *sonchus*; every *pin hole* of the vessel of the male is carried up by corresponding vessels in the outward cuticle of the seed, till it meets and joins the *ligature of the males;* and the female liquor is protruded through the inside of the seed, and is perhaps one of the strongest proofs of the impregnation of the female. In the syngenesian class (see fig. 12.), the delicacy of the vessels, which may be supposed too small for a liquid to flow through them, must not impede the belief that it does so, when we consider

sider the circulation of blood in the diminutive animal that torments the body of the flea or louse. Mrs Ibbetson says she has seen the liquor run up with the utmost celerity through the upper cuticle of a very small seed of a plant belonging to the syngenesian class, till it met the male and continued its course. It is to be understood that the juice from the corolla flows in the rest of the cuticle, and that the largest vessels are those for the *male liquor*. See fig. 12. 13.

Fig. 12. 13.

II. Physiology of Plants.—In treating this part of the subject, we propose to consider, first, the impregnation of seeds, and, second, the irritability of vegetables.

1. *The impregnation of the seed.*—The investigation of what is included under this title, forms one of the most beautiful and interesting pursuits of the vegetable physiologist. Mrs Ibbetson has communicated some curious observations on this subject. Provided with a powerful solar microscope for opaque objects, she proceeds to an examination of the seed, and the first shooting of the infant plant, or rather of the germ or vessel which precedes it; and she remarks that it is almost impossible to ascertain the exact time when the seed is first formed in the pericarp; but that she has always found it in the winter buds when they were large enough for dissection.

It is curious to observe the vessels, which, she says, may properly be called the life, tracing their way to each flower-bud: for a seed may be said to depend for perfection on two *separate moments*: the one in which the life *first enters the seed*, when the whole outward form appears to be perfected; and the second, when the impregnation of the seed takes place, by the ripening of the pollen.

But when the life enters, it leaves a little string, and remains for a long time afterwards in a torpid state. This string crosses the corculum, or heart of the seed, so called because it is the cradle of the infant plant. She then states that the seed is attached to the seed-vessel by two distinct organs, termed by the first botanists the umbilical cord, but as she thinks improperly, since they do not convey nourishment to the infant plant, which is wholly the office of the second set of vessels. We cannot agree with Mrs Ibbetson in her opinion; for although the umbilical cord of an infant contains nourishing vessels, it also contains nerves, and yet we would never think of restricting this term alone to the arteries. The first of the connecting organs Mrs Ibbetson conceives to be the circle of life, first, because without it the plant dies, and, second, because although every other part be eradicated by degrees and the circle of life be uninjured, the plant will grow again.

She has made these experiments many thousand times and with the above results. The circle of life consists of delicate simple vessels, which carry a juice of a particular nature, and may be traced in every part lying between the wood and the pith. These vessels are not to be found in the leaf-bud; for they pass by it to the female flower, where they establish a new life in the seed: a life which will enable it to grow, but not to give life without impregnation. These vessels are the life, therefore, from which all flower branches grow and all root-threads proceed. In calling these vessels the circle of life, Mrs Ibbetson says she only expresses what its office seems to denote.

Mrs Ibbetson goes on to describe the next (or second) organ by which the seed is attached to the seed-vessel. It consists of the nourishing vessels, which she is inclined to think proceed from the inner bark; at least they may certainly be traced thence after the infant plant has left the seed. When introduced, they enter not the seed at the same place as the life does; they come not into the corculum, but pass it, and spread themselves over a small spot below it, which is visibly of a different nature from the rest of the seed. In farinaceous plants this spot is yellow, and yields a milk-white juice; but in other seeds it is white, and gives a glutinous water of a sweetish taste. Mrs Ibbetson thinks it probable that the nourishing vessels come from the fruit *filled with this juice*, which medicated with that part of the seed (which very apparently dissolves), they together form a nourishment suited to the infant plant. When the seed is so far perfected, it remains in an almost torpid state, or growing very little; while the flower expands daily, and the stamens are hastily advancing to enough their perfect state.

It is now that by an almost imperceptible contraction of the lower part of the pistil, the juice is raised to the stigma (A), on which it may be seen hanging in a large glutinous drop, which never falls off. As soon, however, as the mid-day heat abates, this juice, which is peculiar to the pistil, retires again within the tube, the contraction ceasing with the heat that caused it. The same process goes on daily, till the stamina are ripe and ready to give out their interior powder to the pistil, which is always so placed as to receive the greater part of it; and as the anther (B) requires only moisture to burst it, it soon yields that fine and imperceptible dust, which quickly *melting and mixing with the before-mentioned liquid*, forms a combination of so *powerful* and *stimulating* a quality, that it no sooner runs down the interior of the style, and touches the nerve of life in the heart of the seed, than this vessel shoots forth in the most surprising degree, forming directly a species of *circular hook* within the *void;* which in less than two days is often completely filled, though it had perhaps for many weeks before lain in an absolute torpor. This circular nerve is soon covered by an excrescence that hides it; but if the corculum be divided with a fine lancet, the circular hook is discoverable, until the young plant is near leaving its cradle or seed. At the turn of the hook the cotyledons grow, and the root shoots from the covered end. The plant may be now said to lie in the seed in a contrary direction from that in which it will at a future time grow, since the root is above, and the stem below: but nature has provided for their change of place, since it is effected as they leave the seed. It has been already noticed that the nourishment of the infant plant

(A) In the journal it is said "to the pointal;" but certainly stigma is meant, for pistil and pointal are synonymous.

(B) In the journal it is called pollen, but anther must be meant.

Vegetable Physiology.

plant is medicated between the juice brought in the nourishing vessels, and the peculiar spot in the seed, forming a liquid which continues to abound; indeed the infant plant may be said to *repose in it*, till the root has opened the whole or part of the seed. The root then changes its direction, and runs into the earth, soon forming a number of stringy hairs, which serve as so many suckers to draw the liquid nourishment from the earth, while the plant quickly shews, by the rapid progress it makes, the advantage it receives from its change of diet; for it soon raises itself from its prostrate posture, emerges from the seed, and is now seen in its proper direction. The above account, we think Mrs Ibbetson justly remarks, affords a complete confirmation of the sexual system.

In the syngenesian orders, the pistil being mostly single, runs up from the seed; and the juice of the pistil has no other way of reaching the pointal (stigma must be here meant), but by passing through the seed, which it does without producing any effect, or filling up the vacancy at the top of the corculum. But as soon as the juice of the pistil becomes mixed with the pollen, which dissolves in it, the void of the corculum is filled, the hook is soon afterwards formed, and the plant is roused to life. Mrs Ibbetson relates some experiments which she made to ascertain whether the umbilical cord was, or was not, the life of the plant. She placed a bean in the earth, and when the infant plant was ready to leave the seed she opened it with a fine lancet, and cut off the cotyledons, just where they join the heart and the circular hook which have been before described. She then tied a piece of very fine thread round the bean, and replaced it in the earth. The cotyledons grew again, though higher up, but they appeared very weak and sickly for some time. She cut off the root of another bean which had been placed in the earth, and which was of the same age as the above, and found that the root grew again in a few days and appeared quite healthy.

In a third experiment she separated and cut off the nourishing vessels from each side of the bean; but a great number of hairs grew from the wounded part, which, by attaining moisture from the earth for nourishment, supplied the place of the vessels cut off; so that it was not ascertained whether or not the bean would live independent of these vessels, which was the object of the experiment. We observe here, however, a grand provision of nature for the embryo plant: hairs being formed to supply it with moisture when the nourishing vessels are destroyed. Mrs Ibbetson next took a bean which had been about four days in the earth, and opening it with great care took out with a fine lancet the part which she esteems the cord of life, that is, the part which crosses the corculum and shot forth on the first

Fig. 14. 15. impregnation of the plant. *o o*, fig. 14. and 15. represent the nourishing vessels of a bean; L to *n* two seminal leaves or cotyledons; *l l* the cord of life, which is more easily seen in the seed of the lily, fig. 15. *l l* crossing the empty part of the corculum. Mrs Ibbetson took a flower of the lilium genus, as having a large vessel easily attained; and being careful not to separate it from the nourishing vessels, she divided the line of life fig. 16. *l l*, cutting each thread between the seeds, and so cutting off their communication; but did not touch *o o*, which she thinks is the nourishing vessel.

The consequence was, that the seeds of this flower were never impregnated. Mrs Ibbetson next tried the effect of taking the nerve of life from the chesnut, the walnut, acorn, &c; first opening a seed without touching the nerve, that she might be certain that the opening was not the cause of its death. Fig. 17. represents the heart taken out of a seed of the chesnut; *l* is the circular hook already described; *o o* the nourishing vessels, and *l l* the line of life, which was taken out from some seeds where it crosses the heart at *m*. Fig. 18. is the seed of the gooseberry; *o* the nourishing vessels, *e* the line of life, and *m* the corculum or heart. Fig. 17. Fig. 18.

She found that all those seeds from which she took the nerve of life died; and that the others, which had been merely laid open, lived. She remarks that it is only at the beginning of life, that the plant can be killed by this process; for when older, if the nerves of life decay, they shoot out above the declining part, and run into any part of the stem that is pure, to preserve themselves. Mrs Ibbetson then states that this nerve is the source of life in very decayed trees; and is also the cause of a double pith, or at least the appearance of it, in many trees.

To observe this line of life, seeds must be examined in their first formation; for when it has done its office, it detaches itself. When the seed is boiled, the line of life and nourishing vessels mark themselves by becoming of a dark colour.

2. *Irritability of vegetables.*—In entering upon this subject, we ought to warn our readers, that very opposite opinions have been entertained respecting it; some physiologists of the greatest eminence allowing that we have satisfactory proofs of the irritability of vegetables in a variety of plants, but more particularly in the motions of the mimosæ, dionea, &c.; while others of no less respectability ascribe these motions to the influence of light, heat, or some other mechanical agent.

As neither muscles nor nerves have ever been demonstrated in the vegetable structure, of course the proofs of the irritability of vegetables are drawn from the intimate analogy which seems to exist between the motions of some plants and those of animals. Some physiologists, from observing the similarity of motions in the two kingdoms, were naturally led to ascribe them to the same cause; others, from not being able to observe the same motive organs, namely, muscles, in both kingdoms, denied that plants could possess irritability; a third set, waving the idea of irritability in the vegetable kingdom, have laboured to shew that the motions of plants depend on mechanical causes alone.

We shall first notice the observations of Mrs Ibbetson, who ascribes the motion of plants to the spiral wires which we have described. Her opinion is founded upon a number of new observations made with the solar microscope, which we shall proceed to relate.

1st, The spiral vessels are not to be found in any plants to which motion is unnecessary.

She could not observe these vessels in any of the firs, in any of the plants which spread their leaves upon the surface of the water, in any of the sea weeds (c), of the lichens, or of the grasses; and she does not think that

(c) She afterwards excepts the *confervæ*, which have motion.

Vegetable Physiology.

that they exist in the scolopendrums or lemnas. We would here observe that if these observations were completely true, they would certainly afford a strong proof in confirmation of her opinion; but we suspect that they are not altogether just, especially as we observe a discrepancy in the papers of Mrs Ibbetson. Thus at one part she has given us a very minute description of the spiral vessels in the runners of the *poa reptans*, and now she says they are not to be found in the grasses (D).

Mrs Ibbetson's second argument is, that if a plant whose leaves present their faces to the light, be turned so that the backs are to the sun, the leaves in a few hours will regain their former position; but if this be often repeated, although the plant will not suffer, yet the leaves will be longer at every repetition in returning to their former situation, or will cease to move at all. She accounts for this by saying, that the spiral-like elastic vessels are relaxed by the operation, and lose their power of coiling into their usual form.

Others would account for the above fact by saying that the irritability of the plant was exhausted by these repeated and unnatural actions; in the same manner as the mimosa becomes gradually less sensible to impressions when too often renewed.

Mrs Ibbetson's third argument is, that those leaves which have most motion, are provided with most spiral vessels, and have these vessels most twisted; as in the *populus tremula*.

Fourth proof. Mrs Ibbetson divided the spiral vessels of a vine leaf while growing, without touching the nourishing vessels; and from that moment it never contracted, and when placed with its back to the light, it did not alter its position, though it was long before it decayed. Both electricity and galvanism cause these leaves to contract, by affecting the spiral wires (not the cuticle), for when the leaf is deprived of these vessels it does not contract at all.

We would here remark that we suspect much, in the above experiment, that more than the spiral vessels was divided: at any rate there is very great discordance between Mrs Ibbetson's experiments and that of M. Calandrini, who found that vine leaves turned to the light when they were separated from the stem and suspended by a thread.

Fifth argument. Mrs Ibbetson observed, when she placed some of the spiral vessels taken from a cabbage leaf upon one end of a long netting needle, and caused a candle to approach, that they were much agitated, and at last flung themselves off the needle. We think no conclusion can be drawn from what is here stated.

The fresh water *conferva* and the dodder tribe, are the only plants, without leaves, that Mrs Ibbetson is acquainted with, which have spiral vessels.

Mrs Ibbetson says that the spiral vessels are so very tough, and so very tightly coiled, in the leaf stem (*petiole*) of the *geranium cordifolium*, that she has by means of them been enabled to draw up the leaf; but it is difficult to be done.

The sixth proof is drawn from the effect produced by moisture on Captain Kater's hygrometer, which will be noticed soon.

General Observations.—Mrs Ibbetson says the spiral wires may be considered as a secondary cause of motion, as they are primarily acted upon by light and moisture. By means of the spiral wire, all the movements of plants are made; by it, flowers open in the morning and shut in the evening; the leaves turn, and the creeping plants wind in their regular order. Mrs Ibbetson says, the opening of the flower at a different time of the day, or its turning in a different manner, does not militate against the above statement; as strong light and dry weather produce a contraction of the wire, while darkness and moisture effect a dilatation of it. It depends wholly upon the position in which the spiral wire is placed, whether by its dilatation the flowers shall be opened or shut, as in mechanics the same spring may be made to turn to the right or to the left, to open or to shut a box. Most of the flowers which Mrs Ibbetson has observed to close at noon, have an extremely limber corolla, formed only of a double cuticle without pabulum; and hence they are soon overcome by heat, and relaxation directly takes place; as in the *convolvulus nil*, the evening or tree primrose, &c.

We must add, however, that we regard this account of the spiral vessels with some degree of doubt. We suspect that the spiral vessels, if they have the power of opening or shutting a flower, will always act in one uniform manner; i. e. if they are able to open it, they will always do so, and *vice versa*.

The *nymphea alba* raises itself out of the water, and expands, about seven o'clock in the morning; and closes again, reposing upon the surface, about four in the evening. Now its petals are much thicker than those of the *leontodon taraxacum*, which shuts up its flowers between eight and nine in the evening.

We could multiply instances; but we conceive we have said enough to shew, that the flowers with the most slender corolla are not uniformly those which soonest close.

Mrs Ibbetson says, contrary to the opinion of Mirbel, that the case in which the spiral vessels are inclosed is capable of being stretched; indeed it is formed of so thin (or rather so loose) a substance, as plainly to be intended to dilate and contract. The case is composed of a very few thin vessels, interlaced with an extremely fine spiral wire; while the large spiral vessels fill up the case in an irregular manner, the nourishing vessels form a regular circle of tubes around it. See fig. 29. and 30.

Of the Indian grass (*andropogon contortum* of Linné), of which Captain Kater's hygrometer is formed.—The chief part of it is made with the spiral awn of an Indian grass, which readily untwists in a moist atmosphere, and *vice versa*. Now Mrs Ibbetson asks, if the most trifling change of moisture can untwist one sort of vegetable fibre, and by this means manage an instrument, why should not a quantity of similar formed fibres or spiral vessels produce the same effect on leaves and flowers? She says, Captain Kater's hygrometer moves very sensibly if a finger be placed within half an inch of the fibre (awn.) Now, the most sensitive plant we have will not move but with the touch."

We are quite aware of the effects of moisture on some vegetables.

(D) She found the spiral vessels also in the *andropogon contortum*.

Vegetable Physiology.

vegetables. We have strong proofs of it in some of the mosses, as in the *bryum hygrometricum*, which, if the fruitstalk be moistened at the bottom, makes three or four revolutions; if the upper part be moistened, it turns the contrary way.

We can scarcely compare these motions with those of the mimosæ; for it is quite evident that they are produced by moisture: but as we are to speak of the motions of the mimosæ in a little, we would only observe, that when Mrs Ibbetson says "the sensitive plant will not move but with the touch," she argues against herself; for this shews that it is acted upon by the same causes as animal muscles, and that it is not governed by moisture alone.

The only sensitive part of the Indian grass is the awn, which is formed of a leather-like substance, infinitely thicker and stronger than the usual spiral vessels in plants. The awn is formed of two apparently flat pieces, with a cylindric hollow running through the middle, which is filled with a thick spiral wire. Fig. 21. 22. 23. and 24. Each side of the awn is bristled; but the bristles do not add to its sensibility.

Of the Nettle.—The awn or sting of the nettle is a long pipe with a bag at the end divided into two parts; the smaller contains the poison, and the larger is situated below it. This bag seems also to be composed of a leather-like substance, and it is likewise affected by light and moisture.

The moment the upper part of the pipe is touched, the under part of the bag whirls up, breaks the poison bladder, and throws its contents violently up the pipe, burning the person who touches it.

Light thrown upon the bag by means of the solar microscope, produces the same effect as touching it. The poisonous liquor is protruded up the pipe with great force, till it issues out at the minute aperture at the point; but before it does so, the pipe is bent down with a jerk, by means of the spiral wire.

The spiral wire winds round the bag at the bottom of the pipe; and it is by the action of this wire that the bag is made to contract. The nettle lays down its stings every evening, just as the sensitive plant does its branches. See fig. 19, and 20.

Mimosa Sensitiva.—The motions of this plant are regulated not only by the spiral wire, but also by a bag of a leather-like substance, which is capable of contraction and dilatation.

We shall next give Mrs Ibbetson's plate respecting the structure of this plant, with her description.

Fig. 25. Fig. 25. is a representation of the springs which govern each leaf; *d, d* is the stalk. Each leaf has a base *c, c*, which serves to concentrate the spiral wires. These passing over in every direction, being drawn through the narrowest parts of the stem *b b b b*, press the stem together; and, when touched, lay the leaves, one on the other, the whole way down the leaf-stalk. But, before the stimulus is applied, the stem is flattened in a contrary direction. The ball of the leaf is hollow and filled with oil. The parts *e e* and *p p*
Fig. 26. (fig. 26.) are made of that leathery substance, which forms the cuticle, and is contracted by the light in the solar microscope. The parts *e e* contain the oil which serves to lubricate the knots (we suppose), and enable them to slip over each other; beside, probably, acting some important part in the formation of the various gasses and juices in the composition of the plant.

When touched, the whole string relaxes at *o o*, and lets the branch fall. This it would also do at *m*, if it were not supported by the wood-vessels turning into the leaf. Fig. 27. is the part *e c p p* uncut, and in its natural sate. Mrs Ibbetson thinks that not only the motions of this plant, but of all others, depend upon the spiral wires which contract and dilate by the action of light and moisture. She adds, that there are no spiral wires in the seminal leaves of the *mimosa sensitiva*, and that the seminal leaves have no motion whatever.

In farther illustration of this subject, we shall next present our readers with some observations by Mr Lyall, lately published in Nicholson's Journal *, respecting the irritability of the *mimosa pudica*, and some other plants.

* Vol. xxv. 92.

"It is well known (he observes), if we take a leaf of this plant, similar to what is represented (fig. 31.), and then, by means of a pair of scissars (completely dry), cut off half the pinnula A, this pinnula will contract at its joint, either immediately, or in a few seconds; its neighbour, or opposite pinnula, B, closing at the same time, or soon after.

"The pinnulæ A and B having come into contact, there is a pause, or a short cessation, of motion; but in the course of a few more seconds, the next pair of pinnulæ, CC, will also shut up, and the same will happen with every pair of pinnulæ of that pinna successively; only with this difference, that the intervals between the shutting up of each pair of pinnulæ will be shorter, the farther it is from the pinnula that was cut. After the whole of the pinnulæ of this pinna have completely closed, and a little interval, then the joint D will bend so as to allow the pinna to drop considerably.

"Nevertheless, the motion is often not so obvious in this joint, as in that to be mentioned.

"A longer pause will now intervene, in some cases so long as to make us suppose that all motion is at an end; but at length the joint E suddenly bends, and astonishes the beholder.

"The petiole F now, instead of forming an acute angle with the stem above the joint, forms a very obtuse angle with it.

"We shall now have another cessation of motion, and then the joint, H, will slightly bend; then another pause, then a shutting up of the pair of pinnula, H, and so on with the other pinnulæ, till the whole pinna is closed. The motions, however, will not be so regular in this pinna as they were in the other; for as the pinnulæ II approach, they press forward the next pair, and so on with all the rest."

These motions, the author supposes, are not occasioned by impulse; for a bit of the pinnula may be cut off almost without producing any motion.

But, allowing that a little motion were produced, it comes naturally as a question, Why does the motion become so extensive? how is the impulse communicated to the origin of the petiole? The author does not think that these questions will ever be satisfactorily answered upon mechanical principles.

He admits indeed, that a structure exists in the *mimosa sensitiva*, corresponding to what Mrs Ibbetson has described;

described; although he seems to have some doubts respecting it. He then proceeds to inquire, whether by such a structure, acted upon by heat, light, or moisture, we could possibly explain the motions of the *mimosa pudica*. "On the experiments above related, (he observes), I presume no one would say, that moisture was the cause of motion, as the scissars were quite dry."

It is to be remembered also, that this plant will perform its motions under water.

As there was no change of light, consequently this had no share in the effect. Besides, when moisture is produced (Mr Lyall certainly means darkness) in consequence of the abstraction of light, all the pinnulæ shut up at the same time; not, however in the regular order mentioned in the experiment. Neither does the motion take place from change of temperature, for the temperature was not altered.

A great many questions will here suggest themselves, as, How does it happen that the motion is produced? how does it become so extensive? how comes it that there are regular motions and pauses, &c.?

The author concludes, by saying, that it is vain to attempt any mechanical solution of the phenomenon mentioned above, "which would seem to depend on an exquisite irritability in the plant itself."

Dionæa Muscipula.—Mr Lyall does not think that the motions of this plant are to be explained in the manner spoken of by Broussonet, who ascribed them to the evacuation of a fluid from the leaf, which will be noticed when we speak of the *droseræ*. For the leaf may be touched without causing any efflux of fluid whatever, and yet it will contract completely.

Comparetti's explanation respecting the motion of this plant is not admitted; because it seems improbable, is contrary to analogy, and inadequate to explain the phenomenon.

Of the Drosera Longifolia and Rotundifolia.—As many of the muscles of the animal system, as the heart, diaphragm, &c. act quite independent of the will, and as these parts are highly irritable, Mr Lyall wishes to show, that a voluntary command of a muscular force should not be taken into the definition of the word irritability, as has been done by some. Mr Lyall says, "By irritability, I understand, that property inherent in some bodies (or rather parts of bodies), by which, when a stimulus is applied, they are enabled to contract.

The leaves of the drosera rotundifolia, when properly unfolded, lie round the stem in a stellated manner. The footstalks of the leaves vary in length from half an inch to an inch and a half. The leaves are covered on their upper surface by a number of hairs, varying also in length from one line to three-eighths of an inch, and are each terminated by a little gland, which gland is covered by a transparent viscid fluid, presenting a fine appearance.

The chief difference between the drosera longifolia and rotundifolia is in the shape of the leaves; those of the former being obovate, while those of the latter are of an orbicular shape.

Mr Lyall mentions the observations of Mr Whately, who, it would appear, was the first in this kingdom who described the contractions of the droseræ when irritated.

Mr Whately and Mr Gardom had observed some insects imprisoned in the leaves of this plant, and hence were led to press with a pin the centre of other leaves in their natural and expanded form, when they very suddenly contracted, and, as it were, encircled the pin.

Roth had noticed, in 1779, that the leaves of the droseræ moved, when irritated. He placed an ant upon the middle of a leaf of the drosera rotundifolia, but so as not to disturb the plant. The ant endeavoured to escape, but was held fast by the clammy juice of the points of the hairs, which was drawn out by its feet into fine threads; in some minutes the short hairs on the disk of the leaf began to bend, then the long hairs, and laid themselves upon the insect. After a while the leaf itself began to bend, and in some hours the end of the leaf was so bent inwards as to touch the base. The same happened when the experiments were made on the drosera longifolia, but more rapidly.

Roth also found that the hairs bent themselves when he touched them with the point of a needle, with a hog's bristle, or when he placed a very small piece of wood the weight of an ant upon the leaves.

Mr Lyall next gives us an account of his own experiments. He says, "that for five months, he almost, every day, had the species of droseræ under his eye, either at home or in the country;" and he confesses, that he never saw such a rapid contraction of the leaves of the drosera rotundifolia, as had been noticed by Messrs Whately and Gardom: but in all his experiments the contraction was gradual, though it seldom failed to happen, if the plant was in good condition. In most of his experiments an hour was necessary for the complete bending of all the hairs; and it required some hours for the perfect shutting up of the leaves. Hence it is evident, that whoever has a wish to notice the motions of the droseræ, must not set out with the expectation of seeing a rapid motion, similar to what happens in the mimosæ, follow the application of a stimulus; but, to observe the ultimate effects, must watch with an attentive eye, for at least 20 minutes.

In accounting for the manner in which these motions are performed, various opinions have been held. Broussonet suspects that the disengagement of some fluids influences them. He says, that the insect, by absorbing the fluid which is on the points of the hairs, empties the vessels of the leaf, which folds upon itself; and the quickness of the action is proportional to the number of hairs touched by the insect.

Our author observes, that "this theory, at first sight, does not appear even to be plausible; for, how is it possible that an insect can absorb a thick tenacious fluid? No doubt, however, part of this fluid will be attached to the part of the insect which touches it; but this seems quite unconnected with the contraction of the leaf. On the 30th of July, Mr Lyall brought from the country a number of plants of the drosera rotundifolia, and, on inspecting them, he found many of the hairs of the leaves deprived of their viscid fluid; but yet both they and the leaf remained quite expanded and in good condition. Next day, about four o'clock, he placed a small bit of sulphate of copper, in the disk of one of these expanded leaves, and by six o'clock most of the hairs on one side of the leaf, even the outermost, had bent themselves over the bit of copper; this seems to to prove the inaccuracy of Broussonet's theory. In other experiments, he placed small bits of bread or wood, or three or four of the central hairs, without touching the other hairs, or the viscid fluid on their ends; and in a few hours he found that all the hairs had contracted around the foreign body. In some plants, the sulphate of copper was placed upon some of the small hairs in the disk of the leaf, without touching the leaf itself; yet the bending of the hairs and leaf was complete.

"We have here proof (he adds), 1st, That the leaves do not contract when deprived of their viscid fluid, which ought to have been the case if Broussonet's theory had been true. 2dly, That the contraction takes place even when the viscid fluid does not cover the little glands. 3dly, That the contraction follows, although the foreign body is not brought into contact with all the hairs.

The opinion of Sennebier, who appears to have ascribed the motions of the droseræ to the effect of pressure is next examined. "Sennebier seems (it is observed) sensible, that the contractions of the leaves take place even when light bodies are placed on them, which circumstance of itself would lead us to suspect, that pressure is not alone the cause.

"I know (it is added), that, if we press on the centre of a leaf with a pin, &c. we may cause its margin to approximate the pin; and this certainly would be owing to a mechanical cause. But, suppose we see the contraction take place, as I have done, when a body specifically lighter than the leaf itself is placed in the centre, as a bit of rotten wood; should we be still inclined to ascribe it to a mechanical cause? Admit that it is the case. Suppose, then, we place the same bit of wood on the margin of the leaf, what effect ought to follow? If it were owing to a mechanical cause, or the weight of the foreign body, as in the last mentioned case, then we should expect, that the part of the margin of the leaf, on which the bit of wood rested, would be depressed; which undoubtedly is not the case: but, on the contrary, the margin rises, and then contracts towards the foreign body, or towards the footstalk of the leaf.

"That this motion does not depend on pressure, may be still better illustrated, by placing a fly, or some other body, on the apex of a leaf of the drosera longifolia. The hairs near the foreign body will contract around it, and then the apex of the leaf will rise upwards, and turn inwards, until it touches the base. Or, if the offending body is small, the leaf will become convoluted around it."

From the result of his experiments, the author thinks, that the motions of the leaves of the droseræ cannot be explained on mechanical principles. He conceives, that these motions are performed, if not by muscles, at least by *something* which is equivalent to muscles in the animal body.

It appears that the leaves of the drosera rotundifolia and longifolia remain completely expanded during the hottest sunshine and driest weather; during the coldest and wettest weather; during the greatest darkness, and, finally, during the brightest light of day. This, however, is to be taken in a limited sense, i. e. only during the expansion of the leaves, not during the cold of winter. "Here, then, neither heat, cold, dryness, dampness, darkness, nor light in general, at all affect the leaves; but, if a foreign body be applied to the leaf so as to stimulate, then it will shut up" in the manner we have already described. See *Vegetable* ANATOMY, SUPPLEMENT.

EXPLANATION OF PLATES DXLI. DXLII. AND DXLIII.

[*Note, that some errors in the references to figures in the text may be corrected by this explanation, which is accurate.*]

Fig. 1. Part of a branch, shewing the manner in which the line of life, *c c*, enters into the flower-bud, *a*, and passes by the leaf, *b b*.

Fig. 2. A flower-bud, showing the line of life, *c c*, running up to each flower, *a, a, a, a, a, a, a*, and the pith terminating at *b*.

Fig. 3. Section of the stem of a tree; *a*, the rind; *b*, the bark; *c*, the inner bark; *d*, the wood; *e*, the spiral nerves; *f*, the corona or line of life; *g*, the pith; *h, h*, the silver grain; *o, o, o*, the bastard grain.

Fig. 4. Cylinders of the inner bark.

Fig. 5. Cylinders of the wood.

Fig. 6, 7, 8, 9. Commencement of the growth of leaves, exhibited in different stages. *a, a, a, a*, The mid-rib; *b, b, b*, the young vessels appearing like cotton; *c, c*, the spiral nerves; *d*, the smaller vessels crossing each other. Fig. 9. also shews, *e, e*, the fine vessels growing up each side of the mid-rib; and *f*, the pabulum.

Fig. 10. Leaf-bud of the lime-tree.

Fig. 11. Leaf-bud of the horse-chesnut about January.

Fig. 12. A seed-vessel of the class syngenesia; *a*, the calyx; *b*, female florets; *c*, male and female florets.

Fig. 13. Section just above the seed-vessel of the dianthus. *a*, the calyx proceeding from the bark; *b*, the the corolla, from the inner bark; *c, c, c, c*, ten stamina from the wood; *d*, the seed-vessel; *e*, the pistil from the corona or circle of life.

Fig. 14. Representation of the bean. *o, o*, the nourishing vessels; L to *n*, the seminal leaves, or cotyledons; *l*, to *l*, the embryo.

Fig. 15. *o*, The nourishing vessels; *l l*, the embryo in the seed of the lily, crossing the empty part of the corculum.

Fig. 16. Shews, *l, l*, the line of life; *o, o*, the nourishing vessels.

Fig. 17. Represents the heart taken out of the seed of a chesnut. *l*, the circular hook; *o, o*, the nourishing vessels; *l, l*, the line of life, which was taken out where it crosses the heart at *m*.

Fig. 18. The seed of the gooseberry. *o*, the nourishing vessels; *l*, the line of life; *m*, the corculum or heart.

Fig. 19. The sting of the nettle, as viewed with the solar microscope; *z*, the bag of poison; *x*, the spiral wire.

Fig. 20. The sting after the poison has been thrown to the point; *x*, the spiral wire contracted.

Fig. 30. Spiral wire still more magnified.

Fig. 31. Leaf of the mimosa pudica.

VEGETATIVE SOUL, among philosophers, denotes that principle in plants, by virtue of which they vegetate, or receive nourishment and grow.

VEHICLE, in general, denotes any thing that carries or bears another along; but is more particularly used in pharmacy for any liquid serving to dilute some medicine, in order that it may be administered more commodiously to the patient.

VEII, in *Ancient Geography*, a city of Etruria, the long and powerful rival of Rome; distant about 100 stadia, or 12 miles, to the north-west; situated on a high and steep rock. Taken after a siege of 10 years by Camillus, six years before the taking of Rome by the Gauls: and thither the Romans, after the burning of their city, had thoughts of removing; but were dissuaded from it by Camillus (Livy). It remained standing after the Punic war; and a colony was there settled, and its territory assigned to the soldiers. But after that it declined so gradually, as not to leave a single trace standing. Famous for the slaughter of the 300 Fabii on the Cremera (Ovid). The spot on which it stood lies near Isola, in St Peter's patrimony (Holstenius).

VEIL, a piece of stuff, serving to cover or hide any thing.

In the Romish churches, in time of Lent, they have veils or curtains over the altar, crucifix, images of saints, &c.

A veil of crape is worn on the head by nuns, as a badge of their profession: the novices wear white veils, but those who have made the vows black ones. See the article NUN.

VEIN, in *Anatomy*, is a vessel which carries the blood from the several parts of the body to the heart. See ANATOMY, N° 123.

VEIN, among miners, is a fissure in the horizontal strata which contains ore, spar, cauk, clay, chert, croil, brownhen, pitcher-chert, cur, which the philosophers call the *mother of metals*, and sometimes *soil of all colours*. When it bears ore, it is called a *quick vein*; when no ore, a *dead vein*.

VELA, a remarkable cape on the coast of Terra Firma, in South America. W. Long. 71. 25. N. Lat. 12. 30.

VELARIUS, in antiquity, an officer in the court of the Roman emperors, being a kind of usher, whose post was behind the curtain in the prince's apartment, as that of the chancellor's was at the entry of the ballustrade; and that of the ostiarii at the door. The velarii had a superior of the same denomination, who commanded them.

VELEZ-DE-GOMARA, a town of Africa, in the kingdom of Fez, and in the province of Eriff. It is the ancient ACARTH. With a harbour and a handsome castle, where the governor resides. It is seated between two high mountains, on the coast of the Mediterranean sea. W. Long. 4. 0. N. Lat. 35. 10.

VELITES, in the Roman army, a kind of ancient soldiery, who were armed lightly with a javelin, a cask, cuirass, and shield.

VELLEIUS PATERCULUS. See PATERCULUS.

VELLUM, is a kind of parchment, that is finer, evener, and more white than the common parchment. The word is formed from the French *velin*, of the Latin *vitulinus*, "belonging to a calf."

VELOCITY, in *Mechanics*, swiftness; that affection of motion whereby a moveable is disposed to run over a certain space in a certain time. It is also called *celerity*, and is always proportional to the space moved. See QUANTITY, N° 11 and 14, &c.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue.

The nap or shag, called also the *velveting*, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channelled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp. The principal and best manufactories of velvet are in France and Italy, particularly in Venice, Milan, Florence, Genoa, and Lucca: there are others in Holland, set up by the French refugees; whereof that at Haerlem is the most considerable: but they all come short of the beauty of those in France, and accordingly are sold for 10 or 15 per cent. less. There are even some brought from China; but they are the worst of all.

VENAL, or VENOUS, in *Anatomy*, something that bears a relation to the veins. This word is also used for something bought with money, or procured by bribes.

VENEERING, VANEERING, or *Fineering*, a kind of marquetry, or inlaying, whereby several thin slices or leaves of fine wood, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying: the one, which is the more ordinary, goes no farther than the making of compartiments of different woods; the other requires much more art, and represents flowers, birds, and the like figures. The first kind is what we properly call *veneering*; the latter we have already described under MARQUETRY.

The wood intended for veneering is first sawed out into slices or leaves, about a line thick: in order to saw them, the blocks or planks are placed upright in a kind of vice or sawing press: the description of which may be seen under the article just referred to. These slices are afterwards cut into slips, and fashioned divers ways, according to the design proposed; then the joints being carefully adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground or block of dry wood, with good strong English glue. The pieces thus joined and glued, the work, if small, is put in a press; if large, it is laid on the bench, covered with a board, and pressed down with poles, or pieces of wood, one end whereof reaches to the ceiling of the room, and the other bears on the boards. When the glue is quite dry they take it out of the press and finish it; first with little planes, then with divers scrapers, some whereof resemble rasps, which take off dents, &c. left by the planes. When sufficiently scraped, the work is polished with the skin of a

a sea dog, wax, and a brush and polisher of shave-grass: which is the last operation.

VENEREAL, something belonging to venery; as the *lues venerea*, &c. See MEDICINE *Index*.

VENERY, is commonly used for the act of copulation, or coition, between the two sexes; it has also been employed by old writers as applicable to hunting or *the chace*, as *beasts of venery*.

VENESECTION, or PHLEBOTOMY, in *Surgery*. See SURGERY *Index*.

VENETIAN BOLE, a fine red earth used in painting, and called in the colour shops *Venetian red*.—It is dug up in Carinthia, and sent from Venice to all parts of the world; but the use of it is much superseded by a bright colcothar of vitriol.

VENICE, STATE OF, formerly a celebrated republic, which for nearly ten centuries formed one of the most powerful maritime states of Europe. Its dominions lay chiefly along the coasts at the head of the Adriatic sea, comprehending not only a considerable tract round the city of Venice, but several districts both to the east and west of that sea, together with the islands of Corfu, Zante, Cephalonia, Cerigo, and some others of less note in the Archipelago. It was bounded to the north by the Alps, to the west by the duchy of Milan, and to the east by Croatia, a province of Turkey in Europe.

1 Situation and boundaries.

The republic of Venice is said to have taken its rise from a small Italian colony, who in the middle of the 5th century were driven by Attila king of the Huns from the cities of Aquileia, Verona, Mantua, &c. and took refuge in the group of small islands where now stands the city of Venice. Here they established themselves, and formed a small independent state, adopting the consular form of government which had so long prevailed at Rome. By the end of the 5th century they had become of consequence, and were able to raise and maintain a fleet and a small army. They engaged in a war with the Lombards, and distinguished themselves against the Istrian pirates, and the inhabitants of the neighbouring port of Trieste. They also assisted Justinian in his contest with the Goths, and received from him and his general Narses, many marks of favour and distinction,

2 Origen. An. 452.

About the year 697, the tribunitian power, which had prevailed in Venice from the end of the 5th century, was abolished, and the states elected a supreme magistrate, whom they called doge, or duke. He was to represent the honour and majesty of the state; to assemble and preside at the great council, where he had a casting vote in all disputed points; to nominate to all offices, places, and preferments, and to enjoy the same authority in the church as in the state. Excepting a short intermission of about five years, the power of the doges continued till the fall of the republic.

3 Establishment of a doge or duke. An. 697.

Under the doges, the power and wealth of the republic continued to increase. In 765, the Heraclians and Gezulans, subjects of the republic, revolted, and threw themselves on the protection of the emperor Charlemagne. That emperor settled them for the present at Malamoe, in the neighbourhood of the Venetian capital; but from this asylum they were quickly driven by the forces of the republic, Incensed at this affront committed against his authority, Charlemagne ordered his son Pepin to declare war against the Venetians; but as Astolphus king of the Lombards was then laying waste the territories of the church, the troops of Pepin were, by the intreaties of the pope, dispatched against that powerful monarch; and though, on the defeat of Astolphus they marched against the Venetians, it does not appear that the enterprise was productive of either honour or success. The war with Pepin was renewed in 804, on occasion of Obelerio, the doge of Venice, shewing an inclination to favour the Greek emperor Nicephorus against Pepin. Obelerio was related to the French monarch, having married his sister; and as on this account the Venetians were jealous of the attachment of their doge, he was superseded, and Valentin nominated commander in his place. Pepin had collected a numerous and well appointed army, and had fitted out a fleet to act against the Venetians by sea. With this formidable force he advanced directly to Venice, but here he was opposed with all the valour of independent citizens fighting for their liberties.

4 War with the emperor Charlemagne. An. 765.

The Venetians, however, notwithstanding the most obstinate defence, the most vigorous sallies, and their selling every inch of ground at an incredible expence of blood, were at length reduced to that part of the city south of the Rialto *(see the next article)*; this stream and their own bravery, being now their only defence. While Pepin was preparing to throw a bridge over the canal, they resolved, as a last effort, to attack Pepin's fleet, and to vanquish or die in defence of their liberty. Embarking all the troops they could spare, they bore down with the advantage of the wind and tide, upon the enemy, and began the attack with such fury, as obliged the French admiral to give way. The lightness of their ships, and the knowledge of the soundings, gave the Venetians every advantage they could wish: the enemy's fleet was run aground, and the greater part of their troops perished in attempting to escape: the ships were all to a few either taken or destroyed. During this action at sea, Pepin resolved to assault the city by land, not doubting but the garrison was so weakened by the number of forces they had sent on board the fleet, as to be able to make but a slight resistance. Having for this purpose thrown a bridge over the Rialto, he was marching his troops across it, when he found himself attacked on every side by the Venetians from their boats, and others who had posted themselves on the bridge. The battle was long, bloody, and doubtful, until the Venetians employed all their power to break down the bridge; which at last yielding to their obstinate endeavours, a prodigious slaughter of the French ensued; they fought, however, like men in despair, seeing no hopes of safety but in victory; but all communication being cut off with the troops on shore, they were to a man either killed or drowned. The number of slain was so great that the space between the Rialto and Malamoe was covered with dead bodies, and has ever since gone by a name expressive of the prodigious slaughter. Pepin was so struck with the intrepidity of the Venetians, that he raised the siege, abandoned the enterprise, and concluded a peace with the republic.

5 Intrepidity and success of the Venetians. An. 804.

In 839, the Venetians engaged in an offensive and defensive alliance against the Saracens, with the Greek emperor Michael, to whose assistance they sent a fleet of 60 galleys. In an engagement which took place between the allied fleets and that of the Saracens, the former

6 Venetian fleet defeated by the Saracens. An. 839.

Venice.

mer were completely defeated, and almost all the Venetian galleys were either taken or destroyed. On the news of this defeat, the capital was thrown into the greatest consternation, justly dreading an attack from the victorious Saracens. This alarm, however, soon subsided, on finding that the barbarians had turned off on the side of Ancona. The city now became a prey to internal dissension. Popular tumults were frequent, and in one of these the doge was murdered. By the prudent and vigorous administration of a succeeding doge, Orso Participato, good order was re-established, and at the commencement of the 10th century, the reputation of the republic for military prowess was much advanced by a victory gained over the Huns, who had invaded Italy, and defeated Berengarius.

7
Increased power of the republic.
An. 1084.

Towards the close of the 11th century, Venice began to make a considerable figure among the states of Europe, having acquired the sovereignty of Dalmatia and Croatia, with which in 1084 they were formally invested by the Constantinopolitan emperor.

8
Take an active part in the crusades.
An. 1096.

About this time a crusade, or holy war against the Saracens, was preached up by the emissaries of the pope, and the Venetian republic engaged in the undertaking with such ardour, as to equip a fleet of 200 sail, under the command of the doge Vitalis Michael. Before he sailed for the coast of Asia, however, the doge found it necessary to chastise the Pisans, whom he defeated in a terrible engagement. He then sailed for Askalon, at that time besieged by the Christian forces, and it was chiefly by his valour that that city, as well as Caipha and Tiberias, fell into the hands of the Christians. From these victories he was recalled to repel an invasion of Dalmatia by the Normans, whom he also defeated, carrying off considerable booty. His successor assisted Baldwin in the conquest of Ptolemais, but was defeated and killed in attempting to quell a rebellion of the Croatians.

9
Dispute with the Greek emperor,

Under the government of Domenico Micheli, who succeeded Ordelapho, the pope's nuncio arrived at Venice, and excited such a spirit of enthusiasm among all ranks and degrees of men, that they strove whose names should be first enrolled for the holy war. The doge, having fitted out a fleet of 60 galleys, sailed with it to Joppa, which place the Saracens were at that time besieging. The garrison was reduced to the last extremity when the Venetian fleet arrived, which surprised and defeated that of the enemy with great slaughter; soon after which the Saracens raised the siege with precipitation. Tyre was next besieged, and soon was obliged to capitulate; on which occasion, as well as on the taking of Ascalon, the Venetians shared two-thirds of the spoils. While the doge was absent on those important affairs, the emperor of Constantinople, jealous of the growing power of the Venetians, resolved to take advantage of their apparent incapacity to resist an attack at home. The Venetians, however, had timely notice of his approach, and instantly recalled the doge, who on his return laid waste and destroyed the country round Chios, seized on the islands of Samos, Lesbos, and Andros, then belonging to the emperor, and reduced several places in Dalmatia which had revolted.

10
and with Barbarossa.
An. 1173.

In 1173, the republic ventured to oppose Frederick Barbarossa in his attack on the pope. Frederick, after a haughty reply to an embassy sent him by the Venetians, dispatched against them his son Otho, who soon arrived before the city with 75 galleys. The doge Sebastiano Ziani sailed out with the few vessels he had got equipped, to give the enemy battle. The fleets met off the coast of Istria, and a terrible engagement ensued, in which the imperial fleet was totally defeated, Otho himself taken prisoner, and 48 of his ships destroyed. On the doge's return, the pope went out to meet him, and presented him with a ring, saying, "Take this, Ziani, and give it to the sea, as a testimony of your dominion over it. Let your successors annually perform the same ceremony, that posterity may know that your valour has purchased this prerogative, and subjected this element to you, even as a husband subjecteth his wife." Otho was treated with the respect due to his rank, and soon conceived a great friendship for Ziani. At last, being permitted to visit the imperial court, on his parole, he not only prevailed on his father to make peace with the Venetians, but even to visit their city, so famed for its commerce and naval power. He was received with all possible respect, and on his departure attended to Ancona by the doge, the senate, and the whole body of the nobility. During this journey he was reconciled to the pope; and both agreed to pay the highest honours to the doge and republic.

11
They gain possession of Constantinople.
An. 1204.

In the beginning of the 13th century, the Venetians in conjunction with the French, besieged and took Constantinople, as has been related under the article CONSTANTINOPOLITAN HISTORY, N° 144—146, which they held till the year 1261.

12
War with the Genoese.

In the mean time the Genoese, by their successful application to commerce, having raised themselves in such a manner as to be capable of rivalling the Venetians, a long series of wars took place between the republics; in which the Venetians generally had the advantage, though sometimes they met with terrible overthrows. These expensive and bloody quarrels undoubtedly contributed to weaken the republic notwithstanding its successes. In the year 1348, however, the Genoese were obliged to implore the protection of Visconti duke of Milan, in order to support them against their implacable enemies the Venetians. Soon after this, in the year 1352, the latter were utterly defeated with such loss, that it was thought the city itself must have fallen into the hands of the Genoese, had they known how to improve their victory. This was in a short time followed by a peace; but from this time the power of the republic began to decline. Continual war with the states of Italy, with the Hungarians, and their own rebellious subjects, kept the Venetians employed, so that they had no leisure to oppose the Turks, whose rapid advances might have alarmed all Europe. After the destruction of the eastern empire, however, in 1453 the Turks began more immediately to interfere with the republic. Whatever valour might be shewn by the Venetians, or whatever successes they might boast of, it is certain the Turks ultimately prevailed; so that for some time it seemed scarcely possible to resist them. What also contributed greatly to the decline of the republic, was the discovery of a passage to the East Indies by the Cape of Good Hope in 1497. Till then the greatest part of the East India goods imported into Europe passed through the hands of the Venetians; but as soon as the Cape was discovered, the conveyance by the way of Alexandria almost entirely ceased. Still, however, the Venetian

An. 1348.

power

Venice.

power was strong; and in the beginning of the 16th century they maintained a war against almost the whole force of France, Germany, and Italy, associated against them in what has been called the *League of Cambray*. Soon after, however, we find them entering into an alliance with the king of France against the emperor.

13 Opposed by the league of Cambray. An. 1508.

After this, nothing of importance occurs in the history of the Venetian republic till the year 1645, when the republic was involved in a new and sanguinary conflict with the Turks, in defence of the important island of Candia. The transactions to which this war gave rise, and the spirit and bravery displayed by the Venetians, in defending their colonial possessions, are amply detailed under the article CANDIA.

14 New wars with the Turks. An. 1645.

At the end of the 17th century, the Venetians obtained an important acquisition of territory by the conquest of the Morea, which at the peace of Carlowitz in 1699, was formally ceded by Turkey to the state of Venice *.

15 The Venetians conquer the Morea; An. 1687.

* See Mod. Univ. Hist. vol. xxvii.

During the war of the Succession, the states of Venice observed a strict neutrality. They considered that dispute as unconnected with their interests; taking care, however, to keep on foot an army on their frontiers in Italy, of sufficient force to make them respected by the belligerent powers. But soon after the peace of Utrecht, the Venetians were again attacked by their old enemies the Turks, who beholding the great European powers exhausted by their late efforts, and unable to assist the republic, thought this the favourable moment for recovering the Morea, which had been so lately ravished from them. The Turks obtained their object, and at the peace of Passarowitz in 1715, which terminated this unsuccessful war, the Venetian states yielded up the Morea; the grand seignior on his part restoring to them the small islands of Cerigo and Cerigetto, with some places which his troops had taken during the course of the war in Dalmatia.

16 which is soon after restored to Turkey. An. 1715.

From the peace of Passarowitz to the conclusion of the 18th century, the affairs of Venice ceased to form an interesting part of the history of Europe. Ever since the league of Cambray, the republic, weakened by its continual struggles with Turkey, had declined in power and in consequence, and was incapable of opposing a barrier to the encroachments of its more powerful neighbours. During the first war which the French republic maintained against the emperor in Italy, the states of Venice afforded a tempting object to each of the contending parties; and in May 1797, the capital was occupied by a body of French troops, who under pretence of quelling a tumult that had arisen in the city, took possession of the forts, and subverted the existing authorities. By the treaty of Campo Formio, concluded in October of the same year, the French consented that the emperor should take possession of the Venetian territory, with the islands in the Archipelago, which had been subject to the Venetian republic. At the treaty of Presburg in 1805, Austria was compelled to cede the Venetian states to the kingdom of Italy, of which these states continued to form a part till the overthrow of the French power in 1814, when they reverted to Austria.

17 The state of Venice becomes a province of Austria.

An. 1797.

It is not necessary for us to be very minute in our account of the late constitution and government of Venice. The government was strictly aristocratical, being vested in the great council or senate, in which each of the nobility had a seat. The nobility were extremely numerous, being computed at not fewer than 2000, whereas the whole population of the state did not exceed 2,500,000. Besides the great council, or *il consiglio grande*, there were four others; one composed of the doge and six counsellors, called *la signoria;* another called *il consiglio du pregodi*, consisting of about 250 of the nobility; a third united to *la signoria*, consisting of 28 assessors, or great sages, which gave audience to ambassadors; and a fourth, composed of 10 counsellors, who took cognizance of all criminal matters, and before whom even the doge himself must appear, if accused. The secret business of the state was often carried on by spies and informers; and there were in the ducal palace several statues of lions with open mouths, which formed so many receptacles for secret and anonymous information.

18 Constitution, government, &c. of the late republic.

The office and privileges of the doge of Venice have been already mentioned under the article DOGE. Of late this office was little more than nominal; and the doge was a mere state puppet, without authority and without power. His establishment, however, was splendid, and his revenue not contemptible. The mode of electing the doge deserves notice, as it was well calculated to prevent bribery, or the exertion of party influence. He was elected by a plurality of voices, and held his dignity for life. In his election they made use of gold and silver balls, which were put into a vessel, and served for balloting. Those who drew nine golden balls, first elected 40 counsellors, who drew 12 others, and elected 25 in addition. Of this number nine persons, who had drawn golden balls, chose 40 more; 11 of those, appointed in the same way, chose 41 counsellors, who finally proceeded to the election, till 25 votes or more fell upon the same person, who was then declared doge. After this election they placed the ducal cap upon his head, upon which he took possession of the doge's palace. He never uncovered his head to any person, because he did not wear the cap in his own name, but in that of the republic.

The military strength of the Venetians consisted of nearly 30,000 land forces, under the command of a capitano, who was always a foreigner of distinction; besides a considerable fleet, which they boasted could, in time of war, be increased to 60 men of war, and above 100 galleys. The ordinary revenues of the state have been computed at rather more than 1,000,000l. sterling, a considerable part of which arose from the customs, and the duty on salt made at Corfu and Chiosa.

VENICE, the city which was the seat of government of the Venetian republic, is built on 72 small islands at the head of the Adriatic or gulf of Venice, about five miles from the main land. That part of the gulf which lies between the city and the continent forms a kind of *laguna* or lake, which, at low water, is very shallow, and on the opposite side of the islands there are numerous shallows, the channels between which are marked by stakes, to direct ships in entering the port. The lagunes that lie between the islands form so many canals that intersect the city in all directions, and over these the streets communicate by not fewer than 500 bridges. The principal or *great* canal is broad, and has a serpentine course through the middle of the city, but the others are narrow and crooked. The streets are also narrow and winding, but clean and neat. The houses are built on piles, and have each a door opening to the adjacent

Venice ‖ Ventilator.

adjacent canal, and another to the street. As the narrowness of the streets but ill adapts them for walking in, the only places of resort on land are the *Rialto*, a noble bridge across the great canal, bordered with booths and shops and the great square of St Mark, or *Piazza di St Marco*, an irregular quadrangle, formed of several buildings some of which are magnificent. Of these, the *ducal palace* where the business of the state used to be transacted; the patriarchal church of St Mark; the steeple of St Mark, at a little distance from the church; the church of St Geminiano; and the *new* and *old Procuraries*, are most deserving the notice of travellers. The canals form the great medium of communication, as well as the principal scene of relaxation and amusement to the inhabitants. Here ply numerous gondolas, (see GONDOLA, and *Macgill's Travels*, vol. i.) which are rowed with admirable speed and dexterity by the gondoliers; and here are occasionally held races, or rather rowing matches. As the canals are, of necessity, the receptacles of all the filth of the city, they become, in hot weather, very offensive. The whole city is about six miles in circumference, and the inhabitants were formerly estimated at 160,000, but have been continually decreasing since it lost its independence: at present they are not supposed to exceed 100,000.

The inhabitants of Venice formerly carried on a flourishing trade in silk manufactures, gold lace, mirrors and other articles of glass, besides military stores and implements of war. At some distance from the city there is a large and commodious lazaretto, where ships coming from the Levant unload their goods, and perform quarantine from 20 to 40 days.

This celebrated city, once the seat of power, opulence and the fine arts, whose carnival revelries have been the subject of so many animated descriptions, has undergone a melancholy change. Her streets and canals no longer resound with the strains of the musician and the serenades of watchful lovers, and her gay gondolas, which were formerly occupied by fashionable groups and parties of pleasure, are now become the vehicles of trade, or serve for the accommodation of the soldier and the mechanic. The trade of the city, which had long declined, has, since the cession of the Venetian territory to Austria, been almost entirely transferred to Trieste. Venice is 72 miles E. by N. of Mantua; 115 N. E. of Florence; 140 E. of Milan; 212 N. of Rome, and 300 N. by W. of Naples. E. Long. 12° 33′. N. Lat. 45° 26′.

VENIRE FACIAS, in *Law*, is a judicial writ lying where two parties plead and come to issue, directed to the sheriff, to cause 12 men of the same neighbourhood to meet and try the same, and to say the truth upon the issue taken.

VENTER, signifies the belly; but it is also used for the children by a woman of one marriage: there is in law a first and second venter, &c. where a man hath children by several wives; and how they shall take in descents of lands.

VENTILATOR, a machine by which the noxious air of any close place, as an hospital, gaol, ship, chamber, &c. may be discharged and changed for fresh.

The noxious qualities of bad air have been long known; and no one has taken greater pains to set the mischiefs arising from foul air in a just light than Dr Hales; who has also proposed an easy and effectual remedy by the use of his ventilators; his account of which was read to the Royal Society in May 1741. In the November following M. Triewald, military architect to the king of Sweden, informed Dr Mortimer secretary to the Royal Society, that he had in the preceding spring invented a machine for the use of his majesty's men of war, in order to draw out the bad air from under their decks, the least of which exhausted 36,172 cubic feet in an hour, or at the rate of 21,732 tons in 24 hours. In 1742 he sent one of them, formed for a 60 gun ship to France; which was approved of by the Royal Academy of Sciences at Paris; and the king of France ordered all the men of war to be furnished with the like ventilators.

Plate DXLIV. fig. 1.

The ventilators invented by Dr Hales consist of a square box ABCD (fig. 1.) of any size; in the middle of one side of this box a broad partition or midriff is fixed by hinges X, and it moves up and down from A to C, by means of an iron rod ZR, fixed at a proper distance from the other end of the midriff, and passing through a small hole in the cover of the box up to R. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever FG (fig. 2.) Fig. 2. moving on a fixed centre O; so that by the alternate raising and pressing down of the lever FG, the midriffs are also alternately raised and depressed, whereby these double bellows are at the same time both drawing in air, and pouring it out, through apertures with valves made on the same side with, and placed both above and below the hinges of the midriffs. In order to render the midriffs light, they are made of four bars lengthwise, and as many across them breadthwise, the vacant spaces being filled up with thin pannels of fir board; and that they may move to and fro with the greater ease, and without touching the sides of the boxes, there is an iron regulator fixed upright to the middle of the end of the box AC (fig. 1.) from N to L, with a notch cut into the middle of the end of the midriff at Z; so that the midriffs, in rising and falling, suffer no other friction than what is made between the regulator and the notch. Moreover, as the midriff ZX moves with its edges only one-twentieth of an inch from the sides of the box ABCDFE, very little air will escape by the edges; and therefore, there will be no need of leathern sides as in the common bellows. The end of the box at AC is made a little circular, that it may be better adapted between A and C to the rising and falling midriff; and at the other end X of the midriff a slip of leather may be nailed over the joints if needful. The eight large valves through which the air is to pass, are placed at the hinge-end of the boxes BK (fig. 2.) as at 1, 2, 3, &c. The valve 1 opens inward to admit the air to enter, when the midriff is depressed at the other end by means of the lever FG. And at the same time the valve 3 in the lower ventilator is shut by the compressed air which passes out at the valve 4. But when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. And it is the same with the valves 5, 6, &c. of the other box; so that the midriffs are alternately rising and falling, and two of the ventilators drawing in air, and two blowing it out; the air entering at the valves 1, 3, 6, 8, and passing out at the valves 2, 4, 5, 7. Before these last valves there is fixed to the ventilators a box QQNM (fig. 3.) as a common receptacle for all the air which comes out of these valves; Fig. 3. which

which air passes off by the trunk P, through the wall of a building. See Description of Ventilators by Stephen Hales, D. D. Lond, 1743, 8vo.; and for the method of freeing mines, ships, prisons, &c. from noxious air by means of fire-pipes, see PNEUMATICS, N° 371.

VENTRI Inspiciendo, is a writ to search a woman that saith she is with child, and thereby withholdeth lands from the next heir: the trial whereof is by a jury of women.

VENTRICLE, properly denotes any little cavity; but is more particularly used by physicians and anatomists for the stomach and certain cavities of the heart and brain.

VENTRILOQUISM, an art by which certain persons can so modify their voice, as to make it appear to the audience to proceed from any distance, and in any direction. See PHYSIOLOGY *Index*.

VENUS, in Pagan worship, the goddess of love and beauty. Cicero mentions two other deities of this name. Venus, styled *Urania* and *Celestis;* and the *Venus Pandemos* or *Popularis*, the wife of Vulcan, and the goddess of wanton and effeminate love. To the first the Pagans ascribed no attributes but such as were agreeable to the strictest chastity and virtue; and of this deity they admitted no corporeal resemblance, she being only represented by the form of a globe, ending conically. Her sacrifices were termed *nephalia*, on account of their sobriety. To her honey and wine were offered, and no animal except the heifer; and on her altars the wood of figs, vines, or mulberries, was not suffered to be burnt. The Romans dedicated a temple to this goddess, to whom they gave the name of *Verticordia;* because she turned the hearts of lewd women, and inspired them with modesty and virtue.

But the most famous of these goddesses is the wife of Vulcan; who is represented as springing from the froth raised by the genitals of Saturn, when cut off by Jupiter and thrown into the sea. As soon as she was formed, she was laid in a beautiful shell embellished with pearl, and wafted by gentle zephyrs to the isle of Cytherea, whence she sailed to Cyprus. At her landing, flowers rose beneath her feet; she was received by the Hours, who braided her hair with golden fillets; and then wafted her to heaven, where her charms appeared so attractive, that most of the gods desired her in marriage; but Vulcan, by the advice of Jupiter, gained possession by putting poppies into her nectar. As Venus was the goddess of love and pleasure, the poets have been lavish in the description of her beauties; and the painters and statuaries have endeavoured to give her the most lovely form. Sometimes she is represented clothed in purple, glittering with gems, her head crowned with roses, and drawn in an ivory car by swans, doves, or sparrows; at others she stands attended by the Graces; but in all positions, her son Cupid is her inseparable companion. She was honoured as the mother of Hymeneus, Cupid, Æneas, and the Graces, and was passionately fond of Adonis and Anchises.

This goddess was principally worshipped at Paphos and Cyprus; and the sacrifices offered to her were white goats and swine, with libations of wine, milk, and honey. Her victims were crowned with flowers, or wreaths of myrtle.

VENUS, one of the planets. See ASTRONOMY *Index*.

VENUS's Fly-trap. See *DIONÆA Muscipula*, BOTANY *Index*.

VENUS, a genus of shell-fish. See CONCHOLOGY *Index*.

VEPRECULÆ, diminutive from *vepres*, "a briar or bramble;" the name of the 31st order in Linnæus's Fragments of a Natural Method. See BOTANY *Index*.

VERA-CRUZ, a sea-port town of North America, in New Spain. This city is almost the sole channel of communication between Mexico and the mother country. It is beautifully and regularly built, and is situated in an arid plain, destitute of running water, on which the north winds have formed hills of moving sand. Near the town are considerable marshes and stagnant pools, which occasion intermittent fever among the inhabitants. The population of Vera-Cruz in 1803 amounted to 16,000. The port is not very secure; though it is the best on the Mexican coast. The trade of this town is very extensive: the exports consist of gold and silver in ingots, cochineal, sugar, flour, indigo, salted provisions, tanned hides, vanilla, soap, campeachy wood, &c. and amount annually, according to Humboldt, to 4,620,000l. sterling; while the imports, consisting of linens, woollens, cottons, paper, mercury, iron, brandy, wine, &c. amount only to 3,150,000l. W. Long. 96. 15. N. Lat. 19. 12.

VERAGUA, a province of New Spain, bounded on the east by that of Costa Rica, on the west by Panama, on the north by Darien and the gulf of Mexico, and on the south by the South sea. It is about 125 miles in length from east to west, and 60 in breadth from north to south. It is a mountainous barren country; but has plenty of gold and silver. Conception is the capital town.

VERATRUM, a genus of plants belonging to the class polygamia, and in the natural system arranged under the 10th order, *Coronariæ*. See BOTANY and MATERIA MEDICA *Index*.

VERB, in *Grammar*. See GRAMMAR, chap. iv.

VERBASCUM, a genus of plants of the class pentandria, and in the natural system arranged under the 28th order, *Luridæ*. See BOTANY *Index*.

VERBENA, a genus of plants of the class of diandria, and in the natural system arranged under the 40th order, *Personatæ*. See BOTANY *Index*.

VERD, CAPE, a promontory on the west coast of Africa, 40 miles north-west of the mouth of the river Gambia. W. Long. 17. 38. N. Lat. 14. 45.

The islands of Cape de Verd are seated in the Atlantic ocean, about 400 miles west of the Cape. They are between the 13th and 19th degree of latitude; and the principal are 10 in number, lying in a semicircle. Their names are, *St Antony*, *St Vincent*, *St Lucia*, *St Nicholas*, the *isle of Sal*, *Bona Vista*, *Mayo*, *St Jago*, *Fuego*, and *Brava*.

VERDICT, (*Vere dictum*), is the answer of the jury given to the court concerning the matter of fact, in any case civil or criminal, committed by the court to their trial and examination. See LAW, N° clxxxvi. 51. and TRIAL.

VERDIGRISE, the acetate of copper, much used by painters as a green colour. See COPPER, CHEMISTRY *Index*.

VERDITER, or VERDATER, a preparation of copper, sometimes used by painters, &c. for a blue; but

but more usually mixed with a yellow for a green colour. See COPPER, CHEMISTRY *Index*, and *COLOUR-Making*, N° 28.

VERGE (*Virgata*), in *Law*, signifies the compass of the king's court, which bounds the jurisdiction of the lord steward of the household; and which is thought to have been 12 miles round.

The term *verge* is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by holding it in his hand, and swearing fealty to the lord of the manor.

VERGERS, certain officers of the courts of king's bench and common pleas, whose business it is to carry white wands before the judges. There are also vergers of cathedrals, who carry a rod tipped with silver before the bishop, dean, &c.

VERGIL, POLYDORE. See VIRGIL.

VERJUICE, a liquor obtained from grapes or apples, unfit for wine or cyder; and chiefly used in sauces, ragouts, &c.

VERMES, the sixth class of animals in the Linnæan system, comprehending five orders. See NATURAL HISTORY, and CONCHOLOGY and HELMINTHOLOGY *Index*.

VERMICELLI, or VERMICHELLY, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes. It was first brought from Italy; and is chiefly used in soups and pottages.

VERMICULAR, an epithet given to any thing that bears a relation or resemblance to worms.

VERMIFORMIS, in *Anatomy*, a term applied to various parts in the human body, bearing some resemblance to worms.

VERMILION, a bright and beautiful red colour, composed of quicksilver and sulphur, in great esteem among the ancients under the name of *minium*. See CHEMISTRY, N° 1701, and 1713; but what goes by the name of minium amongst us, is a preparation of lead, known also by the name of *red-lead*. See CHEMISTRY, N° 1832.

VERMIN is a general term, denoting those animals which are either directly or indirectly injurious to mankind, the inferior animals, or the fruits of the earth; as fleas, caterpillars, flies, worms, &c.

VERMIN, *Destruction of*. As we propose in this article to point out the means of destroying some of those animals that are hurtful or troublesome to man, we shall employ the term vermin, in a more extended sense, including also under it, mice, rats, moles, &c. We shall endeavour to collect the most useful observations that have been made on the means of diminishing or extirpating such animals as are obviously injurious. We cannot avoid here remarking, that although the seemingly excessive increase of one species of animals is hurtful or inconvenient to another, or to man himself, and their existence is attended with great loss and damage, by their infesting and destroying grains and other fruits of the earth destined for the food of man or those animals that are subservient to him; we are not of opinion that this excess ought to be considered merely as a useless excrescence in the great scale of being; nor are we of opinion that their numbers ought not to be reduced, because we are too short-sighted to comprehend the wise purposes for which they are called into life. We have heard such a doctrine held up, although we are inclined to suspect that it is founded on a love of singularity, or indolence, rather than proceeding from pure motives of benevolence. But we must abstain from such discussions, and occupy the limits allotted to the proper subject of consideration.

Rats and Mice.—Various methods have been proposed for the destruction of these vermin. The following preparation has been recommended as very effectual. Take of the seeds of stavesacre (*delphinium staphisagria*), or of lousewort (*pedicularis palustris*), powdered, more or less as the occasion requires, one part; of oat meal, three parts: mix them well, and make them up into a paste with honey. Lay pieces of this paste in the holes, and on the places where mice and rats frequent; and it will effectually kill or rid the places of those kind of vermin by their eating of it.

Some time ago the society for encouraging arts proposed a premium of 50l. for a preparation capable of alluring or fascinating rats so that they might be taken alive. In consequence of this, a great number of new traps, &c. were invented, and the following methods of alluring the rats to a certain place were published. One of the methods which is most easily and efficaciously practised, is the trailing of some pieces of their most favourite food, which should be of the kind which has the strongest scent, such as toasted cheese or boiled red herrings, from the holes or entrances of the closet to their recesses in every part of the house or contiguous building. At the extremities, and at different parts of the course of this trailed track, small quantities of meal, or any other kind of their food, should be laid to bring the greater number into the tracks, and to encourage them to pursue it to the place where they are intended to be taken; at that place, when time admits of it, a more plentiful repast is laid for them, and the trailing repeated for two or three nights.

Besides this trailing and way-baiting, some of the most expert of the rat-catchers have a shorter, and perhaps more effectual method of bringing them together; which is the calling them, by making such a whistling noise as resembles their own call; and by this means, with the assistance of the way-baits, they call them out of their holes, and lead them to the repast previously prepared for them at the places designed for taking them. But this is much more difficult to be practised than the art of trailing; for the learning of the exact notes or cries of any kind of beasts or birds, so as to deceive them, is a peculiar talent which is attained only by few.

In practising either of these methods of trailing or calling, great caution must be used by the operator to suppress and prevent the scent of his feet and body from being perceived; which is done by overpowering that scent, by other scents of a stronger nature. In order to do this, the feet are to be covered with cloths rubbed over with asafœtida, or other strong smelling substances; and even oil of rhodium is sometimes used for this purpose, but sparingly, on account of its high price, though it has a very alluring as well as disgusting effect. If this caution of avoiding the scent of the operators feet, near the track, and in the place where the rats are proposed to be collected, be not properly observed, it will very much obstruct the success of the attempt

Vermin. tempt to take them; for they are very shy of coming where the scent of human feet lies very fresh, as it intimates to their sagacious instinct the presence of human creatures, whom they naturally dread. To the abovementioned means of alluring by trailing, way-baiting and calling, is added another of very material efficacy, which is the use of oil of rhodium, which, like the *marum syriacum* and *valerian* in the case of cats, has a very extraordinary fascinating power on these animals. This oil, as it is extremely dear, is therefore sparingly used. It is exalted in a small quantity in the place, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be last brought together, in order to their destruction: and it is used also by smearing it on the surface of some of the implements used in taking by the method below described; and the effect it has in taking off their caution and dread, by the delight they appear to have in it, is very extraordinary.

It is usual, likewise, for the operator to disguise his figure as well as scent, which is done by putting a sort of gown or cloak, of one colour, that hides the natural form, and makes him appear like a post, or some such inanimate thing, which habit must likewise be scented as above, to overpower the smell of his person; and besides this, he is to avoid all motion till he has secured his point of having all the rats in his power.

When the rats are thus enticed and collected, where time is afforded, and the whole in any house and outbuildings are to be cleared away, they are suffered to regale on what they most like, which is ready prepared for them, and then to go away quietly for two or three nights; by which means those that are not allured the first night, are brought afterwards, either by their fellows, or the effects of the trailing, &c. and will not fail to come duly again, if they are not disturbed or molested. But many of the rat-catchers make shorter work, and content themselves with what can be brought together in one night; but this is never effectual, unless where the building is small and entire, and the rats but few in number.

The means of taking them when brought together are various. Some entice them into a very large bag, the mouth of which is sufficiently capacious to cover nearly the whole floor of the place where they are collected; which is done by smearing some vessel, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of food. This bag, which before lay flat on the ground with the mouth spread open, is to be suddenly closed when the rats are all in. Others drive or frighten them, by slight noises or motions into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being secured. Others, again, intoxicate or poison them, by mixing with the repast prepared for them, the *coculus indicus*, or the *nux vomica*. They direct four ounces of *coculus indicus*, with 12 ounces of oat-meal, and two ounces of treacle or honey, made into a moist paste with strong beer; but if the *nux vomica* be used, a much less proportion will serve than is here given of the *coculus*. Any similar composition of these drugs, with that kind of food the rats are most fond of, and which has a strong flavour to bide that of the drugs, will equally answer the end. If indeed *coculus indicus* be well powdered, and infused in strong beer for some time, at least half the quantity here directed will serve as well as the quantity before mentioned. When the rats appear to be thoroughly intoxicated with the coculus, or sick with the nux vomica, they may be taken with the hand and put into a bag or cage, the door of the place being first shut, lest those who have strength and sense remaining should escape.

In destroying rats, advantage may be taken of that remarkable degree of instinct which they possess of deserting one place, where they find themselves disturbed or harassed, and retiring to new haunts. It is well known, that after one or two rats are poisoned, or taken in traps, or wounded or otherwise injured, and afterwards permitted to escape, the whole colony immediately disappears. The practice, however, of destroying rats that frequent dwelling-houses, by poison, should be as much as possible avoided; for they retire to places behind the wainscot, &c. from which, after death, their putrid bodies emitting a most offensive smell cannot be removed. But it is far less difficult than is generally imagined to secure the different apartments of a dwelling house, and even the cellars, from the inroads of rats and mice, and thus to prevent their unwelcome visits, by shutting up the passages through which they enter. Stone and lime, when they can be applied, are effectual; but common plaster, by introducing pieces of broken pottery ware or glass, along with it, will also answer the purpose; and even a piece of cork, with a pin or two stuck through it to prevent them from eating it away, is a complete barrier to mice entering through a hole in wood, and may even prevent the entrance of rats.

We have seen this method of shutting up the holes, as soon as they were opened by the industry of the enemy, steadily pursued for some time, attended with the fullest success, even in an old house of considerable extent, and finished from top to bottom with wood, some of which was much decayed.

Often for the sake of food, rats and mice frequent gardens, fields, and woods, in the summer season; but, on the approach of winter, they return to their former haunts in the habitations of man; and, accordingly, it is observed, that houses which are free from those vermin during the summer, swarm with them about the end of harvest. Attention to this circumstance in the habits of these animals, may be the means of securing us from their visits and depredations: for if, at the time alluded to, every hole and cranny through which rat or mouse can enter, be shut up, and carefully kept close and secure, the perseverance of the foe is exhausted and overcome by repeated and constant resistance, and thus he is forced to abandon the unequal contest, and to retire to other haunts where his motions are less interrupted.

Various other methods have been proposed for the destruction of rats; and although we have thrown out a hint against the use of arsenic for this purpose, in dwelling-houses; yet where it can be employed with perfect safety, and without risk of the nuisance alluded to, as in cellars and outhouses, it is undoubtedly one of the most effectual to which we can have recourse.

Suffocating these vermin by means of the fumes of sulphur, as on board of ships, in granaries, and other buildings, which can be shut up, is sometimes also successfully.

Vermin. cessfully practised. Rats and other vermin have also been effectually destroyed and eradicated by burning wood in close apartments, thus producing fixed air or carbonic acid gas, by which they are also suffocated.

Moles.—Various methods have been proposed for the destruction of these animals. But the following observations on this subject, which we shall give in the words of the author, seem to be more satisfactory than any thing we have met with.

"The great damage (says he) which moles occasion in cultivated land, and particularly gardens, is well known; and the best means of remedying this evil is by destroying all those that make their appearance, as far as possible. The secrets which quacks sell for extirpating these destructive animals are of very little avail; and even poison produces no effect, as the mole does not drink, and lives only on roots and worms. In regard to gins and traps, the moles must be enticed to them by some kind of bait, which does not always produce the intended effect. Buffon advises a trench to be dug around the hills under which they conceal themselves, and thus to cut them off from all communication with the neighbouring ground. This method requires three or four people to dig trenches; and though it may prove effectual, it is attended with too much trouble. The other methods proposed by different naturalists are neither easier nor more certain.

"It is well known that this animal lives under the earth; and if at any time it comes forth from its holes, it is only when compelled to do so, in consequence of large quantities of water accumulated after the heavy rains which fall in summer, or when the earth is so much parched and dried by the continued drought, that it can no longer continue its labour: but it again creeps back into the earth when it finds a spot convenient for its purpose.

"This animal, as already remarked, feeds upon roots and worms, and for this reason is generally found in rich fertile soil; but never in that which is marshy or stony. In the winter time it retires to elevated places, because it is there best secured from inundations. In summer, however, it descends to the low hillocks and flat land, and above all makes choice of meadows for the place of its residence, because it finds the earth there fresher and softer for it to dig through. If the weather continues long dry, it repairs to the borders of ditches, the banks of rivers and streams, and to places contiguous to hedges.

"The mole breeds generally at the beginning of winter, and the months when they are found big with young are January and February. In the month of April a great many of their young may be seen. Among 122 caught in the month of May by my method, there were only four big with young. This animal cannot live without digging; it is obliged to find its nourishment in the bowels of the earth; and on that account is under the necessity of making those long subterranean passages which are found between one mole-hill and another. In general it begins to dig five or six inches under the surface; it scrapes the earth before it on one side till the quantity becomes too great for it to labour with ease; it then works towards the surface; and by pushing with its head, and the assistance of its nervous paws, gradually raises up the earth which incommodes it, and which produces those small hills so common in fields. After getting rid of the earth in this manner, it proceeds forwards, and continues its labour as before. The farther it goes the more hills are produced. At each period of its labour it throws up four or five.

"In places overgrown with grass and shrubs, the mole is often contented with only forcing a passage through between the roots: and when the earth in gardens has been newly watered, it keeps itself at the depth of scarcely half an inch under the surface. This animal shews an equal aversion to great cold and violent heat; and in order to avoid both, it forces its way, when either prevail, to the greatest depth in the earth.

"It continues its labour at all times, because it is necessary for it to procure nourishment. It is absolutely false that it sleeps throughout the winter, as some naturalists have asserted; for it throws up the earth in the coldest season, as well as during the summer. It is most busily employed towards the end of winter, and at that period forms the greatest number of hills. To this it is impelled by more than one reason. In the first place, it must provide nourishment for its young; secondly, it finds it easiest at that time to dig its way through the earth; and lastly, as the air begins to be milder, the animal then recovers that strength which it had lost during the intense cold. At this season, therefore, it is most proper to pursue means for extirpating this animal, as it can be destroyed with greater ease while employed at its labour.

"The male is much stronger than the female, and the hills thrown up by the former are much larger as well as more numerous. The periods when the mole is most busily employed in digging are in the morning, at sunrise, at noon, and at sunset. In dry weather moles are observed to throw up the earth for the most part only at sunrise, and in winter when the earth has been somewhat heated by the sun's rays.

"A person may easily discover how many moles are contained in a certain space of ground, by counting the fresh raised mole-hills which have no communication with each other. I must remark also, that this animal has very bad sight, being almost totally blind; but its hearing, on the other hand, is so much the more acute.

"I shall now proceed to the method of destroying them. Immediately at day-break it will be necessary to make a tour round the garden or meadow, from which it is wished to extirpate the moles; for at that time they will be all found at work, as may be seen by the hills newly thrown up. If the person is then close to the hill, he must proceed as the gardeners do, and turn up with a stroke of the spade the hill together with the digger. The passage is then cut through before the animal is aware of the attack, and therefore it has not power to escape. If the mole-hill be fresh, even though the animal may not be throwing up earth, the person ought not to lose his time in waiting, but should immediately proceed to the operation above mentioned.

"If you find a fresh hill standing by itself, which seems to shew by its situation that it has no communication with any other, which is always the case when the mole has worked from the surface downwards in endeavouring to procure a more convenient habitation, after the hill has been turned up with the spade, a bucket of water should be poured over the mouth of the passage. By these means the animal, which is at no great distance, will be obliged to come forth, and may be easily caught with the hand.

"You

"You may discover also whether a hill has any communication with another, if you apply your ear to it, and then cough or make a loud noise. If it has no communication with the neighbouring hills, you will hear the terrified animal make a noise by its motion. It will then be impossible for it to escape; and you may either pour water into the hole, or turn up the hill with a spade until the mole is found; for in general it never goes deeper into the earth than from fifteen to eighteen inches.

"When any of the beds in a garden have been newly watered, the mole, attracted by the coolness and moisture, readily repairs thither, and takes up its residence in them, making a passage at the depth of scarcely an inch below the surface. In that case it may be easily caught. When you see it at work, you need only tread behind the animal with your feet on the passage to prevent its retreat, and then turn up the hill with a spade; by which means you will be sure to catch it.

"When you dig after it with a spade, the animal forces its way downwards into the earth in a perpendicular direction, in order that it may better escape the threatened danger. In that case it will not be necessary to dig long, but to pour water over the place, which will soon make the animal return upwards.

"People in general are not aware of the great mischief occasioned in fields and gardens by these animals. We are, however, informed by Buffon, that in the year 1740 he planted 15 or 16 acres of land with acorns, and that the greater part of them were in a little time carried away by the moles to their subterranean retreats. In many of these there were found half a bushel, and in others a bushel. Buffon, after this circumstance, caused a great number of iron traps to be constructed, by which in less than three weeks he caught 1300. To this instance of the devastation occasioned by these animals, we may add the following: In the year 1742 they were so numerous in some parts of Holland, that one farmer alone caught between five and six thousand of them. The destruction occasioned by these animals is, however, no new phenomenon. We are informed by history, that the inhabitants of the island of Tenedos, the Trojans, and the Æolians, were infested by them in the earliest ages. For this reason a temple was erected to Apollo Smynthius, the destroyer of moles.

Insects.—Many insects, in the different states of existence through which they pass, are exceedingly troublesome and destructive. Sometimes they spread their devastations in the state of *larva* or *grub*, and sometimes in that of perfect insect.

Of the coleopterous insects, the grub of the cockchaffer, which is a brownish or chesnut-colured beetle, commits the greatest ravages. This beetle appears during great part of the summer, the most plentiful in May or June, and hence called the *May bug*. It flies only in the evening, and lodges during the day under the leaves of trees, which it devours, and is sometimes in such numbers, as to defoliate whole woods. The beetle deposits its eggs in the earth, and from these are hatched white or bluish grubs, that feed on the roots of grass, corn, and other vegetables, during the whole summer. In the winter they lie deep in the earth; but in the spring, as vegetation advances, they rise to the surface, and renew their work of destruction. In this state they continue for four, five, or six years, before they change to the chrysalis state, in which they remain till the month of May, when the perfect insect appears. As these insects require so many years to assume the perfect form, they only appear occasionally sufficiently numerous to be extensively destructive to the crops of grain, or vegetables in general. Their numbers, however, have often produced great alarm, and even excited the attention of governments to offer rewards for an effectual method of destroying them.

In the spring season, if the weather prove warm, when the land is ploughed up, these grubs are generally so near the surface as to be turned up with the plough; and being thus exposed, they are picked up and devoured by various birds, which, it is suggested, should not be disturbed or driven away in this salutary labour. When these grubs infest meadow land, it has been proposed to drown them in their holes by overflowing it. But it is supposed that this plan would not be successful, even where it is practicable, unless there is a bed of clay immediately under the soil, to retain the water for a sufficient length of time. A more efficacious way is recommended to prevent the increase of the grubs, by destroying the flies in May or June, before they have deposited their eggs. This may be done by shaking and beating the trees and hedges in the middle of the day; and, as this is a work which may be performed by children, it is a less difficult task than would at first sight be imagined. Domestic fowls are remarkably fond of these beetles, so that a double object is thus gained, the destruction of the beetles and the procuring of food for the poultry.

Some species of the dermestes, and also of the genus *ptinus*, are exceedingly destructive in the cabinets of naturalists, and also to furniture. Various methods have been recommended to stop their ravages. We believe the most effectual is spirit of turpentine, when it can be properly applied. A solution of corrosive sublimate is sometimes employed, but it should be recollected that it seldom fails in time to produce some chemical change on animal and vegetable matters. Objects of natural history, as birds, animals, &c. are sometimes exposed to the moderate heat of an oven, or before a fire, for several hours; but this method will also be attended with injurious effects, unless practised with great care. Insects which infest furniture have been destroyed by the application of oil, and allowing it to remain for a day or two, before the furniture is rubbed up. Japanned or varnished furniture may be secured from the effects of these insects, by re-coating it, when they are in the larva state, by which they are deprived of air. Railing, and other works out of doors, which are exposed to the weather, are sometimes eaten with insects, and particularly by some of the larvæ of the genus *curculio*. The wood thus attacked may be prevented from farther ravages, by a fresh coat of paint.

The earwig is a destructive insect in the flower, kitchen, and fruit garden. To prevent their depredations, it has been recommended to take them by the hand, when they come out during the night in search of food. They may be taken also by rolling up a piece of paper, and hanging it up on the plants which they infest; for in these places they take shelter through the day. Another method of destroying them has been mentioned, and that is to watch them towards morning with the view of discovering the haunts to which

they

Vermin.

they resort during the day; and this discovery being made, which may perhaps be a melon frame, dunghill, or heap of rubbish, the removing of which will destroy the greater number of those troublesome insects.

The small insect which commits such depredations among turnips, by eating the seedling leaves as soon as they appear, as frequently to destroy whole crops, is supposed to be a small black polished beetle, belonging to the genus *chrysomela*. It does not seem to be well ascertained whether this small beetle, which is better known by the name of turnip fly, commits its ravages in the larva or in the beetle state. It is said that it prefers the leaves of the common radish to those of the turnip, and it is therefore recommended to sow radishes along with the turnips to prevent the destruction of the latter.

Of the insects belonging to the order hemiptera, there are some which are exceedingly destructive. The cock-roach, a native of the warmer parts of America and the West Indies, is a very troublesome, and a very voracious insect. It has been introduced into this country, and particularly into the seaport towns, in consequence of commercial intercourse. It comes out to feed in the night-time, and eats of almost every thing that comes in its way. Cock-roaches are easily taken by the following method. Cover the outside of a deep glass or bason with paper; introduce some bits of bread or sugar into the bason or glass, and set it in a place frequented by the cock-roaches. They creep up by means of the paper on the outside, and drop into the vessel; but in consequence of its smooth polished surface, they cannot effect their escape. In the same way crickets and beetles may be taken and destroyed. It is quite unnecessary to speak of the means of destroying the myriads of locusts which not unfrequently infest eastern countries, and particularly Egypt and Syria; for no means are likely to be devised, which promise to resist the effects of such an host of foes, by whose ravages every green thing is consumed; but the insect itself becomes, among the poorer inhabitants of those countries, a partial substitute for the fruits of the earth which it has destroyed. The insects are taken, reduced to powder, and converted into a kind of meal.

The common or the bed-bug is a very troublesome, and a very common inmate in the crowded houses of many large towns in this country. Its usual haunts are the crevices of wood, and particularly those pieces of furniture which are usually kept in the warmest corners of the apartment. Cleanliness will perhaps be found the best preservative against the introduction and increase of these insects; but sometimes even the greatest care and attention are ineffectual in keeping houses entirely free from them. When it can be conveniently done, they are completely destroyed by immersing the furniture in boiling water, or by baking it in an oven; and by filling up the crevices or holes which were their haunts, with glaziers putty, their return and increase will thus be prevented. But a very effectual method of destroying bugs, is to wash the places which they frequent with spirit of turpentine, and then filling up the holes as already mentioned. It is a curious circumstance in the history of these insects, that some persons entirely escape from their attacks, while to others they are exceedingly troublesome and distressing. It is said that lavender-water, sprinkled over the bed-clothes, often prevents their approach. How far this is the case, we have had no opportunity of ascertaining.

Vermin.

The small moth, which in the caterpillar state commits such ravages on woollen cloths, furs, and other animal substances, which remain for any length of time in dark undisturbed places, may be destroyed with the greatest certainty and facility, by exposing the substances on which they are suspected to make their depredations, to the vapour of spirit of turpentine, or brushing them with a brush dipped into the same fluid. This should be done about the months of September or October; but their effects may be prevented by placing the cloths, furs, &c. which are likely to become their residence, in an airy situation, about the months of July and August.

The different kinds of lice are very numerous. Every animal has its peculiar species, and even mankind are not free from this pest. It is often the consequence of indolence and nastiness, and it is observed that the lice which infest any animal increase prodigiously when that animal becomes languid and sickly. We believe that the application of spirits of turpentine, already so often recommended, would also be effectual in this case; but mercurial preparations afford a certain remedy against these insects. For this purpose a very small quantity of what is called mercurial ointment may be employed. At the same time it ought to be recollected, that cleanliness is the best preservative. A singular notion prevails in this country, and even among persons who are by no means in the lowest rank of life, that it is a good sign of health when children's heads are infested with these animals; and on this account they are not very anxious in having them entirely eradicated. A moment's reflection may show the absurdity of such an opinion, so that it would be a waste of time to adduce serious arguments against it.

It is perhaps more difficult for mankind to secure themselves and their habitations from the visits of the common flea. Cleanliness, however, may do much even in effecting this; and in particular it appears to us, that it would be extremely useful, frequently to rub up with a piece of cloth the more inaccessible parts of furniture or apartments, or perhaps it would answer better to employ a small hard brush. By the less accessible places we mean the corners and crevices of rooms and furniture where dust is apt to collect, and especially the canvas part of a bed. We are persuaded that spirits of turpentine might also be found useful for the destruction of these very troublesome insects. The Scotch myrtle (*myrica gale*, Lin.) a plant very common in low and moist moorish places in this country, is said to be an excellent remedy, in consequence of its powerful aromatic odour, against the attacks of these animals. For this purpose, the plant is strewed about the apartment or bed which is infested with fleas.

The following method of destroying or driving away all kinds of noxious vermin from fields and gardens, it is said, has been proved by experience to be effectual. It is recommended by M. Socoloff, and the account of it is taken from the Petersburgh Transactions *. "As the destructive power of quicklime (says the author), heightened by a fixed alkali, which corrodes, dissolves and destroys all the tender parts of animals, has been long known, I thought this mixture would be the best means for accomplishing the object I had in view. I took three

* Phil. Mag. i. 169.

Vermin. three parts, therefore, of quicklime, newly made, and two parts of a saturated solution of fixed alkali in water, and thence obtained a somewhat milky liquor sufficiently caustic, highly hostile and poisonous to earthworms and other small animals; for as soon as it touched any part of their bodies, it occasioned in them violent symptoms of great uneasiness. If this liquor be poured into those holes in which the earthworms reside under ground, they immediately throw themselves out as if driven by some force; and, after various contortions, either languish or die. If the leaves of plants or fruit-trees, frequented by the voracious caterpillars, which are so destructive to them, be sprinkled over with this liquor, these insects suddenly contract their bodies and drop to the ground. For, though nature has defended them tolerably well by their hairy skins from any thing that might injure their delicate bodies, yet, as soon as they touch with their feet or mouths leaves which have been moistened by this liquor, they become as it were stupefied, instantly contract themselves, and fall down.

"I had not an opportunity of trying a like experiment on locusts; yet we may conclude, and not without probability, from their nature, and the general destructive qualities of the above liquor, that they, in like manner, may be driven from corn-fields, if it be possible to sprinkle the corn with the liquor by means of a machine.

"With regard to plants or corn, these sustain no injury from the liquor, because it has no power over the productions of the vegetable kingdom, as I have fully learned from experience; or, if any hurt be suspected, all the danger will be removed by the first shower that falls. This liquor may be procured in abundance in every place where lime is burnt. If the lime be fresh, one part of it infused in about seventy parts of common water will produce real lime-water. The want of the fixed alkali may be supplied by boiling wood-ashes in water, and thickening the ley by evaporation.

"The liquor might be employed also to kill bugs and other domestic insects which are noxious and troublesome; but on account of its strong lixivious smell, which disposes the human body to putridity, I dare not recommend the use of it in houses that are inhabited. Besides, bugs may be easily got rid of, as I have repeatedly found from experience, by the oily pickle that remains in casks in which salted herrings have been packed. To this liquor they have a strong aversion; and, if they are moistened with it, they die in a very short time *."

* Phil. Mag. i. 169.

For destroying insects and caterpillars, which infest fruit-trees, the following method is recommended as having been successfully practised. The author observes that "The present year, for instance, (1805), offers a singularity which I have not before perceived. In some districts the cherry tree has experienced, at the time of its blossoming, colds and winds which have prevented it from setting; but another plague, not less disastrous has attacked the cherry-trees and plum-trees over several districts in France. Great swarms of little animals resembling *vine-fretters*, but which are not so in reality, established their habitations at the extremity of the branches of the cherry-trees. As soon as a branch was attacked, the leaves curled, and the juice was dried up. On opening the leaf, a considerable number of ants was discovered, which, jointly with the insect which began the ravages, sucked the branch, and made it wither. What I have remarked is, that usually, when the vine-fretters attack any tree, the neighbouring tree very soon experiences the same fate; but the attack of this year is only partial. In an alley of cherry-trees which I possess, seven trees have been attacked, but not those which are next each other. One tree was placed between two which were very much damaged by these insects, and yet this one was not hurt.

"On these vermin the smoke of tobacco had no effect at all; this convinces me that they are different from the ordinary kind.

"Plum-trees, when attacked by the same insect, do not lose their fruit like the cherry-trees; but the little animals cover them with more rapidity, so as to extirpate even the appearance of fruit.

"Having effectually watered a plum-tree, I covered it with ashes, in the manner we treat beans and cabbages, and the vermin were destroyed: but this is only practicable with a tree of low height.

"I made one remark, which I think is essential to communicate: it is, that plum-trees planted in ground which is not necessarily watered, are less attacked by these insects than those which have experienced a humidity communicated by the plants in their neighbourhood, to which watering is absolutely necessary. I had one planted in a bed of artichokes: we know very well that this plant requires plenty of water; and the tree was entirely covered with insects. Its leaves withered, and the fruit fell off; while two other plum-trees, in ground not watered at all, were much less attacked. This convinces me that these were not the ordinary vermin abundant in dry seasons.

"I was only able to protect my cherries a little, by cutting off the extremities of the damaged branches.

"Several people had recourse to sulphur; but I did not follow that method. The smoke of sulphur destroys the insect, I admit, but it is at least equally dangerous to the tree; I always prefer an aspersion of the tree with soap-suds. This very year I experienced the good effects of it. I saw my plum-trees look green again, and the insects abandon them. The aspersion is very easily managed, by means of watering-pots or small garden-engines. I have also employed a ley of wood-ashes with the same success as soap and water.

"An observation equally important which I have made is, the great damage done this season in all orchards by the caterpillar. As soon as they devoured the young leaves, they attacked the fruit. In spite of the great care taken in spring to get rid of them, the number of these insects is incredible. I have seen them unite on the large branches, fix their nests to them, and protect them by means of the downy matter which covers the buds of the ensuing season. Whatever precaution is taken, it is almost impossible not to destroy these buds. It is only necessary to take off these nests and burn them; and this is the only way of getting rid of the coveys. I employed the same aspersion for my apple-trees, and by that means got rid of their enemies also *.

* Phil. Mag. xxiv. 213.

"The following methods are practised in Germany for freeing granaries from mites or weevils:

"1. Cover completely the walls and rafters, above and below, of the granaries which are infested by weevils, with quicklime slaked in water in which trefoil, Vermin.

wormwood, and hyssop have been boiled. This composition ought to be applied as hot as possible.

The following method, discovered by M. Catin, is proposed for destroying earth-fleas, bugs, ants, &c.

"Take black soap, of the best kind, one pound three quarters, the same quantity of flowers of sulphur, mushrooms two pounds, and sixty measures of river or rain-water. Divide the water into two parts, one of which must be poured into a vessel destined for that purpose: suffer the soap to dissolve in it, and add the mushrooms after they have been a little pounded. Boil the other half of the water in a kettle, and tie up the sulphur in a bit of rag or piece of fine linen, and suspend from it a sufficient weight in order that it may sink in the water. During the time the water is kept boiling, which must be at least 20 minutes, stir it continually with a stick, and press the bag containing the sulphur, that the latter may be forced out into the water, and communicate to it the necessary strength and colour.

"When the liquor is taken from the fire, pour it directly into the cask, and stir it round for a considerable time: the process of stirring must be repeated daily till it acquire a fetid smell. Experience has shown that the more fetid the mixture is, its activity is the greater. Each time that the mixture is stirred, the cask must be stopped immediately after. When you wish to use the liquid, nothing is necessary but to sprinkle a little of it on the plants which you are desirous of preserving, or to dip their branches in it. It will be better, however, to make use of a syringe, having at the end a head, an inch or an inch and a half in diameter, pierced with small holes. This instrument may be used for tender plants; when you apply the liquid to trees, a syringe with larger holes must be employed.

"Caterpillars, beetles, earth-fleas, bugs, and the tree-lice which infest orange trees, will be destroyed by the first application of the liquid. Insects which reside below the earth, such as wasps, hornets, ants, &c. require that the liquid should be squirted out gently, and without intermission, that it may better penetrate to their nests. Ants nests, according to their size, require from two to three measures of liquid, and in many cases it must be applied for twenty-four hours. When the ants assemble in another place, the process must be repeated. Two ounces of *nux vomica* may be added to the mixture, and boiled along with the sulphur."

The use of elder as a preservative to vegetables against the depredations of insects is detailed in the following observations.

"Common elder has appeared to me useful, 1st, For preventing cabbage plants from being devoured or damaged by caterpillars; 2d, To prevent blights, and their effects on fruit and other trees; 3d, To preserve corn from yellow flies and other insects; 4th, To secure turnips from the ravage of flies, &c.

"1st, The strong and fetid odour of a bunch of elder leaves induced me to think that different kinds of butterflies might be incommoded by it in proportion to their delicacy. I therefore took some young twigs of elder, at the period when butterflies began to appear, and whipped well with them some cabbage plants, but in such a manner as not to damage them. Since that time, during two summers, though the butterflies hovered round the plants, I never saw one of them settle on them; and I do not think that a single butterfly was hatched on the cabbages treated in this manner, though a neighbouring board was dirtied by them in the usual manner.

"2d, After a short reflection on the effects here mentioned, and on blights, which, in my opinion, are chiefly occasioned by small flies and small insects, whose organs are still more delicate than those of the former, I was induced to whip in the same manner with elder twigs, as high as I could reach, the branches of a plum-tree which grew in an espalier. The whipped leaves remained green and in a good condition, while from at least six inches above to the top of the tree the rest of the leaves were blighted, wrinkled, and full of worms. It is here to be observed that the tree was in full flower when I whipped it, therefore much too late for this operation, which ought to have been performed once or twice before flowering. But I am of opinion, that if trees were besprinkled with a strong infusion of elder every eight or 15 days, the success would be certain, and that there would be no danger of injuring either the flowers or the fruit.

3d, What the farmers call the yellows in corn, and which they consider as a kind of blight, is the effect, as every one knows, of a small yellow fly with blue wings, nearly of the size of a gnat. It lays its eggs in the ear of wheat, and produces a worm almost invisible to the naked eye, but which, when seen by a magnifying glass, is a large yellow larva, having the shining colour of amber. This fly is so productive, that I have counted upwards of forty worms in the chaff of one ear of wheat, which was a number sufficient to destroy it entirely. I therefore proposed to make my experiment as soon as possible; but the heat and drought of the season having advanced the wheat more than usual, it was in flower before I could attempt it. Next morning, however, at break of day, two servants having drawn bundles of elder over the ears of wheat on each side of the furrow, backwards and forwards, in places where the wheat was not so far advanced, I hoped that the fetid effluvia of the elder would prevent the flies from remaining on the ears that were covered with them: and, indeed, I was not entirely disappointed; for, on examining my wheat some time after, I found that the part which had been beaten with elder was much less damaged than that which had not been treated in the same manner. I have no doubt, that, had I employed this precaution sooner, the corn would have been completely preserved. Should this be the case, the process is simple; and I flatter myself that fine crops of corn may be saved by these means from this small insect, which is so destructive to them. One of these yellow flies laid on my thumb at least eight or ten eggs, of an oblong form, in the small interval of time which I employed in walking over two or three furrows, holding it by the wings, and which I could not observe without the assistance of a magnifying glass.

"4th, It often happens that whole crops of turnips are destroyed while young, in consequence of being pricked by certain insects. I have great reason to think that this evil may be prevented in an effectual manner, by causing a person to draw a bunch of elder, sufficiently large to cover about the breadth of a foot, over the young turnips, going backwards and forwards. What confirms me in this idea is, that, having drawn a bunch of elder over a bed of young cauliflowers which had begun to be pricked, they afterwards remained untouched by these insects.

"Another

"Another fact which tends to support this idea is that when my neighbourhood, about eight or nine years ago, was so infested with caterpillars that they devoured all the vegetables, leaving scarcely a green leaf untouched, they spared the elder trees amidst this general devastation, and never molested them. In reflecting on these circumstances, I am of opinion that the elder might be introduced with advantage in our gardens, as the means of preserving fruit-trees and various plants from the rapacity of insects.

"The dwarf elder appears to me to exhale a much more fetid smell than the common elder, and therefore ought to be preferred in making experiments on this subject *."

* *Phil. Mag.* xv. 63.

VERMONT, one of the states of the North American republic. It is entirely an inland state, and has New Hampshire on the east, Massachusetts on the south, New York on the west, and Canada on the north. Its area is 10,237 square miles; and the inhabitants in 1810 amounted to 217,895. The country is traversed by the Green mountains, from which the state takes its name; but though hilly and uneven, it is generally fertile. The whole surface in its natural state is thickly wooded. The snow lies from the middle of December to the middle of March. The extreme summer heat is about 94° F.; the extreme winter cold 27° below zero; the mean heat $43\frac{1}{7}$. Lake Champlain forms the western boundary of this state for three fourths of its length, and Connecticut river the eastern boundary through its whole extent. There are several small streams besides these, but no other considerable rivers in the state.

There are rich mines of iron in Vermont, and mines of lead and copper of less importance. Marble and slate are also found in it. Its natural forests furnish timber of large size, and a great variety of kinds. Of quadrupeds, there are the bear, wolf, wild cat, fox, ermine, racoon, beaver and musk rat. The lakes and rivers furnish a great variety of fish.

The inhabitants have a more florid complexion than those of the middle and southern states. They are temperate and industrious, and with a few exceptions are engaged in agriculture.

The legislature consists of a general assembly chosen annually by ballot, by the male taxable citizens of twenty-one years of age; and the executive power is vested in a governor, lieutenant-governor, and twelve counsellors chosen along with the representatives. A peculiar feature in the constitution, is the council of censors, thirteen in number, chosen every seven years by the people, to examine and report upon the proceedings of the executive and the representatives, and with power to call a convention of the people to amend the constitution. The judges are chosen annually by the council and assembly. A portion of land out of each township is set apart for the support of the clergyman of any denomination that is first settled. The prevailing sect are the Congregationalists, the next in number the Baptists. Tracts of land have been set apart also for the support of schools. There are two colleges, at Burlington and Middlebury.

The value of houses and lands in this state in 1799 was 16,723,873 dollars, and in 1814 it was 32,747,290, and the average value of lands at the latter period was 6 dollars 40 cents per acre. The manufactures of this state in 1810 were valued at 4,325,824 dollars; and the exports in 1817 amounted to 913,201 dollars.

VERNACULAR, a word applied to something that is peculiar to any one country.

VERNAL, something belonging to the spring-season.

VERNIER SCALE, a scale excellently adapted for the graduation of mathematical instruments, thus called from its inventor Peter Vernier, a person of distinction in the Franche Comté. See NONIUS.

Vernier's method is derived from the following principle. If two equal right lines, or circular arcs, A, B, are so divided, that the number of equal divisions in B is one less than the number of equal divisions of A, then will the excess of one division of B above one division of A be compounded of the ratios of one of A to A, and of one of B to B.

For let A contain 11 parts, then one of A to A is as 1 to 11, or $\frac{1}{11}$. Let B contain 10 parts, then one of B to B is as 1 to 10, or $\frac{1}{10}$. Now $\frac{1}{10}-\frac{1}{11}=\frac{11-10}{10\times 11}=\frac{1}{10\times 11}=\frac{1}{10}\times\frac{1}{11}$.

Or if B contains n parts, and A contains $n+1$ parts; then $\frac{1}{n}$ is one part of B, and $\frac{1}{n+1}$ is one part of A. And $\frac{1}{n}-\frac{1}{n+1}=\frac{\overline{n+1}-n}{n\times\overline{n+1}}=\frac{1}{n}\times\frac{1}{n+1}$

The most commodious divisions, and their aliquot parts, into which the degrees on the circular limb of an instrument may be supposed to be divided, depend on the radius of that instrument.

Let R be the radius of a circle in inches; and a degree to be divided into n parts, each being $\frac{1}{p}$th part of an inch.

Now the circumference of a circle, in parts of its diameter 2R inches, is $3,1415926\times 2R :: 1^\circ : \frac{3,1415926}{360}\times 2R$ inches.

Or, $0,01745329\times R$ is the length of one degree in inches.

Or, $0,01745329\times R\times p$ is the length of 1°, in pth parts of an inch.

But as every degree contains n times such parts, therefore $n=0,01745329\times R\times p$.

The most commodious perceptible division is $\frac{1}{8}$ or $\frac{1}{10}$ of an inch.

Example. Suppose an instrument of 30 inches radius, into how many convenient parts may each degree be divided? how many of these parts are to go to the breadth of the vernier, and to what parts of a degree may an observation be made by that instrument?

Now $0,01745\times R=0,5236$ inches, the length of each degree: and if p be supposed about $\frac{1}{8}$ of an inch for one division; then $0,5236\times p=4,188$ shows the number of such parts in a degree. But as this number must be an integer, let it be 4, each being 15″; and let the breadth of the vernier contain 31 of those parts, or $7\frac{1}{4}°$, and be divided into 30 parts.

Here $n=\frac{1}{4}$; $m=\frac{1}{30}$; then $\frac{1}{4}\times\frac{1}{30}=\frac{1}{120}$ of a degree, or 30′, which is the least part of a degree that instrument can show.

If $n=\frac{1}{5}$, and $m=\frac{1}{36}$; then $\frac{1}{5}\times\frac{1}{36}=\frac{60}{5\times 36}$ of a minute, or 20″.

The following table, taken as examples in the instruments commonly made from 3 inches to 8 feet radius, shows the divisions of the limb to nearest tenths of inches, so as to be an aliquot of 60's, and what parts of a degree may be estimated by the vernier, it being divided into such equal parts, and containing such degrees as their columns show.

Rad. inches.	Parts of a degree.	Parts in vernier.	Breadth of vernier	Parts observed.	
3	1	15	$15\frac{1}{4}$	4′	0″
6	1	20	$20\frac{1}{4}$	3	0
9	2	20	$10\frac{1}{4}$	1	30
12	2	24	$12\frac{3}{4}$	1	15
15	3	20	$6\frac{3}{4}$	1	0
18	3	30	$10\frac{1}{4}$	0	40
21	4	30	$7\frac{1}{4}$	0	30
24	4	36	$9\frac{3}{4}$	0	25
30	5	30	$7\frac{1}{8}$	0	20
36	6	30	$5\frac{1}{4}$	0	20
42	8	30	$3\frac{7}{8}$	0	15
48	9	40	$4\frac{5}{9}$	0	10
60	10	36	$3\frac{17}{10}$	0	10
72	12	30	$2\frac{7}{12}$	0	10
84	15	40	$2\frac{2}{3}$	0	6
96	15	60	4	0	4

By altering the number of divisions, either in the degrees or in the vernier, or in both, an angle can be observed to a different degree of accuracy. Thus, to a radius of 30 inches, if a degree be divided into 12 parts, each being five minutes, and the breadth of the vernier be 21 such parts, or $1\frac{3}{4}^{\circ}$, and divided into 20 parts, then $\frac{1}{12}\times\frac{1}{20}=\frac{1^{\circ}}{240}=15''$: or taking the breadth of the vernier $2\frac{7}{12}^{\circ}$, and divided into 30 parts; then $\frac{1}{12}\times\frac{1}{30}=\frac{1^{\circ}}{360}$, or $10''$: Or $\frac{1}{12}\times\frac{1}{50}=\frac{1^{\circ}}{600}=6''$; where the breadth of the vernier is $4\frac{1}{4}^{\circ}$.

VERONA, a city of Italy, capital of the Veronese, and in the territory of Venice, now subject to Austria; situated on the river Adige, in E. Long. 11. 24. N. Lat. 45. 26. It is seven miles in compass; and is strongly fortified. It contains 57,400 inhabitants.

VERONESE, a district of Italy, in the Austro-Venetian territories; bounded on the north by the Trentino, on the east by the Vicentino and Paduano, on the south by the Mantuano, and on the west by the Bresciano. It is about 35 miles in length, and 27 in breadth; and fertile in corn, wine, fruits, and cattle.

VERONESE. See CAGLIARI.

VERONICA, a genus of plants of the class of diandria; and in the natural system arranged under the 40th order, *Personatæ*. See BOTANY *Index*.

VERSAILLES, a town of France, in the department of Seine and Oise, 10 miles west-south-west of Paris. It contained 26,000 inhabitants in 1817, and since the Revolution has been created a bishop's see. In the reign of Louis XIII. it was only a small village. This prince built here a hunting-hut in 1630, which Bassompierre calls "the paltry chateau of Versailles." Although the situation was low and very unfavourable, Louis XIV. built a magnificent palace here, which was the usual residence of the kings of France till the 6th of October 1789, when the late unfortunate Louis XVI. and his family were removed from it to the Thuilleries. The buildings and the gardens are adorned with a vast number of statues, done by the greatest masters, and the water-works are all worthy of admiration. The great gallery is thought to be as curious a piece of workmanship of that kind as any in the world: nor is the chapel less to be admired for its fine architecture and ornaments. The gardens, with the park, are five miles in circumference, and surrounded by walls. There are three fine avenues to Versailles; one of which is the common road to Paris, the other comes from Seaux, and the third from St Cloud. E. Long. 2. 12. N. Lat. 48. 48.

VERSE, in *Poetry*, a line consisting of a number of long and short syllables, which run with an agreeable cadence.

VERSE is also used for a part of a chapter, section, &c.

VERSIFICATION, the art or manner of making verse; also the tune and cadence of a verse. See POETRY, Part III.

VERSION, a translation of some book or writing out of one language into another. See TRANSLATION.

VERT, in *Heraldry*, the term for a green colour. It is called *vert* in the blazon of the coats of all under the degree of nobles: but in coats of nobility it is called *emerald;* and in those of kings *venus*. In engraving it is expressed by diagonals, or lines drawn athwart from right to left, from the dexter chief corner to the sinister base.

VERTEBRÆ. See ANATOMY, N° 30.

VERTEX, in *Anatomy*, denotes the crown of the head. Hence vertex is also used figuratively for the top of other things: thus we say, the vertex of a cone, pyramid, &c.

VERTEX, is also used in *Astronomy* for the point of the heaven directly over our heads, properly called the *zenith*.

VERTICILLATÆ, the name of a class in Ray's and Boerhaave's Methods, consisting of herbaceous vegetables. It is also the name of the 42d order in Linnæus's Fragments of a Natural Method.

VERTICILLUS, a mode of flowering, in which the flowers are produced in rings at each joint of the stem, with very short foot-stalks. The term is exemplified in mint, horehound, and the other plants of the natural order described above.

VERTICITY, is that property of the loadstone whereby it turns or directs itself to one particular point.

VERTIGO, in *Medicine*. See there, N° 82.

VERTUMNUS, in *Mythology*, a god who presided over gardens and orchards, honoured among the Etruscans, from whom the worship of this deity was transmitted to the Romans.

Vertumnus had a temple near the market-place at Rome, being represented as one of the tutelar deities of the merchants. The commentators on Ovid say, that

that he was an ancient king of Hetruria, who, by his diligent and successful cultivation of fruit and gardens, obtained the honour of being ranked among the gods.

VERUMONTANUM, in *Anatomy*, a small eminence near the passages where the semen is discharged into the urethra.

VERVAIN. See VERBENA, BOTANY *Index*.

VERTOT D'AUBOEF, *Rene Aubert de*, a celebrated historian, who descended from a noble and ancient family in Normandy, and born in 1655. At 16 years of age he became a Franciscan friar; afterwards he entered into the order of the Premonstratenses, in which he had several benefices: and at length was a secular ecclesiastic. He became secretary to the duchess of Orleans, member of the Academy of Inscriptions, and historiographer of Malta. He died at Paris in 1735. His principal works are, 1. The History of the Revolutions of Sweden. 2. The Revolutions of Portugal. 3. The Revolutions of the Romans. 4. The History of Malta. These works are written in elegant French, and translated into most of the languages of Europe.

VERULAM. See BACON.

VESALIUS, ANDREAS, a celebrated physician and anatomist, was born at Brussels about the year 1512. He studied physic at Paris under James Sylvius; but applied himself chiefly to anatomy, which was then very little known, dissections being esteemed unlawful and impious: and it appears from his work *De Humani Corporis Fabrica*, that he perfected himself in this useful knowledge very early. About the year 1537, the republic of Venice made him professor in the university of Padua, where he taught anatomy for seven years; Charles V. called him to be his physician, as he was also to Philip II. king of Spain. Vesalius was now at the height of his glory, when all of a sudden he formed the design of taking a journey to Palestine; concerning which journey we are told the following story. A young Spanish nobleman he attended, being believed to be dead, Vesalius obtained leave to open him to explore the true cause of his illness; but when he opened the breast, he perceived symptoms of life, and saw the heart beat. The parents, not satisfied with prosecuting him for murder, accused him of impiety to the inquisition, in hopes that tribunal would punish him with greater rigour: but the king interposing, saved him on condition of his making a pilgrimage to the Holy Land. He was shipwrecked on his return, and thrown upon the island of Zante, where he perished, in 1564. He was the author of several works, the principal of which is *De Humani Corporis Fabrica*.

VESICATORIUM, a BLISTER; an application of an acrid nature made to any part of the body, in order to draw a flux of humours to that part, and thus elevate the scarfskin into a blister.

VESPA, the WASP; a genus of insects belonging to the order of hymenoptera. See ENTOMOLOGY *Index*.

VESPASIAN, the 10th emperor of Rome; remarkable for his clemency and other virtues. See ROME, N° 332—339.

VESPERS, in the church of Rome, denote the afternoon service; answering in some measure to the evening prayers of the church of England.

VESPERTILIO, the BAT; a genus of quadrupeds, belonging to the order of primates. See MAMMALIA *Index*.

VESSEL, a general name given to the different sorts of ships which are navigated on the ocean, or in canals and rivers. It is, however, more particularly applied to those of the smaller kind, furnished with one or two masts. See SHIP.

VESTA, in pagan worship, the same with Cybele. See CYBELE.

VESTA the *Younger*, in pagan worship, the goddess of fire, was the daughter of Saturn and Cybele, and the sister of Ceres. She was so much in love with chastity, that on Jupiter's ascending the throne and offering to grant whatever she asked, she only desired the preservation of her virginity, which she obtained.—Vesta was not represented in her temple by any image.

VESTA, one of the lately discovered planets, of which the elements have been determined by Dr Gauss in a communication to the Royal Society of Gottingen.

Elements of Vesta.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the 5th of the ides of June; that is, on the 9th of the month.

VESTALS, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge; they were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom was one superior to the rest, and called *vestalis maxima*.

The vestals were chosen from six to ten years of age, and obliged to strict continency for 30 years; the first 10 of which were employed in learning the ceremonies of religion, the next 10 in the performance of them, and the 10 last in teaching them to the younger vestals.

The

The habit of the vestals consisted of a head-dress, called *infula*, which sat close to the head, and from whence hung certain laces called *vitta;* a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBLE, or VESTIBULE, in *Architecture*, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the staircase.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, consisting of the minister, church-wardens, and chief men of most parishes, who make a parish vestry or meeting. By custom there are select vestries, being a certain number of persons chosen to have the government of the parish, make rates, and take the accounts of church-wardens, &c.

VESUVIAN, a mineral substance. See MINERALOGY *Index*.

VESUVIUS, a celebrated volcano of Italy, six miles east from the city of Naples. This mountain has two tops; one of which only goes by the name of *Vesuvius*, the other being now called *Somma;* but Sir William Hamilton is of opinion, that the latter is what the ancients called *Vesuvius*.

1
General description of the mountain.

The perpendicular height of Vesuvius is only 3700 feet, though the ascent from the foot to the top is three Italian miles. One side of the mountain is well cultivated and fertile, producing great plenty of vines; but the south and west sides are entirely covered with cinders and ashes; while a sulphureous smoke constantly issues from the top, sometimes attended with the most violent explosions of stones, the emission of great streams of lava, and all the other attendants of a most formidable volcano. The first of these eruptions recorded in history took place in the year 79; at which time the two cities of Pompeii and Herculaneum were entirely buried under the stones and ashes thrown out. Incredible mischief was also done to the neighbouring country, and numbers of people lost their lives, among whom was Pliny the Elder.

2
Account of the first eruption recorded in history.

It is the opinion of the best judges, however, that this eruption was by no means the first that had ever happened. The very streets of those cities which were at that time overwhelmed are said to be partly paved with lava. Since that time 30 different eruptions have been recorded, some of which have been extremely violent. In the year 1538, a mountain, three miles in circumference, and a quarter of a mile in perpendicular height, was thrown up in the course of one night.

3
Of the eruption in 1767.

The first great eruption taken notice of by Sir William Hamilton was that of 1767, which, though very violent, was mild in comparison with that of 1538.

4
Nine eruptions from 1767 to 1779.

From this time (1767) Vesuvius never ceased for ten years to send forth smoke, nor were there many months in which it did not throw out stones, scoriæ, and cinders; which, increasing to a certain degree, were usually followed by lava; so that from the year 1767 to 1779 there were nine eruptions, some of them very considerable. In the month of August that year, however, an eruption took place, which, for its extraordinary and terrible appearance, may be reckoned among the most remarkable of any recorded concerning this or any other volcano.

5
Account of the great eruption in 1779.

During the whole month of July the mountain continued in a state of fermentation. Subterraneous explosions and rumbling noises were heard; quantities of smoke were thrown up with great violence, sometimes with red-hot stones, scoriæ, and ashes; and towards the end of the month these symptoms increased to such a degree as to exhibit, in the night-time, the most beautiful fireworks that can be imagined.

On Thursday 5th August the volcano appeared most violently agitated; a white and sulphureous smoke issued continually and impetuously from its crater, one puff seeming to impel another; so that a mass of them was soon accumulated, to appearance four times the height and size of the volcano itself. These clouds of smoke were exceedingly white, so that the whole resembled an immense accumulation of bales of the whitest cotton. In the midst of this very white smoke, vast quantities of stones, scoriæ, and ashes, were thrown up to the height of 2000 feet; and a quantity of liquid lava, seemingly very heavy, was lifted up just high enough to clear the rim of the crater, and take its way down the sides of the mountain. This lava, having run violently for some hours, suddenly ceased, just before it had reached the cultivated parts of the mountain, near four miles from the spot whence it issued. The heat, all this day, was intolerable at the towns of Somma and Ottaiano; and was sensibly felt at Palma and Lauri, which are much farther off. Reddish ashes fell so thick on the two former, that the air was darkened, and that objects could not be distinguished at the distance of ten feet. Long filaments of a vitrified matter, like spun glass, were mixed, and fell with these ashes; several birds in cages were suffocated, and the leaves of the trees in the neighbourhood of Somma were covered with white and very corrosive salt.

6
Extraordinary effusion of fire by the approach of stormy clouds.

About 12 at night, on the 7th, the fermentation of the mountain seemed greatly to increase. Our author was watching the motions of the volcano from the mole at Naples, which has a full view of it. Several glorious picturesque effects had been observed from the reflection of the deep red fire within the crater of Vesuvius, and which mounted high amongst those huge clouds on the top of it: when a summer storm, called in that country a *tropea*, came on suddenly, and blended its heavy watery clouds with the sulphureous and mineral ones, which were already like so many other mountains piled up on the top of the volcano. At this moment a fountain of fire was shot up to an incredible height, casting so bright a light, that the smallest objects were clearly distinguishable at any place within six miles or more of Vesuvius. The black stormy clouds, passing swiftly over, and at times covering the whole or a part of the bright column of fire, at other times clearing away and giving a full view of it, with the various tints produced by its reverberated light on the white clouds above in contrast with the pale flashes of forked lightning that attended the tropea, formed such a scene as no power of art can express. One of his Sicilian majesty's gamekeepers, who was out in the fields near Ottaiano whilst this storm was at its height, was surprised to find the drops of rain scald his face and hands; a phenomenon probably occasioned by the clouds having acquired a great degree of heat in passing through the above-mentioned column of fire.

On the 8th, the mountain was quiet till towards six o'clock in the evening, when a great smoke began to gather over its crater; and about an hour after a rumbling

Vesuvius.

bling subterraneous noise was heard in the neighbourhood of the volcano; the usual throws of red-hot stones and scoriæ began and increased every instant. The crater, viewed through a telescope, seemed much enlarged by the violence of last night's explosions, and the little mountain on the top was entirely gone. About nine o'clock a most violent report was heard at Portici and its neighbourhood, which shook the houses to such a degree as made the inhabitants run out into the streets. Many windows were broken, and walls cracked by the concussion of the air on this occasion, though the noise was but faintly heard at Naples. In an instant a fountain of liquid transparent fire began to rise, and gradually increasing, arrived at last at the amazing height of ten thousand feet and upwards. Puffs of smoke, as black as can possibly be imagined, succeeded one another hastily, and accompanied the red-hot, transparent, and liquid lava, interrupting its splendid brightness here and there by patches of the darkest hue. Within these puffs of smoke, at the very moment of emission, a bright but pale electrical fire was observed playing briskly about in zig-zag lines. The wind was south-west, and, though gentle, was sufficient to carry these puffs of smoke out of the column of fire; and a collection of them by degrees formed a black and extensive curtain behind it; in other parts of the sky it was perfectly clear, and the stars bright. The fiery fountain, of such immense magnitude, on the dark ground just mentioned, made the finest contrast imaginable; and the blaze of it reflected from the surface of the sea, which was at that time perfectly smooth, added greatly to this sublime view.

7 Immense fountain of lava thrown up by Vesuvius.

The lava, mixed with stones and scoriæ, having risen to the amazing height already mentioned, was partly directed by the wind towards Ottaiano, and partly falling, still red hot and liquid, upon the top of Vesuvius, covered its whole cone, part of that of the summit of Somma, and the valley between them. The falling matter, being nearly as inflamed and vivid as that which was continually issuing fresh from the crater, formed with it one complete body of fire, which could not be less than two miles and a half in breadth, and of the extraordinary height above mentioned, and cast a heat to the distance of at least six miles round. The brushwood on the mountain of Somma was soon in a blaze, and the flame of it being of a different colour from the deep red of the matter thrown out by the volcano, and from the silvery blue of the electrical fire, still added to the contrast of this most extraordinary scene.

The black cloud, increasing greatly, once bent towards Naples, and threatened the city with speedy destruction; for it was charged with electrical fire, which kept constantly darting about in bright zig-zag lines. This fire, however, rarely quitted the cloud, but usually returned to the great column of fire whence it proceeded; though once or twice it was seen to fall on the top of Somma, and set fire to some dry grass and bushes. Fortunately the wind carried back the cloud just as it reached the city, and had begun to occasion great alarm. The column of fire, however, still continued, and diffused such a strong light, that the most minute objects could be discerned at the distance of ten miles or more from the mountain. Mr Morris informed our author, that at Sorrento, which is 12 miles distant from Vesuvius, he read the title-page of a book by that volcanic light.

All this time the miserable inhabitants of Ottaiano were involved in the utmost distress and danger by the showers of stones which fell upon them, and which, had the eruption continued for a longer time, would most certainly have reduced their town to the same situation with Herculaneum and Pompeii. The mountain of Somma, at the foot of which the town of Ottaiano is situated, hides Vesuvius from the view of its inhabitants; so that till the eruption became considerable it was not visible to them. On Sunday night, when the noise increased, and the fire began to appear above the mountain of Somma, many of the inhabitants flew to the churches, and others were preparing to quit the town, when a sudden and violent report was heard; soon after which they found themselves involved in a thick cloud of smoke and ashes; a horrid crashing noise was heard in the air, and presently fell a vast shower of stones and large pieces of scoriæ, some of which were of the diameter of seven or eight feet, which must have weighed more than 1000 pounds before they were broken, as some of the fragments which Sir William Hamilton found in the streets still weighed upwards of 60 pounds. When these large vitrified masses either struck against one another in the air, or fell on the ground, they broke in many pieces, and covered a large space of ground with vivid sparks of fire, which communicated their heat to every thing that was combustible. These masses were formed of the liquid lava; the exterior parts of which were become black and porous by cooling in their fall through such a vast space; whilst the interior parts, less exposed, retained an extreme heat, and were perfectly red.

8 Distress of the inhabitants of Ottaiano.

In an instant the town and country about it was on fire in many parts, for there were several straw huts in the vineyards, which had been erected for the watchmen of the grapes; all of which were burnt. A great magazine of wood in the heart of the town was all in a blaze; and had there been much wind, the flames must have spread universally, and all the inhabitants would have been burnt in their houses; for it was impossible for them to stir out. Some, who attempted it with pillows, tables, chairs, the tops of wine casks, &c. on their heads, were either knocked down or soon driven back to their close quarters under arches and in the cellars of their houses. Many were wounded, but only two persons died of their wounds.

To add to the horror of the scene, incessant volcanic lightning was whisking about the black cloud that surrounded them, and the sulphureous smell and heat would scarcely allow them to draw their breath. In this dreadful situation they remained about 25 minutes, when the volcanic storm ceased all at once, and Vesuvius remained sullen and silent.

Some time after the eruption had ceased, the air continued greatly impregnated with electrical matter. The duke of Cottofiano told our author, that having, about half an hour after the great eruption had ceased, held a Leyden bottle, armed with a pointed wire, out at his window at Naples, it soon became considerably charged. But whilst the eruption was in force, its appearance was too alarming to allow one to think of such experiments. —He was informed also by the prince of Monte Mileto, that

9 Vast quantity of electric matter in the air.

Vesuvius. that his son, the duke of Popoli, who was at Monte Mileto the 8th of August, had been alarmed by the shower of cinders that fell there; some of which he had sent to Naples weighing two ounces; and that stones of an ounce weight had fallen upon an estate of his ten miles farther off. Monte Mileto is about 30 miles from the volcano. The abbé Cagliani also related, that his sister, a nun in a convent at Manfredonia, had written to inquire after him, imagining that Naples must have been destroyed, when they, at so great a distance, had been alarmed by a shower of ashes which fell on the city at 11 o'clock at night, so much as to open all the churches, and go to prayers. As the great eruption happened at nine o'clock, these ashes must have travelled 100 miles in the space of two hours.

10 Damage done by the eruption at Ottaiano.

Nothing could be more dismal than the appearance of Ottaiano after this eruption. The houses were unroofed, half buried under the black scoriæ and ashes; all the windows towards the mountain were broken, and some of the houses themselves burnt; the streets choked up with ashes, in some narrow places not less than four feet thick; and a few of the inhabitants who had just returned, were employed in clearing them away, and piling them up in hillocks, to get at their ruined houses. The palace of the prince of Ottaiano is situated on an eminence above the town, and nearer the mountain. The steps leading up to it were deeply covered with volcanic matter; the roof was totally destroyed, and the windows broken, but the house itself, being strongly built, had not suffered much.

11 Vast fragments of lava thrown out.

An incredible number of fragments of lava were thrown out during the eruption, some of which were of immense magnitude. The largest measured by Sir William Hamilton was 108 feet in circumference and 17 in height. This was thrown at least a quarter of a mile clear of the mouth of the volcano. Another, 66 feet in circumference and 19 in height, being nearly of a spherical figure, was thrown out at the same time, and lay near the former. This last had the marks of being rounded, nay almost polished, by continual rolling in torrents or on the sea-shore. Our author conjectures that it might be a spherical volcanic salt, such as that of 45 feet in circumference mentioned by M. de St Fond, in his Treatise of Extinguished Volcanoes. A third of 16 feet in height and 92 in circumference was thrown much farther, and lay in the valley between Vesuvius and the Hermitage. It appeared also, from the large fragments that surrounded this mass, that it had been much larger while in the air.

Vesuvius continued to emit smoke for a considerable time after this great eruption, so that our author was apprehensive that another would soon ensue; but from that time nothing comparable to the above has taken place. From the time of this great eruption to the year 1784 our author kept an exact diary of the operations of Vesuvius, with drawings, showing, by the quantity of smoke, the degree of fermentation within the volcano. The operations of the subterraneous fire, however, appear to be very capricious and uncertain. One day there is the appearance of a violent fermentation, and the next every thing is tranquil; but whenever there has been a considerable ejection of scoriæ and cinders, it has been a contant observation, that the lava soon made its appearance, either by boiling over the crater, or forcing its way through the crevices in the conical part of the mountain. An eruption took place in 1784, but without any remarkable circumstance, and another in 1794 which destroyed 5000 acres of cultivated land.

Vesuvius | Victor.

VETCH. See Vicia, Botany *Index*.

VETERAN, among the ancient Romans, an appellation given to a *soldier* grown old in the service, or who had made a certain number of campaigns.

VETERINARY art. See Farriery.

VEXILLUM, in *Botany*; the upper petal of a pea-bloom, or butterfly-shaped flower, which is generally larger than any of the others.

VIALES, in mythology, a name given among the Romans to the gods who had the care and guard of the roads and highways.

VIATICUM, in Roman antiquity, an appellation given in common to all officers of any of the magistrates; as *lictors*, *accensi*, *scribes*, *criers*.

VIBEX, is sometimes used by physicians, for a black and blue spot in the skin occasioned by an efflux or extravasation of blood.

VIBRATION, in *Mechanics*, a regular, reciprocal motion of a body, as a pendulum.

VIBURNUM, a genus of plants of the class pentandria; and in the natural system arranged under the 43d order, *Dumosæ*. See Botany *Index*.

VICAR, a person appointed as deputy to another, to perform his functions in his absence, and under his authority.

Vicar, in the canon-law, denotes a priest of a parish, the predial tithes whereof are impropriated or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman who receives them, and only allows the vicar the small tithes, or a convenient salary. See the article *Parson and Vicar*.

VICE, in ethics, is ordinarily defined an elective habit, denoting either an excess or defect from the just medium wherein virtue is placed.

Vice, in smithery and other arts conversant in metals, a machine or instrument serving to hold fast any thing they are at work upon, whether it is to be beaten, filed, or rivetted.

Vice is also used in the composition of divers words to denote the relation of something that comes instead or in the place of another; as vice admiral, vice-chancellor, &c. are officers who take place in the absence of admirals, &c.

VICEROY, a governor of a kingdom, who commands in the name and instead of a king, with full and sovereign authority.

VICIA, a genus of plants of the class diadelphia; and in the natural system arranged under the 32d order, *Papilionaceæ*. See Botany *Index*.

VICISSITUDE, the regular succession of one thing after another; as the vicissitude of day and night, of the seasons, &c.

VICTIM, denotes a sacrifice offered to some deity, of a living creature, as a man or beast, which is slain to appease his wrath, or to obtain some favour.

VICTOR, Sextus Aurelius, a Roman historian, who flourished under the emperors Constantius and Julian; as we learn from many passages in his own writings, and also from Ammianus Marcellinus. This historian relates, that Constantius made him consul, and honoured honour him with a brazen statue, on account of his excellent qualifications; although, as he owns of himself, he was born in an obscure village, and of poor and illiterate parents. It is commonly believed that he was an African. Two books of his are extant in the historical way: one *De viris illustribus urbis Romæ;* the other, *De Cæsaribus;* to which is prefixed *Libellus de origine gentis Romanæ*. The whole makes an abridged history of Rome, from its foundation down to the reign of Julian inclusive.

VICTORY, the overthrow or defeat of an enemy in war or combat.

VICTORY, in Pagan worship, is represented by Hesiod as the daughter of Styx and Pallas; and Varro calls her the *daughter of Heaven and Earth*. The Romans erected a temple to her, where they prayed to the gods to give success to their arms. They painted her in the form of a woman, clad in cloth of gold. In some medals, she is represented with wings flying through the air, holding a laurel crown in one hand and a palm in the other; but in other medals, she is seen standing upon a globe, with the same crown and branch of palm.

VIDA, MARCUS HIERONYMUS, bishop of Alva, in Montserrat, and one of the most excellent Latin poets that have appeared since the Augustan age, was born at Cremona in 1470. Having distinguished himself by his learning and taste for literature, he was made bishop of Alva in 1552. After continuing two years with Pope Clement VII. at Rome, he went to reside upon his see; where, for 30 years, he performed all the offices of a good bishop and a good man; and though he was mild, gentle, and full of goodness, he was so far from wanting spirit, that when the city of Alva was besieged by the French, he used all possible means to prevent its being given up, by strenuously exhorting the people, and, when provisions were scarce, by supplying them at his own expence. His Poetics, and poem on the silk-worm, pass for his masterpiece; his poem on the game of chess is also greatly admired. He also wrote hymns, eclogues, and a poem entitled *Christiados* in six books; all which are in Latin, and have gained him a great reputation. His works in prose consist of dialogues, synodical constitutions, letters, and other pieces. He died in 1556, soon after being made bishop of Cremona.

VIENNA, the capital of the circle of Austria, in Germany, and of the whole German empire, is the place where the emperor resides. The city itself is not of very great extent; nor can it be enlarged, it being limited by a very strong fortification; but it is very populous. The streets, in general, are narrow, and the houses built high. Some of the public buildings are magnificent; but they appear externally to no great advantage, on account of the narrowness of the streets. The chief of them are the imperial palace, the library, and the museum; the palaces of the princes Lichtenstein, Eugene, &c. Vienna was twice ineffectually besieged by the Turks; namely, in 1589 and 1683. At the latter period, the siege was raised by John Sobieski, king of Poland, who totally defeated the Turkish army before the walls of this place. To strengthen the city against future attacks, no houses without the walls are allowed to be built nearer to the glacis than 600 yards; so that there is a circular field of that breadth all round the town, which has a very beautiful and salutary effect. These magnificent suburbs, and the town together, are said to contain above 320,000 inhabitants; yet the former are not near so populous, in proportion to their size, as the town; because many houses in the suburbs have extensive gardens belonging to them, and many families, who live during the winter within the fortifications, spend the summer in the suburbs. The cathedral is built of free-stone, is 114 yards long, and 48 broad, and the steeple is 447 feet high. The university had several thousand students, who, when this city was besieged, mounted guard. Beside this, there is the academy of Lower Austria; and the archducal library is much frequented by foreigners, as it contains above 100,000 printed books, and 10,000 manuscripts. The academy of painting is remarkable for the fine pictures it produces. The archducal treasury, and a cabinet of curiosities of the house of Austria, are great rarities. The inhabitants, in general, live in a splendid manner; and people of distinction have all sorts of wines at their tables, which they are very free with to foreigners. There is a sort of harbour on the Danube, where there are magazines of naval stores, and ships have been fitted out to serve on that river against the Turks. Vienna is an archbishop's see. It is seated at the place where the river Vienna or Wein, falls into the Danube, 30 miles west of Presburgh, 350 north-north-east of Rome, 520 south-east by south of Amsterdam, 565 east of Paris, and 680 east-south-east of London. E. Long. 16. 15. N. Lat. 48. 13.

VIENNE, a department in the west of France, forming part of the ancient Poitou. It derives its name from the river Vienne which runs through it, and falls into the Loire. There are extensive tracts of heath in this department; but the soil in other parts yields in abundance, grain, hemp, flax, fruits, and vines. Cattle, fish, game, and poultry, are plentiful. There are extensive forests and mines of coal, antimony, and iron. The manufactures, which consist of coarse woollens, linen, leather and paper, are trifling. The extent of this department is 689,883 hectares, and in 1817 it contained 253,048 inhabitants. Poitiers is the chief town.

VIENNE, *Upper*, a department of France, lying south of the Loire, on the upper branches of the river Vienne. The surface of the country is in general hilly, and the soil poor. It produces little wheat, but considerable quantities of rye and barley, and raises great numbers of cattle, horses, and mules. The hills are generally covered with wood, among which chesnuts abound. There are mines of iron, lead, copper, antimony, and coal. The manufactures consist of metals, coarse woollens and linens, handkerchiefs, pottery, &c. The extent of this department is 570,035 hectares, and the population in 1817 was 243,195. Limoges is the chief town.

VIGIL, in church history, is the eve or next day before any solemn feast; because then Christians were wont to watch, fast, and pray, in their churches.

VIGILS of Plants, a term under which botanists comprehend the precise time of the day in which the flowers of different plants open, expand, and shut.

As all plants do not flower in the same season, or month; in like manner, those which flower the same day, in the same place, do not open and shut precisely at the same hour. Some open in the morning, as the lip flowers, and compound flowers with flat spreading petals;

petals; others at noon, as the mallows; and a third set in the evening, or after sunset, as some geraniums and opuntias; the hour of shutting is equally determined. Of those which open in the morning, some shut soon after, while others remain expanded till night.

The hours of opening, like the time of flowering, seem to vary, according to the species of the plant, the temperature of the climate, and that of the season. Flowers, whose extreme delicacy would be hurt by the strong impressions of an ardent sun, do not open till night: those which require a moderate degree of heat to elevate their juices, in other words, whose juices do not rise but in the morning or evening, do not expand till then; whilst those which need a more lively heat for the same purpose, expand at noon when the sun is in his meridian strength, Hence it is, that the heat of the air being greater betwixt the tropics than elsewhere, plants which are transported from those climates into the cold or temperate climates of Europe, expand their flowers much later than in their native soil. Thus, a flower which opens in summer at six o'clock in the morning at Senegal, will not open at the same season in France and England till eight or nine, nor in Sweden till ten.

Linnæus distinguishes by the general name of *solar* (*flores solares*) all those flowers which observe a determinate time in opening and shutting. These flowers are again divided, from certain circumstances, into three species, or kinds:

Equinoctial flowers (*flores æquinoctiales*) are such as open and shut at all seasons, at a certain fixed or determinate hour.

Tropical flowers (*flores tropici*) are such whose hour of opening is not fixed at all seasons, but accelerated or retarded according as the length of the day is increased or diminished.

Meteorous flowers (*flores meteorici*) are such whose hour of expansion depends upon the dry or humid state of the air, and the greater or less pressure of the atmosphere. Of this kind is the Siberian sow-thistle, which shuts at night if the ensuing day is to be clear and serene, and opens if it is to be cloudy and rainy. In like manner the African marigold, which in dry serene weather opens at six or seven in the morning, and shuts at four o'clock in the afternoon, is a sure indication that rain will fall during the course of the day, when it continues shut after seven.

VIGO, a sea-port town of Galicia in Spain, with an old castle and a fort. It is seated in a fertile country by the sea-side. It was rendered famous by a sea-fight between the confederate fleet commanded by Sir George Rook, and a squadron of French men of war, in which the English took four galleons and five large men of war, and the Dutch five galleons and one man of war. W. Long. 8. 43. N. Lat. 42. 14.

VILLA FRANCA, the name of several towns; one in Piedmont, three miles east of Nice; another of Catalonia, 18 miles west of Barcelona; a third, the capital of St Michael, one of the Azores; and a fourth, a town of Estremadura in Spain, 57 miles south-east of Salamanca.

VILLAGE, an assemblage of houses inhabited chiefly by peasants and farmers, and having no market whereby it is distinguished from a town. The word is French, formed of *vil* or *vilis*, "low, mean, contemptible:" or rather, from the Latin *villa*, a country-house or farm.

VILLAIN, or **VILLEIN**, in our ancient customs, genotes a man of servile or base condition, viz. a bondman or servant.

VILLENAGE, in *Law*. The folk-land or estates held in villenage, was a species of tenure neither strictly feodal, Norman, or Saxon; but mixed and compounded of them all; and which also, on account of the heriots that usually attend it, may seem to have somewhat Danish in its composition. Under the Saxon government there were, as Sir William Temple speaks, a sort of people in a condition of downright servitude, used and employed in the most servile works, and belonging, both they, their children, and effects, to the lord of the soil, like the rest of the cattle or stock upon it. These seem to have been those who held what was called the *folk-land*, from which they were removeable at the lord's pleasure. On the arrival of the Normans here, it seems not improbable, that they who were strangers to any other than a feodal state, might give some sparks of enfranchisement to such wretched persons as fell to their share, by admitting them, as well as others, to the oath of fealty; which conferred a right of protection, and raised the tenant to a kind of estate superior to downright slavery, but inferior to every other condition. This they called *villenage*, and the tenants *villeins*.

These villeins, belonging principally to lords of manors, were either villeins *regardant*, that is, annexed to the manor or land: or else they were *in gross*, or at large, that is, annexed to the person of the lord, and transferable by deed from one owner to another. They could not leave their lord without his permission; but if they ran away, or were purloined from him, might be claimed and recovered by action, like beasts or other chattels. They held indeed small portions of land by way of sustaining themselves and families: but it was at the mere will of the lord, who might dispossess them whenever he pleased; and it was upon villein services, that is, to carry out dung, to hedge and ditch the lord's demesnes, and any other the meanest offices: and their services were not only base, but uncertain both as to their time and quantity.

A villein could acquire no property either in lands or goods: if he purchased either, the lord might seize them to his own use; unless he contrived to dispose of them again before the lord had seized them, for the lord had then lost his opportunity.

In many places a fine was also payable to the lord, if the villein presumed to marry his daughter to any one without leave from the lord: and by the common law, the lord might also bring an action against the husband for damages in thus purloining his property. For the children of villeins were also in the same state of bondage with their parents; whence they were called in Latin *nativi*, which gave rise to the female appellation of a villein, who was called a *neife*. In case of a marriage between a freemen and a neife, or a villein and a freewoman, the issue followed the condition of the father, being free if he was free, and a villein if he was villein, contrary to the maxim of the civil law, that *partus sequitur ventrem*. But no bastard could be born a villein, because by another maxim of our law he is *nullius filius*; and as he can *gain* nothing by inheritance, it were hard that he should *lose* his natural freedom by it. The law, however, protected the persons of villeins against atrocious injuries of the lord: for he might not kill or

Villenage. or maim his villein; though he might beat him with impunity.

Villeins might be enfranchised by manumission. In process of time they gained considerable ground on their lords; and in particular strengthened the tenure of their estates to that degree, that they came to have in them an interest in many places full as good, in others better than their lords. For the good nature and benevolence of many lords of manors having, time out of mind, permitted their villeins and their children to enjoy their possessions without interruption, in a regular course of descent, the common law, of which custom is the life, now gave them title to prescribe against their lords; and, on performance of the same services, to hold their lands in spite of any determination of the lord's will. For though in general they are still said to hold their estates at the will of the lord, yet it is such a will as is agreeable to the custom of the manor; which customs are preserved and evidenced by the rolls of the several courts-baron in which they are entered, or kept on foot by the constant immemorial usage of the several manors in which the lands lie. And as such tenants had nothing to show for their estates but those customs, and admissions in pursuance of them, entered on these rolls, or the copies of such entries witnessed by the steward, they now began to be called *tenants by copy of court roll*, and their tenure itself a *copyhold*.

Privileged VILLENAGE, a species of tenure otherwise called *villein socage*. See TENURE.

Ancient demesne consists of those lands or manors which, though now perhaps granted out to private subjects, were actually in the hands of the crown in the time of Edward the Confessor, or William the Conqueror; and so appear to have been, by the great survey in the exchequer, called the *doomsday-book*. The tenants of these lands, under the crown, were not all of the same order or degree. Some of them, as Britton testifies, continued for a long time pure and absolute villeins, dependent on the will of the lord; and common copyholders in only a few points. Others were in a great measure enfranchised by the royal favour; being only bound in respect of their lands to perform some of the better sort of villein-services, but those determinate and certain; as, to plough the king's land for so many days, to supply his court with such a quantity of provisions, and the like; all of which are now changed into pecuniary rents: and in consideration hereof they had many immunities and privileges granted to them; as to try the right of their property in a peculiar court of their own, called a *court of ancient demesne*, by a peculiar process denominated a writ of right close; not to pay toll or taxes; not to contribute to the expences of knights of the shire; not to be put on juries, and the like.

These tenants, therefore, though their tenure be absolutely copyhold, yet have an interest equivalent to a freehold: for though their services were of a base and villenous original, yet the tenants were esteemed in all other respects to be highly privileged villeins; and especially for that their services were fixed and determinate, and that they could not be compelled (like pure villeins) to relinquish those tenements at the lord's will, or to hold them against their own: *et ideo* (says Bracton) *dicuntur liberi*.

Lands holding by this tenure are therefore a species of copyhold, and as such preserved and exempted from the operation of the statute of Charles II. Yet they differ from common copyholds, principally in the privileges before mentioned: as also they differ from freeholders by one especial mark and tincture of villenage, noted by Bracton, and remaining to this day; viz. that they cannot be conveyed from man to man by the general common-law conveyances of feoffment, and the rest; but must pass by surrender to the lord or his steward, in the manner of common copyholds: yet with the difference, that, in the surrender of these lands in ancient demesne, it is not used to say, "to hold at the will of their lord," in their copies; but only, "to hold according to the custom of the manor."

Villenage ‖ St Vincent.

VILLI, among botanists, a kind of down like short hair, with which some trees abound.

VILLOSE, or VILLOUS, something abounding with villi or fibres like short hair; such is one of the coats of the stomach.

VINCA, a genus of plants of the class pentandria; and in the natural system arranged under the 30th order, *Contortæ*. See BOTANY *Index*.

St VINCENT, one of the windward Caribbee islands, which received its name from being discovered on the 22d of January, the feast of that saint. It is inhabited by a race of people, of whom Dr Robertson gives this account: "There is a great distinction in character between the Caribbees and the inhabitants of the larger islands. The former appear manifestly to be a separate race. Their language is totally different from that of their neighbours in the large islands. They themselves have a tradition that their ancestors came originally from some part of the continent, and having conquered and exterminated the ancient inhabitants, took possession of their lands and of their women. Hence they call themselves Banaree, which signifies a man come from beyond sea. Accordingly, the Caribbees still use two distinct languages, one peculiar to the men, and the other to the women. The language of the men has nothing common with that spoken in the large islands. The dialect of the women considerably resembles it. This strongly confirms the tradition which I have mentioned. The Caribbees themselves imagine that they were a colony from the Galibis, a powerful nation of Guiana in South America. But as their fierce manners approach nearer to those of the people in the northern continent, than to those of the natives of South America, and as their language has likewise some affinity to that spoken in Florida, their origin should be deduced rather from the former than from the latter. In their wars they still preserve their ancient practice of destroying all the males, and preserving the women either for servitude or for breeding."

It remained a long time after it was discovered inhabited by these people, and by another race improperly styled *Black Caribs*, who are in reality negroes descended, as is generally believed, from some who escaped out of a Guinea ship wrecked upon the coast, and gradually augmented by such as from time to time fled thither from Barbadoes. These nations were often at war; but when their quarrels were composed, they had a strength sufficient to prevent strangers from settling by force. The French, about half a century ago, at the request of the Caribs, made a descent from Martinico, and attacked the negroes, but were repulsed with loss; and found it their interest to conciliate a friendship with both nations by

St Vincent, Vinci.

by means of presents, and furnishing them with arms and ammunition.

St Vincent was long a neutral island; but at the peace of 1763, the French agreed that the right to it should be vested in the English; who, in the sequel, at the instance of some rapacious planters, engaged in an unjust war against the Caribbees, who inhabited the windward side of the island, and who were obliged to consent to a peace, by which they ceded a very large tract of valuable land to the crown. The consequence of this was that in the next war, in 1779, they greatly contributed to the reduction of this island by the French, who, however, restored it by the peace of 1783. Since that time it has continued in the possession of Great Britain. During the French revolutionary war, the Caribs revolted; and, assisted by the French, spread desolation over the whole island; but by the exertions of the governor and the British forces in the West Indies, the revolt was quelled.

St Vincent is in length about 24 miles, and about 18 in breadth. The climate is very warm. The country is in general hilly, in some places mountainous; but interspersed with a variety of pleasant valleys, and some luxuriant plains, the soil being everywhere very fertile, and the high grounds are at least in general easy of ascent. Few islands are so well watered with rivers and springs. The inhabitants raise all kinds of ground provisions in plenty. The rivers supply them with variety of fish. W. Long. 61°. N. Lat. 13°.

VINCI, Leonardo da, an illustrious Italian painter, descended from a noble Tuscan family, was born in the castle of Vinci, near Florence in 1445. He was placed under Andrea Verochia, a celebrated painter in that city; but soon surpassed him and all his predecessors so much as to be reputed the master of the third or golden age of modern painting. But his studies were far from terminating here; no man's genius was more universal: he applied himself to arts, to literature, and to the accomplishments of the body; and he excelled in every thing which he attempted. Lewis Sforza duke of Milan prevailed on him to be director of the academy for architecture he had just established; where Leonardo soon banished all the Gothic fashions, and reduced every thing to the happy simplicity of the Greek and Roman style. By the duke's order he constructed the famous aqueduct that supplies the city of Milan with water: this canal goes by the name of *Mortesana*, being above 200 miles in length, and conducts the water of the river Adda quite to the walls of the city. In 1479, he was desired to construct some new device for the entertainment of Louis XII. of France, who was then to make his entrance into Milan. Leonardo accordingly made a very curious automaton in the form of a lion, which marched out to meet the king, reared up on its hinder legs before him, and opening its breast, displayed an escutcheon with fleurs-de-lis quartered on it. The disorders of Lombardy, with the misfortunes of his patrons the Sforzi, obliging Leonardo to quit Milan, he retired to Florence, where he flourished under the Medici: here he raised the envy of Michael Angelo, who was his contemporary; and Raphael, from the study of his works, acquired his best manner of designing. At length, on the invitation of Francis I. he removed to France when above 70 years of age; where the journey and change of climate threw him into his last sickness: he languished for some months at Fontainbleau, where the king came frequently to see him; and one day rising up in his bed to acknowledge the honour done him, he fainted, and Francis supporting him, Leonardo died in his arms. His death happened in 1520. Some of his paintings are to be seen in England and other countries, but the greatest part of them are in Florence and France. He composed a great number of discourses on curious subjects; but none of them have been published but his treatise on the Art of Painting.—For his anatomical knowledge, see Anatomy (history of), p. 669.

Vinci, Virgil.

VINCULUM, in *Algebra*, a character in form of a line or stroke drawn over a factor, divisor, or dividend, when compounded of several letters or quantities, to connect them, and shows that they are to be multiplied or divided, &c. together by the other term.

Thus $d \times \overline{a+b-c}$ shows that d is to be multiplied into $a+b-c$.

VINE. See Vitis, Botany *Index*.

VINEGAR, Acetum, an agreeable acid, prepared from wine, cyder, beer, and other liquors; of considerable use, both as a medicine and a sauce. The word is French, *vinaigre;* formed from *vin*, "wine;" and *aigre*, "sour." See Acetic *Acid*, and Chemistry *Index*.

Eels in Vinegar. See Animalcule, N° 9.

VINEYARD, a plantation of vines. The best situation of a vineyard is on the declivity of a hill facing the south.

VIO, Thomas de. See Cajetan.

VIOL, a musical instrument of the same form with the violin, and, like that, struck with a bow.

VIOLA, a genus of plants of the class syngenesia; in the natural system arranged under the 29th order, *Campanaceæ*. See Botany *Index*.

VIOLATION, the act of violating, that is, forcing a woman, or committing a rape upon her.—This term is also used in a moral sense, for a breach or infringement of a law, ordinance, or the like.

VIOLET. See Viola, Botany *Index*.

Violet-Crab. See Cancer, Entomology *Index*.

VIOLIN, or Fiddle, a musical instrument mounted with four strings or guts, and struck or played with a bow. The style and sound of the violin is the gayest and most sprightly of all other instruments; and hence it is of all others the fittest for dancing. Yet there are ways of touching it, which render it grave, soft, languishing, and fit for church or chamber music.—It generally makes the treble or highest part in concerts. Its harmony is from fifth to fifth. Its play is composed of bass, counter-tenor, tenor, and treble; to which may be added, a fifth part: each part has four fifths, which rise to a greater seventeenth.

VIOLONCELLO, of the Italians, is properly our fifth violin; which is a little bass violin half the size of the common bass violin, and the strings bigger and longer in proportion; consequently its sound is an octave lower than our bass violin; which has a noble effect in concerts.

VIPER. See Ophiology *Index*.

VIRAGO, a woman of extraordinary stature and courage; who has the mein and air of a man, and performs the actions and exercises of men.

VIRGIL, or Publius Virgilius Maro, the most excellent of all the Latin poets, was the son of a potter of of Andes, near Mantua, where he was born, 70 years B. C. He studied first at Mantua; then at Cremona, Milan, and Naples; whence going to Rome, he acquired the esteem of the greatest wits and most illustrious persons of his time; and among others of the emperor Augustus, Mæcenas, and Pollio. He was well skilled not only in polite literature and poetry, but also in philosophy, the mathematics, geography, medicine, and natural history. Though one of the greatest geniuses of his age, and the admiration of the Romans, he always preserved a singular modesty, and lived chaste at a time when the manners of the people were extremely corrupt. He carried Latin poetry to such a high perfection, that he was justly esteemed the prince of Latin poets. He first turned himself to pastoral; and being captivated with the beauty and sweetness of Theocritus, was ambitious to introduce this new species of poetry among the Romans. His first performance in this way is supposed to have been written U. C. 709, the year before the death of Julius Cæsar, when the poet was in his 25th year: it is intitled *Alexis*. Possibly *Palæmon* was his second: it is a close imitation of the fourth and fifth Idylls of Theocritus. Mr Wharton places *Silenus* next; which is said to have been publicly recited on the stage by Cytheris, a celebrated comedian. Virgil's fifth eclogue is composed in allusion to the death and deification of Cæsar. The battle of Philippi in 712 having put an end to the Roman liberty, the veteran soldiers began to murmur for their pay; and Augustus, to reward them, distributed among them the lands of Mantua and Cremona. Virgil was involved in this common calamity; and applied to Varus and Pollio, who warmly recommended him to Augustus, and procured for him his patrimony again. Full of gratitude to Augustus, he composed the *Tityrus*, in which he introduces two shepherds; one of them complaining of the distraction of the times, and of the havock the soldiers made among the Mantuan farmers; the other rejoicing for the recovery of his estate, and promising to honour as a god the person who restored it to him. But our poet's joy was not of long continuance; for we are told, that when he returned to take possession of his farm, he was violently assaulted by the intruder, and would certainly have been killed by him if he had not escaped by swimming hastily over the Mincio. Upon this unexpected disappointment, he returned to Rome to renew his petition; and during his journey seems to have composed his ninth eclogue. The celebrated eclogue, intitled *Pollio*, was composed U. C. 714, upon the following occasion: The consul Pollio on the part of Antony, and Mæcenas on the part of Cæsar, had made up the differences between them; by agreeing, that Octavia, half-sister to Cæsar, should be given in marriage to Antony. This agreement caused an universal joy; and Virgil, in his eclogue, testified his. Octavia was with child by her late husband Marcellus at the time of this marriage; and whereas the Sibylline oracles had foretold, that a child was to be born about this time, who should rule the world, and establish perpetual peace, the poet ingeniously supposes the child in Octavia's womb to be the glorious infant, under whose reign mankind was to be happy, the golden age to return from heaven, and fraud and violence to be no more. In this celebrated poem, the author, with great delicacy at the same time, pays his court to both the chiefs, to his patron Pollio, to Octavia, and to the unborn infant. In 715, Pollio was sent against the Parthini, a people of Illyricum; and during this expedition, Virgil addressed to him a beautiful eclogue, called *Pharmaceutria*. His tenth and last eclogue was addressed to Gallus.

In his 34th year, he retired to Naples, and laid the plan of his Georgics; which he undertook at the intreaties of Mæcenas, to whom he dedicated them. This wise and able minister resolved, if possible, to revive the decayed spirit of husbandry; to introduce a taste for agriculture, even among the great; and could not think of a better method to effect this, than to recommend it by the insinuating charms of poetry. Virgil fully answsred the expectations of his patron by his Georgics. They are divided into four books. Corn and ploughing are the subject of the first, vines of the second, cattle of the third, and bees of the fourth.

He is supposed to have been in his 45th year when he began to write the Æneid; the design of which was to reconcile the Romans to the government of Augustus. Augustus was eager to peruse this poem before it was finished; and intreated him by letters to communicate it. Macrobius has preserved to us part of one of Virgil's answers to the emperor, in which the poet excuses himself: who, however, at length complied, and read himself the sixth book to the emperor; when Octavia, who had just lost her son Marcellus, the darling of Rome, and adopted son of Augustus, made one of the audience. Virgil had artfully inserted that beautiful lamentation for the death of young Marcellus, beginning with—*O nate, ingentem luctum ne quære tuorum*—but suppressed his name till he came to the line —*Tu Marcellus eris:* upon hearing which, Octavia could bear no more, but fainted away, overcome with surprise and sorrow. When she recovered, she made the poet a present of ten sesterces for every line, which amounted in the whole to above 2000l.

The Æneid being brought to a conclusion, but not to the perfection our author intended to give it, he resolved to travel into Greece, to correct and polish it at leisure. It was probably on this occasion that Horace addressed that affectionate ode to him, *Sic te Divæ potens Cypri, &c.* Augustus returning victorious from the east, met with Virgil at Athens, who thought himself obliged to attend the emperor to Italy: but the poet was suddenly seized with a fatal distemper, which being increased by the agitation of the vessel, put an end to his life as soon as he landed at Brundusium, in his 52d year. He had ordered in his will, that the Æneid should be burnt as an unfinished poem; but Augustus forbade it, and had it delivered to Varius and Tucca, with the strictest charge to make no additions, but only to publish it correctly. He died with such steadiness and tranquillity, as to be able to dictate his own epitaph in the following words:

Mantua me genuit: Calabri rapuere, tenet nunc
Parthenope: cecini Pascua, Rura, Duces.

His bones were carried to Naples, according to his earnest request; and a monument was erected at a small distance from the city.

Virgil was of a swarthy complexion, tall, of a sickly constitution, and afflicted with frequent headachs, and spitting of blood. He was so very bashful, that he often ran into the shops to prevent being gazed at in the streets;

streets; yet was so honoured by the Roman people, that once coming into the theatre, the whole audience rose up out of respect to him. He was of a thoughtful and melancholy temper; he spoke little, and loved retirement and contemplation. His fortune was affluent; he had a fine house and well furnished library near Mæcenas's gardens, on the Esquiline mount at Rome, and also a delightful villa in Sicily. He was so benevolent and inoffensive, that most of his contemporary poets, though they envied each other, agreed in loving and esteeming him. He revised his verses with prodigious severity; and used to compare himself to a she bear, which licked her cubs into shape.

The best edition of Virgil's works are those of Mosvicius, with the notes of Servius, printed at Lewarden in 1717, two vols 4to; and that of Burman, at Amsterdam, 1746, in four vols 4to. There are several English translations, which are well known.

VIRGIL, *Polydore*, an English historian, born at Urbino in Italy, was sent in the beginning of the 16th century by Pope Alexander VI. as sub-collector of the Papal tax, called *Peter-pence*, in this kingdom. He had not been long in England before he obtained preferment in the church; for in 1503 he was presented to the rectory of Church-Langton in the archdeaconry of Leicester. In 1507 he was collated to the prebend of Scamlesby in the church of Lincoln; and in the same year was made archdeacon of Wells, and prebendary of Hereford. In 1513, he resigned his prebend of Lincoln, and was collated to that of Oxgate in St Paul's, London. We are told, that on his preferment to the archdeaconry of Wells, he resigned the office of sub-collector to the pope, and determined to spend the remainder of his life in England, the History of which kingdom he began in the year 1505, at the command of Henry VII. That work cost him 12 years labour. In 1526, he finished his treatise on Prodigies. Polydore continued in England during the whole reign of Henry VIII. and part of that of Edward VI. whence it is concluded that he was a moderate Papist. In 1550, being now an old man, he requested leave to revisit his native country. He was accordingly dismissed with a present of 300 crowns, together with the privilege of holding his preferments to the end of his life. He died at Urbino in the year 1555. As an historian, he is accused by some as a malignant slanderer of the English nation; yet Jovius remarks, that the French and Scotch accuse him of having flattered that nation too much: (See his *Elog*. cap. 135. p. 179.). Besides the above, he wrote, 1. *De Rerum Inventoribus;* of which an English translation was published by Langley in 1663. It was also translated into French and Spanish. 2. *De Prodigiis et Sortibus*. 3. *Episcoporum Angliæ Catalogus*. Manuscript. 4. *De Vita Perfecta*, Basil, 1546, 1553, 8vo. 5. *Epistolæ Eruditæ;* and some other works.

VIRGINIA, one of the United States of the North American republic. It is bounded by the sea and the bay of Chesapeake on the east, by Maryland and Pennsylvania on the north, by Ohio and Kentucky on the west, and by North Carolina on the south. Its greatest length east and west is 350 miles; its breadth 220; and its area is about 56,000 square miles. About one-third of the surface of this state is occupied by the different ridges of the Alleghany chain, which traverse it in the direction of north-east and south-west. These ridges rise to the height of about 3000 feet, and are generally covered with natural wood. That part of the country which lies immediately along the shores of the ocean and the Chesapeake bay is generally flat, sandy, and so poor as to admit of cultivation only on the banks of the rivers. This tract extends about 60 or 80 miles inward. Beyond it, as far as the foot of the Blue ridge or eastern chain of the Alleghanies, the soil is greatly superior, and bears excellent crops of wheat, maize, barley, tobacco, hemp, &c. The soil of of the broad valleys between the Alleghany ridges is similar, and that on the western slope of the mountains reaching to the banks of the Ohio, is believed to be the richest of the whole.

In point of climate, this state is probably one of the most agreeable in North America. The extremes of heat and cold, at Mr Jefferson's seat of Monticello, are 98° above, and 6° below zero. The mean annual temperature at Williamsburg is 57°; and the average annual quantity of rain 47 inches.

It is remarkable that, proceeding on the same parallel of latitude westwardly, the climate becomes colder in like manner as when you proceed northwardly. This continues to be the case till you attain the summit of the Alleghany, which is the highest land between the ocean and the Mississippi. From thence, descending in the same latitude towards the Mississippi, the change reverses; and, if we may believe travellers, it becomes warmer there than it is in the same latitude on the seaside.

The principal rivers of this state are, James's river, which falls into the Chesapeake bay after a course of 270 miles, through the greater part of which it admits of boat navigation; York river; Rappahanock; the Patowmac, which separates Virginia from Maryland; the Shenandoah, which falls into the Patowmac; the Monongahela; the Ohio; and the Kenhawa. These rivers afford a great extent of inland navigation, and have contributed much to the improvement of the state.

Iron and lead ores are found and worked in several places. Native copper, manganese, and antimony, have also been discovered. Lime is abundant on the west side, and coal is found on both sides of the mountains. Salt is also extracted in great quantities from springs on the banks of some of the branches of the Ohio.

The wild animals are now scarce on the east side of the Alleghanies, but the bear, wolf, deer, racoon, opossum, are still numerous in the western parts. There are rattlesnakes and serpents of a large size, but they are rarely met with. The remains of the mammoth have been found also in this state. There are various species of wild fowl, of which the most esteemed are the turkeys. The rivers and bays contain a great variety of fish; with which the towns on the coast are generally well supplied.

This state was first settled in 1607 when the whole inhabitants amounted only to 40 persons. In 1703 they amounted to 60,000; in 1790 to 747,610; and in 1810 to 974,672, including 392,518 slaves. The inhabitants of the upper country are generally much above the average stature of Europeans, and strong and active in proportion. On the coast, where the climate is rather unhealthy, the inhabitants are not so tall or athletic. The Virginians are polite, frank, liberal,

beral, and high spirited; but they are charged with being impetuous, proud, indolent, superficial in their acquirements, addicted to gaming, and lax in their morals. The most prominent defects in their character may be attributed to the debasing influence of slavery.

The legislature consists of a senate and house of delegates; the former composed of 24 members chosen for four years; the latter of two freeholders for each county, and one for each city, chosen annually by the persons possessing land. The executive power is vested in the governor, assisted by a council of eight members chosen annually by both houses of the legislature. The judges are appointed by the legislature, and hold their offices during good behaviour. The clergy are supported by voluntary contributions. The Presbyterians are the most numerous sect.

There are two colleges in this state: That of William and Mary, founded in 1692, is under the direction of 20 governors, who appoint the president and professors, and frame regulations. There are five professorships, viz. law, medicine, mathematics, philosophy, and modern languages. Hampden and Sydney college in Prince Edward county has been lately established. There are academies in all the considerable towns. Hitherto there has been a want of the means of elementary education in this state; but in 1816 the legislature set apart one million of dollars for the support of schools.

The produce of this state consists of tobacco, which is cultivated to a great extent eastward of the Alleghany mountains; maize, or Indian corn, which yields from 12 to 50 bushels an acre; wheat, which yields on an average 15 bushels an acre, being generally raised from land that has been exhausted by crops of tobacco; rice on the borders of the swamps; buck wheat, oats, hemp, and cotton; the last not to a great extent. Potatoes are in general use. Among the fruits are plums, almonds, pomegranates, figs, peaches, and melons. The breeds of cattle and horses are much inferior in general to those of Pennsylvania. Mules and oxen are much employed in agricultural labour. Merino sheep have been introduced, and are extending through the state. Great numbers of hogs are fed on acorns in the woods.

The manufactures of this state are inconsiderable. They consist chiefly of spirits, brewed liquors, salt, cabinet ware, leather, and linen for domestic use. The whole value of manufactures in 1810 was estimated at 12,263,473 dollars.

The exports consist chiefly of tobacco, wheat, maize, lumber, tar, turpentine, beef, pork, peltries, &c. The imports are manufactured articles of all kinds, and West India produce. In 1817 the exports amounted to 5,621,442 dollars, of which 60,204 dollars were for foreign produce, and the rest for articles of domestic growth. In 1815 the shipping belonging to this state amounted to 71,492 tons. The principal trading port is Northfolk; the next in importance is Richmond the capital.

Virginia, like the other states, has advanced rapidly since the revolution; and having still vast tracts of uncleared land, she has yet a great progress to make. The baneful influence of slavery, however, will undoubtedly throw her behind the northern and middle states, and the restrictions on the elective franchise have also a tendency to prevent the industrious classes from settling here. The value of lands and houses in Virginia in 1799 was estimated in the official returns at 71,225,127, and in 1815 at 165,608,199 dollars. But including slaves the value in 1815 was 263,737,699 dollars. Virginia has had the honour of giving four presidents to the republic; Washington, Jefferson, Madison, and Munroe. The two first, as well as several other citizens of this state, have been ranked among most distinguished men whom America has produced.

VIRGO, in *Astronomy*, one of the signs or constellations of the zodiac.

VIRGULA DIVINATORIA, divining rod. See MINE.

VIRTUAL, or POTENTIAL; something that has a power or virtue of acting or doing. The term is chiefly understood of something that acts by a secret invisible cause, in opposition to actual and sensible.

VIRTUE, a term used in various significations. In the general it denotes power, or the perfection of any thing, whether natural or supernatural, animate or inanimate, essential or accessory. But, in its more proper or restrained sense, virtue signifies a habit, which improves and perfects the possessor and his actions. See MORAL PHILOSOPHY, N° 84.

VIRTUOSO, an Italian term lately introduced into the English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences. But among us the term seems to be appropriated to those who apply themselves to some curious and quaint rather than immediately useful art or study; as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

VIRULENT, a term applied to any thing that yields a virus; that is, a contagious or malignant pus.

VISCERA, in *Anatomy*, a term signifying the same with entrails; including the heart, liver, lungs, spleen, intestines, and other inward parts of the body.

VISCIDITY, or VISCOSITY, the quality of something that is viscid or viscous; that is, glutinous and sticky like bird-lime, which the Latins call by the name of *viscus*.

VISCOUNT (*Vice Comes*), was anciently an officer under an earl, to whom, during his attendance at court, he acted as deputy to look after the affairs of the country. But the name was afterwards made use of as an arbitrary title of honour, without any shadow of office pertaining to it, by Henry VI.: when in the 18th year of his reign, he created John Beaumont a peer by the name of *Viscount Beaumont;* which was the first instance of the kind.

A viscount is created by a patent as an earl is; his title is *Right Honourable;* his mantle is two doublings and a half of plain fur; and his coronet has only a row of pearls close to the circle.

VISCUM, a genus of plants of the class diœcia, and in the natural system arranged under the 48th order, *Aggregatæ*. See BOTANY *Index*.

VISHNOU, that person in the triad of the Bramins who is considered as the *preserver* of the universe. *Brahma* is the creator, and *Siva* the destroyer; and these two, with Vishnou, united in some inexplicable manner, constitute *Brahme*, or the supreme numen of the Hindoos. See POLYTHEISM, N° 36.

VISIBLE, something that is an object of sight or vision; or something whereby the eye is affected so as to produce this sensation.

VISIER, an officer or dignitary in the Ottoman empire,

pire, whereof there are two kinds; one called by the Turks *Visier-azem*, that is, "grand visier," is the prime minister of state in the whole empire. He commands the army in chief, and presides in the divan or great council. Next to him are six other subordinate visiers, called *visiers of the bench;* who officiate as his counsellors or assessors in the divan.

VISION, in *Optics*, the act of seeing or perceiving external objects by means of the organ of sight, the eye. See ANATOMY, N° 142, and METAPHYSICS, N° 49—54.

VISTULA, or WEISEL, a large river of Poland, which taking its rise in the mountains south of Silesia, visits Cracow, Warsaw, &c. and continuing its course northward, falls into the Baltic sea below Dantzic.

VISUAL, in general, something belonging to vision.

VITAL, in *Physiology*, an appellation given to whatever ministers principally to the constituting or maintaining life in the bodies of animals: thus the heart, lungs, and brain, are called *vital parts;* and the operations of these parts by which the life of animals is maintained are called *vital functions*.

VITELLUS, the yolk of an egg.

VITIS, or VINE, a genus of the class pentandria, and in the natural system arranged under the 46th order, *Hederaceæ*. See BOTANY *Index;* and for its culture, see GARDENING.

VITREOUS HUMOUR OF THE EYE. See ANATOMY, N° 142.

VITRIFICATION, in *Chemistry*, the conversion of a body into glass by means of fire. See GLASS.

VITRIOL, a compound salt, formed by the union of iron, copper, or zinc, with sulphuric acid; hence called from the colours white, blue, and green, according to the metal. See CHEMISTRY.

VITRIOLATED, among chemists, something impregnated, or supposed to be so, with vitriol or its acid.

VITRIOLIC ACID. See *SULPHURIC Acid* and CHEMISTRY *Index*.

VITRUVIUS POLLIO, MARCUS, a very celebrated Roman architect, was, according to the common opinion, born at Verona, and lived in the reign of Augustus, to whom he dedicated his excellent treatise on architecture, divided into ten books. William Philander's edition of this celebrated work is esteemed. Claudius Perrault has given an excellent translation of it in French, with learned notes. There are also several English translations of Vitruvius.

VITUS'S DANCE. See MEDICINE, N° 284.

VIVERRA, the WEASEL; a genus of quadrupeds belonging to the order of feræ. See MAMMALIA *Index*.

VIVES. See FARRIERY.

VIVIPAROUS, in *Natural History*, an epithet applied to such animals as bring forth their young alive and perfect; in contradistinction to those that lay eggs, which are called *oviparous* animals.

UKRAINE, a large country of Europe, lying on the borders of Turkey in Europe, Poland, Russia. and Little Tartary. Its name properly signifies a *frontier*. By a treaty between Russia and Poland in 1693, the latter remained in possession of all that part of the Ukraine lying on the west side of the river Dnieper, which is but indifferently cultivated; while the country on the east side, inhabited by the Cossacs, is in much better condition. The Russian part is comprised in the government of Kiof; and the empress of Russia having obtained the Polish palatinate of Kiof, by the treaty of partition in 1793, the whole of the Ukraine, on both sides of the Dnieper, belongs now to that ambitious and formidable power. The principal town is Kiof.

ULCER, in *Surgery*. See SURGERY *Index*.

ULCER, in *Farriery*. See FARRIERY.

ULEX, a genus of plants of the class of diadelphia, and in the natural system arranged under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

ULIETEA, one of the Society islands in the South sea. This island is about 21 leagues in circuit. Its productions are plantains, cocoa-nuts, yams, hogs, and fowl; the two latter of which are scarce. The soil on the top of one of the hills was found to be a kind of stone marle; on the sides were found some scattered flints, and a few small pieces of a cavernous or spongy stone lava, of a whitish colour, which seemed to contain some remains of iron, so that it may possibly be here lodged in the mountains in a great quantity. Nothing was seen on this island to distinguish either its inhabitants, or their manners, from the other neighbouring islands. The first Europeans who landed on this shore were Mr (now Sir Joseph) Banks and Dr Solander; they were received by the natives in the most courteous manner, reports concerning them having been their harbingers from Otaheite. Every body seemed to fear and respect them, placing in them at the same time the utmost confidence: behaving, as if conscious that their visitors possessed the power of doing them mischief without a disposition to make use of it.

ULIGINOUS, in *Agriculture* an appellation given to a moist, moorish, and fenny soil.

ULLAGE, in gauging, is so much of a cask or other vessel as it wants of being full.

ULM, formerly a free and imperial city of Germany, but now belonging to Bavaria. It is a pretty large place, defended by fortifications; and the inhabitants, who are chiefly Protestants, amounted to 14,000 in 1800. The town is seated on the Danube, a little above the confluence of that river and the Iller, and carries on a considerable trade. It has many handsome buildings. The principal church is a magnificent Gothic edifice, and is said to surpass all the cathedrals in Germany in height. The Roman Catholics have but two churches, all the rest belonging to the Protestants. E. Long. 9. 59. N. Lat. 48. 25.

ULMUS, a genus of plants belonging to the class of pentandria; and in the natural system arranged under the 53d order, *Scabridæ*. See BOTANY *Index*.

ULSTER, the most northerly province of Ireland. In Latin it is called *Ultonia*, in Irish *Cui Guilly*; and gives the title of *earl* to the dukes of York of the royal family. It is bounded by the Atlantic ocean on the west, St George's channel and the Irish sea on the east, the Deucaledonian ocean on the north, and on the south and south-west the provinces of Leinster and Connaught. Its greatest length is near 120 miles, its breadth about 100; and its circumference, including the windings and turnings, 460; containing 9 counties, 58 market-towns and boroughs, 1 archbishopric, 6 bishoprics, and 214 parishes. Ulster abounds in lakes and rivers, which supply it with variety of fine fish, especially salmon, besides what it has from the sea, with which a great part of it is bounded. The southern parts of it are rich, fertile,

tile, well cultivated, and inclosed; but the greater part of the northern is open and mountainous.—The towns of this province are in general the neatest and best built of any in Ireland, as well as the farm-houses; which in most parts of the kingdom are constructed of no better materials than clay and straw. The inhabitants of Ulster are also more like the English in their manners and dialect than those of the other three provinces: for as it includes within itself the whole, or by far the greater part, of the linen manufactory, the best branch of trade in the kingdom, they have consequently the greatest intercourse with England. An Englishman, in some parts of it, indeed, will imagine himself, from the similarity of their language and manners, in his own country. This province had anciently petty kings of its own. It was first subjected to the English in the reign of Henry II. by John Courcy, the first who bore the title of *earl of Ulster;* but it afterwards threw off the yoke, and was never entirely reduced till the reign of James I. when great numbers of Scots by his encouragement went and settled in it. Of these, most of the present inhabitants are the descendants. This province was the first and principal scene of the bloody massacre in 1641. See ULSTER, SUPPLEMENT.

ULTERIOR, in *Geography*, is applied to some part of a country or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary which separates the two countries.

ULTRAMARINE, a beautiful blue colour used by the painters, prepared from the lapis lazuli by calcination. See LAZULITE, MINERALOGY *Index*.

ULTRAMONTANE, something beyond the mountains. The term is principally applied in relation to France and Italy, which are separated by the Alps.

ULVA, a genus of plants of the class of cryptogamia. See BOTANY *Index*.

ULUG BEIG, a Persian prince and learned astronomer, was descended from the famous Tamerlane, and reigned at Samarcand about 40 years; after which he was murdered by his own son in 1449. His catalogue of the fixed stars, rectified for the year 1434, was published at Oxford by Mr Hyde, in 1665, with learned notes. Mr Hudson printed in the English Geography Ulug Beig's Tables of the Longitude and Latitude of Places; and Mr Greaves published, in Latin, his Astronomical Epochas, at London, in 1650. See ASTRONOMY *Index*.

ULYSSES, king of Ithaca, the son of Laertes, and father of Telemachus, and one of those heroes who contributed most to the taking of Troy. After the destruction of that city, he wandered for 10 years; and at last returned to Ithaca, where, with the assistance of Telemachus, he killed Antinous and other princes who intended to marry his wife Penelope and seize his dominions. He at length resigned the government of the kingdom to his son Telemachus; and was killed by Telegonus, his son by Circe, who did not know him. This hero is the subject of the Odyssey.

UMBELLA, an UMBEL, a species of receptacle; or rather a mode of flowering, in which a number of slender footstalks proceed from the same centre, and rise to an equal height, so as to form an even and generally round surface at top. See BOTANY.

UMBELLATÆ, the name of a class in Ray's and Tournefort's methods, consisting of plants whose flowers grow in umbels, with five petals that are often unequal, and two naked seeds that are joined at top and separated below.

The same plants constitute the 45th order of Linnæus's Fragments of a Natural Method. See BOTANY.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella.

UMBER, or UMBRE, a fossil brown or blackish substance, used in painting. See MINERALOGY *Index*.

UMBILICAL, among anatomists, something relating to the umbilicus or navel.

UMBRELLA, a moveable canopy, made of silk or other cloth spread out upon ribs of whale-bone, and supported by a staff, to protect a person from rain, or the scorching beams of the sun.

UMPIRE, a third person chosen to decide a controversy left to arbitration.

UNCIA, in general, a Latin term, denoting the twelfth part of any thing; particularly the twelfth part of a pound, called in English an *ounce;* or the twelfth part of a foot, called an *inch*.

UNCTION, the act of anointing or rubbing with oil or other fatty matter.

UNCTION, in matters of religion, is used for the character conferred on sacred things by anointing them with oil. Unctions are very frequent among the Hebrews. They anointed both their kings and high-priests at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The unction of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said that none of the emperors were ever anointed before Justinian or Justin. The emperors of Germany took the practice from those of the eastern empire: King Pepin of France was the first who received the unction. In the ancient Christian church, unction always accompanied the ceremonies of baptism and confirmation. Extreme unction, or the anointing persons in the article of death, was also practised by the ancient Christians, in compliance with the precept of St James, chap. v. 14th and 15th verses; and this extreme unction the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are affected with some mortal disease, or in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of it; because the palms of their hands have been already consecrated by ordination.

The oil with which the sick person is anointed represents the grace of God, which is poured down into the soul, and the prayer used at the time of anointing expresses the remission of sins thereby granted to the sick person; for the prayer is this: "By this holy unction, and his own most pious mercy, may the Almighty God forgive thee whatever sins thou hast committed *by the sight*," when the eyes are anointed; *by the hearing*, when the ears are anointed; and so of the other senses *.

* *The Sincere Christian instructed from the Written Word.*

UNDECAGON, is a regular polygon of 11 sides.

UNDECEMVIR, a magistrate among the ancient Athenians, who had 10 other colleagues or associates joined with him in the same commission. The functions of the undecemviri at Athens were much the same with those of the late *prevots de marechaussee* in France. They took care of the apprehending of criminals; secured them in the hands of justice; and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Callisthenes was but 10, which made 10 members, a scribe or notary was added, which made the number 11.

UNDERSTANDING. See METAPHYSICS and LOGIC.

UNDERWALDEN, a canton of Switzerland, and the sixth in rank. It is bounded on the north by the canton of Lucern and by the lake of the Four Cantons, on the east by the high mountains which separate it from the canton of Bern, and on the west by the canton of Bern. The religion of this canton is the Roman Catholic.

UNDULATION, in *Physics*, a kind of tremulous motion or vibration observable in a liquid, by which it alternately rises and falls like the waves of the sea.

UNGUENT, or OINTMENT, in *Medicine* and *Surgery*, a tropical remedy or composition, chiefly used in the dressing of wounds or blisters. See MATERIA MEDICA.

UNICORN, an animal famous among the ancients, and thought to be the same with the rhinoceros.

Sparmann informs us, that the figure of the unicorn described by the ancients has been found delineated by the Snese Hottentots on the plain surface of a rock in Caffraria; and therefore conjectures, that such an animal either does exist at present in the internal parts of Africa, or at least once did so. Father Lobo affirms that he has seen it. Mr Barrow, in his *Travels in Southern Africa*, affords additional reason to believe in the existence of this curious animal.

UNICORN-Fish. See MONODON, CETOLOGY *Index*.

UNIFORM, denotes a thing to be similar, or consistent either with another thing, or with itself, in respect of figure, structure, proportion, or the like; in which sense it stands opposed to difform.

UNIFORMITY, regularity, a similitude or resemblance between the parts of a whole. Such is that we meet with in figures of many sides, and angles respectively equal, and answerable to each other. A late ingenious author makes beauty to consist in uniformity, joined or combined with variety. Where the uniformity is equal in two objects, the beauty, he contends, is as the variety; and where the variety is equal, the beauty is as the uniformity.

UNIFORMITY, is particularly used for one and the same form of public prayers, and administration of sacraments, and other rites, &c. of the church of England, prescribed by the famous stat. 1. Eliz. and 13 and 14 Car. II. cap. 4. called the *Act of Uniformity*. See LITURGY.

UNION, a junction, coalition, or assemblage of two or more different things in one.

UNION, or *The Union*, by way of eminence, is more particularly used to express the act by which the two separate kingdoms of England and Scotland were incorporated into one, under the title of *The kingdom of Great Britain*. This union, in vain attempted by King James I. was at length effected in the year 1707, 6 Annæ, when 25 articles were agreed to by the parliament of both nations; the purport of the most considerable being as follows:

1. That on the first of May 1707, and for ever after the kingdoms of England and Scotland shall be united into one kingdom, by the name of *Great Britain*.

2. The succession to the monarchy of Great Britain shall be the same as was before settled with regard to that of England.

3. The united kingdom shall be represented by one parliament.

4. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed.

9. When England raises 2,000,000l. by a land tax, Scotland shall raise 48,000l.

16, 17. The standards of the coin, of weights, and of measures, shall be reduced to those of England throughout the united kingdoms.

18. The laws relating to trade, customs, and the excise, shall be the same in Scotland as in England. But all the other laws of Scotland shall remain in force; but alterable by the parliament of Great Britain. Yet with this caution, that laws relating to public policy are alterable at the discretion of the parliament; laws relating to private right are not to be altered but for the evident utility of the people of Scotland.

22. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and 45 members to sit in the house of commons.

23. The 16 peers of Scotland shall have all privileges of parliament; and all peers of Scotland shall be peers of Great Britain, and rank next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords, and voting on the trial of a peer.

These are the principal of the 25 articles of union, which are ratified and confirmed by statute 5 Ann. c. 8. in which statute there are also two acts of parliament recited; the one of Scotland, whereby the church of Scotland, and also the four universities of that kingdom, are established for ever, and all succeeding sovereigns are to take an oath inviolably to maintain the same; the other of England, 5 Annæ, c. 6. whereby the acts of uniformity of 13 Eliz. and 13 Car. II. (except as the same had been altered by parliament at that time), and all other acts then in force for the preservation of the church of England, are declared perpetual; and it is stipulated, that every subsequent king and queen shall take an oath inviolably to maintain the same within England, Ireland, Wales, and the town of Berwick-upon-Tweed. And it is enacted, that these two acts "shall for ever be observed as fundamental and essential conditions for the union."

Upon these articles and act of union, it is to be observed, 1. That the two kingdoms are so inseparably united, that nothing can ever disunite them; except the mutual consent of both, or the successful resistance of either, upon apprehending an infringement of those points which, when they were separate and independent nations, it was mutually stipulated should be "fundamental and essential conditions of the union." 2. That whatever else may be deemed "fundamental and essential conditions," the preservation of the two churches, of England and Scotland, in the same state that they were in at the time of the union, and the maintenance of

Union ‖ United Brethren.

of the acts of uniformity which established the liturgy, are expressly declared so to be. 3. That therefore any alteration in the constitution of either of these churches, or in the liturgy of the church of England (unless with the consent of the respective churches, collectively or representatively given), would be an infringement of these "fundamental and essential conditions," and greatly endanger the union. 4. That the municipal laws of Scotland are ordained to be still observed in that part of the island, unless altered by parliament; and as the parliament has not yet thought proper, except in a few instances, to alter them, they still, with regard to the particulars unaltered, continue in full force.

For an account of the union of Ireland with Great Britain, thus forming the *united kingdom of Great Britain and Ireland*, see IRELAND, N° 120.

UNISON, in *Music*. See INTERVAL.

UNIT, or UNITY, in *Arithmetic*, the number one; or one single individual part of discrete quantity.

UNITARIANS, in ecclesiastical history, a name given to those who confine the glory and attribute of divinity to the One only great and supreme God, and Father of our Lord Jesus Christ.

UNITED BRETHREN, or *Unitas Fratrum*, a society of Christians, whose chief residence is at Herrnhut in Saxony. They are commonly called Moravians from their original country, and Herrnhuters, from their chief place of residence. Some account of this society has already been given under HERRNHUT; but as that account may, by some, not be deemed sufficiently full, we shall here add a summary of their institutes, derived from a communication by one of their own clergy.

Though the church of the United Brethren is episcopal, their bishops possess no elevation of rank or pre-eminent authority, their church being governed by synods or consistories from all the congregations, and by subordinate bodies, called conferences. The synods are generally held once in seven years. In the first sitting a president is chosen; and the elders appointed by the former synod to superintend the unity, lay down their office, though they still form a part of the assembly, as well as the bishops, the lay elders, and those ministers who have the inspection of several congregations in one province.

Questions of importance, or of which the consequences cannot be foreseen, are decided by lot, though this is never used till after mature deliberation and fervent prayer. In the synods, the state of the unity, and the concerns of the congregations and missions, are taken into consideration.

Towards the conclusion of every synod, a kind of executive board is appointed, called the *elders conference of the unity*, consisting of 13 elders, and divided into four committees or departments, one for superintending missions into heathen countries; a second for watching over the conduct of congregations; a third for managing the economical concerns of the unity, and a fourth for maintaining the discipline of the society. These conferences, however, are amenable to a higher committee, called the elders conference, the powers of which are very extensive. It appoints and removes every servant in the unity, authorises the bishops to ordain presbyters or deacons, and to consecrate other bishops, and in short, possesses the supreme executive power over the whole society.

United Brethren, United Provinces.

A bishop of the United Brethren can discharge no office but by the appointment of the synod, or of the elders conference. Indeed their deacons can perform every office of the bishops, except ordination, and appear to confirm young persons when they first become candidates for the communion. Even female deacons are employed for the purpose of privately admonishing their own sex, and visiting them in cases of sickness. There are also lay elders, whose business it is to watch over the constitution and discipline of the unity; to enforce the observance of the laws of the country in which missions are established, and to guard the privileges conferred on the brethren by the government under which they live.

On Sunday, besides the public prayers, one or two sermons are preached in every church, and after the morning service, an exhortation is given to the children. Previous to the holy communion, which is administered on some Sunday once a month, and on Maunday Thursday, each person, before he communicates, must converse on the state of his soul with one of the elders. Love feasts are frequent, and on Maunday Thursday the society have a solemn foot-washing.

Our limits will not permit us to give a systematic view of the doctrinal tenets of the Brethren. Though they acknowledge no other standard of truth than the sacred scriptures, they adhere to the Augsburg confession, and speak respectfully of the 39 articles of the church of England. They profess to believe that the kingdom of Christ is not confined to any particular party, community, or church; and they consider themselves as spiritually joined in the bond of Christian love to all who are taught of God, and belong to the universal church of Christ, however much they may differ in forms, which they deem non-essentials. For a fuller account of this society, see Crantz's Ancient and Modern History of the Protestant Church of the United Brethren, London 1780, and An Exposition of Christian Doctrine, as taught in the Protestant Church of the United Brethren, London 1784.

UNITED PROVINCES, otherwise called the *Republic of Holland*, or the *Batavian republic*, a maritime country of Europe, occupying that part of the Netherlands which lies between Austrian Flanders and Brabant, now forming a part of the kingdom of the Netherlands, which was erected in 1814. It is bounded on the north and west by the German ocean or North sea, and on the east by Westphalia. These provinces are situated between the parallels of 51° 10′, and 53° 35′ N. Lat. and between 3° 10′, and 7° 5′ E. Long. In British miles the length of this country from north to south, is estimated at 165, its breadth from west to east about 100, and its area at 10,000 square miles. 1 Situation and extent.

Before the French revolution, this part of the Low Countries was divided into seven provinces, viz. GUELDERLAND or GELDERS, HOLLAND, ZEALAND, UTRECHT, FRIESLAND, OVERYSSEL and GRONINGEN, besides the dependencies of *Dutch* BRABANT and *Dutch* FLANDERS. During the time the country was incorporated with France, it was divided into eight departments. The following table gives a general view of the subdivisions, area in geographical miles, population and chief towns of these provinces. 2 Division.

Provinces.	Subdivisions.	Area.	Population in 1796.	Chief Towns.
I. GUELDERLAND.	Nimeguen, Zutphen, Arnheim	1840	217,828	NIMEGUEN, Zutphen, Arnheim.
II. HOLLAND.	North Holland, South Holland	2000	828,542	AMSTERDAM, Rotterdam, Hague, Leyden, Haarlem, Helvoetsluys and Alkmaer.
III. ZEALAND.	West Zealand, East Zealand	uncertain	82,212	MIDDLEBURG, Flushing.
IV. UTRECHT.	Emeland, Abhoude, Montfort, Wyk	510	92,904	UTRECHT, Amersfort.
V. FRIESLAND.	Oostergo, Westergo, Zevenwolde, Northern islands	1155	161,513	LEEWARDEN, Dockum, Franeker, Harlingen, Bolswert.
VI. OVERYSSEL.	Salland, Twenthe, Woollenhoven, Drenthe	1792	135,060	DEVENTER, Zwol, Campen, Coeverden.
VII. GRONINGEN.	Groningen, Ommeland	640	114,555	GRONINGEN, Winchoten.
GENERALITY lands (A)	Drent, Dutch Brabant	2000	247,849	Bois-le-duc, Breda, Bergen-op-Zoom.
			1,880,563	

A great part of these provinces is composed of islands formed by the mouths of the large rivers which here disembogue their waters into the German ocean. The principal islands are *Walcheren*, *Joostland*, *South* and *North Beveland*, and *Wolfersdyk*, composing West Zealand; *Schowen*, *Duiveland*, *Fertholen*, and *St Phillipsland*, forming East Zealand; *Goeree* in *South Holland*, the *Texel*, *Vlieland*, and *Ameland*, to the west and north of Friesland.

3 Colonies. The Dutch had formerly considerable colonial territory; but this is now reduced to Java, Sumatra, and the Molucca islands, with some other settlements in the East Indies; some trifling factories on the Guinea coast; St Eustatius and part of Surinam in South America.

4 Surface, soil, &c. The face of the country is, in general, extremely uniform, consisting of large tracts of marshy pastures, or sandy heaths, interspersed with several large rivers, and numerous canals. There are a few hills in the eastern districts, but the coasts are so low, that, but for the *dykes* or sea walls, they would be inundated by the sea. The soil consists almost entirely of *alluvial* earth and vegetable mould, and is very productive. The climate is moist, inconstant, and peculiarly insalubrious to strangers; intermittent fevers and similar diseases, the attendants on a marshy and watery soil, being extremely frequent. The winters are colder and the summers hotter than in Britain.

5 Rivers and lakes. The principal rivers of the United Provinces are the Rhine, the Maese or Meuse, and the Escaut or Scheldt, which separates them from French Flanders. There are few lakes of any note, except the sea of Haerlem, near the Zuyder Zee.

There is little interesting in the natural history of Holland; the animals and plants resembling those of the adjacent countries of France and Germany and its mineral products being extremely few. Its chief artificial products are flax, tobacco, madder and flower roots, butter and cheese. The state of agriculture is but little advanced; as almost the whole country is under grass, and the corn produced is not nearly sufficient for home consumption. 6 Produce and agriculture.

The changes which the coasts of the Dutch provinces have undergone, in consequence of the shifting of the beds of rivers, the encroachments or retiring of the sea, and tempests from the German ocean, render their progressive geography an interesting object. We find that in the latter periods of the Roman empire, the river Rhine divided itself into two great branches at Burginasium, the modern Schenk, about five miles north-west of Colonia Trajana, near the present Cleves. The southern branch joined the Meuse at the town of Mosa or Muvi, while the northern branch passed by Durstadt, Utrecht, and Leyden, to the ocean. The northern branch of the Rhine was joined to the Yssel by the canal of Drusus (see BATAVORUM *Insula*), while this latter river flowed into a considerable lake called Flevo, now a southern portion of the Zuyder Zee. When the canal of Drusus was 7 Progressive geography.

(A) See each of these articles in the general alphabet.

United Provinces. was neglected, the waters of the Rhine poured into the Yssel with such violence as to increase the lake of Flevo to a great expanse of waters, so that instead of a river which once ran from that lake to the sea for nearly 50 Roman miles, there was opened the wide gulf which now forms the entrance. In the mean time, the northern branch of the Rhine became much diminished, and the canal of Drusus gradually disappeared. The estuaries of the Meuse and the Scheldt being open to great inroads from the sea, have also materially changed their figure and position; and the latter in particular, which once formed merely a triangular island, divided into four or five smaller branches, which are now extensive creeks, dividing the islands of Zealand and South Holland. In the beginning of the 15th century, the estuary of the Meuse suddenly formed a vast lake to the south-east of Dort, overwhelming 72 villages, and 100,000 inhabitants. By a subsequent change, the Rhine was again subdivided, the northern branch falling into the Leck, while the southern formed the modern Waal.

The early history of these provinces, from their subjection by the Romans, till they fell under the dominion of the Spanish monarchy, has been already given under the article NETHERLANDS, so that we have here to relate only those transactions which have taken place since the accession of Philip II. to the crown of Spain (B).

8 State of the Dutch provinces at the accession of Philip II. An. 1556.

At the death of Charles V. the Dutch provinces were in a very flourishing condition. In this small tract were then reckoned not fewer than 350 large walled cities, and 6300 considerable towns or large villages, all become rich by their application to arts and commerce. The same application had diffused a spirit of independence among the inhabitants, who were jealously alive to every invasion of their rights and privileges. The reformed religion had made considerable progress among all ranks, and the doctrines of Calvin had been embraced by a great majority of the people. Hence, nothing could be more impolitic than the measures taken by Philip to advance the cause of popery, and to enforce obedience to the tyrannical acts of his deputies. The establishment of a court of inquisition, the increase of the number of bishoprics, the appointment of Cardinal Grandvele to be chief counsellor to the duchess of Parma, then regent of the Netherlands, and the enormous taxes levied to support the Spanish forces, were no trifling grievances, and created such a spirit of disaffection, that when the duchess assumed the reins of government, in the year 1560, the murmurs of the people could no longer be suppressed.

9 Discontent occasioned by the tyrannical measures of Philip. An. 1564.

A deputation of the malcontents, at the head of whom were William prince of Orange, and his brother Louis of Nassau, with the counts of Egmont and Horn, waited on the duchess at Brussels, and insisted either on the dismissal of Cardinal Grandvele, or the calling of an assembly of the states-general. The duchess thought proper to comply with the former of these requests, but as that minister was succeeded by two of his creatures, who trod exactly in his footsteps, and in particular increased the religious persecutions, and the power of the inquisition, the popular ferment became greater than ever. The patriots sent Count Egmont to Madrid, to lay their grievances before the king; but that monarch with his accustomed insincerity, returned a favourable answer to their remonstrances, without changing any of the obnoxious measures of the government at Brussels. In the mean time the diabolical combination that had been formed between Charles IX. of France and Isabella of Spain, for the massacre of the protestants, which soon after took place, had been whispered in the Low Countries, and in consequence a general association was formed for the purpose of abolishing the court of inquisition. This association, headed by Henry de Brodenrode, a descendant of the earls of Holland, waited on the regent in such a formidable body, that she was obliged to promise the exertion of her utmost influence towards obtaining their demands. It is said, however, that she could obtain no better terms from the bigotted Philip than that heretics should in future be hanged instead of burnt. 10

The people break out into open rebellion.

As the people found that their dutiful remonstrances could obtain no redress, they determined to take into their own hands the necessary reformation. In several towns in Flanders, the people assembled, destroyed churches, pulled down images, and committed other acts of violence. The principal inhabitants, however, while they were preparing to resist the oppressive acts of the government, behaved with more temperance and moderation; a new oath of allegiance had been exacted, and this the counts of Egmont and Horn, probably with a view to temporise, were induced to take, but the prince of Orange steadily refused, and retired into Germany, whither he was followed by great numbers of all ranks and conditions, so that within a few days 100,000 families had left the Low Countries. This emigration so much alarmed the duchess of Parma, that she resigned the regency. 11

Duke of Alva appointed governor of the Netherlands.

The duchess was succeeded by the duke of Alva, who had been sent into the Netherlands with an army of 10,000 veteran troops, to intimidate the people, and enforce obedience to the civil power. We have already drawn the character of this bloody man (see ALVA), and have shewn how well he was calculated to execute the orders of a tyrannical and bigotted master. He no sooner entered on his government than the whole country was filled with terror; Counts Egmont and Horn were ignominiously executed, and the estates of the prince of Orange were confiscated. 12

The prince of Orange takes the command of the patriots.

This prince and his brother had been labouring to support the cause of their injured countrymen among the German

(B) There is no part of the history of nations more interesting in itself, or more replete with useful lessons to rulers and to subjects, than that which records the struggles of a brave people to preserve or regain their liberties and independence. Hence the glorious contest which the Dutch provinces maintained against the power of Spain, and by which they finally triumphed over tyranny and oppression, might well deserve a much fuller detail than our confined limits will enable us to afford. In the compendious view which we have here given of these transactions, we have endeavoured to catch the more prominent features, and thus in some measure preserve the spirit of the picture. We may refer our readers for a minute account of these events to *The Modern Universal History*, vol. xxxi. and Watson's *History of the Reigns of Philip II. and Philip III.*

United Provinces.

German princes, and had raised a detachment of Germans, by which they were enabled to make head against the regent. The prince of Orange, who had been always a favourite with the people, was now rendered more popular in consequence of his sufferings in their cause, and was invited to take the command of the armed bodies which were preparing to resist the duke of Alva.

13
Commencement of hostilities.
An. 1569.

The prince first penetrated into Brabant, and attempted to surprise Ruremond, but was defeated by a detachment of the Spanish army; but his brother soon after overpowered a body of Spaniards, and killed 600. In a subsequent engagement, however, with the main body of Alva's army, Prince Louis was entirely defeated, and all his infantry cut in pieces. The prince of Orange finding that he could not at present keep the field against so formidable an enemy, and that his soldiers deserted in consequence of his ill success and want of pay, was, in 1569, obliged to disband his army, and return to Germany.

14
Cruelty of the duke of Alva.

The duke of Alva did not fail to make the most of his success. All the prisoners taken in the last campaign were put to death, and the 100th part of every man's estate, with a tenth of all merchandise, were exacted as an annual payment from the inhabitants, under the penalty of military execution. The states offered to pay an annual subsidy of 2,000,000 florins, in place of these taxes; but these offers were rejected with disdain.

15
A fleet fitted out by the patriots.
An. 1571.

The people thus driven to despair, were resolved to strain every nerve to resist these oppressive acts. The tradesmen in the towns shut their shops, and the peasants refused to bring provisions to the markets. In the mean time a squadron of ships, which is known by the name of *gueux*, had been fitted out by the prince of Orange, and the command given to Lumey. The trifling success of this squadron, which had captured Briel, in the island of Voorn, and repulsed a force sent against it by the duke of Alva, induced the Zealanders to collect all their ships, and also oppose the enemy at sea. A considerable advantage was gained by this fleet, against a Spanish squadron commanded by the duke of Medina Celi. The duke was entirely defeated, many of his ships were taken, and the Zealanders carried off a booty of nearly 1,000,000 of livres.

16
Successes of the Orange party.

To increase his army, the governor had draughted men from the garrisons of most of the fortified towns, and thus exposed these to the attacks of the patriots. Accordingly, Lewis of Nassau surprised Mons, the count de Bergues gained possession of several towns in Overyssel, Guelderland, and Friesland; while another party of the malcontents made themselves masters of North Holland. The duke of Alva now began to feel that he had gone too far, and attempted, when too late, to conciliate the good opinion of the people. He published an edict consenting to remit the most oppressive taxes, if the state could suggest any other method of raising the necessary supplies, and he convoked the states-general of the Provinces to assemble at the Hague. His promises and his threats were, however, now disregarded; and the states who, in contempt of his authority had assembled at Dordrecht, openly espoused the cause of their country, declared the prince of Orange commander of the national forces, and raised a considerable sum for the payment of his troops.

The prince's forces now amounted to 15,000 foot and 7000 horse, with which he advanced into Brabant, and took Ruremond by assault. He then possessed himself of Mechlin, Oudenarde, and Dendermonde, and having levied contributions on those inhabitants who adhered to the government, he marched towards Mons then besieged by the duke of Alva, with an intention to raise the siege, by bringing the duke to a general action. This, however, Alva declined, and Mons was obliged to capitulate.

17
Reverses.

In the midst of these succeses, a damp was thrown over the ardour of the patriots, by the news of the horrid massacre of St Bartholomew *, and in the same degree the spirit of the Spaniards revived. The prince of Orange found himself obliged to retire to the province of Holland, leaving the cities which he had taken at the mercy of the army. Mechlin opened its gates, and was pillaged without mercy, while the other towns were evacuated by the garrison, and loaded with heavy impositions. In a short time nothing remained to the patriots, but the provinces of Holland and Zealand; but these stood firm in the cause of liberty, and soon became the seat of a sanguinary warfare. Frederick de Toledo was detached by the duke of Alva to reduce the insurgents in these quarters. He quickly reduced Waerden, where his soldiers committed the most horrid acts of barbarity. The capture of this place was followed by that of Haerlem after an obstinate resistance.

* See France, N° 142.

18
Naval victories of the Zealanders.

To balance this ill success by land, however, the Zealanders obtained many important advantages by sea. They attacked the harbour of Antwerp, and carried off several ships; and when the governor equipped a squadron to oppose them, it was thrice encountered by Wertz, the Zealand admiral, and totally defeated. In the mean time the Spanish forces, under Frederick of Toledo, consisting of 16,000 veterans, sat down before Alkmaer, the capital of Holland, a town without regular fortifications, and defended only by 300 burghers and 800 soldiers, in great want of provisions, and without any prospect of speedy relief; yet this place, though attacked with great vigour, by a battery of 20 pieces of heavy cannon, which effected a breach in one of the walls, held out against every attempt, and the Spanish soldiers who attempted to storm the place by the breach, were repulsed with great slaughter, and Frederick was at length compelled to raise the siege.

19
Heroic defence of Alkmaer.

Notwithstanding these partial successes, the affairs of the patriots were still in a precarious situation. Don Louis de Requesnes, who had succeeded the duke of Alva in the government, was directed to carry on the war with the utmost vigour. The prince of Orange had, after a long siege, made himself master of Middleburgh, but had sustained a great loss by the defeat and death of his brother Louis. The patriotic cause derived some advantage, however, from a mutiny which took place in the Spanish army, but this advantage was of a transient nature.

20
The States apply for assistance to Elizabeth of England.
An. 1575.

In the commencement of the year 1575, an attempt at negociation took place between the contending parties, but they could come to no terms of accommodation, and the war was continued with great virulence. Though much distressed in his finances, Philip made extraordinary efforts to crush the patriots, and succeeded so far, that they almost despaired of ultimate success. In this dilemma they sent a deputation to Queen Elizabeth of England, offering to become her subjects, if she

would

United Provinces.

would afford them her protection; but from political reasons she declined the offer. The distresses which Philip now experienced, and the death of his deputy Requesnes, did more for the cause of the patriots than all their own exertions.

Profiting by those events, in the latter end of this year they attacked and carried the citadel of Ghent; while the inhabitants of Antwerp, in revenge for having been pillaged by the Spanish garrison that held the citadel, united in the common cause, by what was called the pacification of Ghent.

21 who at length sends them a supply of money. An. 1576.

A second application to Queen Elizabeth met with more success, and she advanced them the sum of 20,000l. sterling, on condition that they would not invite the French into their territories, that they would listen to any reasonable terms of accommodation, and repay the loan in the course of the ensuing year. Agreeably to these conditions, a cessation of hostilities was granted to the states by Don John of Austria, the present governor, and a treaty was entered into with him for disbanding the foreign troops. The weak state of the government required some concessions, and Don John acceded to the pacification of Ghent, by which most of the demands of the patriots were granted. The provinces of Holland and Zealand, however, conceiving that by this treaty the other provinces had conceded too much, refused their concurrence, and hostilities soon recommenced.

22 The war renewed with fresh vigour. An. 1578.

The king of Spain dissatisfied with the concessions of Don John, recalled that governor, and appointed the archduke Matthias in his room, while he made additional preparations for a vigorous prosecution of the war. The states-general in their turn made another application to Queen Elizabeth, and obtained from her, not only a promise of 100,000l. sterling, but of a body of forces consisting of 5000 foot, and 1000 horse; in return for which, the states agreed to put into her possession certain fortified towns, and to transport and pay the forces. These supplies, however, Elizabeth afterwards declined sending, though she professed all possible good will towards the provinces and their cause. A change of measures which about this time took place in the states of Guelderland and Groningen, in favour of the protestant interest, contributed not a little to aid the general cause of the patriots, though several of the provinces were still torn by intestine dissensions and jarring interests. At last the prince of Orange, perceiving that little confidence was to be placed in the unanimity of provinces rent by faction, different in religion, and divided by ambition, political maxims, and private interest, formed the scheme of more closely uniting the provinces of which he was governor, and cementing them with those more contiguous, in which the protestant interest prevailed. Such an alliance was subject to fewer difficulties than attended the more general one of uniting all the provinces; it was in fact the only measure that could be proposed with safety, and it was prosecuted with that alacrity and address for which William was deservedly celebrated.

23 Union of Utrecht. An. 1579.

On the 23d of January 1579, deputies from the provinces of Holland, Zealand, Utrecht, Friesland, Groningen, Overyssel, and Guelderland, met at Utrecht, and signed the alliance ever since known by the name of the *Union of Utrecht*, the basis of that commonwealth so renowned by the appellation of the *United Provinces*. This treaty of alliance was founded on the infraction of the pacification of Ghent solemnly acceded to by Philip, and the late invasion of certain towns in Guelderland. It was not hereby intended to divide the seven provinces from the other ten, or to renounce the pacification of Ghent; its object was to preserve the liberty stipulated in that pacification, by more vigorous operations, and united councils. The chief articles of this union were the following.

That the seven provinces shall unite themselves in interest as one province, never to be separated or divided by testament, donation, exchange, sale, or agreement; reserving to each particular province and city all its privileges, rights, customs, and statutes. In all disputes arising between either of the provinces, the rest shall interpose only as mediators. They shall assist each other with life and fortune against every foreign attempt upon any particular province, whether to establish sovereignty, the Catholic religion, arbitrary measures, or whatever else may appear inconsistent with the liberties of the province, and the intention of the alliance. All frontier towns belonging to the United Provinces shall, if old, be fortified at the expence of the provinces; if new, at the joint expence of the union. That the public imposts and duties shall be farmed for three months to the highest bidder, and employed with the king's taxes in the public service. No province, city, or member of the union, shall contract an alliance with any foreign prince or power, without the concurrence of all the other members. That foreign powers shall be admitted into the alliance, only by consent of all the contracting parties. As to religion, the provinces of Holland and Zealand shall act in that particular as they think advisable: the rest shall adhere to the purport of the edict published by the archduke Matthias, which prescribed, that no man should be oppressed on account of conscience. All the inhabitants from the age of 18 to 60, shall be trained and disciplined to war. That peace and war shall be declared by the unanimous voice of all the provinces; other matters that concern the internal policy shall be regulated by a majority. That the states shall be held in the usual constitutional manner, and coinage shall be deferred to future determination. Finally, the parties agree, that the interpretation of these articles shall remain in the states-general; but in case of their failing to decide, in the stadtholder.

24 Heroic behaviour of the prince of Orange.

Soon after the union of Utrecht, King Philip did all in his power to detach the prince of Orange from the new confederation. He offered to restore him to all his estates, to indemnify him for all his losses, and give him the first place in his esteem and favour; but William was too wise to rely on the promises of a prince who had already shewn himself perfidious, and too generous to abandon a cause in which he had embarked from no interested motives. He determined to share the fate of the United Provinces, and not to disappoint the hopes which they had conceived of his conduct.

25 Successes of the duke of Parma against the United Provinces.

In the mean time the duke of Parma was doing his utmost to disconcert the projects of the prince of Orange, and to reduce the provinces to their obedience to Spain. He besieged and took the town of Marsien; invested Maestricht, and carried it after a siege of four months, and reduced the republican general La Noue to such straits, that he was glad to retreat under the cannon of Antwerp. At length the Provinces, by the advice of the prince of Orange, resolved to solicit the assistance

United Provinces.

assistance and protection of the duke of Anjou, to whom they had formerly applied in vain, and to offer him the sovereignty of their territories. Accordingly, in 1580, they solemnly renounced their allegiance to Philip, and acknowledged as their sovereign, Francis Hercules de Vallois, duke of Alençon and Anjou; and in the following year they published an edict, entitled the abdication of Philip king of Spain, for ever excluding that monarch from any right or authority over the Netherlands.

26
Inauguration of the duke of Anjou as duke of Brabant.
An. 1582.

In the beginning of the year 1582, the duke of Anjou, who had already taken an active part in favour of his new subjects, and had opposed the duke of Parma with some success, arrived in Holland from England; and in the month of February he was solemnly installed at Antwerp as duke of Brabant. It appears, however, that the prince of Orange, though he had been the great promoter of this measure, and even placed the ducal coronet on the head of the new sovereign, still possessed the greatest influence and authority in the United Provinces.

27
Assassination of the prince of Orange.
An. 1584.

When Philip of Spain found that he could not bribe the prince of Orange to his interest, he resolved to use every method to rid himself of so dangerous an opponent. Soon after the signing of the union of Utrecht, Philip had proscribed the prince, and offered a reward of 25,000 crowns to any person that should bring him dead or alive to Madrid. The greatness of the reward, and a bigotted regard for the interests of the Catholic religion, prompted several to attempt murdering the prince of Orange. He narrowly escaped assassination in 1582; but, two years after he met his unmerited fate at Delft, by the hands of one Guion, or, as he is commonly called, Balthazar Gerrard. About the same time the duke of Anjou died in France; and the provinces of Holland and Zealand appointed Maurice, son of the late prince of Orange, to be their stadtholder and captain general. For an account of the actions of this great man, see the article *Maurice of Nassau*.

28
A truce for twelve years concluded with Spain.
An. 1609.

Philip II. died in 1598, and Philip III. prosecuted the war with the United Provinces with as much rancour as his predecessors, but with much worse success. The great defeat sustained by the archduke Albert in 1600, and many subsequent disasters, induced the court of Madrid at length to listen to terms of accommodation. In 1607 a suspension of hostilities took place, and the year following a treaty on terms favourable to the Provinces was concluded for 12 years.

29
Renewal of hostilities.
An. 1621.

At the expiration of the truce, both parties prepared for a renewal of hostilities; but now the Spaniards fought with considerable disadvantage: From a strange policy, which they have since frequently practised, in their contests with the powers of Europe, the Dutch contrived to advance their commercial interests at the expence of their enemy. A very lucrative trade took place between the principal Dutch ports and those of Spain, by which the Spaniards were supplied by their enemies even with ammunition and warlike stores. At the same time the Dutch enriched themselves by numerous prizes taken from the Spaniards, and, in particular gave a severe blow to the resources of the court of Madrid, by capturing the flota from Mexico, a prize valued at 15,000,000 of livres.

30
Conclusion of peace.
An. 1648.

These repeated losses of the Spaniards proved the inutility of their continuing the war against a people so determined as the Dutch. Accordingly, in 1648, they agreed to a treaty of peace, by which his Catholic majesty renounced all right and sovereignty over the states-general of the United Provinces; and these provinces were henceforth declared a free and independent republic. It was also agreed between the contending powers, that each should remain in unmolested possession of those places which they severally held at the signing of the treaty.

31
Flourishing state of the republic.

From this time to the year 1670 we meet with nothing very remarkable in the history of the United Provinces. By invariably pursuing the maxims of prudence, industry, and frugality, the republic had attained the highest pitch of grandeur. Amsterdam was become the emporium of Europe, and the richest city in the universe. The population of the provinces, especially of Holland, was much greater than at any former or subsequent period, though it is scarcely credible that, as some authors affirm, Holland alone should then contain 3,000,000 of inhabitants. The states dispatched ministers and consuls to China, Siam, and Bengal; to the Great Mogul, the king of Persia, and the khan of Tartary, the grand signior, the czar of Russia, and the princes of Africa. They were considered as an important weight in the scale of Europe; and no treaty was concluded without the concurrence of their ambassadors.

32
Dispute with France.
An. 1672.

It is not surprising that the successes of the Dutch, and the prosperous condition in which they now beheld themselves, should have rendered them rather arrogant towards the neighbouring states. Louis XIV. of France had conceived himself affronted by a foolish boast of one of the Dutch ministers, and he was particularly jealous of the advantage which the new republic had acquired over his subjects in the trade to India. The triple alliance formed about this time between England, Sweden, and the United Provinces, was an additional motive with the French king to break of all intercourse with the Dutch, and to curb their growing power. He began by prevailing on Charles II. of England to abandon the triple alliance; a request to which that worthless monarch, alive to nothing but his pleasures and his avarice, readily agreed, on condition of being well paid for his treachery. Louis also persuaded several of the German princes to unite their forces with his against the republic; and of all the Germanic body, only the elector of Brandenburg interested himself for the safety of the states-general. The French king assembled an army of 100,000 men, which he divided into four columns, one commanded by himself in person, with the assistance of Marshal Turenne; another by the prince of Condé; a third by General Crequi, and a fourth under the conduct of the duke of Luxemburg. Such an army drawing towards the frontiers could not but terrify the Dutch, now torn with civil and religious factions. The partisans of the Orange family were for abolishing the perpetual edict, and raising William prince of Orange to the dignity enjoyed by his predecessors; but the De Witt faction opposed him violently though they could not prevent the young prince from being chosen captain-general and high-admiral. Many hoped that William's new dignity would incline his uncle Charles II. to return to the triple alliance; but that hope was frustrated by the conduct of his majesty, who, in conjunction with the most Christian king, declared

United Provinces.

clared war against the states-general on the 7th of April. A month after, the elector of Cologne and bishop of Munster followed the example of the two kings. The Dutch put themselves in the best posture of defence that circumstances would admit. Maeastricht was strongly garrisoned; the prince of Orange had assembled an army of 25,000 men, with which he advanced to the banks of the Yssel; and the Dutch fleet cruised off the mouth of the Thames, to prevent the junction of the naval forces of England and France, which amounted to 150 ships. All Europe watched the first motions of the two powerful kings, seconded by the best generals of the age.

33 Commencement of hostilities.

Holland could be attacked only by the Rhine or the Meuse, and the French generals and ministers differed by which of these inlets the first impression should be made. At length, after much deliberation, it was determined to attack the Dutch on both these sides at the same time, in order the more to disconcert their councils. The campaign began with the siege of Rhinberg, Vesel, Orsoi, and Rurick, four towns well fortified, and deemed the keys of Holland. Nothing could oppose armies so well appointed, led by generals so skilful and so experienced. The four towns were compelled to surrender within a few days of each other; and a severe defeat sustained by a body of Dutch troops, in attempting to defend the passage of the Rhine, by the prince of Condé, served still more to dishearten the troops of the states-general.

34 Rapid successes of the French.

It is almost incredible with what rapidity towns and fortresses yielded to the fortune of his majesty's arms. The reduction of Betau, the most fruitful country of the United Provinces, and the surrender of Tolhusfert, obliged the prince of Orange to abandon the Yssel, lest he should be attacked in the rear, and to retire to the very heart of the country, as far as Rhenen in the province of Utrecht. By this means the town of Arnheim, the forts of Knotsemborough, Voorn, St André, and Shenck, this last the strongest in the Netherlands, with a variety of other forts and towns, surrendered as soon as summoned; and at last Nimeguen, a town strong from the nature of the works and fortifications, and garrisoned by 8000 fighting men, including the inhabitants, was invested. After the citizens had for eight days exhibited signal proofs of courage in defence of their liberties, they were forced to yield to the superior skill of Turenne.

35 The Dutch compelled to inundate their country. An. 1672.

The only means by which the Dutch could arrest the progress of the enemy was, to open the sluices and inundate the country. The town of Utrecht set the example, which was soon followed by many others, and in a short time Holland, Brabant, and Dutch Flanders, formed one vast lake, the towns rising like islands in the midst of the waters. An embassy was also sent to the king of England, to request that he would prevail on Louis to relax in the severity of his attack. Charles pretended a compliance with this request; but as his interference produced no effect, it is probable that he was not sincere. In the space of three months, Louis conquered the provinces of Guelderland, Overyssel, and Utrecht, took about 50 towns and forts, and made 24,000 prisoners. The latter, however, were soon released for a trifling ransom. The very successes of the conquerors tended to weaken their force, as they were compelled to leave behind them several strong bodies of troops, to garrison the captured towns. This induced the French to listen to proposals for a negociation, which, however, came to nothing.

Marshal Turenne, now appointed generalissimo of the king's army on his majesty's return to Paris, marched to oppose the elector of Brandenburg and the German general Montecuculi, who had joined their forces, and were about to pass the Rhine. For three whole months were the elector and Montecuculi employed in abortive attempts to effect a passage at Mentz, Coblentz, Strasburg, and other places. This answered the purpose of making a powerful diversion in favour of the Dutch, though they could not accomplish their design of joining the prince of Orange. After repeated disappointments, the imperial army directed its march to Westphalia; and Turenne followed, in order to keep the bishop of Munster steady to his engagements. For half the campaign he, with a body of 16,000 men, baffled every stratagem of the elector and Montecuculi, the latter the most renowned general of the empire, at the head of an army near triple his strength. He obliged them to go into winter quarters, in a country harassed and exhausted; and confirmed the bishop of Munster in the alliance of France, at the very time he was on terms with the emperor. He obliged the elector of Brandenburg, who took the chief command during Montecuculi's illness, to abandon the siege of Warle, took Unma Kamen, Altena, Berkemham, and several other towns and fortresses. By continuing his operations, he forced the elector out of his winter quarters again into the field, chased him from post to post, until he obliged him to quit Westphalia, repass the Weser, and retire with precipitation into the bishopric of Hildersheim. After taking possession of the elector's towns in Westphalia, he pursued him into the bishopric of Hildersheim, and at length, by mere dint of superior genius, forced him to seek shelter in his hereditary dominions. All this was effected after Louvois had appointed the marshal's army quarters in Alsace and Lorrain, amidst the rigours of a severe winter, opposed by a superior enemy, by the artifices of Louvois, and seconded only by his own prudence, and the affection of his troops, which he maintained in defiance of all the difficulties, hardships and dangers, they encountered. It was indeed supposed, that Montecuculi was prevented from giving Turenne battle by the remonstrances of Prince Lobkovitz, the emperor's ambassador, influenced by the gold of Louis. Certain indeed it is, that Montecuculi's illness arose from his chagrin at seeing all his projects frustrated by the unsteady dilatory conduct of the court of Vienna. Louis's negociations disturbed Europe no less than his arms. His tools and creatures swarmed in every court. Leopold could not be prevented from declaring in favour of Holland; but his ministers were bought off from seconding the emperor's intentions. The whole English nation exclaimed against the alliance of their kingdom with France; but Charles stood in need of French gold to supply his extravagance and profligacy. The elector of Bavaria had indeed been compelled by Louis to retire to his capital; but it was by dint of intrigue that he was forced from his alliance with Holland, and constrained to make a peace with France.

While the French generals were thus carrying all before them, the combined fleets of France and England were

United Provinces

were scarcely less successful against the maritime power of the Dutch. The English squadron under the duke

36 Transactions of the Dutch at sea.

of York, uniting to that of France under D'Estrees, thrice engaged the Dutch fleet commanded by De Ruyter; and though neither party could boast of much advantage, the check sustained by the Dutch admiral was of essential service to the cause of the allies.

37 Change of fortune,

At length the tide of fortune began to turn in favour of the United Provinces. The court of Spain, jealous of the growing power of France, embraced the cause of the Dutch; and sent an army of 10,000 men to the assistance of the prince of Orange, while the mercenary king of England was compelled by his parliament to withdraw from his unnatural alliance with the French king; and the late ill success among the allied troops of France and Germany cooled the elector of Cologne and the bishop of Munster, in their friendship towards Louis. Thus that monarch, forsaken by his allies, was compelled to maintain singly a war against the empire, Spain, and the United Provinces. The accession of the prince of Orange to the throne of England, in 1688, gave an additional blow to the French power, by bringing on an intimate connection between England and Holland.

38 and consequent peace with France. An. 1697.

At length Louis was compelled to negociate for peace, which was concluded in 1697, by a treaty extremely favourable to the United Provinces.

39 Summary of the Dutch affairs from the end of the 17th to the beginning of the 19th century.

After the death of William III. the same plan of humbling the French king, was, in conjunction with the states-general, pursued by his successor Queen Anne; and the numerous and important victories of the duke of Marlborough and Prince Eugene, led to the famous treaty of Utrecht, in 1713. See Britain, N° 340—371. In 1747, the office of stadtholder was declared hereditary in the princes of Orange. In the war that took place in 1756, between France and England, a French party was formed in Holland, in opposition to the stadtholder, who favoured the alliance with England. Hence arose a jealousy between the two allies, which, during the American war, increased to an open rupture. See Britain, N° 427, and N° 598, *et seq.* In 1787, some disputes took place between the stadtholder and the states-general, which induced the former to require the assistance of the king of Prussia. That monarch accordingly sent an army of 18,000 Prussians to Amsterdam, under the duke of Brunswick, who, in 1788, brought the whole country into subjection, and reinstated the stadtholder in his authority. See Prussia, N° 73. In 1794 the republican armies of France having overrun the greater part of Flanders, took possession of the Dutch provinces, which they converted into the Batavian republic. The stadtholder found refuge in England, and the allied armies of Germany and Prussia retreated into Germany. See France, N° 409, et seq. In the summer of 1799, a considerable British force landed in the Texel island, made themselves masters of the Dutch fleet, and, in conjunction with a body of Russians, gained some advantages on the continent. Being opposed, however, by a superior French force, the army was obliged to reimbark, and return to England. See Britain, N° 1069. By the treaty of Amiens, concluded in March 1802, all the colonies taken by the British were restored to Holland, except the island of Ceylon. On the renewal of hostilities in 1803, the Batavian republic was again compelled to take an active part against Britain, and in consequence again lost the Cape of Good Hope, and several other colonies, besides having her trade entirely ruined. Soon after the imperial diadem of France was conferred on Napoleon Bonaparte, his brother, Louis, was appointed king of Holland. Louis, however, proved to be a man not calculated to serve his brother's purposes. He was considerate and humane, paid great attention to the complaints of his subjects, employed none but Dutchmen in his government, and continually exerted his influence to soften the harsh measures of which he was compelled to be the instrument. The nation was sensible of his good services, and Louis was highly popular. But in the same proportion as he gained the confidence of the nation, he lost that of Napoleon; who at length determined on setting him aside. Louis learned what was intended, and escaped the humiliation of being deposed, by resigning the crown to his infant son on the first of July 1810. On the 9th July, Napoleon issued a decree, annexing the United Provinces to the French empire. From this period Holland followed the fortunes of France, till the battle of Leipsic shattered the French power. On the 15th November, 1813, one month after the battle of Leipsic, a simultaneous rising took place in all the most considerable towns. The French garrisons were feeble and soon mastered; and on the 21st November, a deputation arrived in London to invite the prince of Orange to return, who accordingly arrived there on the 30th, and obtained immediate possession of the government. By the treaty of Paris, 30th May 1814, the ten provinces of the Netherlands were united to Holland, and the prince of Orange took the title of king of the Netherlands. This plan of union was not favourably received on either side, there being an ancient grudge between the two countries, which was strengthened by commercial jealousy, and by difference of religion, the Dutch being chiefly of the reformed church, and the Belgians catholics. The population of both countries in 1818 was 5,266,000.

40 Population of the United Provinces.

According to the statistical table given in N° 2, the population of the United Provinces in the year 1796, appears to amount to 1,880,469 individuals; but this enumeration being made while the French had possession of the country, was believed to be under the truth. By returns made to the government in 1818, the population amounted to 2,016,159.

41 Constitution and government.

In the late republic of Holland, previous to the French revolution, the states-general formed the great council of the nation. That assembly was formed by deputies from the provincial states, and was invested with the supreme legislative power. It could not, however, make peace or war, form new alliances, or levy taxes, without the consent of the provincial states, nor could these determine any point of importance, without the consent of each of the cities that had a voice in their assembly. The stadtholder exercised a considerable part of the executive power, though in later times his power became very limited. The grand pensionary was properly a minister of the province; and though he possessed great influence, being a perpetual member of the states-general, and of the secret committee, he was considered as inferior in rank to all the deputies.

42 Revenues.

The revenues of the United Provinces arose principally from taxes imposed on each province and city, according

cording to their ability. These consisted chiefly of a general excise, a land-tax, a poll-tax, and hearth money; and are supposed to have amounted to 3,000,000l. sterling.

43 Military strength.

Before the French revolution, the Dutch maintained a peace establishment of 30,000 men, which in war was augmented to above 50,000, chiefly by mercenary troops from Germany. Their naval establishment was highly respectable; and at the end of the 17th century it exceeded that of any other maritime power in Europe. Before the late war they could muster 40 sail of the line, 40 frigates, and 10 cutters. Since the celebrated engagement off the Dogger Bank during the American war, the Dutch have been scarcely able to cope with the English at sea; and the victory off Camperdown in October 1797, with the subsequent loss of the Texel fleet in 1799, proved the deathblow to the naval power of Holland.

44 Religion.

Before the late change of government, the established religion of Holland was Presbyterianism, according to the doctrines of Calvin; though all sects of Christians were tolerated. The church was governed by consistories, classes, and synods, from which there was an appeal to one great national synod, subject to the controul of the states-general.

45 Language and literature.

The Dutch language is a dialect of the German, and in many respects bears a considerable resemblance to the Old English and Lowland Scotch. The literature of the United Provinces has long been respectable; and the universities of Leyden, Utrecht, Groningen, Harderwyck, and Franeker, have produced many eminent and celebrated men in almost every department of science. Grotius, Erasmus, Boerhaave, Leuwenhoeck, Swammerdam, Grævius, Burrman, Hooguween, &c. are names mentioned with admiration and respect in the annals of literature.

46 Manufactures.

The Dutch manufactures consist principally of fine linens, earthen ware, chiefly manufactured at Delft, especially white and painted tyles, tobacco-pipes, borax, oil, starch, paper, leather, woollen and cotton cloths, snuff, tobacco, and gin.

47 Commerce.

The commerce of the Dutch was formerly more extensive than that of any other country in Europe. They carried on a trade with every quarter of the globe, and in particular their East India Company was perhaps the richest society of merchants in the world. Holland was almost the exclusive centre of the spice trade; and the extensive fisheries on the coast of Greenland and in the North sea, supplied the greater part of Europe with whale oil and herrings. Besides this external commerce, they carried on a considerable inland traffic with the interior of Germany, from which they brought immense quantities of timber. Vast rafts of trees, many hundred feet in length, set out annually from the forests of Andernach, and other places on the Rhine, and proceeding down the river under the direction of a great body of labourers, that formed a village of huts on the surface of the raft, sailed down the Rhine and the Waal to Dort, where the timber was disposed of, and where one raft has been sold for 30,000l. sterling. All the foreign trade of Holland may now be considered as annihilated, but the inland traffic in wood and spirits still continues.

The inland commerce of the United Provinces is greatly promoted by the facility of conveyance from one part of the country to another, by means of the numerous canals.

48 Character of the Dutch.

The Dutch are, by constitution, a cool, or rather phlegmatic people, laborious, patient, obstinate, and persevering. When stimulated by any predominant passion, as avarice, or formerly love of liberty, they are capable of great exertions. Economy and order in the management of their pecuniary concerns are common among all classes, with whom it is an established maxim to spend less than their income. Interest and love of money regulate all their actions, and appear to supplant in their breasts every noble and generous feeling. These prominent features in the national character are, of course, modified by the rank or situation of the different orders in society. The higher ranks value themselves much on their distinctions, are reserved to strangers, but affable and obliging to those with whom they have had an opportunity of becoming acquainted; friendly, candid, and sincere. The mercantile men and traders are, in general, fair and honest in their transactions; though their natural thirst of gain sometimes tempts them to deceive and overreach their customers. The lower ranks are ignorant, dull, and slow of apprehension, but open to conviction, and patient of fatigue and labour.

49 Manners and customs.

Dress, among the Dutch, is regulated less by fashion, then by an attention to climate and season. The moisture and inconstancy of these require a greater quantity of clothing than is found necessary in other countries under the same latitude; and, among the ordinary classes, bread hats, large breeches, and thick boots and shoes, are still almost universal. Most of the women wear hats with low crowns and very broad rims, with jerkins and short petticoats; and, what appears exceedingly ridiculous to strangers, the boys and girls wear the same dress as the men and women.

A close attention to regularity and neatness in the streets and the interior of the houses prevails throughout the United Provinces, but is most conspicuous in North Holland. This was at first rendered necessary by the nature of the climate, to prevent rust and mouldiness from destroying their utensils and furniture, and has since become a habit, conducive at once to comfort and to health. The manner of living in Holland was, till of late, not a little gross. Their diet consisted much of high-seasoned and salted meats, butter, cheese, and spirituous liquors. In no country was gormandizing reduced more to a system. Convivial entertainments were extremely frequent; and the interval between the more substantial meals of dinner, tea, and supper, were filled up with cakes, fruits, jellies, and other light things; not to mention smoking and drinking, which supplied the place of conversation (c). If we may rely on the report of a late writer on the statistics of Holland*, the style of living is now much changed, though not much improved

* *Metelerkamp. Sea Month. Mag. for Nov. 1807.*

(c) We must admit, that, in so moist and cold a climate, a full and generous diet may be safe if not necessary; but the Dutch, like many of our own countrymen, absurdly carried the same system into their tropical colonies.

United Provinces || University.

improved. Animal food is become extremely rare, and its place is supplied by a greater proportion of gin, tea, and coffee. The prevailing amusements in winter are dramatic entertainments and skaiting, in which latter they are exceedingly expert.

The Dutch taste for formal gardens, straight walks, trees and hedges clipped into fantastic shapes, and flower roots, has long been proverbial, and has been treated with more contempt and ridicule than it deserves. At worst, these are but harmless propensities; and, if indulged in moderation, are well suited to relieve the sameness and inactivity of a retirement from the busy scenes of trade and commerce.

UNITY, in *Poetry*. There are three unities to be observed, viz. the unity of action, that of time, and that of place. In the epic poem, the great and almost the only, unity, is that of the action. Some regard indeed ought to be had to that of time; for that of place there is no room. The unity of character is not reckoned among the unities. See POETRY, Part II. Sect. 3.

UNIVERSAL, something that is common to many things; or it is one thing belonging to many or all things.

UNIVERSE, a collective name, signifying the whole world; or the assemblage of heaven and earth, with all things therein. See ASTRONOMY and GEOGRAPHY.

UNIVERSITY, is the name of a corporation formed for the education of youth in the liberal arts and sciences, and authorised to admit such as have studied in it, to certain *degrees* in different faculties, which not only serve as certificates of proficiency in science, but also confer on those who obtain them considerable privileges within the university, as well as some rank in the state without it. Universities generally comprehend within them one or more colleges; but this is not always the case; for the university of St Andrew's was in being before either of its colleges was founded, and it would continue in being, with all its privileges, though both its colleges were levelled with the dust.

In every university with which we are acquainted, there are four faculties, viz. *Theology*, *Law*, *Physic*, and the *Arts and Sciences*, comprehending mathematics, natural and moral philosophy, &c.: and in Oxford, Cambridge, and some other universities, *Music* is considered as a fifth faculty. In each of these there are two degrees, those of *Bachelor* and *Doctor*; for though in the universities of Great Britain and Ireland we have no such degree as *Doctor in Arts and Sciences*, our *Master of Arts*, answers to the degree of *Doctor in Philosophy*, which is conferred by many of the universities on the continent.

Universities in their present form, and with their present privileges, are institutions comparatively modern. They sprang from the convents of regular clergy, or from the chapters of cathedrals in the church of Rome, where young men were educated for holy orders, in that dark period when the clergy possessed all the little erudition which was left in Europe. These convents were seminaries of learning probably from their first institution; and we know with certainty, that in Old Aberdeen there was a monastery in which youth were instructed in *theology*, the *canon law*, and the *school philosophy*, at least 200 years before the university and King's College were founded. The same was doubtless the case in Oxford and Cambridge, and probably in every town in Europe, where there is now a university which has any claim to be called ancient; for it was not till the more eminent of the laity began to see the importance of literature and science, that universities distinct from convents were founded, with the privilege of admitting to degrees, which conferred some rank in civil society. These universities have long been considered as lay corporations; but as a proof that they had the ecclesiastical origin which we have assigned to them, it will be sufficient to observe, that the pope arrogated to himself the right of vesting them with all their privileges; and that, prior to the Reformation, every university in Europe conferred its degrees in all the faculties by authority derived from a papal bull.

It is perhaps no improbable conjecture, that the church of Rome derived her idea of academical honours from the Jews, among whom literary distinctions extremely similar subsisted before the nativity of our Saviour. Among them, the young student, with respect to his learning, was called a *disciple*; from his minority a *junior*; and the *chosen* or *elected*, on account of his election into the number of disciples. When he had made some progress in knowledge, and was deemed worthy of a degree, he was by imposition of hands made חבר, *a companion* to *a Rabbi*, the person who officiates using this form, *I associate thee*, or, *Be thou associated*; and as soon afterwards as he was thought worthy to teach others, the *associate* was raised to the rank of *Rabbi*. Whether this process suggested the idea or not, it has certainly some resemblance to that by which a young man in our universities passes through the degree of *Bachelor* to that of *Master of Arts*, or *Doctor*.

The most ancient universities in Europe are those of OXFORD, CAMBRIDGE, PARIS, SALAMANCA, and BOLOGNA; and, in the two English universities, the first colleges are those of *University*, *Baliol*, and *Merton*, in the former, and *St Peter's* in the latter. Oxford and Cambridge, however, were universities, or, as they were then called, *studies*, some hundreds of years before colleges or schools were built in them; for the former flourished as a seminary of learning in the reign of Alfred the Great, and the other, could we believe its partial partizans, at a period still earlier. The universities of Scotland are four, ST ANDREWS, GLASGOW, ABERDEEN, and EDINBURGH. In Ireland there is but one university, viz. that of DUBLIN, founded by Queen Elizabeth, and very richly endowed.

An idle controversy has been agitated, whether the constitution of the English or of the Scotch universities be best adapted to answer the ends of their institution; and, as might be expected, it has been differently decided, according to the partialities of those who have written on the subject. Were we to hazard our own opinion, we should say, that each has its advantages and disadvantages; and that while the English universities, aided

The account given by a late traveller (see Barrow's *Voyage to Cochin-China*) of the luxurious mode of living at Batavia, affords a melancholy, but accurate picture of Dutch gluttony.

aided by their great schools, to which we have nothing that can be compared, are unquestionably fitted to carry their young members farthest in the knowledge of the learned languages, the mode of teaching in our own universities is better adapted to the promotion of arts and sciences, and the communication of that knowledge which is of most importance in active life.

UNIVERSITY-Courts, in England. The two universities enjoy the sole jurisdiction, in exclusion of the king's courts, over all civil actions and suits whatsoever, where a scholar or privileged person is one of the parties; excepting in such cases where the right of freehold is concerned. And then by the university charter they are at liberty to try and determine, either according to the common law of the land, or according to their own local customs, at their discretion; which has generally led them to carry on their process in a course much conformed to the civil law.

This privilege, so far as it relates to civil causes, is exercised at Oxford in the chancellor's court; the judge of which is the vice-chancellor, his deputy, or assessor. From his sentence an appeal lies to delegates appointed by the congregation; from thence to other delegates of the house of convocation; and if they all three concur in the same sentence, it is final, at least by the statutes of the university, according to the rule of the civil law. But if there be any discordance or variation in any of the three sentences, an appeal lies in the last resort to judges delegates appointed by the crown, under the great seal in chancery.

As to the jurisdiction of the university courts in criminal matters, the chancellor's court at Oxford, and probably also that of Cambridge, hath authority to try all offences or misdemeanors under the degree of treason, felony, or mayhem; and the trial of treason, felony, and mayhem, by a particular charter, is committed to the university jurisdiction in another court, namely, the court of the lord high steward of the university.

The process of the trial is this. The high steward issues one precept to the sheriff of the county, who thereupon returns a panel of 18 freeholders; and another precept to the bedells of the university, who thereupon return a panel of 18 matriculated laymen, *laicos privilegio universitatis gaudentes:* and by a jury formed *de medietate*, half of freeholders and half matriculated persons, is the indictment to be tried; and that in the guildhall of the city of Oxford. And if execution be necessary to be awarded in consequence of finding the party guilty, the sheriff of the county must execute the university process; to which he is annually bound by an oath.

VOCABULARY, in *Grammar*, denotes the collection of the words of a language, with their significations, otherwise called a *dictionary*, *lexicon*, or *nomenclature*. See DICTIONARY.

A vocabulary is properly a smaller kind of dictionary, which does not enter so minutely into the origin and different acceptations of words.

VOCAL, something that relates to the voice or speech; thus vocal music is that set to words, especially verses, and to be performed by the voice; in contradistinction to instrumental music, composed only for instruments, without singing.

VOCATIVE, in *Grammar*, the fifth state or case of nouns. See GRAMMAR.

VOETIUS or VOET, GISBERT, an eminent divine of the 16th century, was professor of divinity and the Oriental tongues at Utrecht, where he was also minister. He assisted at the synod of Dort; and died in 1676, aged 87. He wrote a great number of works; and was the declared enemy of Des Cartes and his philosophy. His followers are called *Voetians*. Voetius had two sons, *Daniel* and *Paul*, both authors. *John Voetius*, the son of Paul, was doctor and professor of law at Herborn, and wrote a commentary on the Pandects.

VOICE, a sound produced in the throat and mouth of an animal, by peculiar organs.

Voices are either articulate or inarticulate. Articulate voices are those whereof several conspire together to form some assemblage or little system of sounds: such are the voices expressing the letters of an alphabet, numbers of which joined together form words. Inarticulate voices are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

For a description of the organs of the voice, see ANATOMY; see also PHYSIOLOGY *Index*.

VOICE, in *Grammar*, a circumstance in verbs, whereby they come to be considered as either active or passive, *i. e.* either expressing an action impressed on another subject, as *I beat;* or receiving it from another, as, *I am beaten*. See GRAMMAR.

VOICE, in matters of election, denotes a vote or suffrage.

VOICE, in *Oratory*. See DECLAMATION; READING, N° 5.; and ORATORY, N° 129—131.

VOLANT, in *Heraldry*, is when a bird, in a coat of arms, is drawn flying, or having its wings spread out.

VOLATILE, in *Physics*, something that is easily dissipated by fire or heat.

VOLATILE Alkali. See AMMONIA, CHEMISTRY *Index*.

VOLATILISATION, the art of rendering fixed bodies volatile, or of resolving them by fire into a vapour.

VOLCANO, a name given to burning mountains, or to vents for subterraneous fires. See GEOLOGY *Index*, ÆTNA, HECLA, &c.

VOLERY, a bird-cage, of such a size that the birds have room to fly up and down in it.

VOLGA, the largest river in Europe, derives its origin from two small lakes in the forest of Volkonski about 80 miles from Tver, a town in Russia. It is navigable a few miles above that town. This noble river waters some of the finest provinces in the Russian empire, and at last falls into the Caspian sea by several mouths, below Astracan.

The Volga is subject to annual inundations. In the year 1774, the inundations exceeded the lowest watermark by nearly 40 feet, since which period they have been rather on the decline; for in 1775, they rose only to 39 feet 2 inches above that mark; in 1782, they rose to 26 feet; in 1785, to 25 feet 2 inches; and in the year 1791, their height was the same. Pallas is of opinion that this phenomenon may have originated from the diminished quantity of snow and rain which had fallen in the higher countries; from the greater evaporation of the Caspian sea, and the gradual extension of the different mouths of the river, or perhaps from the joint operation of all these causes.

VOLITION,

Volition || Voltaire.

VOLITION, an act of willing. See METAPHYSICS.

VOLLEY, a military salute, made by discharging a great number of fire arms at the same time.

VOLONES, in Roman antiquity, slaves who in the Punic war voluntarily offered their service to the state, which is the reason of the appellation; upon which they were admitted to citizenship, as none but freemen could be soldiers.

VOLT, in the manege, a round or circular tread; and hence, by the phrase *to make volts*, is understood a gate of two treads, made by a horse going sidewise round a centre, in such a manner that these two treads make parallel tracks; one larger, made by the fore-feet, and another smaller, made by the hind-feet; the croup approaching towards the centre, and the shoulders bearing out.

VOLTAIRE, FRANCIS AROUET DE, a celebrated French author, was born at Paris, February 20. 1694. His father, Francis Arouet, was *ancien notaire au Chatelet*, and treasurer of the chamber of accounts; his mother, Mary-Margaret Draumart. At the birth of this extraordinary man, who lived to the age of 85 years and some months, there was little probability of his being reared, and for a considerable time he continued remarkably feeble. In his earliest years he displayed a ready wit and a sprightly imagination; and, as he said of himself, made verses before he was out of his cradle. He was educated under Father Poré, in the college of Louis the Great; and such was his proficiency, that many of his essays are now existing, which, though written when he was between 12 and 14, show no marks of infancy. The famous Ninon de l'Enclos, to whom this ingenious boy was introduced, left him a legacy of 2000 livres to buy him a library. Having been sent to the equity schools on his quitting college, he was so disgusted with the dryness of the law, that he devoted himself entirely to the muses. He was admitted into the company of the abbé Chaulieu, the marquis de la Fare, the duke de Sully, the grand prior of Vendôme, Marshal Villars, and the chevalier du Bouillon; and caught from them that easy taste and delicate humour which distinguished the court of Louis XIV. Voltaire had early imbibed a turn for satire; and, for some philippics against the government, was imprisoned almost a year in the Bastile. He had before this period produced the tragedy of *Oedipus*, which was represented in 1718 with great success; and the duke of Orleans happening to see it performed, was so delighted, that he obtained his release from prison. The poet waiting on the duke to return thanks; "Be wise (said the duke), and I will take care of you." "I am infinitely obliged (replied the young man); but I intreat your royal highness not to trouble yourself any farther about my lodging or board."

He began his *Henriade* before he was 18. Having one day read several cantos of this poem when on a visit to his intimate friend, the young president de Maisons, he was so teased with objections, that he lost patience, and threw his manuscript into the fire. The president Henaut with difficulty rescued it. "Remember (said Mr Henaut to him, in one of his letters) it was I that saved the Henriade, and that it cost me a handsome pair of ruffles." Some years after, several copies of this poem having got abroad, while it was only a sketch, an edition of it was published, with many chasms, under the title of *The League*. Instead of fame and friends, the author gained only enemies and mortification, by this first edition. The bigots took fire at it, and the poet was considered as highly criminal for praising Admiral Coligny and Queen Elizabeth. Endeavours were even used to get the piece suppressed; but this strange design proved abortive. His chagrin, on this occasion first inspired him with the thought of visiting England, in order to finish the work, and republish it in a land of liberty. He was right; for King George I. and more particularly the princess of Wales, afterwards queen of England, raised an immense subscription for him. Their liberality laid the foundation of his fortune; for on his return to France in 1728, he put his money into a lottery established by M. Desfortes, comptroller-general of the finances. The adventurers received a rent charge on the *Hotel-de-Ville* for their tickets; and the prizes were paid in ready money; so that if a society had taken all the tickets, it would have gained a million of livres. He joined with a numerous company of adventurers, and was fortunate.

His *Lettres Philosophiques*, abounding in bold expressions and indecent witticisms against religion, having been burnt by a decree of the parliament of Paris, and a warrant being issued for apprehending the author in 1733, Voltaire prudently withdrew; and was sheltered by the marchioness du Chatelet, in her castle of Cirey, on the borders of Champagne and Lorraine, who entered with him on the study of the system of Leibnitz, and the Principia of Newton. A gallery was built, in which Voltaire formed a good collection of natural history, and made an infinite number of experiments on light and electricity. He laboured in the mean time on his Elements of the Newtonian Philosophy, then totally unknown in France, and which the numerous admirers of Des Cartes were little desirous should be known. In the midst of these philosophic pursuits he produced the tragedy of *Alzira*. He was now in the meridian of his age and genius, as was evident from the tragedy of *Mahomet*, first acted in 1741; but it was represented to the procureur-general as a performance offensive to religion; and the author, by order of Cardinal Fleury, withdrew it from the stage. *Merope*, played two years after, 1743, gave an idea of a species of tragedy, of which few models had existed. It was at the representation of this tragedy, that the pit and boxes were clamorous for a sight of the author; yet it was severely criticised when it came from the press. He now became a favourite at court, through the interest of Madame d'Etiole, afterwards marchioness of Pompadour. He was appointed a gentleman of the bed-chamber in ordinary, and historiographer of France. He had frequently attempted to gain admittance into the Academy of Sciences, but could not obtain his wish till 1746, when he was the first who broke through the absurd custom of filling an inaugural speech with the fulsome adulation of Richelieu; an example soon followed by other academicians. From the satires occasioned by this innovation he felt so much uneasiness, that he was glad to retire with the marchioness du Chatelet to Luneville, in the neighbourhood of King Stanislaus. The marchioness dying in 1749, Voltaire returned to Paris, where his stay was but short. The king of Prussia now gave Voltaire an invitation to live with him, which he accepted towards the end of August

gust 1750. On his arrival at Berlin, he was immediately presented with the *Order of Merit*, the *key of chamberlain*, and a *pension* of 20,000 livres. From the particular respect that was paid to him, his time was now spent in the most agreeable manner; his apartments were under those of the king, whom he was allowed to visit at stated hours, to read with him the best works of either ancient or modern authors, and to assist his majesty in the literary productions by which he relieved the cares of government. But a dispute which arose between him and Maupertuis soon brought on his disgrace. Maupertuis was at some pains to have it reported at court, that one day while General Manstein happened to be in the apartments of M. de Voltaire, who was then translating into French the Memoirs of Russia, composed by that officer, the king, in his usual manner sent a copy of verses to be examined, when Voltaire said to Manstein, "Let us leave off for the present, my friend; you see the king has sent me his dirty linen to wash, I will wash yours another time." A single word is sometimes sufficient to ruin a man at court; Maupertuis imputed such a word to Voltaire, and succeeded. It was about this very time that Maupertuis published his very strange Philosophical Letters; and M. de Voltaire did not fail to heighten, with his utmost powers of raillery, every thing which he found, or could make ridiculous, in the projects of M. Maupertuis, who was careful to unite his own cause with that of the king; Voltaire was considered as having failed in respect to his majesty; and therefore, in the most respectful manner, he returned to the king his chamberlain's key, and the cross of his Order of Merit; accompanied with four lines of verse, in which he, with great delicacy, compares his situation to that of a jealous lover, who sends back the picture of his mistress. The king returned the key and the ribbon; but they were not followed by an immediate reconciliation. Voltaire set out to pay a visit to her highness the duchess of Gotha, who honoured him with her friendship as long as she lived. While he remained at Gotha, Maupertuis employed all his batteries against him: Voltaire was arrested by the king's orders, but afterwards released.

He now settled near Geneva; but afterward being obliged to quit that republic, he purchased the castle of Ferney in France, about a league from the lake of Geneva. It was here that he undertook the defence of the celebrated family of Calas; and it was not long before he had a second opportunity of vindicating the innocence of another condemned family of the name of *Sirven*. It is somewhat remarkable, that in the year 1774, he had the third time a singular opportunity of employing that same zeal which he had the good fortune to display in the fatal catastrophe of the families of Calas and Sirven.

In this retreat M. Voltaire continued long to enjoy the pleasures of a rural life, accompanied with the admiration of a vast number of wits and philosophers throughout all Europe. Wearied at length, however, with his situation, or yielding to the importunities of friends, he came to Paris about the beginning of the year 1778, where he wrote a new tragedy called *Irene*. By this time his understanding seems to have been impaired, either through the infirmities of age, or continued intoxication by the flattery of others; and he ridiculously suffered himself to be crowned in public with laurel, in testimony of his great poetical merit. He did not long survive this farce: for having overheated himself with receiving visits, and exhausted his spirits by supplying a perpetual fund of conversation, he was first seized with a spitting of blood; and at last becoming restless in the night-time, he was obliged to use a soporific medicine. Of this he unluckily one night took so large a dose, that he slept 36 hours, and expired a very short time after awakening from it.

VOLUME, in matters of literature, a book or writing of a just bulk to be bound by itself. The name is derived from the Latin *volvere*, "to roll up;" the ancient manner of making up books being in rolls of bark or parchment. See BOOK.

VOLUNTARY, in *Music*, a piece played by a musician extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition to try the instrument, and to lead him into the key of the piece he intends to perform.

VOLUNTEERS, persons who, of their own accord, for the service of the prince or state, serve in the army without being enlisted, to gain honour and preferment.

VOLVOX, a genus of animals belonging to the *vermes infusoria*. See HELMINTHOLOGY *Index*.

VOLUSENUS. See WILSON.

VOLUTA, a genus of shell-fish. See CONCHOLOGY *Index*.

VOLUTE, in *Architecture*, a kind of spiral scroll used in Ionic and Composite capitals, whereof it makes the principal characteristic and ornament.

VOMICA, in *Medicine*, an abscess of the lungs. See MEDICINE, N° 186.

Nux Vomica, in *Pharmacy*. See MATERIA MEDICA *Index*.

VOMIT. See EMETIC, MATERIA MEDICA *Index*.

VOMITING, a retrograde spasmodic motion of the muscular fibres of the œsophagus, stomach and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm; which when gentle create a nausea, when violent a vomiting.

VOORN, one of the islands of Holland, lying at the mouth of the Maese, opposite to Rotterdam.

VORTEX, in *Meteorology*, a whirlwind, or sudden, rapid, and violent motion of the air in circles; or that motion of the water called an *eddy* or whirlpool.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and round the same axis.

VORTICELLA, an animalcule. See MICROSCOPE.

VOSGES, a department in the east of France, forming part of the ancient Lorraine. It takes its name from Mount Vosges, which forms its eastern boundary. It is traversed by the upper branches of the Moselle. The soil of this department is poor in the hilly parts, but tolerably fertile in the plains. It produces vines, though not to a great extent. There are mines of iron, copper, lead, and silver, and quarries of marble. The manufactures are trifling. The extent of the department is 587,955 hectares, and the population in 1817 was 334,169. Epinal is the chief town.

VOSSIUS, JOHN GERARD, a most learned and laborious writer of the 17th century, was of a considerable family in the Netherlands; and was born in 1577, in the palatinate, near Heidelberg, at a place where his father John Vossius was minister. He was made director of the college of Dort, and afterwards professor of eloquence and chronology at Leyden, from whence he was called in 1633 to Amsterdam, to fill the chair of professor of history. He died in 1649.

VOTE, the suffrage or resolve of each of the members of an assemblage, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament.

VOTIVE MEDALS, those on which are expressed the vows of the people for the emperors. See MEDAL.

VOW, a solemn religious promise or oath. See OATH. The use of vows is found in most religions. They make up a considerable part of the Pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprise. Among the Jews, all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow in any thing lawful and possible, he was obliged to fulfil it. If he appointed no particular time for accomplishing his vow, he was bound to do it instantly, lest by delay he should prove less able, or be unwilling, to execute his promise. Among the Romanists, a person is constituted a religious by taking three vows; that of poverty, chastity, and obedience.

Vows, among the Romans, signified sacrifices, offerings, presents, and prayers made for the Cæsars, and emperors, particularly for their prosperity and the continuance of their empire. These were at first made every five years, then every 15, and afterwards every 20, and were called *quinquennalia*, *decennalia*, and *vicennalia*.

VOWEL, in *Grammar*, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice. The vowels are six in number, viz. A, E, I, O, U, Y.

VOWEL, *John*. See HOOKER.

UPHOLSTER, UPHOLSTERER, or *Upholder*, a tradesmen that makes beds, and all sorts of furniture thereunto belonging, &c.

UPLAND, denotes high ground, or, as some call it, *terra firma*, by which it stands opposed to such as is moorish, marshy, or low.

UPLAND, a province of Sweden, bounded on the north-east by the Baltic sea, on the south by the sea of Sudermania, and on the west by Westmania and Gestricia, from which it is separated by the river Dela. It is about 70 miles in length and 45 in breadth, and contains mines of iron and lead. Stockholm is the capital.

UPSAL, a rich and considerable city of Sweden, in Upland, with a famous university, and an archbishop's see. The town is pretty large, and as straight as a line; but most of the houses are of wood, covered with birch bark, with turf on the top. On an eminence, to the south of the town, is a ruined castle. It was formerly the residence of the kings, and is now the usual place where they are crowned. It is seated on the river Sala. It is 26 miles north-west of Stockholm. E. Long. 17. 48. N. Lat. 59. 52.

UPUPA, a genus of birds belonging to the order of *Picæ*. See ORNITHOLOGY *Index*.

UR, in *Ancient Geography*, a citadel of Mesopotamia, situated between the Tigris and Nisibis; taken by some for Ur of the Chaldees, the residence of Abraham. What seems to confirm this is, that from Ur to Haran, the other residence of the patriarch, the road lies directly for Palestine. And it is no objection that Ur is said to be in Mesopotamia; because the parts next the Tigris were occupied by the Chaldeans, as seems to be confirmed from Acts vii. 2, 4. It is called *Orche*, in Strabo; *Orchoe*, in Ptolemy.

URALIAN CHAIN, a range of mountains which form part of the boundaries of Asia; anciently known by the name of *Riphæi Montes*. See RIPHÆI *Montes*, and GEOLOGY *Index*.

URANIA, in fabulous history, one of the nine Muses, was supposed to preside over astronomy. She is commonly represented in an azure robe, crowned with stars, and supporting a large globe with both hands.

URANIUM, one of the lately discovered metals. See CHEMISTRY and MINERALOGY *Index*.

URANOSCOPUS, a genus of fishes belonging to the order of *jugulares*. See ICHTHYOLOGY *Index*.

RAPHAEL D'URBINO. See RAPHAEL.

URCHIN, or HEDGEHOG. See ERINACEUS, MAMMALIA *Index*.

Sea URCHIN. See ECHINUS, HELMINTHOLOGY *Index*.

UREA. See CHEMISTRY.

URETERS. See ANATOMY, N° 101.

URETHRA. See ANATOMY, N° 107.

URIC Acid. See CHEMISTRY *Index*.

URIM and THUMMIM, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high-priest dressed in his robes, and having on his pectoral or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus, and several others, maintain, that it meant the precious stones set in the high-priest's breast-plate, which by extraordinary lustre made known the will of God to those who consulted him. Spencer believes that the urim and thummim were two little golden figures shut up in the pectoral as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim as there are particular authors that wrote about them. The safest opinion, according to Broughton, seems to be, that the words *urim* and *thummim* signify some divine virtue and power annexed to the breast-plate of the high-priest, by which an oraculous answer was obtained from God when he was consulted by the high-priest; and that this was called *urim* and *thummim*, to express the clearness and perfection which these oracular answers always carried with them; for urim signifies "light," and thummim "perfection:" these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident. The use made of the urim and thummim was to consult God in difficult cases relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URINAL, in *Medicine*, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons. It is usually of glass, but sometimes of metal.

URINE, a fluid, separated from the blood, and carried by the emulgent arteries to the kidneys, from whence it descends to the bladder by the ureters, and is from time to time emitted thence by the canal of the urethra. See ANATOMY, N° 107. For the properties of urine, see CHEMISTRY *Index*.

URN, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers; now seldom used but in the way of ornament over chimney-pieces, in buffets, &c. The great use of urns among the ancients, was to preserve the ashes of the dead after they were burnt; for which reason they were called *cineraria*, and *urnæ cinerariæ*, and were placed sometimes under the tombstone whereon the epitaph was cut; and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

UROGALLUS. See TETRAO, ORNITHOLOGY *Index*.

URSA, in *Astronomy*, the name of two constellations in the northern hemisphere

URSULINES, in church history, an order of nuns, founded originally by St Angela of Brescia, in the year 1537; and so called from St Ursula, to whom they were dedicated.

URSUS, the BEAR, a genus of quadrupeds belonging to the order of *feræ*. See MAMMALIA *Index*.

URTICA, a genus of plants of the class of monœcia; and in the natural system classed under the 53d order, *Scabridæ*. See BOTANY *Index*.

URTICA Marina. See *ANIMAL-Flower*.

USANCE, in *Commerce*, is a determined time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called because regulated by the usage and custom of the places whereon they are drawn.

USE, in *Law*, the profit or benefit of lands and tenements; or a trust and confidence reposed on a person for the holding of lands, &c. that he to whose use the trust is made shall receive the profits.

USHANT, an island of France, 15 miles west of the coast of Britanny, at the entrance of the British channel.

USHER, an officer or servant who has the care and direction of the door of a court, hall, chamber, or the like.

USHER of the Black Rod, the eldest of the gentlemen ushers, daily waiters at court, whose duty is to bear the rod before the king at the feast of St George, and other solemnities.

USK, a river of Wales, which rises on the west of Brecknockshire, and runs south-east through that county and Monmouthshire, falling into the mouth of the Severn.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of brandy, or other spirits, put a pound of Spanish liquorice, half a pound of raisins of the sun, four ounces of currants, and three of sliced dates; the tops of baum, mint, savory, thyme, and the tops of the flowers of rosemary, of each two ounces; cinnamon and mace well bruised, nutmegs, aniseeds, and coriander seeds, bruised likewise, of each four ounces; of citron or lemon, and orange-peel, scraped, of each an ounce: let all these infuse 48 hours in a warm place, often shaking them together; then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it is to be put an equal quantity of neat white port, and a gallon of canary; after which it is to be sweetened with a sufficient quantity of double refined sugar.

USTION, in *Pharmacy*, the preparing of certain substances by burning them.

USUFRUIT, in the *Civil Law*, the use or enjoyment of any lands or tenements; or the right of receiving the fruits and profits of an inheritance, or other thing, without a power of alienating or changing the property thereof.

USURER, a person charged with a habit or act of usury.

USURIOUS CONTRACT, is any bargain or contract whereby a man is obliged to pay more interest for money than the statute allows.

USURPATION, in *Law*, is an injurious using or enjoyment of a thing for continuance of time, that belongs of right to another.

USURY, an unlawful contract upon the loan of money, to receive the same again with exorbitant increase. Under the article INTEREST, it was observed, that by statute 37 Hen. VIII. c. 9. the rate of interest was fixed at 10l. per cent. per annum: which the statute 13 Eliz. c. 8. confirms, and ordains, that all brokers shall be guilty of a *præmunire* who transact any contracts for more, and the securities themselves shall be void. The statute 21 Jac. I. c 17. reduced interest to 8l. per cent.; and it having been lowered in 1650, during the usurpation, to 6 per cent. the same reduction was re-enacted after the Restoration by statute 12 Car. II. c. 13. and, lastly, the statute 12 Annæ, st. 2. c. 16. has reduced it to 5 per cent. Wherefore not only all contracts for taking more are in themselves totally void, but also the lender shall forfeit treble the money borrowed. Also if any scrivener or broker take more than 5s. per cent. procuration-money, or more than 12d. for making a bond, he shall forfeit 20l. with costs, and shall suffer imprisonment for half a-year.

UTERUS. See ANATOMY, N° 108.

UTICA, in *Ancient Geography*, a town of Africa Propria, on the Mediterranean: a Tyrian colony, and older than Carthage, (Sil. Italicus); its name, according to Bochart, denoting *old*: reckoned second to it; but after the destruction of Carthage, became the capital and centre of all the Roman transactions in Africa, according to Strabo; who adds, that it stood on the same bay with Carthage, at one of the promontories called *Apollonium*, bounding the bay on the west side, the other to the east called *Hermeia*, being at Carthage. It became famous by the death of Cato who thence was called *Uticensis*.

UTRECHT, one of the seven United Provinces or States of Holland, wholly surrounded by Holland and Guelderland, excepting a small part of it that borders on the Zuyder Zee. Its greatest length is about 32 miles, and breadth about 22. It enjoys a good air; and in most places the soil is fruitful, but in some sandy, or what is called *turf-ground*, and in others overrun with wood. It is watered by the Leck, Rhine, Vecht, and other smaller rivers, besides several canals; of which that extending from the village of Vreeswyk to Utrecht is one of the chief.

UTRECHT, in Latin *Ultrajectum*, *Trajectum vetus* or *inferius*, or *Trajectum Rheni*, capital of a province of the same name, so called from its ancient ferry or passage here over the Rhine; the word being compounded of *trecht*, which in Dutch signifies "a ferry," and *oud* or *olt*, i. e. "old." It is a fair, large, and populous city, situated 19 miles from Amsterdam, 25 from Rotterdam, and 27 from Leyden. Here is a stately town-house, with a commandery of the Teutonic order, and a celebrated university, which was founded in 1630, since which it hath flourished greatly, though it has not all the privileges of most other universities; being wholly subject to the magistrates of the city. The mall without the town, having five rows of lofty limes on each side, is very pleasant: and the physic-garden belonging to the university is extremely curious. There are five churches here that have chapters; but the members of these purchase the places, of which some cost 6000 or 7000 guilders. The streams which run through several of the streets, contribute much to the beauty and cleanliness of the town; and the canal that is cut from the Leck, and passes through it to Amsterdam, will carry ships of any burden. Pope Adrian VI. was a native of this city. Here, in 1579, the memorable union was formed between the seven provinces; and, in 1713, the celebrated peace concluded between France on the one part, and the allies on the other. The Papists have a nominal archbishop of this city; and there is a silk manufactory carried on in it, which employs a number of hands. The inhabitants are supposed to amount to 30,000. E. Long. 5. 8. N. Lat. 52. 7.

UTRICULARIA, a genus of plants of the class of diandria; and in the natural system arranged under the 24th order, *Corydales*. See BOTANY *Index*.

UVA URSI. See ARBUTUS, BOTANY *Index*.

VULCAN, in Pagan worship, the god of subterraneous fire and metals, was the son of Jupiter and Juno; and was said to be so remarkably deformed, that his father threw him down from heaven to the isle of Lemnos, in which fall he broke his leg, and there he set up his forge, and taught men how to soften and polish brass and iron. Thence he removed to the Liparian isles, near Sicily, where, by the assistance of the Cyclops, he made Jupiter's thunderbolts, and armour for the other gods. Notwithstanding the deformity of his person, he had a passion for Minerva, and by Jupiter's consent made his addresses to her, but without success. He was, however, more fortunate in his suit to Venus; who, after marriage, chose Mars for her gallant; when Vulcan exposed them to the ridicule of the other gods, by taking them in a net.

VULGATE, a very ancient Latin translation of the Bible, and the only one acknowledged by the church of Rome to be authentic. See BIBLE.

VULNERARY, in *Medicine*, an epithet formerly given to remedies supposed to possess virtues for the cure of wounds and ulcers.

VULTUR, a genus of birds belonging to the order of *Accipitres*. See ORNITHOLOGY *Index*.

VULVA. See ANATOMY, N° 132.

UVULA. See ANATOMY, N° 102.

UZ, or UTZ, the country and place of residence of Job. In the genealogy of the patriarchs there are three persons called *Uz*, either of which might give this district its name. The first was the grandson of Sem, by his son Aram (Gen. xxii. 23.), who, according to Josephus, occupied the Trachonitis, and Damascus, to the north of Palestine: but Job was among the sons of the East. Another *Uz* was the son of Nahor, Abraham's brother (Gen. x. 21.), who appears to have removed, after passing the Euphrates, from Haran of Mesopotamia to Arabia Deserta. The third *Uz* was a Horite, from Mount Seir (Gen. xxxvi. 28.), and thus not of Eber's posterity. Now the question is, from which of these Job's country, Uz, took its name: Not from the first, as is already shown; nor from the second, because his country is always called *Seir*, or *Edom*, never *Uz*; and then called a *south*, not an *east*, country, in Scripture. It therefore remains, that we look for the country and place of residence of Job in Arabia Deserta; for which there were very probable reasons. The plunderers of Job are called *Chaldeans* and *Sabeans*, next neighbours to him. These Sabeans came not from Arabia Felix, but from a nearer Sabe in Arabia Deserta (Ptolemy); and his friends, except Eliphaz the Themanite, were of Arabia Deserta.

UZBECK TARTARY. See TARTARY.

W.

W, or w, is the 21st letter of our alphabet; and is composed, as its name implies, of two v's. It was not in use among the Hebrews, Greeks, or Romans; but chiefly peculiar to the northern nations, the Teutones, Saxons, Britons, &c. But still it is not used by the French, Italians, Spaniards, or Portuguese, except in proper names, and other terms borrowed from languages in which it is originally used, and even then it is sounded like the single v. This letter is of an ambiguous nature; being a consonant at the beginning of words, and a vowel at the end. It may stand before all the vowels except *u*; as *water*, *wedge*, *winter*, *wonder*: it may also follow the vowels *a*, *e*, *o*, and unites with them into a kind of double vowel, or diphthong; as in *saw*, *few*, *cow*, &c. It also goes before *r*, and follows *s* and *th*; as in *wrath*, *swear*, *thwart*: it goes before *h* also, though in reality it is sounded after it; as in *when*, *what*, &c. In some words it is obscure, as in *shadow*, *widow*, &c.

WAAG, a river of Hungary, which rises in the Carpathian mountains, and falls into the Danube opposite to the island of Schut.

WAAL, a river of the United Netherlands, being one of the branches of the Rhine, which runs from east to west, through Guelderland; passing by Nimeguen, Tiel, Bommel, and Gorcum; and, uniting with the Maes, falls into the German sea below the Briel.

WACHENDORFIA, a genus of plants of the class of of triandria; and arranged in the natural method under the 6th order, *Ensatæ*. See BOTANY *Index*.

WADD, or WADDING, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber; or to put up close to the shot, to keep it from rolling out.

WADSET, in *Scots Law*. See LAW, N° clxix. 1.

WAFERS, or *Sealing Wafers*, are made thus: Take very fine flour, mix it with glair of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread the batter, being made thin with gum-water, on even tin plates, and dry them in a stove; then cut them out for use.

You may make them of what colour you please, by tinging the paste with brasil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGER *of Law*. See (*Wager of*) LAW.

Wager of Battel. See (*Wager of*) BATTEL.

WAGGON, a wheel-carriage, of which there are various forms, accommodated to the different uses they are intended for. The common waggon consists of the shafts or rods, being the two pieces which the hind horse bears up; the welds; the slotes, or cross pieces, which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree turn in wheeling the waggon across the road; the chest or body of the waggon, having the staves or rails fixed thereon; the bales, or hoops which compose the top; the tilt, the place covered with cloth, at the end of the waggon. See MECHANICS, Sect. iv.

WAGTAIL. See MOTACILLA, ORNITHOLOGY *Index*.

WAIFS, BONA WAVIATA, are goods stolen, and waived or thrown away by the thief in his flight, for fear of being apprehended. These are given to the king by the law, as a punishment upon the owner for not himself pursuing the felon, and taking away his goods from him. And therefore if the party robbed do his diligence immediately to follow and apprehend the thief (which is called *making fresh suit*), or do convict him afterwards, or procure evidence to convict him, he shall have his goods again. Waived goods do also not belong to the king till seized by somebody for his use; for if the party robbed can seize them first, though at the distance of 20 years, the king shall never have them. If the goods are hid by the thief, or left anywhere by him, so that he had them not about him when he fled, and therefore did not throw them away in his flight; these also are not *bona waviata*, but the owner may have them again when he pleases. The goods of a foreign merchant, though stolen and thrown away in flight, shall never be waifs: the reason whereof may be, not only for the encouragement of trade, but also because there is no wilful default in the foreign merchant's not pursuing the thief, he being generally a stranger to our laws, our usages, and our language.

WAIGATS STRAITS, situated between Nova Zembla and Russia, through which the Dutch sailed to the north, as high as 75°, in order to discover a north-east passage to China and the East Indies.

WAINSCOT, in building, the timber-work that serves to line the walls of a room, being usually made in pannels, and painted, to serve instead of hangings.

WAIVE, in *Law*, a woman that is put out of the protection of the law. She is called *waive*, as being forsaken of the law; and not an *outlaw* as a man is; by reason women cannot be of the decenna, and are not sworn in leets to the king, nor to the law, as men are; who are therefore within the law; whereas women are not, and so cannot be outlawed, since they never were within it.

WAKE, the print or track impressed by the course of a ship on the surface of the water. It is formed by the re-union of the body of water which was separated by the ship's bottom whilst moving through it; and may be seen to a considerable distance behind the stern, as smoother than the rest of the sea. Hence it is usually observed by the compass, to discover the angle of lee-way.

A ship is said to be in the wake of another when she follows her on the same track, or a line supposed to be formed on the continuation of her keel.

Two distant objects observed at sea are called in the wake of each other, when the view of the farthest is intercepted by the nearest so that the observer's eye and the two objects are all placed upon the same right line.

WAKE is the eve-feast of the dedication of churches, which is kept with feasting and rural diversions.

Mr Whitaker, in his History of Manchester, has given a particular account of the origin of wakes and fairs. He observes, that every church at its consecration received the name of some particular saint; this custom was practised among the Roman Britons, and continued among the Saxons; and in the council of Cealchythe, in 816, the name of the denominating saint was expressly required to be inscribed on the altars, and also on the walls of the church, or a tablet within it. The feast of this saint became of course the festival of the church. Thus Christian festivals were substituted in the room of the idolatrous anniversaries of heathenism: accordingly, at the first introduction of Christianity among the Jutes of Kent, Pope Gregory the Great advised, what had been previously done among the Britons, viz. Christian festivals to be instituted in the room of the idolatrous, and the suffering day of the martyr whose relics were reposited in the church, or the day on which the building was actually dedicated, to be the established feast of the parish. Both were appointed and observed; and they were clearly distinguished at first among the Saxons, as appears from the laws of the Confessor, where the *dies dedicationis*, or *dedicatio*, is repeatedly discriminated from the *propria festivitas sancti*, or *celebratio sancti*. They remained equally distinct to the Reformation; the dedication-day in 1536 being ordered for the future to be kept on the first Sunday in October, and the festival of the patron saint to be celebrated no longer. The latter was, by way of pre-eminence, denominated the *church's holiday*, or its peculiar festival; and while this remains in many parishes at present, the other is so utterly annihilated in all, that Bishop Kennet (says Mr Whitaker) knew nothing of its distinct existence, and has attributed to the day of dedication what is true only concerning the saint's day. Thus instituted at first, the day of the tutelar saint was observed, most probably by the Britons, and certainly by the Saxons, with great devotion. And the evening before every saint's day, in the Saxon Jewish method of reckoning the hours, being an actual hour of the day, Wake. and therefore like that appropriated to the duties of public religion, as they reckoned Sunday from the first to commence at the sunset of Saturday; the evening preceding the church's holiday would be observed with all the devotion of the festival. The people actually repaired to the church, and joined in the services of it; and they thus spent the evening of their greater festivities in the monasteries of the North, as early as the conclusion of the seventh century.

These services were naturally denominated from their late hours *wæcan* or *wakes*, and *vigils* or *eves*. That of the anniversary at Rippon, as early as the commencement of the eighth century, is expressly denominated the *vigil*. But that of the church's holiday was named *cyric wæcan*, or church-wake, the church-vigil, or church eve. And it was this commencement of both with a wake, which has now caused the days to be generally preceded with vigils, and the church-holiday particularly to be denominated the *church-wake*. So religiously was the eve and festival of the patron saint observed for many ages by the Saxons, even as late as the reign of Edgar, the former being spent in the church, and employed in prayer. And the wakes, and all the other holidays in the year, were put upon the same footing with the Octaves of Christmas, Easter, and of Pentecost. When Gregory recommended the festival of the patron saint, he advised the people to erect booths of branches about the church on the day of the festival, and to feast and be merry in them with innocence. Accordingly, in every parish, on the returning anniversary of the saint, little pavilions were constructed of boughs, and the people indulged in them to hospitality and mirth. The feasting of the saint's day, however, was soon abused; and even in the body of the church, when the people were assembled for devotion, they began to mind diversions, and to introduce drinking. The growing intemperance gradually stained the service of the vigil, till the festivity of it was converted, as it now is, into the rigour of a fast. At length they too justly scandalized the Puritans of the last century, and numbers of the wakes were disused entirely, especially in the east and some western parts of England; but they are commonly observed in the north, and in the midland counties.

This custom of celebrity in the neighbourhood of the church, on the days of particular saints, was introduced into England from the continent, and must have been familiar equally to the Britons and Saxons; being observed among the churches of Asia in the sixth century, and by those of the west of Europe in the seventh. And equally in Asia and Europe, on the continent and in the islands, those celebrities were the causes of those commercial marts which we denominate *fairs*. The people resorted in crowds to the festival, and a considerable provision would be wanted for their entertainment. The prospect of interest invited the little traders of the country to come and offer their wares; and thus, among the many pavilions for hospitality in the neighbourhood of the church, various booths were erected for the sale of different commodities. In larger towns, surrounded with populous districts, the resort of the people to the wakes would be great, and the attendance of traders numerous; and this resort and attendance constitute a fair.—Basil expressly mentions the numerous appearance of traders at these festivals in Asia, and Gregory notes the same custom to be common in Europe. And as the festival was observed on a feria or holyday, it naturally assumed to itself, and as naturally communicated to the mart, the appellation of *feria* or fair. Indeed several of our most ancient fairs appear to have been usually held, and have been continued to our time, on the original church-holydays of the places: besides, it is observable, that fairs were generally kept in church-yards, and even in the churches, and also on Sundays, till the indecency and scandal were so great as to need reformation.

Wake ‖ Wales.

Wake-Robin. See ARUM, BOTANY *Index*.

WALACHIA, a province of Turkey in Europe, bounded on the north by Moldavia and Transylvania; on the east and south by the river Danube, and on the west by Transylvania. It is 225 miles in length, and 125 in breadth; and was ceded to the Turks by the treaty of Belgrade, in 1739. It abounds in good horses and cattle; and there are mines of several kinds. The soil is so fertile, that it is capable of producing any thing; and there are good pastures, with wine, oil, and all manner of European fruits. The inhabitants are chiefly of the Greek church.

WALCHEREN, an island of the Low Countries, and one of the principal of those of Zealand; separated from Dutch Flanders by the mouth of the Scheldt. It is about nine miles in length, and eight in breadth; and though it lies low, has good arable and pasture land. The chief town of this island and the whole province is Middleburgh. But the principal sea port is Flushing, which is strongly fortified. Walcheren was taken by the British forces in August 1809; but it soon after was abandoned, the troops having suffered severely by sickness.

WALDEN, a town of Essex, commonly called *Saffron Walden*, with a market on Saturdays, and two fairs on Midlent Saturday for horses, and November 1st for cows. It is remarkable for the plenty of saffron that grows about it. This town was incorporated by Edward VI. and is governed by a mayor and 24 aldermen. It is 27 miles north-west-by-north of Chelmsford, and 43 north-east of London. E. Long. 0. 20. N. Lat. 52. 4.

WALDENSES. See WALDO.

WALDO, a merchant of Lyons in the latter part of the 12th century, who applying himself to the study of the Scriptures, and finding no warrant there for several of the Romish doctrines, particularly that of transubstantiation, publicly opposed them. His followers, who from him were called *Waldenses*, being chased from Lyons, spread over Dauphiné and Provence; upon which Philip II. is said to have razed 300 gentlemen's seats, and destroyed several walled towns to stop their growth: but this, instead of suppressing, spread them over a great part of Europe. The articles of their faith, which they drew up and dedicated to the king of France, agreed in most points with those of the present Protestants. In the year 1200, those of them who dwelt in the province of Albigeois in Languedoc, from whence they were called *Albigenses*, stood upon their defence; upon which Philip drove them into Bohemia, Savoy, and England. The crusade against them is said to have consisted of 500,000 men, who wore their crosses on their breasts, to distinguish themselves from those who went to the Holy Land, and wore them on their shoulders.

WALES, a country situated in the south-west part of of Britain, into which the ancient Britons retired from the persecution of the Saxons. Anciently it was of greater extent than it is at present, and comprehended all the country beyond the Severn; that is, besides the 12 counties included in it at present, those of Herefordshire and Monmouthshire, which now are reckoned a part of England, were then inhabited by three different tribes of the Britons, namely the Silures, the Dimetæ, and the Ordovices. The Romans were never able to subdue them, till the reign of Vespasian, when they were reduced by Julius Frontinus, who placed garrisons in their country to keep them in awe. Though the Saxons made themselves masters of all England, they never could get possession of Wales, except the counties of Monmouthshire and Herefordshire, formerly a part of Wales. About the year 870, Roderic king of Wales divided it among his three sons; and the names of these divisions were, *Demetia*, or *South-Wales; Povesia*, or *Powis-Land;* and *Venedotia*, or *North Wales.* Another division is mentioned afterwards in the records, viz. North Wales, South Wales, and West Wales; the last comprehending the counties of Monmouth and Hereford. The country derived the name of *Wales*, and the inhabitants that of *Welsh*, from the Saxons, who by those terms denote a country and people to which they are strangers; for the Welsh, in their own language, call their country *Cymry*, and their language *Cymraeg*. They continued under their own princes and laws from the above-mentioned period, and were never entirely subjected to the crown of England till the reign of Edward I. when Llewellin ap Gryffith, prince of Wales, lost both his life and dominions. Edward, the better to secure his conquest, and to reconcile the Welsh to a foreign yoke, sent his queen to lie in at Caernarvon, where she was delivered of a prince; to whom the Welsh, on that account, the more readily submitted. Ever since that time, the eldest sons of the kings of England have commonly been created princes of Wales, and as such enjoy certain revenues from that country.

As to the character of the Welsh, they are said to be a brave hospitable people; and though very jealous of affronts, passionate, and hasty, yet are easily reconciled. The common people look with a suspicious eye on strangers, and bear a hereditary grudge to the English nation, by whom their ancestors were expelled from the finest parts of the island. The gentlemen are apt to value themselves upon the antiquity of their families; and with some reason, as they can generally trace them much higher than the inhabitants of most other countries.

All the better sort, both in town and country, can speak English, especially in the counties bordering upon England. The common people, in general, only speak their own language, which is the ancient British; and not only differs entirely from the English, but has very little affinity with any of the western tongues, unless we should except the Gaelic, Erse, or Irish. It is said to be a dialect of the ancient Celtic, and in many respects to resemble the Hebrew. Most of the clergy are natives of the country, and understand English so well, that they could exercise their functions in any part of Britain. The public worship, however, is as often performed in Welsh as in English, excepting in the towns, where the latter is the prevailing language. According to the returns in 1811, the population of Wales was 611,788.

The country, though mountainous, especially in North Wales, is far from being barren or unfruitful; the hills, besides the metals and minerals they contain, feeding vast herds of small black cattle, deer, sheep, and goats, and their valleys abounding in corn, as their seas and rivers do in fish. Here are also wood, coal, and turf, for fuel, in abundance.

Wales is bounded on all sides by the sea and the Severn; except on the east, where it joins to the counties of Chester, Salop, Hereford, and Monmouth. Its length, from the southernmost part of Glamorganshire to the extremity of Flintshire north, is computed at about 113 miles; and its greatest breadth, from the river Wye east to St David's in Pembrokeshire west, is nearly of the same dimensions, being about 90 miles.

After the conquest of Wales by Edward I. very material alterations were made in their laws, so as to reduce them nearer to the English standard, especially in the forms of their judicial proceedings: but they still retained very much of their original polity, particularly their rule of inheritance, viz. that their lands were divided equally among all the issue male, and did not descend to the eldest son alone. By other subsequent statutes their provincial immunities were still farther abridged: but the finishing stroke to their dependency was given by the statute 27 Hen. VIII. c. 26. which at the same time gave the utmost advancement to their civil prosperity, by admitting them to a thorough communication of laws with the subjects of England.—Thus were this brave people gradually conquered into the enjoyment of true liberty; being insensibly put upon the same footing, and made fellow-citizens, with their conquerors.

It is enacted by the 27 Hen. VIII. 1. That the dominions of Wales shall be forever united to the kingdom of England. 2. That all Welshmen born shall have the same liberties as other king's subjects. 3. That lands in Wales shall be inheritable according to the English tenures and rules of descent. 4. That the laws of England, and no other, shall be used in Wales; besides many other regulations of the police of this principality. And the 34 and 35 Hen. VIII. c. 26. confirms the same, adds farther regulations, divides it into 12 shires, and in short, reduces it to the same order in which it stands at this day; differing from the kingdom of England in only a few particulars, and those too of the nature of privileges (such as having courts within itself, independent of the process of Westminster-hall), and some other immaterial peculiarities, hardly more than are to be found in many counties of England itself.

WALKING Leaf, an insect. See *MANTIS Sycifolia*, ENTOMOLGY *Index.*

WALL, in *Architecture*, the principal part of a building, as serving both to inclose it, and to support the roof, floors, &c.—Walls are distinguished into various kinds, from the matter whereof they consist; as plaster or mud walls, brick walls, stone walls, flint or boulder walls, and boarded walls. See ARCHITECTURE.

Cob or *Mud WALL.* In those parts of England where stone is scarce, it is usual to make walls and houses of mud,

mud, or, as it is called in Devonshire, *cob*; which is a composition of earth and straw, wet up somewhat like mortar, but well beat and trod together. When a wall is making, after being raised to a certain height, it is allowed time to pitch or settle before the work is resumed. Some value themselves on their skill in building with this composition; the price, when materials are found, is generally in Devonshire 3s. per perch of 16½ feet; but a stone foundation costs more. Houses built with this, being covered with thatch, are very dry and warm; a cob wall, if in a good situation, will last 50 or 60 years or more. When pulled down, they are used as manure, and new earth employed to rebuild with.

WALLACE, Sir William, a gallant general of the Scots, who endeavoured to rescue his country from the English yoke; but being taken prisoner, he was unjustly tried by the English laws, condemned, and executed as a traitor to Edward I. in 1304. See Scotland, N° 103, *et seq.*

WALLACHIA. See Walachia.

WALLER, Edmund, a celebrated English poet, was the son of Robert Waller, Esq. of Agmondesham in Buckinghamshire, by Anne, the sister of the great Hampden who distinguished himself so much in the beginning of the civil wars. He was born in 1605; and his father dying when he was very young, the care of his education fell to his mother, who sent him to Eton school. He was afterwards sent to King's college in Cambridge, where he must have been very assiduous in his studies, since, at sixteen or seventeen years of age, he was chosen into the last parliament of King James I. and served as burgess for Agmondesham. He began to exercise his political talent so early as the year 1623; as appears from his verses "upon the danger his majesty (being prince) escaped in the road of St Andero;" for there Prince Charles returning from Spain that year, had like to have been cast away. It was not, however, Mr Waller's wit, his fine parts, or his poetry, that so much occasioned him to be first publicly known, as his carrying off the daughter and sole heiress of a rich citizen, against a rival whose interest was espoused by the court. It is not known at what time he married his first lady; but he was a widower before he was 25, when he began to have a passion for Sacharissa, which was a fictitious name for the lady Dorothy Sidney, daughter to the earl of Leicester, and afterwards wife to the earl of Sunderland. He was now known at court, caressed by all who had any relish for wit and polite literature; and was one of the famous club of which Lord Falkland, Mr Chillingworth, and other eminent men, were members. He was returned burgess for Agmondesham in the parliament which met in April 1640. An intermission of parliaments having disgusted the nation, and raised jealousies against the designs of the court, which would be sure to discover themselves whenever the king came to ask for a supply, Mr Waller was one of the first who condemned the preceding measures. He showed himself in opposition to the court, and made a speech in the house on this occasion; from which we may gather some notion of his general principles in government; wherein, however, he afterwards proved very variable and inconstant. He opposed the court also in the long parliament which met in November following, and was chosen to impeach Judge Crawley, which he did in a warm and eloquent speech, July 16th 1641. This speech was so highly applauded, that 20,000 copies of it were sold in one day. In 1642, he was one of the commissioners appointed by the parliament to present their propositions of peace to the king at Oxford. In 1643, he was deeply engaged in a design to reduce the city of London and the Tower to the service of the king; for which he was tried and condemned, together with Mr Tomkins his brother-in-law, and Mr Challoner. The two latter suffered death; but Mr Waller obtained a reprieve: he was, however, sentenced to suffer a year's imprisonment, and to pay a fine of 10,000l. After this, he became particularly attached to Oliver Cromwell, upon whom he wrote a very handsome panegyric. He also wrote a noble poem on the death of that great man.

At the Restoration, he was treated with great civility by Charles II. who always made him one of the party in his diversions at the duke of Buckingham's and other places. He wrote a panegyric upon his majesty's return; which being thought to fall much short of that he had before written on Oliver Cromwell, the king one day asked him in raillery, "How is it, Waller, that you wrote a better encomium on Cromwell than on me?" "May it please your majesty," answered he, "we poets generally succeed best in fiction." He sat in several parliaments after the Restoration, and continued in the full vigour of his genius to the end of his life, his natural vivacity bearing him up, and making his company agreeable to the last. He died of a dropsy in 1687, and was interred in the churchyard of Beaconsfield, where a monument is erected to his memory. Mr Waller has been honoured as the most elegant and harmonious versifier of his time, and a great refiner of the English language. The best edition of his works, containing poems, speeches, letters, &c. is that published in quarto by Mr Fenton, to 1730.

WALLIS, Dr John, a celebrated mathematician, was educated at Cambridge; where he became fellow of Queen's college, and continued so till, by his marriage, he vacated his fellowship. In 1640, he received holy orders, and became chaplain to the lady Vere. While he lived in this family, he cultivated the art of deciphering; and it is said that the elector of Brandenburgh, for whom he explained several letters written in ciphers, sent him a gold chain and medal. In 1643 he published, "Truth tried; or Animadversions on the Lord Brooke's treatise, called *The Nature of Truth*, &c." The next year he was chosen one of the scribes or secretaries to the assembly of divines at Westminster. Dr Peter Turner, Savilian professor of geometry in Oxford, being ejected by the parliament-visitors in 1649, Mr Wallis was appointed to succeed him in that place. In 1653 he published at Oxford a Grammar of the English Tongue in Latin. In 1655 he entered the lists with Mr Hobbes; and their controversy lasted a considerable time. In 1657 the Doctor published his Mathematical Works. Upon the death of Dr Langbaine, he was chosen custos archivorum of the university. After the Restoration he met with great respect, the king himself entertaining a favourable opinion of him on account of some services he had done both to his royal father and himself. He was therefore confirmed in his places, admitted one of the king's chaplains in ordinary, and appointed one of the divines empowered to review the book of common prayer. He complied with the terms

Wallis || Walpole.

terms of the act of uniformity, and continued a steady conformist till his death. He was one of the first members of the Royal Society, and corresponded with many learned men. In 1697, the curators of the university press at Oxford thought it for the honour of the university to collect the mathematical works of the Doctor, which had been printed separately, some in Latin, some in English, and published them all together in the Latin tongue, in three vols, folio. He died in 1703. He speaks of himself thus: "It hath been my endeavour all along to act by moderate principles, being willing, whatever side was uppermost, to promote any good design for the true interest of religion, of learning, and of the public good." Besides the works above mentioned, he published many others.

WALLOONS, a name for the inhabitants of a considerable part of the Netherlands, viz Artois, Hainault, Naum, Luxemburgh, and part of Flanders and Brabant.

WALNUT-TREE. See JUGLANS, BOTANY *Index*.

WALPOLE, SIR ROBERT, earl of Orford, was born at Houghton in Norfolk, September 6th, 1674, and educated on the foundation at Eton school. Thence he was elected to King's College in Cambridge; but, succeeding to the family estate by the death of his elder brother, he resigned his fellowship. In 1700, he was chosen member of parliament for King's Lynn, and represented that borough in several succeeding parliaments. In 1705, he was nominated one of the council, to Prince George of Denmark, lord high admiral of England; in 1707, appointed secretary at war; and, in 1709, treasurer of the navy. In 1710, upon the change of the ministry, he was removed from all his posts, and held no place afterwards during the queen's reign. In 1711 he was expelled from the house of commons for what they called notorious corruption in his office as secretary at war. The borough of Lynn, however, re-elected him; and, though the house declared the election void, yet they persisted in the choice. In the well-known debate relating to Steele for publishing the Crisis, he greatly distinguished himself in behalf of liberty, and added to the popularity he had before acquired.

On the death of the queen, a revolution of politics took place, and the Whig party prevailed both at court and in the senate. Walpole had before recommended himself to the house of Hanover by his zeal for its cause, when the commons considered the state of the nation with regard to the Protestant succession: and he had now the honour to procure the assurance of the house to the new king (which attended the address of condolence and congratulation), "That the commons would make good all parliamentary funds." It is therefore not to be wondered at, that his promotion soon took place after the king's arrival; and that in a few days he was appointed receiver and paymaster-general of all the guards and garrisons, and of all other the land forces in Great Britain, paymaster of the royal hospital at Chelsea, and likewise a privy counsellor. On the opening of a new parliament, a committee of secrecy was chosen to inquire into the conduct of the late ministry, of which Walpole was appointed chairman; and, by his management, articles of impeachment were read against the earl of Oxford, Lord Bolingbroke, the duke of Ormond, and the earl of Strafford. The eminent service he was thought to have done the crown, by the vigorous prosecution of those ministers who were deemed the chief instruments of the peace, was soon rewarded by the extraordinary promotions to the offices of first commissioner of the treasury, and chancellor and under treasurer of the exchequer.

Walpole.

In two years time he resigned all his offices, on account of a misunderstanding which took place between him and the rest of the ministry about certain supplies demanded for the support of his majesty's German dominions. On the day of his resignation he brought in the famous sinking-fund bill, which he presented as a country gentleman, saying, that he hoped it would not fare the worse for having two fathers; and that his successor Mr Stanhope would bring it to perfection. His calling himself the father of a project, which hath since been so often employed to other purposes than were at first declared, gave his enemies frequent opportunity for satire and ridicule; and it hath been sarcastically observed, that the father of this fund appeared in a very bad light when viewed in the capacity of a nurse. In the next session of parliament, Walpole opposed the ministry in every thing; and even Wyndham or Shippen did not exceed him in patriotism. Upon a motion in the house for continuing the army, he made a speech of above an hour long, and displayed the danger of a standing army in a free country, with all the powers of eloquence. Early in 1720 the rigour of the patriot began to soften, and the complaisance of the courtier to appear; and he was again appointed paymaster of the forces, and several of his friends were found soon after in the list of promotions. No doubt now remained of his entire conversion to court measures; for before the end of the year, we find him pleading as strongly for the forces required by the war-office as he had before declaimed against them, even though at this time the same pretences for keeping them on foot did not exist.

It was not long before he acquired full ministerial power, being appointed first lord commissioner of the treasury, and chancellor of the exchequer; and, when the king went abroad in 1723, he was nominated one of the lords justices for the administration of government, and was sworn sole secretary of state. About this time he received another distinguished mark of the royal favour; his eldest son then on his travels being created a peer, by the title of Baron Walpole of Walpole. In 1725 he was made knight of the Bath, and the year after knight of the Garter. The measures of his administration, during the long time he remained prime or rather sole minister, have been often canvassed with all the severity of critical inquiry. It is difficult to discern the truth through the exaggerations and misrepresentations of party. He has indeed been accused of employing the sinking fund for the purposes of corruption, of which it was long the fashion to call him the father; but the man who reflects on the transactions of Charles II. and his infamous cabal, will acquit him of the latter part of this charge. He was an enemy to war, and the friend of commerce; and because he did not resent some petty insults of the court of Spain so suddenly as the fiery part of the nation thought he should have done, a formidable opposition was formed against him in the house, which had influence enough to

Walpole. to employ in its cause almost all the wit of the nation. Pulteney and Pitt were the great leaders of the party in the house of commons; while Bolingbroke and Pope and Johnson, and almost every man of genius, exerted themselves without doors to enlighten, by pamphlets in prose and verse, the minds of the people, and show the necessity of a Spanish war. This he strenuously opposed, because he knew that the foreign settlements of that power are very remote, and in a climate destructive to Englishmen; and that such of them as we might be able to take, we could not possibly retain. The opposition however prevailed. The nation was indulged in a war, of which it surely had no cause to boast of the success; and it is now universally known, that the greater part of those who with honest intentions had, either in parliament or out of it, been engaged to run down the minister, lived to repent of their conduct, and do justice to the man whom they had so pertinaciously vilified.

In order to encourage commerce and improve the revenue, Sir Robert projected a scheme for an extension of the excise, as the only means of putting a stop to the frauds of merchants and illicit traders. This was another ground of clamour to the orators within, and the wits without, doors; and while the opposition represented it as a measure big with public mischief, Swift and Pope occasionally alluded to it as an oppression calculated to deprive private life of all its comforts. The minister was therefore obliged to abandon the scheme; but in a succeeding administration it was partly carried into execution, at the express solicitation of the principal persons concerned in that article of trade which it was suggested would be most affected by it; and afterwards the most popular minister that ever directed the councils of this country declared in full senate, that if a time should ever arrive which was likely to render the project feasible, he would himself recommend an extension of the excise laws as a measure of the greatest advantage to commerce, to the revenue, and to the general interests of the kingdom.

In 1742 the opposition prevailed; and Sir Robert being no longer able to carry a majority in the house of commons, resigned all his places, and fled for shelter behind the throne. He was soon afterwards created earl of Orford; and the king, in consideration of his long and faithful services, granted him a pension of 4000l. per annum. The remainder of his life he spent in tranquillity and retirement, and died, in 1745, in the 71st year of his age.

He has been severely, and not unjustly, censured for that system of corruption by which he almost avowed that he governed the nation; but the objects which he had in view are now acknowledged to have been in a high degree praise-worthy. Johnson, who in the earlier part of his life had joined the other wits in writing against his measures, afterwards honoured his memory for the placability of his temper, and for keeping this country in peace for so many years; and Mr Burke has * declared, that his only defect as a minister was the want of sufficient firmness to treat with contempt that popular clamour, which, by his yielding to it, hurried the nation into an expensive and unjust war. But his rancorous prosecution of Atterbury bishop of Rochester (see ATTERBURY), by a bill of pains and penalties, may be considered as something worse than a defect: it was a fault for which no apology can be made; because, whether that prelate was innocent or guilty, of his guilt no legal proof ever appeared. In that instance the conduct of the minister was the more extraordinary, that on other occasions he chose to gain over the disaffected by mildness and beneficence, even when he had sufficient proofs of their guilt. Of this the following anecdote, communicated by Lord North to Dr Johnson, is a sufficient proof. Sir Robert having got into his hands some treasonable papers of his inveterate enemy Shippen, sent for him, and burnt them before his eyes. Some time afterwards, while Shippen was taking the oaths to the government in the house of commons, Sir Robert, who stood next to him, and knew his principles to be the same as ever, smiled; upon which Shippen, who had observed him, said "Egad, Robin, that's hardly fair."

* *Letters on a Regicide Peace.*

Walpole ‖ Walsingham.

To whatever objections his ministerial conduct may be liable, in his private character he is universally allowed to have had amiable and benevolent qualities. That he was a tender parent, a kind master, a beneficent patron, a firm friend, an agreeable companion, are points that have been seldom disputed; and so calm and equal was his temper, that Pulteney, his great rival and opponent, said, he was sure that Sir Robert Walpole never felt the bitterest invective against him for half an hour.

About the end of Queen Anne's reign, and the beginning of George I.'s he wrote the following pamphlets. 1. The Sovereign's Answer to the Gloucestershire Address. The Sovereign meant Charles duke of Somerset, so nicknamed by the Whigs. 2. Answer to the Representation of the House of Lords on the State of the Navy, 1709. 3. The Debts of the Nation stated and considered, in four Papers, 1710. 4. The Thirty-five Millions accounted for, 1710. 5. A Letter from a foreign Minister in England to Monsieur Pettecum, 1710. 6. Four Letters to a Friend in Scotland upon Sacheverell's Trial; falsely attributed in the General Dictionary to Mr Maynwaring. 7. A Short History of the Parliament. It is an account of the last session of the queen. 8. The South-Sea Scheme considered. 9. A Pamphlet against the Peerage Billl, 1719. 10. The Report of the Secret Committee, June 9th, 1715.

WALRUS. See TRICHECUS, MAMMALIA *Index*.

WALSH, WILLIAM, an English critic and poet, the son of Joseph Walsh, Esq. of Abberley in Worcestershire, was born about the year 1660. He became a gentleman commoner of Wadham college, Oxford, but left the university without taking a degree. His writings are printed among the works of the Minor Poets, printed in 1749. He was made gentleman of the horse in Queen Anne's reign; and died in 1708. He was the friend of Mr Dryden and of Mr Pope; the former of whom esteemed him the best critic then living; and Mr Pope has celebrated his character in the Essay on Criticism.

WALSINGHAM, a town of Norfolk, with a market on Fridays, and a fair on Whit-Monday, for horses and pedlars ware; it is seated not far from the sea; and in former times was famous for its college of canons, and was greatly frequented by pilgrims who went to pay their devotions to the image of the Virgin Mary at the chapel, where there are two fine springs, called the

the *Virgin Mary's wells*. Not many years ago there were found here by a husbandman, 100 urns full of ashes, which were supposed to be those which the Romans filled with the ashes of the dead. It is 22 miles north-west of Norwich, and 117 north-north-east of London. E. Long. 0. 53. N. Lat. 52. 56.

WALSINGHAM, *Thomas*, an English Benedictine monk of the monastery of St Alban's, who lived about the year 1440. He applied himself to the history and antiquity of his country, in quality of historiographer to the king; and composed the History of King Henry VI. with other works.

WALSINGHAM, *Sir Francis*, minister and secretary of state during the reign of Queen Elizabeth, and one of the greatest politicians of his time, was descended from a noble and ancient family at Chislehurst. After having made great progress in his studies at Cambridge, he was twice sent ambassador to France, and at his return to England was employed in the most important affairs, became secretary of state, and was one of the commissioners for the trial of Mary queen of Scotland. Sir Francis was undoubtedly one of the most refined politicians and most penetrating statesman that any age ever produced. He had an admirable talent, both in discovering and managing the secret recesses of the heart. He had his spies in most courts in Christendom, and allowed them a liberal maintenance; for it was his maxim, That knowledge cannot be bought too dear. In 1587 the king of Spain having made vast preparations, which surprised, and kept all Europe in suspense, Walsingham employed his utmost endeavours for the discovery of that important secret; and accordingly procured intelligence from Madrid, that the king had informed his council of his having dispatched an express to Rome, with a letter written with his own hand to the pope, acquainting him with the true design of his preparations, and begging his blessings upon him; which for some reasons he could not disclose till the return of the courier. The secret being thus lodged with the pope, Walsingham, by means of a Venetian priest, whom he retained at Rome as a spy, got a copy of the original letter, which was stolen out of the pope's cabinet by a gentleman of the bed chamber, who took the key out of the pope's pocket while he slept. After this, by his dexterous management, he caused the Spaniards bills to be protested at Genoa, which should have supplied them with money for their extraordinary preparations; and by this means he happily retarded this formidable invasion for a whole year. In short, he spent his whole time and faculties in the service of Queen Elizabeth; on which account her majesty was heard to say, "That in diligence and sagacity he exceeded her expectations." However, after all his eminent services to his country, this man gave a remarkable proof at his death, which happened on the 6th of April 1590, how far he preferred the public interest to his own; he being so poor, that excepting his library, which was a very fine one, he had scarcely effects enough to defray the expence of his funeral. His principal works are, 1. Memoirs and Instructions for the use of Ambassadors, with his Letters and Negociations. 2. Political Memoirs.

WALTHERIA, a genus of plants in the class monadelphia, and in the natural system arranged under the 37th order, *Columniferæ*. See BOTANY *Index*.

WALTON, BRYAN, bishop of Chester, a learned English divine, who gained great reputation by his edition of the Polyglot bible, with his Prolegomena in the beginning; which is more exact, says Father Simon, than any other which had been published on that subject. He died in 1661.

WAMPUM, the money used by the North American Indians. It is much used in all their treaties as a symbol of friendship. It is made of a shell of a particular species of VENUS.

WAPENTAKE, is the same with what is called a *hundred*; especially used in the north counties beyond the river Trent. The word seems to be of Danish original, and to be so called for this reason: When first this kingdom, or part thereof, was divided into wapentakes, he who was the chief of the wapentake or hundred, and who is now called a *high constable*, as soon as he entered upon his office, appeared in a field on a certain day on horseback with a pike in his hand, and all the chief men of the hundred met him there with their lances, and touched his pike; which was a sign that they were firmly united to each other by the touching their weapons. But Sir Thomas Smith says, that anciently musters were made of the armour and weapons of the several inhabitants of every wapentake; and from those that could not find sufficient pledges for their good abearing, their weapons were taken away and given to others; from whence he derives the word.

W A R.

INTRODUCTION.

1 Division of the subject.

IN treating the subject of war, we may consider it first in a *political* and *moral* point of view, as one of those powerful engines employed by civil governments, to bring about some ends which they deem beneficial to the community over which they preside; and secondly, in a *theoretical* and *practical* point of view, as a *science* or an *art*, which the necessities or the follies of mankind have rendered an important object of consideration, not only to certain individuals, but in some measure to society at large.

2 Political objects and causes of war.

From the numerous calamities incident to war, it should be presumed that no wise or good government would have recourse to means so dangerous and expensive, till after all other means of producing the ends they have in view had failed of success. The ostensible objects for which a nation or community engages in a war, are usually to prevent or repel the assaults, encroachments, or invasions of its neighbours; to revenge some insult or injury which the community, its allies, or dependents, may have sustained; to compel some other nation or community to respect what are called the *law of nations*, and the *rights of civil society*; or to preserve

Introduction.

preserve that due and equable *balance of power* among neighbouring states, which has of late been considered as an essential point in the political economy of civilized nations. We say that these are usually the *ostensible* objects of war; for though it will scarcely be denied that ambition, avarice, religious bigotry, a desire of dominion, and a thirst of military fame, have been the real causes of many of those long and bloody wars which have desolated the face of nature, and heaped misery and wretchedness on millions of human beings, we believe few heroes and conquerors, either of ancient or modern times, have had the honesty or effrontery to avow these as the real motives of their military expeditions. Yet, if we examine the pages of history, we shall scarcely find a war, from the Battle of the Kings recorded by the sacred historian, to the present contest which has for 17 years involved all Europe in confusion and bloodshed, and reduced many of its fairest states and provinces under the subjection of a single monarch, in which *one* or other of these latter motives has not, at least to one party, been a principal inducement.

Among the political objects of war, we must not omit to mention one which, though perhaps less openly avowed than any other, has, in monarchical and aristocratical governments, always formed a material part of the state policy;—we mean the object of preventing tumults and commotions among the people, by engaging them in a foreign war. It was long ago observed by a good judge of human nature *, "that no body can be healthful without exercise, neither natural body nor politic;" and that "to a kingdom or a state, a just and honourable war is the true exercise." That politicians have often acted on these principles, is certain. On the justice of the principles themselves, we presume not to decide, though we may safely express a doubt whether the remedy be not worse than the disease, and whether these popular commotions might not be prevented with equal ease, and with more advantage to the nation, by employing the populace in such works of improvement as may advance the manufactures, commerce, or internal comforts of the state.

* *Bacon.*

3
Exuberant population regarded as a primary cause of war.

An able and ingenious writer considers a redundance of population as one of the chief primary causes of war. "One of its first causes and most powerful impulses, was undoubtedly an insufficiency of room and food; and, greatly as the circumstances of mankind have changed since it first began, the same cause still continues to operate, and to produce, though in a smaller degree, the same effects. The ambition of princes would want instruments of destruction, if the distresses of the lower classes did not drive them under their standards. A recruiting serjeant always prays for a bad harvest, and a want of employment, or, in other words, a redundant population †." This redundance he proposes to obviate, and thus to counteract one of the principal causes of war, by throwing obstacles in the way of marriage. Without calling in question the justness of his position, we do not see the necessity of the remedy which he proposes. We must acknowledge ourselves such friends to the increase of population as to think that every encouragement ought to be given to it, instead of throwing obstacles in its way. There are few countries so populous, or so completely cultivated, as to render it necessary to plunge them into wars, in order to diminish the number of inhabitants, which might be abundantly supported, were agriculture encouraged, and gluttony repressed.

† *Malthus on Population*, Edit. 1803. p. 500.

4
Impolicy of war.

Whatever may be the objects for which a nation goes to war; whatever the causes which have induced her to have recourse to such an expedient, we may venture, from history and experience, to affirm that she will gain little solid advantage by the contest. She may drive an invading enemy from her dominions, and pursue him to his own; she may acquire plunder and territory, and may raise her name among the neighbouring states by her victories and prowess; but all these, except the *first*, will scarcely compensate for the blood and treasure which she has expended, and for the check given to her agriculture, manufactures and commerce, by drawing off many of the labouring part of the community to supply the fleets and armies of the state. These are the inevitable consequences even of a successful war; and should it prove otherwise, the calamities and distresses of the vanquished may readily be conceived. Even to the established government of a state, war, while it appears to strengthen their hands and increase their influence, is fraught with difficulty and danger. No situation of affairs is so well calculated to show the abilities or insufficiency of a cabinet as this, and melancholy is the fate of that nation whose administration is then conducted by a weak, inexperienced, or profligate ministry; but be they ever so able or so upright, still the want of success, or a reverse of fortune, will lower them in the opinion of the people, and will compel them at last to conclude a disadvantageous, perhaps a dishonourable peace, or quit their posts and leave the task to a more popular or successful administration.

The evils of war do not terminate on the return of peace. Many of the burdens which it had imposed on the people must still continue, to discharge the debt contracted by the state; while the sudden disbanding of the fleets and armies pours into the community numbers of idle and dissipated men, averse to labour, and accustomed to scenes of confusion, slaughter and rapine. At no time are robberies, murders, or seditions, so frequent as on the termination of a long protracted war; at none are the internal peace and quiet of a nation in so much danger.

5
Moral evils of war.

On the *moral* evils of war we surely need not enlarge. In itself, when undertaken without necessity, it is an act of the most criminal and atrocious nature; and the aggressors are accountable for all the horrid consequences which may attend it. "The pomp and circumstances of glorious war" may form a desirable subject for the poet and the historian; but the Christian and the philosopher must regard it with horror and detestation, as the greatest evil with which providence has been pleased to arm the hands of its ministers to punish and afflict mankind. A late amiable and learned prelate has laboured to prove that "the frequency, duration, and cruelty of wars (in Christendom) are less now than in ancient times;"* but we think that neither his reasoning nor his examples are capable of establishing the first part of this position. If we take the last 700 years, and compare it with an equal period of ancient history; if we recollect the *crusades*, the almost continual struggles between France and Britain, the civil dissensions in both these mighty empires, the wars between the Russians and their neighbours, the Turks, the Poles, and the Swedes; if we advert to the reigns of Edward

6
War scarcely less frequent now than formerly.

* *Porteus's Sermons*, Serm. xi.

Introduction. Edward III. of England, Charles V. and Philip II. of Spain, Louis XIV. of France, Gustavus Adolphus and Charles XII. of Sweden, Frederick II. of Prussia, and Catherine II. of Russia; and lastly, if we turn our attention to the long and ruinous contests which distinguish our own times, we shall find little cause to boast of having profited by the specific lessons of our Saviour, whose great object was to promote "*peace on earth,*" *and good will and brotherly love among the children of men.*

7 Modern wars less sanguinary than those of ancient times.

There is indeed one consolatory circumstance with respect to the modern system of warfare, that our wars are now less sanguinary than those of ancient times. The immense slaughter which attended some of the battles in the Greek and Roman wars, where the greater part of the vanquished army was frequently put to the sword, is familiar to our classical readers; but in modern warfare, even of the large armies that have appeared in the field on the continent of Europe, we seldom find so many as 30,000 killed and wounded on both sides, a number vastly inferior to what fell of the Romans at Cannæ, and by no means equal to the loss of the Carthaginians at the battle of Zama. This diminished slaughter is attributed, and we believe with justice, to the use of fire-arms; and it is computed that in this mode of fighting not more than one musket ball in 40 takes effect, and not more than one in 400 proves fatal. The introduction of these weapons, therefore, however it may be declaimed against by theorists, must be considered as a real improvement in the art of war; and it is sincerely to be regretted that the use of them should be laid aside. If, however, the present practice of deciding battles by the bayonet and the sabre be continued, it is to be feared that we shall soon rival the ancients as much in the sanguinary nature of of our wars as in their frequency.

8 What war is justifiable.

After what we have said on the impolicy of war, and the moral evils which attend it, it will scarcely be expected that we should allow it to be justifiable, except in cases of necessity. Indeed we think that war can be justified only on the principles of self-defence. When a nation is invaded, or attacked in relation to her undoubted rights and principles, it is then, and then only, that she has a pretence for war. We will not, indeed, go so far as to assert, that she ought to await the attack. Whilst she takes the best methods for defending her territories at home, it is doubtless proper, especially for a maritime state, to meet the enemy half-way, and by a timely and spirited resistance, endeavour to avert those greater evils which would attend a system of pusillanimity and neglect.

In the present state of human nature, war must be regarded as a necessary evil, and as it is sometimes unavoidable, the principles and practice of it must be studied by those who are to superintend or to conduct its operations. It is this necessity that has given occasion to the art of war, the practice of which is to form the subject of the present article.

9 War considered theoretically.

Before we enter on the immediate object of this essay, however, it may not be improper to enumerate those branches of knowledge which constitute the *principles* of the military art, and of which no officer who expects to have a principal command in military operations should be ignorant. We shall first mention those sciences which should form a part of the education of every commanding officer, whether military or naval; and we shall then distinguish between those which are most applicable to the land and the sea service.

Among the first branches of a military education must be enumerated the modern languages of French and German; GEOGRAPHY, by which we would understand, not merely the description of countries, states, and kingdoms, but a knowledge of their political constitution, resources, and productions, and of the manners, customs, and character of their inhabitants; HISTORY, especially that of modern Europe, and of the Greeks and Romans. Among particular histories we would recommend those of Polybius, Xenophon, Tacitus, with the Commentaries of Cæsar, in ancient history; and Davila's account of the civil wars of France, Guicciardini's history of the Italian wars, the history of the seven years war by Frederick the Great, with a particular attention to the best histories of his own country, and of the wars in which she has been engaged. After these preliminary branches follow the rudiments of mathematics, including common and logarithmic ARITHMETIC, the elements of theoretical and practical GEOMETRY, plane and spherical TRIGONOMETRY, the principles of SURVEYING, CONIC SECTIONS, and their application to PROJECTILES; certain parts of natural philosophy, especially MECHANICS; and the principles of DRAWING plans, maps, and charts.

Besides these, a military officer should be instructed in FORTIFICATION and GUNNERY, the nature of military exercises, and the duties of the various officers attached to an army; while the naval officer should particularly attend to ASTRONOMY, HYDRODYNAMICS, NAVIGATION, the principles of SEAMANSHIP and of SHIP-BUILDING.

10 Practice of war.

There is perhaps no art or profession, in the practice of which the superiority of *example* over *precept* is more apparent than in war, insomuch that we may lay it down as an axiom, that no man can be a soldier or a sailor from theory alone. It is not from books that we are to learn the art of war, though there is no doubt that they may greatly assist and improve the skill and experience acquired in the field or on the ocean. In these active scenes have been found the great commanders, whose lives and actions are perused with so much avidity; and the only method of successfully imitating their exploits, and emulating their fame, is to encounter the dangers and the hardships to which they were exposed, and to learn how to command, by first learning to obey. A considerable share of the mechanical part of war may be acquired in a well-regulated military or naval school; but the experience necessary for a commander is to be gained only in actual service.

The practical part of war is usually divided into *military tactics*, and *naval tactics;* a division which we shall here adopt, though we have thought proper to bring the whole under one article. As the space, which we had originally allotted to these subjects, has unavoidably been reduced one half, we shall be able to give little more than a general outline, especially of *military tactics*, reserving the fuller discussion for *naval tactics*, which to a nation whose chief dependence is on her fleets, must be the most useful and the most interesting part of the subject.

It would be vain for us to attempt any historical account

Introduction.

count of the progressive improvements that have been made in the art of war. Indeed this would be to repeat much of what has already been detailed under the principal historical articles of this work; for the history of nations, as it is commonly treated, is little more than a history of their wars. We might, no doubt, bring forwards much curious information respecting the offensive and defensive weapons of different ages and countries, and the character and organization of their armies; but for those and other matters of a similar nature, we may refer our readers to the following respectable authorities: Vegetius *De re militari*; Polybius's *History, with the Commentaries of* Folard; Salmasius *De re militari Romanorum*; Tacitus's *Vita Agricolæ*; Rollin's *Ancient History*; Potter's *Grecian Antiquities*; Kennet's and Adam's *Roman Antiquities*; Goguet's *Origin of Laws, Arts, &c.*; Daniel *Histoire de la Milice Françoise*; Gough's *Sepulchral Monuments*; Ascham's *Toxophilus*, and Grose's *History of the English Army, and Essay on Ancient Armour*.

At a period like the present, when the two greatest powers of Europe are struggling for glory and dominion, it will not be thought uninteresting, or irrelevant to the subject of the present article, if we offer a comparative statement of the present military and naval establishments of these two mighty empires, with a sketch of the military character of their armies; and with these we shall conclude our preliminary observations.

II
Present military establishment of the French.

According to a statement made to the French government at the commencement of 1805, the grand total of the French armies consisted of 570,964 men; viz. infantry of the line, 341,412; light infantry, 100,130; cavalry, 77,488; artillery, 46,489; engineers, 5445. Since that time, more than 100,000 have been added, and, according to the best authority, the present total does not fall short of 700,000 men *. This vast body is divided into companies for both cavalry and infantry; a certain number of companies forming a battalion of infantry, or a squadron of cavalry. The denomination of regiment is appropriated to the cavalry and artillery, while a similar body of infantry is called a half brigade. The commanding officer of a regiment is called colonel; but the commander of a large body of infantry is called chief of brigade. The names of lieutenant-colonel and major are changed for those of chief of a battalion and chief of a squadron. Those general officers which in other armies are called major-generals, are, in the French service, denominated generals of brigade, and lieutenant-generals are there generals of division.

* Edin. Review, vol. xiii. p. 455.

The corps of engineers has for its officers 8 inspectors general, 34 directors, 124 captains of the first class, 117 captains of the second class, 33 lieutenants of the first class, 21 of the second class, and 20 pupils under the lieutenants. Attached to this corps are 6 companies of miners, commanded by a chief of battalion. Each company is officered by a captain-commandant, a second captain, first and second lieutenant. Twelve battalions of miners; each battalion, containing 8 companies, forming in all 1606 men, including officers. The battalion staff is composed of a chief of battalion, an adjutant major, and an adjutant. Each company is officered by a captain, a lieutenant, and sub-lieutenant.

To raise and recruit this great military force, the French government has, since the year 1798, had recourse to one of the most tyrannical measures which was ever adopted by a despotic monarchy, we mean that of *conscription*, by which every man within a certain age, is made liable, under circumstances of the greatest rigour, to serve in the armies of the state. This system of conscription is exceedingly complex; but we are enabled, from a respectable periodical publication, to present such a summary of it as will be readily understood. France is divided into about 30 military governments, subject to a general of division and his staff, to which commissaries are attached as executive officers. The civil division consists of 122 departments; 24 of which have been acquired since the overthrow of the monarchy, exclusive of Tuscany, not included in any part of this statement. The departments are divided into districts or *arrondissements*, from three to five in number; the *arrondissements* into cantons, and the cantons into municipalities, amounting to about 55,000. Each department is governed by a prefect and his council, composed of a commissary of police, a mayor, and certain inspectors, denominated *counsellors of prefecture*; the district or *arrondissement*, by a subprefect and his council, of a similar formation. The cantons and municipalities are under the supervision of an administration, composed of the civil authorities, with a president at their head. A mayor, a commissary of police, and two officers of the government, styled *adjuncts*, are allotted to each division having a population above 5000 souls. These several authorities are in strict subordination to each other, and at the controul of the prefects and subprefects, who, themselves, are charged with a weighty and inflexible responsibility as to the military levies.

By the code *de la conscription*, all Frenchmen, between the ages of 20 and 25, are liable to serve. They are divided into five classes, from which the municipal administration draws up the lists for the ballot. These are transmitted to the prefects, by whom they are sent to the war minister, and when properly adjusted, the subprefect proceeds to the drawing of the quota imposed on each district. The conscripts drawn are formed into three divisions, the first called *conscripts for actual service*, the second the *reserve*, and the third *supplementary conscripts*. They are marched in companies of 100 men, to the places which are established as depots, where they are furnished with their arms and clothes. After this they are trained and exercised, so as to be inured to unremitting labour and fatigue.

What gives peculiar energy to the French military system, is the circumstance that their officers rise by merit and experience, and not by interest. By a law of the directory, no person (with the exception of engineers) could become officers, who had not served three years in a subordinate capacity. The revolution naturally opened the way to merit; and, seconded by this admirable policy, has filled all the posts of their army with men, who unite in themselves the qualities of the soldier, with the excellencies that qualify for command. It is not hazarding too much to assert, that nine-tenths of the present French officers have sprung from the ranks. Educated in distant camps, they know no other country, and, habituated by long devotion to the trade of war, it has become their element and their passion. Their whole fortune is staked on the sword; and their attachment is therefore necessarily secured, under the

auspicious

Introduction

auspicious influence of a leader, whose indefatigable ambition occupies them in their favourite pursuits, and whose *liberal impartiality* feeds the hope of preferment, and divides the fruits of conquest. To their credit and example is due much of that spirit, which, notwithstanding the causes of alienation hitherto observed, seems to animate the whole frame of the army; and no small share of that portentous success which has attended the course of the French arms. Of the eighteen *marechaux d'empire*, fourteen have either emerged from the ranks, or ascended from the lowest employments. Most of the generals of division, and others who hold the principal commands, have the same origin, and sufficiently prove, that war is an experimental science, and that military renown is not the prerogative of birth, but the harvest of toil, or the bounty of fortune *.

* *Ibid*, p. 431—451.

12 Late naval establishment.

We have no certain means of ascertaining the present naval establishment of the French empire, though, as it may be said to have the command of the navies of Holland, Russia, and the remains of that of Denmark, it must still be regarded as of no trifling strength. The principal fleets are indeed kept blocked up by those of Britain, in the harbours of Brest, Rochefort, Toulon, the Scheldt, and the Texel; but the escape of any of these might be the means of conveying a considerable military force to the remaining colonies, or to the less powerful allies of France. In 1791, the French fleet consisted of 73 ships of the line, 67 frigates, 19 corvettes, and 67 small craft, making a total of 226. Since that time, however, have taken place the great naval victories of Howe, St Vincent, Duncan, and Nelson, by which the greater part of *that* navy has been carried into British ports.

13 Present military establishment of Britain.

In estimating the military establishment of Britain, we shall, for the sake of more accurate comparison, first take the same period of 1805. The British land forces then consisted of 21,223 cavalry, 124,878 infantry (including 20,747 men for limited service, and 21,208 belonging to foreign and provincial corps in British pay), 89,809 militia, 8559 artillery, besides about 430,000 volunteers, making a total of 674,469. To these must be added the royal artillery, the horse brigade, the brigade of gunners and drivers, and companies of foreign artillery, amounting to 16,670, and the corps of artificers and labourers, including 704 men. Thus the whole military force of Britain, in 1805, amounted to 691,843 †.

† *Playfair's Geography*, vol. ii.

Since the passing of Mr Windham's act, this number is somewhat diminished, though our military force is now probably more effective. At the end of 1808 it stood as follows. Two regiments of life-guards, one regiment of royal horse guards, 7 of dragoon guards, 25 of dragoons, 3 battalions of riflemen, 7 battalions of foot-guards, 5 of light infantry, 176 battalions of infantry, a corps of royal horse artillery, a regiment of royal foot artillery, a corps of royal engineers, a brigade of artillery drivers, and a waggon train. The dragoons, independent of the royal life and horse guards, amounted to 19,200; the battalions of riflemen and light infantry to 8000; the infantry of the line to 149,600; the king's German legion to about 20,000; exclusive of about 96,000 regular militia, 250,000 local militia, and about 50,000 volunteers; making an effective force of about 580,000 men.

Each regiment of not more than 500 men is officered by a colonel, a lieutenant-colonel, a major, 10 captains, 10 lieutenants, 8 ensigns, an adjutant, quarter-master, paymaster, a surgeon and assistant surgeon; a serjeant-major, a quartermaster-serjeant, with 30 ordinary serjeants, 30 corporals, a drum-major and 20 drummers. If the regiment amount to 750 men, it has usually an addition of second lieutenant-colonel, a second major, 10 serjeants, and 10 corporals.

The gradation of rank among the officers of the British army is as follows. Under the king, who commands the whole as *captain-general*, is the *commander in chief*, then follow the *field-marshals*, *generals*, *lieutenant-generals*, *major-generals*, *brigadier-generals*, *colonels*, *lieutenant-colonels*, *majors*, *captains*, and *subalterns*. The different departments of the army are under the superintendence of an *adjutant-general*, a *quartermaster-general*, a *barrack-master-general*, a *commissary-general*, a *paymaster-general*, a *board of ordnance*, and a *medical board*. See ADJUTANT, QUARTERMASTER, &c.

The army of the line is recruited by enlistment; the recruits receive a bounty, and are engaged to serve for a limited period, or for life. The militia is filled up by ballot, in the several counties to which it belongs, and also receives recruits by enlistment or by proxy. Hence the British soldier, while he considers himself as the servant of the king and the state, justly boasts of partaking in the general liberty of the subject. He is protected by fixed and definite laws, against the discretionary power of his commanding officer, and is encouraged to perform his duty by the liberality of his country; and not, as in France, compelled to it by the fear of punishment. His discipline indeed is strict; but he feels none of that severe and tyrannical coercion which seems to be the first principle of motion in the armies of Napoleon.

14 Naval establishment.

In its naval establishment, Britain justly boasts of being superior to every nation in the world. The number of her fleets, and the courage and discipline of her seamen, have given her the unrivalled dominion of the seas, of which it would be difficult for the whole combined navy of Europe to deprive her. In 1809, the naval force of Britain consisted of 157 ships of the line, 19 from 50 to 44, 184 frigates, 181 sloops, 308 brigs, making a *total* of 849 in commission; besides 56 of the line, 12 fifties, 56 frigates, 44 sloops, 24 brigs, *total* 192 in ordinary and refitting; and 50 ships of the line, 20 frigates, 20 sloops, 10 brigs, *total* 100, building: making a grand *total* of 1141.

The progressive advance of our navy will appear by attending to the following recital of its tonnage at different periods, from the reign of Henry VIII. to the present time.

	Years.	Tons about
At the death of Henry VIII.	1547	12400,
Edward VI.	1553	11,000
Mary,	1558	7000
Elizabeth,	1603	17,000
James I.	1625	19.000
Rebellion,	1641	22,400
At the death of Charles I.	1649	uncertain.
At the Restoration,	1660	57,460
At the death of Charles II.	1685	103,558
Abdication of James II.	1688	101,900

At

Introduction.

	Year.	Tons about
At the death of William III.	1702	159,000
Anne,	1714	167,170
George I.	1727	170,860
George II.	1670	321,200
31st December,	1788	413,660
	1806	776,000
	1809	800,000

It appears, however, that notwithstanding the vast increase of our navy, not a single dockyard has been added to it since the reign of William III. about 109 years ago, at which time the tonnage of the naval force of this kingdom amounted to nearly 160,000 tons; it is now nearly 800,900 tons, or about five times as large *.

* *Statement by Lord Melville.*

In sketching the military character of the French and British armies at the commencement of the 19th century, we shall avail ourselves of the observations of an anonymous, but able and apparently impartial publication, which appeared soon after the peace of Amiens, entitled *The Military Character of the European Armies at the Peace of Amiens.*

15 Military character of the French army.

The astonishing success which has attended the French arms on the continent of Europe, is to be attributed partly to the regular organization and severe discipline established by the *Code de la Conscription*, but it is still more to be ascribed to the skill, experience, and activity of their officers. The French generals early discovered the advantages resulting from dispatch. The alertness of the soldiers, the lightness of their baggage, and their inattention to regularity in time of action, enabled them to execute their movements with a celerity which has frequently ensured success. In an open country, lines could not be preserved without difficulty. The French armies were therefore formed in columns. Brigade succeeded brigade, and when one division was repulsed, and fell back on the columns in the rear, those in their turn attacked the enemy, or sustained his shock, and fresh troops perpetually came forward, to supply the place of those which had been defeated.

The French battalions have no field-pieces attached to them; but this want is amply compensated by their flying artillery, which is composed of the flower of the French soldiers, and by its boldness and rapidity of movement, supplies the place of that large train of artillery with which the other European armies are usually burdened. It is a constant maxim in the French armies to have a body of reserve, composed of their best troops, and under the command of an able general. If the main body should be beaten, the reserve covers their retreat, and on more than one occasion it has snatched the victory from the hands of the enemy.

The French generals, like rich and bold gamesters, are incessantly tempting fortune. They look upon their losses as nothing, provided they succeed in the end. The little value at which they estimate their men, the certainty of being able to replace them, the personal ambition of their chief, and the customary superiority of their numbers, afford them an advantage which cannot be counteracted but by great skill, conduct and activity.

16 Military character of the British army.

The soldiers of Britain are as intrepid by land as her sailors by sea. Their want of success on the continent cannot be ascribed to their want of bravery, but rather to the organization of the British armies, their inferiority of numbers, or the inexperience of the officers by whom they are commanded. Most of their commanding officers, instead of conforming to general regulations, follow their own particular plans and ideas, according to their several geniuses, acquirements, and prejudices. In a nation, which, from the spirit of its constitution and the habits of its people, is formed rather for naval than military operations, a ministry, however enlightened, scarcely possesses that authority which is necessary to give uniformity to the different departments of the army, to constitute a regular and corresponding whole, and to surmount those obstacles which are thrown in the way of all uniformity of military system, by the distance and distribution of the troops. The small numbers in which British troops are generally compelled to act on the continent, and their mixture with those of other nations, to which they are sometimes even subservient, are circumstances extremely disadvantageous.

In a military life, good faith, honour, and courage, are the principal qualifications, and these are eminently conspicuous in the British army. Their military ardour is greater than what is seen in any other service, but this is in a great measure damped among the officers by the difficulty of promotion. Interest with ministers, and the necessity of raising money to defray the expences of the different departments of the state, though far from being the most equitable, are here unhappily among the first means of military promotion.

The soldiers of the British army are possessed of elements to enable them, under a commander of abilities and officers of experience, to be the best troops in the world. They require neither brandy nor self-conceit to make them brave; their courage is innate; it is a national instinct. Their officers too usually possess much greater information on general topics than those of all other European nations, as education is more cultivated in Britain than elsewhere. They are attached to their profession, and follow it rather from generous motives and military spirit, than like mercenaries from a view of interest and profit.

On the political and moral principles of war, see Cicero *De Officiis*, Grotius *De Jure Belli et Pacis*, Puffendorff's *Law of Nature and Nations*, and Machiavel's *Discorsi*; and on the principles of war considered as a *science*, see a *memoir* by Maizeroy, in the 40th volume of *Histoire de l'Academie des Inscriptions et Belles Lettres*, and Folard's *Commentaries on Polybius*.

PART I. MILITARY TACTICS.

27 Nature and object of military tactics.

Some writers on the military art distinguish *tactics* from what they call *strategy*; understanding by the latter the science of military movements when not in sight of the enemy, or at least out of the range of their shot; while they describe the former to be the science of military movements in sight of an enemy, or within the range

Military Tactics. range of cannon shot. We do not see the necessity of this distinction; and under the head of military tactics we shall consider whatever relates to military operations on land.

It is not possible for us, within the very scanty limits to which we are now reduced, to give any thing like a regular treatise on the military art. We shall therefore endeavour to select the most useful and interesting topics, and supply the place of disquisition by numerous plates with appropriate explanations.

The science of military tactics comprehends the disposition and arrangement of troops, whether on marches, in camps, or in line of battle; the attack and defence of posts; the construction and superintendence of the works by which they are to be defended; the conducting of sieges; and the defence of besieged places. These are the principal operations of a soldier, and these we shall briefly consider nearly in the order in which we have enumerated them.

18 Of directing the march of an army

To direct the march of an army is not one of the least difficult parts of a general's duty. To do this with ability, he must be well acquainted with the nature of the country through which his troops are to pass, with the obstacles which are likely to oppose them in their progress, and with the disposition of the inhabitants. Our business here is only with the first of these considerations. There are three descriptions of countries which may become the theatre of war; an open country intersected by rivers, a mountainous, and a woody country. The march of an army through the first, as far as respects the face of the country alone, is seldom difficult, except in the passage of rivers, which we shall consider by and bye; and the last description of country is now so uncommon in Europe, that we need not dwell on it. A mountainous country, however, presents numerous difficulties to call forth the abilities and experience of a commander, as in such a country, not only are the roads winding and difficult of access, but the unevenness of the ground, and the intervals between the hills, render it very easy for an enemy, with a small force, to oppose and distress a numerous army.

19 through a mountainous country. Plate DXLIV.

The plan in Plate DXLIV. is intended to illustrate the march of an army through a mountainous country. At A is shown the position of the army previous to its march, with the artillery and baggage P, drawn up under their proper escorts, in front of the camp. At B are parties of hussars constituting the advanced guard of the army on its march; and at C are parties of infantry forming the advanced guard of the columns in which the army is disposed. D represents the infantry forming the head of the columns; E the park of artillery and waggons attached to it; F, battalions of artillery, G the cavalry, H the baggage of the army, and I their escort. At K are parties of hussars and at L parties of dragoons. M represents the infantry of the reserve forming the rear guard, and N platoons of infantry sent forward upon the heights, to cover the flanks of the principal columns. At O are villages in front of the position where the army is to encamp, and which have been taken possession of by the light infantry.

The number of columns into which the marching army is to be divided, will depend on the number of roads or accessible approaches that lead to the position which it is to take up. In the present case there are only two principal roads, each leading across the river, and winding through the valleys to the principal heights, so that the army must march in two divisions. The usual disposition of the columns is as follows. Four or five brigades of infantry, according to the number which composes the army, should be placed at the head of each column; the same partition should be made with regard to the artillery, which must follow the infantry; the cavalry must march next, and the baggage of each column, well escorted by infantry, must follow the cavalry, then the rest of the corps of light horse which are not detached; and the dragoons are placed the last, in order to dismount, and sustain the rear-guard in case it shall be attacked.

20 Of the passage of rivers.

An army seldom proceeds far without encountering a river in its march, and as it commonly happens in a country which has become the seat of war, that the bridges are destroyed or rendered impassable, the army must cross the river, either by swimming, at some ford, or by temporary bridges thrown over for the purpose. It is most advantageous to cross a river at some part where the stream is divided by small islands, unless the river be so shallow that it may be easily forded. If it be necessary to construct a bridge, this is best done by means of boats or pontoons, and all the necessary apparatus should be ready at the place of crossing at an appointed hour, and every measure should be taken to avoid confusion, and to be prepared for the enemy, who will probably dispute the passage. The two heads of the bridge when constructed should be entrenched, and well furnished with troops, and, if possible, the islands in the neighbourhood should be fortified by proper works, to prevent the enemy from destroying the bridge, or incommoding the labourers employed in its construction.

If the river be narrow, it is best to cross at some place where it makes an angle, especially if, as commonly happens, one of its banks be higher than the opposite bank, so that the higher ground may be defended by a battery. If the river be fordable by infantry, care should be taken beforehand to clear the bed at the ford, and render the banks easy of access.

Plate DXLV. fig. 2.

The lower figure of Plate DXLV. illustrates the passage of a river. AAA represent bridges of boats; B, redoubts by which the bridges are protected; C, a battery, under cover of which the infantry work at the construction of the redoubts; D, a battery, to prevent the enemy from annoying the army on its march; E, the march of the army; F, the artillery distributed among the brigades of infantry; G, infantry forming in columns to open on the opposite side through the intervals of the redoubts; H, march of the columns in the front of the redoubts, where they halt to give time for a part of the cavalry to form upon its flanks; I, a battery erected to facilitate the forming of the cavalry; K, cavalry, which in gaining the opposite shore, forms in order of battle, and posts itself upon the flanks of the infantry; L, eight battalions in column upon the right wing of the army, to go and examine the village and attack the enemy in it, in case he should be possessed of it; M, hussars and dragoons, who have taken possession of the height which is on the left wing of the army; N, a brigade of infantry posted next the height, covering the left wing of the cavalry; O, the disposition of the army marching up to the enemy.

It is in general a very difficult task to defend the passage

Military Tactics.

sage of a river against an army that is determined on crossing it. Indeed, if the river be of such a nature as to present several points by which an enemy can cross, and if the defending army be not of such strength as to meet their opponents in the field, such a defence will be almost impracticable. Where it can be attempted, however, and where sufficient notice can be procured of the enemy's approach, all the boats and barks found on the river should be removed or destroyed, to prevent the enemy from using them in constructing his bridges. Both banks of the river should be carefully reconnoitred, that the fords and other accessible points of passage may be sufficiently obstructed; and the ground which might protect the enemy's passage, should in particular be attended to. Roads sufficiently wide to admit of many columns, should be made along the side of the river to be defended, that a great number of troops may be advantageously disposed. It must be confessed, however, that if the accessible points extend along a considerable tract of country, and if the bank of the river next the enemy overhang that on the opposite side, a defence will be nearly impossible.

21 To defend the passage of a river.

Fig. 1. The upper figure of Plate DXLV. shews the manner of disposing the troops to defend the passage of the river. A, the march of the main army in three parts to defend the river; B, the camp of the light horse, infantry, and dragoons, on the wings of the army; C, castle and village, guarded by light infantry; D, a town occupied by the infantry belonging to the army; E, bridge broken down; F, islands occupied by infantry; G, posts of infantry distributed along the side of the river; H, batteries established along the side of the river; I, posts of cavalry, to keep the communication between the camps; K, bridges constructed to preserve the communication of the islands; L, bridges for the communication of the camps.

22 Basis of modern military operations.

Modern warfare is distinguished from that of the ancients, not more with respect to the arms which it employs, than the multitude of stores, ammunition, and provisions necessary for a campaign. The number of horses now employed for drawing the artillery, and the ammunition waggons, as well as to mount the great increase of cavalry, considerably adds to the quantity of military stores required by the troops. This has produced the necessity for magazines, established in such number, and at such distances from each other, as may most expedite the operations of the campaign; and these magazines require not only to be fortified themselves, but to be strengthened by forts or redoubts in their vicinity. To these magazines modern writers on the art of war have appropriated the term of *basis of military operations*, and the roads by which an army receives its subsistence from the magazines, are called *lines of operation*. The situation of the principal magazine, and the length and direction of the lines of operation, are considered as of the highest importance. With respect to the first and second of these, we must refer to Templehoff's History of the Seven Years War, where the question is considered with great minuteness and scientific accuracy. The direction of a line of operations may be illustrated by the first seven figures of Plate DXLVI.

Plate DXLVI. fig. 1. Fig. 1. represents a line of operation forming the segment of a circle, having a line of posts ACB towards the enemy's country, and two principal fortresses DE within the segment. As this circular segment is supposed to surround a part of the enemy's territory, and is strengthened by the two fortresses AB, at the extremities of the basis, it is esteemed the most advantageous form. On the other hand, if the segment had its circumference directed towards the enemy, as in fig. 2. it would form the worst possible direction for a basis; for here the fortresses CD, placed in the circumference, are very much exposed, and might be easily taken by detachments from the columns E and F. The only way of preventing this would be to detach troops from A and B laterally, to incommode the columns E and F, and to take up a strong position either at g or h. The more the segment approaches to the elliptical form, as in fig. 3. it is the less susceptible of defence, as is evident from the relative position of the three fortresses A, C, and B. Fig. 2. Fig. 3.

Fig. 4. The line of operation represented by fig. 4. consisting of salient and obtuse angles, such as A c B, B d G, constitutes an excellent form, as it resembles the outworks of a fortress, and it is as impracticable for an enemy to enter into the interior of this basis, as to carry a curtain between two flanks. The two fortresses $c\,d$ are not nearly so much exposed as C in fig. 3. as if one of them were attacked, it would be easy to make a diversion from the other into the enemy's country. If the points which terminate the basis advance as in fig. 5. it will be a favourable circumstance, especially if the most advanced post were bounded by the sea, or by a large river. Fig. 5.

Fig. 6. The basis which we have been considering consists of curved or angular lines. Now, let us suppose two bases, the one A h B, fig. 6. forming merely a straight line, while the other $c\,e\,g\,d\,f$, has two of its lines $e\,c$ and $d\,f$ advanced towards the enemy. This latter is the more advantageous, as it exposes so much more of the enemy's country. In general, it is a good rule to construct fortresses opposite to those of the enemy, as here the fortress g, if moderately strong, is capable of protecting the whole line from e to d, against the three opposite forts A h B. It is a great fault for any part of a basis to recede, as $d\,c$ from the line of the enemy AB, fig. 7. so as to form an angle with it, as here all the country between A and c is exposed to the hostile attacks of A and B; but, if the line were parallel to that of the enemy, as $d\,e$, it would be a good position. Fig. 7.

23 Establishment of camps. Next to the establishing of magazines, and providing for their security, and that of the lines by which they are connected, it is of the highest importance for a general when he takes the field, to select the proper positions where he may encamp his army, so as to be readily defended against the attacks of a superior enemy, and have an easy communication with his own posts. In selecting such a situation he must be guided partly by the nature of the country, and partly by the situation of the enemy; but if possible, he should choose a position which is rather elevated, and which may be protected on the flanks or rear, either by the natural situation of the ground, or by works thrown up for that purpose. It should not be too near the bank of a river, though it may be of advantage to have such an object in front. The encampment of an army in such a situation is pointed out by Plate DXLVII.; where A is the camp of the main body of the army; B, an advanced camp, composed of dragoons and hussars, in order to cover the right of the army, to guard the passes by which the enemy might make incursions upon the flanks and rear of the army, molest the convoys, and cut off the communications

Plate DXLVII.

Military Tactics

nications; C, villages and bridges, guarded by the light infantry; D, posts of dismounted dragoons in the front of their camp; E, posts of dragoons on horseback, to secure the communication between their camp and that of the main body of the army; F, bridges built to keep up the communication between the grand and the advanced camp; G, bridges and villages guarded by detachments of infantry; H, grand guards of horse; I, guards of infantry; K, bridge, village, and mill, guarded by the infantry belonging to the army; L, camp of dragoons and hussars, covering the left of the army, and supporting the light infantry; M, villages and bridges guarded by the light infantry; N, posts of dismounted dragoons in the front and on the flanks of their camp; O, posts of dragoons on horseback; P, posts and detachments of hussars, to patrole in front and on the flanks of the army and their camp.

24 Intrenched camp.

It often becomes necessary, either from an inferiority of numbers, or from the nature of the ground, to intrench or fortify a camp. In general this is done by digging deep ditches round the most defenceless part; driving pallisades in front of this ditch; forming an embankment of felled trees, with their unlopped branches pointing towards the enemy; or, where there is time for such an operation, and where the proper materials can be obtained, constructing redoubts or regular outworks, capable of being defended by artillery.

Plate DXLVIII.

Plate DXLVIII. represents a camp intrenched in an open country, without any peculiar advantages of defence. A, the main body of the army encamped behind its intrenchments; B, the camp of the troops of reserve; C, camp of the dragoons, to secure the rear of the army; D, camp of hussars, to cover the ground on the right of the army; E, villages and redoubts guarded by the light infantry to secure the camp of the hussars; F, bridges built to secure the communication of the army with the ground on the right, and to favour the retreat of the troops posted on the opposite side; G, brigades of artillery distributed on the flanks, and along the whole front of the army; H, the park of artillery; I, a bridge intrenched, to secure the communication between the army and the ground on the left; K, villages and farm houses, guarded by detachments of hussars and light infantry, to patrole in front of the army.

Plate DXLIX.

Fig. 1.

In Plate DXLIX. are shown other methods of intrenching a camp in the neighbourhood of a town or village, and in situations where the camp can be protected by inundations. Fig. 1. represents an intrenched camp in the neighbourhood of a town. A, a deep marshy valley, with an unfordable rivulet across it. B, a redoubt constructed on a mountain, by which the right wing is *appuyed*. C, a small wood in front of the mountain. D, a line which connects two fleeches together at the foot of the mountain, where the village of Weilheim is situated. E, a rivulet, over which are thrown bridges of communication, to facilitate an intercourse between the camp and the redoubt on the hill. F, an eminence with a gentle declivity, at the foot of which is the village of Mansfeld, surrounded by defiles and hollow roads. G, defiles and hollow roads. H, lines which run along the circumference of the heights about Weilheim, forming a retrenchment. I, close works. L, a redoubt which masks the entrance into Stemmern. M, a small wood, cut down in order to have a full view in front of Stemmern. N, a thick wood which covers some high mountains by which the left wing is supported. O, an abattis which is made across the wood for greater security. P, infantry pickets. Q, a redoubt on a small eminence, constructed for the purpose of covering the opening behind the left wing of the camp. R, a line of communication from the last redoubt to the left of the intrenchment. S, several passages 30 feet broad and closed in by chevaux-de-frize, to afford an opportunity for the cavalry to advance, should the enemy be foiled in his attack against any part of the works. T, the infantry and cavalry encamped behind the retrenchments; the infantry in the first line, and the cavalry in the second. U, X, Y, Z, four roads behind the camp to facilitate the retreat of the army, should it be pressed.

Fig. 2, 3.

Fig. 2. and 3. represent an intrenched camp with inundations in front. Fig. 1. *a b*, two dykes 40 paces long, 5 broad, and as many high. CD two rows of stakes from 4 to 5 inches thick. E, the coffin formed by means of stakes filled up. It is eight feet broad. F, the adjacent country, inundated by the rivulet being forced out of its current by the last dyke and by *a* and *b*. G and H, the outlets which the rivulet seeks, to continue its course. I, small creeks or ends of ditches dug about the ground. Fig. 3. represents the current of a rivulet, with a dyke to occasion inundations. Camp, with the several dykes in front, which are calculated to produce inundations. The spaces between these dykes are called coffins, viz. 1, 2, 3, 4, 5.

25 Construction of redoubts.

We have mentioned the works by which the field posts are fortified, and which are usually called *redoubts*. As the construction of redoubts is generally a work of the moment, and falls within the province of the commanding officer of a detachment, it is proper that we should here describe the most useful and expeditious methods of raising such works. These methods are illustrated by the plans in the upper part of Plate DL.

Plate DL Fig. 1.

Fig. 1. shows the plan of the ordinary square redoubt which is constructed in the following manner: When a proper spot has been chosen, a line *a* AE is drawn of a sufficient length, and at one extremity *a* is drawn *a* C perpendicular to it. Then from *a* towards C and E are set off the dimensions proposed for each side of the parapet within the fort, allowing 2 or $2\frac{1}{2}$ fathoms for 30 men, 4 fathoms for 50, and so in proportion for a greater number. These lines being ascertained, a picket is placed at C, with a cord attached to it, and with the length *a* C is described an arch, and from the point E, with the same distance, another arch is described, intersecting the former in F. Then joining EF and CF, the square forming the inner parapet is completed. Within the square, at the distance of 2 or 3 feet, is described another square I, L, M, N, having its sides parallel to those of the former. This marks the breadth of the banquette, where the men are to be drawn up. Again, on the outside of the first square at about 8 or 9 feet distance is drawn a third square O, P, Q, R, determining the outer side and thickness of the parapet. This thickness is only calculated to resist musket balls; as, if it is to stand against cannon, it should be at least 18 feet. Lastly, at rather a greater distance from this third square is drawn a fourth S, T, V, X, marking the breadth of a ditch that is to surround the redoubt. The

Military Tactics. The lines being finished, *fascines* or faggots of brushwood are to be laid between the two innermost squares, as a foundation to support the earth of the banquette; a second range is laid on the lines AB, GH, to support the inside of the parapet, and a third on the square O, P, Q, R, to strengthen the outside of the parapet, leaving a space through all the *fascines* to the ditch, on the side least exposed to the enemy, as at B, for an entrance. It is sometimes convenient to make this entrance take a winding direction, as is shown at T, fig. 2.

Fig. 2. Fig. 3. Fig. 3. exhibits a section of these works, where AB is the breadth of the ditch at the top; MN its breadth at the bottom; FN its slope, on a line with the outside of the parapet, called the *scarp*, and GM its slope towards the open country, called the *counterscarp*. AL and ID represent the *fascines* forming the outer and inner slopes of the parapet, the interval between them being filled with earth trodden down hard. At E is the banquette. DC is the thickness of the parapet below, and IL its thickness above, which forms a slope for the more convenient firing of musketry.

In this square redoubt it is evident that the men must fire straight forward in lines perpendicular to the sides of the squares, as in fig. 4. As it is often of great consequence that the directions of firing should cross each other, the better to flank the enemy, the banquette is sometimes formed with angles, as in fig. 5. so that the men may stand two together in little *redans*. As, however, such a construction takes up too much time and labour for ordinary occasions, M. Le Cointe prefers a circular redoubt, such as is represented at fig. 6. where the men may fire from every part of the circumference. The construction of such a redoubt is extremely simple, and differs only in its first step, viz. describing the concentric circles, which is done with a cord fastened at one end by a picket at a central point C.

Fig. 4. Fig. 5. Fig. 6.

The strength of the redoubt will be much increased, if the ditch can be filled with water, as by turning into it the stream of a rivulet. See Q, fig. 7. If the ground be uneven, so that the water will not run equally into every part of the ditch, dams must be raised, as C, to keep up the water in the higher parts, whence it may run to the lower, after the former are full.

Fig. 7. Fig. 7. represents a plan of the square redoubt, with a wet ditch, when completed. A, the inner ground of the redoubt; B, the bottom of the ditch; CDE, the dam of earth; F a dam of boards, planks or fascines; G the upper part of the redoubt, made with fascines or with earth thrown out of the ditch; H, the lower part of the redoubt cut into the earth; I, the berme or space left at the outer bottom of the parapet, to keep up the earth; L, the entrance of the redoubt; M, the inside of the parapet; N, the outside of the parapet; O, the banquette; P, the glacis; Q, the river introduced to fill the ditch with water.

26 Of detachments sent to attack or defend a post.

The attack and defence of posts are among the most important departments of what the French call *la petite-guerre*, and in a country where fortified towns are rare, constitute a considerable part of field operations. We shall consider them rather more at large than we have the preceding parts of military tactics.

When an officer is detached either to attack or to guard a post, he should provide himself with a cord regularly divided, for the purpose of describing lines, and raising temporary works, and should procure a skilful and confidential guide, from whom he may derive the requisite information respecting the nature of the country, and the breadth and goodness of the roads. He should dispose his party in such a manner that an advanced guard of cavalry, as A, fig. 8. Plate DL, should set out first, preceded by a small detachment of about six horsemen, headed by a corporal, as B, C, C; two horsemen in the middle, and two on each side. While the main body is moving along the principal road, as from H to F, a detachment of about 8 or 12 horsemen, according to the strength of the corps, should be sent about 50 paces on each side, by way of wings, as DD; and from each of these wings 2 men should keep 50 paces farther out, as at EE, by which means the country will be properly examined, and surprises from the enemy prevented. On coming near a wood, as at NN, the cavalry should spread, the better to scour the outskirts and the wood itself. When the corps is numerous, the cavalry should be formed into squadrons, as G, G, G, and the infantry into platoons, as F, F, F, marching alternately along the road.

Fig. 8.

If, on the march, the advanced guard come to a cross road, or the entrance of a hollow way, as at I, I, where it is likely they may be met by a party of the enemy, they should immediately prepare for an attack; and if the commander of the main body observe his advanced guard in action, he should immediately draw off his platoons of infantry, and form them on the side of the road, as at L, L, L, or on some neighbouring height, as at M, M, that they may be out of the way of the enemy's cavalry, and ready to engage if occasion should require it.

On the march the party should carefully avoid villages, and rather halt or refresh his men in a wood, or some other concealed spot.

27 On reconnoitring.

The commander of a detached party must take the safest and most effectual methods to reconnoitre the country through which he is to pass, without being observed or suspected by the enemy. The method of doing this recommended by M. Jeney will frequently succeed, and is as follows: He supposes himself with his party at Soest in Westphalia A (fig. 2. Plate DLI), and the enemy posted at Bervick B, two leagues from him. To know the situation of this place without stirring from Soest, he takes the map of the country: and from Soest as the centre, he draws a circle, whose circumference passes half a league beyond Bervick. He draws a circle of the same size upon a leaf of paper, to make his plan, as in fig. 2. and then places Soest in the centre A, and marks all the villages which he finds in the map near the circumference upon his plan, with the distances and bearings as they are represented in the map, making use of a pencil to mark the places DDD, so as to correct the errors more easily which the map may have led him to make.

Plate DLI. fig. 2.

Having thus formed his plan with a scale of two leagues, he goes to the burgomaster of the town of Soest, where he causes some of the most intelligent inhabitants to come, and speaking to them freely and openly, induces them to communicate all the information for which he has occasion.

The better to conceal his designs, he begins his reconnoitring by Brockhusen, a village distant from the enemy. He asks the distance from Soest to Brockhusen;

Military Tactics.

sen; if they say it is a league and three-fourths, he corrects the distance of his plan, which made it two leagues; then he informs himself of all that is to be found on the road from Soest to Brockhusen, chapels, houses, woods, fields, orchards, rivers, rivulets, bridges, mills, &c. If they say that a league from Soest they pass the village of Kinderking, he marks that place upon his plan. He asks if the road from Soest to Kinderking be crossed by any other road; if there be any morass or heath; if the road be inclosed, paved or straight; if there be any bridges to pass, and at what distance. He takes care to mark every thing on his plan, forgetting nothing, even to mills, bushes, gibbets, gullies, fords, and every thing that can be got from their information; which will probably be perfect, because one always knows more than another. He continues his questions from Kinderking to Brockhusen, and advancing by little and little, observes the same method on the roads of the other villages round, marked DDD. In this manner he cannot fail to acquire an entire knowledge of all the places; besides, he finds himself imperceptibly instructed in the position of the enemy, by seeing the different routes by which he can approach with the greatest security.

28 Attack of posts.

For the attack of an enemy's post, such men should be selected as are brave, cool, and experienced; or if the affair require a considerable number, the detachment should be divided into platoons, some composed of picked men for the real attack, and others of ordinary soldiers for feints. The men should be provided, besides their arms, with such instruments as may be necessary for pulling down or scaling the enemy's works, such as shovels and pickaxes for fascine parapets; hatchets for pallisadoes or chevaux de frize, and scaling ladders for stone or brick work. Having made the proper disposition for his attack, and procured the necessary guides, the commander of the detachment should set out in the night, so as to be at the place of attack two or three hours before daybreak, taking care to march with as little noise or parade as possible.

If the post to be attacked be an ordinary redoubt, such as we have described in N° 25. on hearing the signal previously agreed on, all the divisions are to rise at once from the place where they should have lain concealed; the first ranks should leap into the ditch, and soon after the second should follow, and both together assist in undermining the angles of the scarp, or cutting away the stakes which may impede their progress. If the parapet be faced with stone or brick work, care should be taken that the ladders be not too short, and great expedition should be used in mounting them, and especially in following the leading men in the assault, if they should be knocked down by the fire of the enemy.

Should the ditch be filled with water, and too deep to be waded, it may be crossed on temporary bridges made of planks, supported on empty casks, or the ditch may be filled up with casks full of earth. If, as often happens, the ground be obstructed with caltrops, these must be swept away by dragging trees with their leaves and branches over the ground (A).

In attacking posts of considerable magnitude, such as villages, it is best to divide the attack, and to make a feint on those parts which seem best defended, while the true attacks are reserved for those situations which seem most difficult of access, and where consequently, the enemy is least upon his guard. As soon as part of the village has been carried, some divisions of the detachment should hasten to strengthen their position, by possessing themselves of some church, or high ground, from which they annoy the enemy.

29 Defence of posts.

When a post is once occupied, if it be thought of sufficient consequence to retain it, the best methods should immediately be taken to protect it against an attack of the enemy. The infantry to remain under arms in the middle of the place, the cavalry to patrole without, while the commanding officer, escorted by a dozen horsemen, goes to examine the environs to make his arrangements; having sent several small detachments before, to cover him in time of reconnoitring.

Having remarked the places proper for his guard, defence, and retreat, as well as the dangerous ones by which the enemy can make approaches secretly to surprise him, he should choose the most convenient in the front of his post to fix his grand guard D, (fig. 1. Plate DLI.), which must face the enemy. He must mark the heights for this guard to place their vedettes EEEE, and regulate the number according to the exigencies of the situation. In a covered country you must not be sparing of them, and must reinforce every guard. At 50 paces from the front of the grand guard a non-commissioned officer with eight horsemen should be always ready to set out at K, to go and reconnoitre, when the vedettes have observed any party.

Plate DLI. fig. 1.

If the post to be defended be merely a redoubt, it will be proper to keep in readiness a number of trees cut down with their branches, to stop up any breaches made by the enemy's shot. The men employed in the defence should stand in three ranks, the front and centre ranks with fixed bayonets, and the third rank provided with long pikes, so as to project as far as the bayonets of the front rank. On the enemy's approach, the men should reserve their fire till the enemy come up to the glacis, and the rear rank should be furnished with hand grenades, or lighted faggots, to throw among the enemy, when they attempt to scale the parapet.

In the defence of a village or small town, guards should be posted at the entrance of the principal streets; trenches should be cut across the streets, and cannon planted behind them, while a detachment of cavalry should occupy the market-place, or broadest street, to attack the enemy, if they force an entrance. If the advanced guards are driven in, they should retire with coolness and deliberation, defending their posts from house to house, till proper support can be given them from the body of the detachment.

If there be any dangerous place capable of covering the approaches of the enemy in the environs of the post, and

(A) The principal engines employed in the attack of posts, are represented in Plate DLV, to which we shall presently refer.

Military Tactics.

and out of the circuit of the patroles, there should be a guard placed there, more or less strong according to the importance of the place, and care should be taken to preserve the communication. The guards and picquets being placed, the detachment that was sent out on the roads must be called in, and then go to work to lodge the party in the gardens that open upon the country, and the commanding officer's quarters; beating down hedges, filling up ditches, and levelling a piece of ground large enough to draw up the whole corps. The horses to be put under cover in barns, contiguous to the gardens; but in case there are no barns, they may substitute sheds open on one side, that the horses may go out together in case of an alarm. The officers should occupy the houses in the neighbourhood of the sheds, and one of each company remain day and night with the company, to prevent any of the men from entering the village without leave, upon any pretence. The commanding officer must acquaint the officers of his having chosen the place M for the rendezvous in case of a retreat; which ought to be at some distance from the village, and on the side he judges most convenient for retiring to the army. At sunset the grand guard are to return to the post and join the picquet, the half of each to mount alternately till daybreak, and then the grand guard to return to the place which they possessed the day before. The sentries and vedettes should be doubled, and all the passages shut up with waggons placed in two rows, except one for sallying out at in case of a retreat, made wide enough for the passage of the patroles or the whole cavalry.

The corporals of the ordinary guard should lead the relief of the vedettes every hour, setting off together; but when they come to the passage of the post A, they must separate into two parties, the one to the right to relieve the vedettes BBB, the other to the left for the vedettes CCC; then each of them, with the parties they have relieved, should go on at their head a quarter of a league by the two routes pointed out in the plan, to examine the environs, supposing an hour to each. Besides this reconnoitring, the captain of the grand guard should send two patroles in the night. To fill up the intervals, they should set one about half an hour after the corporals, and make the same round.

30 Mode of fortifying villages.

In defensive operations in an open country, the fortifying of a village or a church-yard may often prove of importance, as such posts well defended may obstruct the movements of the enemy, and give time for a sufficient force to collect to meet them in the field. We shall therefore describe the most approved mode of strengthening these positions.

When it is proposed to fortify a village, inquiry should first be made respecting the surrounding country, whether there are woods, hills, or rivers near the village, whether the roads be accessible, whether provisions can be easily obtained, &c. If the village is to be occupied as a post of defence merely, the woods, rivers, ravines, or heights, may afford advantageous outposts or situations for batteries or ambuscades; but if it is to be possessed as an advanced post on the eve of a battle, the woods next the army should be cut down, the hollows filled up, and every thing removed which may obstruct the freest communication between the village and the main army; while on the side of the enemy, every obstruction by works, trees, &c. should be thrown in the way of his approach. The roads should be broken up or intersected with deep ditches.

If there be good hedges or deep roads parallel to the village, or in such a situation as to front the enemy, these will serve as breastworks, and for shelter. The hedges should be cut down to within four feet of the bottom, their tops sloping towards the country, and deep ditches should be dug in front. If the roads are deep, *banquettes* or *steps* must be thrown up next the hedge to raise the men to the proper height for firing. For want of such natural means of defence, it will be necessary to throw up intrenchments on the side next the enemy and on the flanks.

Plate DLII. fig. 1.

Fig. 1. Plate DLII. will explain the method of doing this in a village, under ordinary circumstances. The village stands in a plain, and in front of the army, which is distant from it about 600 paces, *a*. The front of the intrenchment consists of three fleeches or arrows, *b*, *c*, *d*, joined together by lines. There are wolf-holes before the works that cover the left flank *e*: the line *g*, which crosses some swampy grounds, is broken in several places *i*; and the grove of wood *l*, is cut down, to prevent the enemy from approaching under cover of it. As the right flank, consisting of a level plain, is more exposed than any other quarter, in addition to the works made of earth, which are thrown up at *m*, trees are collected, and heaped up in the form of an abattis, *n*. These are defended by a discharge of musquetry from the intrenchments, whose lines are raised as high as possible behind the growing hedges *o*, which inclose the gardens. It has however been judged necessary to throw the works up in a forward position *p*, and to have an interval between them and the hedges, lest the houses should be set on fire by the enemy, and the troops be exposed to it. Every thing is left clear and open at the back of the village, in order to secure a free intercourse with head-quarters.

Other measures, however, must be adopted in the fortifying of villages which lie at so great a distance from the camp, that the enemy might surprise and take possession of them before any succours could be sent; for in that case, intrenchments must be thrown up throughout the whole of their circumference. If, on the contrary, one of the wings of the army should be supported by such a post, it would be more judicious to put the flank in a state of defence, and to lengthen the works in that quarter, to prevent the enemy from turning it.

If it should be judged expedient, under the circumstances of the army being cantoned, to fortify a village which lies in a plain, other means must be used; for in that case there would not be troops enough to defend it. Should there be a sufficiency of men, intrenchments must be thrown up in the manner we have described, and fleeches must be adopted to cover them behind, with lines to connect the vacant intervals; but if there be a scarcity of soldiers, nothing but what is absolutely necessary must be done; for it is highly impolitic to attempt more than can be easily defended. Under these circumstances you must be satisfied with erecting small works, or using barricadoes to mask the entrances; here and there likewise fleeches must be constructed, whose communication will be kept up by the garden hedges. If the village should stand on an eminence, it may

Military Tactics.

may be fortified with more facility, and many things may be omitted, as the natural situation is itself a respectable post.

Should there be a very great disproportion between the extent of the village, and the number of men intended for its defence, and the latter should be too small, a part only must be fortified, and the remainder of the houses must be secured by lines. Sometimes indeed it is found necessary to burn or destroy them, to prevent the enemy from approaching the fortified parts, under cover of the buildings.

But if the garrison should not be sufficiently strong even to defend a part of the village, you must be contented with fortifying the church and church-yard, or the castle if there be one. If any of these posts be thought defensible, troops must occupy them on the first alarm; but this must be done in perfect safety, and without the soldiers being exposed to be cut off on their march. This precaution is above all others necessary where villages are so long and open that the cavalry may enter them at every opening. On this account the ordinary roads and avenues must not only be obstructed, but the garden hedges must be repaired, and every opening must be closed, which may be easily done by driving stakes into the earth, and nailing boards across them, which will prevent any sudden irruption of the cavalry, from which alone any danger is to be apprehended on occasions of this sort; for the infantry would scarcely advance, except by surprise, before the garrison could occupy its station. If any apprehensions are formed of an attack, the soldiers must not be absent from their post, either in the dusk of the evening, or at night; they must, on the contrary, be assembled in the intrenchments during that period, to be ready in the neighbouring houses, always clothed and accoutred.

31 Method of fortifying a church and church-yard. Fig. 2. & 3

A church and church-yard afford an admirable post of defence, especially if, as usually happens, they are seated on an elevation. In fortifying such a post, we should first block up every road and bye way leading to it, by means of waggons or carts, with their wheels taken off and loaded with dung or earth; trees laid across, or chevaux de frize. The narrow paths may be barricadoed with rails, with their points standing upwards, and a little outwards, having behind them thick branches of trees, or logs of wood, with a ditch in front. These previous precautions being taken, the doors of the church should be pierced in several places, about eight feet from the bottom, with holes large enough to admit the muzzle of the musquet, and platforms should be raised with steps within for the men to fire from. Other loop holes should be made at the bottom of the doors just above the level of the ground, and a ditch must be dug within, about three feet deep, so as to admit of men firing from thence through these lower loop-holes. See fig. 2. The doors must also be secured by barricadoes, consisting of pallisades driven several feet into the ground, and set extremely thick, some being deeper than others, so as to leave spaces between them and the top for loop-holes. See *a*, *a*, fig. 3. This barricado is technically called *tambour*. The walls of the church must also be pierced in various places as directed for the doors, see fig. 3. and ditches must be dug within them, and scaffolding erected as before.

Again, on the outside of the church, a ditch is to be dug as close to the walls as is consistent with safety to the foundation, about 12 feet in breadth at the top, and four in depth; and from the further side of this ditch the ground should be gradually sloped towards the open country. Through the main door of the church an opening should be made about two feet above the ground, sufficiently large to admit of one man passing through without much difficulty, so that when the church-yard becomes untenable, the garrison may retreat into the church.

It must not be forgotten to secure the means of a cross fire. If the church be built in the form of a cross, cross firings may be easily procured through the proper loop-holes; but when this is not the case, loop-holes should be made through every salient angle of the building, or tambours, such as represented in fig. 3. must be formed wherever it can be conveniently done.

Men must be distributed in the upper part of the building. These men will take out the tiles or slates in different places, in order to observe the approaches of the enemy, and to fire upon him when he comes within musket-shot. The lower windows of the tower or steeple must likewise be barricadoed, and have loop-holes made in them. The pavement of the church must be taken up, and the stones or bricks be carried to the top of the building, to enable the besieged to let them drop upon the enemy, when he gets sufficiently near. In order to render the defence as practicable as possible, you must also collect some large barrels or tubs, and keep them constantly at hand filled with water, for the purpose of extinguishing any fire which might break out in the church, or be effected by the enemy's shells.

Fig. 4.

Fig. 4. shows a plan of the church and church-yard thus fortified. *a*, *a*, *a*, *a*, the wall of the church-yard; *b*, *c*, tambour work in the front of the entrances; *d*, the church; *e*, *f*, tambour work constructed opposite the doors; *g*, the sacristy or vestry.

32 Of ambuscades.

Connected with the attack and defence of posts is the subject of ambuscades, which we must now briefly consider.

Ambuscades may be formed in any place where a part may lie concealed, to surprise the enemy in passing. They are easily carried into execution in woods, hollow places, and large deserted buildings; but the placing of an ambuscade in any situation requires previous accurate information with respect to the movements of the enemy. When the commander of a party has been directed to form an ambuscade, to surprise a convoy of artillery, baggage, or provisions, or a body of recruits going to reinforce the enemy, he should first make every necessary inquiry respecting the route which the enemy is to take; the situation of the places near which he is to pass, and the post to which he is about to march. He must also inquire with seeming anxiety about the roads which lead in an opposite direction, on which he should seem more intent than on his main object. Having concerted his plan, he should set out at the head of his detachment if possible, and leaving his post on the side opposite to his true route, the better to conceal his design. If the place where he intends to plant his ambuscade be not far distant, he should come into his true route about half way, and there place half his infantry in ambush to favour his retreat. But when the country where he proposes going is distant, and the march

Military Tactics.

march requires at least two nights, he must conduct his party by meandring from wood to wood, if there be any. He must not forget to provide necessary refreshments for the day, which must be passed in some concealed place where he may not be perceived, and must cause three rations of oats to be carried for each horse.

Proper precautions having been taken to guard any cross road or bridge that may lie near the place of ambuscade, the commanding officer should take care to be at least two hours before the enemy, and to place the ambuscade on that side, by which, if worsted, he may retire with the greatest safety.

Plate DLIII. fig. 2.

Plate DLIII. fig. 2. will illustrate the proper method of laying an ambuscade. A represents the infantry of the surprising party, which ought to be placed at least 600 paces behind B, the cavalry, so that, if pursued, they may both fall back to A, and make good their retreat to the guard at the bridge or cross road; or to another party of infantry placed in ambush half way. If the ambuscade be placed in a wood, an intelligent non-commissioned officer should be chosen to get upon a high tree C, from which he can see the march of the enemy, and give notice of the most essential circumstances. The first of these is the seeing the advanced guard; the second is the approach of the corps, and the third is the time when their front is advanced as far as the ambuscade B; for which the commanding officer should instruct the observer what signals he is to make from the top of the tree, to communicate the necessary information without speaking, which may be done by means of a small cord D, of a brown or green colour, so as to be least perceptible. Let this cord be placed as in the plan, so that no branch interrupt it, with one end in the hand of the observer, and the other in the commanding officer's hand in the ambuscade B.

As soon as the advanced guard appears, the observer must pull the cord, and the commanding officer cause the party to mount and remain in deep silence. If by a stratagem, which is practised for particular reasons, the advanced guard is immediately followed by the corps, which may be easily known by their being more numerous than ordinary, and not followed by any other corps, that the commander may not be deceived by the enemy, the cord should be drawn a second time, and a third time when their front is advanced as high as the ambuscade. At that instant the party must rush out, and furiously attack the flanks of their centre in the following manner.

If the advanced guard E is formed only of an ordinary number, they should be allowed to pass; and at the approach of the principal part or convoy F, the chief to be informed by the second pulling of the cord. At the moment the head of the convoy shall be advanced as high as B, the cord must be pulled the third and last time; and at this signal the party must rush out without being perceived, and suddenly attack the centre on the flank, engaging only with their swords, and making such a noise as to prevent the enemy from hearing the orders of their officers. They must disarm all whom their bravery shall throw in their way, taking care not to scatter or pursue too far, unless it be certain that they are so far from their army or parties, on account of which they cannot be affected; for in either of these cases they will not fail to run at the noise, and disturb the retreat.

In all secret expeditions, great circumspection should be used, that the party be not seen or betrayed; as if they be discovered by the advanced guard before the blow be struck, the enterprise must be immediately abandoned, and the party retire. When the guide, or any one of the party deserts, and cannot be catched, a retreat must immediately be thought of, or the ambuscade must be placed somewhere else; but to prevent such a misfortune, the officers should be charged to examine frequently whether they have all their men.

An ambuscade should never be formed for cutting off the enemy's retreat, as this will drive him to despair, and make him rally and attack the party with desperate resolution. There may be an exception to this, when it is pretty certain that the whole party of the enemy may be cut off or taken prisoners, either from the smallness of their number, or from the peculiar situation of the place of ambuscade.

Several ambuscades should not be formed at once, except for the purpose of seizing foragers, in which case they should be disposed so that the sentinels may see from one to another. Then the first guard which sees the foragers, should commence the attack, and can soon be assisted by the rest of the party.

In all ambuscades, no sentries should be placed but officers or non-commissioned officers. On downs, behind mountains, or in gullies, the sentries should lie with their bellies on the ground, and their feet towards the ambuscade, the body covered with a gray or green cloak, according to the colour of the ground, with their heads a little raised and wrapped in a handkerchief of straw green-colour, or white in time of snow, so as not to be easily perceived. The numbers of sentinels cannot be determined, but they should be disposed so as to watch on all sides of the ambuscade, and stop every one who may inadvertently approach too near. The sentries should give notice of what they discover by gestures, to which all the officers should be very attentive. In countries where there are no woods, vineyards, or hedges, an ambuscade may be placed in a field of hemp or corn, or some sort of grain, provided it be high enough to cover the men, at least with the help of art. When the stalk of the corn is not high enough, some of the infantry must be set to work with spades and pickaxes, which they must have brought along with them, for the purpose of digging holes in the field deep enough to make up for the defective height of the corn.

Fig. 1.

An ambuscade often forms part of a stratagem for bringing on an action with a party of the enemy which would be superior, were it not for some advantage of this kind, as in the following case. See Plate DLIII. fig. 1. Suppose the whole party to set out from A, marching under the conduct of a trusty guide by covered ways at a distance from the enemy. Being come to the place C, which ought to be in the environs, and as high as the field of battle, the infantry should be concealed out of the road far from the sight of passengers. This must be the centre of correspondence with the army, the rendezvous of the booty, and support the retreat of all the cavalry, of which there should be as many detachments as there are attacks proposed to be made. We shall suppose six of 100 men each, and they must

Military Tactics.

must go secretly by particular routes to their respective posts, E, D, F, G, H, I. Neither trouble nor expence should be spared to procure good guides. Each detachment should lie in ambush half a league, if necessary, from the object of the attack BKKKK.

The noise of the musketry in the armies is to be the signal for their irruption; and then bravery, intrepidity, and courage will give wings to the people. The second detachment D will glance imperceptibly between the villages, and fall like thunder on the camp B; and while 80 attack all whom they meet, the other 20 should light their torches at the fires that are to be found everywhere, and spread the flames rapidly to the straw of the tents. As they cannot fail to have the picquet of the camp soon at their heels, they must strike their blow with all possible expedition, without stopping to plunder, being content with the glory of having excited a general alarm, capable of confounding the whole army, and contributing to the gaining of a battle.

At the same time that the detachment D attacks the camp B, the others, E, F, G, H, must with equal violence attack the villages K, K, K, K, which they have in front, doing the same the first did in camp, except that they may seize as plunder every thing which they can conveniently carry off, with which these villages are commonly filled, seizing the best horses, hamstringing others with the stroke of a sword, and setting fire to all the places which contain the enemy's baggage. Each detachment should cause some horsemen to advance beyond the village, to observe the motion of the troops, who will not fail to run to their assistance. As soon as they perceive them, they must make their retreat as fast as possible by the routes which the commanding officer has preconcerted, and which are represented in the plate by the coarse lines. The sixth detachment I, in ambush on the side of the road leading from the camp, should remain there, to seize all the enemy who think of saving themselves by flight.

33 Of retreats.

When the commander of a detachment finds himself obliged to abandon a post, or that it is not worth defending, it becomes necessary for him to prepare for his retreat. This is often a difficult and dangerous affair, and requires much prudence as well as bravery on the part both of officers and men. If possible, he should retreat on that side which forms a communication with the general basis or line of posts occupied by his party. The following observations on lines of retreat, connected with the lines of operation described in N° 22, will be found of importauce.

Plate DXLVI. fig. 8.

A retreat on a single line is a fault of the utmost magnitude, for it is evident that if the army C (fig. 8. Plate DXLVI.) retire from it towards B, along the line AB, the enemy may send besides, two corps *a*, *d*, against the flanks of this army, which would separate it at the point B, and in this case it would be surrounded. Nor is this the only disadvantage, for all the country situated to the right and left of the line AB, would fall into the hands of the enemy; while, in a retreat, it is always a rule to cover as much of the country as possible.

Fig. 9. Fig. 10.

A concentric retreat is of such a nature, that in an extensive position they fall back to one more confined, so that the two lines of operation at the extremities AB, (fig. 9.) unite at the object of retreat C, forming an acute angle, or as at fig. 10. an obtuse angle; such a retreat would have no better issue than the former. The same disadvantages which result from retreats on a single line would likewise attend this. There is one circumstance which might induce a general to retreat in this manner, and that is, with the view of covering any important place, a capital, for example, by taking an advantageous position, which is indicated by C, in the figures; the important place required to be covered would probably be at D. But nevertheless this measure would be ineffectual if the enemy were at all versant in the art of war, and operated on the flanks of the army they were pursuing. The best method of covering a country, which is in our rear, is to proceed against the flanks of the enemy which is advancing; and by this intrepid and bold movement, to change our defensive operations into those of an attack.

Fig. 11.

A retreat conducted in parallel lines, as the basis AB, in four corps, 1, 2, 3, 4, or the lines AC, EG, FH, BD, is doubtless better than the concentric retreats which we have just considered. In the first place, the country is better covered by means of the parallel lines; secondly, the enemy cannot so easily insult the flanks of the retreating army, provided that this is in a condition to perform the same manœuvre with regard to them, and thus obstruct their progress; lastly, they would be afraid of advancing with too much precipitation, from the moment their attention is divided by the attempt which may be made against them. But there might be something still better attending it, viz. to retire in an eccentric direction, as we shall show presently.

The excellence of parallel retreats is maintained from the idea that they cover a country better, and likewise stop the progress of an enemy, when opposed in a direct line. Certainly this appears evident to the eye; but the sight is often the medium only of error. It is the *ignis fatuus* which leads us into the mire, and the present instance is a proof of it. This opinion was not indeed well founded among our predecessors, and still less is it so among the moderns. We do not now arrest the progress of the enemy, by presenting ourselves to their strongest part, viz. their front; but, on the contrary, by intercepting their flanks, which are the weakest parts; by harassing their rear; by menacing their provisions and their communication with the sources of their vigour and power. It follows from hence, that eccentric retreats are the best. An army (fig. 12.) who retires from *a*, *b*, *c*, *d*, *e*, towards *f*, *g*, *h*, *i*, *k*, runs no risk of seeing the enemy advance in the segment *f*, *k*; for he would, by such a movement, be in danger of being surrounded.

We may lay it down as a rule, that it is essentially necessary, in all retreats, to divide into different columns, in order to divert the attention of the enemy; and it is fully demonstrated that there is not in war a more important maxim. We might show that this method of attracting the attention of the enemy to many different points at once is, properly speaking, exciting a degree of apprehension with regard to his flanks and rear. But it naturally results from all that has been said relative to the inutility of diverging offensive operations, as well as those which are directed by a single line, or by an acute angle, that eccentric retreats are of all others the most preferable. Since concentric operations are the most advantageous in attacking, eccentric ones must necessarily possess the same advantages in defence; every thing

thing should be in opposition, in two different kinds of warfare, which are in their nature and interests contradictory.

In conducting a retreat, as in all other field operations, an army should assume, as the principal object, its own magazines, and the safety of its lines of convoy, rather than the army of the enemy; and it should never take a position opposite the enemy, but rather on one side of him.

34
Of battles.

We have hitherto considered military operations in the field, as they are subservient, or preparatory to, that most important consequence of war, a *battle*. We must now examine what are the causes which should induce a general to hazard or avoid a battle; and if he determine on a general action, what are the best methods of disposing the troops under his command.

At present, actions in the field are distinguished into two kinds, according as they are more or less general. When the whole of the adverse armies are engaged, it is called a *battle;* but where only a part of each is concerned, a *combat*. The latter of these, however desperate, does not in general involve such important consequences as the former; but as in a general engagement, the vanquished party usually lose the greater part of their artillery and baggage, and are compelled to retire and leave the country behind them at the mercy of the victors, a prudent general never hazards such losses without important reasons.

35
Reasons for hazarding a battle.

When an army is superior to its opponents in number or discipline; when discord prevails among the chiefs of the adverse army; when a neglect of the ordinary precautions in marching, encamping, or other obvious duties, demonstrate their incapacity; when it is necessary to relieve a considerable town or post that is besieged by the enemy; when it is apprehended that the army will be dispersed or ruined, without a general engagement; when intelligence has been received that reinforcements are approaching to the enemy, which will render him superior; when the enemy has received, in some preceding action, a considerable check which he has not yet recovered, or when the army whose general is thus canvassing the advantages and disadvantages of a battle, is in such a state, that every thing ought to be hazarded for its relief, the commander is warranted in giving battle to the enemy.

36
Reasons for avoiding a general action.

On the contrary, when less is to be hoped for from a victory than feared from a defeat; when the army is inferior either in number, courage, or discipline, to the enemy; when it is in expectation of being reinforced by a strong detachment of fresh troops; when the enemy is so advantageously posted that it would be impossible to bring him to an engagement on equal terms, or to force his entrenchments; or when there is a prospect, by temporising and declining battle, of ruining the army of the enemy by disease, famine, or desertion, it would be wrong to place the fortune of the campaign on the issue of a battle.

37
Preparation for a battle.

When a general engagement has been resolved on, the general is to devise the means of carrying it into execution, so as to have the strongest presumption of success. He is to arrange, with the officers of his staff, the manner in which the troops are to be divided and disposed, or what is called the order of battle; he should assign to his several officers their respective posts, and see that copies of the order of battle be given to those that have a separate command. The proper officers should take care that the troops under their command be properly armed and equipped, and that they are allowed time to rest and refresh themselves before the engagement. The heavy baggage, and every thing that might encumber the operations of the troops, should be removed, and placed at a distance under a proper guard. A reserve should be formed near the park of artillery, consisting of some of the bravest and best disciplined troops, headed by the most experienced officers.

38
Circumstances to be attended to during the action.

In time of action, the commander in chief should be so situated as to be able to issue his orders with the least difficulty, and to observe as far as possible the operations of his troops, and more especially the effects of the first attack. Every other general officer must keep his own station, to direct the charge of the troops, or to rally and re-form those which have been routed and dispersed. When the action becomes general, and is obstinately contested, the commander-in-chief should direct the principal efforts of his troops against that part of the enemy's line which makes the greatest resistance, and should himself hasten to this spot, to animate his men to greater activity and exertion by his presence and exhortations.

The artillery of the army should accompany the first line, and the remainder of the troops should follow the movements of those before them, so as to preserve the proper distance between the lines, and march with the least possible disorder and confusion. If the first line give way, the second should march up to its relief, and either charge the enemy, or keep him employed till the first line has time to rally and re-form. If, however, as often happens, the other lines are struck with a panic on observing the repulse of their predecessors, the reserve should be brought up, and it is probable that their courage and resolution will reanimate the scattered troops, and turn the fortune of the day.

39
Order of battle.

In forming the order of battle, regard must be paid to the nature and situation of the place where the battle is to be fought; to the number and quality of the troops engaged, and to the mode of fighting which is most likely to take place during the action, or to decide the victory. There are two principal methods of forming troops in order of battle, the column and the line. The former of these was most in use among the ancients, has been greatly recommended by Folard in his commentaries on Polybius, and practised with the most brilliant success by the French armies since their portentous revolution. This order of battle is adapted chiefly to cases where the activity of the troops can be relied on, and where much firing with musketry or artillery, is not expected to take place, and where of course the affair is to be decided principally by the pike or the bayonet. It is also well calculated for a body of infantry who are to resist the attack of cavalry. It is obvious that from the close arrangement of troops in column, this disposition must expose them more to the fire of a line, and must endanger their being flanked or surrounded by an enemy whose front is more extended. The relative advantages and disadvantages of the column and the line, will be more readily perceived by attending to the following principles.

From the order of battle as a basis are deduced many instructive

Military Tactics.

instructive principles relating to what are called *lines of marching* and *lines of firing*, which constitute a considerable part of the elements of modern tactics.

40
Principles of marching and firing, deduced from the order of battle.

There are as many lines of marching arising from the order of battle, as there are soldiers in the first rank of the line or column, and as the soldiers approach towards the enemy, these lines of marching, at least in the infantry, produce lines of firing. It is the nature and relative advantages of different lines of marching and firing that we now propose to consider.

Plate DXLVI. fig. 13.

Let us suppose two lines of troops, A and B, fig. 13. extended opposite to each other, of which A is considerably longer than B at each extremity, or, as it is termed, outflanks it. It is evident that B may be surrounded by A, as from the superior numbers of A, B may be attacked in flank and rear. It is therefore evident that when the numbers are unequal, and the contest is to be decided by firing, the greater number must prevail, if both are arranged in lines.

Fig. 14.

Again, the line AB (fig. 14.) being attacked by the line *c d*, the flank B cannot extend itself parallel to *c d*, if this line advances always in front towards A. The line attacked is surrounded, and even so pressed upon, that they must all take flight towards A. If any troops by chance should endeavour to form upon the line *e f*, they would not have time; taken in front and in flank by the enemy's fire, they could never resist such an attack. The cavalry would experience the same disadvantages in a similar case. Horsemen attacked to the right, to the left, and in front, could not defend themselves; the celerity of the horses, no doubt, would enable them to deploy quicker than the infantry; but, by the same reasoning, the enemy's cavalry, which is advanced upon their flank, would likewise advance the quicker from the point B, towards the opposite wing A, which a corps of infantry could not possibly do. Thus it would be equally difficult to form the line *e f*; every thing would be overthrown, and they must retire in the greatest disorder towards A. It is hence clear that every effort should be made by an army in line of battle, to turn the enemy's flanks with its front.

Concentric lines of marching and firing well executed, are exceedingly important. Hence it is that a fortress must yield when it is besieged, as the fire from the fortress is *eccentric*, while that of the besiegers is *concentric*. Hence, too, sorties from a garrison rarely succeed, because they are eccentric operations.

When an army is much weaker than its opponent, if the former be compelled to an action, it should throw itself on the enemies flanks; and to do this with effect, the enemy's front should be kept occupied, so as to draw off his attention from his flanks. If the line were long, he would have time to convey all that part opposite to the side attacked, as A (fig. 15.) into the line *e f*, before the attacking army *e d* could entirely overthrow and repulse the flank B, which would be the object of their efforts. In this case, things would again be equal; for an engagement in front would take place, the issue of which is always doubtful. If, however, they occupy the line AB, by corps sent for that purpose, as *g* and *h*, while, with a greater force, they attack in flank, then it would be impossible for any part of AB to throw themselves into the line *e f*, before having beaten *g h*; and the time would probably be too short for this operation, if *c d* pushed in front in a vigorous manner. From this it follows that the army AB, though the stronger, can do nothing better at this time than quit the field of battle, as it will otherwise be surrounded. Now, the attacking army have nothing to do but to effect an eccentric retreat; namely, to fall back with the left wing upon *i k*, and with the right upon *l m*, provided CD do not obstruct the passage; for in that case, the retreat of the right wing, or of that part of the army nearest the flank B, would be on *n*, in order to create in the enemy *c a* some solicitude for his left flank *d*. It is by such eccentric retreats that the pursuit of the enemy is prevented. They dare not venture it, if they do not wish to be taken in flank themselves, and to become in their turn exposed to an escalade and a concentric fire, and consequently a terrible havoc. Eccentric retreats in tactics are equally as advantageous as in strategy. The latter kind alarm the enemy with regard to his lines of operation, and consequently prevent him from advancing; the former make him afraid of exposing his flanks and rear, and hinder him from pursuing.

Fig. 15.

From these considerations it appears that it is no great misfortune for an army to be attacked in its centre, and divided. If the army be divided in two at the centre, it will retire eccentrically on *e* and *f* (fig. 16.). By this movement it will throw an obstacle in the way of all farther progress on the part of the enemy, who has divided in the middle the dotted line AB. It is impossible for the enemy *c d* to advance in front between *e* and *f*; they would take him in flank on both sides; he must therefore advance in front towards *e* and *f*, both at the same time. In this position *e* and *f* might detach forces to the rear of *c d*, and operate at once on its provisions and in its country. It would be sufficient for that to send some corps from their flanks to the points A, B. It is likewise possible for them to advance entirely to the left and right, if they have any magazines at *g* and *h*, which nevertheless would not be exposed by the marching of the flanks towards A and B, and would always be sheltered from the enterprises of *c d*. A third combination likewise would be to attack immediately *c d*, which, from its position, would be exposed on both its flanks. In this last case, *c d* would have no other resource than to operate on that part of the flanks *e* and *f*, which are opposite to the points A, B, to compel *e f* to retreat, and replace its front in the direction of A, B. Fig. 16.

It does not require a great body of men to occupy the front of the enemy, while the rest of the army attack the flanks. It is best done by means of a scattered troop, or what the French call *tirailleurs*, consisting of light infantry, which are usually instructed in the following manner. The troop, formed into two ranks, divides in such a manner that there may be a space between the two, as indicated in fig. 17. The second rank, placed behind the intervals left by the first, secures its flanks. When they attack, the second rank, CD, passing through the intervals of the first AB, advances to the line EF, and fires. The great advantage arising from this, is that of forming a more extensive front than when they are wedged in elbow to elbow; secondly, they keep up a more fatal fire with their musketry, because each soldier, being unmolested by the one next to him, aims better, and continues his firing without interruption; thirdly, a less number of men is lost, because Fig. 17.

Military Tactics.

bayonets, it would be sufficient for a division of the line AB to make a conversion on the flank of the *échellon* *c d*, while they are fighting in front, and overthrow it before *e f*, 300 paces distant, or even the second line of the *échellon*, could come up to afford it any assistance. Thus, according to all appearances, the line AB would conquer all the *échellons* successively, and this the more easily as they would be taken in flank as soon as *c d* is obliged to fly.

The most useful, and in fact the only process for reinforcing an attack, is to have a second line of cavalry behind a first of infantry; in case of bad success they secure and cover their retreat, and complete the disorder of the enemy's infantry, if they come to an engagement.

When the infantry is ranged *en echiquier*, a first line when beaten, may retreat by files through the lines in the rear, without creating any disorder in the second, on account of the extensive spaces; but it is not the same with the long phalanx in open order. The cavalry, placed immediately behind the infantry, protects an attack much better than if there were between them a second line of infantry; for in the first instance, there would be no hindrance to their hastening to the succour of the runaways, and receiving them in their bosom. Hence there should be only two lines, one of infantry, and one of cavalry; and this is the more important, because the two lines of infantry cannot be useful, except in as far as they are beyond the shot of the cannon; it is evident, therefore, that they should be considered rather as a reserve of fresh troops than as a second line of combatants. Hence, the superadded strength which is supposed to be given to the *échellons*, by double lines of infantry, is quite illusory.

Cannons which fire concentrically, assist greatly the efficacy of an attack; but this measure may be employed as well for right lines as for the *échellons*: in an attack of the latter kind, the batteries should not be placed before the division *c d*, but before *e f*, to enfilade that part of the line AB, which would attempt to fall back to make a conversion, in case it were attacked in flank by *c d*.

It is impossible to take the enemy in flank by the diagonal or side-step, executed during the march, if, previous to commencing their march, they are not already considerably by their wings; for they would completely frustrate that scheme, if they made directly with their flanks a movement to the side. During the same time they would pass over a more considerable extent of ground than with an oblique step, because they move in a direct line, and in front, and obliquely, both at the same time, which would considerably shorten their distance; and likewise because they march on one of the sides and you on the hypothenuse, which is longer. It is therefore impossible to succeed in stretching beyond the wings of the enemy, while they are advancing in front in the order of battle, if they know how to conduct themselves.

There is, however, one advantage to be noticed, which the *échellons* possess over the uninterrupted oblique front, which is, not exposing the flank to the enemy advancing in front. The *échellons* naturally possess this advantage, while the oblique front cannot obtain it without being much more extensive than the enemy's front; for the oblique line, formed into *échellons*, changes into a number of parallel lines by a conversion (fig. 38.), and they may, by this movement, defend their flanks against the enemy. But still the best way is to attack him in his own flanks, whilst his front is amused with detached corps, and the columns should be prepared for the principal attack out of sight of the enemy, in the same manner as an admiral adopts at a considerable distance, his measures for gaining the windward of the enemy. No manœuvres within cannon-shot can possibly be attended with success, if the enemy be skilful.

41 List of remarkable battles.

Much useful military instruction may be derived from perusing the accounts of the most celebrated battles, detailed by writers of ancient and modern history; and we could here enumerate a long list of these engagements, many of which have been described in the historical articles of this work. A few, however, must suffice. Of ancient battles we may notice those of MARATHON * in 490 B. C.; Platæa, 479; LEUCTRA *, 371; the GRANICUS *, 334; ARBELA *, 331; the Thrasymene Lake †, 217; CANNÆ *, 216; ZAMA *, 202; Magnesia ‡, 190; Nepheris, 147; PHARSALIA *, 48; and PHILIPPI *, 42. Of modern battles, the most important are those of HASTINGS *, A. D. 1066; the Indus ||, 1221; Bannockburn §, 1314; CRESSY *, 1346; POICTIERS *, 1356; AGINCOURT *, 1415; Bosworth **, 1485; Flodden §, 1513; Pavia, 1525; Narva ††, 1700; BLENHEIM *, 1704; RAMILLIES *, 1706; Pultava ††, 1709; MALPLAQUET *, 1709; Fontenoy ‡‡, 1745; Prague and Colin ||||, 1757; Lissa or Leuthen ||||, 1757; Minden, 1759; Freyburg, 1762; Jemappe, 1792; Tirlemont, 1793; Fleurus, 1794; Lodi, 1796; Zurich, 1799; Ulm, 1800; Marengo, 1800; Austerlitz, 1805; and Wagram, in 1809.

By way of illustrating the modern French tactics, and more fully explaining what has been said on the order of battle, we shall here give a detail of the battle of Jemappes, in which Dumourier entirely defeated General Clairfayt, by enticing him from a situation where he was impregnable.

42 Battle of Jemappes. Plate DLIV.

In the beginning of November 1792, when Dumourier arrived with his army in the vicinity of Mons, he found the Austrian general Clairfayt occupying a strong position on the heights near the village of Jemappes, where he had entrenched himself, and was defended by nearly 100 pieces of cannon. The position of the Austrians was extremely formidable. Their right extended to the village of Jemappes, and formed a square with their front and left, which stretched to the causeway of Valenciennes. They were posted on a woody mountain, where they had erected, in an amphitheatre, three tiers of redoubts. Their whole force amounted to about 16,000 infantry, and 3000 cavalry.

The army of Dumourier was much more numerous than that of Clairfayt, but not so well supplied with artillery. The elevation of the Austrian batteries, too, gave them such an advantage, that the French cannon could produce but little effect.

On the 5th of November, Dumourier had fully reconnoitred the Austrian camp, and, by way of feint, made an attack with his infantry on the village of Carrignon, while he kept up a brisk cannonade on their left. Towards evening the French army encamped opposite to Jemappes, with its left wing extending to Hoorne, and its right to Fremery. As Dumourier resolved

Military Tactics.

solved to make a decisive attack on the height of Jemappes the next morning, he ordered his troops to abandon the village of Carrignon which was commanded by the enemy's cannon.
