 BEGINNERS OF ALL CLASSES.-No. 1 By the Rev. J. S. Hexscow, M.A., Rector of Hitcham, Suffolk Experience has shown the efficiency of a plan I have followed in giving practical lessons in systematic botany to children in a village school. I believe somewhit similar lessons might be rendered effective in any school, or wherever students associate for the purpose 0 receiving instruction in this department of natura history. We must impress on beginners that they have to substitute strictly "scientific ideas" for whatever "vulgar notions" they entertain concerning all the parts of plants for which we have names in common use The natural sciences have made great progress of late years, and it is high time that many vulgar notions, too often synonymous with vulgar errors, should be thus corrected. It is no uncommon? mistake to fancy there must be some easy royal road to botady where every technical term employed to faollitate the progress of this science may be avoided; and therefore, that strictly scientific ideas can be aqquired without them. We might as well fancy we may conveniently reject the Arabic numerals, and dispense with the multiplication table, whilst grounding ourselves in the common rules of arithmetic. It is certainly advisable not to employ more technical terms than are really important ; but no teacher should shun the use of such as are so. As soon as the scientific ides, embodied as it were in a technical term, is duly appreciated, there is no longer any difficulty about recollecting that term. Many botanical terms have been anglicized from the Latin, or Latinized Greek words employed by scientific writers, who use the Latin language in order to enable botanists of different countries to be mutually intelligible in their descriptions of plants.We cannot too earnestly or too early inculcate apon students that they must begin by learning "how so observe" before they can expect to acquire any acctrate knowledge of the structure of plants. Nonobservers, content with such information as may be derived from books, will find themselves at a loss whenever they attempt to solve some of the simplost botanical problems.

In order that he may be able to deliver the description of practical lessons I am about to suggest, I suppose the teacher can ascertain (no matter how) which names of the flowering plants, and a few others, which grow wild, or happen to be conmonly cultivated in the gardens of his neighbourhood. According to my own judgment, English names for our wild flowers, aud English terminology for their classification, are be is adapted for the use of schools in which no Latin is taught, or in places where the children are not likey, ind after life, to extend their observations much bey be

## terminology.

Plant List.-A list of the native plants which have been observed within a specified area, that of a parish for example, should be hung up in the school-room. If t be printed, each pupil should receive a copy. In 1850 prepared and printed a list (in English) of such wild printed it with above 50 additional species, chiefly prinded by my little village observers. The generic and specific names have mostly been selected from those
given in Hooker and Arnoti's British Flora. In the given in Hooker and Arnoti's British Flora. In the dopted from Lindley's Natural System. I experienced an inconvenience in regard to these English names for the orders, in having to recal terms which had not been constructed on any general rule, and several of which bear no resemblance to the correthought it better to Anglicize the Latin orders, by substituting a common termination, "anths" (flowers), for that of the genitive cases of the genera regarded as wore or less typical of each. An objection may possibly be made that I am burdening science with a fresh set of synonymes for the orders. A little reflection will, 1 think, show that this is not done to an objectionable extent. There is gxat difference between the classical terminology in common use, and substituting one which is merely the same word in an English dress. No botanist could foresee that the English terms for Ranunculaeee, Berberaceæ, Papaveraceæ, Rham nacea, Loranthaceæ, Apocynacere would be Crow-
foots, Berberids, Poppyworts, Rhamnads, Loranths, foots, Berberids, Poppyworts, Rhamnads, Loranths,
Dogbanes. But every botanist may predetermine, by the rule laid down, that the anglicized terms for these orders would be Ranunculanths, Berberidanths, Papaveranths, Rhamnanths, Loranthanths, Apocy where the more usual Lative and typical genus, as in Cruciferæ, Leguminose, Umbelliferæ, Compositæ, it may be advisable to employ the synonymes Crueifers, Legumens, Umbellifers, and Composites, in addition to the terms derived by the genera ule, viz., Brassicanths, Vici ranths. The peculiar advantages of the plan proposed determine for himself what should be the English synonyme for every order. 2d. It qualifies any one who may be taught systematic botany by means of an English terminology, to refer without embarrassment to authors who employ a Latin one. Why not then
at once teach botany by the Latin terminology? Do so, whenever it can be doue appropriately and conveniently but in village schools at least, or wherever an English terminology may be most advisable, it is better to avoid all purely Latin terms for the classes and orders whils ing strictly English terms for the genera and species. Plant-stands.-Against the wall, at one end of the above another. All the wild flowers which can le procured in flower or fruit at the some time, are disposed systematically upon them. Each plant has the ar its class, order, genus, and species belo replenished with fresh specimens as the old ones decay. Thus they have continually brought before them the position which each plant occupies in the matural system. This mode of classification gradually becomes so familiar that the more advanced schoars can readily separate a bundle of wild flowers into thei aatural orders, and group these in the exact sequence abserved in the plant list and on the plant-stands. They also seldom err in referring a garden plant, if it happen to belong to any of these orders, to its right position
amang them. If they are unacquainted with its order, they will most probably place them in the right sections of the classes to which it belongs.
Any plant brought for the first time in flower during the season, is recorded in a separate list by the child
who brings it. Thus in 1851, H. R. (aged 13 years) Mrought
 And so or to the Meadow Grass

Pestruction of the description of the dimensions and unacceptable, but this must be deferred to another communication.

## LONGEVITY OF THE PEAR TREE

The greater or less duration of life in a Pear tree depeuds-lst, On its natural constitution. 2d, On that nnture of the soil and depth of the subsoil where the tree is planted. 4th, On the means taken to renovate it, such as moderate pruning, thinning, or cutting back, performed every two or three years. 5 th, On manure moderate degree of vigour and a continuous bearing condition. It would be useless to enlarge upon these points, about which there can be no question. A variety
it is to grow and produce its fruit, should have a suf ficiently hardy constitution. It is only by repeated sowings that the Pear tree can be sufficiently naturalised our cold and variable climate
Before making au extensive plantation as an orchard, it is important to know the constitution of the variety and its peculiar mode of growth. It is likewise prudent o ascertain by observing the vigour of the trees, whether the variety is worsed upon a sution not. When the tree is planted a dention is wholly directed to make it take an easy direction, one suitable to its manner of growth. The early pruning of its shoots and stems is performed with the view of es
tablishing a harmony between the main branches. By removing superfluous shoots by summer pruning, an preventing bifurcations in the branches, a five straigh stem, with lateral branches growing in proper directions and at regular distances, is obtained. These operations are performed in the first year towards midsummer, or at the fall of the leaf. The slight wounds are at these periods more easily healed over, and the sap directis
别 gorous, and are at the same time possessed of all the roperties requisite for orchard culture, it is advisable o choose free stocks, or wildings, which likewise preent every appearance of healthy vigour and firm growth. In order to have stocks of this description, seedlings are planted and allowed to grow in the same
place for two years. The best growers are then selected place for two years. The best growers are then selected
and planted out for being worked. In the following summer they are budded, not ${ }^{\text {at }} 6$ inches above the ground, but at 2,3 , or 4 feet high. On examining large number of old trees, of great size, it is pretty generally found that the bud has been inserted about and the the space between the lowest bart, but and the ground, or at some point above that part, bu seldom lower. Those trees 80 worked resist sun In a light free soil, with a rich deep subsoil, in which water does not stagnate in winter, the trees preserve throughout their individual existence a healthy degree of vigour, and bear abundantly. If the soil is rich in humus, or if it is a marly clay of some depth, resting upon an equal depth of silicious gravel mixed with brick earth, lying upon thicker beds of sand which bsorls misture the orowth of the Pear tree will there borns moisture, he grow. the will bear buit a far fluveur and wereally live loncer. We foun hiner We found growing in such soil in and of Flanders a variety of Pear under the name of Poire variety known among the Romans as the Pyrus horeana, the fruit of which ripened about the same time as Barley. This majestic tree has two upright paralle tems, is 12 feet in circumference, and 45 feet high. In 1854 it produced 15 sacks of Pears. The bark is deeply rent in many places, indicating that the tree was of great age. The farmer, himself 85 years old, told me that his grandfather, who died 60 years ago at the age of 92 , had frequently told him that in his early circumference. It is supposed that this tree is about 250 years old. It is still far from being worn out, having produced in 185415 sacks, as above stated, and in 1855 it yielded six sacks, and it is again pushing nown by the name of Mansuette, an excellent kitchen Pear (the Mansuette of Duhamel is a table Pear), there is a tree which is not lese than 200 years old, and it is as productive as the one alrealy mentioned. Its branches, loaded with fruit, hang down like those of a Weeping Willow. These two trees, as well as severa of having been grafted at 2 , 3 , or 4 feet high. To keep them in good condition, all the care which they receive merely consists in pruning off every wo or three years useless shoots tending to cause confusion, in spreading well decomposed manure over the ground before winter, and in applying every year at without disturbing the turf over the roots, exceptiog perhaps for 2 or 3 feet round the trunk
These two instances, and others that might be given, prove that the Pear tree, when its constitution is strong and hardy, can sustain for a long period the severities of careful treatment, attain the age of 300 yeare. It is in the conditions of soil already pointed out, and more especially in ground sloping to the west that this result may be obtained. There is no doubt that among the modern varieties which have been bained in the present century by the system of Van Mons, there are
several sorts of excellent dessert Pears, ripening in long succession, the trees of which would live as long as the Poire à Froment or the Mansuette. This anticipation is founded on the observation of these varieties where they have been cultivated for $8,10,15$, or 25 years
The Urbaniste of Coloma becomes a fine tree; grown as a standard, it attains a great length, and its fruit preserves its qualities even in it was raised in 1786. It is now generally acknowledged that 20 years after this variety appeared, its name was changed id France to Beurré Piquery

The Beurré $\mathrm{d}^{\prime}$ Hiver du Printemps, or Suprême as well as arous and hardy than the Erbaniste,
upon in coming into bearing, especially when worked excellent quality even in a less favourable soil than that required by the Urbaniste. This sort, as yet but little cultivated, is easily known by its thick olive green shoots, of a darker or lighter shad
Colmar Neil, named by Van Mons after Dr. Patrick Neil of Edinburgh. Can a more vigorous or finer tree be seen? It has the appearance of a Poplar.
Beurré Kennes, Beurré Berckmans, Beurré SterckCons la Conr or Meŕhal do har (Duc d'Orleans ?), Désiré Cornelis, Belle Julie, Madame Eliza, Souvenir d'Esperin, Triomphe de Jodoigne, in a light deep soil, Wilbelmine, named by Jan Mons in honour of the Princess of Prussia, Queen of the Netherlands, and which has received in France the name of Beurre d'Amanlis, was considered by the late Van Mons as one of the most vigorous and finest of his fruits. We might swell this list with several other still more recent varieties, bat which have not as yet been suffciently proven. Well, these 13 sorts are worth more for orchard culture in our climates than all those which have been obtained in previous ages.
It is quite certain that these varieties will attain as great au age as the old sorts which still exist in our orchards, but which are allowed to die out because they are eclipsed by varieties which are better in every Meryeille d'Hiver, Bergamotte trevely the are for in which have never borne any better fruit than that which they produce at the present time
From what has been stated, it appears that the Pear tree, whether grown upon its own roots as a seedling, or worked upon another seedling, attains a great age, bu that this age depends on its constitution, upon the soil in which it is grown, and upon the treatment which the tree receivess is sindividual existence, like
living things, is limited. J. De Jonghe, Brusels.

## VEGETABLE PATHOLOGY.-No. CXXIX

516. Paristite (Ascomyces).-Ascomyces is one of the simplest of fungi. It consists of an almost rudimentary mycelium producing at once without the intervention of whideorophores sliort clavate or obvate asc, , which, contains 8 or 16 ovate or subeliptic sposid pure wheraly the case with the whole pation in which an ascomycous fungns can exist, and it is thi circuartance that blane and view when they proposed the name, which indicates a funguse fanga. prodacis . This howerer is not the whole strut lid structure which the plan present. Besides the asci, of from three to four individuals, and occasionally a spore is seen pullulating at the side exactly after the fashion of yeast globules. The question then arises, what is the nature of hese secondary bodies; are they a furthe development of the sporidia, or are they a secondary form of fruit like the bidium which constantiy precede Erysiphe? I am inclined to the second opinion, because I do not know of a single instance in which sporidia germinate after the manner of these bodies. We have then, even in so very simple a fungus, a secondary form of fruit, but whether both
517. The genus was first proposed by Montagne and Desmazieres in the place cited above from specimens collected in the South of France on the leaves of Quercus coccifera. "It affects almost exclusively the under surface, and generally makes the leaves more or less bullate. This species is characterised by its blueish tint, incling in age to yellow or tawny. $A$ sect the undescribed distorts the leaves and sto Thentalis Europera in Scotland and was sent to me mird oceurs since by Dr. Dickie and Mr. Gardiner. A third occurs very commonly on the under side of Thut leares, in which it makes little bullate patches, This is Aymnsporium leucospornm, Mont. It is howerer cospecimens last ine the others, as 1 ascertained from spacne had seen autumn gathered by myseli. Dr. Mond therefor considered it seconary arm different genus. A fourth is described by myself in the eleventh voume of the Journal of the Horticultural Society of London It formed shallow bullate spots on Pear leaves, and was referred by me to Oidium on account of the secondary fruit, as I had mistaken the nature of the secondary fruit, as asci, considering them merely as the trans'ormed cells of the matrix. An examination of the species on Waluut leaves convinced me of my error, which I am lad to correct. A fifth species, perhaps the most curious of all, has been sent to me from various quarters during this and the past year. , which are strangely blisters on the leaves Peachiree, which the same way distorted the curled leaves are whe ungenial weather in spring aced by cold but bad state of drainage, in consequence fompand by a of which the leaves cannot get
dant moisture, and therefore find a vent in the forma tion of new tissue.
518. It is doubtful whether any material injury is done

to the plant by these fungi except in the case of the
Trientalis and Peach. In the former instance the plant is nearly destroyed, as it is not the leaves alone which is nearly destroyed, an in the latter there can be no doubt that the health of the tree must be more or less affected according to the urgency of the case. It is obvious that if
danger or injury is anticipated, the best plan is to dust danger or injury is anticipated, se singe them with some solution containing sulphur, which latter may be the better plan, as it is the under side of the leaves which is principally affected.
519 . I shruuld have been gled to have studied this in connection with the Peach blister, bat I have found it
impossible to procure specimens during the last two years, though it was formerly a very prevalent affection.* In the Peach leaves affected by the Ascomyces I find inierpsosed between it in healthy leaves eight or mor layers of merenchymatous + cells. It is to these that the incrassation of the leaves is due. The under side dea not seem to be much deranged, except perhaps The spores, both within and without the asci The spores, both within and without the asci, were
yellow with iodine, and were not altered on the application of sulphuric acid. Our hgure, which is borrowed from the Transactions of the Horticulural sociey of bullatus, Berk. M. J. B.

## Home Correspondence.

Village Butan\%-I am much pleased with an article in your impression of Saturday last on "Botany in Village Education." It is certainly a triumphant proof of the advantage of introducing other subjects than botany, of sll subjects, is the one most likely to intel est the children. There is not a child who does not delight in wild flowers; why not take advantage of this prein wild flower8; why not take advantage of this preas botany into every village sclool in the kingdom? as botany into every vilage school in the kingdam? of "J. S. H." at his own school is a proof. It is an absurd error to suppose that the children in the so-called lower ranks of life have no talent for anything more ele-
vating than what will just fit them for household servants. vating than what will just fit them for household servants. Many of them have just as much innate taste and talent the most fashonable boarding schools in Clifton ; it may be, more. Where such talent exists it a a sin to repress it, especially now when, thanks to the liberal spirit of to cay, any one talent, if made the most or, is suficient rank. Every one knows what Hullah's system singing has done for village schools. No one now eof poses that village school children cannot sing. Let us poses that a few years hence the same may be said for botany and every other useful science. $O, B, N, P$.

## Brighton, July

Disease in Washervoomen. -I am a gardener and my wife takes in washing. She used to be a atrong, bustling, active body, with no fault to speak of except a pain in her temper now and then. Wen, she has been siling for five or six years, and every day gets worse, temper included. Bemides, she has got agreat lump in her side. This has been coming on ever since she left off soap and took
to using some stuff to make linen white without trouble. to using some stuff to make linen white without trouble. The doctor says that the stuff is slow poison, and will kill her in time. Do any of your numerous readers know whether it is the stuff or not? They say it is
some vegetable; but I don't think so for I never did some vegetable; but 1 don't think so, for 1 ne
smell any veretable like it. Market Harborough.

Weston and other Country Shows.-" Somerset" seems to know somerhing of the roguery practised in managing country shows; and perhaps he has also some If not I can assured him some of the exhibitors at them. ful extent , so much so that it cugried not to a shameticed. I know many a consei-ntious good grower to ticed. I Enow many a consci-ntious good grower to give over exhibiting because he could not compete with his crafty and often-times indolent neighbour. At the time such shows as Cheltenham, Chepsrow, Weston, Troubridge, \&c., take place there is quite a stir amongst some of our Bath exhibitors, who "ransack alout" to get sufficient, as they say, to make the thing pay them. If exhibutions are to be got up for the gratification of the public, I think it is quite a moekery to have a schedule requiring exhibitors to show plants, \&c., of their own grosth. It would be much more conscientions to allow persons to purchase plants for showing at such exhibitions. Then the honest man might purcha-e sufficient to go with his own to make up a collection of it would plaee it out of the power of dishonest persons it would place it out of the power of dishonest persons
to do as they now do. But such exhib tions will never
 however, meend therefope do not present flit faces. It is not,
fear, be carried on honestly. I however consider it the uttermost of his power; and I can see no channel through which it may be done more effectually than through the Gardeners' Chronicle. Robert Shackell, Locks brock Nursery, Beth.

Gwano applied to Roses.-Mr. Rivers in his Rose catalogue says :-"Fro a neat surface dressing for autumnal Roses wood ashes and guano have proved excellent fertilisers, in the proportion of half a peck o
guano to a bushel of ashes, applying a quarter of a peek of the mixture to each tree in a circle of 18 inches in diameter round the stem, and letting it remain undisturbed on the surface. The ashes retain the moistur from the dew and showers, and the effeet in giving a rigorons growth with an abundant erop of flowers in should te has been very apparenk will some one b so good as inform 'me whether he has tried this, and found it succeed, for I have been using it as directed and fear that its only result will be to kill my Roses, for observe that the bark of the shoots which have come in contact with the mixture has turned black, and to al pearance many of my Roses are dying. W. M. A July 9.

Quercus sessilifora.-I beg to inform your subscriber "Diss" that he will find several fine specimens of Oaks, supposed to be sessiliflora, in Llauwrst Park, near St. Asaph. They have fine straight boles from 20 to 2 feet without a branch, and a girth of 15 feet, and most magnificent spreading, top in full vigour. I can procure acorns for "Diss" if he will
far to see the trees. $A$ Welsh Subscribcr.

Frosts in $Y$ rkshire.-Between the night of Monday June 30, and the morning of Tuesday, July severe frost occurred here, which rrom its uncommonness at this season is worthy of record. Tuesday when I perceived fact about midday on planted Potatoes quite black. Some labouring men who were up very early on that day inform me that the Grase and fenees were quite white at half-past $40^{\circ}$ clock and even at 6 o'elock the white frost was lying on the north side of fences, \&c. Upon inquiry of Mr. Milner surgeon to the convict prison, who keeps a day and night register of meteorological phenomena for Mr . Glashier, I learn that the minimum on the Grass in the prison was $33^{\circ}{ }^{\circ}$ F., showing the influence of high walis and surrounding buildings in preventing the excessively low temperature which may occur in more pen aituations. It is remarkable that earlier plante uninjured. Both looked equally tender before the frost, but now the influence of ripeness is obvious Persons who can spare the time would do well to collate the rain-fall, variations of temperature, and other atmospheric phenomena of the present season with that of 1848. The rain-fall here up to the close of June is in excess of every year since 1848, and I suspect the resemblances in other respects are unortunately too many; so that it is not beyond the bounds of possibility that we may experience somewhat or the same results which at that period brought with Wem so much suffering. W. R. Boorditith, No. Andvew's, Wakefield
Qardeners' Bencvolent Institution.- The letters that have appeared on this interesting subject leave no doubt upon my mind that the interests of the charity demand
a reconsideration of the rules. They show too that selfish motives are by no means confined to those who claim for a subscribing gardener a priority of rights over an unsubscribing one. When "T." says that he would not give his help because he knew nobody to beuefit by it, he only says that he did not choose to spend a guinea a year without getting something for it. Narrow-minded feelines of that sort have no right to be called liberal. It stands to reason that a man who has done his best to help the charity while he could, ought to have a better chance of becoming a pensioner when he wants it than he who has done nothing. I cannot see what likeness there would be between this charity and a benefit club if such a rule were to be entorced.
Why not do this? When the candidates are known, Why not do this? When the candidates are known,
place them according as they have subseribed-in this way perhaps

Well, there is one vacancy. Then let the struggle be between T. J. and X. L. Or, if you like, let the first four go to the ballot; and let T. J. and X. L. count exclule S. K. It might perhaps be a rule that no difference should be made between a man who has subseribed only five years and one who has not sukscribed at all, and then all who have subseribed between five and 10 years should have an equal chance, and so on with those who have subscribed from 10 to 15 , and
from 15 to 20 , and from 20 to 30 , and so on. Some such plan might, I am sure, l, thonght of. There ought always to be some sort of competition. One who thinks his oun plans disregarded, tut still a Priend.

Bottled Fruit.-A, Z. has followed Mr. Lovejoy's plan of botting fruit ever since his method was published and with perfect success until this year, when in the first lot done there were three dozen bottles of
green Currants and Gooceberries, and out of that number all have fuiled exuepting geven or eight. Think-
ing the fault might be that the fruit was gathered too young, a second lot was tried, and was followed by the same result, each lot going off in a fortnight after bottling, the fruit bursting through bang, bladder, and cement. The fruit was picked from A. Z.'s own garden and from the same trees as the preceding years, and done in every particular the same; the trees are beautifully healthy, and quite free from blight. Is the failing general this year or can Mr. Lovejoy account for it any way? A reply would be esteemed a great favour. July 4th.

## Eortette\%.

Royal Botanic, Regent's Park, July 9.-This mes this Society's last meeting this season. The day was cloudy, and one or two slight showers fell during the afternoon. Notwithstanding this, however, there was a fair attendance of visitors. With the exception of Orchids, which were scarce, the exhibition was on the whole a good one. Stove and Greemhouse plants were abundant, and generally in good condition. Cape Heaths were unusually well flowered; Pelargoniums chisias wore searcely less gay than they in June; there were some admirable groups of Variegated Plants, and the display of fruit occupied two sides of a long tent.
In Collections of 20 Orchids, Mr. Keele, gr. to J. Butler, Esq., of W ool wich, sent Cattleya citrina with two handsome yellow blossoms; Miltonia spectabilis, with nearly 100 blooms on it ; Anguloa Clowesi, with two large yellow flowers; the rich orange-scarlet Lelia cinnabarina ; Cattleya superba, with three remarkably well coloured blossoms ; and a fine specimen of Brassia verrucosa major. In Mr. Gedney's collection of 20 plants were some beautiful examples of Phalenopsis, Calanthe Masuca, the latter extremely well flowered, the White Phaius, and Galeandra Funcki. Mr. Woolley, gr, to H. B. Ker, Esq., sent the singular-looking Uropedium Lindeni, Cattleya crispa, beautifully flowered Saccolabium guttatum and Epidendrum verrucosum Of Groups of 12 Plants Mr. Ciarke, of Hoddesdon, had the best. It contained two examples of the bes variety of Cattleya Mossire, and Aerides affine an odoratum. These last were beautifully flowered.
In Mr. Carson's collection of 6 Orchids were Cattley crispa with three noble spikes of flowers, Oncidium Lanceanum, Cattleya superba, and the singular Cycnoches Loddigesi. Mr. Morris sent Cattleya Forbesi and Sr moper oculata, the last extremely well flowered The Deadman showed 3 finely-bloomed Stanhopeas Mesew white Cattleya Wagueri was extibited by slightly stainhouse, of York. Its flowers are large, sighty stained in the lady Dorothy Neville again showed Peristeria some.
fuseata.
Of Collections of 16 Stove and Greenhouse Plants the bent came from Mr. May, gr. to H. Colyer, Esq., of Dartford. It contained two handsomely flowere Allamandas, Dipladenia crassinoda, a large specimen of Ixora javanica, Gompholobium polymorphum, in the
form of a bush; the White Ixora, one or two Ever form of a bush; the White Ixora, one or two Ever
lastings, Rondeletia speciosa, and the showy Kalosanthea coccinea. Mr. Doda, gr, to Sir J. Cathcart, Barto, sen a well flowered Clerodendron, a magnificently blossomed Allamauda nearly 5 feet high and as much through the yellow Relhania equarrosa, a useful plant at thi season ; and a gond Rondeletia. The best specimen of the latter, however, we ever saw was in Mr. Green collection; it was well grown, profusely flowered from bottom to top, and the blossoms were unusually well coloured. The last-named grower also had Stephanotia, Allamandas, Echites atro-purpurea, Kalosauthes, an Aphelexis in good condition.
Of Groups of 12 Stove and Greenhouse Plants the best came from Messrs. Fraser, who sent Kalosanthes, Heathe Vinces 1 Fandas, and a good Statice Hol fordi. The last-named plant was also furnished by Messrs. Cutbush, of Barnet, from whom likewise came the pretty Hoya bella, Cyrtoceras reflexum, and a well flowered Phenocoma proliferum,
In Collections of 10 Stove and Greenhouse Plant Mr. Carson had two Allamandas, Dipladenia crassinod unusually well coloured, Aphelexis macrantha grandiflora, Ixura javanica and coccinea, and Exostem longiflorum.
Of Groups of 6 Stove and Greenhouse Plants Mr. Rhodes sent Dracophyllum gracile, an excellent plant for cutting flowers from for bouquets, the White Ixora Erica tricolor, and Dipladenia crassinoda. Mr. Willianis furnished a hure Pimelea and the pretty Heath calle E, ventricosa Bothwelliana
collection of Kalosanthes was shown by Messrs. Fraser. The plants were well grown and flowered. There was, however, nothing new amony them
Plants remarkable for fine foliage were contribute by Messrs. Veitch, Lee, Jackson, and others. In
the first group were Palms, Crotons, Coleus Blumei, Diefl group were Palms, Crotons, Coleus bsotte Dieffenbachia picta, with large pale green leaves spords Variegated Pandanus, Caladiums, Rhopalas, among whech was R. Jonghi ; and the variegated Arund Donax.

Among what were shown as New Plants were Clematis lanuginosa pallida, with pale blue flowers quite eight inches in diameter, from Mesors. Standish Noble : Achimenes "Vivid," a brilliant rosy scarlet soz with blossoms much larger than those of A. coccian

Eucharis granditic ra trom Messers. Henderson ; Philesia
buxifolia, the new scarlet De phinium Cardinale, Lepbuxifolia, the new scarlet De phinium Cardinale, Leptodactylon, the pink Rhododendron Princess Royal, the hardy Desfontainia spinosa with long bright red tubular
flowers tipped with yellow, Wellingtonia, Rhopalas and flowers tipped with yellow, Wellingtonia, Rhopalas and other plants remarkable for fine foliage from Messra, Veitch. The Dolphinium just mentioned is a truly fit, and it is oue which as soon as it shall have become known must necessarily prove a universal favourite, The blossoms which are bright orange scarletare produeed in great profusion. In addition to the plants shown by him at the Crystal Palace, and mentioned in our report of that exhibition, Mr. Glendinning had Cerasus ilicifolia in flower, small plants of Chusan Palm, Mandirola Rozeli, and the white Lysimachia lineariloba, some further account of which we hope to give very soon.
Cape Heaths were exhibited in excellent condition Among them was the new E. Spenceriana, from Mr.
Glendinning, of the Chiswick Nursery. Its flowers are of a bluish lilac colour, and beautifully transparent.
Among Ferns, of which some fine collections were shown, were good examples of Hymenophyllum Tun-
bridgense, Woodsia ilvensis, and one or two vther scarce inds.
Fuchsias were in excellent condition. Six plants from Mr. Bray were all that could be desired, both in regard to growth and bloom. The best sorts among them were Honeybell, white with a scarlet corolla speciosa, Pearl of England, and Perfection. Mr England's Glory, and Clio ; and of dark sorts, Glory (Banks') and Duke of Wellington. Mr. Gaines had Snowball, Psyche, Fearless, and Monarch.
Pelargoniums, as we have slready stated, were numerous and well bloomed. Of sorts of 1854 and 1855 , Mr. Turner had Wonderful, Meteora, Fair Ellen, collection of remarkable looking French kinds, among which the following are especially worthy of notice, viz., Talma, pink with a dark top; Roi des Pourpres, crimson and spotted on all the petals; Dr. Andry delicate pink, large and showy and regularly crimped round the edges of all the petals; $G$. Odier, spotted rosy hiac ; and J. Odier, bright brown with a showy white centre. Messis. Veitch had a variety named beautifully formed flowers with dark top and white under petals, and altogether appeared to be a step in the right direction. To blossoms of considerable beauty kinds.
Calceolariss were tolerably numerous, more especially the shrubby varieties, which are evidently fast driving rmer kind Mr. Turner sent good plants of Orange Perand King of Sardinia. The last has rich deep reddish brown flowers of good shape. Mr. Cole sent St. Alban's Gem, a half shrubby kind, with large flowers edged with yellow ; Golden Cluster, Snowfake, white
but indifferent in shape; Queen of Yellows, and Cassandra.
Among Petunias the most remarkable was the double white Imperial, which looks as if it would form a good plant for cutting flowers from for bouquets.
Of Verbenas there was a collection from Mr. ort called Belle of the Village, which has a fine trus of well formed flowers with crimson centres.
The display of fruit, as we have already remarked, Was very extensive. The best collection came from contained well coloured Royal George Peaches, Murray and Violette Hâtive Nectarines, three Pine Apples, Trentham Hybrid and Cashmere Melons, Muscadine Trentham Hybrid and Cashmere Melons, Muscadine,
West's St. Peter's, Mill Hill and Black Hamburgh West's St. Peter's, Mill Hill and Black Hamburgh
Grapes, Sir Harry, Goliath, Bicton White, and other Grapes, Sir Harry, Goinath, Bictien Brown Turkey Figs, Late Duke Cherries and Raspberries. Mr. Fleming, gr, to the Duke of Suther land at Trentham, contributed four excellent Pine Apples, very fine Black Hamburgh Grapes, Keens' Seedling and Myatt's Strawberry, Coe's Golden Drop, Reine Claude de Bavay, and Early Orleans Plums, Noblesse and Early
Magdalen Peaches, and Elruge Nectarines, Black Tartarian and May Duke Cherries, Brown Ischia Figs, and Trentham Hybrid and Hybrid Cashmere Melons. Mr. Constantine sent Black Hamburgh and Royal Muscadine Grapes, Hautbois and other Strawberries, Brown Royal Figs, stanwic! Nectarines not very well coloured Cherries, and a Melon or two Mr. Watson, of Ealing also showed a collection.
Pine Apples were good, more especially Queens of which several magnificent fruit were shown by Mr Barnes, of Bicton. The weights of these we could not
ascertain, but they mu:t have been upwards of 6 lbs . Mr. Jones had four most beautiful fruit, and goond Providences were shown by Mr. Fleming and Mr.
Dods. Many other Pines, in all respecte excellent, Dods. Many other
were also exthibited.

Grapes were shown in abundance, but many of what should have been black were red, and some of the white sorts were unripe. Of boxes of 12 ibs , the best came from Mr. Henderson, gr. to Sir Geo. Beaumont, Bart. and for Collections of 3 kinds the first prize was awarded to Mr. Glendinning, of the Chiswick Nursery, for beautiful bunches of Grizzly and White Frontignan
pecimens. Black Hamburgh well coloured, and in all respects beautiful, were furnished by Messrs. Hen-
derson, Forbes, Tillyard, Fleming, and others; and Black Princes from Messrs. Boyd, May, Turnbull, and Hill. Of Muscadines, Mr. Tillyard had the best; and large and fine bunches of Dutch Sweetwater came from specimens and well ripened, came from Mr. Clarke; and Messrs. Turnbull, Dods, and Taylor had all likewise good bunches of this variety. Mr. Tillyard sent excellen Frontignans, and Mr. Forsyth finely fruited Vines in pots.
A seedling Black Grape, with a full Muscat flavour, was shown by Mr. Snow, gr. to Earl De Grey. The berries were oval in shape, and the bunches large large; but altogether it is a Grape which cannot fail to large; but altogether it is a Grape which cannot fail to
be a favourite. Mr. Mitchelf, of Brighton, likewise showed a new white Grape, with bunches as large as hose of the Syrian, but different apparently from that variety. The berries were said to be well-flavoured.
Mr. Carpenter, of Birmingham, also showed a new white Grape, which, however, appeared to be much nferior to Busby's Golden Hamburgh
Though Peaches and Nectarines were shown in large quanties, there was not a dish of bad fruit among them. Mr. Richards and Mr. Forsyth had also rood fruit, as had likewise Messrs. Frost, Turubull, Fleming, Booth, and Davis. Amung Peaches the sorts consisted generally of Ruyal George and Noblesse, and among Nectarines the kinds were mostly Elruge and Violette Hâtive. Of the latter Mr. Munro, gr. to Mrs. Oddie furnished a boxful or two of highly coloured fruit
Plums Washington and Greengage were exhibited Mr. Munro and Mr. Fleming
Mr. Snow's Figs were large and uncommonly well ripened. The kind was the Brown Turkey, which was also shown in good condition by Mr. Ewing
Mr. Munro exhibited a dish of Moorparl Apricots.
Of Cherries the best Black Circassians that were perhaps ever seen came from Mr. Taylor, market gardener, Brentford. They were black as jet and quite double the size of those of ordinary growth. Mr. now had a capital dish of some white kind.
The best Strawberries came from Mr. Tillyard. The sinds were Goliath, British Queen, Bicton Pine, and ir Harry. Among other sorts were Keens Seedling, Eleanor, Victoria, Myatt's Surprise, Early Pine, the Filbert, Prestoe's and Patrick's Seedling, and Alice Maude.
Melons: none of them were very well flavoured. Among green-fleshed sorts the Beechwood obtained the first prize.

Botanical of Edinburgh, May 8.-The President in the chair. The following papers were read, viz:On the Sexuality of the Algee. By Dr. F. Cohn. 2. On the preparation of Sugar and Arrack from Palms
in Ceylon. By A. Smith, M.D. Three Palms yield sugar in Ceylon. By A. Smith, M.D. Three Palms yield sugar
in Ceylon: The Coco-nut Palm (Cocos nucifera), the Palmyra Palm (Borassus flabelliformis), and the Kittul or Jaggery Palm (Caryota urens). From each of these Palms the juice of the flowering stalk is co!.
lpeted under the name of 'loddy, and from it sugar, nown in the East as Jaggery, is regularly prepared but it is from the Palmyra Palm that almost all the Palm sugar is obtained. It is from the sugar of the Coco-nut Palm that arrack is made in Ceylon. This Palm becomes productive in about six or seven years, In collecting toddy, the spathe is stripped off irom the spadix before it has fully expanded: the spadices are afterwards beaten between pieces of hard wood, lices are cut with a sharp knife so as to allow the juice bout 40 days, at nearly the average rate of half-agallon in 24 hours. When it is intended to prepare jaggery from the toddy, great care is kaken by burning pieces of wood in the small earthen vessels attached to he flowers, and rubbing their interior with charcoal, to remove any impurities likely to promote fermentation Vateris in adica are placed in antion, chips of the bark of fateria incica are placed in each, so as to retard Ceylon is entirely jaggery from the Kittul juice, which Ceylon is entirely made from the kitul juice, which the other two Palms, and of a quality much more highly prized by the natives. When toddy is collected for the purpose of making arrack, no care is taken to trees it rapidly advances. If attention is not paid to the fer mentation, acetic acid is formed, and this often cause the arrack to take up lead from any portion of tha metal with which it may be brought into contact. Dr Smitu then entered into details as to the presence lead in arrack, which was traced to the modes of pre paration. 3. On the occurrence of Scalariform Tissu R. Harkness, F.G S. 4. Notice of nome additions to th Cryptogamic Flora of Edinburgh. By Mr. W. Nichol.

## 3) ottres of Books.

The new number of the Journal of the Linnea ocicty is chiefly occupled with a learned paper on the natural order Luganiacese, by Mr. Bentham, who, we affinity of Desfontainia may be with Fagrea. Dr. Vinen

## extract entire :

Much interest has been excited by the frequent occurrence in this country of the galls of Cymips quereus. petion, and they appear from a recent commutication in the Gardencrs' Chronicle to have increased to such an extent during the past season as to do vast mischief to the trees infested by them, rendering them unproductive of acorns, and even threatening their entire destruction.
"In a recent conversation with Mr. Westwood on this subject, he informed me that these galls had been used in Devonshire for the purpose of making ink, and at the same time suggested that it would be desirable to know whether they contained sufficient tannin to render them useful substitutes for the ordinary galls of this, and thought the result might be sufficiently interesting to ing is the result of my examination. By macerating 100 grains of Devonshire galls in æether and water, a residue was obtained weighing -0.74 grains . this contained 17 grains, or about two-thirds, of tannic and gallic acids. ha order to estimate the comparative value of these galls with those of commerce, 100 grains of best Aleppo galls were submitted to the same treat ment with rether and water. The residue weighed 58.50 grains, contaiaing 56 grains of tannic and gallic acids. Of the superionty of the foreign galis there can of course be no doubt ; but in comparing the results of these two analyses, it is necessary to observe, that the the best gals operated on were very heavy specimess of not been perforated by the Cymins, while the Devenshire galls had all been perfomad and therefore contained much smaller proportion of tannin than would have been the case if they had been examined at an earlier period. If we compare the published analyses of period. If we compare the pubistied analyses of quantity of tannin obtained by different chemists. The following are the principal :

## Sir Hum Pelouze Leeonnel <br> Guibour Mohr

"However widely these results may vary, they are entitled to every credit, and ligh are are these two last-mentioned chenists, their well-hown accuracy will encure eath inclined to think that these great discrepancies are owing to accidental causes, among which the Variabie nature of the seaco, which intable so mach the quantity and intensity of all vegetale secretions, may be a principal one. With the small amount of tanain found in the Devonshire gails I must confess mysel much disappointed; but I hope in the ensuing summer to procure some of them at an earlier period, and before they have been perforated by the oynips. Thave doubt that they would then be found to contain enough tannin to justify their being collected for commercial purposes, and if they were gathered at the prope season, before the Cymins has escaped, and when the gall is in its most vicoions and valuable state, anothe good result would finluw. The insect would be pre vented from increasin to what seems to be a mischie vous extent, and a check would be put to the serious injury if not entire destruction, with which the Oak plantations in some of our southern counties appear to pe threatened

We observe, contrary to our expectation, that the Society proposes to continue the publication of it 4 to Trapsactions, the first Part of Vol. XXII. being announced for November

A Practical Swiss Guide. Longmans. Small 8vo. Pp. 112. Is this an innkeeper's puft? or what is it ? Ostensibly is something between a Murray and a Bradshaw. What to see and how to see it may be ascertained from its races, and railway tariffs, fares, \&cc., are indicated in an intelligible manner. But as regards hotels, the information is most unsatisfactory, only one being often named in places where others ought also, in justice to travellers themselves, to have been mentioned. Thus the stranger is not apprised of even the existence of such places as the Hotel de l'Europe in Havre, the best hote in the town; nor of the Hotel du Nord and Hotel de Bains in Boulogne ; nor of the Hotel du Grand Monarqu in Aix-la-Chapele; although these are at least as deserving of recommendation as the places named in thi practical guide. Another piece of practical information which a stranger emstantly wants is the situation of the post-office, but this is not mentioned. We confess we ook with great suspicion upon the practitioner who has ot up this book when we find him coolly tellin people how to cheat their companions. At p. vii., under the head Swiss Dlligences, we have the following precious instructions :-"The sittings are numbered-1, 2, are compers of the coupe ; $\pm, 5$, compers of the interieur, facing the ronte. No time should be lost in engaging thooe desired; but if previously filled, a little gentle persuasion with the conducteur (guard), which a couple of frases may represent, will often effect a change"
With such a specimen before us of the anthor's notions of fair dealing he must not wonder if we decline recommending his book to public favour.
Temperance in the Camp (a penay tract, published by Tweedie, 337, Strand), is an excellent address to the roops before Sebastopol last Christmas, Regiment, and should be circulated by everybody in districts where drunkenness prevails.

## Miscellaneous

On Deep Cultivation.-Were we to examine the depth to which the roots of many of our cultivated plants will penetrate a loose open soil in quest of food, deep cultivation affords to the roots of plants. The deep cultivation affords to the roots of plants. The deeply, not only to change the surface, as some suppose, deeply, not only to change the surface, as some suppose,
but to allow the roots of their crops to range as deeply as they please, and without this assistance the enormous crops of first-rate produce they get from their land could not be obtained. If deep cultivation is requisite in the rich and deep alluvial soils of the Thames valley, how much more so is it on poor and shallow soils, which afford comparatively only a limited pasturage for the roots of plants. It is true, gravelly and rocky subsoils are almost beyond the reach of improvement; as the expense of breaking up the substratum would, in most instances, be too great to pay. But this is not always the broken up with good results, as well as some gravelly subsoils, particularly where the layers of gravel are thin and mixed with clay or ferruvinous matter, rendering them impervious to water, as well as to the roots of plants. By breaking through this crust, so as to admit a free passage for the water, a marked improvement follows. Clay subsoils, however retentive, are
capable of being reclaimed; but this is a work of time, capable of being reclaimed; but this is a work of time, up the clayey bottom to the depth of twelve or eighteen inches, according to its nature, each time the ground is dug or trenched. This bottom, when forked up, should be kept as open as possible, which will facilitate the passage of water through it, and the salts and ammonia carried down by the rains from the manuring, \&ce., of the upper soil will in time reduce its tenacity, assisted have decomposing action of the air, whicy, tising this, you will find your land gradually increasing in depth and productiveness. Many calcareous and slaty rocks are likewise capable of improvement when broken up and exposed to the action of the weather, and when shallow soils rest on these descriptions of rocks, by all means break up a stratum of it yearly below the top soil. Many hard compact marls of the red sandstone and lias formations are as unfavourable for the growth of plants as rock or gravel, and yet when broken ap and exposed to atmospheric influences, they make fertile soils capable of producing every kind of crop. I remember some 15 or 16 years back paying a visit to many of your readers will recollect was the first amateur Dahlia grower of that day, and his plants were growing apparently in a mass of stones. The garden of this gentleman was situated on the side uf one of the olitic ranges which surround Bath, with barely a broken up two feet in the rock; this Mr. Davis had surface soil and a little nianure ; the luxuriance of his Dahlias and general gardeu produce was remarkable, and may perhaps be rememlered by those of your readers who visited Entree Hill at the time in question. To obtain a sufficient depth of soil for the roots of vegetables to penetrate is one means, and a very great one, of increasing their produce. Plants growing in soils made open for a considerable depth are much less liable to suffer in dry weather, as their roots are in a position to obtain moisture at a lower depth, and hence
the suitability of deep soils for summer crops; the same soils are likewise warmer in winter. A soil from which the water passes through freely can never be very damp, and relatively never very cold; nor are they so dry in the surface soil causes the moisture therein to be given off by evaporation, and this produces an upward action of the moisture contained in the soil below, to supply that which has escaped by exhalation and the surface We shall find, then, that in proportion to the power of corresponding rise of watery particles throughout the entire mass of soil below. This will positively keep the soil moister, because it is more open and porous, than a shallow soil with a compact subsoil, which would ssme time as it prevented its escape downwards. By all means then for vegetablea have a mass of soil, if practicable, from two to three feet deep, sufficiently when needed $\underset{\text { x }}{ }, Y$. Z in the plorist, Fructitist and Garden Miscellany for May.

Potato.-In its raw state this vegetable has a slightly acrid taste; on boiling it becomes sweet. In its sound state it is almost without odour, when it is worm-eaten it acquires a perfume calledj "The Marshal's," or that of the Vanilla Bean. The water in which it has been boiled has the taste of s weak auimal broth. Besides starch, its priscipal resembling glaten. When the Potato is cut, this matter exudes in a liquid milky state, viscid at first, diffusible through water, bat soon becoming solid on exposure to water, it appears in the form of granules of about ${ }^{2} \times{ }^{1} \overline{0} \delta$ of an inch in diameter, which were rendered brown by tincture of iodine. Probably this matter is concerved Potato is subibjoct of the changes to which the Sweet nutritious quality as an article of diet. Dis. Dary in the Edin. New Philosophical Journal.

## Calendar of Operations.

(For the ensuing week.)

## PLANT DEPARTMENT

Conservatory, \&c.-Now that many of the Camellias Azaleas, and other plants will be removed to thei summer situation, out of doors painting or other
repairs required by any of the plant houses may be repairs required by any of the plant houses may be more conveniently done than at any other season. Meantime however the weather is rather unfavourable
for painting, for to do this except when the wood thoroughly dry is a very inconvenient and troublesome way of wasting money ; but other necessary repair may be done so as to allow of proceeding with paintin whenever the weather will admit, without the hindrance of having other work to execute first. Where houses are painted sufficiently often to keep the paint always good-which is the cheapest method in the endthere will be no difficulty in getting the wood dry, but where the wood is allowed to become nearl base before repairing is thought of, the house should by all means be kept dry inside, covering the outside with a car clom in the case of showers, and allowing a fortnight of bright warm weather to
thoroughly dry the wood hefore the work is commenced. It is oftentimes very difficult to attend to this, but It is oftentimes very difficult to attend to this, if the work is to stand it must be done at whatever in-
convenience. Stove.-If there are sickly or badly rooted specimens here, they must be frequently examined for red spider, otherwise they will become nursery for this pest, from which it will soon spread to adjoining plants. Also guard against the increase of mealy bug, and keep black thrips and green-fly in check by timely applications of tobacco smoke. See that young growing stock is not allowed to suffer for want of pot room, and attend carefully to the watering, giving manure-water to all plants in free growth that enjoy it. Gardenias, \&c., which have been removed to the conservatory while in bloom should be replaced in heat as soon as their beanty is over, in order to allow of getting their growth matured before the dull cloudy days of November. Give every altention to plants for wiater blooming, affording them a moist warm temperature,
and using every care to prevent their sustaining any check at the present season. Onchins.-The growing stock will require the assistance of a little artificial heat while the weather continues wet and cloudy, if only allow of admitting fresh air and preventing damp, Shading must be promptly attended to when brigh sunshine occurs. Allow them however as much light as they will bear pithout injury, using a very light screen and only when absolutely necessary. Keep the foliage clear of insects, and dust by frequent syringings or spongings as may be necessary.

FORCING DEPARTMENT
Pinkatres.-Plants wished to show fruit at ouce, backward in doing so, should, provided the growth has been well matured and checked, having been kept dry at the root for a time, have a good soaking of water, induce an active root action, and if the plants have been properly treated they will seldom fail of showing fruit ance, bat everything depends upon the growth being vell matured and checked. Avoid syringing plante overhead that are in bloom, save on the mornings of bright days, and then but lightly, for syringing in the fternoon while the plants are in bloom is the principa cause of deformed frinit. Young stock bused growing robust stocky plants; see that the plants are afforded sufficient room for the development of their foliage, and do not heep the atmosphere so warm and moist as to induce weakly growth ; attend to repotting as this may se required by any of the stock, and see that all are well supplied with water at the root, whether in pots or
planted out in the open bed, as any neglect in watering at the present season will probably result in the plants ruiting prematurely. Vineries.-Give every attention to preserving the foliage in houses where the fruit has been cut, until the wood is thoroughly ripened. If red spider is at all troublesome, give the Vines a good washing with the engine, but do not injure the foliage by dashing the water against it too powerfully. Give abundance or air, keeping the house as cook as tain a moist atmosphere where the fruit is swelling, sprinkling the passages, borders, \&c., frequently. Look sharply after insects here, particularly where plants are grown under the Vines, and if black thrips or red spider be detected wash the infected leaves carefully, and look over them occasionally afterwards until the pest is fairly got out. See that the border are not allowed to become too dry, and give strong in pots intended for very early forcing next season should be in a forward state by this time, in order to permit of getting the wood well ripened, and allow them directions, using every means to keep clear of insects.
flower gardin and surdbberies.
Continue to clear everything away deaying and to introduce good thinss trom pots in the reserve ground. Agnod reserve ground, if properly situated and systematiasetul plots of ground about a garden. Such a valuaile adjunct would, however, require the constant attendauce of a man possessiny some little knowledge flowers, and therefore could not be carried out where there is a stint of labour. Decayed patches of bulbs
which are required to sland for early spring flowering may have dressy Verbenas or other things introduced from pots between them. Cuttings of Pansies should be got out in succession before the shoots are too much
exhausted. All boundary or other hedges should be exhausted. All boundary or other hedges should clipped forthwith.
hardy fruit and kitchen garden
Tomatoes must be regularly attended to, keeping the hoots thin and stopping them above a cluster of fruit, for if the plants are allowed to ramble and grow too freely there win be a poor chance in an unfavourable season of securing a good crop of fruit. Shallots, if left in the ground after the bulbs are matured, are apt to mildew and rot in wet weather, therefore these should be pulled as soon as the tops begin to decay, and spread out in an airy place to dry before storing them away. Get herbs in flower cut and dried for winter use. Where a sufficient breadth of Celery is not yet planted
out, this must be attended to as speedily as possible, and must must be attended to as water, \&c., until wel established well cared for otherwiee good sized stuff need hardly be expected. Earth up former plantings, and encourage rapid growth by occasional waterings with manure water. See that a good bed of some use. Ply the treely among all growing erops both fur the the he frely among an gor crop, both surface of the soil after heavy rains. Look over all trained fruit trees frequently for the purpose of stopping and shortening any gross shoots, and keeping the growt nicely regulated; also get the young shoots of wal trees laid in where not already done.

## MEETINGS FOR HE ENG NEAK <br> 

The meeting at Chelmsford next week promises by the entries both of stock and implements, and by all the preparations already completed, to be a useful and successful one. The implements selected yesterday for trial by the Judges are being tested in actual
operation this day, and the trals will he continuerl on Mondav. The attention of the Judges is this
year restricted in the class of tillage implements prizes being, however, also offerel for reapinymachines and steam-chitivators. Thie inspection being thus less crowded and less hurrier! will, we In addition o the private triais before Judges, implements o all kinds will be exhibited at work upon the Tuesday when the yard will be opened at a charge of $2 s .6 d$. each person. This charge will be continued through Wednesday and Thursday, the cattle yard, however being open on the former day after the Jidges hav made their award, at a charge of 58 . each.
Friday the yards will open on payment of $1 s$. apiece.
The whole of the yards and trial grounds are on the left-hand side of the railway as you arrive from London; the implement and cattle yards with the light land trial ground being almost close at hand ; while the heavy land trial ground is a mile and half away. The soil on this field is of a stiff though somewhat gravelly nature, and the field is sur rounded hy a first-rate promise of Wheat, Beans, and Vetches, all clay land crops, while Barley also grows luxuriantly close by. It is evi-
dently a transported soil, and not due to the London clay on which it rests.
The visitor will be interested in seeing as he turns into this field, in the cutting through which the road approaches it evident sections of those furrows on the surface of the original geological formation of the district, to which Mr. Trimagr has called attention. These furrows in the London clay have bocome filled with the more porous and even gravelly material constituting the subsoil of the present surface, and as seen here they illustrate Ivery obviously the theory on which Mr. Trimari explains the success of the Keythorpe system
of drainage. $\mathbf{A}$ drain cut across these gravel-filled natural ditches in the London clay at once convert them into diains, and gives them at little cost all that efficiency for draining the land through which they ron, which is to be attained in the case of artificial cuttings only by a large expenditure in labour and material.
We may refer here to a very full and been puhlished in a Supplement to the Fisser Herald of July 8, and which in its separate form is obtain able through any of the booksellers in the town.
The following remarks are intended to meet the case of a correspondent whose breeding flock has got into had condition, as may be gathered from the following sentence extracted from his letter lambs still keep dying from the tapeworm.* The ewes that survive seem better, though many are still miserable objects." Oar remarks upon this case are given here as others may be circumstanced similarly to our correspondent. He writes as
6 I
I shall not hesitate to adopt any advice yo may have the kindness to afford me. I have tried everything that farmers and shepherds can suggest, but without arriving at a satistactory result. My intention was to draft out carefully all the ewes that have been ill and that still show symptoms of indisposition, only retaining such as are indubitably
healthy. It strikes me that the flock has been suffered by continued neglect on the part of worth less shepherds to get into a very low condition, that diarthea has been suffered to degenerate into dysentery, and that so many have fallen a victim to thi- nd its accompanying fever. In some cases the intestines have appeared perfectly healthy, and yet the poor brutes have gradually wasted away and died. At all events this is a very serious disease, whatever it may be and wheresoever it may have come; and you may do me, and others similarly any means which may enable me and my fellowany means which may
sufferers to overcome it.

Amongst the many causes of disease affecting sheep and cattle, the administration of nnwholesome or insufficient food, or food at irregular intervals, is perhaps the most. prolific, for although the effects o the weather and undue exposure number many victims, yet the first-named class of causes, as many specific diseases, but also predispnses the animals to others, and by depriving them of animal heat and vital energy renders them pecuiiarly susceptible to the evil influence of atmospheric ther morbid agents.
These natural laws were abandantly illustrated amongst our armies before Sebastopol. Insufficient and unwholesome food not only produced Dysentery
The tape-vident thast the diong worme is mot the Roo or Cothe. Oy What rare. A stoan thread-like worm: Ascurides is much more
deprived the sufferers of the capability of resisting the effects of expoure to the weather, and thus endered them susceptible to rheumatic affections and diseases of the chest. So whether we have an incompetent Commissary for our army, or an unrustworthy shepherd for our flocks, the effects are similar. It is in vain to say there is plenty of food at Balaklava if only half rations are given out on the heights, or that there is plenty of food coming forward for the flock if they are deprived of wholesome provender at the present time.

This rule exists in full force amongst horses; if they are worked severely, or insufficiently fed, and particularly if both these causes are in operation at the ame time, a favourable soil is at once afforded for he production of disease. One animal perhaps exhibits glanders or farcy, and quickly the disease spreads throughout the stud, and many are the victims which succumb. In a flock of sheep, either by the negligence of the shepherd or from some error of judgment, the sheep are kept or a long time without food, or it is unwholesome in quality or insufficient in quantity; the digestive organs become deranged, diarrhcea is produced, or dysentery follows, the animals become impoverished and then, if exposed to wet or undue exposure, disease of the chest is produced; the membrane lining the chest and covering the lungs (pleura) become affected with inflarmation, not of a violent kind (the animal has nut strength for this), but slow or sub-acute inflanmation, and thus adhesions take place; and when at lengit the animal succumbs to these complicated forms of disease it is found that not only do the lights (lungs) grow on to the sides and abscesses or watery effusions occur, but the bowels are diseased either with patches of inflammation or ulceration, or the coats become thickened and degenerated. When disease of the alimentary canal soes on for some time it is by no means unusual, particularly in young animals, fo parasites to rint in the diseased tissues, and countless number of minute thread-like worms ascarides) are thus manifested after death.
When a disease of the character we have de scribed breaks out in a flock of sheep it becomes a question for serious consideration as to what is the est conrse to puisue. The dusing of a flock of heep is a tedious and troublesome and generally an unsatisfactory affair, for often before such means gress as to place many of its subjects beyond the reach of medicine. If diarrhœes or dysentery present we should recommend small doses of calome and opium, but we should place more reliance on change of food and locality. Salt should be placed within reach of the sheep, and the best Linseed or Linseed-cake should be broken up and administered daily as food, in quantities varying from a quarter to half a pound. There should also if possible be one or two changes of the green food in the course of the day; our object should be to bring the animals forward for the butcher with all due speed and we should be very cautious as to breeding from any that have exhi' ited the leart trace of disease for if the constitution of the animal has been
impaired there is very great danger of the future offspring being sickly. W.C. $\stackrel{S}{ }$.

The relations of geology to the subject of land rainage deserve attention. The structure of the earth in its alternations of pervious and impervious strata is admirahly adapted for the supply of springs, the issues of which augment our streams, and as these strata are seldom perfectly horizontal but dip at various angles of inclination, so naturally the waters in the strata would incline along these lines of dip and get their exit at such places where the strata have been exposed by deep valleys, the bottoms of which are mostly occupied by stream arising therefrom. Now in our own island the whole of the strata of which it is composed have general dip from the N.W. to the S.E., and hence onr larger streams take their rise from the S.E. side of mountain ranges : thus the Severn flows eastward from the mountains of Montgomeryshire, and the Thames from several sources along the line of dip of the strata of the Cotteswold hills. Rivers therefore may he viewed as the natural main drains of our country, and these act well or ill according as they are or are not cleared from obstructions The smaller drains are dependant on these main drains, and should always be made with reference to the mains, for the former depend upon gealogical tructure no less than the latter.
Rivalets are usually caused by the excess of water which constantly gashes out from a natural spring, such springs taking place from the top of some one or other of the impervious beds, and run off as fast as it is collected upon them a perfect
system of drainage is ensured; it, huwever, the
tratum, as is mostly the case, has an undulation stratum, as is mostly the case, has an undulating sur-
face, water which falls as rain $n$ av be confined in basins of a greater or less siz, which must be in ffect broken at the edges in order to let out the water, and this may frequently be done most effecually by a deep cutting on one side, the side chosen in most cases being within the line of dip, because such bavins are tilted to a greater or less extent acording to the amount of the dip, and thereore less work would be required on the tilted side.
Here then, where knowledse of this kind can be arrived at, our efforts at draining may be much faciitated, for, in the absence of this knowledge,
frequently happens that the most scientific drainer may be for a long time at fault as substrata.
In draining, as in most other matters connected with rural economy, it is much to be regretted that our feelings and sympathies should be hedged in by our boundary fences, and that each man should act so
much for himself regardless of his neighbour. If we study Nature we soon become aware that she has always a comprehensive plan of action which we explain as her laws; and what we often find true with regard to a single field will be no less so for a wide district. That one drain applied according to the principles of science mav be of more service than a hundred badly employed, may be no less true for a district than a field; but we must take care that while acting upon general laws we do not overlook hose flexures and undulations in Nature's system opposed to the rigid straight-lined, stiff method of working which wonld reduce it to a merely mechanical case. Hence, if in draining we to embrace a wide district our labour would be mach simplified, as we should act in accordance with the geological structure of a country, wherezs draining as present carried out has reference to the mere nechanical structure of isolated patches of soil, each of which is gridironed in much the same
manner, and according to some should present a uniformity in size of pipe, depth of drain, and nearness of the lines of work. Nature's system is one aiming at thorough drainage; its failures are owing to local hindrances which may in most instances be eferred to geological structure, and a perfect knowledge of the science of geology is thas of vital importance in the proper conduct of draining on a
comprehensive scale. Wanting this, each man pitches his own small pipe, which may or may not be in concert with that of his neighbour. Harmony of action, so essential to success on a great scale, is thus rendered impossible.

## DIARY OF A DAIRY FARM

Ir may be well to offer a few hints at this season when the weather becomes wamn, upon the care and watchfulness requisite to be observed in all dairy operations. The attention necessary to be paid to the manageast month should by no mischief occasioned by the milk being allowed to become heated before being brought to the dairy will be manifest in the quality of the cheese, and when a dairywoman suspects that care has not been exercised do prevent this, she will allow the milk to remain in the cheese tub before putting the rennet to it for 20 minates to quiet any irritation in it that may have been caused by improper management, or by the cows running with the fly. There is a very injurious practice adopted om some farms, when the cows are milked in the fields, of using a dog to bring them to a certain spot for the rouble of walking milkers, and to save them the treated quietly and accustomed to be called, they will generally obey the summons and be more disposed to stand until the process of milking is performed than if they had been previously hunted by a dog. It has been observed aiso that the cows are often driven away from the milkers by the dor before they are finished, and sometimes when this occurs two r three times, and the persons so employed do not eel the interest which they ought to do, they will allow the cow to walk off with a portion of milk which ought to have been left. This is not only a present loss but fatare mischief necurs; it does seem most desirable be milked on ady account whatever. The use of saltpetre, which has before been recommended in cheeso making, should by to means be omitted now, it will have reat effect in keeping the curd sweet, which is of importance. In cases where it is allowed to become sour he fat separates from it, and passes into the whey, Where it may be seen swimming in large particles, ver! different to the appearance of the cream which rises asily discovered by an experienced eye; and car hould be taken to prevent the cheese becoming impoverished by in this When in the loft the sour cheeses are easily discovered, they become hard, and nothing will cause any blue coat
to rise upon them ; therefore every sour cheese is discarded by the factor as inferior in quality.
It is requisite also to pay great attention to the management of the cream during the warm weather, the quality if the butter so naterially depending upon the care thus exercised. When taken off the milk should be put in the coolest place that can be provide gor the purpose ; when the convemence of and underground cellar offers itself it is leetter for the cream
than the dairy, where much heat is caused by the process of cheesemaking. Attention slould be paid to trequent stirring, and changing the utensils containing the milk The churn should be prepared by having a quantity of cold water allowed to stand in it some hours before the
cream is put into it, and the operation of churning should now be performed very slowly, and either early in the morning or in the cool of the evening; if the
latter, the butter should be worked and salted, and allowed to remain until the morning before being made up, when it will be sufficiently firm and in a proper ood plan to put a little saltpetre into each cream tin about the size of a walnut, pounded; it will keep it cool and prevent fermentation.
The cows mas this month get the advantage of a change to the aftermath in the newly cleared hay fields; nd even should this Grass be short, it is young and fresh and tends much to milk, so that the yield of the dairy longer by allowing the cows frequent change in these pastures. If the weather has been such as to allow of a rapid growth of this young Grase, so that the cows
readily satisfy themselves, and they will feed eagerly great care should be taken so that they can only have access to it \& fow hours daily at first, as they are very
liable to suffer from hoven, which is often dangerous or even fatal in its consequences. Old pastures supply much the most wholesome food for the weaning calves, and high dry situations should be chosen for them. Old seeds is perhaps the most 'healthy food for them, and calves so fed have proved much less affected by the farmers suffer greatly from losses by desth in thei stock of weaning calves, viz., the hask, which begins to show its symptoms at this season; a frequent cough with loss of flesh and refusing food, are the too sure signs of the disease. Many remedies are resorted to, but none can be relied on as at all sure to effect a cure when the lungs have taken the disease. Every means of prevenlungs have taken the disease. Every means of preven-
tion should be carefully tried, and keeping the calves on dion should be carefully tried, and keeping the calves on The other di-ease smong young stock which admits of no The other di-ease among youngstock which admits of no
certain cure is the quarter ill, or evil; this generally certain cure is the in the best and most thriving condition, and if calves are fed on very rich pastures this disense is often fatal t, numbers of calves of the first or second
year. If convenient they should be brought into yards at night, and fed on cut Clover or Italian Rye-grass, as keeping them from food while heavy dews are on the pastures has proved good for keeping them in good
healthy condition. Care should be taken, as the weaning calves get their longer and thicker coats, to
see they do not suffer from being infested with lice, which are chiefly found about the head, neck, and shoulders, and hinder the animals from doing well. A dry day should be chosen, when the calves should be this simple remedy is quite effectual to destroy the lice and restore the coat and skin to a heal thy condition, and avoids all risk from the use of poisonous applications, which many causes, the varialle state of the atmosphere, \&ce., render highly injudicious for use, and from whic the writer has witnessed nost dongerous results.
A recipe is added here for making cream cheese hich has been found successful:-
Take a quart of cream, or if not desired rery rich add 1 pint of new milk; warm it in hot water until it is
about the heat of milk from the cow. Add a table-spoonful about the heat of milk from the cow. Add a table-spoonful
of rennet, let it stand till thick, then break it slightly with a spoon, and place it in a frame 8 inches square and 4 inches deep, in which previously put a fine canva cloth; press it slightly with o weight, let it stand 17 hours, then put a finer cloth in the frame-a little powdered salt should be put over the cloth. It will be fit fo use in a day or two

HOME FARM MANAGEMENT.-No. VI.
When a farm manager has newly entered to a charge, and has secured the services of suitable workmen, he ought to determine the general course of management he is to pursue. I have indicated how he should care for the nighest interests of his workmen, but I have yet to refer to the system of managing them best calculated to keep forward the work and secnre a fair profit
on the farming operations. There is an immense dif ference between the various modes of laying out agri cultural work as well as in the handling of worknen. One manager with 20 men under his care shall often get as much work performed in a given time as another workmen are in every respect equal to each other in workmen are in every respect equal to each other in overseer to the other, man by man, yet the result will remain the same. The fault is not to be charged against the 25 men, but against the person who has the laying out of their work and the handling of them. He may understand pertectly well how the labour ought to be completed, but if he fail to adopt the simplest means by which it might be so, the exertions of one or two of
the men will soom be frittered away. Or should he
simply fail in puting every man in his right place, and way from time to time, the labour of several individuals must speedily be squandered. Even should the duties or the day of each worlman be nssigned to him only on the spur of the moment-when from the fact that a number of them are standing waiting for orders some number of them are standing waiting for orders some
lesire is felt to hurry them off as speedily as possibledesire is felt therry them of as speedily as possible-
the likelihood is that injucicious instructions will be given, and loss to the empliyer the necessary result. The planning out of work to the best advantage requires good deal of thonght, and the duties of every day during the previous evening. Whaty by the steward cool and easy managers may think or say, the fact is that the frequent losses met with in home farining are more generally to be accounted for in the immense amount of manual and horse labour thrown away Take masmanagement than in low prices or poor crops.
Tat the small silver, says the money saver, the avertigns will take care of themselves. To the farm manager it may be said, "Take care that the small money the workman gets is laid out to the best possible advantage; as for the quarters of Wheat they will not ofar wrong unless the management is hopelessly bad. results has much need to be studied by the great results has much need to be studied by the farmer, of others. Wherever it is practicable-and it is so in olmost every case-the firm steward should have as much work as possible done by contract instead of by
day's wages. If a fair rate is given for piece work it is not the good workman who will object to the arrangement, but the man who knows his inability, or has a disinclination to earn an ordinary wage by his own
exertions. There are certain kinds of work of course on a farm that cannot be done except by hired workers but a great many of the daily operations which are usually classed under this head might certainly be per formed by contract. Everything connected with draining, fencing, and road-making, whether partialiy or wholly belonging to the tenant's share of improvements, works as digging, hoeing, mowing, reaping, and in some cases threshing, forming of compost heaps, and lifting of root crops, which belong exclusively to the tenancy department, may be execated by special agrement with great advantage. It is the overseer's duty to farm which of them might be let by the piece advantageously and which should be done by hired worls. O doubt he must possess a comprehensive knowledge
doubt he must possess a comprehensive inowledge of the prices that "ught to be paid for different kinds sometimes hurtful to his employer's interests and other imes to those of the working-man, while between these parties he ought, as far as in his power, to do tull justice There is one thing in reference to home farm worl Which should never be neglected, that is, always to keep
the labour forward in its proper season. A farmer who is constantly behind with his work is in cousequence both a great waster and a great loser. It is true that forward the labours of a farm at unseasonable times and there are some furmers who persist in ploughing strong clays when they are much too wet for the opera tion-who attempt to pulverise such soils when they are not allowp clammy state-and who even at ha field to not it for being stacked with eatery. These men may think that they are what are termed "pushing farmers," but they are nothing else than wholesale blunderers. That is not the may to l:eep forward farm work. As far as the weather will permit, it should be done just when skill says it ought to be so, bat neither arlier nor later. It should be a universal rule with the farmer that nothing which can be well done one day ought to lee delayed till the next. Let him by all
means exprcise patience when the weather is untavourable for the prosecution of his labours, but when the reverse is the cyse not a moment should be lost. Those who have the charge of home farms are frequently more lit erally furnished with extra hands when they considerable advantage at certain seasons. Even in this we have a very good reason why home farming, if properly conducted, ought to be equally profitable with the farming of tenant farmers. True, the manager is not acting on !ins own account, but if he a a fill quali
fied man that will make no difference whatever. Cer tainly he has to worls at greater expense in some cases thon a tenaut would need to do, but he has generally better cummand of capital, workmen, horses, and im plements; and if these are all properly applied, a fai profit under ordinary circumatances will be reeeived as matter of course. J. Lockhart Morton, Lasswade, Mid Lothian.

THE COMPOSITION OF MILK.
Tere chemical examination of milk discovers in it an oily matter, butter, and a saccharine substance, the caseine-which has the same composition as the fibrin of Whest, the phosphates, from which bone is built up, and the saline compronds which exist in blood. It is mown to be a sture richly furnished with the raw material of beef these materials exist in the mulk different animals is found not to be the same, and, as is well hnown, both the quality aud quantity of cowa' mills
are subject to considerable variation. The following No, analysed in France ; Nos a and 3 , of milk supplied to the union worlo laboratory ; No. 4 of cows milk, and No. 5 of human milk, examined in German by Haidieu (sce Table) The caseine in milk is held in sclution by soda, but the butter is merely suspended through it in a fively divided butter is merely suspended through it in a foely divided which a thin, colourless, and transparent liquid is ren dered opaque, and of a white colour, by the suspension in it of extremely minute particles of fatty matter:-

One of the most important constituents of milk, with reference to its value for human food, is the nitrogenised substance caseine. The proportion of this com pound is found to be influenced by the kind of food suppich in the and and to rich in nitrogenised compounds. According to Bous singault, the average amount in cows milk ranges from 3 to 4 per cent.; other observers have, however, give a much higher average, Playfair, in England, estimating it at $4 \cdot 16$

In milk, casein exists in two conditions, partly in solution, and in part forming transparent capsules which invest the globules of fat and keep them from coalescing as occurs when they consolidate jato butter. The existences of a delicate membrane investing the fat chemist Raspail, was not until lately demonstrated. It a thin layer of fresh mille be spread on a piece of glase and examined by the microscope, it is os or abules swimming in a colourless and transparent liquid. These globules consist of the oily matter of the milk, sur rounded, as I have said, ly a capsule of casein. Th micrescope, invesing marer, drops of acetic acid, are also employed in the investigation, when the globules become distorted, and drops of at cau be seen emerging from them.
The chief method adopted in this country for the exa mination of mill is by the measurement of the quantity of cream which it is capable of affording. For this pur pose, a simple instrument, termed a lactometer, or mil gauge, is used, which consists of a table and narrow glass, usually about ten inches in length, and an inch in diameter, and graduated into 100 equal parts, th cale commencing at the top of the glass. When milk to remain at rest for ' 4 hours, it will be found that the cream, at the expiration of that time, has separated, forming an opaque layer on the surface of the mili The thickness of this layer, measuring from the division where the opacity commences to the surfase of the cream, is ascertained by reference to the figures engraved on the side of the glass, and the number of degrees observed indicates the persentage of cream in the milk. A number of these tubes are required for use in the dairy, and may be conveniently placed in a wooden stand, so as to admit of the comparative examination of several samples of milk; they may be procured at the glass-house, apparatus. Though this form of instrument is recommended by its simple construction, and the apparent accuracy of its indications, yet to obtain perfectly correct results several precautions are necessary, and eve when properly employed its results are to be regarded as only comparative. It affords us no information with respect to the proportions in which the casein and other constituents of milk are present, and gives us merely an approximation to the actoal amount of cream which the milk contains. From the circumstance that the lactometer is at present very generally em ployed in this country, and that it has been adopted n estimating the quality of the milk supplied to the workhouses, it will be useful to consider the

1. When mili is taken from the cow and placed in the collecting pans it has no sourness. But very soon thecomes slightly sonr, and it is found that the produc ion of acidity is promoted by whatever elevates the temperature of the milk. The guantity of acid gradually ncreases 00 much that it coagulates the caseine, , ad When the souring of the milk is quiekly produced, fom the vessels containing traces of sour mill, or from an elevated temperature of the senson or of the milk-r00m, it will usually be observed that the amount of cream separated will vot be so great as when the souring and consequent congulation is retarded. The spongy mass which the coagulated caseine forms entangles some of the particles of cream, and prevents their ascent to the surface of the uilk. The influence, therefore, which the slow or rapid coagalation of milk exercises in promoting or retarding the separation of the cream enables us to explain the discordance in the resulis obtained in the use of the ordinary milk gauge, and shows ns how mueh
epercentage of cream, as indicated by the tube in a ness of its coagulation. It also explains the beneficial effects of the practice of keeping the milk in shallow vessels at a moderate temperature, 80 as to avoid it becoming too rapidly sour, and to favour the more easy ascent of the butter globules. You can readily under stand from the statement just made, how it may some times happen that a sample of fresh milk placed in the tube immediately after milking will yield a larger percentage of cream than the mily from which it has been taken when examined after it has been carried for several miles and exposed to the action of the air, and also agitated in contact with the air contained in the milk vessels, and probably brought int
. It a forg aome traces of acidity.
of thilk drawn from the udder is the por tion of the milk drawn from the udder is much richer in butter than that which is first drawn, while the other con stituents maintain the same relative proportions. A merely mechanical cause is commonly assigned for this difference of composition by agricaltural writers, and you will find is stated that it is to be ascribed to the fatty matter accumulating upon the surface of the milk in the adder, while the more dense watery portion will be collected in the under part, and consequently be first drawn away.

But this explanation is no longer admissible, as it has been found by experiment that the same thing prevails with respect to woman's milk drawn in fractional porthat the the breast. As, however, the fact is certain that then that whishast drawn is is is obvious that in proceeding to estimate the amount of cream which the mile a cow is eapable of afording our somples the milk of a cow is capable of affording, our samples should be taken from the entire quantity of care to thoroughly mix together the various portions.

From the observations which have been made, the following practical conclusions with respect to the use of the lactometer may, I conceive, be drawn:-lst.
That it affords purchasers a very uncertain method of calculating the actual yalue of milk, as its indications are the milk may have undergone when brought from a distance. 2d. As it is incapable of indicating the amount of the valuable muscle-forming caseine, or of the sugar milk, it cannatters. Which are essential consernation with respect to the actual value of milk as an article of food.
. That as the thickness of the layer of cream which a sample of milk may throw up in a given time will be influenced by the length of the tube, the temperature to which it is exposed, the portion of the milk examined, and the influence of mechanical and chemical causes, it cannot be regarded as indicating correctly the actual richness of the milk in cream; and it follows that the purchaser is not entitled to consider a sample of milk as deficient in cream, even when it fails when tested in the workhouse to give the same percentage as when examined by the contractor

The second method of distinguishing the value of milk is based upon the fact, that opacity of milk depenuls npon the corpuscles of fatty matter which are suspended on it, and that consequently the more cream it contains the greater will be the obstacle opposed to the passage instrument, called a lactoscope, has been invented in Paris, by Donne, for the purpose of accurately determining the degree of transparency which the milk poswhich may be pushed into the other like the joints of telescope, and the end of each tube is closed with glass, so that when milk is poured into the outer tube by a small opening on the side, by pushing in the inner
a layer of mill of any thickness may be obtained.
The apparatus is placed on a stand, the value of the milk is estimated by the thickness of the layer of it through which the light of a small wax taper at a fixed distance can be observed, the value of the milk being in the inverse ratio of the transparency; the larger the amount of fat present, the greater, of course, will be measured by a scale on the instrument, and a table sold with it shows the percentage of cream to which it cor-responds.-Jounal of the Chemico-Agricultural Socicty.

## Home Correspondence.

## The Cow Parmin.-Seeing a long letter in the Agri-

 cultural Gazette on the Cow Parsnip, by Mr. Samuel Taylor, of Wotton Parade, Gloucester, I am induced toinform you that, at the first Root Show of the first Farmers' Club establishod (Ashbocking), a keeper of a lanatic asylum at Ipswich brought many roots and packets of seeds of the Cow Parsnip, which he recom-
anended as being very prolific, and excellent food for mended as being very prolific, and excellent food for
cows and swine. The price of the plants was I believe 2. 6 d . each, and the packets of seed the same. I bought a root (anxious not to lose a season), and several others 1 ought roots or seed. My plant took and produced a stem 6 or 7 feet high, with a spreading bead as large as seed just like common Parsnip seeds. A gale of wind, however, seattered them over my garden, where they became a nuisance difficult to be got rid of; no catile or stocs would eat it, and I destroyed it as soon as pos-
sible. One seed had been blown over into a field, shere it produced a large plant as no beast, sheep,
or swine touched it. A rat-catcher coming pas
requested a portion of it. I gave him the whole and he said it was worth 12 . to him to entice rats not I do not know. Mr. Masters, of the Folly Farm, Ipswich, bought either roots or seed and sowed it at the corner of a field and hurdled it round to
keep the stock from it. When offered to them they refused to touch it, nor did they when the hurdles wer removed; and such was the case with others. believe it was at the same root show that the great ${ }^{\circ} \mathrm{Cow}$ Cabbage seed was shown and distributed (the price in London was 1 s . per seed). I had a few seeds given me, Pollard tree some 10 feet from the ground, and with this little assistance it did reach the height the vendor of this noble Cabbage said it would, even suitable fo venues to gentlemen's residences. Thappened to pas the shop where this monster Cabbage was to be seen, had been fed with it, but escaped being duped for once

## Makers of Almanacks suppose An bonest plodding farnuer knows

Charles Poppy. [It is within our personal knowledge that Mr. Naylor has no personal interest whatever serve by his recommendation of this plant to the atten tion of farmers.] -. Your correspondent Mr. Taylor in describing and extolling the "Heracleum Giganteum Sibericum" as a gigantic plant proposes it to be cultivated for the use of cattle food. It will be recollected that about three years ago we called aitention in the chronicle to mental pont whe Hon Lady Matilda Moore, of West Iskesley, which she had grown to great perfection by the instructions given her by Mrs. Loudon. It grew with ns with a shaft o stem 14 to 15 feet in height and as large as a man leg, with beautiful umbulated white flowers at top som mensure, and the plant leaves five feet broad [!]. W however recommend it not as fit, or relished by cattle it being rancid and ill flavoured, and we had an idea that it was poisonous, though it is probable its
medicinal properties are of some value if pointed out. The "Heracleum Sphondillium" however we recom mend to be cultivated for pigs, cows, and rabbits they are remariably fond of it, and will thrive and fatten upon it with a very hithe degree. Thi is a very common indigenous plant to this country tenacious and cold. We again beg to repeat that it ma be profitably and very much improved by cultivation and the maner of growing it to perfection is to som the seed in autumn in rows. on ground well trenched and dunged, 2 feet apart, aud the plants 1 foot distan in the ced, 2 fet apart, aud the plants 1 foot distan will not germinate for a twelvemontl, but will lie dormant all the summer months, and often perish by dormant all the summer months, and often perish by
the sun ; if sown in autumn the plants will appear the sun; if sown in autumn the plants will appear
in early spring, and will be fit to be cut three times a year, and will afford abundance of useful fodder for rabbits, pigs, and cows. It will be recollected that we recommended it to be grown in gardens for rabbits and pys in large towns, as it will thrive in almost all correspondents and readers with a portion of its seeds by their forwarding us a stamped envelope addressed to its destination, and a few stamps as a remuneratio or our trouble. A. Mardy \& Son, Maldon, Esse
Stables.-" "J. W," of Peterborough, quite misunder quite "B. H. cart-horse stables. "W. B. H. dilections, but considers all "J. W.'s" requirements carried out in his treatment, and withont any annoyance of one horse to another. "W. B. H." intends his five horses in each rectangular building of say 30 feet by 24 feet to see each other, and therefore also in two senses to be able to chaff with each other, by having the upper part of the divisions merely separated by railings. The height of the building should be sufficient to allow of large openings and grates of perforated zinc the whole length and width of the building, and open to the ronf, thus securing perfect and abundant ventiation. made any size required, ouly leaving one of the middle ones as the entrance, by a little arrangement, for all the five boxes to open into, and also for the corn and chaff and the harness of the five horses. "W. B. H." finds his horses require but little exercise or amuse ment after work, except those of feeding and rest ; thus he fancies his plan holds out comfort as well as economy in space, labour, and food, for each five horses under
each man's care. As to food for horses, "W. B. H." believes the more food is prepared for digestion in the horse's stomach the better. Hence bread made from any ground corn, as he has experienced, is better than any unprepared or unground. W. B. Hurnard, Gumey's Manor, Hingham, Nonfoll.

The Hay Crop.-Since the date when a short article appeared in the Agricultural Gazette upon this subject, the writer has witnessed the ricking of a prodigious quantity of hay, which so far as propitious weather was But the making has been performed indifferently by many persons. Much indeed has been effected, but

Most counties have their own peculiar method of hayMiddlex appeare to Middesex appears to claim pre-eminence. The writer request the attention of hay farmers to three or four rules, which, if followed, will not fail to bring to the rick hay as perfectly made as the character of the weather will permit. Choose sunny weather, if possible a time when the wind is north-easterly. Cut early in the morning, and till 9 oclock let the forkers
follow the mowers aud shake or ted all the Grase follow the mowers and shake or ted all the Grass every lump, not leaving a single knot, and strew it evenly over the ground. By such rigid tedding the hay will heat more regularly in the stack, and consequently will be less liable to fire; it will also be more in quantity when cut into trusses, and bring a greater price. It must be self-evident that regularity of texture will fered to lie in swath ("e always except a wet or dripping season), the under surface of the Grass will remain damp, the upper will become withered, and the interior or middle part will be rendered tough and flaccid without beio $o$, the herbe in the kuots, or bring the herbage into a regular and equable condition. Here it must be ristinctly stated that we saw close at hand a vast crop, amounting to at
least 2 tons per acre, so tedded; it was ricked in condition on the third day, that every fork bore the hay from the cart to the rick, light, and without a single knot. True it is that hands were in plenty, and no labour was spared. On the other hand, a great crop not half tedded was stacked; it was heavy, lumpy, and and beargifol colours or shades, dest characterises wel made hay. These few hints, if favourable weather returns, may secure a crop of Grass, which, it is agreed during many years past. $J$ any th

## Miscellaneous.

Seeding of Weeds.-One of the most fertile sources of the continuation of weeds is that of constantly allowing which seed on the land. Now, the enormous increas the follow the he following table of observations made upon a few of

| Pastingea sativ ${ }^{\text {a }}$.. | Will Parenip.. | $610 \times$ | $\times$ |  |  | always perfect the quantities of seeds above tabulated but the list gives a Iretry accurate notion of the numbers of seeds which might be perfected under circumstances favourable to their development, and from it will at once be gathered the important practica fact that, allowing for the casualties to which seeds are constantly liable, yet enough would be left, where seeding is allowed but for a single year, to give trouble for that weeds be destroyed before their seeds are ripe, or indeed nearly ripe, as the ripening process is often com pleted by the juicesin the stems, especially of pulled weeds pleted by the juices in the stems, especially of pulled and Thistles, when pulled and laid by as we saw last year, yet ripened muel see, and thei involucres, opening in the sun, were wafted on the breeze to an indefinite distance; and it should be

recollected that one-the primary head-may ripen long ed that one-the primary heale weed-growt may follow from a delay which has allowed only thi one head to perfect its seed. Each plant of Groundse might in this way be increased 50 fold, each plant Thistle may produce an increase of 150 fold Hence then preding should be done as early is possible, either with the horse-hoe, common hoe, o sometimes the Dutch he, and when thus early cut down, may safely be left to wither on the ground; but it should be borne in mind that if any individua plants among them are shediling their seed at the time and are not talien away, the very hoeing ensures safe plantation. It is precisely in this way that colts
foot is often much increased. The flowers of this plant appear in spring before the leaves. By the tinie the seed is ripe the leaves become conspicuous; hoe is then set to work to cut down the latter, which the ripened seeds are sown, when, if left, the might have flown away to a distance. Now it may be that the roots of the Coltsfoot-for it is not destr been gathered, but the sown seeds will insure that the pes shall give us more work to do at a future time The patches of Coltsfoot flowers should therefore be
cut down as soon as they appear, and by this means we of the plant by eutting off the leaf-buds. Many other of the plant by cutting of the lear-buds. instaw that a knowledge of the natural history of weeds show that a knowledge of the natural history of weeds
is of great importance in enabling us to subdue them. is of great importan
Professor Buckman.

## Calendar of Operations.

Cheshire.-The appearance of the grain crops has undergone a great change since our last communication, in consequence of a terrific storm on Monday night and early on Tuesday morning. have an unsightly appearance, and it is much to be feared have received a considerable amount of injury, but to what extent it is at present impassible to say; of course a great deal wall depend apon the weather for the next few weeks, and if it should be fine
the result may not prove so bad as is generally anticipated. The early Potato fields have for the last fortnight been scenes of busy employment to the labourer from $30^{\prime}$ clock in the morning until the afternoon, when the Potatoes are sent off fresh to the differeat markets; and the growers are now taking advantage of the
change in the weather to trausplant Mangel Wurzel and Swedee, or to sow the Green Melon Turnip, now so much in favour, or other kinds for a second crop. The hay haryest has been retarded, and in many instances mowing has been auspanded for a time, to enable the farmer to bring all available power into the Mangel or Turnip field. There are great complaints of Mangel Wurzel excellent crops, and it has been our good fortune to bave an abundance of plants to spare from our general crop, which we are now planting upon the early Potato ground. Grass is still plen-
tiful, and cattle generally are doing remarkably well. The growth of Clover upon good land has been very rapid, and we striking," from the effects of over luxnriant herbage. One case has come ander our own observation, where a loss of 20 per cent In a healthy flock of sheep has been sustained in about nine days a good make. $W$. $P$. ing Turnips, after one of the most difficult seasons we remember. From thil $12 t h$ May till we finished sowing there were only ur neighbours who have strong or wet land have been in a much worse case. The dry lands in the valley were all sown in good time last month, but on the stronger out-lying lands there is a considerable breadth which will remain unsown. Where Turnips have been got in they are generaliy looxing well, though in some hinning our $\mathrm{S}^{2}$ edes on the 5th inst, and first-sown yellow are quite ready for the hoe, A good breadth of seeds has been cut, and the crop promises well. Corn has improved greatly in appearance since our last report. Wheat has not yet "shot," but the ear, some early spots of the former being out. liye of which good deal is sown mixed with Wheat, has been fully out for apwards of a fortnight. Potatoes look strong and healthy, and have every appearance of a full crop. Grass is abundant, and ambs are abundant and cood At Stagshowbank on the 4th inst. the show of short-horns was very poor. Galloways and Irish were more abundant, and quality fair. For all sorts there was slow but dear sale. We have carefuly examined our iron cove used exactly 1 la , win the alus of and we the weight of which when new we did not ascertain. Wester Ross, July 7 .-The weather still continies unsettied, and to-day we have heavy ard continued rain. The wheat crop is now in a very precarious state, in regard both to its hoomirg
season, and to its uncommon luxuriance. Much depends in any eason on the weather we have for some weeks previous to harvest, but this year there is a double risk. Already patches of Wheat are lodged, which never can approach maturity, as the
most advanced fields are not yet fully in ear, whilst the later and heavier fields, although now ranker than in ordinary seasons, are common amount of foresight to enable one to tell that our Wheat this year will be of a quality greatly inferior to our last year' crop. In 100 qrs. of Wheat of last year's growth we would many of the heavier fields now growing will vield little else than dressings. Oats and Barley are looking well everywhere, and ir not too heary also will be abundant crops. We will not only have a full average of straw this year, but a surplus over and Turnip sowing has been completed not last year's deficiency rould have wished. It was impossible to get the ground, in such wet state, made thoroughly clean, or where clayey, rightly pulverised. However, they are coming away as well as migh complain of too much rain, in their earlier stapes their rearch easily impeded. The earlier sown $\mathbb{S}$ wedes have been singled, and as weeds of all shapes and sizes are making astounding pro gress, every hand that can wield a hee will be much needed for some weeks. As our green crop lot this year lies alongside the Turnip crop at once surprising to passers by and hirghly adva tageous to ourselves. No pains or expense were saved to prepare the soil, and supply the best manure; but unfortunately part of the seed we purchased was bad. A large proportion of it never came above ground, and those that did braird advance so slowly, needed to bring them to a decent size. This is surely tantalising enough. No seeds should be used without being previously tested, be the character of the seedsman from whom they are has been for many years: very crop is more abundant than it weather being so unsuitable. Heture Gress is where, and there is a great demand for stock.

## Notices to Correspondents

Bones on Pasture in Cherbibe.-A Subscriber sayb, "Having month from Mr. Dutton, at Chester, respecting the application of bones to old Grass land, I would be obliged if he would state the sort of bones, whether bone dust or ground bones, the quan tity per acre, and the proper time to apply, and if by themselves shall be very much obliged.] $X Y Z$. It is much the beat we mo saeep on Clovgrs:
and place always a little in advance of the fold enough for a meal and place it in troughs within the fold, repeating this uniti hurdles. Nothing can be simpler, and no description is neg the The superiority consists in the entire consumption of the erop and its entire conversion into mutton and manure.
"three out of fire", We are reminded that not "two of four" but during the past session were given to the writers of agricultura papers; Mr. Uumphrey Chamberiain, of Kempsey, near Wor cester, havigg had one awarded to bim for his paper on Mr. Chamber, Which is properly an agricultural subject. To the attention of our readers.

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACEINES,

SOLE MANUFACTURER, IRON AND WIRE WORKS, NORTH STREET, LEEDS REGISTERED JULY 24, 1855.-No. 3739.
THE ADVANTAGES OF THESE MACHINES supersede all others by having I small Wheel in front of the Grass Box, consequently will mow verges and round flower beds, wet or dry, and by the simple adjustment of a thnmb screw, in front, can be raised or lowered to cut the Grans any length required; and having two Rollers behind, and a small one in front, they roll the
width they cut; they will turn in very little room, and cut at the same time. All the working parts Width they cut; they will turn in very little room, and cut at the same time. All the working parts
made much stronger than the old machines. The bottorn Blades are so constructed that they cannot tear ap the ground; they are only drawn, and not pushed and drawn as in other machines, consequently do not require half the power to work them. The three frat simes can be worked by sue person with ease; the two latter with a pony or donkey.

Testimonial from Joshava Major, Esq.; Landscape Gardener, Knostrop.
To Mr, Grean, Linne-Sis, Am I alway appreciate public and usefil improvementa, I most gladly give my tostimony to Your hichly improved Mowing and Rolling Machine. The one sent for my inapection and trial (cutting a breadth of 24 inches) was drawn on flat ground with ease by one person, and although at the time of trial the lawn was wet. it was cut with the greatest with ease and pleasure, providing the Grass, is not too long. For extensive places I should say the 24 or 20 inches would he most suitable; for pven in undulating ground two parsons may work it; but in flower gardens, when beds, \&cc.. gre crowded, elther of the simaller sizes would be best. I congratulate you on your very valuable invention, which in my opinion, entirely surpasses, and must eventrally supersede all others, for it is not only froe from intricacy and easy to the workman, but extremely expeditioas in its operations, and consequently must prove a great saving in the management of Grass lawns, and a great boon to

Other Testimonials may be had on application to the Manufacturer.
The above Machines are warranted to answer the purpose as described, or may be returned, and may be had of all principal Ironmongers, Nurserymen, and Seedsmen in England; also Mr. Charnas Garrood, Superintendent of Agricultaral Department, Crystal Palace, Sydenham.

## Cht Garventeg Chromicle.

SATURDAY, JULY 19, 1856.
mretives por tab ensuing werk.
Durine the months of June and July a handsome orange-coloured fly may be observed flying heavily about Rose bushes. It is about the same size and general colour as the female of the Gooseberry sawfly, but it is of a more robust figure, with shorter thicker limbs, and its colour is a much richer and brighter orange, with a black head and antenne, the whole of the middle of the thorax and the thickened fore margin of the fore wings shining black; the legs also are orange coloured, with the tips of the tibiz and joints of the tarsi ringed with black. The wings also are tinged with orange. It measures about two-fifths of an inch in length, and the expansion of the wings is about four-fifths of an inch. The male has a more slender body with the antennæ thickly covered in front with fine erect hairs, whilst those of the female are naked and rather clubbed at the tip. In its colours the male resembles the female. It belongs to the family of Sawflies, Tenthredinidæ, and to the genus Hylotoma, which differs from the genus containing the Gooseberry species in having only three joints to the antenne, the third being very long and ciliated in the males or subclavate in the females. The species is named Hylotoma Rose, and is by no means rare. Cultivators of Roses will do well to keep a sharp look out for these sawflies and destroy every individual, which is a matter of no difficulty, because the insect is in the first place very conspicuous in its colours, and in the second place is by no means so active as some of the other species of Sawfly. If these precautions are not taken, the Rose bushes will very soon show the results of such inattention.
These results consist, in the first place, in the deposition of the eggs by the female, not upon midribs of the underside of the leaves, as in the eass of the Gooseberry sawfly, but in the tender substance of the finest and most healthy of the young shoots. A small slit is made with the saw of the female in the longitudinal direction of the shoot, and an egg introduced, another similar slit is then mads at the distance of about one-twelfth of an inch, and in this manner the shoot is sawed into to the extent of an inch or an inch and a half. Irritation immediately commences, the space adjoining each slit swells into a little convex spot, on opening which the egg is found beneath the surface below the slit. This prosess is moreover attended with the curling of the twig, which by degrees becomes black and shrivelled in its appearance, the extremities of the wig also dying off.
The eggs quickly hatch, and then the second result of inattention becomes manifest. The young grubs are very hangry and attack the young leaves with great vigour, as many as a dozen being sometimes found on a single leaf. These larve are full grown at the end of July and beginning of Angust: they so closely resemble the caterpillars of the Gooseberry bushes, that even an experienced eye would assert them to be identical, although producing perfect insects belonging to different genera. They are orange yellow on the back, the lower parts of the sides and two segments after the head pale greenish white. The head is yellow with a black spot on each side and a small black ring round the minute antennæ, the face with a triangular black spot divided down the centre by a pale line above the month. The segments of the body are covered with black dots, and it is in the arrangement of these dots that the chief difference exists between this insect and the Gooseberry caterpillar, each joint, in fact, has a large black spot close above the legs and another at the base of each leg; there is a transverse row of six small black dots in the anterior wrinkle of the segment followed by six larger spots, below which on each side is the sporacle or breathing pore, and another transverse row of eight spots across the hind part of each joint: besides the six legs attached in pairs
o the first three segments following the head, there legs. These larvæ generally sit with their bodies much curved, so as to lay hold of the surface of the eaf, or twig, with the anal pair of feet, whilst they hold the anterior part of the body upon the edge of the leaf which they are in the act of devouring, placing the three legs on the opposite sides on the corresponding sides of the leaf, so as to stand edge-wise.
When fall grown the larva descends to the ground, where it forms an oval cocoon of a strong silken texture among the leaves and bits of earth, and in which it remains until the following June, when the perfect insect appears just in time to allow its progeny to renew their attacks on the young leaves. I. O. W.

They are grand folks at Weston-super-Mare. In that happy spot money bears far less than its customary valne. Guineas are thrown about like shillings, and hospitality is boundiess ; for all is joy and abundance. Even Horticultural Exhibibitors are contented with but little, so few and simple are their wants.
It appears from papers on our table that in this Arcadia there is a Horticultural Society, well supported, and well attended. In the year 1855 it enjoyed an income of 2201 . and held a show. Of that income, however, 15l. were specially contributed for cottagers' prizes and specially awarded ; so that the otherrise available income was about 2051. That all this should have been contributed was what was to have been expected from the wealth of the place; that it should have been all spent and about $30 l$. more does honour to the genius of the Committee. The show would seem to have been held in a field; some tents were provided, a Yeomanry band and a Militia band were present, while a couple of county police protected the company from intrusion, and gave dignity to the scene. The Committee to whose hands the arrangements were entrusted being determined that nothing should be left undone on their part, applied themselves in earnest to their work. First of all they set apart a quarter of their money for the exhibitors, doubtless thinking that if half the expenses of a Chiswick Exhibition consist in prizes, a quarter must be enough for Weston-super-Mare, the gardening of which they regarded as only half as good. Then they had a Yeomanry band for which $21 \%$. were paid, and a Militia band valued at only forty shillings, exclusive of the band-master who figures as costing forty shillings more. The Committee seem however to have felt that there was some thing shabby in the last arrangement, and so, by way of amends, they put both the bands together and spent $22 l$. in refreshing them. By this contrivance they brought the reward of the bands nearly up to that of the exhibitors, from which we learn the comparative importance in which the latter are held. If there were any doubt upon the matter it is removed by another charge of 92 . 11s. fo refreshing " amateurs, nurserymen, gardeners, and censors," rather less than half what was felt to be due to the bands.
Such being the estimation in which the gardening part of the exhibition was held by the Committee, we rather wonder to find that they devoted $14 l$. to decorating the tents in which garden productions were placed, and $25 l$. more to decorating the streets through which folks passed to look at them. This trade of decoration must be in great prosperity at Weston-super-Mare; it looks indeed as if the meeting had been held for the purpose of admiring it, or else the county police, who must have been personages considering that each received forty shillings, the price of a whole militia band, for his distinguished services, or eight times as much as a London mounted inspector.
One other feature in the arrangements of the Committee seems worthy of especial notice, and that is the homage they paid to the fourth estate of the realm. Next after King, Lords, and Commons comes the Press, more than their equal, over each a viceroy. At Weston it is held in the deepest veneration, and the Committee testified their awe at approaching it by placing one-eighth of all they had at its disposal. Five-and-twenty pounds were aid before the shrine of the printer.
Strange to say some inhabitants of the place are nevertheless dissatisfied ; call for accounts, consult together, talk of jobs, and other scandal about the Committee. Can any thing be more unjust? It is surely reasonable that gentlemen should be fed
as such." Bands want drink like other people, and as for the Militia there is no bottom to their throats. What is done in London is no rule for Weston-saper-Mare ; one Weston constable is worth a dozen London inspectors, and must be paid
well for the Horticultural Society to spend only 202 pon their printing but their tiekets and cir culars, and placards are nothing to what is seen at Weston. It may as well be expected to give exhibitors their breakfasts at $2 s$. a-head, because that is Gunter's charge; what have Weston purveyors in common with people keeping a shop n such a place as Berkley Square
Certainly it is very disagreeable that contributors should murmur ; the more ground, indeed, there is for murmuring the more disagreeable it is. But grumbling is a national peculiarity, and Somersetshire does not enjoy an immunity. For ourselves we greatly regret to hear such complaints, because they seem to indicate an impossibility of promoting Horticulture by exhibitions in country places. It is needless to say that doings like those at Weston must be fatal to associations of any kind; and unless some check can be put to them by the gentlemen of England provincial meetings will soon become a mere matter of history, as many have indeed become already. This is, however, a subject for adjustment on the spot. Those at a distance can only direct attention to what is wanted.

We understand that there are still some packets of seed of Deodar, and two or three other kinds of Conifers, ready to be distributed to any Fellow of the Horticultural Society who may apply for them at 21, Regent Street. The meeting on Tuesday next, although not held for any specific purpose, will include very instructive specimens of the quality of most of the important varieties of garden Bean, and will show what their comparative value really is.

PRACTICAL LESSONS IN BOTANY FOR
beginners of all classes.-No. II.
By the Rev. J. S. Hessiow, M.A., Rector of Hitcham, Suffolk. The plant stands are easily constructed (for 15cl. each) of narrow strips of deal, cut from half-inch and quarterinch planks (it required, they may be stained for 6 cl ., or painted for $7 d$. each). They are supported on two iron staples (2rd. ench) driven into the wall. Each holds 18 common draught vials (at 8 s .6 d . per gross). As the vials are cast exactly linch in diameter, the holes are bored with a centre-bit a little larger: 16 stands, therefore, hold 2 gross of vials, rather more than are likely to be wanted for such wild flowers as can be procured in blossom at one time. The labels are made up of card-board cut to a pattern, and slipped between two narrow slits contrived in front of the stands. The annexed cut represents one end of a plant-stand, and will satisfy any village carpenter as to the mode of construction. A is $\frac{3}{5}$ inch broader than B , to allow of the label-slit being $\frac{3}{1-1}$ inch wide, between $G$ and $D$. To produce the upper slit, a thin slice ( $m$ ) of wood for the middle, and another ( $n$ ) for each end, are introduced between F and B . These slices are trimmed to the same angle as the labels, which allows of these standing accurately before the vials in the middle and ends. A small screw (as well as glue) is advisable for securing $F$ at the places where the slices re internosed. The labels conplaces where the the lase the the or he chas, time with the rest, should be methodically arranged for ready reference. This can be done by inscribing

Thus $62,13,7$, indicates the position of the "dark Mullein" (Verbascum nigmum) in Hooker and Arnotts British Flora. If packed uprightly between partitions in a box the labels are easily sought for when wanted, or returned to their proper places. They should be varnished with a weak solution of shell-lac in alcohol or naphtha, according as the nose of the operator may be fastidious about smells or not. If a tumbler full of the varnish be prepared, the cards can first be dipped from the bottom up to the part where they are narrowed off. The undipped portion can then be inserted between the leaves of a book, to retain it in a horizontal position until sufficiently dry, which it will be in a few minutes. The upper end may then be similarly pre pared. The junction line made by the successive dippings will be hidden behind the strip F . The labels should not be packed together for 24 hours after they have been varnished, else they will be apt to adhere The varnish protects them from moisture, and admits of their being washed if they get dirty.
During a botanical lesson, reference to the classification of the plants in the list and on the stands may be conveniently aided by a tabular view (in large letters) suspended on the wall above the plant stands. By inserting only the two or three first letters of the several words, an effort of memory is invited for recalling them. The Italic letters within the brackets would thus be omitted in this table :-

The orders of the flowering plants are here referred to one or other of eight columns or compartments, five which belong to Dicotyledons and three to Monoco yledons.
Botanical Diagramb.-A slight experience, latel obtained with the first of series of nine diagrams in course of preparation for the Government Department of Science and Art, has satisfied me that they will be found serviceable to both teachers and pupils. These diagrams are at present io the hands of the eminen botanical artist, Mr. W Fitch. As he is anxions to prepare as many as pos sible of his own drawing from fresh specimens, th series will hardly be cou plete before the end plete bn. Fach diagram illustrates one of the eigh luarans in the above tabro olar view the classification with the exception of the with the excoup of Calye extensive group of Calyd floral Dicotyledons, wmor requires two. piants have been selectes for the illustrations, Their of important orders fruit are inflorescence and rural size and enlarged figures of the flower, fruit, seed, de., are added, with dissection the parts exposed bein explained on the diagram.
at the back and top the three figures which belong to the order, genus, and species in whatever author may be adopted for the names on the plant-list.

School Herbarium. - It would afford amusement the teacher, greatly aid diligent pupils, and securh

F as a cabinet in one corner of the school memoranda may be made on the paper to which few specimens are glued, noticing the leading characteristics of genera or species. Thus, if the "bulbous Crowfoot" (Ranunculus bulbosus) were selected as a type of this genus, the following memorandum would be found Pistils

| Pistils | $\infty$ | A nectariferons pore, covered by a scale at the |
| :--- | :--- | :--- |
| Stamens | $\infty$ | base inside each petal | | Stamens | a | base inside each petal. |
| :--- | :--- | :--- |
| Petals | 5 | Many of tinis genus acrid and poisonous. |
| Senals | 5 |  |

To "pilewort Crowfoot" (Ranunculus Ficaria) might be appended
$\left.\begin{array}{l}\text { Petals about } \\ \text { Sepals about } \\ 3\end{array}\right\}$ The parts of the perianth vary much.
Root with numerous tuberous fibres.
Leaves heart-shaped (cordate), crenate
To "water Crowfoot" (Ranunculus aquatilis).
No scale over the pore on the petal.
Floating leaves not much divided
lating leaver not linear segments,
A few remarks on the preparation of such a local berbarium may not be unacceptable :-

1. Procure a good bundle of drying paper. Bentall's, manufactured for the purpose, is the best. But any, walerably thick and bibulous, answers the purpose. For want of better, old newspapers will suffice. These dry-
ing papers will outlast a long life. There is much coning papers will outlast a long life. There is much convenience in having them
ahout 16 inches by 10 .
2. The drying process is greatly assisted by introducing "ventilators" here and there between the papers. They may be made of the size recommended for these, and are constructed of strips of wood a quarter of an inch square. One set is laid in parallel lines a quarter of an inch asunder, and another set is placed in the same way upon and at right angles to the to serve the outside strips may be half an inch wide, their end as sort of frame. The strips are tacked at kind of lattics-work through which is liept up a con tinued evaporation of whatever moisture has been im. wibed by the drying paper. This simple plan obviates to a great degree the necessity of continually changing and drying the papers in the packets under pressure.*

3. Specimens selected for the herbarium should be as complete as possible. Small species can be dried entire. In larger plants we should select specimens with entire leaves, buds, flowers, and if possible with fruit. Mere scraps of plants are worthless, Where a specimen is too large for the paper, it may be divided into two or more pieces. The different pieces may be glued on one paper or more. The specimens selected in the fields should be brought home in a tia box, dignified by botanists by the game of Vasculum. They may thus be kept fresh even during the hottst weather for a con siderable time.
4. A quart bottle containing a few ounces of corrosive sublimate may be filled up from time to time with onepoisonous solution may be laid on the dried specimens with a hair pencil, and greatly protects them from the attacks of insects. When a specimen is stiff enough, it may be dipped in the solution poured into a shallow dish. Specimens thus poisoned must be allowed to dry again between the drying paper, or their leaves will be apt to shrivel. A very slight pressure is now all that is equired.
5. Stiff pale-coloured cartridge paper (about 19 s. the ream) is, from its comparative cheapness, well adapted herbaria to $16 \frac{1}{2}$ by $10 \frac{1}{2}$ inches; but for a school her barium of local British plants, 14 by 91 inches will be quite large enough. The dried specimens should be attached to such paper by a moderately strong solution of common glue. A small copper glue-pot, kept hot over a night-light, will be found convenient for the purpose. Where a specimen is too flaccid to be held up with a pair of forceps whilst being glued on the the table, aud after being touched here and there with the glue, the paper to which it is to be attached may be laid over it.

I have not thought it necessary to enter into details with respect to drying plants for the herbarium, but the above hints may bs useful to some who already know the general process.
(To be continued.)
The annexed cut represents a plan noticed in the Gardeners Chromicie, vol. 185a, p. 164 , for carrying ventilators on a journey. Those suggested above are somewhat simpler
and would occupy one-third less space. Eiditor.

VEGETABLE PATHOLOGY.-No. CXXX.
520. Parasite (Erysiphe.* Mildew.) - The word mildew, which is derived from the German (menl thau -meal dew), properly denotes those white and mealy summer. Theyare familiar objects to every plants in but are widely diffused, and often so conspicuous that they cannot fail to attract the attention of all who are gifted with observant eyes. It is scarcely possible to walk in the woods in autumn without seeing many a young Maple bush as effectually powdered as if a quantity of flour had been dredged over it, and though this is perhaps the most conspicuous case, there are
many other plants which suffer almost as many other plants which suffer almost as grievously. The Hop, the Vine, the Rose, the Hawthorn, the Peach, the Strawberry, and various other plants, whether in the stove or in the open air, are often damaged by the little
parasite, which may either advance no further tha parasite, which may either advance no further than the
white mealy stage as is the case with the Vine mildew, or may put on entirely new characters as the Hop and
Pea mildew.

521 . In the mealy stage the mildew to the naked eye unassisted by magnifying powers, looks extremely like flour sparingly scattered. In some parts it is spread more thickly than others, and there are generally little white specks in which it is collected into little heaps.
Examined under the microscope it is found to consist of necklace-like threads springing from a creeping mycelium which either clothes the surface, s nding down little suckers which adhere firmly to the leaf and ultimately decompose its tissue, or else it crawls amongst the intercellular spaces, sending up the fertile threads from the stomata. This perhaps may depend in some measure upon the nature of the surface. Where there are few or no stomates on the upper surface of the leaves, as in the Vine, the habit may be different from leading to ample intercellular cavities. The effect in either case is the same. The mycelium in the one case as completely as in the other exhausts the leaf and diverts the nourishment which was intended for the plant. The joints of the necklace-like threads or Oidium vary somewhat in form, being sometimes cylinOidium vary somewhat in form, being sometimes cylin-
drical, sometimes elliptic, and sometimes swollen like a drical, sometimes elliptic, and sometimes swollen like a
tun, but there are no very striking differences. After a tun, but there are no very striking differences. After a
time the upper joints fall off and germinate, and thus propagate the plant with great rapidity. Nor is it very nice as to the object on which the spores fall. The Grape mildew, for instance, may be communicated to plants placed beneath the Vines, or on which the spores are thinly sprinkled.
523. Sometimes instead of the joint itself germinating, its endochrome, without any increase of size in the joint, becomess organised, and gives birth to multitndes of minte sporidia, each of which is capable of germina tion within the external cell, so that the original spore looks like a little hedgehog, in consequence of the germinating threads projecting from its surface in every direction.
524. Some of the joints, however, pat on a totally different structure. They swell immensely without however losing entirely their original form, their outer coat becomes organised and cellular, in which case they are called pycnidia, and finally they give birth to yyriads of little oblong bodies which are sometimes capable of germination. It is conjectured that they doubtful. They are entirely destitute of motion and external appendages, and are probably mere repre sentatives of the spermatozoids of higher plants
525. Some species never go beyond this stage, or have

not been observed to do 50 , as is the case with the Vine mildew; but more frequently little knots appear form the creeping threads which gradually swell and $\frac{\text { form globose perithecia, surrounded by one or } \mathrm{m}}{\text { * From suci } \beta n, \text { a word more properly signifying rust. }}$

Whoris of threads which are often singularly beautiful in point of form and symmetry. These perithecia some times, like the pycnidia, contain nothing more than but in ther oble obg bodies of doubidul character variable numbes they increace in size, an whit turn contains from two to eight sporidia, or some larger indefinite number. The asci are generally of large size as are frequently the sporidia, which germinate readily. 526. We have then five different forms of fruit, three of which at least have the power of reproduction. We need not then be surprised at the immense rapidity with which they are developed, or the immense mischief which they cause by their parasitic habits. It is more especially in dry weather that they flourish, though when once established it is not a little adverse weather which effectually checks them. Indeed unless some remedy be applied at an early stage of growth they run their course, whether that is confined to the Oidioid stage as in the Grape mildew, or the parasite proceeds to "orm perithecia as in the Hop mildew, and the end is the more or less complete destruction of the plant on which they grow.
527 . The cultivator, then, must carefully watch for the very first appearance of his enemy, and at once apply the prescribed remedies. A very glight degree of intelligence, without the aid of more than a common pocket lens, will suffice to show him what he has before him. Our illustrations represent-1. Erysiphe graminis in the Oidioid stage, with a perfect perithecium and the asci extracted from it. 2. The formation of the perithecia from the mycelium in Erysiphe Pisi. M.J. B.

## Home Correspondence.

Fine Mildew.-Having the mildew very badly in my Grapes, could you advise me what to apply to them to eradicate the disease? I have kept my vinery perfectly dry, and have applied sulphur to the pipes and floors of neither ? I have also applied a compositon, bat most of them late, so that few of them are colouring. The mildew has attacked the Vines in a small greenhouse when in bloom, and also the leaf; I have applied sulphur there as well as in the vinery $S$. perfectly useless, or something worse, to apply sulphur in the manner described in this letter. The only way to make it act is to syringe the leaves and berries, and, immediately, while they are wet, to dust the sulphur over the mildewed spots.]

Fillage Botany.-In your excellent article on this subject last week you allude to the difficulty of finding teachers to instil the science into the minds of peasan girls in village schools. It seems that this grave hind rance to the advancement of useful learning will always, in a great measure, exist till these subjects are introduced into the Government Training Schools, and form part of the instruction of pupil-teachers. These pupil teachers are always selected from the cleverest girls in village schools, and those best qualified to impart their knowledge to others. Such a courge as this must afford an opening as pupil-teachers to many girls who have no tuste for other subjects, which according to the present arrangement are indispensable. I believe I can divine a reason for the outcry that is raised in certain qu arters about "common things." It is that certain ciasses are beginning to be jealous of throwing open everything to the people, and think to stem the tide of everything to the people, and thiak to stem the tide of But no ! But no! It is too late. The eyes of the people are no onger closed to their best interests. Popalar advancement will have its way, and it is more for the interes stream, than to excite animosity by vain efforts to stream, than to excite animos
stem it A Constant Subscriber.

Royal Exchanges.-The two following anecdotes, I believe, have never been in print. Some few years ago a block of cottages apparently converted out of a bari and said to have a doubtful title were put up for sale by auction. The auctioneer threatened to knock them down for 100l., when he observed a blacksmith of the name of Tiley nod his head; the price was advanced to guineas, and getting no other nod the property was knocked down to Tiley, who stoutly asserted he had not bid, but uitimately took them. A year or two afterwards her Majesty bought the ground on which her marine residence of Osborne in the Isle of Wight stands, and this block of cottages being within the ground proposed to form a park, Tiley was asked to sell it, and consented. No price was then named, but a few days after he was informed that it had been valued at $500 l$., which sum he gladly received. He was very wrath with which sum he gladly received. He was very wrath with quite forgiven him. The following is another royal exchange. Four cottages also stood within the lands exchange, Four cottages also stood within the lands
proposed to be converted into a park for her Majesty's proposed to be converted into a park for her Majesty's
marine residence at Osborne. The owner was astred marine reaidence at Osbome. to sell them, and expressed a wish to have in exchange four cottages built elsewhere. near Newport. The houses were duly erected, and in the centre of the front wall on a goodly sized stone he had cut in bold relief "The Royal Exchange." H. W. Niunn, Broadlands, Isle of Wight
The Origin of Wheat is Eyilops.-The following passage occurs in a letter addressed by M. Gaillardot, a scientific traveller in Syria, to M. Puel, Vice-Secretary of the Botanical Society of Paris, and is printed in the Bulletin of that Society vol, iii, p. 103. The letter is dated Saida, Syria, 15th Sept., 1855:-"Amongst the

Grasses wheh are gruwing with the plants 1 have
named to you, may be observed Andropogon halepensis Hordeum bulbosum, an Egilops triaristata, respecting which 1 must relate to you a fact which will probar, when crossing the AntiLibnanas on my way to Damescus, I gathered some tuft of Etgilops above the village of Cta. Some peasants of this village, who had joined me that they might the more safely cross the Boghar-Jantha, and who had several times observed with surprise my gathering the plants I met with, began to laugh, and one of them, approaching me, said, "Do you know what it is you not believe it open the spike and examine the grains, you will then be convinced.' Certainly the fellow knew no more of the labours of M. Esprit Fabre d'Agde than the latter knew of the popular traditions of the Syrian Arabs when he commevced his admirable investigations respecting the conversion of Eigilops into TritiJ. D. H.

Ciant Apple Tree.-There is at the present time very remarkable Apple tree growing in an orchard in the occupation of Mr. Pitts, of Powderham, near
Exeter. This tree has been Enown to produce seven Exeter. This tree has been known to produce seven hogsheads of cider in a single season. People now in the neighbourhood have assisted in gathering up af bushels of Apples from under it in a morning. Many of the inhabitants remember this tree about the beginning of the present century as a very fine one, every side and with an altitude in proportion. There is hon and proportion ; till its present appearance would argue that if it bore fruit in proportion to its size, its productive powers have not been over-rated. The trunk six feet from the ground gives a circumference of six feet four inches-another tree apparenty of the same kind in the same orchard girts six feet two inches.
Several others have arrived at nearly the same size. Weveral others have arrived at
How to use Peashells.-It has been often said that the man is a benefactor to his country who makes two blades of Grass grow where one only grew before, and by parity of reasoning it ought to be a good work to pared from what is commonly thrown away. Soyer informed us some years since how good pottage migh be made of very scanty materials, and his principles might be extended in many other directions. We have shoots of young Peas, but that can scarcely come under the head of economy. There is, however, an article which only for the pigs, which is really an excellent material for the formation of pottage. Those who have attended the French markets at a sufficiently early hour will have probably lamented over the misery of the people who carry off at a low price the Pearshe,ls for pottage, so if they had partaken of such soup as at a very following directions may be altered according to circumstances. They will, however, as they are produce very excellent dish. Take three quarts of water in
which meat has been boiled the previous day, and place it on the fire with a small t-asponful of pepper and three larger of salt (if the broth has been made with fresh meat), taking care, however, that neither ingredient is and a bundle of herbs, ineluding agood quantity of Chives or sweet Leeks, and if possib'e a sprig or two of Tarragon Wh small quantity only of the latter will be requisite. When the Pea-shells are sufficiently boiled pour the whrained off, pound the Peashelis and herbuor is strained off, pound the Pea-shells and herbs
mortar, returning them to the colander and rubbing mortar, returning them to the colander and rubbing of Peas, two Lettuces shred rather small, the more stalky the better, provided they are properly blanched, and a couple of sprigs of Mint, and you will have a soup which would not disyrace any table, especislly if a little fried bread is added, and an ounce of white sugar. If a thick soup is preferred a little flour and butter or other thickening must be used. It is not necessary to have anything stronger than common broth as the foundation. pared will doubt so far of the wisdom of the people who placed before them. An attempt was made some time since in the Finchley schools at teaching matters which might be practically and economically useful in after life, and the manuals of industry which were published have the meritat least of being extremely amusing if they are not know that such matters are notaltogether despised by the persons for whose benefit they are intended. Books on the subject are eagerly perused, and it is a fact that in a writer of these remarks is conversant, the book which has the greatest sale after Bibles and Prayer Books is a cheap Treatise on Cookery. A really good book on the subject, written by a person or sound sense and actually labourer at ordinary wages and with a cottage allotment, would command a very extensive sale. Such a book should comprise what is commonly called Sich Cookery as well as that of Health, and should give a few
pive in a plain and simple manner the principles of the common culinary processes, without an attention to which the best materials will be thrown away. There is not ane Fnglish cook out of ten who knows when to the best meat which was ever produced will be hard and unpalatable. This is but one example out of twenty of the alsolute necessity of such knowledge to form the absolure necessity of such
tolerable plain cook. I/. J. B.

Tomple frarlens.-A gentleman writing in the Times from the Temple, complains of various nuisances which he is obliged to endure in his chambers, and doubts whether these gardens will te what I have represented them till certain works are removed. No one can say but that the smeli from lare egas works must be injurious to health and vegetation. The same writer refers effects of the gas works. I bey to say that this unfortunate lot of trees has been visited by a locust, or what is commonly called caterpillar. They are committing sad ravages all ov $t \mathbf{r}$ the garden; and I understand that the country is, in different parts, in the same condition. This, therefore, can have nothing whatever to do with the smoke nuisance. In this opinion 1 dare say
concur. Samucl Bronme, Temp'e Gardens, Jully
Spiral Crouth.-The specimen you have illustrated under this head at p. 452 , and of which you have mislaid the particulars, was contributed by me. It was
a piece of the common Spearmint which had found its way to market and thence into the hands of a friend of mine, from whom I obtained it; I am quite ignorant of the circumstances of its growth. It appeared to have been (in its early stages) encircled very closely by some Bindweed or other; both had had a desperate struggle tor the mastery, the one growing outwards and upwards, the other prestictor" tightening its rasp every day, the other puting forth rreat vital power to overcome the same and thus forced into the unusual form which the specimen had assumed; unusual form which the epecimen, had assumed
the leaves also as will be perceived, had been forced into the alternative of developing themselves just where they could find an outlet hetween
Country Shows.-I, one of the many, can c rroborate the assertions of your correspondent, "Shacklewell," whose startling revelations of practices at Local shows are suticient to disgust all who cherish the least principle of honour and lonesty. I have ample evidence to show that they are more frequent at Cheltenham than in any other known locality. Being a competitor, I have had ocular demonstration of the system. Suburban growers, not satisfied with initiating themselves into the gressly to sui heir comittee, and procurin a the heir convenience, furtiring, such plants as will obtain soch and such prizes, so as to ensure a good return and profit: this must ultmately destroy the Society, whose prosperity is even now declinivg. Great Britain has no town more eligible for goo shows, or where more libera support woal than Cheltenham, but it it has been, and still is subjected that it has become it has been, and still is subjected, that it has become
by-word among those who would otherwise contribute largely towards its support. J. R.T. Hucclecote ciluacestershive. [We have been obliged to curiail con siderably this commulication.

## Borieties.

British Pomological, July 17, Mr. Turner Slough in the chair. This meeting was specially convened for the purpose of testing the value of some of the newer kinds of Strawberries. First on the list was Carolina superba from Mr. Kitley of Bath. This is a most excellent variety with a flavour resembling that of the British Queen, or rather perhaps that of the old Pine which was stated to be one of its parents. It is regards size we may mention that some of the fruit regards size we may mention that some of the fruit
measured five inches in circumference. Its perfect hardiness, and whether it will force or not are the only puints about it which have not yet been
satisfactorily proved. Sir Harry from Mr. Underhill was next brought under notice; but as the flavour of the fruit was spoiled by its having been packed in Moss, it was recommended that it should be again brought forward on the 4 th of August, when the suciety next meets. Admiral Dundas was exhibited by agreeable. It was suggested that it might, however, be a good sort for preserving. Some of the berries measured $5 \frac{3}{9}$ inches in circumference. The same exhibitor also showed what was called Downton Improved, and another seedling, both of which were recommended to be reproduced in August. Unripe fruit of evidently a very late Strawberry came from Messrs. Stewart oc
Nelson, of Liscard, in Cheshire. Empress Eugenie from Mr. Knivett, of Isleworth, was shown. It is a very large kind, some of the finest fruit of red and teuder, and in flavour superior to that of most large fraited kinds. Mr. Snow again showed his new Black Grape with a Muscat fiavour. It wes pronounced by all present to be a first-class sort, and it house with the Black Hamburgh. It was named Snow's
Muscat Hamburgh. A new French Grape came from

Mr. Rivers. It had the flavour of the Sweetwater with a slight tinge of musliness, and lonked as if it would make a good sort for out-of-door culture.

Extomological, June 2.- W. W. Saunders, Esq., F.R.S., President, in the chair. The President antion of Mr. Douglas as one of the secretaries, and expressed the regret of Society at the tuss cellent an officer as Mr. Douglas had proved himetf to be during seven jears' service. He further announced that the Council proposed Mr. Janson to fill his place, Society Mr F Bond exhibite next meeting of the Society. Mr. .. Bond exhibited a remarkable monstrosity occurring in Biston hirtarius, the body and
wings of which were female; but the antennæe were wings of which were female ; but the antennæ were
semipectinated. Mr. S. Stevens exhitited specimens of Petasia nubeculosa, Xotodonta carmelita, and N. Dic tæoides recently captured, together with larvae since hatched from eggs deposited by the females; also a selection of beautiful Coleoptera and Lepidoptera re tured by Mr. Bates. Mr. Douglas exhibited the case of a new species of Coleophora found upon Genisa angice also Cryptocephalus Coryli, Lebia crux minor, and other rare beetles recently captured. Mr. Stevens exhilited drawings of the larva and pupa of the singular LepidoLimonium on the Esex boas Catain Cox mmunLimoni Lime Lime Hawk moth under the bark of a Plane tree, particles of wood. Mr. Armitage exhibited various in teresting Coleoptera recently captured in the South of France. Mr. Saunders read a notice of the transforma tions of various Lepidopterous insects observed Natal by Mr. Plant. Mr. Westwood read a memoir on the Wing Veins of Insects, and a paper by Mr. White, containing descriptions of some new Homoptera from Borneo and the adjacent islat.ds, was read. The aunual excursion of the Suciety was fixed for the 2 1st June at

Fruit Culture. Under this name Messrs. Groombridge have commenced the issue of shilling pamphlets upon he cultivation of fruits. The author is to be Mr. George McEwen, lately gardener at Arundel Castle, and one of our most intelligent cultivators. He takes the Strawbsrry for a commencement, and, trite as the subject is, has known how to give it practical interest. The way in which a successful man achieves success is always ndeed a subject of legitimate curiosity. What Mr. IcEwen's general views are will be gathered from his preface, and especially from the following extract:

I cannot but thiuk that horticulture is as yet in its infancy, and seeing that the opinion of Bacon, that gardening is the purest of earthly pursuits,' is being endorsed by a growing host, who are entering with desirous to aid in oiving patronising ond direction to these efforts, to increase the taste, and so to eularge the boundaries of human happiness, even in 'common things.
will be distinctly understood, that whilst I intend to deal with practical details, rather than draw inferences, or trace causes, I have no sympathy with the sound practice are at variance; on the contrary, I am persuaded that, just in proportion as we advance in scientific inquiry, and penetrate into the mysteriss of nature, in a right spirit, the more satisfactory become
our daily toils; and that the closet and the field will yet unite in full harmony in giving utterance to certain sounds, telling of fixed principles, unvarying laws, and of the inexhaustible stores of wealth and nutriment the atmosphere, on the earth, and under the earcui, existing for, and waiting to be unlocked, and appied industrious men the minds and hands of inquiring ang the joys of all that live."
the joys of all that live." Three woodcuts, one which is coloured, will render the number attractive to those who prefer exercising their eyes rather than their understanding.
Memorials of his Time ; by Hemy Cockbum. 8vo. Black. For once reviewers are of the same mind. The delightful volume before us has been received with isvorr. by men of all shades of opinion and all varieties of tant It is pre-eminently the book of the teason. Of a work that has been so largely quated in all manner of revins to journals, and newspapers, it would be superfioust say more in this place were it not that the borticula $1 t$ is tastes of Lord Cockburn have been overlooked could it evident that he was a lover of gardening; nor coly callihave been ond a mind, and such eminently social habits. Ever in his "idho and tells us, he loved "to stand and admire the bue as yellow buls of Crocuses rising admire the blue and yelo the first days of spring in through the clean earth, in the first days of sprigity the garden of old Dr. Monro." And when days be down these gentle reminiscences of former days passed his days.
"For many years almost all my Saturdays, Sundass and holidays, were passed at Niddrie. I sighed howe every holday as lostt that was no architectural or much
hiscorical, interest. But the garden! the garden! un- for that science, with such a garden, such funds, and
seen and unseeing, it was a world of its own. That such a class. It was nearly alout the same time that unwalled flat space, of only four or five acres, contained absolutely everything that a garden could supply for 'man's delightful use '' Peaches and Oak', gravel walks, and a wilderness 'grotesque and wild, a burn and a ables and glorious bolly hedges-everything delightful either to the young or the old. Eden was not mor varied. And Eden is well worthy of its reputation, if it unbroken course of domestic security and pleasure death began, about 1815, to extinguibh, and circumstances to scatter, the gay and amiable family of which I was virtually a member; and I have since seldom revisited the generally silent walls. But the days Niddrie are among the last I can forget.
"My father was a friend of the Sir William Dich of Prestonfield, who flourished when I was a boy; a great sportsman, handsome, good natured, and (which goes a only boys (and how we were envied from the hill-side! who were always at liberty to play in his grounds, and to use his nice boat. So I knew the place thoroughly The reeds were then regularly cut over, by means of ground ; and this made Duddingston Les, close to the its present size. All between the loch and the house was a sort of Dutch garden, admirably kept. Besides the invariable bowling-green, which formed the open-air drawing-room of all our old houses, it had several long smooth lanes of turf, anciently called bowling alleys, parterres and lawn interspersed, fountains, carved stone seats, dials, statues, and trimmed evergreen hedges. How we used to make the statues spout! There was a it was impossible to tire. A very curious place.
What a striking sketch of an old Scotch garden
The Lords of Session have numbered other lovers of gardening in their illustrious ranke, but not one more guage he uses in describiag the establishment of the Horticultural Society of Edinburgh is a complete reflec tion of his mind :-
"The Horticultaral Society was chiefly the work of Patrick Neill, a printer ; a useful citizen, a most intel igent florist, author of an excellent Horticultural Tour in Flanders, of the article Gardening in the EncycloThe exotics in his little acre-garden at Canonmills put many a grander establishment to the blush. He was also an archzologist, which made him one of the few Society was one of the first buds of that extraordinary and delightful burst of floral taste which has since poured such botanical magnificence over our great places, and such varied and attainable beauty round our cottages, It is not in our public establishments, or in our great private collections, that its chief triumph is to lie looked in the poor man's garden ; in the prevalence of little flower societies; its interest as a subject of common practical works that are to be found in the houses of the humblest of the people. I cannot doubt its proving a great civiliser. In innocence, purity, and simplicity, th lorist-not the scientific botanist, but the florist of his own little borders, is the only rival of the angler. I wish we had a good Flowery Walton.
At that time he had settled at Bonaly, in the parish of Colinton, close by the northern base of the Pentlands, "I began," he says, "by an annual lease of a few
aquare yards and a scarcely habitable farm-house. But, square yards and a scarcely habitable frrm-house. But a village, and erected a tower, and reached the dignity of a 20 -acred laird. Everything except the two burns, the few old trees, and the nountains are my own work, and to a great extent the work of my own hands ness than has been my lot here; where the glories of the prospects, and the luxury of the wild retiremen have been all enhanced by the progress of my improve mappy, and often tremble in the anticipation that the cloud must come at last. Warburton says that there was not a bush in his garden on which he had not hung a speculation. There is not a recess in the valleys of the Pentlands, nor an eminence on their summits, that is not familiar to my solitude."
We need not say that the charm of this book is its amiable and gentle, but most entertaining and valuable gossip about all manner of men and things that a long
carcer brought the author acquainted with. Two horticultural bits are not unworthy of standing by the sid of the legal, historical, municipal, and political scraps in which the work abounds. The first is a note upon the Royal Botanical Garden:
"It was in 1823, I think, that the last fragment o our Royal Botanical Garden was removed from its transplantation of the whole to its present site at Inverleith was completed. No garden could be made to walk a mile with less injury to its liealth. Scarcely a sheir first or tree was lost, and after recovering from their first sickness, they looked fresher and prouder than ever. Dr. Graham, the Professor, was a respect abant, Macnab, ha good teacher, and in his first lieuie nant, Macnab, he had a most admirable practical man. That chair is one of the best botanical prizes in Britain.
Fow things of the lind ane more enviable than a taste

The Horticuitural Suciety; about the same time that 1809, opened its kindred and adjoining 'Experimental Garden.' Coniucted, as it was at first, by such men as Ellis and Neill it could scarcely fail, and has alway done as well as low funds allow. Hut Flora and done as well as low funds al

The seend relates to markets of Ediuburgh, and to "The opening in 1826 of an ear
"The opening in 1826 of an establishment callod the New Town Markets at Stochbridge recalled some curious, though not distant, recollections of Edinburgh. It was only about 15 or 20 years before that our only fish market was in the Fish Market Close, a steep, narrow, stinking ravine. The fish were generally thrown out on the street at the head of the close, Women ; and then sold unwashed-for there was not drop of water in the place-from old, rickety, scaly, wooden tables, exposed to all the rain, dust, and filth an abomination the recollection of which greatly im paired the pleasantness of the fish at a later hour of the

Yet when the market was removed to its present situation below the North Bridge, there was an outery as if hereditary nastiness, like other abuses, had been was ay time, necessary or comfort. I doubt if there was a single fish shop in Edinburgh so early as the a process. They were entirely in the pass through as bad a process. They were entirely in the hands of a college of old gin-drinking women who congregated with stools and tables round the Tron Chureh. A lew of the aristocracy of these ladies-the burgo-mistresses, who booths-marked their dignity by an awning of dirty canvas or tattered carpet; and every table had its tallow candle and paper lantern at night. There was gutter, which, however, was plentifully used. Fruit had a place on the table, but kitchen vegetables lay bruised on the ground. I doubt if there was a fruit shop in Edinburgh in 1815."

## We wish int 1815. <br> words, a good gord, to borrow some of our author'

 words, a good gardening Cockburn.
## Garden Memoranda

Mr. Francis's Nursery, Hertpord.-Those who are desirous of seeing Roses in perfection on Manetti stocks should lose no time in paying a visit to this nursery, where many thousands are grown in this way, and most of the finer kinds being now beautifly in blossom, an opportunity is aforded not for which it has how far this stuck answers the purposes from the many been recommended; but also of selecting from the many planting next autumn. That Roses will not only grow and thrive, but also bloom profusely on the Manetti stock there is here ample proof both in-doors and out. Buds ake well on it, lut it should be remarked that the tocks are properly prepared to receive them, and that they are inserted so near the ground that it is expected they will uitimately root into it, and so in time render the tops in some degree independent of the stock. Immense quantities of dlanetti are grown here for sale. We sav Roses, fruit trees, shrubs, and evergreens, compre with Roses, fruit trees, shrubs, and evergreens, comprised the principal stock of the Nursery. 'Ro grow Roses well on the gravelly soil which constitutes the staple of this nursery Mr. Francis finds that he must transplant often, manure heavily, and fallow here and there, as ground becomes vacant, with Potatoes. The manure employed is laid up in a large heap to rot, and is freely mixed with road scrapings; the "house pail" is also poured over it every morning. In this way a compost is obtained which is lasting in its effects, and therefore the ground is always kept in "good heart," a condition which Roses above all things require, and in culture. Standards here as elsewhere are worked on the common Briar, but this season Mr. Francis is trying how far the Manetti may or may not be suitable for lialf standards. The Celine is also employed here as a stock ; but, as has just been stated, dwarfs are all or very nearly so, on the Manetti, on which most arieties seem to thrive, with the exception of La Reine, with which it does not appear to agree. Mr Francis, however, says he does not despair of ye making even this grow on it.
A plantation of Géant des
A plantation of Géant des Brtailles stated to contain 2000 plants, is at present all in full flower here, and presents, as may be imapined, a striking appearance. is however quite as useful as the Géant, though not so brilliaut. These two varieties being profuce bloomers and lasting long in beauty, would make excellent bedders, and should, we think, be larsely employed for that purPrevost, Duchess of Sulherland, and flowers of that class, we need nut speak; but of General Jacquemino be said. Both are large Roses possessed of hardly colours, very fragrant, and in all respects highly colours, very fragrant, and in all respects highly attractive. No good collection can be considered
complete without them. Mrs. Rivers and Madam Vidot are two beautiful pale bluah varietieg, which require only to be seen to become universal favourites. Gloire de Dijon is also a fine Rose niti a Noisette habit, large and double. Madam Domage is the way of Baronne Prevost, is a large showy variety,
which caunot tail to tind admurers. Lior fine form, few beat General Castellane. Leon des Comhats is a good gool colour: and Auguste Guinoisean, is a beautiful arge full red variety, rood in shape, and sltogether desirable sort. The above are a few first-rate kinds but among them Géant des Batailles, Jules Margottin and General Jachuemmot are the varieties to
which we would more particularly direct attenWhich we would more particularly direct atten
tion. The first, which is not only the earliest bu the latest hose of the season is now pretty well known, the second is not half so much cultivated as it sloould be, and to a delightful perfume, the third adds a brilliancy of colour which is seldom met with, and which wil always recommend it. This and a very dark seedlin aamed Victor Truillard, from Mesars. Standish and Noble, were the two Roses that appeared to be mos admired at the last exhibition in Regent's Park.
As regards the cultivation of Roses, Mr. Francis says they should always be planted, if possible, in a compost of stiff loam, rotten dung, night-soil, and leaf mould Where they have grown siroug after three or four years standing, they may be taken up, the ground well renewed the roots closely pruned, as well as their shoots very much thinned, and then rlanted in the same situationthey will then produce as fine hlooms as when firs ransplanted trom the Nursery. This should always b one in the farly part of November. Roses bloom we the first year after being transplanted, if carefully attended to. They should, when transplanted, have strong stake attached to each standard to prevent the wind from moving them, and then well mulched round during winter. The ensuing epring and summer they should be plentifully supplied with liquid manure For pruning, with the exception of Teas and Chinas, December and January are considered the best months many sorte, such as Hybrid Chinas, Hybrid Bourbons and some of the strongest growing Noisettes and Bourbons, require very little pruning; about every third year they should be pruned-in close, so as to make then produce new wood, and to prevent the plants getting old and ugly in appearance. The the shoots taken off, it being found to flower only on the last year's wood. Another excellent plan for atandard Hybrid Chinas, many of the Pillar Roses and Standard Climbers, is to prune them in quite close just after they have done flowering ; they will then produce new shoots the same summer, and flower abundantly the next season. February and March are considere the best months for pruning Teas, Chinas, and Bourbons

For protecting Roses, when planted out on their own roots, such as Teas, Chinas and Bourbons, dry Moss,
Fern, or small Spruce Fir boughs, may be stuck round the plants, which will Fir boughs, may be stuck roun sharp frosts; also the very much protect them from covered with rotten manure early in December, which should be dug in the following spring.

## Miscellaneous.

Influence of Soil on the Distribution of Plants.-In memoir presented to the Imperial Academy of
ciences of Vienoa, March 6,1856, M. Stur, treating of sciences influence of the soil on the distribution of plants, gave the results of the observations made by himself in he Alpine region of Austria. The soil on which plants live is either rocky or disintegrated. The "rocky" or
solid soil is either of calcareous or argillaceous and solid soil is either of calcareous or argillaceous and siliceous nature. The "disintegrated" or "etrital soil is composed of fragments from the "rocky," agglutinated by mineral substances of tertiary origin; it contains therefore lime, silica, and alumina, in more or less equal portions. The rocky soil prevails in the higher eleva tions of the Alpine region ; the detrital soil fills up the bottoms of the valleys and depressions. The first cor responds to the continents surrounding the tertiary sea or to the islands emerging from it ; the second indicates the extension of this sea itself, as formed by drift deposited on its bottom. The nature of the roots is an essential condition for the thriving of any plant on either of these soils. Species with annual fleshy, or with compound fasciculated roots, or with underground stems, can only live on detrital soil ; those with woody roots with numerous ramifications are best fitted for the rocky soil. A comparison of the flora of the higher calcareous region with the mica-schist flora proves the plants of either of them, although equal in size, to differ so materially from each other in shape, that it must be admitted that the geological constitution of the soil has an influence on the vegetation covering its sur ace. Alpine plants carried down by the streams into the plain increase in size and grow moxe luxuriantly in their new station. Forest trees shrink more and moore in size and shape as they reach greater elevations Both these facts bear witness to the influence of climatal conditions on the development of vegetable life. Cereals occur exclusively on the detrital soils o the lower region. They follons the Alpine tertiary gravel in its variations of altitude; butare ouly able to produce a rich harvest where they grow on a detrital nearly composed of lime, atumis same soil is like nearly equal proportions. plants of the lower reginn. If this soil be mixed with heterogeneous substances (as salts, on the seahore, on the banks of saline lakes, on plains with saline fforescence, or alove saliferous rocks), new genera and species, cot occurring under oruinary circumstances,
make their appearance. The Pine (Pinus abies, L.) accommodates itself to every sol, and therefore ranges
from the lower to the upper region, maning the limits between, and participating in both. Its vertical oscillations correspond to those of the cereals, and to the distribution of detrital soil accessible to atmospheric heat. New vegetable forms, together with new rocks, make their appearance in the higher rocky regions Such are certain species peculiar to the calcareous micaschist, as Artemisia nana, Sand., Lomatogonium carinthiacum, Rehb., Gentiana prostrata, Haenke, Herniaria alpina, L., Braya alpina, Hoppe, \&c. Wherever a great variety of rocks near to, or interstratified with, each other appear within a comparatively narrow space, the plants pass from one of these soils to another, undergoing at the same time frequent alterations of form speces nearly allied to each other are pecuiar to such spots, producing hybrid and intermediate forms. The
distribution of genera and species in the upper region distribution of genera and species in the upper region
answers exactly to the geological constitution of the soil. Calcareous and mica-schistose Alps have every one their peculiar flora. Near Windisch-Matzey and Heiligenblut the mica-schist and the calcareous micaschist floras appear side by side. At the "Tauern" of Radstadt, where nearly all Alpine rocks are heaped together, the floras of the calciferous rocks, of the micaschist and of the calcareous mica-schist appear simultaneously. M. Stur appended to his memoir a catalogue of about 1000 species of plants collected by him within the Alpine region, and arranged according to their localities and to the geological constitution of their native soil. Communicated by Count Marschall to Annals of Natural History.

## Calendar of Operations

(For the ensuing week.)

## plant department

Conservatory, \&c.-Orange trecs and other plants known to be liable to the attacks of red spider must he
frequently examined for this pest, and well washed with the engine immediately it is perceived, takin' cane to bruise or injure the foliage, and placing the affected plants so that every leaf may be reached. Also keep a sharp look out for other insects, and spare no trouble to
keep these under. Go over the twiners frequently and keep the shoots nicely regulated, cutting out where necessary, to prevent their being too thick, and
shortening any that hang down so low as to interfere with other things. Attend promptly to the removal of with other things. Atend promptiy to the removal of
decaying specimens before they liecome unsighty ; and decaying specimens before they leeome unsighty; and
also eee to having plenty coming forward with which to supply their places. Cold pits. The stock here will pro-
bably require rearrangement about this time, as some of the specimens, having completed their season's growth, will be better in a shady situation out of doors, and their removal will allow of giving more space to those left Young growing stock and late flowering plants that have yet to make their season's growth should receive the most careful attention, as if well treated they will
make rapid and vigor us growth at this season, and nothing in the way of good soil, careful potting, or proper accommodation will compensate for the want of this. Indeed, there is no possibility of securing free growth from hard-wooded plants in tright hot weather
except by moderate shading and maintaining a mois atmosphere by sprinkling the plants overhead morning and evening, and air must be given liberally to keep the wood strong, avoiding as much as possible ex posure to drying winds. Any of the specimens
which require more pot room should be shifted as soon as possible, taking care to have the ball moist, and keeping them rather closer and the atmosphere moister than usual for a fortnight after potting. Get
the young shoots tied before they begin to fall on the ground and injure each other. Cut down Pelargonium as soon as the wood is properly hardened, and keep
them very sparingly supulied with water at the root them very sparingly supplied with water at the root until they start into growth, but sprinkle them overhead frequently, which will cause them to break more strongly. Get cuttings of favourite sorts rooted, and attend to those that were struck early in the season. Continue to pot Cinerarias as strong suckers can be obtained, placiug them in a close part of a cold frame until they get established in their pots; but avoid placing them in heat, where they syeedily become a prey to insects, millew, and never do any good. Let adequate precautions be used to protect the tender greenhouse plants, placed tempcrarily out of doors, from the effects of frequently recurring storms of wind and rain screens may be advantageously employed; all stakes and supports should be proved, and the pots closely examined, lest the plants suffer from defective drainage or the presence of worms. The young reserve stock for filling blanks in the stove should be sedulously encouraged by progressive potting, and a warm equable Torenia asiatica, will amply repay attention bestowed on their culture; decayed L'eech leaves, with a mixture of eharp sand, form a compost peculiarly suitable to the first-named plant. The stock of pot Roses should be looked over, useless wood and decayed blossoms soil, and burnt earth may be used effectually. Camellias which have matured their flower-buds may receive additional assistance either by soil or manure-watcer, as
circumstances alcw.
forcing derartment.
Pineries.-Air should now be given liberally to young stock in dung pits, in order to secure strong stocky drying winds by giving bach and front air liberally drying days, for this would not serve the end in view ; but a moderate circulation should be secured at night, giving no more during the day than may be necessary to prevent the temperature getting too high. This, with careful attention to the state of the roots, keeping the bottom heat regular, the soil in a nice healthy state as to moisture, and giving a liberal supply of manure water to such as are well rooted, will be found much more conducive to strong stocky growth than exposing the plants ton freely to hot drying winds, which would probably check and throw them into fruit prematurely.
Use every means to afford plants swelling their fruit a thoroughly moist atmosphere, sprinkling passages, \&c. frequently, and shutting up early on the afternoons of bright days, giving a gentle dewing with the syringe, and saturating the atmosphere by sprinkling every available surface ; also give these plenty of clear strong manure water at the root until the fruit begins to change colour, when the soil should be kept rather dry, which will improve the flavour. Vineries.-Attend to former directions as to thinning the fruit in houses intended to furuish a late supply, and see that the bunches are severely thinned, and also that the crop left is not too Weavy in proportion to the strength of the Vines Where the fruit is swelling, be careful to maintain a
moist state of the atmosplere, and give every possible moist state of the atmosphere, and give every possible
attention to the roots, beeping the border in a healthy attention to the roots, keeping the border in a healthy
state as to moisture, and if watering is found necessary, use good strong manure water. where the fruit is colouring, and do not allow plants in pots to remain in the house to cause damp, which, despite every care in ventilating, is apt to sette on the berries and spoil the bloom. Where the fruit is ripe and expected to hang for some time, the atmosphere of the house should be kept as cool as possible ; but a little fire heat will probably be necessary occasionally in order to keep the atmusphere dry. Peaches.-Expose trees freely to the nir trom which the ruit has been
gathered, lieeping the ventilators open day and night, and spare no attention which may be necessary to pre serve the foliage in a clean healthy state until the young wood is well matured. Where the fruit is ripening,
shading the liouse on the forenoons of bright days will prolong the supply, and will not injure the flavour as much as would be the case with most other fruis.
Fics. Trees swelling their second crop muct be well Fics. - Trees swelling their second crop muct be well
attended to with water, giving sufficient to moisten the whole of the border thoroughly, if this has been allowed to become dry while the first crop was ripening. Use the syringe freely on the foliage, shatting up eally in order to keep the atmosphere moist.
flowfr garden and sirbubberies.
After the plants have fairly covered the ground the great point will be to preserve that symmetrical appearfower garden is absolutely ne wich in a render the effect pleasing. To do this will involve frequent attention and considerable labour for some time to come, as many of the plants will be inclined to grow much to trongly for others, and will also be continually encroach ing upon the ellgings and extending beyond their prope imits. Plants of a weakly habit of geowth, as, for instance the more slender growing varieties of Verbena, may be assisted in dry weather by an occasional watering
with manure water ; but for those that grow too strongly there is no help except thinning and pegging down the sloots. In shortening back shoots that incline to extend beyond the edges of the beds, avoid the least appearance of formality by thimning out the under shoots and keeping all parts of plants, of equal depth or michness, ar allow according to the arrangement. Climbers on walls must be attended to as they advance in growth, keeping the young shoots neatly laid in, \&c. The climbing Roses will also require to be gone over occasionally, for the purpose of cutho hould be cut out at the same time, to allow or laying in the strong young shoots which will bloom much
finer next season than the old wood would do Phloxes and other herbaceous plants must be neatly tied up; but avoid hudding the shoots to gether, as is sometimes done even about well kep places to save time. Any of the perpetual blooming Roses that have flowered very freely should be assisted stable or farm-yard tank; indeed, too much of this can hardly be given to any of the autumn-flowering varieties.
hardy fruit and kitchen garden.
Select a bit of open light ground and prepare it for manu spinach by giving it a heary dressing of should be sown at once, and in drills in beds, allowing wide allevs so as to be able to gather the crop without trampling the ground, also provide ground for winter Onion, \&c. Finish planting out Brocenl and winter greens as speedily as ground can be obtained, for, unless the autumn should prove very favourable, those planted after this time will not attain much Get Endive planted out on very rich soil, also Let suce, to maintain the succession, and attend to other small
salad herbs. See to securing a good supply of Parsley for winter use, which is always largely in demand. A good bed should be planted in some convenient place for protecting it during severe weather in winter. The soil should be of a light texture, deep, and thoroughly drained as a preventive against damp in winter. New plantations of Strawberries should be made at once, selecting the strongest young plants and keeping them well supplied with water until they get established Attend to Celery and all recently-planted crops with water if the weather happens to be warm and dry

## COTTAGERS' GARDEX

Savoys, Green Kale, and Cabbage plants may yet be planted with every chance of success. A good breadth of Turnips might be sown, and a few rows of winter Spinach would prove remunerative. We recommend a
few ridges of Celery most particularly ; its value as an rew ridges of Celery most particularly; its value as an ingredient in soup alone should recommed it.

## The Amitultuxal Gateter.

 sATURDAY, JULY 19, 1856.The Chelmsford meeting of the Agricultural Society has been signalised by the enormous prices which the breeding stock exhibited have reached This annual gathering is now rapidly acquiring for its live stock show what its implement departmen has long possessed, the character of a great annua market. In the one, too, as in the other, the real aware of merit is that given by the voice of those self-constituted judges-purchasing spectators. And it is no surprising thing that here heretofore elsewhere the official awards and those of the public elsewhere the officia in every instance been the same. The importance of the official judgment is however not diminished in the least by the circumstance, that in the long run it is liable occasionally to be overruled. The need of accuracy here rests upon the fact that a large per centage of purchasers are necessarily guided by the opinions of others rather necessarily g confidence in their own; and the responsibility of the Society's judges is great just in propor tion to the influence it thus possesses in effecting the distribution of parlicular kinds of stock.

There is thus need of anxious care that the office goo
perience in the particular class of subjects submitted for their decision : and no where is this more im, portant than in the case where breeds of live stock portant than in the case where to be adjudicated on. Distinctions of a merely local character and prejudices founded on them are so liable to warp the judgment that the difficulty of obtaining the services as judges, of well qualified and experienced men who are not themselves exhi bitors, is very great. For instance, South Downs, Hampshire, Wilts, and Shropshire Downs may all compete as short-woolled sheep, and a partiality for local characteristics will often incapacitate a man who may be otherwise well fitted for the office of juror on the merits of the breed. Whether the causes here suggested may have been in operation at Chelmsford or not, certain it is that the awards in the class of South Downs have been canvassed with unusual severity. It is stated on one side that Mr. Jonas Wers's sheep which has received the second prize is not the best of those he shows, and that "the best sheep in the yard" is thus passed over unnoticed by the judgres; while, on the other side, Mr. Overman's ram to which the first prize has been awarded, is defended in its first place on the ground notonly of its own undoubted merit, but also because of a recent award in its favour by the judges at the late Norwich agricul tural meeting. We do not pretend to determine the controversy, or to say on which side of it the truth of the matter lies. Its mere existence is sufficient to call the attention of the Society most anxiously to the subject of the appointment of its judges, whose awards must command the respect of exhibitors if the Society itself is to be of any service to the country. That it is at present of great service both by determining merit in the stock exhibited and by bringing together buyers and sellers of it, was plain to any visitor at Chelmsford during the English breeders were present as buyers in the English breeders were present in short-horns more especially their demand was most imperfectly met by the supply. Prices thus ruled exceedingly high. Mr. Townkfiex's prize bull "Master Butterfy" was sold, Camperdown, Geelong, Victoria, one of the finest cattle districts of Australia for the enormons sum of 1260\%. Mr. Ambler's prize bull calf was sold for 200 guineas. Lord Walsinghamis prize Southdown ewes, which received the first and second prizes in their class, were sold for 20 guineas and 17 guineas a-piece respectively. Three of Mr. Onerman's sheep were let for the season mo. wand's prize white sow of small breed, with which he won the prize in its class at Paris, was sold for 35 guineas. These are prices indicating remarkable activity in the market for all kinds of well bred stock-prices sufficient to maintain all the energy and skill and therefore the reputation of our breeders.
As to the Implement department of the show it is sufficient to sefer to the report in the following columns, where the success of the reaping machine, the progress towards, we hope, an nltimate success of the steam plough, the competition among ploughs, cloderushers and cultivators, which are the principal features of the meeting, are reported in detail.
On the general relation of the Society to exhibitors in this department, we merely refer to the two main facts of the matter, that a portion only of the machines exhibited were subjected to trial and examination by the jadges, and that the rest were shown at work under the superintendence of their respective manufacturers. Both of these are steps in the right direction, the one ensures a fuller investigation and therefore a more trustworthy official judgment of the implements exhibited: the other recognises the unquestionable truth, that the personal interest of exhibitors is after all the true incentive to efforts after im provement, and that free and unconstrained competition will lead most rapidly to the success of those who heartily engage in i

## APPEARANCE OF CROPS

Rhins of Galloway.-On the generality of the soils of the district the white crops of all kinds iromise to be bulky, and with favourable weather Wheat is just a hand ; the weather for the last few days has been exceedingly wet and stormy for the season, and has done a good deal of injury to the farthest advanced Wheat the Potato crop, and the Beans. Turnips do not look well, and many complaints have been made about the fly. Mangel looks very sickly, the weather being much too wet and cold tor it. A. H. M'Lean, Stranraer.

Southampton.- Wheat thin on the light lands, pretty good on heavier soils; very good in some instances. Barley a good crop. Oats pretty good. Beans Barley a good crop. Peas pretty good. Grass crops good. Root

## crops various; in many instances 1 IV.

Cavar and Longrord.-Wheat little but very promising-no mildew. Oats over average. Turnips only late but eafe. Potatoes very luxuriant, abundant, and as yet no blight. In this poor and wild
district there is very litte else than Potatoes and Oats, district there is yery hitle else than Vetches. The meadowing generally on low lands not fit for tillage and in boggy soils, these are rarely if ever manured. There are reports of some oppearance of
blight on the Potato leaves, but nothing on which I can rely; there is a great brendth of them, and as they were tor the most part early planted, there is every prospect of a greater sapply of them than we have had aince the appearance of the disease. For many year past the Wheat in Ireland has suffered severely from think, we much so as almost to cause its rejection, some five or six years grown a small pateh, a very small one, of Mummy Wheat, which has suffered so much from mildew as to produce scarcely a plump than one-fifth filled; this year in my little patch there is not a rusted leaf. It is however a first trial on this land. J. M. Goodiff, Serably, County Cavan.
Northumberland-Wheat, Barley, and Oats on free dry lands in the valley of the Tyne are looking well, and if the weather be favourable for blooming will be a full average crop. On some early spots the ear is fully out, and with a few warm days would be so generally. On strong and wet lands the crops look harvest till the last week of August at soonest Beans and Peas there are very few grown. Hay and seeds cut up well; there is none yet stacked, and the weather is very broken. Potatos look song and growing vigorously, and look like being a full crop. On wet lands the crop will be bad and a much smaller breadth will be sown than had the season been favourable. Thomas P. Dod, Anick Orange, Hexham

Wetherby, Yorkshire. - Wheat on our limestone is very vigorous but is thin of plant. The crop must be
only very moderate. Barley is very good. Oats better than usual. Beans very full crop. Potatoes good. Turnips are extremely promising. Hay the
heaviest crop known for yeara. The wet weather has done mischief to the heavy crops of grain, especially Barley. Half the hay crop of this district is at the present moment undergoing saturation for the fourth or last week has caused great expense to the hay grower unless w an immense injury to the crops of hay. J. Hannam here is every prospect of an abundant crop. Winte Wheat is now in ear, and the earliest fields are blooming; there is generally abundance of louk, and the ears are both large and close, the exception is where the
crop is afier plain fallow, which lost plant in spring, but happily plain fallows are now all but superseded. Spring
sown Wheat is remarkably luxuriant, and in point of sown Wheat is remarkably luxuriant, and in point of Barley, and Beans are all excellent, and the danger is that they will be too bulky. Potatoes are not so promis ing in appearance as they were a fortnight ago; some fields have been considerably thinned of plants by the stems or roots having become rotten from the surface of the earth downwards. Tursips have been much damaged by the fly, and are now late and in rather a precarious situation, still with a favourable is generally in the rich, and a heavier crop than it has been for some years. July 15, George Hope, Fenton Barns, Drem.
Hants, -The erops of Grass are pretty good, hay arop good, and mostly well harvested. Swedes and
Turnips very much injured by the fly. Potatoes good Turnips very much injured by the fly. Potatoes good

- some disease. Wheat promised well in April, siuce which time it has grown worse ; the present prospect i not good ; thin on the ground ; very uneven, and considerably blighted. Barley promised well; but has allen off very much of late; it has pat on a white hue very frosts of last week, and the week before, how that may be I do not know; but from personal observation from Alnsford in Hants, to Dorchester, where I have generally are not good; and the Barley, especially, has put on a very suspicious look. There is no distinc-
tion-chalk, gravel, and loam, seem alike affected. The tion-chalk, gravel, and loam, seem alike affected. The
Turnips in Dorsetshire are good. James Eames, Bech Farm, Lymington.

GREAT MEETING OF THE AGRICULTURAL SOCIETY OF ENGLAND AT CHELMSFURD.
The celebrated apophthegm, that England could not bear an annual revolution, is quite as applicable to our agricultural implements as to our political and social in-
stitutions. To the journalist, who has to chronicle these annual meetings, it would certainly be more agreeable i he coald announce annually some innovation on the processes of ploughing, sowing, reaping, and threshing, beginning to attain perfection, while according to some authorities, they are only in their infancy. It would be well perhaps for the cause of agricultural progress, if we
coultainly better that we cannot. We require time to digest as well as to eat, and our implement makers supply us with such profusion of material that the requires, moreover, time to wear from repletion. He plements before he is compelled to purchase another nder the penalfy of being pointed out as quite out of ate, and altogether hehind the requirenaents of the age Monday, a private trial before the judges of the mplements competing for the prizes; which, how ver, were offered to one class, that of tillage imple ments, only, and to the implement field this year was added a department for the exhibition of imple. ments in mution, to enable farmers to form a judg ment on their comparative merits, as well as for the benefit of the sight-seers. If we might ven ure to suggest further changes, it wowld be hat the farmers in some district-a fresh an their farn year-should be induced to make trial on their farms results should be reported by a jury-constructed on the rand jury principle as to numbers and verdict by the mainrity-one half to consist of the mostactive practical farmers of the neighbourhood, and the other half of some of the leading members of the Society mos ccessible to the district. The report should also con tain a detailed account of the reasons for their decision. A trial of this kind would come, we should think, under the rule of the society, which provides for the indemni-
fication of farmers fur any loss which they may sustain rom experiments undertaken at the suggestion and under the direction of the Society. We are sure ther are many farmers who would allow the experiments to be conducted on their land witheut compensation, so that the chief expense would be for the professiona assistance which it might be considered necessary to associate with them. Let us proceed, however, to record what actually took place at Chelmsford in the depart ment of implements in motion. The order of proceeding was this: There had been, as we have said, the private rials before the judges during the preceding week, and cause of steam culture is certainly making an advance, but the time must be long before it will be able to adapt itself to varying circumstances
in the same manner as is done by the plough in the same manner as is done by the plough worked by horse power, and with such beautiful Suffolk were almost tempted to wish that the day may be far distant. Still steam ploughing is making a certain mount of progress.
The resping machine has attained success, the result of progress already made. There were three reaping machines at work on Tuesday on a piece of Rye near the show-yard, Bell's, Dray's, and M'Cormick's, with a somewhat longer stubble certainly than mowing or fagging, but much closer than reaping, and whether like Dray's with the tilt delivery they laid the corn in separate sheaf-heaps, or like the others in was much less seatering, and necessity for raking, than in the case of mowing Wheat It may be well to remark here that the main difficulty hitherto has been to effect a good delivery of the cut
corn. M'Cormick's appears to place the swath less corn. Mrenly than Bell's, which has been improved by the substitution of elastic belts for a revolving wel
corn in this machine falls directly backwards, with the course of the machine, and it is delivere parallelly with this direction also, only a certain 'way the land from a lrater height than the root end, fall farther from the machine, and so the swath lies some what across the line of motion, enabling the binders to collect it easily. These reapers have now made such progress to pexfection that no large farm should be ought to be gangs of labourers going about from tinera fill reaping with them by tho acre, like th inerant crill-men of some districts, and the itineran steam threshing machines of the present day. With its first appearance in England a few years back, we have seen the Wheat and Oats of a whole tarn cut with it; and except where it was laid, it made ng machines are not more generally adopted we mus confess suprises us. Their value cousists not so much in the lower price at which they cut the crop as in the command over it which they confer on the farmer and the loss from the shedding of the grain which they prevent. On the eastern and the western sides of England, under the same conditions of climate, two prac ices prevaillas to the period of cutting wheat. On the western side they cut it while the straw is still far from
dead, and the grain comparatively soft. The skin of the grain thus treated is thinner, and the grain is pre ferred by the millers. On the eastern side, on the corn the the poplation of being cut; there is mos The district is therefore dependent on itiserant harves men, of some of whom it would be well rid. The farmers are often short of hands and large quantities of grain are slied from over-ripeness. On this latte the field es con mistake, for the broadshare is in shed corn, therefore, comes up to tell how much has been wasted, and it proclaims in the plainest language
that the loss has been sumelent to seed the ground, ase in many cases much more than sufficient that the reaping machines would come into pla there the true way to render them popular is to enlist the sympathies of the men on their side, by putting the machines in the form of an advantage to them by the abridgement of their toils and by the larger wages which they can obtain by means of them rather than as saving of money to the farmer in the cost of harreasing. Norfolk, aysin, is a level county with large fields
in which reaping machines could be used with the greatest advantage. We have heard it alleged there against their use, that they call mow it cheaper. If they can, the quantity of rakings are very great, and the dirt in the quantity of damaged grain obtained from the rakings enormous. We camot help thinking thererore, that even there, where labour is comparatively lew, the introduction of the reaping machine into general vantag
But we return to the implements in motion in the ard. Of these the most important are the threshing orchne. What a change has taken place in the procems he rule, the during 30 or 40 years. Then the finil was was chiefly used in Scotland and the border counties Threshing machines were to be found in some of our best cultivated English counties worked by horses. Now the uncertain water power, and the motil more threshing machine, even in the districts where the two st in favour, and the sole questions now are between the fixed and the lucomotive steam engine, and which threshing machine $t$ s select out of all the perplexing variety exbibited on Tuestay and Wednesday. the open field there were seven locomotive engines axhined by the following makers. We take thom \& May, Whitmore, Burrel of Thetford, Turner, Roby, and Scott. Iu their separate stands steam threshing machines were exhibited at work by the following makers:-Clayton \& Shuttleworth had a complete set of fixed implements for threshing and dressing the grain hreaing, winnowing riddling ohe hreshing, straw shaking, winnowing, ridaing, chal exbibited a portable machine: Hornsby, locomotive Sparkes \& Son of Norwich, locomotive; Barret, Exall, A Andrew, a stationary engine; Clayton \& Shuttle worth, a combined portable threshing straw shaking, winnowing, riddling, chaff separating and Barley horning machine; also a set of fixed machinery for threshing and dressing the grain for markict at one operation. Ransome exhibited the locomotive which obtained the prize at Carnisie , Garetor soricultural machinery in cluding corn mill chaff cutter and cake crusher; Holmes \& Sons, a locomotive threshing machine; Dray, a locomotive. This then was the variety of threshing machines and other cognate implemente, with which the science, kill have provided for the farmers.
The requirements in a threshing machive are that it hall thresh clean; that it shall not injure the grain. The iojury done to the grain by threshing with machinery was formerly the urand anument of the adhe ents of the flail. The third requisite is, that performing hese operations well the machme shall work cheaply that is, with as little consumption of cual as possible.
With regard to breaking the straw, that was formerly considered an advantage rather than a defect, as it.was he sooner decomposed in the dungheap. The old Scot tish threshing mills reduced it almost to the state of very long chaff. Now, however, when feeding with arious mixtures in which straw cut into chaff enters argely, the more unbroken the straw comes from the careshing machine the better is it suited to the ehaff
cutter. As regards clean threshing, the different mplements appeared nearly on an equality We could scarcely find a grain of corn in the straw decould scarcely find a grain of corn in the straw de-
livered by any of them. As regards breaking of the corn, that appears to be the point to which the makers of these implements pay the least attention; we observed several which bruised it considerably; when pointed out, there was always some excuse oftered machine. Let us here advert to the question, whether to a farmer about to purchase a threshing machine these exhibitions alone would furuish data for a decision, or whether the more prutricted trial of a year's duration on the farm would not better meet the equirements of the case. It is worthy of considerationd protracted trials of the comparative merits of the different implements, be they ploughs, threshing machines, chaff-cutters, or anything else, would not be n object well worthy the at!eution of the Society. After the passage in which this suggestion was throw out had been written, we were gratified to hear a reporething like this course is likely to be adopted. It is said that the award of the prize for the best reaping-machine to be deftrred till the harvest, when the trial will tale place on the farm of Mr. Fisher Hubbs.
We must not close this brief enumeration of the steam-driven machinery thus exhibited at work without noticing Clayton's combined clay-preparing and brics naking machine, for working either by steam or ho, 3000 power, which claims to produce from 20,000 to 30,0 , bricks per day, according to size, combining the pugem of
$\overline{\text { bricks, delivered alternately from each end. We }}$ remember when, some thirty years back, the very
mention of a project for making bricks and tiles hy mention of a project for making brieks and tiles hy machinary by those best qualified, as was supposed, as practical brickmakers to form an opinion; now, these machines have reached such a point of perfection as greatly to have reduced the cost of draining, and no longer
to require the offer of the Society's prizes as a stimulus to invention.
Monday, $J u^{\prime}$ y 14.-The implement trials commenced on Friday afternoon with the heavy land ploughs of Messrs. Ransome, Howard, Ball, Busby, Hensman, Warren, and Goss and Peene. In ploughing 8 inches the iron plonghs over the wooden ones was strikingly manifested; and the long mould-boards particularly of Messrs. Howard, Ransome, and Ball, hid the very difficult work in a leautiful manner.
Early on Saturday morning the reaping machines were privately put through a preliminary trial, just to get all their working parts in order.
On the light land field the general purpose ploughs were tried, belonging to Messrs. Ransome, Howard, and Fry. Sets of light iron harrows were also put into active competition, the exhibitows being Bentall, Howard, Ransome, Coleman, Hill and Smith, an Sanders and Co
On the heavy land the ploughs were again tried at a depth of 9 and ultimately of 12 inches-the contest Late in the afternoon the clod-crusher trials began, there being no less than 16 on the ground. Several novelties appeared in these mplements, Crosskill's axle; and Utting's being on an entirely new principle, cutting deeply through the hardest clods, instead merely pressing upon and abrading their surface.
On Monday the rollers and clod-crushers were subjected to further experiments; those worked belonging
to Utting, Carson, Wallis, Cambridge, Cousine, Day \& to Utting, Carson, Wallis, Cambridge, Cousine, Day \& Exall, and Coleman.
The light land ploughs were tried, and every precaution taken to obtain a fair test of draught by the registering dynamometer of Mr. Bentall and Mr. Amos. The Ploughs were those of Messrs. Ranso
In the afternoon the Reaping-machines were set to work upon a piece of Rye; but a heavier and more lodged crop of Wheat would be a much better sest of their capabilities, so that an adjourned trial would immediate decision of merit which has been pronounced.
Five machines were set to work,-Crosekill's Bell Crosskill's Bell with very important inprovements Burgess and Key's M'Cormick, Dray's Hussey; and Dray and Palmer's "Union." The latter has a curved platiorn of radiating rollers, by which the corn can be
delivered sideways instead of behind, -a man raking, as with Hussey's machine. Dray's improved Hussey with tippling platform to facilitate delivery; and
skeleton knives to prevent choking,-worked exceed ingly well. Burgess and Key's archimedean roller platform delivered the corn in most excellent style.
Crosskill has introduced a most admirable improvement into his Beli's reaper,-consisting of three belts of vulcanised India-rubber, with wooden studs upon thero, which passing from side to side across the front of an great ease and regularity.
The great object of interest, however, were the three competing methods of steam-ploughing, which on Saturday and Monday, and for some following days, to the public
Mr. Boydell's new engine, enabled by the inimitable "endless railway" to travel over any inequalities of surface, has shown that it can drew very great weights, and heavy tillage-implements in deep work behind it. the pace of two miles per hour, dragging behind it five common ploughs, although these were set so doeply into
the ground that apparently three or four horses would the ground that apparently three or four horses would
have been required to draw one. Coleman's immense frame of eight ploughs rigidly fixed, seems to be unadapted for its purpose; though when several of the ploughs were renoved, a much nearer approach was made to good working. No sufficient tests were applied to Boydell's locomotive, so that the actual draught-power all practical engineers tharmed, but and tear from travelling continually over arable land must prove a point however seems very clear, that for conveying farm engines from place to place, especially over soft ground, no better auxiliary can be desired than the ondless railway, a stationary engine and hauling apparatus, promising fairest with'regard to tillage operaions by steam-power
Mr. Smith, of Woolston, Buckinghamshire, acecmplished some baulk-ploughing or ribbing, with a peculiarshaped implement adapted to his own novel method of husbandry; but not having succeeded in "turning over the soil,"'sceording to the Society's condition, he can hardly be said to atand as a claimant for the large reward still awaiting adjudication. He uses a eommon portable engine and a fixed windlass, four "matehblocks" or anchored pulleys, and a wire rope in two
lengths, extending along the ends and sides of the plot
to be tilled. The anchors are set in holes dug for the to be tilled. The anchors are set in holes cug for the
purpose ; and the implement is turned round by the ropes at each end of the work with very litule trouble or los of time.
Mr. Fowler's plan has several equally new contrivances. His anchorages, of which there are only two
instead of four, are siatted along the headland as instead of four, are shatted along the headlands as
required, without digying holes, thus economising on of the principal expenses hitherto encountered. The frame mounted on large wheels, carrying eight ploughs fixed four at each end, pointing in opposite directions and these sets are in work alternately. The experiments made seem to indicate that with about 1 horse poever in 10 hours, including the turnings at the end and deep in 10 hours, including the turnings at the end and Cotgreave's trenching plough constructed for this work the hardest ground was turned up and completely inverted in a broken state 12 inches deep. As yet, we have only
estimates and opinions to offer ; but in a short time, we understand, longer experiments are to be made with the dynamometer, and the extent of ground ploughed in a day actually measured; and then we shall poseess
trustwortlyy data on which to rest our hopes of success for this ingenious mechanical combination. And on another occasion we shall endeavour to give our readers a clear idea of the two wire-rope ploughing schemes
which were exhibited in operation at Chelmsford. Tuesdar, July 15.-Iu the heavy-land trial grounds this morning Ransome, Howard, Busty, Carson, Warren, and others were pitted against one another in a last attempt to determine the merits of their respective phoughs. The land was a hardened clayey soil-here and there with gravel in it-in as unfavourable condition for ploughing as could be imagined, and yet some of the furrows turned over were as clean and squarely cut as if the soil had been perfectly fit for work. furrow horizontal below, perpendicular on one side, and trending $45^{\circ}$ from the perpendicular on the other, was
opened, and the sides and edges of the mass turned over reminded one of the diagrams of the theorist.
We do not yet know the award of the judges, but cannot doubt that it will be received by Mr. Howard, whose plough, with a mould-board more than 5 feet long-a sole plate about a yard in length-and a mould board rising from the sole at so smail an angle as to
remind one of the rig and build of a clipper yacht performe of the rig and luild of a clipp labour to the ploughmand horses than any other. The maintenance of excellence and merit is of great importance, even nationally, in To son of a firm manufacturing their plough we shal refer again.
Arong the other implements shown to-day in this field was the trench plough of Mr. Cotgreave, drawn along by 12 horses. It opened two furrows, and out
of each lifted two slices of subsoil, or rather tore two lower furrows, throwing the material so moved on the tremely unfit condition for worl, and the implement needed three men to hold it to its work while the twelve
horses pulled it along. It adopts Mr. Fowler's plan of a second set of ploughs facing those at work, but carried in the air ; the beam, in which both sets are built,
being bent to admit of one being thus lifted out of work when the nther is in operation. At the end of the field the sel that has been carried is dropped and the other lifted out of the soil, and the trace chain being carried to the other end, the machine is drawn back again, a one-way turning of the furrows being the result ; vieldy a machine. without any attempt to toking at it when at work that so unwieldy an affair is altogether unsuitable to horse labour, an enormous waste of power occurring wherever so many animg many years ago Mr. M^Ewan, of Blackdab, introduced a trenching plongh which did better work and was calculated to do better work than this implement seems likely to perform furrow a foot deep and of unusual width, and four horses following pulled another plough along, which lifted 6 or 8 inches of subsoil from this furrow, and
placed it on the surface of the ploughed land. The construction of combiwed implements in atrempted adaptation to steam power is taking agricultural im plement makers out of the reach of their customers and
of agriculturists generally, who merely look wonderingly of agriculturists generally, who merely look wonderingly to labour at ander circumstance which in July are entirely unedapted to its ability, what Mhus Mr. Coled along, coni not make good works which it might have done else where ; and Mr. Smith's (Woolston, Bucts) ridglets over the stirred subsoil, hardly suggested by its rough performance what it actually does in favourable 100 acres are thus annually cultivated with efficiency and success
Among the successes of the more cumbrons machines exhibited must certainly be named Boydell's traction engine, to which we have already referred. At first its progress strikes with ludicrous astonishment. A
pair of heavy wheels takes the greater portion of the weight of the machine ( 9 or 10 tons). A smaller pair
in front takes a portion of the forepart of the woight, and carries the helmsman, who guides its progress by turning these fore-wheels very easily, thus guiding the machine along eronked ronds aud through narrow gates
with great faclity. It mounted into the field without diffiwith great faclity. It mounted into the field without diffi-
culty, and had nulled Biddell'sscarifier on the previous day culty, and had pulled Biddell'sscarifier on the previous day
6 or 8 inches deep through the substance of that hardened 6 or 8 inches deep through the substance of that hardened soil, showing that but a small portion of its power is wasted in moving its great weight along. The great sboes which hang loosely to the circumference of is wheels are placed successively by their own weight on dry ground they had the effect of bridging over furrows and inequalities, while in wet and soft land they hindered the sinking of the machine in the tively even and atremoly hard surface as tried the machine to-day, they were of course for the most part merely a useless encurabrance. The most part merely a useless encurabrance. The the double cylinder gives motion, and through which the whole force of the machine is conveyed, gears into ference: $n$ the draught chain being in effeet fastened to erence; and the draught chain being in effeet fastened to the axle of the driving wheels, i,.c, pulled aloug at the
rate of its motion over the ground, of course a double power may be brought to bear upon this draught chain, the wiole diameter of the driving wheel being in effect lever, the fulcrum at one end on the ground, the reaistsoce or weight half-way between the two extremities, and the power at the other end where the leaves of tis pinion successively push at the cons upon the circumference of the whel. But the advantage apparently gained by this pusition of the pinion on which Mr. Boydell insists with much confidence, is not real after all. The velooity of the pinion must be doubled to produce the same rate of movement onwards as if it were placed on a level with the axis of the wheel, and as much is lost as gained.
e may xefer bere to the trial of Bentall's and Coleman's scarifier on land exceedingly unfit for the operation either of stirring or of paring teeth, the superiority being with the hatter tool.
loderushers were exhibited at work in great variety and number, the discs, some of them in two rows, each clearing the intervals in the other, all of them running independently on a commen axie differed exceedingly in the form or footh or form of edge on which the teeth were placed. It is nor, we believe, in practice a material question what particular patter on the soil the machine shall leave behind it as in is drawn forward. All that is necessary is that consider abie weight shall be brought to bear upon every cloc over which the dises severally pase, and it must be broken.

Weonesday was generally devoted to an examination of the implements in the yard. If we fallow spectatore in their tour around the several stands we shall be able to point out a few of the more remarkable notabilities exhibited, leaving till another week a more detailed account of those we now pass by. Mr. Lawes exbibits Beadon's patent gutter tiles, which appear in the roo erected as a specimen to be a cheap and efficient substitute for wooden or metallic spouting.

A large straw lifter shown by Mr. Hayes, of Eltom, Oundle, attracts attention by its height even before yor enter the yard; it is adapted to tahe eve strathen end of shaker when working win the threshing machine, and to carry it up two octagon drums, their dien is made wh tines, drives by ande machinery to carry up th straw, diven by suitable mach hery a car sharbin but reduced.
Mr. Sawney, of Beverley, attaches to his winnowing machine his apparatus for separating the rough seeds of hariff (clivers), which is a nuisance in samples of What they corn and clivers are received on an en for delivered in front of the apparatus. The clivers whic adhere to the revolving or endless cloth are carried adnered until they come in with the clothcleaner, by which means they are deposited in a drawer ized uler the olth
Mr. Burrell, of Thetford, shows a model of a brickkiln calcuiated greatly to hasten and to cheapen manufacture. It consists of a long building with two channels on the ground floor alongide one another large ennugh to receive iron waugons loaded witt the bricks running on a train. sive waggon loads are introduced at the far end of this chimney and gradually pushed up towards th greatest heat, attaining ultimately a perfect red heat and hen passing as gradually through the other channel where they gradually cool. Over both the channels drying sheds are erected so that the heat lost by the coling bricks is all conveyed to where a preliminary artificial drying of the bricks is effected.
Several large Clover shelling appraratus are exhibited, all on a common principle of a rough conical drum with many beaters revolving in a conical cover, and rabbing, by its rapid motion, the seed out of the Cinver heads, hich are passed between the two. Mr. Huckale, of Chipping Norton, continues to exhibit his patent turnip chinner, in which, by a remarkably simple contrivance,
he roughness of its operation, owing to the onward me roment of the machine, is perfectiy obviated. He also shows a horse-hoe for hill sides in which a second
the slope successfully combats the downward tendency given to the horse-hoe by its weight.
Mr. Sparke, of Norwich, exhibits a good contrivance in a saw-bench calculated to facilitate operations with heavy timber. The revolving saw-band shown hy Messrs. Barrett \& Exall also deserves and receives he attention of spectators.
Messrs. Garrett showed Mr. Chambers' ingeninus manure distributor and his drop-drill apparatus which attached to Spooner's water drill collects seed, manure, and water, and drops them mixed and all together at ment to collect a general distribution of water on to the rows when the seed is sown, it is weli still further to economise it by confining it to those points in the rows Mr. Samuelson shows, seed shall germinate.
Mr. Samuelson shows, among his other implements, A narrow Grass-cutter, adapted for Grass edging, and interesting therefore to our horticultural readers.
The cheapest cart, and really, we believe, as good as any in the yard, is shown by Mr. Eaton, of Twywell, tail-board, and costs 94.9 s.
An ingenious Barley hummeller is shown by Barnard
\& Bishop, Norwich, where a horizontal gridiron stamper is worked by crank movement, which makes it push the grains from it as the operation is completed by it. A root-rasper, where a perforated roughened dise for cutting, and a roughened dise for holding the roots rasped, revolve in two different directions, and form the two sides of the hopper in which the roots to be operated

We may here mention the this stand
We may here mention that a number of graters, generally on the saw-tooth priaciple of Mr. Philipps (Brandon), are shown by different makers. In one these teeth are arranged spirally upon a barrel, enabling a spiral worm olving between the teeth to keep them clean.
An ingenious corn sieve, adapted by Mr. Burrell, of Thetford, to his threshing-machine, and exhibited separately, consists of a sloping riddle moving to and iro in its own plane. The wires are parallel, and rows keep them clean, and force the grains of Wheat to jump over them in their passage downwards.
We may here refer to Mr. Bullock Webster's model of farm-buildings, constructed on the principle of a uniform shedding, capable of erection at 12s. to $20 s$. per foot run, according as timber is provided on the spot or not, and capable of subsequent adaptation to any purpose that is desired.

Thurspay.- The cattle show opened to the public this morning is characterised by extraordinary number and excellence in the horse classes, considerable number and general merit in the classes of short-horns, a comparatively small but good show of Herefords, a numerous and Tery excellent (with some few exceptions) show of Devons, and a small and imperfect show of foreign
cattle. Among sheep there is a wonderful exhibition of southdowns where Lord Walsingham carries off all the prizes for old sheep and for ewes, and Mr. Overman and Mr. Jonas Webb take the prizes 1st and 2d for breeding rams. The Leicester breed is represented by selections from the flocks of Messrs. Watkins, Paulett, Radmore, Cresswell, Borton, Simpson, Turner, Finget, Hannam ; and that of Longwools is a small one contributed to as usual by Messrs. Browne, Garne, Hewer Lane, and Walker. The show of pigs is generally classes.

As to individuals deserving notice among the general Tun of excellence, we may refer to Mr. Towneley's prize bull, Master, Butterfly, Mr. Booth's beautiful yearling
heifer, Queen of the May, Lord Berwick's prize heifer, Queen of the May, Lord Berwick's prize Hereford Bull, H. R. H. Prince Albert's yearling bull, "Zouave," bred by Mr. Turner, of Barton. In
Horses it is worthy of notice, that notwithstanding the Horses it is worthy of notice, that notwithstanding the number, and merit of those representing the Suffolk
breed, the judges had the courage to award the first prize to a Clydesdale horse, the property of Prince Albert; of course the decision is indignantly condemned by eastern counties spectators generally, but the judges are men whose opinions may nevertheless safely be accepted. The Clydesdale does we believe unite activity and strength in the proportion best adapted to the farmer's purposes-and we believe the first prize animal to be a good specimen of its kind. We slaill next week give a fuller account of the horses, as well as of other classes of stock.

On the sheep exhibited we may remark generally.
As we shall next week show by our tables the number of sheep exhibited this year falls far short of the standard of several previous shows, the South Downs, however, greatly exceeding the number either at Lincoln or Carlisle. Much of the explanation of course lies in the character of the district which is not given to the breeding of sheep, and exhibitors have an eye to business as well as to honour in bringing many specimens of their animals from long distances.
Next week we will give an outline of the principal excellencies and defects of the different animals of note, and content ourselves
The Leicesters are certainly
excellence asters are certainly not so remarkable for excellence as on sume former occasions, by which we and first-chase animat so large a proportion of beautirul The Share animals.
this class everybody has been very superior; and in tery general reflections have been verbally made, and
it is not for us to set up ou opinion against the carefully-considered awards of those whom the Society chooses for their known judgment say that, while much admiring and commending the prize Rams, there are animals in competition which we would rather have preferved, not so much for thei size and substance as for their greater perfection o ymmetry, and other points of extraordinary merit
The Long-Woolled Sheep are, in our view, generall superior in quality to those shown last year; though not coming up to the wonderful degree of size, and splendid proportions, characteristic of the Lincoln Show
The foreign classes contain individuals of the Brittany Normandy, and Charolaise breeds, the last beautiful both for symmetry and size, while their pure white colour and general merit indicate apparent relationship to our wn breed of short-horns.
We append the award of the judges.
SHORT-HORNS
Judges: Capt. T. Ball, Messrs. J. Grey, and T. Parkinson.
Class 1. Bulls over 3 and under 4 years old.- 1 st, Lient.-Co Towneley, of Towneley Park, Lancaster (Muster 1hitterfly); 2 d,
Mr. Heary Ambler, of Watkingon Hall, Hallifax (Grand Turk) han 1 ye. Bulls calved since the 1st of July, 1854, and mor Otley (General Bosquet); 2d, Mr. M. Barrowby, of Dishforth Class 3. Bulk (Mark Anton
Class 3. Bull Ualves above 6 and under 12 months old.-1st Class Ambler (Napoleon)
Cows in Milk o
ley (Roan Duchess II.) ; 20 ,
Class 5. Heifers in Milk or in Cali not VI.).
1st, Lieut.Col. C. Towneley (Victoria): 2d, Mr. R. Stratton, of
Broad Hinton, near Swindon (Marcia

Booth, of Warlaby near Northallerton (Queen of May); 2 d ,
Taplow Court, near Maidenhead (Bettine).

## HEREFORDS.

Jodges: Messrs. S. Bloxridge, W. Tindall, and J. Williams, Class 1. Bulls calved previously to the 1st of July, 1854, an near Shrewsbury, (Napoleon III.); $2 d$, Mr. E. Price, of Courthouse, 1'embridge, near Leominster, (Goldfinder).
Clase 2. Bnlls calved since Julr 1. 1Sil, and more than 1 yeir
Id. 1st, Mr. W. Raester of Thumhill, near Hereford, Id. 1st, Mr. W, Raester of Thumbhill, near Hereford,
Favourite Chance), 2d, Mr. E. Williams, of Llowes Court, Class 3. Bull Calves above 6 and under 12 years old. 1st, Mr
V. Perry, of Cholstrey, near Leominster, (Cholstrey Boy) Class 4. Cows in Milk or in Calf,-1st, Mr. W. Perry, (Carlisle Class 5. Heifers in Milk or in Calf, not exceeding 3 jears old. 1st, Lord Berwick (Carlisle); 2d, Mr. Raeste
Class 6. Yearling Heifers.-1st prize, $10 l$, DEVONS
Class 1. Bulls calved previonsly to the 1st of July. 1854, and not exceeding 4 jears old.- 1 st, Mr. J. Quartly, South Molton,
(Sultan); 2d, Mr. W. M. Gibbs, of Bishop's Lydeard, near Taunton.
Class 2. Bulls calved since the 1st of JuIF, 1854, and more than 1 year old,- 1 st, his Royal Ilighness Prince Albert (Zouave), C, Mr. C. J. Halse, of Molland, South Molton (Earl of Essex). Class 4. Cows in Milk and in (Bosquet).
Clit.- 1st, Mr. J. Quartley (Stately); 2d, Mr. W. Farthing (Fancy).
Class 5. Heifers in Calf or in Milk not exceeding 3 years old.
1st, Mr. J. Quartly (Nonpareil); 2d, his Royal Highness Class 6. Yearing Heifers.-1st prize, 102., to Mr. E. Pope, of
Great Toller, near Maiden Newton (Fancy) ; 2d, Mr. J. Hole, of inowle Iouse, Somerset.

CATTLE OF ANY OTIIER BREED
Class 1. 1st, Lord Sundes; 2d, Mr. J. S. Turner, of Chynton
Class 2. Ist, Mr, G. D. Badham, of Ipswich.
Class 3. Covs in Milk or in Calf. - 1 st , Mr
ilton Selmeston, Sussex ; $2 \mathrm{ad}, \mathrm{Mr}$. T. M. Mr. Jud Gon, of Castinge, of
cre, Suffulk. cre, Suffulk.
Class 4. Heifers in Milk or in Calf.- 1 st, Lord Sondes
Class 5. Yearling Heifers.-1st, Mr. G. Class 5. Yearling Heifers-lst, Mr. G. D. Padham, Judges : Messrs.

## HORSES.

## Class 1. Stallion

Burns, W.
for Agricultural Purposes, foaled previousip 2d, Mr. Manfred Biddell, of Plarford Class anghess Prince Albert; Class 2. Stallions for Agricultural Parposes, foaled in the year
1854.-1st, Mr. G. M. Sexton, of Earl's Mall, near Sudbury Sufolk; 2 d, Mr. M. D. Badham, In Eswich. Hall, near Sudbury,
Class 3. Agricultural Stallions fivaled in the year 1855.--1st, Mr. Samuel Claydon, of Little Linton, Cambridge. Class 4. Mares and Foals for Agricultural Purposes.-1st, Mr.
f. Carter, Chelmsford ; 2d. Mr. N. G. Barthropp, Woodbridge,
Suffolk. Class 5. Fillies for Agricultural Purposes.-1st, Mr. S. Wrinch, Colchester; 2d, Mr. Samuel Clayden.

## DRAY HORSES.

Class 1. Stallions foaled proviously to January, 1854.-1st. W Baker \& Son, of Stapleford, near Cambridge (Young Inkermana.)
Class 2. Stallion foaled in 1854 . Class 2. Stallion foaled in 1854.-1st, Mr.C. Timm, of Nottingham (Great Northern.)

## LEICESTER SHEEP

SHORT-WOOLLED SHEEP
Judges: Messrs. G. Brawn, H. Chamberlain, and P. Purves. Class 1. Shearing Rams,-1st. Henry Overman, of Weasennear, Cambridge.
Class 2. Rams of any other Age.-1st, Lord Walsingham,
Merton Hall, near Thetiord, Nortolk, Jertcn; 2d, Lurd Wa Class 3. Pens of five Shearling Ewes.-1st, Lord Walsingham

LONG WOOL SHEEP.
Class 1. Shearling Rams. - 1 st, Mr. James Walker, of North-
veah, Gloucester; 2d, MI. T. B. Brown, of Hampen, near Ando Class. Mams of any other Age. - 1 st , Mrr. William Lane, of
Croadfield Farm, near Northleach, Gloucester: 2d. Mr Garne, jun., of filkenny Farm, Bibury, near Fairtord, Gloncester Class 3. Pens of five shearling Ewes, - 1st, Mr. William Lane ; PIGS.
Judges: Messrs. Arnold, Denman, C. Randall, and T. Trotter. Class 1. Boars of a large Breed.-1st, Ker. C. T. Jares, of
Ermington, near Ivy liridge, Devon, for Fimperor; 2d, Mr Class 2. Boars of a Small Breed.-1st, Mr. Thomas Crisp of Arthington, near Olley, Yorkshire . $d$, Mr. Richard England, Class 3. Breeding Sows of a Large Breed.-1st, Mr. W. B
Wainman, of Carhead, near Crosshills, Yorkshire. Class 4. Breeding ISows of a Small Breed, - 1st, Mr. H. Scott
Fayrvard, of Folkington, near Willingdou, Sussex. st, Rev. C. T. James.
Class 6 . Pens of Three Breeding Sows of a Small Breed Mr. R. H. Watson, of Bolton Pari, near Wigton, Cumberland. SPECIAL Prizes.
Class 1. Thorough-bred Stallions.-1st, Messra. Robert and ames Moffat, of Newton-of-Rockcliffe.
Class 2. Hunter Stallions.-1st, Samuel Adams, of Great Waltham, near Chelmsford.
Class 3. Coaching Stallions.-18t, George Rayson, of Highbea
Castle Farm, Carlisle. Class 4. Hackney Stallions.-1st, Mr. William Jex, of Hopton near Lowestoft, Snffolk.
Class 5. Hunter Mares.-No award.
Class 7. Geldings of any Age for Hunting Purposes,--1st, Mr. Suffilk. Ber, of the Shrubbery, Hasketon, near Woodbridge
Class 8. Geldings under Four Years Old for Hunting Purposes 1st, the Earl of Danner of Cobbam Hail near Grag Purposes. Class 9. Hackney Geldings of any Age.-1st, Mr. Francis Class 10. Hackney Geldings under Four Years Old.-1st, Frederick Barlow. FOREIGN STOCK
Judges: MM. E. Gareau, de Gingins d'Eclépins, and Hon. M.
Bulls of any Pure Foreign Race,- $\mathbf{1}$ st, Comte de Bouille Villars, 4th, Mons. Eluard, Cheina et Marue; Mons. Allier, Seine et Oise;
 Judies of Polltre: Messis. J. Baily and G. J. Andrews.

IMPLEMENT PRIZES

The Annual Dinner of the Society gathered a thousand of its members together in the pavilion, at 4 o'clock this afternoon. There was a good deal o excellent speaking. The president elect, Mr. J. E Denison, in naming "Agricultural Sncieties at home and abroad," referred, of course, to the Paris Exhibition, and pointed out that amidst all England's numerous contributions to that gathering of breeds, there was an extrarrdinary deficiency in specimens of produce shown. To take an instance, a solitary
The tuast of the evening was given most eloqueutly and efficiently by M. De Trehonnais and the chairman, the retiring president, Lord
Portman, in an excellent address, gave a most
instructive review of Agricultural progress, referring in
succession to live stock, implements and produce, and succession to live stock, implements and produce, and extent of their expectations, efforts, and application,
drying hay and corn by artificial You did me the honour to publish in your Paper the 14 th of June, some remarks, which I ventured to address to you on the subject of harvesting agriculcural produce by the use of currents of dry heated air, originating, on my part, in the belief that very important objects might be thus attained, by means which would be efficacious, simple, and economical
I have since continued to turn my attention to the subject, being still more convinced than at the outse that great benefits are attainable, and in some parts of the kingdom the wetness of this season has amply
proved the existence of the evils requiring to be obviated. Hay-making and the curing of Oak bark have been much interfered with by the rains which have fallen place season critical for those processes, and at any place at which an artificial system had been in action all evils and risks could have been avoided under any and all circumstances.
But the object of the communication which I now presume to make, is to advert to higher authorities than my own on this subject. The views I stated had occurred to myself without a knowledge of the opinions of other persons, but I have recently referred to the article "Haymaking" in Morton"s Cyclopredia of Agriculture vol. ii., p. 15 ; and I there find observations amply con firmatory of the views and opinions which I had expressed in my former communication to you, Reference is perimental Researe the the Food of Animals,
1 to 79 (Longman \& Co., 1846), and on a perve, Pp that work I have found abundant confirmation of the importance of the subject, and passages in the work whe great encouragement to completion of uch ion preservation of Grass and other farm produce, with all their valuable qualities unimpaired. I beg leave to give some ides of the import of his more extended tatements

The great cause of the deterioration of hay is the water which may be present, either from the incomplete removal of the natural amount of water in the Grass, by drying, or by the absorption of this fluid from the atmos phere. Water when existing in hay from either of which one of the most important consticuents of the Grass-viz. sugar-will be destroyed." "The onl method which we have found to succeed in preservin Grass perfectly entire is by drying it by means of artificial heat. Rye-grass contains at an early period of which may be removed by subjecting the Grass to a temperature considerably under that of boiling water but even with a heat of $120^{\circ}$ the greater portion of the water is removed and the Grass still retains its green colour, a character which appears to add greatly to the
relish with which cattle consume this kind of provender. relish with which cattle consume this kind of provender.
When this dried Grass (as it may be truly termed by way of distinction from hay) is examined, it will be found consist of a series of tubes, which, if placed in water will be filled with the fluid, and in some measure assume he aspect of its original condition. In this form cattle will eat it with relish and prefer it to hay, which in comparison is blanched, dry, and sapless. The advantages obtained by this method of making hay, or sufficiently obvious. By this means all the constituents of the Grass are retained in a state of integrity; the sugar, by the absence of the water is protected from Grass is salts are not exposed to the risk of being washed out by the rains, as in the common process of hay-making The amount of soluble matter capable of being taken up by cold water is, according to the preceding trials, as much as 5 per cent. or a third of the whole soluble matter in hay. We may therefore form some notion of the injury liable to be produced by every shower of
rain which drenches the fields during hay harvest. It is not only, however, the loss which it sustains in egard to sugar and soluble salts that renders hay so much less acceptable than Grass to the appetite of cattle. The bleaching which it undergoes in the sun deprives it of the peculiarity which distinguishes the ts green Colouring matter other; Grass deprived of appearance of straw, so that hay ought to be termed Grass straw." "Some improvement in the preparation of hay is imperatively demanded in such localitie In a moist climate, especially like that exhibited in Scotland during the last year, it appears highly desirable hat farmers should possess on their premises a drying dried,
Such being the object to be attained, I entertain Martin's Place the apparatus of Mr. Hazard (No. 8, St calculated, at a Trafagar Square, London) is admirably ratus or the fuel in its use), to attain the ends desired and I have reason to believe that Mr. Hazard would

## practical experiments, at a very moderate expense-an

 expense which would be amply compensated if success attend them, if carefully male, does nut seem to admit of doubt. To render the process perfect, some simple arrangement would no doubt be eventually advantageous in addition to the currents of heated air supplied by the heating apparatus, to secure its rapid action on the Grass; some simple machinery would be readily contrived, in the nature of a hay-making machine, to work under cover, and to act on one spot, the Grass being supplied to it ; but in the first instance the end migh be attained by the free use of the pitchfork in tossing abour required wrould be less than the heated air. Th abour required woul be less than the labour required hay-the process would be much more rapid than in the field, in proportion to the higher temperature employed Ine action of the heated and dry air. T.F. Kennedy July 9.
## Home Correspondence

Mr. Fouter on Dartmoor.-Of all the interesting agreeable, and satiffactory reading that is to be found in your Paper, the few lines in a late number which describe the results of Mr. Fowler's experiments on the esting and satisfactory mind, near hear of the reclama tion of waste lands, whether in England, Scotland, Wales, or Ireland, without experiencing the greatest satisfac faction and pleasure. The importance of the subjec cannot be over-estimated, and I shall therefore not apo ogise for asking you to endeavour to ohtain, for general benefit, all the details you can respecting Mr. Fowler' experiments. If you could induce Mr. F. or his bailif write an exact history of his proceedings from 184 confer the greateest benefit on the greatest number. If your could merely obtain his general plan of working, you could merely obtain his general plan of working
with suggestions as to errors of practice which afterexperience would have avoided, you will also obtain much for which your readers will warmly thank you. But if such letters as those which were after wards published under the name of "Talpa" could be obtained from Mr. Fowler, it would be an immense advantage to others engaged in the same pursuit. The nature of the soil; the advantages or disadvantaces of climate that he had ; the vicinity or otherwise of lime hat most important agent in such a work; the kind of roads, steep, bad, or both !-the distance from his market: all these pros should be fairly stated. I will not detain you longer, having said enough and more if you see the subject as I do. M. G. Y. [In reply to Talpa' and write largely on my mode of cultivation here, but in a few lines I may impart the pith of all I could say if I indulged in a long history, and I may pre face by observing, after nine years' experience, that had I to begin again I should proceed precisely in the same Way I have done. The first step was to make the round quite dry by stone drains. The next operation following in same furrow, so as to completely plough mix the soil 18 inches deep, and thus break the hard crust or pan; then the fields went through a course Turnips the that is, one or two crops of Oats and Turnips, the last well limed, say 4 tons per acre $f$ cattle dung 20 . per ton; then a good dressing ficial dressing applied sits 34 tons of Swedes per statute acre were the publicly attested yield, prizes having been awarded right and left by btaining perfectly clean ground and a fine tilth, about 25s. to 30 s. worth of Grass seeds per acre sown mostly without a grain crop, and times of seeding May to August ; the ground rolled before and after sowing ith a light stone roller. In November a very heavy tone roller drawn over all the pastures, and this moderately moist-if not wait until it is. I let my mproved Grass fields last from 12 th of May to Novemer 8 , when, according to my custom, they will remain idle to next May. The hammer fixed the rent, the occupiers seem highly pleased with the condition of heir stock, the Grass being abundant. I send you the Western Times, in which you will find my brief report of flowing is the notice of the convict farm referred to:"The pigs, about 100 in number, claim attention; they are all of a dark colour, and though not of large frame, are most symmetrical animals, evidently possessing great aptitude to fatten, and the number of choice quality, with scarcely a coarse one amongst the lot, clearly demonstrate the care and judgment exercised in producing such a stock, as nearly all have been bred inside the prison boundary wall. The next attractions were the haymaking and rickbuilding operations, each of which appeared to be progressing in a most satisfactory manner ; the estimated quantity of hay thus secured, and in first-rate order, was 60 tons- 40 to 50 are to get, in addition to which about 40 tons of the 1855 crop are in the yard, so that their stock of hay, be little if any short of 150 tons. The Sivede crop, like many others this season, is severely punished by the fly the other crops, considering that they are chiefly the complete and signal change which convict labour
acres Oats, 15 acres Potatoes, 17 acres Tumips, 10 acres Carrots, Cabbage, and Parsnips. Thus not
 vour of what are generally designated 'the out desert society, when judiciously managed, causes the voure and old) about 75 , are choice, and號 the male side pure, as two first-class bulls of this breed are liept. Two ther items, in justice to the prisoners, I ought to tone walls round the fien the most magnificent one ulls row the eye of man of abo about 2000 tons of peat turf now drying for fuel, and min part of this brilliant gas for the prison will be made, the remainder forms a valuable substitute for coal."

Labour Gazette. I have observed in your valuable Journal of the 28th June a very important suggestion in the leading article regarding communication between mployers and labourers, and I do hope from your taking up the subject some plan will be adopted to complete that communication which is at present so imperect as to be quite inconsistent with our existing means of locomotion, and a great hindrance to improvements. About three years ago I wrote to the Poor-law Commissioners on this subject, and recommended that there should be established in London a "Labour Gazette," in which capitalists in all parts of the world might advertise their demands for labour, and that a copy hould be furnished to each "board of guardians" in Great Britain and Ireland; and that, in order to prevent a glut of labour in any given quarter, an ffice should be established in London through which all applications for labour slould be made and from which all information should be given as to any demand leing supplied or not; and then, as we know the poor labourers often have not the means of transit, and as before "the New Pooraw the parish authorities frequently lent money to labourers to go away for employment, I recommended that the guardians of each union should be empowered to advance money to facilitate employment in this way, a security of the employers, who would always como the guardians interested, the amount of wages offered and also the accommodation prepared for the labourers. took up the matter from having been some time "guardian," and seeing that in my parish (being an open one under a dean and chapter, lords of the manor) we have about 25 able-bodied labourers more than the land of the parish demands, and hearing that frequently pitalists at various distances requir not know how to obtain them. Gur phashes might be empowered to advertise labous, and W. W Mat expense so doing on the po W. W. Malet, Ardeley Vicarage, Buntingford

Agricudturat Maxims-1. All plants, whatever be their nature, receive in the main the same kind of nourishment during the early part of their growth; therefore whatever gives nourishment to the plants we cultivate will also encourage the growth of weeds. 2. Two kinds of plants growing close together will necessarily rob each other of the nourishment which the soil is capable of giving; therefore if weeds are allowed to grow amongst the plants we cultivate, the food which dravm fors the will just be mech Her also the necessity of placiog our plants at auch a distance from each other that they may not rob one another of the nourishment each ought to have 4 . The nourishment which weeds receive from the soil would give life and nutriment to the grain or other plants we cultivate Weeds ought, therefore, never to be allowed to produce their second leaves, they ought to be cut up as soon as they appear; and this is much easier done when they first appear than when they are two inches lomg No weeds should be allowed to blossom, or indeed to exist amongst any crop, as they not only keep the influeace of the sun and air from the soil and and leaves of the crop, but they absorb the moisture and nourishment of the soil and air, which ought to go to the production of the crops we cultivato. 6. By planting your seed in land that is full of the roots and seed of weeds, you employ at least one half of your labon and capital in producing them, while only the remainder goes to the production of your crop along with a large crop of weels, which, shedding their seed in the soil, will again produce another more abundant crop of weeds next year, and require an increased amoun labour and capital to clear the ground of them . Decaying vegetable and animal matter in the soil increases its productiveness ; therefore the soil should ever be producing plants (as they receive much of this nourishment from the atmosphere), if it were only for the purpose of being tarned into the soil to be again decomposed and add decaying matter to it. 8. The soil which has produced a good crop of any kind of plan may again produce gond crops of the same plant; if the land is in every respect under the same circum stances as at first-the state of cultivation, decomposing vegetable, animal, and mineral matter, heat, light, and moisture being the same. We see the weeds which are natural to the soil prosper in proportion to the cultivation and manure which they enjoy with our crops ; and this they continue to do year after year to make them more productive require to be changed natural to any particular soil it may be cultivated on
he same land year after year and produce abundant returns, if all the manure which the crop prodnced be returned to it and proper cultivation be given it. Cultivation improves all kinds of plants that are matural to the soil and climate. Weeds and their seeds come up as naturally and arrive at as great perfection wor as ever they did, without any change of seed All soils having a rener parous subsoil are most productive, and are dry and porons subsoil are most productive, and ar much easier cultivated than those which have a etentive subsol ; therally you ourht to give it one pornus subsoil naturally you ought to give it one artificially whatever the expense may be, as the with compornd interest. J. M.

## Calendar of Operationg.

South Hants, July 12.-Since my last report of the erops of Ind Turesday, the 7 th and 8 th of this month, very severe gules and drifting showere of rain which has beat the Wheat crops about and whilst in full bloom. The ears of What are chafed, and the green husks stand projecting from the ears-the fags heaten have we seen Wheat in lts green state so sadly knocked about have not suffered so much, these crops not being so forward in growth and maturity. The Turnip crops, especially Swedes,
have been in every part of this county mucls injured by the y, and in many places totally destroyed; durirg the la Wurzel is also very inferior as a crop, and particularly back wand by reason of the very dry and hot weather. The dry ground hay crops have been well secured in excellent conbeen got in in the best order. Much in places remains in swarth and the rains have sgain set in, rendering the safety of these later mowings somewhat precarious. Markets had fallen, and actors had hesitated to purchase Whext unless a reduction of 4s. per quarter was summitted to-double the fall in Mark sallen many degrees in temperature, and has become cold and uugerini. As to Wheat ricks, very fow farma have any at all now; and the present Wheat crops are the thinnest on inspeetion

Wegr Gugesx July 13 - We are still able to report all - ell The crops, if we except Swedes, are sll that can be will well In this immediate locality, we have had but little rain, though it has been heary not far off. We who live nr the flat coast land range of hills behind us, as well as some that take along thie Often in the dry summer months we see the appearance of a heavy thunder storm gathering on tie borders of Hampahire oatakirts are all that we get; but it has this Year been a little more mindful of us, and we have had it sufficient to moisten the Wheat; but the ear still stands up well, and may mature well enough, and if so will be a heary crop. Barley is a fair crop; Oats are variable - some good, and some not up to last year's gnark. Mangel grows well, and presents a strong contrast to partly its canse) a ton liastily prepared reception for the seed when the land was wet and cold. Some have failed in sowing Swedes, and many have had to sow twice, and are taken, enough to spoil the crop, but not to induce us to plough I believe that the canse is to some extent forcing work when the land was not in a proper state. We have finished hay making, and have lad one of the best crops, and a good season to make it Clover, which was not ticin leas thang a fortnight from the time it was cut, and as the second crop came up quickly with the heavy dews at night it made our days short for carrying, and many have lad to move it again through carting too soon. The unusualiy large quantity uf sed saved. Trifolium incarnatum seed is now tht to cut, and is likely t.) yield well. Here where
we hare to buy in leansonck we are not able to btain the gain from our large supply of Grass that might be expected, alth cugh beef and mutton are ver dear yet the price that is paid for thie Tha Potato crop louks better than it has been for years. The prices paid for mowing Clover has been about 3s, $6 d_{\text {, }}$ for meado is 4. per acre. Our prices for fagging Whent and putting it in
. 0 保 mowing Rarley and Oats, $3 s$.; but here, as everywhere else tork is done. Swede boeing is just begun and soon as the eingliny is likely to be from $5 s$ s. to 8s, according to the state of
the land. Although day w:uges are higher here than in many places (being from $12 s$. to 1 jos a week) piece-work is not much

## Notices to Correspondents.

Ampress: Martin Doy's wonld much ollige us by sending his pouldress, Which we bave mislaid. Poultry: JBN. Your chickens have the" "Gapes." Place them luce the stem of a opacco-pipe, and br winding a silk hand kerchief round the bow, hlow the fumes into the pan until the emoke begins to appear trum the sides, then remove the ctoth but in the collrse of a minute or two will recoper both their lea and senses. This "smoke nuisance" three times, when in almost every case which has come under our notice a care has been effented. Out of 100 chickens which one brine being errspondent. The old belts serve for the season, quantity is meeded intervals as the stock is used. A large season of the weaker cheese-making towards the end of the Small Farm: X $Y$ Z. ## The chationteg" Chromicle

,
Some weeks ago we received from a correspondent a complaint of which the following was the substance. It was represented that a practice has been recently adopted by Messrs. Gibbs, Bright, \& Co. the Liverpool firm of Messrs. A. Giras \& Sons, agents for the Peruvian Government, which the writer legarded as being by no means creditable to a firm of their standing, if not a positive fraud on purchasers of guano in that market. It was said that when Messrs. W. J. Myrrs \& Co. held the agency and for some years after the transfer of it to Messrs. Gibbs, Brigut, \& Co., it was the practice to sell by auction, "with all faults," any portion of a cargo which happened to be damaged by leakage or otherwise. Recently, however, they have kiln-dried any wet and damaged guano, subsequently mixing it with the bulk of the cargo, in which process our correspondent was of opinion that a large portion of the ammonia must be evaporated.

No one can doubt our readiness to expose mal practices in the guano trade; but in this as in all other cases we feel bound to examine scrupulously the stafements that are forwarded to us. This we hold tu be the positive duty of all journalists, otherwise irreparable wrong may be sustained by the innocent. Such an inquiry has been instituted in the present instance, and our correspondent will find that although his information is partly correct, the inference he has drawn from it is wrong.

The facts are these: a large vessel in going into the docks at Liverpool with a full cargo of guano struck on the dock sill and broke her back; the guano conld not be got out for several days, and was of course with every tide saturated with water. Now farmers cannot or do not like to use damaged guano, as there is a difficulty in putting it on the land unless dried and pulverised. Mixers, that is guano makers, however readily buy it, and in order to save the expense of drying, add to it a quantity of dust and rubhish, which they sell cheap!! So large a quantity of damaged guano as that in the
case before us offered the importers an excellent case before us offered the importers an excellent
opportunity for ascertaining experimentally whether
the wet guano could not be dried without much injury, and Mr. Nesbit undertook to conduct the operation. It was evidently important, if practicable, to dry damaged guano and render it fit for use ky the consumers instead of letting it pass into the hands of doubtful rentlemen. We find that Mr. Nesbit succeerled in getting an old kiln at Birkenhead, and his experiment was in all respects, except the cost, suc-
cessful, nearly all the ammonia being preserved. The dried guano however turned out dusty, and was consequently subject to much waste, unless mixed with about an equal quantity of good undamaged guano. This was done ; the mixture was then analysed by Mr. Nesbit's report, who found it of excellent quality. It was afterwards sold according to analysis
In all this we are far from seeing anything to complain of; on the contrary we resiad it as a new proof of the anxiety of the imposters not only to secure the purity and quality of all the guano that they send into the markit, lut to impede the operations of the adulterators, to whom a lot of damaged guano is a perfect Goifsend. To what extent, if any, the guano was injured by the process, Mr. Neseits analysis will show, and the selling price was fixed accordingly.

But although this supposed instance of mal-practice is thus shown to be a misconception, we feel it necessary to warn buyers against the doings of the guano mixers at Liverpool. There is now before as a sample of beautiful stuff, in appearance so exactly like fine Peruvian guano that the quickest eye would fail to distinguish it, and so soft, and smooth, and free from grit that the sense of touch is equally powerless in detecting it. This material is so largely prepared at Lirerpool from clay that two great kilns are constantly at work in drying it, and the whole of it goes into consumption as guano. As a dryer of damaged guano it would be invaluable. Who the honest men are that are reaping a golden harvest off the negligence or simplicity of their customers we do not say; the situation of the works is well known, and it is for Lancashire purchasers, or honest manure agents to bring them to justice. It is pretended, indeed, that their pure and unadulterated guano is not for the English trade, but for the Irish and American markets. We, however, believe that it is for any market where it can e sold.
The public is therefore warned against buying Liverpool guano from any persons of doubtful character; and especially against paying for it until it has been carefully analysed.

Wondfrs will never cease. All the great Grape anowers were beaten the other day by an interloper. Seldom have practical men received a more heavy fall. Great rules were violated ; the wisdom of our forefathers was thrust avide like a piece of useless lumber; and maxims sanctioned by age, wisdom, and the most resolute routine disappeared like the sparkles of Captain Boxfr's fireworks. A hout a hundred exhibitors of Grapes grown in Vineries in all parts of the country produced the evidence of their skill at the last exhibition in the Regent's Park, and, melancholy to relate, were beaten by fruit from a glass shed in a London nursery garden. It is incredible though true. The large silver gilt medal, the lighest offered for Grapes, was awarded to-Mr. Glendinning, of the Chiswick Nursery-for three dishes of Grapes. Our pen shrinks from recording the event.

The business of a nurseryman is to grow Vines for sale, not Grapes for exhibition. If he grows Grapes at all it is only for the purpose of ascertaining that the Vines from which he propagates are correctly named. With this and in view the fortanate winner in the instance before us built a glass shed or lean-to, with a border and walk at the back and tan-pit in front, hot water being added for the necessary heat. This back border is 2 feet wide; the walk, paved with flat tiles, is 2 feet more, and beyond this nothing is provided for the Vines to grow in. As to the composition of the border it appeared to us to consist of little more than the common garden soil of the nursery ground, and we understand that it is nothing else. Along this back border are planted the following Vines in the order in which they follow, and about 4 feet apart. 1, Black Hamburgh; 2, Muscat of Alexandria; 3, Grizzly Frontignan; 4, Whie Frontignan; 5,
Black Prince; 6, Cannon Hali Muscat; 7, White Tokay; 8, Charlesworth Tokay; 9, Barnes' Muscat ; 10, Mill Hill Hamburgh; 11. Reeve's Muscadine 12, Black Frontignan ; 13, Welbeck Trinoli ; 14, a sort undetermined; 15, Black Barbarossa; 16, Royal Muscadine. This, we should say, is as pleasant a party of Vines with different constitutions as could be readily assembled.

They were planted in the narrow back border just
described, in June 1854. A single rod of each was assumed the beautiful rosy tint which is indicative of led up the back wall and down the rafters; and laterals from these rods bore beneath the glass the fruit in question. Fires were, we understand, commenced last March.
We do not pretend to explain the history of the success of the glass shed. Excellent bunches were still hanging from its roof when we inspected it, and we have no doubt that the prize fruit was justly placed at the head of all others. Nor do we care to know why nothing, hetter should have appeared in rivalry. Great paties past, present, or anticipated may have caused it. What we value the bility of also growing, in his own small lean-to, Grapes fit to take their place by the side of the first in the country. The case is parallel to that of the Strawberries lately mentioned at page 356 .

Alarost every market gardener in the neighbourhood of London suffers more or less from a disease in different kinds of Coleworts, which is known by the name of clubbing. It is comparatively rare in many country districts, and where it is prevalent it is rather capricious in its visits, passing from one garden which it has infested for years to another which was previously free. Little is known of its cause, which is attributed variously to insects or to peculiarities of soil and cultivation, and though wood ashes appear to be a tolerably certain remedy, their mode of operation is not at present ascertained
The subjoined sketch gives reduced figures of specimens selected from a large number, which will express the different forms that the roots assume under the influence of the disease better than any words. In one or two cases only the most careful search has detected the presence of larvæ, which appear therefore to have nothing to do with the

production of the malady. These larvee however were in the soundest parts of the roots, and were not therefore-as asserted in the article Anbury of Morton's Cyclopædia-due to the putrescence which the disease soon generates. A microscopic examination has revealed two peculiarities which we have diseases of vegetables. Of the specimens forming the subject matter of this notice, those which were first transmitted were perfectly dry, and when divided their section resembled closely that of one of the brown-skinned Truffles. A thin slice submitted to the microscope exhibited detached patches of cells often more elongated and pointed than those with which they were connected, filled with a pale brownish mass of distinct globose granules, so as to

rosembie very closely the cellular tissue, colour apart, of some of the red seaweeds, or perhaps more closely still a sec ion of the fruit in some of those genera where the spores form numerous distinct groups,* separated by cellular tissue. Each granule, as far as I have seen, had a minute nucleus, and seemed to have a diameter of about $\frac{1}{60001}$ of an inch. The first impression was that they were starch granules, but iodine did not communicate any blue colour, and with sugar and sulphuric acid they *tructure in the frond and fruit.
protein. Such were the appearances in dry specimens Still more curious matters, however, were ex hibited by others which were perfectly fresh There were still the same granules, though almost colourless, presenting the same reaction. In some,
however, after treatment with strong sulphuric acid and chloride of zinc with iodine, two or more nucle appeared. The granules were so abundant that the moisture on the cut surface appeared milky, and when this had dried up they were deposited in little curdlike patches which could be removed with the point of a lancet. Amongst them occasionally were small particles endowed with Brownian motion In other sections the patches had become brown, and the contents of the cells exhibited a very different appearance. Either the endochrome was grumous, contracting strongly on the application of the tests just mentinned, or it was organised in a very different way. The mass was divided into delicate globose or spherically triangular bodies $\frac{10}{100}$ of an inch or more in diameter, filled with minute specks, which moved in every direction with the utmost rapidity, as if there were a swarm of animal cules within the sac. This motion was not destroye by iodine, and was evidently molecular. The granular matter, when free, appeared identical with the brown granules found by Payfn in the Potato disease, though when confined to the mother cells disposed in a different way
From this it will be seen that the peculiar feature of the disease called clubbing is the conden sation and organisation of the nitrogenous matters of the root. The whole energies of the plant are arrested here, and in consequence the leaves make no progresa, and after a short time the plant dies. It is highly probable that the disease arises either from abundant nitrogenous matter in the soil, upon which some chenical influence is exercised either within or without the plant hy the wood arhes, or from the defect of salts of potash. We are not in a condition at present to explain what that exact influence may be, but the fact of the cells being gorged in every part of the root, where there are not vascular bundles with such dense masses of nitrogenised endochrome, and the prevention of the disease by the application of wood ashes which contain several salts of potash, lead us to imagine that these salts are in some way requisite to prevent this accumulation, by entering into new chemical combinations, and at the same time supplying one of those ingredients which abound in Coleworts, and in the absence of a due proportion of which vegetation cannot proceed without disturbance.
Our second figure represents the two different modifications of endochrome. In the right hand figure the gorged cells are represented as subhexagonal Such was the case with what we happened to sketch but they are as often elongated as in the left hand figure. M. J. B.

Practical lessons in botany for
BEGINNERS OF ALL CLASSES.-No. III. By the Rev. J. S. Hexslow, M.A., Rector of Hitcham, Suffilk.
Herborizing Excursioxs.- Oceasional walks for an hour or two with the children of the first class afford important opportunities for awakening curiosity and imparting information. Sunday walks after divine service admit of the party being joined by some who have left school, but retsin a desire for improvement As a general stimulus to exertion, a pic-nic excursion or two during the summer should include all who have shown an interest in the pursuit, by regular attendance at the lessons and by obtaining a sufficient number of good marks for their botanical exercises presently to be described. The most out-of-the-way unintellectual neighbourhood need never feel lonely to those who hav learnt to hold converse with the works of nature ; and Ido not envy the feelings of any apponent of popular less with aversion or beorn, a party of village children actively engaged in examining the results of a halfholiday's research, appeasing good appetites with (to them) a little extra fare, and winding up a happy afternoon with a cheerful song, a thanksgiving hymn and the national anthem. Such children are not likely to be worse prepared for the more staid proceedings of the morrow's school-room. Considering the desultory manner in which instruction has been given them, the knowledge which some children have obtained of our native plańts is certainly remarkable. They oou learn to recollcet what species may have heen exhibited during a season and by whom, on the plant-stands. They generally know when they have
found one new to the plant list. Walking one day found one new to the plant list. Walking one day
through the village, I heard some one running after me. calling out "Mr. H., sir, Mr . H." Turning round, ound a zealous little botanist (M. S., 12 or 13 year old) holding out a bunch of flowers, her features all animation-" A new plant for Hitcham, Sir." "So it is to what order does it belong?" "Composites." "What genus of our Hitcham Composites does it most resemble ?" After a slight examination, the reply was,

Coltsfoot." "You are quite right. But, as you have never been shown the actual genus to which it does belong, 1 must tell you it ie called 'Flabane. 1 dous I will find it out, and tell you more about it when I next visit the school." The plant was "Erigeron acris", Without dwelling on the peculiar advantages which I conceive children must derive from having their observant faculties thus early educated, I will iustance a case where the possession of this description of knowledge would be useful. The position which this girl now occupies of under-nursery maid would enable her to awaken a love for natural history in children entrusted to her care, and to tell them the names and leading peculiarities in the structure of plants. Her's is no soltary instance of the interest wich persons in her situation in life take in such pursuits. Other children who have left school (and alas! they are generally removed far too early, have brought or sent me specimens which they considered might be interesting, frequently from presenting something anomalons in their structure. Some interesting monstrosities have been thus secured to me.
Hard-word Exrrcises, - With young children (perhaps with most beginners) it is advisable to devote a lesson occasionally to the express purpose of showing them how to master the orthography, as well as to obtain facility in the use and application of a botanical terminology. By selecting the most important terms, and showing how these may be employed adjectively, some in combination with the Greek, others with the Latio numerals, or with other terms expressing peculias relations, the student will soon acquire a correct idea of the manner in which botanists empioy many other words more or less technically, without his requiring any pro cise explanation of these. One of the first lessons of
this description (and there need not be many) should show how the "floral whorls" may be expressed botunically, in regard to the number (whether actual or apparent) of their subordinate parts. As soon as the first lessons on the floral whorls have sufficiently impressed the fact, that a flower may consist of Caly, Corolla, Stamens, and Pistils, the corresponding adjee tive terminations, "-sepalous," "-petalous," "-androus," "-gynous," may be pointed out. If the youngest botanical volunteers are told they must not expect to accompany the next pic-nic expedition, unless they shall have learnt to spell correctly these four termina tions, their slates, in a day or two, will present an amount of orthography which would surprise persons unaccustomed to witness the facility with which children master difficulties of this character. A subsequen lesson may exact, within a specified time, correctness of orthography as well as accuracy in combining the Greek numerals with the same four terminations, and the three others named in the following table. Due explanations should be given of the circumstances under which two of them ("-adelphous" and "-dynamous") are to supersede the use of "androus;" and the other ("-phyllous") those of "wepalous" "-petalous" together:-
$\left.\begin{array}{l}\text { Pity } \\ \text { St }\end{array}\right\}$-gynons $\left\{\begin{array}{l}\text {-adelphous } \\ \text {-dynamons }\end{array}\right.$ -phyllous

| v. | c. | v. | c. |  | จ. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 An- | A- | 5 Pent- |  |  | ec- |
| 1 Mon- | - | 6 Hex- |  |  | Endec |
| 2 Di- | - | 7 Hept- | a- |  | Dodec |
| 3 Tri- | - | 8 Oct- |  |  | Icos7 |
| 4. Tetr- | a- | 9 Enne- |  |  | Poly- |

In this talale the abbreviations imply words of which they are the first letters. Pi. Pistil: Sty. Style, opposite to which "gynous" is placed, because this term is employed in a compound pistil to express the number of free styles: St. Stamens: Co. Corolla: Calyx: f. filament: Pe, Perianth: v. rowel and c.consonant, to indicate the manner in which any prefix expressing a numeral is to be employed before words which begin with a vowel or consonant respectively.
The lesson embodied in this table can be much sooner mastered by young children than the multiplication table, or any considerable portion of it. I have never yet tried the plan, but I think our spelling books and copy books might ke made to serve this cause. Such words as Plenipotentiary and Constantinople, to which will probably be added Sebastopol and Petropaulowsal are not more mpportant than Dicotyledon and Augio spermous. Many vulgar errors and certain popualas misdirections concerning botanical character mig thus be corrected, if a few such sentences in our cop books as "Virtue is its ow
Cotyledon, is part of the embryo
Hypnoynous, inserted on the disk
Perigynous, inserted on the calyx.
Epigynous, inserted on the ovary.
Ithalamiforal, cor. hypogynous and polypetalous. Corollifloral, cor. hypogynous and monopetalous. Calycifforal, cor. perigynous or epigynous
Angiospermous, seeds in a vessel.
Gymnospermous, seeds not enclosed.
Such sentences would be sufficiently near to a strictes definition, to serve the purpose of impressing a few leading and important characters on the memory $A$ hotanical class soon becomes as familiar with ideas terms as with their own names; and the scienticice far beyond any them afford a grap by leaming to group plants according to the Linnean system.

## MEASUREMENT, AGE, \&c., OF TREES, AT BLAIR-DRUMMOND, SCOTLAND.

BY JAMES DRUMMOND, GARDENER AT BLAIR-DRUMMOND.
In the year 1836 I measured the height, girth, and spread of the branches of a few of the trees growing in the park of Blair-Drummond, near Stirling, the property of Henry Home Drummond, Esq., the particulars of which are given in the following table, together with a statement of their age, as near as could be ascertained, soil, subsoil, exposure, \&ce. This year, 1856, now 20 years subsequent to the former dare, I have again measured the girth of the most of these trees that are still stand ing, and have inserted the measurements in this table, showing the increase of the girth of their boles at 2 feet, and at 3 feet 6 inches from the ground. To my presen measurements I have not added the height of the trees, the length of their boles, nor the spread of their branches, as I have no doubt the height of the trees and the spread of their branches are in some measure in proportion to the increase of the girth of their boles. My measurements in 1836 were taken for "Loudon's Arboretum Britannicum," iu which worls they were published, and also in his "Gardeners" Magazine."

The number of trees given in my table published in and 32 , with a good number of others growing in' affinity, and as this same transformation takes place in Loudon's "Gardener's Magazine" is 58, which, in the sandy peat in a low moist valley between the house and above table, I have reduced to 43 , on account of a the garden, are greatly admired by all who have any number 'of these trees being overturned and other taste for trees. They are branched from bottom to top, ways destroyed by the winds, \&c., between the dates of the decumbent branches resting on the ground all my two measurements. The Beech, No. 4, was also round. A number of these have naturaly struck roots, rooted out by the wind last winter, but was carefully measured since. It lost a very large limb a number of years ago, previous to which time it had a most picturesque head; but notwithstanding this curtailment, when laid prostrate last winter, it measured round the extremity of the branches neaxiy 300 feet. The Larches, Nos. 9,10 , and 11, with other two that grow near them, were sent from Dunkeld, about 120 years ago by the late Duke of Atholl, who received the first Larches introduced into Scotland in 1727. The Larches sent by the Duke were planted among other trees in the grove here, and have attained to a grea height; but from former measurements, do not seem during the last 30 years to have added to their girths above $4 \frac{1}{2}$ inches in each of these ten yeara, white some the Beeches, Oais, Elms, exactly a criterion for much depends on soil and situation. Among a group of Larches more recently planted in an open situation, at a little distance from the above, I measured 2, one of which girths at 2 feet above the ground 13 feet 10 inches; and at $\delta$ feet nches-11 feet 8 inches; and the other 11 feet inches, at 2 feet from the ground, and at 3 feet 6 inches- 10 feet 6 inches. Larches here, planted between 70 and 80 years ago, measure 10 feet 5 inches, 9 feet 6 inches, 9 feet 11 inches, and 9 feet 8 inches, a 2 feet above the ground; and at 3 feet 6 inches- 9 feet 3 inches, 8 feet, 9 feet, and 8 feet 10 inches. Silver Fir of the same age, in the same sort of soil and situation, measures, at two feet above the ground, 10 feet 9 inches, and at 3 feet 6 inches- 10 feet. " Larch cut in 1839 measured at above a foot above the ground free of the swell of the roots, 9 feet 2 inches having 49 rings of wood, of which 36 were red wood, from the the same age, at the same 10 inches." This tree was growing in dead sand, and contained above 100 feet of solid timber. The Norway Spruce, Nos. 30, 31 ,

* Nos 89 to 43 are trees growing at Burnbank, on the estate of Biair-Drummond, beyond the boundary of the park, and rous tree, No. 39, seemingly of the same age as those trees growin Mushet of Burnbangs the tomb of the then proprietor, Sir George Mushat of Burnbank, his lady, and three of their children; the two trunks at 6 feet from the ground one measured divides int 8 feet in cir cumference, the other 7 feet, in 1836, and now they measure, in 1856, 8 feet 6 inches, and 7 feet 8 inchen.
and formed fine trees round the mother plant, a circumstance which Loudon says, he had "often observeli to take place with the black American Spruce in mossy oil, but never had observed it do so with the Norway Spruce till he saw it in Blair-Drummond." One of these Spruces produced 5 trees from natural layers, all as high as the mother plant. By the weight of a heavy rain last summer the mother plant gave way, but the notherless children are still standing, forming beautiful group. These beautiful trees in this valley and those in the park, which are perhaps not surpassed by any others of the same age for dimensions and beauty of outline, have had great attention paid to them by the proprietor in the way of "thinning aud preserving them from injury, and on this account, no animal but sheep is admitted to the pasture, so that each kind of tree is allowed to display the peculiar beauty of its form and mode of mrowth, and to extend its branches near the ground." From the North British Agriculturist.

## VEGETABLE PATHOLOGY.-No. CXXXI.

523. Parasite (Grape and Hop Mildew). -Though perhaps as many pamphlets have issued froms the press elative to the Grape mildew, as a year or two before is first recorded appearance were published respecting that other kindred pest which attacked the Potato, there has not been such a persevering opposition to the explanation which seems the least beset with difficulties, viz., its origin from the attack of a parasitic fungus. At the present moment there is scarcely a person of any weight who refers the Vine mildew to any other cause, though a few scattered notices, alleging the most different and improbable causes, appear troms time to mone in our journals, indicative of an utter ignorance of the subject on the part of those by whom they are put forth. The consequence has been that priper remedies have been perseverinuly applied and ther eme lies have that hap self only to blame if he suffers any longer from this troublesome pest.
524. The Vine mildew made its first appearance in the east of Kent in 1845, and was in 1847 recognised as a parasitic fungus, to which the name of Oidium Gucheri was given, afier the cultivator who first studied its growth. Amici, however, observed a short time later a transformation of the joints of which the little
the Hop mildew as and Dr. Plomley, it is more than probable that both be long to the same genus. The Vine mildew has not ye been seen to put forth that fruit which is normal in the mildew of the Hop.
525. As every species of Erysiphe in an infant state s an Oillium, and the supposed species of that genus are with great difficulty distinguished from each other, whil very different species of Eirysiphe may commence with a wory similar Oidium, it is quite uncertain wherher the mildew of the Vine is referrible to some old species, or whether it may not be a mere state of some species which fructifies on a different matrix. All that is certain is that Vines were not observed to suffer till the date above described ; that the disease soon crossed the channel and made its appearance in the norther wineya France; that it spread from the original macleus to the north and south, travelling however far more rapidly towards the warmer countries, and even crossing over to the United States with imported hines, though the varieties of itis Labrusca, from which all the American Vines of better quality have sprung, whether in their own or in foreign countries are uniformly exempt 531. Vines were attacked in Switzerland some years since by a white mildew, the spores of which were so abundant that the coats of those who pas-ed through the Vineyards were as white as if they had been in a flour mill.* This fungus, too, consisted of nechlaces of spores, but jud_ing from the figures and description, which represent it as branched, it appears to have been different from the more modern plague. Should it turn out that the Vine mildew is a mere modification of some common form, we must look for the immense development of the parasite to con remarkable as those which ushered in the cholera on remarkable as those which us
its first appearance in England. its first appearance in England
526. The more exposed the Vines are to prevalent winds and the higher they grow the more are ihey subject to attack. Vines which grow in the form of ushes are far less liable than those which are rained high on trellises. Under all circumstancts the certain remedy is sulphur, either in the form of powder, or in solution of some of its combinstions, in which sulphur is deposited in an impalpable powder, on the addition of an acid, and sulphuretted hydrogen given off. That portion of the sulphur which is precipitated, or which was applied in the form of a powder, combines, as it should seem, with the nascent oxygen, which arists from almost every vegetable process, to form sulphurous acid, which is destructive to
the mould. If these methods are not approved, sul-
phurous acid may be gentrated at once in closed buildings from burning sulphur; but in this case care be taken that the Vines themselves do not suffer.
527. The Hop mildew is so essentially the same with that of the Vine that the same observations in great measure apply to both. The same remedies may be
used with the same good effect, a fact which is now appreciated by all intelligent Hop growers to their reat benent. The hop factors were at first prejudiced against the practice, and refused to buy from those grounds in which sulphur had been used ; lut when it became generally known that Hops are always submitted to the fumes of sulphur in the ost house, i was impossible to contend that injury was likely to ensue to the produce of the growing plant frum the application
53.4 Wherever white fungi a.pear, at lenst where the fruit is superficial, sulphur may be applied with great advantage. As regards the Peach mildew, practice had taught its value long before the Grape mildew wa thought of, and it will be found equally efficacious in the ease of Strawberries and other plants which suffer from similar attacks. M.J. B

## Home Correspondence.

Substitute for Sumphire. - The enclosed specimen of
renaria marina has been sent to me from Northumberland as a plant found at Alnmouth, and ther gathered and sold to housekeepers as Samphire for pickling! Salicornia herbacea and Inula crithmoides I vas aware were both in the market under the assumed name of Samphire, but this Northumbrian pretender is We. Crithum.
Whole Meal Mills.-Mills for grinding Wheat cheaply are yet a desideratum. For house use I think the wh quern would not be wholy inapplicable, at least in principle. A conical mill-they have such in Indiaing of two steel surfaces or plates rotating on different centres. It performs pretty well. Wheat mills, how est, by Geore Fiblhouse Wolactur, among the rest by Georve Fielithouse, Wolverhampton. These mills ane made of different size, for man, or steam, or be a two-guinea mill, but had been sold as a stock residue for 30s. However, a 303. Wheat mill can be had, but I do not think it would prove so satisfactory as the two set close, should not answer, particularly if the Whea were crisp and dry. The water might be added boiling hot, if so preferred. I should mention, while on the subject of whole corn bread, that muriatic acid may be had at $2 d$. per lb , wholesale, and baking soda at $2 d$. per lb, wholesale and $3 d$. retail. Henry McCormac, M.D
Belfast.
Cottagers ${ }^{2}$ Shows.- We have an annual exhibition in our parish of horticultural products, and prizes for the best vegetables and fruits for cottagers, but of late years there has been much dissatisfaction, on account of a suspicion they some of the coldagers have purchased the articles they intend to exhiot, and thus have gained prizes for what never grew in their pardens. I think this
is true, and wish to remedy it. We do, indeed, send round persons to examine the gardens of those who propose to compete at the show, but not with ful success, and the only thing I can now think of is to give such persons lilierty to mea-ure the Carrots and Parsnipg, and such other products as are intended to be shown. If any of your correspondents can give me any exhibitnr, they will greatly oblige me. Spectator
Tellingtonia.-I have two plants of Wellingtonia, each upwards of two feet high. They are in excellent loam, and have made shoots nine inches long this year but to my great distress they have lately begun to die off (as per samples sent). What is the matter? Is it the sun, or some disease? I am confident the root are in perfection of health. They stand in full sum A Labourer, Hertfordshire. [The twigs are dying in the same way as is so often observed in Cryptomeria
Nothing fike it in Wellingtonia has before come under ar notice. The plant is usually one of the most sturd and healthy of the Coniferous race.]
Gigantic Lemm.-Is the Lemon of the dimensions stated below unusual? I never saw one half the size. I was grown again-t the back wall of a small, Vinery, in strong rich sonl. I can send more particulars in point, $18 \frac{1}{6}$ inches : girth cylindrical, 14 inches. weing 1 lb .9 oz $E$. [We should be very clad to hear mere this. So large a Lemon has, we think, never before this. So large a Lemon has, we think, never before Shaddocl. Is it a sweet or an acid Lemon ?]
Large Apple Tree.-The Apples produced by the large tree at Powderham, described at p. 486, are simply a cider variety above the average size. In and taste a mild sour. W, M.
Pot.to Thisease.-This malady has reappeared within these last few tays in this locality with all its usual virulence, the tis-ues of the leaf being first affected. The ptack noll after the exhiting the hours, when amal dark spot may be seen upan the lamina of the leaf; it then speeduly spreads to neighbouring parts. Upon being, dug up immediately after the disea.e exhibited

- Probably derived from the German Obst, a term applied
internally, and some were in a state of complete decom-
position. There is, however, a marked difference hetwe crops grown on light and stiff soils, those in the former being badiy afferted, while in the latter the crops, with rew exceptions, have eseaped and as yet have a promising
appearance. J. R. T., Gurducr to C. S. Wintic, E:I Hacelecoste, Gioncestershive.

Autrietica purpurer. - The beauty of this plant when rightly managed may not be known to everybud. My nurstry is noted for cpring flowers, but this plant $t$ coms the attention on visitors more than any other at, and continues oue fins of blussom untl the end June. Its colour conriasts well with that of other plants of similar habit. Tl e advanta_e it possesses ver many osh plauts is that it ornamental whe it were clipped, producing clumps of about 18 inches in height and as much across. The way I treat it is bows:-About this time I pull away the undt portion of the tuft; by so doing the middle keel.s
growing up until it forms beautiful "c mounds." If left to itself it is a sprawling plant, the middle of which die off and becomes ragged. It will not thrive well in we ground, nor under the drip of trees. It howeve amply puys for a good
brook Nuctsiry, Latil.
Bees.-As an important portion of the bee year is at hand I wish to name a matter which has just occurred. Whing to unite two casts, both were fumigated with the smoke was applied. The bees reco ered, but the honey and comb, a portion of which became attached, aequired a most offensive smell and taste, and have reta ned both, so that the honey is unfit for use. Will some bee keeper say if the effiect snould have been otherwise if the smoke had been properly applied, or sugges some mode of stupefying bees to which the objection does not apply? An Inquirer:
Judging Fruit and Vegetables.-If a prize is offered or the best 12 sorts of fruits am I justified in showin (as two of the 12) Cannon Hall Muscat and Blach Hamburgh Grapes? [Yes.] A prize was offered fo
11 were staged: are the judges justified in picking the best nine out of the eleven and awarding them th. prize! Quiz [No.]

## Societics

Horticultural, July 22.- The Riцht Hon. T. F Kennedy in the chair. S. F. Winterbottom, Esq., II Conybeare, Esq, and Mr. Alderman Finnis were elected Fellows, atd a certificate in favour of electing Mr.
Barron, of Elvaston, a Fellow, was read for the first Barron, of Elvaston, a Fellow, was read for the firs inue. On this occasion subjects of exhibition were tolerably numerous. Messrs. Henderson of Pine-apple Place sent a Miscellaneous collection of plants, among which were Catuleya Leopoldi, a variety :lightly different from C. granulata, the prettily spoted-leaved Maranta pardina, two pale coloured kinds of Achimene the two flowered Screptocarpus, three sorts of Begonias, Clerodendron foetidum, Messrs, Veitch's Impriens Jerdonix, and the two handsome hardy Ceniter Thuja gigantea and Thujopsis borealis. Mersrs. E. G Henderson, of Wellingtou Roall, contributed a group o plants remarkable for their beautifully varingated leaves, a hybrid fiesnera and the mule called Tydea ama bilis, one of whose parents was stateld to be Achimene picta. In this cross the orange searlet of the parent has been converted in the offisuring into a clear and beatiful rose, clusely dotted over with minute dar spots. The same tirm also furnished a collection of Gloxinias, comprising sll the newer and better kinds; but from their having only numbers attached to them, we cannot more particularly refer to them. It is greatly to be desired that everything set up tor exhibition should be properly named, a rule which cannot be too strictly adhered to. From C. Leach, Esq., came a faded flower stem of Buphane toxicaria, one of the most poisonous of all Cape bulbs. It has flowered perfectly with Mr. Leach this season at Clapham. Messrs. Veitch furnished six handsome specimens of Orchids, a beautiful plant of Wellingtonia gigantea, the section of whose gigantic trunk is now being exhibited at the Adelaide Gallery, and a spike of their new Larkspur (Delphinium cardinale) with the brilliant (not dull red) scarlet colour of which everybudy was delighter. This is indeed a real acquisition, and the day cannot be far distant when it will be as common in gardens both of rich and poor as
the ordinary blue forms of the genus. Mr. Glendinning the ordinary blue forms of the genus. Mr. Glendinning, of the Chiswick Nursery, again showed plants of his new Larch (Abies Kempferi), which, in addition to its position amony timber trees; the white Important ineariloba; the chinise ureea dye plant, statell to be a species of Rhamus ; a hardy variety of Limonia tritioliata, and the singular hybnd called Mandirula Rovzli, of the history of which some aceunt will le found at $p$. 45 of our voiume for last year. Mr. Parker, of Hornsey, sent Epidendrum maculatum nd Galeandra Stangeana, two of the lessanowy kinds o Orchids. Two sorts of Grass received from Buenos Ayres along with the Pampas frass were furnished by E. Brande, Esq., of Turnham Green, to show that al of what is imported under that name may not lie Gynerium. Sorghum or some great Panicum.
It was mentioned that the best way of securing the

Pampas Grass true was to send out a spike of it for comparison, and then collectors of it knew what wa Wanted, and were more likely to send home genuine seecis. Mr. Wrench showed a few specimens of Myatt's berries ; but unforiug, the best flavoured of all stram monst people have discontinued cultivating it. From the Garden of the Society came a large collection of plants, which were Ar wina lispliasa, vergreen shrub, remarnable for its delightul eronica variegata, a charming hybrid raised by Mr very handsomest greenhouse shrubs in cultivation: the Chinese Adamia versicolor and the Indian A. cyanes, the former piuk, the latter blue, and decidedly the handsomest. The Garden also furnished Myrta
gmi in fret.
The extranrdinary excellence of flavour of the frui of Eugetia Ugni (which this new fruit bearing shrub is and the high character it then received it still maintains o great an acquisition, therefore, cannot fail to receire Leneral attention. Though not absolutely hardy it ma stated that it was by no means difficult to cultivate, and that Fig houses and places of that description would yellow or rather straw caloured French Balsams also came from the Garden. They were beautifully grown nd flowered, a coudition into which they had bee been raised in a cold pit and afterwads They had common areentouse Dancrs Prolific White Goes herry was also shown in a pot loaded with fruit. This was from the orchard house, and was produced to pror hat, contrary to the opinion of many, Gooseberries will et and ripen under glass. Among vegetables there we capital specimens of White Paris Cos and Neapolitan Cal bage Lettuces, two first-rate kinds; Dancer's Cabbage, fine variely of the Battersea ; and Leyden Cauliflower with heads large and good from plants raised from seed sown in February last; excellent Caulifiowers my
therefore be had at this season without the troable of ceping the plants over winter. Finally, the Gard contributed a collection of Beans, among which Mactie Muwarch (by some called Sangster's Wondtrful) elicited general attention on account of the length of its pods hed waster were very plentiful on the staks, 10 inches in length, and contsined fivo Beans. The next sort worthy of particular notice wi singulař pigmy whose stems did not rise above a foot rom the ground. This was as full of pods as it cond hold and appeared to be well adapted for cottagers ao Il gardens. It wes callat Mar warf Prolific. Other sorts were the Mazagan commo and early; Green Long pod, which is valued for it colour ; Johnson's Wonderful, a good kind of Bean and two varieties of Windscr. Of these, as we
stated, the two first mentioned were by far the best.

## Rotices of 3800 5 .

Walton's Complete Angler has just appeared in a ne ress under the auspices of Mr. Jesse ( $8 \mathbf{v o}$, H. G. Bohn p. 4.96) ; and certainly the favourite old gentema ever before put on a more becoming costume. Twenty xcellent engravings on steel and 203 charming Prity by Bradbury Ir. Jesse has carefully collated the notes of al revious editors, selecting the useful, and rejecting th rroneus or obsolete; Mr. Bohn has added his ow notes on fishing waters, and the whole has an excel lent index. Lovers of angling will doubtiess regar his as the princeps of the many editions that have bee reviously published. The volume is aceompanied by well executed portraits of Walton and Cotton.

A Popular History of British Lichers by Dr. W. L Lindsay (square 12mo, L. Reeve) is the latestadaria popular" hell Ree are popular natural history. If some of hem as esst an exection for it relates to anseure subiect ittle understood even among botanists, is extremely well done, and -is iilustrated by 22 excellent coloared plates from the pencil of Fitch. "The purpose of the writer," says Dr. Lindsay, "in laying before the pubbic familiar Natural History of British Lichens, is to open up a hitherto neglected, or at least little read, page of howk of Nature ; to introduce to those who desire an objec to lead them to our coasts or hills, or who requin pursuit combining healthful recreation with scientin nterest, a somewhat new, attractive, and fertile field o lahour; to offer to observers in Natural History a opportunity of contributing towards the filling up of ap, hitherto very conspicuous, in British Botany, an as towards the further develipment of ens ms bim has not met with ity due meed of scientific or pubblic attention, and whose natural history has consequent hitherto rested on a moot insecnre and unssnowledged foundation. They havo ever boon the ado wain ripprobria of Cryptogamic Botany. The dellcate figers froud of the Fern is anxiously tended by jewelled io the in the drawing rooms of the wealthy and the choice
 tiny Moss has been the theme of many a gifted poet
and even the despised Mushroom has called forth
classic works in its praise. But the Lichens, which classic works in its praise. But the Lichens,
stain every rock and clothe every tree, which form

## Where 'er hature's livery o'er the the globe

have been almost universally neglected, nay despised. This neglect is to us the more surprising when we conpreserved, and examined even by the humblest observer The lichenological student requires no cumbrous expensive apparatus: an old knife and hammer, a fe board and paper, with gum or glue for preserving, and a pocket lens and microscope for examining, constitute his whole armamentaria. Nor is it necessary, for the purpose of collecting, to run the risk or suffer the expense of foreign travel : the objects of his search
surround him abundantly; from tlie sea coast to the mountain summit, he will find them on every tree or rock. Moreover they may be collected at all seasons,
in all weathers and climates, at almost all elevations, in all weathers and climates, at almost all elevations,
and in all countries hitherto discovered. But their very familiarity-the very simplicity and inexpensive nature
of their study-has doubtless operated in some degree of their study-has doubtless operated in some degree
as a cause of this neglect; for many minds are irresistibly attracted by the love of everything that is foreign, while others are fascinated by the possession of complex and expensive apparatus or instruments, which it Our own investigations in the forest and on the mountain have two frequently called forth the look of surprise or smile of compassion to permit us to doubt that such studies are popularly regarded as at bes examination of 'Time-stains' or 'Crottles' is considered a wasteful dispossal of time and energy. This feeling evidently originates in ignorance of the structural and utilitarian beauties of the family. We shall have occasion in the following pages to show that, in regard
to its relative position in the scale of vegetable life, this group of plants, humble and insignificant though
appear to be-

## Important in the plan of Him who rank Thamed  Whiloh Nature's self would rue;

that Lichens are of infinite importance as handmaids of Nature in operating her changes on the face of our globe-in softening down the pointed cragg of our surface of the volcanic lava and the coral islet-in a word, that they are the basis of soil and consequently of vegetabion; that an small section, which furnishes the annual value of many thousand pounds; that many others, under the vernacular term 'Crottle,' have been the peasantry in many parts of our country; that in many parts of the world they furnish indispensable important part in the history of Arctic entarprise inasmuch as they have frequently savell the lives of Aretic travellers; and that they are celebrated in the
history of medicine in this and other countries. If, in addition to these high recommendations, we consider that many species have a texture which, by readily imbibing and eagerly retaining moisture, renders them in a sense independent of all climatal changes,
enabling them equally to brave polar cold and tropical enabling them equally to brave polar cold and tropica be inseparable from, but even corrode or disintegrate the hardest and harest rocks, even pure quartz; that the most ample provision has been made by the great Author of all for their reproduction or multiplication under conditions fatal to all higher vegetation, both by the multiplicity and abundance of their reproductive cells- Which sometimes constitute almost the entire delicate nature of these cells, by virtue whereof they are disseminated by every thower or zephyr, and the readiness with which these germinate; and tha throughout the family, both in structure and products, there are many analogies which bind them closely to the Phanerogamia, we cannot fail to increase our
surprise that a curiosity has not l,een sonner awakened to become familiar with the natural history of plants which strew the path of man wherever he roams over the wide world-which constitute the most universally
diffused type of terrestial vegetation. Whether we look upon the Lichens from a scientifie or utilitarian point of view; whether we regard the universality of adaptations to the position which they occupy i: the scale of vegetation, to the part they play in the economy numerous haks in structure and composition whic conneet them with the Phanerogamia-the importance of their products in our arts and manufactures-their celebrity in the part his'ory of British and continental medicine-their comnection with the history of Arctic enterprise-the abuandance of nutritive species in the climate where they are most required for the sustenance of man and the lower animals-and the curions combination which they present of essential simplicity of structure with infinite variety of form, we think wo have a suffieient basis whereupon to found our plem for From of Lichenology."
From this rather long extract it will be see
the author is unmistakeably an enthusiast as well as a proficient. He sees beauty in everything, fectly agree with him in recommending the investivation of Lichenology to young naturalists with gond habis of observation, for they are most curious .hings, and up to a certain point examined withont mucl trouble. No is there any great difficulty in understanding their clas-
sification or ascertaining the names of the common species, especially with the aid of Fitch's excellent figures. We must however observe that the plan of arrangement employed by the author wonld have heen more easily understuod by the learner had the distinccomparative tabular form, genera been expressed in some comparative tabular form, so that the eye might have
taken in at a glance the essential characters by which taken in at a glance the essential characters by which
they are known. It is not too late to provide this even they are known. It is not too late to provide this even might be added to the copies in the hands of the bool sellers, and given to those purchasers who already possess copies.
The following instructive account of Usbea barbata, the common Beard-moss, which infests old trees in Lindsay's mode of dealing with the non-descriptive part of his subject.
" This species is very common on nur older forest rees, especially Firs, coating them with a shaggy grey and Physcias, it constitutes the 'Beard-muss' Tree-moss' of the poets-the 'idie Muss' of Stakks peare. Poets usually refer to filamentous and fruticuose corticolous Lichens as 'Moss;' hence they sper expressively of venerable trees being mossed with trees in the Fir-wnods which are common in this neizh bourhood (Perth) are completely 'mossed' over Branches thus adorned are usually selected for the
purposes of the bird-stuffer, and must be familiar to all who have seen collections of stuffed birds in public or private museums. It is very widely distributed over the world. In India it is one of the most common species; it has also been found in Ceylon ; on Chimborazo, and in Chili, in South America ; in New Holland; as far south as New Zealand and Tasmania and as far north as Lapland. It is said to be replaced in the Aretic and Antarctic regions by another species, Usnea melaxantha, which is interesting in a threefold point of view, but which may be considered a variety of the most' handiar to a porar cese Lichens, closely aseimilating them to the Phanerogamia. Its cross section exhibits a structure resembling, on surerficial examination, that of an exngenous stem, having a distinct axis and a separable cortical layer ; and it is he only saxicolous species, for in the Falkland Islanda, Dr. Hooker says, it covers 'the surface of the quart ocks with a miniature forest, seeking the most exposed stuations, and there attaining its greatest size and imited gengraphical range than others: var, florida, for instance, is inferior in this respect to var. plicata varieties must depend greatly on differences in halititat and climate. What we now regard as varieties were by the older authors considered distinct species ; but they are frequently found graduating into each other in such a way, that it is impossible to determine under which form or name to arrange them, and several of hem may be met with growing in the same forest, nay, on the same tree. Of all the forms the most remarkable is that denominated var. articulata; it is said sometimes to be pendulous from old trees: our own pecimens were prostrate, spreading over the sandy soil of Exmouth Downs; they are from the herbarium Don. It differs from the others no less in the readth and inflated character of the nodes, or articulations, into which its filaments are divided, than in its ;ize ; we have seen specimens attaining about two fee amilianly but this name has probably been more commonit applied to less rare varieties, in which annular decortieation is also frequent. The economical application of U. barbata are not important, but they are numerous and varied. In some parts of the world it is eaten by odder for domestic animals. Bartram states that in Pennsylvania it has been used to yield an orange dye, and Humboldt mentions its use as a dye species in South. America. It appears to have enjoyed great real adyantages which it possesses. it was at one time much used as an astringent, tonic, and diuretic became a favourite remedy in hooping-cough, and under the name of 'Muscus arborei, sen querui,' was even rauded as an anodyne! It was the basis of some hair powders and perfumes, and was also supposed to posse s quare of detonating or combustible mizture Ray states that it was boiled in beer and druuk in catarrh and dropsy; the Laplanders have used it in scald-head and other eruptions in children; and so early as the times of Dioscoridesit is said to have been prescribed thread has been recommended in paper-making but even in these times, when substitutes for linen rags and Flax fabrics in the manufacture of paper have
become matters of necessity, we fear such a substance
reasoa alone, that it contains no fibrous tiseue. (For
res the minute anatomy and development of this species, vide Dr. Speerschneider in the "Botanis
for March 24 and 31, and April 7, 1854.)

## Garden Memoranda

Mr. Skirving's, Walton, near Liverpool.-This nursery, which contains about 100 acres, is situated on high lying ground on the north-west side of the town. least very nearly so, for growth of hardy stock, or a hinse of $L$, and meuto unimprath with the of very well-grown young Vines, to the growth of very woll-urown young Vines, to the growth
of which and the selection of sorts great atiention seeme!! to be paid. Out-doors, however, the case is reversed ; here we have one of the finest nurseries in ments hy means of excellent hedges, chiefly HornpartYew, and Privet, which are necessary here in order to break the force of the sea hreezes, which would otherwise prove very destruetive. Between the hedges the crounds are traversed hy well made walks into the borders, along the aides of which are gathered together choice shrubs and Conifers, which are left there to grow into specimens. In this way persons desirous of purchasing are enabled to select what they want without being even compelled to leave the walks, a great advantage, espiecially in unfavourable weather, and the places of the shrubs removed can afterwards be supplied with facility from quarters behind the hedges. These borders are thus continnally kept well stocked. Deodars and Araucaria imbricata may be found here in thousands, more especially the former, which, until lately, owed its distribution in this country chiefly to Mr. Skirving, who at a enormous expense, through the instrumentality of the late Lieut. Waghorn, introduced the seed in quantity, at aine when the supply through other sources was quite inadequate the dematore not be surprised when we stale hat acres of this fine Conifer may now be seen in this establishment in all stages, from plants 10 inches high to trees of as many
feet. Equally numerous is Araucaria imbricata, the feet. Equally numerous is Araucaria imbricata, the raised in cold pita sore they are sown broadeast on a bed of loam. Of this Conifer there are here large plantations of beautiful plants.
The export trade connected with this nursery is very all parts of the a rigantic manufactory frica alone takes annually from it immense quantities of hardy trees and shrubs, more especially two-year transplanted Spruce Fir, and Larch, Elm and Oak, in the rearing , Mr. Skirving is more successful than our transtiantic friends, who find it cheaper to buy them Ceder is one formser Mount Alas sale, ond or chanties ore also sold of Black Anstrian Pine whis stads salt spray well, and therefore forms exce lent sea-side shelter. Rhododendrons are cultivated in this nursery by the thousand for underwnom, for which nothing answers so well ; for in and pood corer, gaiey when in flower they form a sork cu'tivated for this purpose are of course not highcolnured fine linds, but a race of common varieties, which can be soid by the thousand at a cheap rate.
Mr. Skirving, as is well known, is a great farm seed grower as well as an extensive nursery man, and this ing his land in "good heart" and attending to a rotation of cropping. Thus when a piece of ground is cleared of its stock of trees it is cropped with Swedes, Mangel Wurzel, or Potatoes, a change which is found to be extremely advantageous; for in addition to the beneits merwise confers, it brings these important food crops department ho payder Mr. Skirving's notice. ep the utost importace to the farmer and to the community large that every acre in the kinglom that commanity at larg er ry ing should be is cropped with corn, or Grass, or roots, should be frop quality and quantity. Every improvement gained in this way is clear gain for it costs no more to grow the best sort than the worst, and between the one and the other there is often from 10 to 20 per cent. difference at least. He goes through these crops carefully day by day, marking and making himself in-
timately acciasinted with their differences, not only as respects earliness or lateness, productiveness or the contrary ; but also as regards their general adaptability or atherwise for the purposes for which they are intended, and thus by close observation, and always ronts to something like perfection, and therefore it is une to be wondered at that we find Skirving's varieties of field crops of this kind everywhere cultivated. He knows what he is sending out, for he has previously thoroughly proved their value himself. We wish al dealers were equally careful. The value of he Fuke has acres of it. Though scarcely horticulural, we may mention that we suw a Bearded Wheat*here which sown in April was in ear on the lst of July; some of the same sort had also been sown in the mitule of May, with a view to ascertain whether or not it will riper this season.
In an out.of.the-way corner was what may not in
aptiy the termed a manure manutactury, where mavy hundsed tons of excellent fertilisiug material are made up everyyear as follows :-A piece of ground the required gize is levelled, aud covepel over with a Macadamised or concrete botton which is surroumled by low earthen or concrete botton which is surroumeatey or walls, also made water-tight inside. Within these is prepared the manure, which consists of Within these is prepared of common loany soil to one load of town two loads of common loamy soil to one load of town
dung, sewage, and road scrapings. These are laid up dung, sewage, and road scrapings. here to rot, and by the time they are wanted they are
in good condition fur use. In this little corner, therein good condition for use. In this little corner, there-
fore, may be said to lie the main-spring of success. To use Mr. Skirving's own words, "it is the gasometer which lights up all."
Aromd Mr. Skirving's house-a commodious new buildag-is a prettily arranged lawn ornamented by a piece of rockwork and some good examples of purple ea breezes areany alluded to, and which blow here at times very strongly, have attained a good size. Leading to the house is also an avenue of fine old Sycamores, whose comparative pancity of branches on their windward side unmistakably pount out the kind of treatment to which they are there subjected.

Although in the preceding report attention has only been directed to a few things that are grown by the thousand, yet there is to be found here an excellent collection of ketcrai nursery stock, including fruit trees, Roses, Ghent Azaleas, Dahlias, Hollyhocis, and Herbaceuus plan's. 'To the latter indeed a considerable amount of space has been devoted.

As regards lieeping, it should be mentioned that every where the ground was beautifully clean, the walks in good condition, and the hedges, which were said to reach nearly 20 miles in extent, very neally clipped.

Connected with this nursery is a very extensive seed buainess, the agricultural department of which is entirely under Mr. Skirving's own direction, from the rearing of the seed to its despatch to the farmer. For Mr growing of good heaithy seed of Turnips or Mangel, for this purpose selects land and climate in various parts of England and Scotland to the extent of hundreds parts of England and Scotland to the extent of hundreds suffient seed of his celebrated swede.

## Miscellaneous

The late Mr. Hislop.-One of the liest of cur old gardeners has quitted the scene. John Tislop, a most worthy man and experienced cultivator, died on Sunday, been gardener fur 35 years. Under the name of Quercus he was an oceasional contributor of excellent practical articies to our columns. No one knew better practical articies to secure the respect of acquantances or the affection of friends and relations, aul his death is a heavy loss to the little circle in which he moved. Mr. Hislop was aged 70 ; for many years he had been a corres was aged 70 ; for many years he had been

## Calendar of Operations. (For the ensuing weck.)

PLANT DEPARTMENT
Cosservatory, \&c.-While flowers out-of-doors are plentiful nothing sloould be brought here at present that is not a fair specimen and well hoomed, nor should any plants be allowed to remain here that are at all shabby bad management sumewhere to necupy glass structures with plants of interior interest to such as are pleatiful a the open air. Ii ls not desirable on our opin!on, however, to crowd the house with thowering plants, but the
aim should rather we to have a nolerate number of handsome specimens effective! y arransen, which, while flowers are so plentiful out-of-diors, will he vastly more interesting and pleasing than a larger anount of floral display from plants of no individual minerest or merit
This hind of display nay be antecalle enough at a seasun when flowers are scarce, but it is aseless to hope to maintain the interest of a house at this season by this lind of management. A thin armagement of the pot specimens will also be advisable an atcount of the permanent occupants of the beds or borders, which at in ordea to secure strong well-ripened wond, for maless this is obtained they will not bloom finely. Losols over former directions, and use every meaus to meep insect in the mauagement of this house. Stove,-Such of the in the mauagement of this house. Srove,- Such of the inmates here as are intended for the decoration of the conservatury in auturan and early winter should be carefully looked over, shifiag such as are likely to want more pot room without unnecessary loss of time, so as
to get the pots we.l nilued with roots be!ore their thowering season. Also hicep the shorts tied out rather thinly and exposs the plants to as much sum-hne as they wil bear without scorching their foliage, in order to pronnote stocky growth. Give clear weak liquil manure water to young growing specimens, and repot any of these that are miended to have anuther shift his seazon, so a Maintain a moist growing atmosphere cud apply the syringe vigorously uponany plantaspall infest-ip with red spider. Onchids, - The growing season is far advanced, therefore encuurage any backward plants with plenty of heat and moisture while this can be safely done. that plants growing on blocks and in baskets ar
roperiy suppied with monsture at the root, and to pre week, and immerse those found to we dry in tepid water until the material about the roots is well soalied. Sy ringe lightly morning and evening, and sprinkle the fluors, \&c., frequently, so as to keep the atmosplere thoroughly moist.

## FORCING DEPARTMENT

Pinery.-Attend carefully to growing stock, keeping the bottom-heat regular, and the atmosphere warm and moist, and use every means to secure rapid vigorous growth. This will not be obtained, however, unless all is richt at the root, therefore attend well to watering, and never allow any of the plants to become pot-bound. Give air moderate!y to young stock, and shut up early in the afternoon, giving the plants a gentle wipe with the syringe, and the house a good steaming by wetting every available surface. Continue to pot a few suckers, as they can be obtained of sufficient strength, and do not allow too many to be produced by one plant, as they weaken each other. Indeed we never allow a sucker to grow to any size that is not likely to be wanted for stock, and, unless in the case of any scarce sort, never more thau two on a plant. Plants growing
in beds of soil must be very carefully attended to with in beds of soil must be very carefully attended to with water, giving enough at eacl application to moisten the
whole body of soil; for unless this is attended to, the whole body of soil; for unless this is attended to, the
bottom of the bed will sometimes get quite dry, while the surface is moist. Vineries.- The inside borders of houses intended to furnish a late supply of Grapes should be well soaked with manure water as soon as of antumn set in, for be damp cloudy days and anything likely to cause it should be avoided. Muscats beginning to ripen should be assisted with fire heat, for it is hardly possible to ripen these properly at any season without artificial heat; and those for late use should be pushed on, so as to get them right by the end of next month at the latest; to get them right by the end of next month at the latest; for those ripened later in the season are seldom of good
quality, and we have always found them to liang better when ripened early in autuman than those that were ripened later in the season. Figs. - The second crop on the earliest trees will be fast advancing towards maturity; as soon as the fruit begins to ripen riving air freely every fine day and using a little fire on wet cloudy days, to prevent damp and allow of a gentle circulation of air. Use every care to keep the foliage clean and healthy, and clear of insects, and do not crowd the young shoots. Me kept dry at the root, and freely exposed to air on fine days, avoiding moisture in the atmosphere as far as call be done without injury to the other plants. Do not allow the bottom heat to aecline where the fruit is setting, off. Keep a watchful eye on the foliage, and guard gainst red spider, which, if once sllowed to establish itself, can hardly be removed without greatly injuring the tender foliage.

FLOWER GARDEN AND SHRUBBERIES.
Proceed with Rose budding without delay, keep down all suckers and clear the stems of wild shoots. Strong shoots of Chrysanthemums may now be layered in pots to produce dwari and compact bushes. Those in pots may soon receive their final shift. Layering Carnations nd Picotees may now be proceeded with. Much of nex All seedling plaits should be marked and layered, noticing their various properties as to form, colour, and texture, \&c.; shoruld any seedl ng otherwise fine have serrated petals, it will be advisable to propagate it, as growing it in another situation may to a certais
degree remedy this defect. Continue to plant out cooted pipings of Pinks on beds of well prepared soil but not too rich. A second crop of pipings may also be inserted where an increase of stock is required. Gather seed, and when dry hang it up in paper bags till wanted.

## FLORISTS' FLOWERS,

Carvations and Picoters.-In some localities these favourite flowers will be getting fast into bloom ; the plants in pots should be removed under an awniog similar to that used for 'Tulips. Here they may be arranged on a raised platform or not, according to the aste of the amateur-the Picotees grouped on one side, the Carnations on the other, taking care that the tallest plants are behind, and at the same time conirasting the colours as much as possible. Pipings may be put in on a gentle hotbed, the grass or shoots are usually layered ones, anewhat later jeriod; but where there are smal to layer, it is a good plan to obtain plants struck from cuttings. Plant out in showery weather Pink pipings as above directed; or, should the weather prove dry, cover the bed wi!h any light awning, leep thern moderately moist, and they will sueedily estabish themselves. Ranunculus rots may be taken up as soon as the foliage turns $y+l l w$, for shouid rain ensue, they would emit fresh fiures, and, it then taken up, their destruction would be certain.

## HARDY FRUIT AND KITCHEN GARDEN.

A considerable breadth of Endive may now be planted without delay. High manu ing is necessary to produce this salad in perfection. In planting succeeding crops keep raising the beds higher as the seasun duly thinned. Let a good breadth of ground be pre-
pared for Wiater spinach forthwith by thoroughly trenching and burying a good coat of half rotten manure in the bottom. It generally succeeds best in beds slightly raised. Continue gettinf ont Cape and other Broccolies, and also some late Cauliflowers. An autumn Mushroom bed may now be made; throw the dung together to ferment tur a few days; when half dry, mix one-third of loamy soil with it to keep in check any further fermentation, and tread or beat hard while making the bed, forming the spawn holes immediately it is finished to assist in keeping down the heat. Strawberry runners should be procured for new planta. tions without delay. Those who cannot spare ground fur a new plantation may prick them out in prepareu beds about 6 inches apart, and remove them with balls in October or in the early part of February. For Black Prince, and Elton are insaluale. One of the best of the new sorts we have seen is Kitley's Carolina superba.

## The Savicultural Gabette

SATURDAY, JULY 26, 1856.

The very successful gathering of the English Agricultural Society at Chelmsford terminated on Friday of last week with the formal meeting, when the thanks of the members were very properly voted to the office-bearers and others who during the past year have contributed to its efficiency, and especially to its utility at this the concluding labour of its session. The occasion was more than usually interesting from the circumstance that the prizes to foreign competitors and the medals to the foreign jurors were then presented by the retiring president, Lord Porthan.
Those mainly interested in these meetings are for the most part arrangeable in two classes, viz, buyers and sellers. And we have every reavon to believe that whether in the implement department or in the cattle-yard the Chelmsford meeting has been satisfactory to both. Implement exhibitors as well as cattle-breeders and flock-masters have found a good market, and those who came to buy have had ample scope from which to make their choice. Besides these, however, there are a large number who, though attending the gathering no doubt with an ultimate eye to business, are yet merely spectators during the week of meeting. It is in its influeuce on these that the utility of the Society is chitfly seen.
They come to compare their own means and results, whether in machinery or stock, with the best specimens of both that the present diy affurds; and they go home so far assisted and urged to self improvement that they at any rate know now at what models to aim, and how far from the mark they are at present. That a national suciety, visiting well fitted to serve the purpose of in-tructur in this way is plain from the fact that at every meeting of the Society exhibitors resident in the localty have been but a small minority of the whole body of contributors to the exhibition. At Chelnsford, of
the thirty-nine exhibitors in sheep only four belonged to the locality of the Show, and as the show of sheep at theve meetings is a very fair illustration of the stock defartment generally, we Live a table showing the number of counties itpresented, the total number of exhibiturs, and the number of the exhibitors from the localities visited at
several of the last annual meetiogs; facts which
are interesting as displaying the local benefits con-1 ferred by the Society in this way.

Place of Meeting.

Our illustrations of the other feature in the character of these meetings-that which they present as a great annual market for live stock and for im-plements-must be taken from the sheep stnck also shearling South Down ram in the yard, sold the prize sheep to M. Yvart for the French Government for 150 gnineas; and the influence of the award of the Society's judges may be seen in the fact that during the meeting 40 ewes and rams were sold from this flock, at prices for the latter varying from 50 to
100 guineas, to Germany, France, Prussia, as well as to Sussex and other counties in the United Kingdom. The sum of 150 guineas was offered and refased for another ram shown by Mr. Overman at Chelmsford, and 30 guineas were refused for a single ewe. We mention these facts both as indicative of the extraordinary demand for well-bred stock at the present day in almost all parts of the world-as well as to the credit of an independent flock of the South Down breed descended from ewes purchased 60 years ago in Sussex-the first of their breed that were brought into Norfolk. We have to add on this subject that Lord Walsinghay was offered 250 guineas for his first prize old ram, and that Mr. Rignen refused 15 guineas each for his beautiful pen of shearling ewes, which according to many ought to have stoul higher in the estimation of the Society's judues.
If we almost confine our illustrations to the South Down stock it is because the number and quality of this breed were really the principal feature of the show yard-the other main point requiring notice was the show of horses, of which a report is given below. We have already referred to the show of short-horns and the prices for which some of the animals were sold-that of Devons was good, notwithstanding the absence of Lord Leicrster's stock owing to the recent existence of disease in his herd. That of Leicester sheep was deficient in number, and we had to notice the absence of Mr. Sanday, of Holme Pierre-pont, who had on previous years figured successfully. That of Pigs, which was very good, no doubt suffered in a similar way from the absence of Mr. Fisher Hobbs' stock, which have
but recently recovered from an attack of disteniper.

THE SHOW OF AGRICULTURAL HORSES AT CHELMSFORD.
THIS was expected to be good, and whether we consider the number exhibited or the good qualities of in which they have heen, meetings of society cultural horses of any age above 2 years, no less than 47 animals were entered-a larger number, if we mistake not, than ever were entered before. The ist prize was awarded to a brown Clydesdale horse, No. 228, the
property of Prince Albert, an animal possessing in our eyes all the qualifications of a first-rate agricultural fore legs, and splenth, good loins and quarters, capital fore legs, and splendid action.
4 The second prize was given to a splendid Suffulk 4-year old horse, No. 202, belonging to Mr. Biddell, o
Playiord, near Ipswich, an animal belonging to
race of prize
qualifications.
horse belonang arkahily fine and ponerful grey rarthorse belonging to Mr. I. B. Hhtiyard, was highy commended; and a very superior chestnut horse, the
praperty of Mr. Barthrop (216), was destrvedly comproperty of Mr. Barthrop (216), was destrvedly commented ; as wrill as a stront and handsome lay loursa, the property of Mr. Rust, and a coal black 4 -s eat wid horse belonging to Mr. Blewitt. It is somewhat singular that although black is the most prevailin; colour amonsst cart-horses this was almost the only animal of this colour exhibited
Class 2. - If in the 1st class the Suff.lis hald to contend wihh all England and met with worthy and cuccess. ful competitors, in the younger classts they almost
enjoyed a monopoly of nerit, and consequently sucenjoyed a monopoly of merit, and consequently suc-
ceeded as younger animals in carrying off the greater ceeded as younger animals in carrying off the greater
number of honours. This of comrse may partly be attrinumber of honours. This of conse may partly be attri-
buted to the proximity of 1 . - native county, whose buted to the proximity of t1. "native crunty, whase
reputation, however, they w. sustained. Thus the first prize was awarded to su. 271, a remarkaily promising Suffolk colt, owned by Mr. Eextom, of Earl's Hall, near Sudbury, whilst No. 258 , a scarcely inferior
colt, the pronerty of M1r. Badham, wained the 2d prize. colt, the property of Mr. Badhan, nained the 2 d prize.
A very fine brown colt, belonging to Mes.rs. Spencer, was highly commended; and several others received commendation. Thare were no less than 28 horses entered in this class, of which the majority were Suffulks.
The next class, for agricultural stallions foaled in 1855, was not so numerous. The prize was awarded to Mr. s. Clayden, Suffolk, of considerahle merit, whilst a black Gloncester colt, No. 281, was highly commended. The mares and foals for agricultural purposes, class 4, brought torether no less than 24 mares with their foals, breed. The prize mare, No. 290 , was a very fine mare, though perhaps sonewhat less compact than some other specimens; she was owned by Mr. Carter, of Danbury, whilst the 2 d prize was awarded to an old mare belong-
ing to Mr. N. G. Barthrop, No, 297. A simular prize was bestowed on this mare at the Exeter meeting, and right well has she worn her homours since. We resard her as one of the best specimens of the best qualities of the Suffolk breed. This ofinion was evidently shared by others, if we may judge from the fact of her having realised, although 15 years old, no less than $150 l$. with
her foal. She had remarkably good forelegs. Mr. C Cordy's mare and foal, 287, was highly commended. No. 288 was commended, and other mares rivaling the prize animald were no doubt flassed over for specific reasong.

Class 5, of fillies for agricultural purposes, was also rich in excellence and in numb-rs. The prize animal,
No. 311, belonging to Mr. S. Wrinck, posse-sed conNo. 311, belonging to Mr. S. Wrinck, posse-sed con-
siderable merit; she was, if we mistake siderable merit; she was, if we mistake not, related to
the old mare alluded to in the last class. The second prize was given to Mr. S. Clayden, filly No. 313, an animal though less in size than some others yet very compact, with remarkably good foreleys. Prince Albert's
Clydesdale filly, No. 316 , was highly commended, and Clydesdale filly, No. 316, was highly commended, and prize horse in the first class we may expect in a few vears in the south of England to rival the north in the best specimens of this breed. The finest filly in the show, looking at her in her box alone, we consider was No. 314, the property of Mr. John Ward. A Gloucestershire bay filly, 318, belonging to Mr. Holland, was also worthy of commendation
firs and enencely observing that whils the first and second classes were probably the prineipal
feature in the Show, other classes, such as the mares and fillies, presented stecimens of consilerabte excellet ce. We cannot, however, torbear obeerving that the Suffoliks have of late years much increased in size, aud
though this is a point by no means to be lost sight of, which is that in attaining this olject care should be taken by means of careful selection (ior no Suffolle mare will cross with other breeds) that the bone and sinews below the knee, as well as the action, should keep pace with the increased size of the animal. With regard to the special prizes they brought forward animals of competition as with the agricultural horses. W.C.S.

## a new manure.

Elijaf Suith, gardener at the Wakefield Uniou Workhouse, tried a load of the new manure from the Wakefield Gas Works in 1854. He applied it alone to
1, Early Turnips; 2, Onions; 3, Broceoli ; 4, Cabbage.

The Turnips were particularly fine, having tops upwards of 2 feet 6 inches high, with leaves broader than a man's hand. 2. Onions killed by excess of manure. 3. Broceoli became, a short time after p'anting, as blue as if painted, but still the plants grew fretly Gradually the blue changed to a dark luxuriant green The quaster was the admiration of all who saw it as it did of all in the neightouriood. What was alive was considerably hurt, hut as spring advanced it became uxuriant, and produced as fine hends as could bave been obtained by any manuring whatever. 4. Cabbage planted very late and bad plants. Louked badly all the
winter of $1854-5$, but when the growing geason commenced in spring it looked quite as well as a neighbouring quarter, well manured with stable dung, and hearted as well, though about three weeks liter. Soil a huugry andy loam upon poor sandstone gravel.
John Turner, farmer, Stanley, used a single part of a
load (from Wakefield Gas Works) upon Grass, applied early in January, 1855. Patches of Grass were 'tilled where the manure was put on too thickly, but all around the dead spot the Grass grew in the most beautiful manner. On the lst of May, 1855 , the Grass on the manured spots was $6 \frac{1}{2}$ inches high, while, owing to the dry weather, the rest of the field was bare. The enormous difference of colour and crop was visible to every one. Patches of the finest green Genoa velvet upon an olld brown frieze coat is no inapt picture of the difference. At mowing time there was more than three times the quantity of Grass where this manure was put than there was in other parts of the field. Encouraged by this result he dressed the whole of a 9 咅 acre field in 1856 ane three lands in the middle, which were manured with "short muck." Remarked all through the spring the beautifully dark green colour of the dressed portion and that where most of the manure was put the Grass looked best. The field is now open to inspection, and in the third week in June where the new manure was properly put on the Grass measured on an average, maximum 421 inches, minimum 27 inches. The part not dressed with this manure was, maximum 24 inches,
minimum 14 inches. Soil here a strong cold undrained clay, in many parts wet.
John Thompison, farmer and assistant overseer, Out woor, nesr Wakefield, obtained two small loads from the Wakefield Gas Works, mand mixed it with about an equal amount of soil. This was applied to about acres of Grass. Against it were used- 1 , farm-yard this instance the colour has been throughout better with the new iuanure. It continues to have the same marked difference in colour, it is thicker in the bottom and very much stronger than either of the cther plots against which it was tested. I visited this field in company with a friend, and we were boih struck with the great sapefriend, and we were both struck with the great sape-
riority of the Grass grown with the new tillage. I have riority of the Grass grown with the new tillage. Ihave made several experiments with it myself. In October,
1854 , I applied about a ton to half an acre of land for Cabbage. The severe winter killed a considerable por tion of the crop. Windsor Beans were therefore planted amony part of the Cabbage in the spring of 1855. These produced largely, and the Cabbage which was not killed aid wel. Another prart of the Cabbage crop was destroyed, and the ground planted with loug red Mangel Wurzel in April, 1855. The extremely dry seapon rendered root crops in the neighbourhood very deficient, but notwithstanding the drought, this Mangel looked well and grew freely, and when topped and tailed and weighed at the public weighing machine the crop was found 24 tons 4 cwt . per acre. A crop of White Wheat is now growing upon this half acre, and could not look better. The leaf is broad and almost black green. The straw is particularly stronz, and all who have inspeeted it unhesitatingly pronounce it the best Wheat they have seen this year.
Besides this, an acre of the same kind of White Wheat is growing in the same field. This was sown atter Potatoes, manured with part of the heap mentioned in my essay on the Fermentation of Manure, in the Journal of the Royal Agricultural Society, page 11—12, experiment 5 , and in note page 12, experiment 2. This crop is very fine ; but the former is decidedly superior in three respects. 1. The increased darkness of colour, owing to the more highly nitrogenised manure. 2 . The silicater leaf. 3. Stronger straw, due to the soluble to the silica rendered soluble by the and also, 1 think, (in the presence of silicates) from the nitrogen which (int the presence of silicates) from the nitrogen which earbon and sulphur. Perhaps I ought to add, 4thly, the rather short straw, which renders the crop less iable to lodge. The Potato Wheat averages $40 \frac{1}{2}$ inches in height ; and that grown with the new manure, $37 \frac{1}{6}$. seed, two bushels per acre, sowed broadcast and ploughed down. Since sowing time, nothing whatever has been done to either crop, that no disturbing element rom culture might vitiate the comparison.
A very instructive though unintentional experiment was made in this field. The load of manure from the gas works was shot up and allowed to remain in a heap for a few days, owing to wet. When spread it whs carefuly shovelled up, and nothing was supposed tod left. Un this area nearly every plant of wheat ded not soon as it sprung up; and the few plants which were no mariurial substance, that it is duubtful whether they will ver be ar anything. But around the margin of the heap, uhere relative excess of manure was scatterd, but where there was no drainage from it, the crop is exiremely luxuriant. Oct., 1854.-This manure was applied at the rate of more than 5 tons per acre to a piece of land containing about 300 square yards, Every crop sown or planted on this land was killed, or ere plauted in to borthless, till some Cabbages wa extremely dark in colour, bot smaller than others of the same kind growing on adjacent land manured in the ordinary manner. Potatoes, interlined between Cabbage, rrow freely and are very dark in colour. The known excess purposely applied in this case is only just of harm.

A ton of the manure was mixed with a manure heap, and applied to three acres of Potatoes planted this -pring. Planting began April 22d, and finished May 5th. Part of the sets were sprouted, and set with the spade. The reat were set by the plongh Unless
dry weather connes soon, those which were sprouted will produce too much top.
In the spring of 1856 a plot of bad Grass, which I know has not been manured for ten years, was freely
dressed with this manure. The dressing was as large as can safely be given. This plot was mowed five times by a man in the neiginiourhood, to whom the Grass was given for his horse. Each time the swathe was close and heavy; white on an unmanured portion adjoining, the Grass would hardly stand against the scythe. A beginning to rot at the bottom owing to its thickness. This is a particularly favourable result, when the ditch, in the Wakefield Jounal.

## HOME FARAL MANAGEMENT.-No. VII

One of the first improving operations of a newly established home farm is that oi laying out the land into than a tenant's improvement, but inasmuch as the tearing out of old fences usually pass tolerably well, this undertaking will at least belong to the tenancy depart-
ment. There can be no greater muisance on a farm han numerous old wide spreading earth banks, surmounted by guarled hedgerow trees and scraggy plants of almost every species indigenous to the district, for they harbour both winged and burrowing pests that
interfere with the farmer's arofits. And they are also the means of obstructing the circulation of atmospheric air and the diffusion of light, without a maximum amount of which cultivaterl plants cannot attain a perfect development. Then even in the mere working the small fields into which mumerous hedgerows cu to be encountered. The frequent turnings in plongh ing and other field operations consequent on the short ness of the lands render the labour to a large laying out of the groond in the resy onterence the laying out of the ground in the very outset of home farming, is a work of great importance to the after success of the "perations. It is well not to make the
new fields either too large or too small. If these range from 12 to 20 acres they are of a better size than they would be if either much larger or much smaller. The fences whether dead or alive should be as nearly as possible straight and run at right angles to each other. and belts of wood, and in these instances the curved line of fence can be united to the straight line with advantage. Though the fencing is a proprietor's improvement, it is one which the tenant ought to have performed to his mind, and the farm manager to some extent representing the latter should have his say in everything connected with the division of the land. By his taking care as far as the nature of the ground wil rectangular parallelograms-he will be taking the best ossible measures to ensure the conservation of labour in coming years. It is for this reason that the curved line of fence is inferior to the straight line in the fincWhen of cuvated land.
When a hrme farm manager enters on a new charge the old fences as may appear advisable and be consented to by his employer. But if the land has already been for a number of years in the proprietor's hand and been laid out in fields, he would require to be very proving landowner does not like his works to be mproved upon even though they should be less perfect than he himself could wish, and the zeal of a person newly entrusted with the care of his farming interests, ive very serious offence
Between the laying out of a farm into fields and determining its rotation of crops there is necessarily a farming is in every case to a large extent depens of on the system of cropping that may be adopted. In ne sense the term "rotation of crops" might be nother we shour agricultural nor think lightly of neither desire such a deletion nor think lightly of the evil results which would inevit-
ably spring from it if carried into practice. At one ime it was supposed that some of the particular mineral ingredients required for any species of plant, could only ime in fallow, or heing kept under a different kind of crop Cereas atter green crops or fallow, and not in succession, hecame the plerfection of farming in the eyes of many, and to speak of growing Wheat year after year this there was a great deal of sound common sense, but the limitations it entailed on the farmer were often sermus in their nature. He could not grow an extra breadrh of kind of cleansing crop during the previous year. Now, however, that science has come to his aid the case is Barley after Barley for 20 years if he chooses, or indeed y length of time, provided he mply keep dow requires. Thisplies the chemical ingredients the crop requires. This he may partially do by pulverisation of the soil on 'Iull's principle, and partially by the application of suitable manures. Un argillaceous soils the latter may even be dispensed with, for a time, provided the culture be very complete. And in almost every
case the yield of any particular cereal crop, whether
limited under a certain point simply liy a limitation in fertilisers.

It is something to know that rotation systems are no longer indispensably necessary, und if still adhered to in a great measure by the best farmers in the kin_dom they are so simply because of expediency. Rotation of crops the discore is met abolished, wut may be inproved upon by in the management of home and let farms that system eropping wind afford the largest returns at the least pussible expense, A ccording to marketing or climatic peculiarities modifiaccording to marketing or climatic pecularities modifiand it is the part of a judicious farmer to study the
circumstances under which he is placed. J. Luckloart Morton, Lasszade.

## Fome Correspondence.

Common Llings in Agriculture.-However unnereswithout throwing moch additional linht on the sulvects discussed, yct it may not be altogether a waste of time on the part of the writcr, or too great a trial of the reader's patience, to return occasionally to common things, which are, alter all, most important features in oprations, and embrace more than mere mechanical the cultivation of his land are to podnce ahundart crops and to insure their beng of the best qualuy. 'To obtain these results he must step out of the usual routin follow, the example of othersin every particular, thounot he may take hints and avoid errors. A knowledge of the geolngy of the neighbourhood is ensential to the suceess'ul management of a farm, both with regard to draining and the crops likely to he most renuluerative. of every description of land coming under the hauds of the farmer ; rules may be laid down on principle, tut cannot be arbitrary without producing mistakes and loss. John may sow a fine breadth of Turnips on his 12 -acre field, and his neighbour William on similar piece of ground not be able to perfact roots enough to feed a single beast, though a the time of sowing his treatment was the same. Why was this? The previoua prrparation was in fault. John knew that Turnips required different tillage from Wheat, and benefited by his experience; William only had half his lesson learnt, and like an idle schooltoy be comparatively barren; in such cases the aim would be to carry off the superfluous water, but the means to be adopted would differ nccording to the nature of the soil, whether stiff or light, as well as with regar be strictly observed un all occesions, the drain wie to be strictly observed an all occhsions, the drain-minh
be a too near, too far npart, too deep, or too shailow even the springs might require to be tapped, thus saving great expense. The next step in rdvance is moving the soil to the depth of 12 or 14 inches, for the
purpose of admitting air and destroying annuals; the perennial weeds whose roots lie far below the surface, out of the way even of the long fork, must he kept under during the growing season at any cost, not for one year, but for three or fruur.
This can only be accomplished by sowing grain and roots wide ennugh apart in the rows to work amongst them reeply at first, and on the sur-
face as the crons attain arowth. Manuring heavy land undrained and surface-ploughed is throwing money away. When it can be obrained ater the two first year residence tenants should have a good supply; there is nothing superior to farm-yard muck well looked after, once turned over with alternate layers of burnt weeds and rubbish, ashes, road dirt, \&ce, to which a certain should be dressed with this each year To the holding should be kept, and the farm not left with scarcely an animal, because provision has not been made for wint Farmers may say, "We know all this; tell us somed to Farmers may say, "We know all this; tell us something
new." There are some more cormon thinge to refresh your memories with, which you shall have, too, another day. 'Time enouch for theories. Fulcon.
A Cheapsubstitute for Cuano.-Nbout themidile of the month uf May I procured from the gas works six gailons of floats on the sut face of the tar. I diluted it in six times its amount with water from a pond, and appied it in middle of a meadow firld. The day turned out sunny, and I went to look at the phace in the evening, when lo ! it had been burned. I thourht it rown as though seeing any further what effect it had zupen the ernp. Honever I chanced to $n$ over the same place mana this day, and to my surprise found the Grass of a dark green, aimost black, ithad ber highy manured in the winter. I could tell to half an inch where the water had been put and I consider that there is as much more Grass. I can corn if applied in a judicions manner. I think that it requires ten times it- quantity of pure water to use it
sately, and to be applied in the winter season or in dull sately, snd to be applied in the winter season or in dull
showery weather ; do not choose sunshine. If the water
has so much of the maturns privelple in it why not applied in the winter I think great benefit will be derived from it, but care must be taken to let it lie a few months before carting it on the land. Henry May, he Hope Nurseries, neur Bedale, Forkshire.
Bon,dell's Traction Engine.-Allow me to draw your attention to an oversinht in the concluding remarks of your report on the above engine last week, where your doubled to produce the same of the pinion mast be donbled to produce the same rate of movement on wards wheel and as placed on a level with the axis of the wheel and as much is list as gained." The uniform velocity of the gearing teeth of the pinion around its of the pon of the carriacity of the onward movement renerating point in the vertex of as is the case of the cenerating point in the vertex of a cycloid. It is equal of the unitorm or rotary velocity of the periphery of the arge wheel, it is true, but your reportar appars to overlook the fact that the rotary velocity of the periphery of the carriage wheel and its onward movement at the top are two different things, for the latter is the sum of two equal velocities as in the case of the cycloid already ment:oned, the one being the uniform velocity around the axis, and the other the trauslatory velocity of the wheel rotating over the ground. On a level with the axis you will perceive that the uniform velocity is downwards acrons the path of the carriage a heel and not onwards, and at the bottom of the wheel in the apposite direction from what it is at the top; honce the reason why there are two velocities (or vertex of the cicloid and top of the wheel or in the Such then being the facts one at the bor base. question at issue is this? Does Boydell gain the ranslatory velocity by the peculiar posit of the pinion, the two gearing teeth each pearing in the vertex of a cycloil? (ir, as he himself expresses it, speed! At double effective power without losing power is present the rule is, as you are aware, that of which the wheel in question is an instance, as your reporter justly admits; but you will perceive that Boydell's proposition is not strictly speaking aa excepion to this rule-for his power is gained at the expense space-but half this space he gains, which is quite a different question, although we are apprehensive this is the stumbling block of his opponents. We have all along advocated that the proposition was a new one in mechanics, with presumptive data in its favour, bat solved by experiment, and the experiments at Woolwich by the Board of Orinance-the hauling of Biduelis scarifier and the five ploughs in the heavy and field at Chelmsford fully bear out the accuracy of heoretical data in Boydell has even more than (the experiments) prove his opponents wrong, although they do not solve his proposition satisfactorily. Of the mportance of the proposition in the application of team to auriculture chere cannot be a doubt, were th.ere nothing else introduced than the self-locomotion of a portable encine ; and we must beg to express our regret that something more was not done at Chelmsford to test its accuracy by properly conducted experiments. diced mere scientific question it merits more unprejathan it moitto-" Practice with Science," W. B. [We have further letters on this subject, to appear next week.] Mi. Mechi's Gathering at 7 iptree. - I went as usual to Mr. Mechi's gathering this year but did not perceive of farming improvement either in his system hen compared with lase year. His system of cultivatinn continues high and expensive, though no doubt in the right direction, and those who had not seen it before would gather many useful hints, from the cleaniness of the land and the heavy crops produced, that are calculated to impress upon them the good effects of enterprising perseverance. The gathering was much arger than I have seen it before, thus showing its inuninvited guests, howerer, be that as it may the hosp tality of "mine hos!" was freely distributed to all, and the warm generous reception given was only a repeticordiality of tis rars. Indeed nothing could exceed the cordiality of his reception, the bounty of his hospitality, and the patriotic denire to benefit the auricultural wherst of his country. Although I do not go the hat encth with Mr. Mech, there can be no question hat the farmers of England are greatly indebted to for, and though they may not achnowledge the full will arrive his remarks during his life, the time very clear perception of the future progress of agriculture. The principal object of attraction at Tiptree thie year was the "Great Steam Plough," which may be termed the future "levathan of the snil ;" and all that when scientific in favour is likely to come true improves its applicability, and lessens its cost Mr Mechi's idea of England becoming not only self support ig bat an exporting country of the products of the soil is by me means vis onary ; for when once the spirit of our then in in to the cultivation of the soil, either in the shape of amusement or occupation, neither wealth nor enterprise will be wanting to turn the barren waste into a smiling field.
It is true, as Mr. Mechi said, the land does not increase
that energy, wealth, enterprise, and science, can restore that energy, wealth, enterprise, and science, can reatore where nothing but sterility is seen. That Mr. Mechi Where nothing but sterility is good and deserves well of his country for his enterprise and perseverance in developing the capabilities of the soil no one will deny; but that his system can be pursued altogether with advantage is a question that agricultural 8
The Cow Parsnip.-I am not aware of any expres sion in my letter on this plant that could be construed into a recommendation of it; least of all of any actuated me in introducing the subject to the rttention of your readers. An acquaintanceship of more than 40 years ought, one would imagine, to have been ample protection against any such insinuation as that indirectly thrown out by my old friend Charles Poppy. What have I to gain by it? Nothing! I occupy no land and of the few plants growing in the garden the seed are at the service of any one who wishes for them, I have given away many, but never sold one in my life My letter after all was but a suggestion as to the merit or demerits of a plant of which I know little more than its extruordinary size and rapid growth. I thought, and still think, it a pity that such exuberance of vegetation would eat it (the main point I wished to ascertain), it might be rendered a useful addition to our creen crops. Messrs. Hardy \& Son seem to agree with others in rejecting it as cattle food. On this matter I give no opinion, for on this I know literally nothing. This I do know, that no correct judgment can or ought to be passed on this or any other novelty, without a patien it. Many a plant if suffered to run to seed may be unpalatable and even hurtful to cattle, whilst the same
plant given in an earlier and more suitable stage may be eaten with avidity and advantage. On this point I olicit information, for, as

## A man conviaced against his will,

I hope I may, without any undue feeling of doubt or discourtesy, insist that it have a fair trial, and this it cannot have without various experiments as to the bes sasson for culting it. As to its being poisonous I canno Cow Parsnip, one would think is sufficient to refute any such idea; but this is a matter of no very difficult solution. After all, my object is rather to obtain than impart information, and to this end I shall feel obliged any one who will think it warding as soon as they are ripe, cn receipt of a stamped envelope and address. I only demur to the slighiest insinustion as to quackery, which I detest and abjure as heartily as Charles Poppy or any other man can do Samul Taylor, Wotton Parade, Gloucester, July 19.

## Eactettes.

## ROYAL AGRICULTURAL OF ENGLAND

We will continue the walk round the implement yard commenced last week, and point out any implements In No. I stand to deserve attention.
Messrs. Deane, Dray, \& Co., as commissiun and in 110 large collections of implements of all kinds; the former exhibit M'Cormick's and the latter Hussey's reaper. The in Bell's reaper by Crosskill, and in connection with the iatter there are two contrivances for delivery, both of them very promising, viz., the tipping platform, which gives the cut corn off in bundles in the wake of the in atrument, these needing to be tied and cleared out of the way before the machine can come round again, and the system of rollers radially arranged, invented by Mr.
Palmer, of Stockton, by which the corn is carried to Palmer, of Stockton, by which the corn is carried to one side and delivered without
At No. 2 Messrs. Humphries exhibit steam-engines and threshing machines. There is here one of the new contrivances in riddling machines which this year's exhi and the perforations are inclined to the plane of the riddle, which will not allow the short straws or Pulse to pass through; for they come in contact with the inclined space of the perforation, and by the motion of
the riddle are displaced and carried over the hole. the riddle are displaced and carried over the hole.
At No. 3 Mr. Bigg exhibits his sheep dipping apparatus in full operation, stuffed animals being shown in process of undergoing it. To Mr. Lawes's cheap and efficient. When fixed, they are as firm, and will last as long as the building itself. They require no paint, and will bear the weight of a ladder against them without injury. Well-burnt clay is one of the most durable substances known ; and this system of its great strength, is not lable to accidents. Each tile is about 13 inches long, and the price of each plain purchaser prefers, a man will be sent to fix them at the purchaser prefers, a
rate of $5 d$. per foot.
At No. 5 Messrs. Warner exhibit a number of purope, fire-engines, \&ce, for which, as our advertising Wood \& Son, of Chelmsford, exhibit a large assort-
ment of agricultural implements, including one of the Machinery for washing and wringing clothes is show y Mr. Pearson, of Leeds, at stand No. 7. At is Mr. Crosskill exhihits his well-hnown cloderusher, carts waggons, corn mills, Arcbimedean root-washer, Bell's reaper, ac.
Mtssrs. M'Neill \& Co. at $?$ show specimens of their telt for roofing houses, flour mills, and cottage ovens A very good assortment of mils is shown by Mr. White
of 266 , High Holborn. Messrs. Hornsby \& Son exhibit heir threshing machine, steam-encine, and all othe barn implements, their drills, Sc., at stand 11 . Messrs Day \& Co., exhihit new land rollers. 'The improvements these rollers consist in manking use of narrow edged puts or dises, so arranged as to work side by side with other broad faced parts or presser wheels; the latter having the centre holes made larger than the others diate abrading and self cleaning motion in rolling the soil
Root graters, chaffcutters, \&c., are exhibited by Messrs. A. \& T. Fry, of Bristol, the former chiefly on the principle of Bushe \& Barter's grater.
A very interesting collection of fleeces is shown a 14 ; it illustrates the efficiency of Long's non-poisonon sheep and cattle dressing composition.
A number of articles of kitchen furniture are shown by Messrs. Ransome, of Essex Street, Strand. An nest in half a minute and filling it into skins, is shown by Mr. Nye, of Wardour Street. Mr. Read, of Regent Circus, competes with Messrs. Warner in water engines; and Samuelson shows a large collection of urnip cutters, pulping machines, chaffcutters, cornrushers, mowing machines, \&c. Busby, of Bedale hows his excellent ploughs and horse-hoes, carts, \&c. for loosening Tornips ing and tailing machine, or rather or loosening Turnips in the ground and cutting off the tails, the tops having been previously cut off by a light steel hoe with two blades. Churns and chaffcutters are shown by Cornes, of Walbrook, City. Mr. Hayes, of
Elton, Oundle, shons an elevator for straw. It is made with two octagon drums, diameter of which is 20 inches and thereon is worked a chain with tines, driven by suitable machinery to carry up the straw, and the slow he wear and tear is reduced to the very little power Can be driven by any machine, and the strapy taken three different ways as may be required, being a great saving of labour to the usual way of men carrying the raw up ladders. Price 402
Mr. James's liquid manure distributors, advertised in our columns, are exhibited at stand 23. Messrs. Tux ord show steam-engines and threshing machines; for he former they attained at the last official trials a very high reputation. Mr. Clayton, of the Atlas Works, Dorset Square, exhibits a large collection of his machanery for the manufacture of bricks, tiles,
\&. Farm harness is shown at stand 33 , by \&c. Farm harness is shown at stand 33, by
Alr. Dunlop, of Haddington; and from the extreme west, Haverfordwest, in Pembrokeshire we have machinery exhibited by Messrs. Marychurch. Wirework in the various forms of fencing, aviary work, \&c., is shown by Mr. Standing, of Fishergate Preston. Cart Turnip-cutting machines for carrying aud cutting roots, spreading them over the land carted on, are shown by Messrs. Caldow \& McKinnel, of Dum ries. Messrs. Ransomes \& Sims show an immense col ection of ploughs, grubbers, harrows, chaffeutters machines, steam-engesides barn implements, threshing machines, steam-engines, \&c. Among the ploughs w Smith \& Ashby for one horse, price 30
ines, and chaffcutters. Mr Ches, haymaking mahines, and chaffcutters. Mr. Chamberlain's brick making machine is shown at stand 40. An ingenious boring, mortising, tenoning and dritling machine is shown by Mr. Coulson, of 36, Fetter Lane, Yurk, price 276 Clayton \& Shuttleworth show a number of t
known steam-engines and threshing machines.
Richmond \& Chandler, of Salford, have a large and sell filled stand occupied chiefly by their well-known chaffeutters with the characteristic toothed feed rollers, lately improved by dimiuishing the size of the teeth, chaffeutters, corn-mills and crushers, in which two ollers of equal size revolve against one another at dif ferent velocities. Fisken's stean plough is exhibited a stand No. 49, by Roger, of Stockion-on-Tees
Barrett and Exall, of Reading, show steam-engines, hreshing machines, and all other barn implements Their improvements in the concave to their threshing machine, and their compact horse-power are shown here.
Mr. Boby's (Bury, Suffoth) corn-dressing machine, to
which we referred last week, is exhibited at stand 51 .
ich we referred last week, is exhl is shown 51 . adjoining stand by Mr. Beadel, of Chelmsford. This building is so constructed as to be readily taken to pieces and removed, and re-tixed when required. I ccone enough to contain food. Buildings of this description would be found to be of great service upon farms where the tenant wished o increase his accommodation without erecting perma ent buildings.
The remaining stands we shall resume and describe ext week.
Highland and Agricultural, July 9.-At the half yearly general meeting of this society 45 gentiemen ere admitted as members.
Agricultural Education.-Sir John Staart Forbes
for a supplementary charter to enable them to extens for a supplementary charter to enable them to extead their efforts towards agricultural education, had been satisfaction in congratulating the society on this further step of practical progress in this important department. Agricultural Statistics.-Sir John M'Neilreported that:
 osition to comply with the desir
an early publication of acreage
Pcris Show.-Mr. Hall Maxwell submitted the report on this show. Prizes for Scottish breeds had not been offered until February:-

## No time was lost in making an appeal to the public spirit of the principal breeders; circulars were addressed to them, and meetings were huld in different places liy the Secretary, and the

 meetings were held in different places ly the Secretary, and thereenlt exceeded the most sanguine expectations of the Directors,
for scotland, thothgh small and far remuved from the scene of the

Glarters. With regard to mplements, it is right to explain that attempt to induce makers to come forward. Stock was carried
ree on the different railways, but as the usual rates were charged or machinery,
as an exclusion.
The Chairman said the Society must feel what a great debt of gratitude was due to the Speretary, Mr. Maxwell, for his organisation of this great work and the bility with which he had carried it out. All who were in Paris must be aware of the immense amount of labour which he had to undergo while there. The society undoubtedly owed a deep debt of gratitude to heir Secretary
Sir R. K. Arbuthnot moved that the thanks of the society be voted to Mr. Maxwell for his invaluable services in connection with the Paris Show. The motion vas agreed to by acclamation.
Mr. Hall Maxwell said he felt extremely gratified at is wishes might have could repeat that whatever extions were, they, would have failed but for the assistance of those mintioned in the report. They would like to know how Scotland stood, as compared with other countries, in refereuce to the homours that she carilied off. The report had informed them that Scotland was limited in her exhibition to sheep and cattle. They sent no swine, because they were difficult to carry, and the distance was great, and they were ecessarily limited to cattle and sheep. In these classes Scotland had 100 prizes, England 77, and Ireland 24 Switzerland had been referred to as being the greatest exhibitor. He was not prepared to say whether she was or not, but if they took the cattle, it would be found that she had obtained 58 prizes against the 62 which were gained by Scotland. In sheep she had no prizes, while scotland had 38. Austria had also been spoken of, but Austria included Austria Proper-Bohemia, Hungary, and other places-and represented a union of countries not so united as the United Kingdom of England, Treland, and Scotland. Austria gained 47 prizes for cattle, and 45 for sheep-total 92, ugainst 100 gained by Scotland ; so that in point of fact, if France was had gained a greater number of prizes than any other country, and it should farther be kept in mind that the Scotch exhibitors had but three months' notice, while obtained 9 prizes, including the great gold medal obained by Mr. Lawson; England 2; and Ireland 5 . He did not wish to make invidious comparisons, but in justice to the gentlemen who had enabled the society to make such a report as this, and who had carried off these honours
Inverness Show.-Sir R. K. Arbuthnot gave in the following report:-"The Directors beg to report that the whole arrangements for the Inverness meeting have been satisfactonily arranged. The entries show a diminution in the number of cattle, and an increase in that of sheep, as compared with 1846. According to the arrangements, implements will be placed and judged on Tuesday, 5th August, and tried and exlibited on the following day. The general exhibition of stock will ake place on Thursday the 7 th, to be followed by the public banquet, and prize atock will be brought back for examination on the 8 th.
The Chemical Department. - Dr. Anderson said that there was one department which varıed very little viz., the department of getting analyses for the were generally the most numerous, and this year they had exceeded the average, a vory large number having been made, and very interestins resulis having been obtained. There was one thims he minht notice, and it was of importance to ceual a was in the quality of superphosphate during the last few years.
Mr. Mechis Annual Gathering at Tiptree took place on Saturday last with even more than the usual éclat. Upwards of 500 gentlemen of the agricaltural and commercial classts united to testify their sense of the liberality, frankness, and energy
The processes, extraordinary some years ago, now
more commonly to be met with，of liquid manuring b ing on this system，and of feeding on boards under cover，which are the principal points deserving notice in the Tiptree management，occupied successively the attention of the visitors．

The original poverty of the soil as contrasted with its present fertility，and the correspondiug contrast between the listlessness of landowner and tenant in former days， and the activity and energy of Mr．Mechi，who is him－ self landlord and tenant now，was as usual insisted on， and illustrated by more than the usual foree in the crops which the land this year exhibits
When the visitors had assembled Mr．Mechi，accom－ panied by them，made the tour of the farm．Proceeding first to a field of Italian Rye－grass，he explained the operation of his system of irrigation with liquid manure which was then at work．One of his labourers was
standing in the field holding a gutta percha tube attached to a stand－pipe，connected in its turn with the system of subterranean pipes which are spread like arteries over the whole farm．From this pipe，which he held in his hand like a fireman，and turned at his pleasure in every direction，a stream of liquid manure issued，at the rate of from 80 to 90 gallons a minute，and was thrown over This done，he would fix his hose to a pipe in gnother part of the field，and repeat the process until the whole of it was completely irrigated．The liquid with which it was so drenched consisted of the ordinary sewage from the farmhouse at Tiptree，together with the solid from the farmhouse at Tiptree，together with the solid
manure made by the cattle in the farm buildings，and manure made by the cattle in the farm buildings，and been collected in a reservoir on the premises，and there properly diluted with water for the purpose．The field
of Rye－grass，which grew Wheat last year，had been fed off three times during the present summer，and now for the fourth time bore a luxuriant crop．The underground pipes for conveying the liquid manure over the farm
are 3 inches in diameter，and laid at such a depth from are 3 inches in diameter，and laid at such a depth from soil．He calculates he shall have five feedings and one good crop of hay from this field in the course of the season．The sum of his experience of irrigation is that limited space of pienty of tood and manure on a very when it pays to do so，and yet keep plenty of stock． to be felt for years after，when the irrigation continu come to be grown on the land．He had no hesitation in saying that if all the farms in the kingdom were culti－ vated for the wholethod they would be able to supply fond for the whole community without recourse being that would result from the application by irrigation of the sowage of towns，in the shape of liquid manure，to the land of the country．An adjoining field of Mangel Wurzel which had been drained and irrigated like the
rest of the farm elicited the admiration of the company Mr．Mechi said the cost of his liquid manure works， including engines，tanks，pipes，and everything else con－ nected with them，was 42.58 ．an acre．Iron was cheap when he laid down his mains，and probably they would now have cost him about 6l．an acre．At $7 \frac{1}{2}$ per cent．，
with which he charged himself，it was a most profitable operation．Adverting to the subject of drainage，he said he had drained a bog on his farm which，before with useless，was now the best part of his land；and source principally he was enabled to keep up his system of irrigation．He advised his visitors to drain deep， for he anticipated the time when the application of steam would produce a cultivation of the soil 2 or 3 feet deep， 2 feet drains？On passing a fine field of Wheat he said his experience taught him that by laying out $2 l$ of Wheat more an acre．This field had been alternately Tares and Turnips one year，Beans between the two next crops of Wheat，and then a heavy crop of Mangel
Wurzel．After that he manured it with 2 cwt．of guano and 1 cwt ．of sulphate of ammonia per acre，which was washed in by the rains，but he preferred ploughing it in． It had been further improved by the application of a manure manufactured by Dr．Ritterbandt，from the common＂clinker＂produced in large steann furnaces， and which，on being submitted to a chemical process， yields large quantities of potash of great value as a manure．The next was a Bean field affording promise of an abundant crop，all of which，he said，he should
consume on the farm．This field was wheat lact year， after Mangel Wurzel．He manured it well for the Bean crop．and he meant to sow it next with spring purchased the smallest quantity least to his land，and purchased the smallest quantity of artificial food and
manures，was precisely he who produced his corn at the dearest price per quarter，and was in no condition opposite principle．Thissuas a men who adopted the opposite principle．This was a landlord＇s question quite lords to take the initiative in reference to it．If land－ lords were to have men of skill and ample capital for their tenants they must tempt them by suitable house for their families，good luildings for their stock， machinery for the conversion of their produce，and a Touching mechanical appliances，he said，these they must have if they meant to farm cheap，and they ought never to use a man if they could get an instrument to
nearly six feet high，the land for which he manured with 2 cwt．of guano in the spring．He stated that last year he had 50 acres of Wheat which yielded on an before 70 acres which yielded five quarters all but bushel．

Mr．Mechi next conducted his visitors over the covered sheep and cattle sheds，the barn containing threshing machines and other appliances worked by steam，and the large reservoirs in which the liquid
manure to be used on the farm is accumulated．He explained how，by putting thin layers of straw over the manure from time to time in the sheep shed，without removing the wet layers beneath for months the health of the animals was strikingly preserved，as a proof of which he stated that of 1200 sheep which he had had in plough，exhibited at the Chelmaford meeting，was at work in a field on the farm during part of the day，as Garratt and of Bentall，all of which excited considerable interest．

## 刧と他ws．

The Journal of Agriculture，and the Transactions of the Highland and Agricultural Society of Scotland．July，
1856．W．Blackwood and Son，Edinburgh and London．
The current number of this Journal is full of usefu and instructive matter on the theory and practice of agriculture．We shall elsewhere refer to the important introductory paper by Mr．Russell on the Lawes and Liebig controversy，and in another section of our Paper
we shall give extracts from some of the other contribu tions to its pages；at present we give a paper by Mr Turnips：－
＂Finger－and－Toe in Turnips needs unfortunately no description ；its ravages are but too well and too widely known，and are now exciting general interest and alarm．The extent of knowledge regarding the disease，
however，is very limited，having been hitherto almost confined to an acquaintance with its effects；in so far as regards its cause or its cure，it is as yet involved in almost as much uncertainty as the Potato disease．In 1852 the subject was remitted by the Highland Society o Professors Anderson and Balfour for investigation， and queries were circulated for the purpose of obtaining
information．The facts observable in different districts information．The facts observable in different districts
were thus obtained：but the learned gentlemen by were thus obtained：but the learned gentlemen by
whom the inquiry was undertaken expressed themselves unable to throw much light upon it．At a late monthly meeting of the Society for discussing the cultivation of
Mangel Wurzel，the subject was alluded to the speakers，and the importance of some fit substitute for the Turnip was divelt upon as a consideration that would force itself upon public attention，unless some method were discovered to counteract the progress of the disease．In these circumstances，having been a sufferer myself to a great extent，and having pursued events on my own farm，I willingly accede to the request of the Secretary for a statement of my ex－ perience，believing it to be the duty of every one to communicate whatever information he may posseas

For the sake of precision，I shall confine my re－ marks chiefly to the treatment followed and the effects was formerly subdivided，as is important to note，by a wide fence，consisting of a hedge and ditch，now re－ wide fe
＂In 1846 this field was under Turnips；the variety was Swedes，and，up to the month of August，they looked unusually promising and forward．Unhealthy－ looking spots at this date began to be observable up
and down the field，and gradually extended till I believe there was scarcely a sound root to be found north of the old fence line，and the crop was a dead loss．Of course I was very much puzzled by this novel invasion， the fence line I found pall portion of the fiel Lime had been applied to this part about 10 years previously the north side had probably never been limed，certainly not during my occupancy；so here were at least indi－ cations of the course to be pursued．I may mention idea，now pretty much exploded，that the presence of currease might be attributed to the too frequent re that all along the line of the old fence，where the suil was of course new，the disease first appeared，and the plants completely vanished．Abundant confirmation on this point has since been found in the occurrence disease after old pasture，and on fields never before
under Turnips． ander Turnips．
＂The field then went through the usual rotation on
the four－shift course，and Potatoes were substituted for Turnips，exceurse，and Potatoes were substituted for ments，which were conducted in the following manner I had applied to part of it on the Grass，in autumn 1848，lime at the rate of about 14 tons per acre．Pre－ paratory to sowing the Turnips I applied lime to another portion ：with the seed in the drills I applied artificial ；and I also tried hot lime round some of the young plants after thinning．I had chosen for trial a portion of the field where the destruction formerly had
follows：lime applied to the young plants was quite worked in whilst preparing the land very slightiy bene－ ficial ；but lime applied on the Grass was a thorough cure．I have since that time gone on applying lime to Il the fields affected，at the rate of from 14 to 16 tons per Scotch acre，and with uniform success，excepting in
one instance，where accidentally \＆few carts of lime had been＇＇drowned＇before it could be spread，and conse quently was applied in the state of mortar．The effect was most marked，all around the crop was perfectil healthy，but wherever a shovelful of the cold lime had been thrown，the roots were not worth lifting．The field I have alluded to was under Turnips last year．It was limed on the Grass in 1853，and accident afforded striking confirmation of the propriety of the course I ollow．The hay crop had been stacked on the ground， the lime was applied while some of the ricks wer there，consequently the spaces occupied by ther were unlimed．Two years afterwards there was an there was scarcely a sound those very spaces，wher was striking even at a distance，so great was the dif－ ference between these spots and the rest of the field， and no predetermined experiment could have bee nore decisive or satisfactory than was the result of this accident．

Of course it is impossible on such a subject to lay down rules for the guidance of others，the experience of different individuals in different localities being so various，if not contradictory．My own experience， however，has led me to the following conclusions ：on this farm，and I think I may venture to say in this district，lime is a complete cure，and，so far as I know the only one．The best period for applying it is to have it ploughed in with the lea，or I should rather say applied at that point in the rotation which will admit o one crop intervening before the Turnips are sown，thus securing a thorough incorporation with the soil，and duced Applied immediately after harvest，where Turnips are to be sown，I have found it suitable enough； but generally noticed that though the crop appeared healthy，on examination the presence of disease could be detected，and I therefore much prefer an earlier appli－ cation．It is essential to have the lime ploughed in in a caustic state．I have always followed the system of applying one good dose of lime in preference to two smaller ones applied at intervals，and would recommend not less than 12 tons per Scotch acre as about a prope quantity．The opposite method is，I am aware，advo but I am not aware opinions are entitled to respect muade by others with a view to exttle the point ；and not made by others with a view to settle the point ；and not
having instituted any myself，I cannot pretend to solve In ing instituted any myself，I cannot pretend to solve difficult to be had at any price，it certainly interests al of us to have some more explicit information on the subject．＇

## Miscellaneous

Blood Manure－Chemists and farmers，I believ concur in understanding by this name a manure com－ posed chiefly or entirely of dried blood，and it bear the highest price of any manufactured manure．It is right，therefore，that it should be known that a manure
is sold under that name，which is no more than a super－ phosphate of rather low quality，and containa an ex－ tremely small quantity of ammonia．

Organic matter
Soluble phosphat
Soluble phosphates
Insolulup phosphates
Sulphate of lime
Sulphuric acid

If this substance had been sold as a superphosphate，it would have been correctly named；to call it a blood manure is to mislead the purchaser，and either to induce hind to pay a higher price than the actual value of the substance justifies，or to bay a manure which may not be suited to the crop to which he applies it． Prof．Anderson，in the Journal of Agriculturc．
The Flat and Ridge System of T＇urnip Culture．－The comparative advantages of growing Turnips on the flat and on ridges have frequently been discussed；and BB the main strength of the argument has generally consisted in showing that the flat system of growing roots was indebted for any superiority it might possess to its better retention of moisture in the soil，I make no apology for entering into the matter here．I have had nearly 20 yearss experience in Turnip growing，and sometimes it has seemed more advantageous to system than the ridge，and vice verta．In the flat system than the ridge，and vice vervi．In
moist climates ridges，when formed，leave a kind of moist climates ridges，when formed，leave a kind of
watercourse or channel between the artificial heights， watercourse or channel between the artificial heights，
which acts most conveniently for carrying the super－ fluous moisture away，and not only that，but the ridges are left，in the intervals of dry weather，in a proper state for working the land，for horse or hand hoeing，as the case may be．Where，as in Ireland and Scotland， 40 inches of rain fall in a year，with a much less average temperature than in the south and east of England，ridges are decidedly preferable，as the flat surface would usually be a puddle；but the case is completely reversed in the dry districts of England， where little more than 20 inches of rain fall annually
evaporation is far more than in Scotland or Ireland. The ridge system of growing roots in any country has the merit of permitting of a better and cheaper cleaning of the land when foul than when roots are grown on the flat. The flat system, however, has a decided superiority in a dry climate by retaining on an average on son and sufficient muisture in the hanreference to the growth Turnips on the flat generally in Enyland. Journal of the Royal Agrieultural Society of England.

## Calendar of Operations.

Eserx: Appearance of the Crops.- Since the late storm of by it in a geaeral point of view, and the Potato has hitherto manifested signs of vigorous growth. A bumid atmosphere, mowever, has since prevty disease prevails to some extent, ind is visible in the Potato leaf again. Annther week will n ) doub at present, yet it will soon manifest itseli by the rancid ceemt the leaver when passing then on the road side. Some kinds
the Wheat, too, in tuis neighbourhood have unileryone change for the better, especially the cruwded plants, whicu generally suffer more or less from some तisease or other: ind we
allude particularly to the rariety called "rough chaffed" (and why it should be desipnated thus we are yet at a loss to know, for we would have it "fluff chafied or "satin chaffec, and It is "red gom" whieh prevails in it to rather a fearful exten tieularly. It is so mueh so, that on looking over some of it by the way side it has the appearance of many lady bugs of an Maldom, Essar.
Fivesirie: Appaarance of the Crops.-Wheat-good, but very Fives ; Oats-varions; Barlev-good; Beans-luzuriant; Turnips -backward; Potatoes-indifferent; hay-heavy crop. $A$. Bussell, Kiltohiss, Cupar, Fife, July 16
promise of Wheat is very good; Oats light. Beans full crop perhaps not more than an average of corn; Peas good; Mange not an average; Rape not good; Swedes a failure; Girass very short; a good crop of hay well got. With fine weather the Fen Thowas Aitken, Pinchbeck, Spalding Wertmorland: Appearance of the Crops.-So far as my observation enables me to report, the crops in this meighbourhood may be classed, Wheat and Barley a full, or rather an average
 Turnipa a sufficiency of plant, but small and puny from the lone continued cold and gloomy weather; it is doubtful whether they will attain a full growth. The hay crop good, and much well
Haypshite: Appearance of the Orops.- If this fine ripening Weather continues another week we shall have a large produce ably well. The crop is however very various, but on the whole ce tainly an average-perhaps more. We are sady in want of rain all the sbowers whin we read or ane papers paving missed ul be eond if rain came immediately, but longer delayed I fear they will give up on the chalks and thin lands. Turaips cannot be gnod, and with longer continuance of dry weather will be a fiallure. J. T. Tvoynam, July 24.

## Notices to Correspondents.

Beetroot: a T. There is no dinty on the growth of Beet-that Which your refer to is paid by the manufacturer of sugar from afford to pay a profitable price for English-grown Beet not the heaviest erop that contains most sugar per acro. In they pive, we think, 15s. a ton, a price at which it may be profitable to grow it under a watery sky
Comeretz: Anti-Oxeye. The Portland cement has been recomHampshire Crops: Mr Eiames, Lymminton, tells us, The Potatnes are sadly diseased since he wrote u* last week, and the Tumip are being fast eaten up with the black palmer. All things are suffering very much for want of rain. [In the report lately was complained of.]
Pourtry: $G R$. In judging Cochin China Fowls, the outer colour is the point with which the judges have to do. If a case arose Where every other point was equal, which of late never happens,
we hardly think, even then, the judges would be justified in making the under colour a point of decision, as ther have to the fiture for their probable produce. If we wished to breed light birds, we would prefer those without dark under-featiers: but it is undeniable that all have more or less of dark blood in them, and also that the old-fasbioned isymmetrical than the light ones. The ridiculous stickling for uniform colour, and clear backle, has robbed birds of the qualities formerly found in them, as regards weight and shape. Bow. Clean-lpggod garae bantams are the best for gold pheasants' eggs, as they are light, and the shells
of the eggs are delicate; an ordinary game hen is the best for silver eggs, as they are stronger in the shell and a larger egg. The twist in the tail of a fowl is generally the result of a curve or deformity in the back bone; but it is sometimes the case Where no apparent cause scoounts for it. We have known it to proceed from long confinement in amall basket or coop, very mlight injury will cause it.
TO RABEE WATER: $T O$, Clitheroe says:-Can you or any" of your correspoudents inform me whether the hydraulic ram is ever applied to the raising large bodies of water, say 300 or 400 cubic feet per minute, and if so, is it economically applied? tageosaly applied to large bodies of water, it seems to me there are many situations where it might be so employed, and I should be glad if you conld give me replies to the following questions:-1. Can it be spplited to variable streams; say, if equally applied (withont incurring any expense or loss of time to the raising of 50 feet? 2. Supposing I have a fall of 20 teet, delivering on the averuge 500 f -et of water per mioute, how grent a pur centage of that supply may I calculate upon raising 40 feet above the head of my fill? 3. Supposing I am able to
raise 100 feet per minute, how large onght the pipe to be which raise 100 feet per minute, how large ought the pipe to be which and will the water in this pipe rise equally well at any angle? 4. What mould the cost of a ram calcnlated to raise this quantity of Fator-I mean merely the vaives-and air chamber and beir ittings, hat not including the pipes necessary to it belk into the elevated cistern? 5. Where is there a machine of this tind in snecessful operation? [The ram is of use, we believe, only what a hrge body of water amd a little fill is at int tle watar to a

sole manufacturer, iron and wire woris, north strelet, ledds.

## REGISTERED JULY 24, 1855.-No. 3739.

THE ADVANTAGES OF THESE MACHINES supersede all others by having L a small Wheel in front of the Grass Box, consequently will mow verges and round flower beds,
without any change of Wheels, or addung the old fashivned Roller, as in other ; whll also cut either wet or dry, and by the simple adjustment of a thumb screw, in front, can be raised or lomered to cut width they any length required; and having two Rollers behind, and a small one in front, they roll the made much cut; they will turn in very little room. ard cut at the same time. An the working parts tear up the ground; they are only drairn, and not pushed and drawn as in other machines,

## LIST OF PRICES (NET CASH):-

Testimonial from Joshun Mujur, Enq., Landscripe Gardener, Finostiop.
To Mre Greer, Lare-sin, As aimars appreciate pabic and un improvements. I mont gladiy vive me testimony to in pection (cutting a breadth of 24 inches) was drawn on flat ground with ease by one person, and although at the time of trial the lawn was wet, it was cut with the greatest aicety. So complete and simple is the invention, that amateur gentlemen, and even ladies, may work either the 16 or $20-\mathrm{inch}$ give we mose and pleasure, providing the Grass is not too long. For extensive places I should say the 24 inches . either of the surpasses, and must eventually supersede all otherg, for it is not only free from iutricacy and easy to the workman, but extremely expeditions in its operations, and consequently must prove a great saving in the management of Grass lawns, and a great boon the poblic.-I am, Sir, your mostobedient servant, Joshea Major.

Other Testimonials may be had on application to the Manufacturer.
The above Machines are warranted to answer the purpose as described, or may be returned, and may be had of all principal Ironmongers, Nurserymen, and Seedsmen in England; also Mr. Charles Garbood, Superinten dent of Agricaltural Department, Crystal Palace, Sydenham.

SATURDAY, AUGUST 2, 1856.
That Orchand Housks answer their putpose under good management is sufficiently proved by the numbers that are springing up all over the country. They were wanted. With our deteriorated springs the acquisition of fruit crop had become too much a matter of chance, and with the chances against us. An amateur struggling with cold earth in spring and hailstorms in May was like a gambler playing against the bank. He might win, but was sure to come off in the long run a heavy loser. Orchard Houses put the sma'l $\mu$ rower at his ease as to a crop, and furnish him with much amusement into the bargain. It is something to be able to watch the expanding flowers and mark their setting, and assist at their first attempts at swelling into ripeness without the probability of catching a catarrh; it is more to feel that whatever time, patience, and money are expended will be certain to hring their reward.
For this we have to thank Mr. Rivers. His "Orchard House"* was soon made an amateur's guide, and notwithstanding failures here and there arising from negligence, ignorance, or inexperience, steadily maintained its ground. We, therefore, see with no surprise that a fourth edition has been called for. It is a compliment for the author to be proud of; for it is a public acknowledgment o valuable advice and instruction having been rendered. In the present edition two new topics are introduced; one the cultivation of Plums in such houses; the other a recommendation to apply the method to tropical fruis trees.
To the first of these proposals we heartily accede The crops of Plums obtained last year in the Orchard House in the Horticultural Society's Garden were abundant and excellent, while unprotected trees yielded little or nothing. A reference to our columns of 1855, page 612, will show that Denniston's Superb, Huling's Superb, Reine Claude de Bavay, and a late Plum without a name were the gems of the remarkable exhibition there described. Upon this point Mr. Rivers makes the following new statement :-

Hell known that Plum trees in our climate bloom so early in spring as rarely to escape
the effects of spring frosts; it may safely be asserted that a fair crop of Greengages, away from walls, is realised but three years out of seven, even in the south of England, but two years ont of seven in the midland counties, and seldom or never in Yorkshire. Now, I propose that for those who wish to grow a crop of Plums regularly, and yet not incur a heavy expense, rough-built lean-to orchard houses should be erected in some corner of the premises. so as not to be obnoxious to the eye, of Larch poles, rough half-inch boards, with two or three sliding shutters for ventilation ; in fact, merely a glass-roofed shed on purpose for Plum trees in pots while in blossons and setting their fruit. It is surprising with what vigour and beauty Plum trees
blossom even in the rudest glass structures, and as blossom even in the rudest glass structures, and as
the trees need not remain in the house longer than the end of the first week in June, when all danger of severe spring frosts is over, they may be placed close together, so that a house 20 feet by 12 with path in its centre will hold 96 trees, 48 on each border. The trees may be potted into 13 or 15 -inch pots, and treated exactly as recommended for other orchard house trees; with this difference-all the trees with their young frait on should be removed from the house on the 7th June, and placed in rows or otherwise in the garden to mpen their fruit in the open air. The pots may be plunged in the soil to the extent of one-third, but not more; for if the roots are too cold, the fruit will suffer in flavour, and if the soil be wet and cold, it should be drained or made porous, so that the water passes from the pots rapidly, and the top-dressing of manure must be most abundant. As I have before stated, the very late Plams must be ripened under glass; but all the

varieties that ripen in the open air before the end o. September may be grown in great perfection in this way, and regular annual crops insured, if care is taken to thin the fluit properly, for if too large a crop is extorted, the tree uill have a year's rest. It is quite astonishing how prolific these bushes become in a few years, and by merely pinching off the ends of exuberant shoots, about the end of June, to within 3 or 4 inches of their bases, they soon form themselves into compact round-headed trees quite as ornamental as Orange trees in pots and tubs, and far more gratifying as regards utility; for one would not like to place a dish of English Oranges-cultivated as they are at present-before one's friends, bat English Greengages ave alway: acceptable."
In the views entertained by Mr. Rivers concerning the ripening of tropical fruit trees in heated Orchard Honses we cannot concur without considerable qualification. In the first place very few tropical fruits are worth cultivating; in the next place few are cultivable. Mr. Rrvers himself says :An orchard house for tropical fruits has long been with me a favourite idea, and recently, from my having had a daughter return from a nearly two years' residence in the West Indies, it has reeeived a fresh stimulus. The variety of tropical fruits seems almost endless ; some of them, if I may judge from description, are too rich, others too insipid for English palates, and of the greater part the trees that bear them would require amateur not blessed with a large fortune." That is very like the fact. What are not too big are worthless ; what are gnod are too big. The Cherimoyer is as tall as a larce Pear tree; Guavas, Sapodillas, Water Lemons, and Rose Apples may be attractive in the pages of Paul and Virginia, but Whould be turned away from an Eares to taste dessert. Who cares to taste twice the Loquats that now come from Madeira ; they are about as good as the worst A pricot that ever ripened. Mangosteens can never be had out of palatial gardens; and as to Mangoes they find no favour by the side of a Nectarine. It may be safely asserted that beyond the Pine Apple, the Orange, the Banana, the purple Guava, the Litchi, the Mangosteen, and the Chirimoyer, there is little to be hoped for among tropical produce fit for a dessert. The four first we bave, the three last are all but unattainable.
But while we are obliged to express our want of faith in the merit of the greater part of the fruits still unintroduced, there is one application of a heated Orchard House to which Mr. Rivers draws attention, and in which we agree with him. The Orange tree and all its kindred might really repay the cultivator. In England we hardly know what a good Orange is ; but there is no reason why we should not ripen them as well and as easily as Grapes. A heated Orchard House offers the means.
"As an ornamentai greenhouse and conservatory tree, the Orange is an old friend; and perhaps no tree in the known world has suffered, and does suffer, such vicissitudes of treatment, yet living and seeming-to thrive under them. It glories in a tropical climate, and yet lives and grows after being poked into, those cellar-like vaults ased for its winter quarters on the Continent; it gives flowers in abundance under such treatment, and would even give its fruit-albeit uneatable-if permitted. Nearly the same kind of cultivation has been followed for many, many years in England: it has rarely had heat sufficient to keep the tree in full vigour, and its roots in pots or tubs must have suffered severely from having been placed out of doors in summer on our cool damp soil, and in winter on a stone floor still more cold. If roots could make their complaints audible, what moaning should we hear in our Orangeries all the winter! In cultivating the Orange for its fruit, the first consideration is to procure some of the most desirable arieties; those delicious thin and smooth-rinded Oranges we receive from St. Michael's ; the Maltese Blond-oranges, and the Mandarin would be most desirable: with the present facilities of transport, young trees of these could be procured. There are also some sweet Oranges cultivated in France, of which trees could be readily procured but the first-named varieties seem to me most worthy of the careful cultivation to be given them n the tropical orchard house. The first matter of import is the soil best adapted for the Orange there are many recipes given in our gardening books, but the most simple compost of all, and one that cannot fail, is the following: two parts sandy loam, from the surface of some pasture or heathy common, chopped up with its turf, and used with its lumps of turf about the size of large Walnuts, and ts fine mould, the result of chopping, all mized together, one part rotten manure at least a year old and one part leaf mould; to a bushel of this compost
add a quarter of a peck of silver or any coarse siliceous sand-calcareous sand and road sand are injurious-and the mixture will do for all the fruit trees of the tropical orchard house, as well as for Oranges. In potting the Orange it is better to commence with a pot too small rather than too large; for, unlike the Peach or the Plum, it does not feed rapidly and at once fill the pot with roots. Thus a tree two or three years old may be potted into a 9 -inch pot, suffered to remain for one year, and then removed to a 13 -inch pot, perforated as for other orchard-house trees, in which it may remain (unless the house is very large, and a large tree is wished for) six, seven, or ten years; a portion of the surface soil may be removed, as directed for other orchard-house trees, but not deeper than from 3 to 4 inches, early in February, and the pots filled up with the above compost; and about the beginning of March a surface-dressing of manure should be given. I have observed that the French cultivators strew fresh sheep's manure on the surface; they also place their trees in pure peat earth. I have not seen this mode of culture in England, but it may be tried where peat is abundant.'

Such is the method proposed for this branch of Orchard House cultivation, and we hope to see the recommendation carried out. Gardeners must, however, recollect that there are Crab Oranges as well as Crab Apples, and that the fruit of most of the sorts in cultivation is quite unfit for the table. We should not attach much importance to the Bloodred. It is among the sorts grown in Italy, in Malta and Portugal, and in the Western Islands that search must be made for the fine varieties that are likely to repay the trouble that may be taken to grow Orange trees for their fruit. If this is not done nothing can come of the proposed experiment except disappointment.

If bushes of the Eugenia Ugni, perhaps the richest in flavour of all the uncommon Exotic fruits, were mixed with the Orange plants they would give variety to the appearance of a house, and enhance very materially its value. In our own opinion the Ugni, when properly ripened, ranks with the Vine and the Pine Apple. Its fault is that the berries grow singly, and are no bigger than Black Currants; but on the other hand it produces its fruit in abundance.

Sone years since we stated, upon the authority of French reports, that while the Vine Diskase was producing infinite mischief among European Vines, the American varieties growing amidst them were untonched. Upon this fact we ventured to suggest the possibility of preventing the mildew here by working our cultivated sorts upon American stocks. It is to be feared, however, that this suggestion has not met with encouragement ; for no account of such a trial has reached us. And yet it deserved attention better than many a proposal at which gardeners have eagerly caught.

The French statement is now confirmed upon evidence that can hardly be disputed. Mr. Chorlon, in a useful little work which has just arrived from the United States,* makes the following statement:-
'In the United States the different varieties of the native Vitis Labrusca, as Isabella, \&c., and those of the native Vitis vulpina, as Scuppernong, \&c., with ordinary treatment flourish and ripen their fruit in the open air; while those of the exotic Vitis vinifera, as Chasselas, Hamburgh, \&c., have, excepting in a few solitary instances, proved a complete failure from their tendency to become mildewed. In most parts of the Union there is sufficient light and heat to bring the different varieties of the latter species to maturity, and they are hardy enough to resist the cold, but unfortunately, when the disease (allow the expression) attacks them, the free action of growth is checked, the energy is impaired, and instead of wellhardened wood, there is nothing but an unripened, sappy substance, to withstand the severe winters. The fruit also is rendered worthless from the same cause; and although many attempts have been tried with the most sanguine expectations, they have been as often abandoned."
In these few words an experienced practical Grape grower substantially confirms the French account, and we trust the subject may now be thought worthy of European attention. Not that we would limit the proposed trial to mere grafting un American stocks. On the contrary, the process of hybridizing seems also to promise advantages, notwithstanding the bad quality, as we think, of th: native American Grapes. Their mucilaginous pulp, and strong musky or foxy flavour render them The the American Climape Grower's Guide. Intended especially for the American Climate. Being a Practical Treatise on the
Cultivation of the Grape-Vine in each department of Hot-house, Cold Grapery, Retarding-house, and Out-dor Culture. With the best methods of Heating the same. Every Department being
fully Illustrated. By Wrulum CHositos, author of so The Cold Grapcrs,'\&c. New York: C. M. Sartor \& Co., Agricultural Book Pablishers, 140, Fulton Street, 1856.
unpalatable here; but suppose they were crossed Suppose that such insipid kinds as the Syrian White Nice, and Black Sweetwater were touched with the perfumed races of the United States, or vice versû, there would be fair promise of good and hardier kinds being the result; and if the first generation were crossed again with the Black Hamburgh or White Sweetwater or Muscadine, some further improvement would be almost certain.

We are told by Mr. Chorlton that "two of the best in America at present are Isabella and Catawba, both of which are only natural seedlings ; the former from the species Labrusca, and the latter, which is the famous Wine Grape of the West, most likely an accidental cross between Labrusca and Vulpina.' It must be owned that those sorts, although the best, have little merit ; and he gives a very unflatter ing character to other sorts. On this account, and because of the invincible tendency to disease among the European kinds, he also strongly urges the expediency of trying hybridism, concerning which he speculates thas:-"For producing a fine table Grape, perhaps no better varieties can be chosen than Isabella, or Concord, fertilised with Black Hamburgh, for a black; and Diana, crossed with Chasselas Fontainebleau, for a light-coloured class. For this purpose, it is not advisable to make use of the Frontignans, or Mascats, for the natives have already too much of the musky flavour, and by introducing the sweetness of the Hamburgh and Chasselas, we shall be most likely to produce a Muscat flavour, with the size or beauty of berry, and form of bunch of the two paternal kinds." The opinions of a practical man upon such a point seem to us deserving of consideration.

In connection with the present subject it is not a little curions to see how the American gardeners are in a state of complete confusion as to what is the true Vine Mildew, arising from the attack of Oidium. Mr. C. says there are two diseases in the States, one appearing in the form of brown spots, which eat through the leaves; the other like "a fine and delicate hoary mouldiness." The first he supposes to be the European mildew, while his account shows unmistakeably that it is the second. Let us hope that when Mr. Chonuton sees this remark he will make the American public aware of the mistake.

## New Plants.

180. Lysimachia lineariloba. Hooker in Beechey's Voyage, p. 268.
Mr. Fortune has sent this from China to Mr. Glendinning. It had been previously found only by the naturalists attached to Captain Beechey's Expedition when it visited the Loochoo Islands. It forms a very pretty little herbaceous (?) bush, and is said to be quite hardy. The specimen before us is about 2 feet high, with a perfectly smooth shining red erect stem, branched from the base, and terminating in quadrangular twigs. The leaves are sessile, spatulate near the base, oblongovate upwards, shining, leathery, convex, with a very

slight tendency to crenatures at the edge. The upper part of the stem is covered by innumerable white starry flowers, on long stalks in the axil of deep green leafy bracts. The corolla is divided below the middle, and They are larger than in L. Ephemerum, and perfectly
destitute of colour. The stamens are half as long as the lobes of the corolla. None of the translucent coloured dots that are so common among Lysimachias are to be
found in this species except in the lobes of the found in this species except in the lobes of the calyx where they are oblong, and stand in a row or row and half on either side of the midrib. To us this seems as nice a novelty as more showy flowers. It ought to look well in the narrow trim beds of a well kept parterre. Whether it is really perennial we do not know. It seeds freely.

PRACTICAL LESSONS IN BOTANY FOR
BEGINNERS OF ALL CLASSES.-No. IV. by the Rev. J. S. Henblow, M.A, Rector of Hitcham, Suffolk,
Examinations and Prizes.-Subject-matter for an annual examination may be suggested under the follow. ing heads:-

A few questions viva voce on the general charic. teristics of the more prominent orders, and remarkable deviations from them.
Ex. gr. The ordinarily didynamous condition of the stamens of Labiates, contrasted with the unusal diandrous state of some of them, as in Sage (Salvia), Gypsey-wort (Lycopus), \&c.

Blank schedules attached to about a dozen or more specimens of wild flowers, to be filled up according to the example here given by the words in Italics.

| Slit for inserting the specimen. | Cl.: D. Div.: An. |
| :---: | :---: |
|  | Sec.: Calyciforal (mono, etalous). |
|  | Ord.: Composites or Asteranths. |
|  | Gen.: Plume-thistle. |
| 20th July, 1836, by Jave Finder. | Sp.: Woolly-headed. |

N.B. It has occurred to me since my former comme nication that these label schedules might be uefla, instead of keeping lists of the plants first found by ench child in a season. If each were required to put down all it found, and a good marly allowed for every label correctly filled up: references both to the plant stands for names, and to the plant list for orthography, would be vastly increased, and the results would be more rapid among those who are not so anxions as others to find themselves improving. I have ordered a box with pigeon-holes in which these records of industry may accumulate in future, till the day fos investigating them shall arrive. Three marks instead of one will be allowed for every plant brought in flower for the first time in the season.
3. Blank schedules for the flower, fruit, leaves, de, to be filled up for two dicotyledons and one monocotyledon. The forms of these schedules will be given when I explain how lessons are to be carried on by means of them. Garden specimens may be selected, provided they are of the same orders, though not necessarily of the eame genera, as the wild nowers of the neighbourhood. Lenses, forceps, vasculums, and penknives, are coveted prizes. Books on natural history I need scarcely allude to, as they will be sure to be held in estimation wherever means are fortheoming for procuring such.
Educational and Instructional advantages on Botany.-As these notices profess to be intended for beginners of all classes, perhaps I may be allowed to express my opinion of the advantages to be expected from accepting botany as a branch of a general liberal education.

Many persons are interested with the theories and speculations of botanical physiologists, who are nevertheless disinclined to attend to systematic botany. Under this term I include morphological investigations, because the modern philosophic sys tematist has constant recourse to these in deducing the laws by which he determines the affinities of planse The slow and cautious steps by which the paar system is advanced are not so generally inving, capable of being so readily appreciated, as the discil veries of the physiologist. So far as physiological botany enables a teacher to convey interesting instruc tion to his hearers, this department of the science holds an important advantage over systematic botany; but for purely educational, and indeed for practical pur for purely educationa, and greatly, I had almost shid poses also, the advantage is the latter. Botanical pay exclusively, in favour of the forms a very small brapel siology in its present state forms a very remarked of botany. Some eminent votansts which of late yes me that the great improvements which of brought have been introduced into microscopes have favour, these important instruments into such generd elementhat the examination of minute orgasms and almost tary vegetable tissue, inducing speculations serionsly entirely of a physiological character, have betany to prejudiced the just claims of systematic botnod to a better attention than it is commonly supposental merit. This has proved unfortunate to the gomers progress of the science. As well mithout paying due expect to perfect their as bortanists hope to nasture attention to mathematics, as their physiological researcheafecting the natural Bystem tionate progress towards perf to substantiate the ed But I am now endeavouring to substantiate the
tional uses of systematic botany rather than to maintain A classificatory science has higher aims than the sufficiently important one of training the observant faculties. Correctly pursued it will certainly tend to strengthen the reasonilig powers. The observant faculties may be trained by paying attention to the multiplicity of natural objects which surround us, the majority of which escape
the notice of the many. The mere collector of specithe notice of duly arrange his cabinet without experiencing some advantage in this respect. But if he stop here and content himself with depending upon others for the lists by which he groups his acquisitions, he will obtain comparatively few scientific ideas concerning such minerals, plants, or animals as he may have been at much pains or cost in procuring. He will know nothing of the general principles which have induced others to group and classify such objects as he finds in his lists, or in the brief descriptions of systematic writers. Bet resemblances, and then deducing results from his own investigations, his mind will be occupied in a way which closely approximates, if it be not strictly identical with, the method pursued by a medical practitioner in framing a diagnosis of disease from the symptoms he detects in his patient. The skilful physician takes into consideration every symptom he can possibly notice; his tact and patience are then rewarded by the solution of difficulties which might not even have suggested themselves to a less careful investigator. The power of eliciting truth from circumstantial evidence appears to me a mental qualification of the
same character. If I am correct in these notions, how aame character. If I am correct in these notions, how the future medical or legal practitioner how to observe, and how to draw just inferences from the facts before them.
A little experience, and no great amount of intellectual capacity, suffice for the detection of those external differences by which one organized being is great tact in discriminating numerous varieties among the fancy flowers which the florist confides to his care. The naked savage of Australia recognises by his touch, even in the dark, certain minute shades of difference, by which he distinguishes one gum tree (Eucalyptus) from another, it has been said more readily than an experienced botanist could do so by day! But there is greater difficulty in learning how far we are to neglect greater difficulty in learning how far we are to neglect
superficial or trivial differences (often very imposing to the eye) in searching for those less obvious resemblances which denote a greater or less degree of affinity between the individuals which make up the several "groups to which botanists assign, the terms "species," "genus," "order," and "class." The various differences and resemblances we detect are the data by discovered laws by which the Creator exposes to our admiration the wisdom and goodness of his conceptions, Accurate observation, patient research, cautious inference, elose reasoning, are all needful to the successful progress of every brauch of natural science; and assuredly systematic botany is in no respect behind any attained by the steady application of such means and methods as are needed for eliciting truth.
In many respects systematic botany (including morphology) possesses great advantages over all branches in purposes of general education. In chemistry there is purposes of general edifatite of obtaining a sufficiency of apparatus and the requisite re-agents for enabling indiapparatus and the requisite re-agents for enabing idi-
vidual students to perform experiments for themselves. In mineralogy a few small fragments will indeed suffice for aequiring the use of the blowpipe, and comprehending the agency of chemical tests. But most mineral species are rare, and consequently costly; many are very ill de-
fined. Moreover, no one can strictly claim the title of fined. Moreover, no one can strictly claim the title of amount of mathematics requisite for solving problems in spherical geometry and optics. In some departments of zoology the facilities for giving practical lessons as well as for private study are greater; but are not without drawbacks. In entomology we meet with the objection, serious to many, against teaching children to be regardless of taking animal life, even where the interests of science require and justify it. The entomologist indeed feels convinced he inflicts little or no
pain upon the objects he impales, but the unscientific pain upon the objects he impales, but the unscientific
cannot appreciate his reasons for believing this. It is cannot appreciate his reasons for believing this. It is
more difficult to appreciate those external and internal characters by which insects are systematically grouped, characters by which insects are systematicaly grouped,
than is the case with plants. There would also be difficulty in securing a steady and requisite supply of specimens adapted to class teaching of the kind here adrocated, which does not apply in regard to botany,
If these difficulties stand in the way of entomology, they exist to a greater extent in other departments of
zoology. I have heard this regretted by accomplished instructors. Now, for practical lessons on systematic botany, there is a free Museum on the grandest scale to which the children of every village may resort, and
from whence, by very simple arrangements, the children of every town might be abundantly supplied. The trifling cost of apparatus needed for collecting, preparing, and preserving botanical specimens, is no mean consideration where the many are concerned. After instrument, have served their purpose as an educational aside, as we find mathematics to be by the bulk of those
who have been educated at Cambridge. A ground
work once laid by systematic botany, great facility work once laid by systematic botany, great facility is departments of this seience in after life. Few who have fairly mastered the little technical difficulties which have fairly mastered the little technical difficulties which
beset them in the outset, are likely to regret whatbeset them in the outset, are likely to
ever time they may have spent in doing so.

Many illustrations could be offered of the advantage that might attend the possession of botanical knowledge. For instance, with what different feelings will the poorest emigrant to a distant colony look upon the forests that surround his new home, if he have only learnt to distinguish the principal natural orders o plants. He then knows that some are characterised by peculiar properties, noxious or beneficial to man. He determines at a glance there can be no fear of death in the pot from his trying whether a Crucifer he never Without hesitation fruit he finds upon a Rosanth; but he prudently avoids the most tempting berry of some unknown and possibly poisonous Solananth, and passes by till he shall have obtained proof that he may eat with impunity the fleshy tap-root of a suspicious Umbellifer. How valuable would have been the information that might have accompanied many specimens in those large collections of vegetable productions transmitted by our colonists in an 1855 to the two great exhibitions of England and France! As it was, they mostly arrived without
names or clue to guide the botanist to the affinities of the plants which afforded them. Perhaps I have dwelt too long on preliminary matters. It is time to enter on the first practical lesson adapted to the comprehension of the youngest of botanical volunteers. J. S. Henslow.

ON THE DURATION OF THE VARIETIES of the pear tree.
Some authorities maintain that the varieties of fruit trees have only a limited period of existence, dating from the time the seedling first comes into bearing, and that after this period has elapsed they degenerate, and ultimately disappear. An average duration of from 150 to 250 years is even assigned to a variety. This admitted to be correct it must be supported by sufficient proofs, and these proofs are wanting. On the other proofs, and these proofs are wantisg. On a contrary opinion
When the supposition first took its rise, what wer the varieties of fruit trees which existed in our gardens? In general they were natives of much warmer cimates than ours, or varieties equally tender
with those obtained in our own latitudes. These varieties could only succeed in a good aspect, whe trained in certain ways, or against a wall. When grown as Quenouilles, or as Pyramids, in not very Chaumontel, Saint Germain, Virgouleuse, Doyenne Blanc, Bergamotte de Paques, and Bergamotte ancienne ac., were 10 longer so healthy as trees grown on walls in good situations, and ceased to produce fruit at al comparable in size, form, and quality to that obtained in figourable years from trees grown in that manner. The vions made in other latitudes, and their fruits not pos sessing the forms and qualities ascribed to them, was sessing the forms and qualities ascribed to them, was it degenerating ! These old varieties, when properly propagated, and when planted in a saitable soil and situation, have preserved up to the present time the same degree of vigour and the same state of health which they enjoyed of old, and produce fruit of the same form and quality as they did at the time of their first coming into cultivation. If all these varieties are no longer to be met with in gardens, is their disappearance to be attributed to their becoming extinct through age ? We
should be more inclined to believe that they have should be more inclined to believe that they have cular to be propagated because they required a parti situatione of management, and pecaliat one. It will be the same with some varieties of modern origin as soon as they shall have been eclipsed by others in respect to their hardiness, productiv.
At the end of the last century our orchards were, as they are nows planted with Pear trees, the produce of which was intended for market. Many summer few trees bearing good long-keeping fruits for the dessert. If these comparatively worthless varieties are no longer propagated, but are allowed to become extinct their disapp.
the variety.

Sometimes in going through these orchards we cut strong shoots from the upper part of very old trees, supposed to be seedlings, and yielding fruit which was
esteemed by their possessors. These scions, worked esteemed by their possessors. These scions, worked
upon strong and healthy stocks, are as vigorous at the present day as the trees from which they were taken If in 50 or 100 years another person take scions from the trees which I have grafted, and work them under the same favourable conditions, and so on, there will be no reason why these varieties should not remain in cultivation until replaced by others, better in every respect. But this replacement will be the effect of the becomi understanding of man, ale of reproducing itsel by the graft. It in known for certain that the existence
of every individual tree is limited by its own constitu tion and other causes. It has also been demonstrated proper time and planted in a suitable soil and situation retsins all its properties for an unlimited period.
It should be well ascertained in what manner, and on what lind of stocks, each of the species and varieties should be propagated ; in what soil and in what aspect it succeeds the best ; and in what way it should be trained, whether sgainst a wall or as a pyramid
When a fruit tree appears to be in a declining state, or produces bad fruit for two or three consecutive years, the able cultivator does not seek for the cause in the age of the variety, but in the constitution of the individual tree, and that of the stock which influences it more or less favourably, in the soil, in the subsoil, in the situation where the tree is planted, and in the form the fibrous roots and spongioles have or have not been destroyed by the spade of the gardener who is ignorant of the elementary principles of fruit-tree culture.
In conclusion, the question as to the duration of a rariety of fruit tree possesses but little interest. The only point which engages the attention of the amateur is to know with certainty what are the varieties which he can successfully cultivate in the garden and in the it will in Aht al that has been writen on phof culture fat bo the most complete monograp of possessed of the greatest interest. J. De Jonghe, Brussels.
VEGETABLE PATHOLOGY.-No. CXXXII
535. Parastte (Cyttaria,* Rhytisma, $\dagger$ Dothidea, + dec.). - Besides the ascigerous parasites last described, Which in their perfect state are entirely superncial traverses the large intercellular spaces on the under side of the leaf, there are many real parasites which are side of the lear, there are many real parasice betancal
truly curiosities, others are so frequent or so conspicuous as readily to attract the eye by their scarlet, tawny, or jet black patches ; others are intolerable pests, while others attain a considerable ize and are useful or even indispensable articles of food to the savages who live where they grow.
536. Cyttaria is not only remarkable for its large size, its comblike aspect, its frequently tufted habit, and its affording for many months of the year a valuable article of food to the Fuegians, but also because a fresh crop of fungi grows on the living branches from the same mycelium year after year. A similar habit occurs
in Podisoma and its allies, and the parasite flourishes till the branch is finaliy exhausted. Cyttaria is con fined to species of evergreen Beech. Faint traces of mycelium are visible where the fungus has fallen off, but not to such an extent as might be imagised in a plant of such enduring hasits. The genus is confined strictly to the southern hemisphere.
537. Rhytisma is equally a true parasite, but of very different habits. It is intimately united with the tissues of the plant on which it grows, sometimes affecting the bark, sometimes the leaves. Species occur on the perennial leaves of Andromeda and Ilex, as well as on the deciduous leaves of Acer, Vitis, and Salix, or the herbaceous foliage of Aster and Solidago. The species are seldom of sach size as to be really detrimental Those on the leaves of Aster and Salix are the mos conspicuous, and that on the bark of the latter the most destructive. Fries observed that, in spring, the sporidis are discharged in a visible smokelike cloud from the fallen leaves, just as the new and tender leaves are expanding,
and are thus enabled to establish themselves on the and are thus enabled to establish themselves on the
opening foliage. In Salix there is a thick white stroma, and the fungus is so highly developed that it must make important demands on the strength of the plant. Dichcena, which is very nearly allied, infests the living bark of Oak and Beech in England, but is not confined to those genera. I have it on Cyrilla and other trees from the United States. It is one of the which which oscillate between Llation. Some ot these spech show their intimater between the true and false cuticle. In some cases the true cuticle is not ruptured till a very late period, or may remain intact so long as the parasite flourishes.
538. Dothidea also contains numerous species which live at the expense of previously healthy tissues ; but in general they are so small as to be unimportant, except in the case of some exotic species. An exception, howaver must be made as regards Dothidea typhina Fr. which is, however, now referred to Hypocrea. It lives upon the flowering stems of various Grasses, preventing altogether the evolution of the spike, and presenting instead an orange-coloured cylinder surmounted by portion of the stem, 80 as to resemble a Bulirush. It is or the destruction might be very serious, for where it occurs it is generally in great abundance.
539. One of the most destructive of the group is perhaps Sphceria morbosa, Schweinitz. This is extremely common in Pennsylvania, but scattered about in outher native 28 in South Carolina, and is most injurious to Cultivated Cherries, especially the Morella or Amarella, fare, however, worse. Schweinitz relates that this fare, howerer, 40 years before he wrote was common in Penn-

sylvania, bat a few years after the variety died out
partly from its attacksand partly from theo of a Cynips partly from its attacks and parily from thooe of a Cynips, its companion. The Greengage and some other Plums
never suffered at that time, but at a later period they never suffered at that time, but at a later period they branches, which were at first small, acquired a foot and a half in length, but were never loaded so thickly with perithecis when growing on the Cherry. I have numeroas specimens of this species from different parts of America all presenting the same gouty aspect, and rough with innumerable perithecia. This species has not yet made its appearance in England, but should if cnce arrive, there is little reasou why it sh
establish itself like some other exotic parasites.
540. Many other cases of minute fungi belonging to the mame series and infesting living leaves might be adduced, as, for instance, on the pods of Cruciferse and on the leaves of Cabbages, but their effects are sn papers which is intended rather to have a practical than a theoretical bearing. M.J. B

## Home Correspondence.

Wellingtonias.-Your Hertfordshire correspondent speaks of the branches of bis Wellingtonias dying off ; the same thing happened "ith a plant which I had
from Messrs. Veitch, in the autumn of 1854 . I kept from Messrs. Veitch, in the autumn of 1854 . I kept
it in the greenhouse during the winter; in the spring following I potted it in a 10 -inch pot, it $₫$ rew very strongly for two or three months, I then noticed a spot
on one of the lower branches: I placed it on one of the lower branches; I placed it out of "doors in the sun, but still the lower shoots continued to damp should have lost the plant. Those who have seen it
she said hat it was Potato disense. In August I planted it out in a moderately rich yellow loam, and since that there has scarcely a leaf dropped from it, and the plant the stem at the surface of the ground being two and a half inches in circurnference. Mr. Charms, from the Exeter Nursery, saw it a few days since, and said it wa one of the largest plants he had seen, Two or three plaats in this neighbourhood have suffered in the same way, but now they are growing vigorously. W. II. D. Quercus sessiliflora (see p. 470 ).-I enelose you some
leaves of the Oaks I mentioned for your inspection cannot discover any peculiarity in the leaves, but the geoeral appearance of the trecs is different from most Oaks that I have seen, especially in the straightness and regularity of growth. I send $t$ 'e measurement of one, which is I think of much more than average ensions
Girth,

## 1. foot from ground 6 fet from ground 14 feet from ground

Above that it rather increases up to the spring of the brauches at $22 \frac{1}{2}$ feet from the ground. Total height about 85 feet; diameter of spread of branches about Qu. sessiliflora.]

Victoria Regria - I have had this noble Water Lily remarkably fine this senson. I planted it out on the
$30 \mathrm{th}^{2}$ of A pril in the usual manner in a mixture of loam and river sand, in a brick tank heated with hot first only three leaves nut on if, which were 4 inches in diameter; it then made from three to four leaves each week, and increased rapidly in size, until now it has
six fine leaves on it in the most perfect condition imasix fine leaves on it in the most perfect condition ima-
ginable, each measuring from 6 feet 6 to 6 feet 9 inches in diameter. It is expected to produce flowers in a few days. Hearing that the Victoria has not succeeded a all well in the neighhourhood of London this year, bas induced me to seud you this notice, and as soon as the shall be furnished. WV. Marther particulars respecting it Esq, Harokesyard, Rugeley, Staffordshire.
Pamily Mills for grinding Wheat for whole meal Mread are no longer the desideratum which Dr. factory steel mills can be had at Horselis, 492, Oxford Street, London, at prices varying from one to ten guineas; also instructions for preparing the Wheat and Rasing the mills. J. Burns, Hampton Court.
this Potato I fout Potato.-In getting up a piece of larger and rougher leaves than usual, and in flower. In taking them up I found that one root contained 103 tubers, one ditto 105 , one ditto 123 , and one ditto 157 rouch for the truth of them. The Potatoes wer counted hoth by my men and myself. J. Hudson, Gave dener to Geo. Monn, Esq., Applely Hall, A therston.
Gardeners' Benevclent Institution.-I have just read the various articles which have appeared in your pages discussed dispassionately, I cannot help thinking that there has been "much ado about nothing." The claims of those who have or have not subscribed to the Institution have nothing to do with me; I am quite
convinced that many who have been and are now convinced that many who have been and are now
pensioners of the charity are mere nurserymen or seedmen's nom nees, whose claims as gardeners are for the most part of a very questionable description. For noy own part, on looking the list of pensioners carefully over, I can only recognise two who could be considered gardeners in the full sense of the word; men who made and these two men are Mearns and Blair. Poor Mearas (now men are More) furns mand ylair. Poor yenjoyed
man of his time did so much to promote and inculcate a knowledge of the first principles of horticulture. Blair was a botanieal collector, a man of experience and enterprise, and, withal, a man of first-class gardening skill. In fact, these two men were enthueiasts, and lived for their country, not only practising the Tullian principle of making two blades of Grass grow where
one grew before, but by their example they endeavoure to malse others "go and do likewise." On the xeverse of this picture how easy it would be to point to a man palmed upon the Institution almost at the commencesubscription; of anuther eltected by trade influence a year's pensis, ner, and then, when it was ascer-
tained he had a competency, withdrawn from very tained he had a competency, withdrawn from very
shame by his proposers and promoters; and of others whose claims were not much better. Away then with this discussion about subseribers and non-
subscribers. Let us first know that a man has Jeen a gardener in the full sense of the word, and that he is really deserving of the support of the subscribers, and then let him have it. Such a man is in my estimation, if overtaken by difficulties in his old age, quite as deserving as others who, supported by Lady A. ior los aunual payments of a guinea each; not a bad investment, or an expensive way of providing for a decaying servant. That many subse ibe to the Institution
with no other view than that. of becoming at the expiration of their subecriptions claimants of the pension is too true, and one cannot blame them, the invest-
ment is a good one, and avavice talkes advantage of it. I should like to see the charity, or at any rate the committee, pitch a higher standard, an intellectual standard for pensioners, and then I think the candidates would be much reduced in numbers, and we should have more real merit rewarded. From the commencement to the present time the committe has been much too easy in its admission of cnndidates for the pensions, and such will be the ense until a higher standard of admissibility can be erected. The Institution is a noble one and must be properly supported, hut the Rervant must be the servent end not the director paid charity. He must not have the power of receiving the proxies of subscribers and using them as he pleases. No ; he must be the servant of the charity, and if proxies are returned without being filled up, let them
be at once cancelled. As an old member of the Institution, and for many years a working member of committee, I make these remarks, and I warn properly managed, they must to a great extent manage it themselves. It must no longer remain a matter of patronage in the hands of two or three who have little sympathy with any but their customers; but candidates must stand upon their own merits and claims, and then, and not till then, "right will prevail." An Old Member of Committee. [Of course we must admit a reply to this letter : and we hope it will be furnished by the Committee. With that reply the subject must drop as far as we are concerned.
Subwrban Qardens-I maw a pretty effect the other day at Wells (Somernet) which is woethy of imitation; it is that of making the flat roof of the porch a platform for a low stage for plants in flower. Those I saw looked porch, no part of the stage being visible, if indeed- there was any, or merely plants arranged according to their case window. Somerset.
Roses.-I am glad to see that you select for admiration Roses which are really distinct in colour and character so many being now introduced with but the fraction of a shade of difference between them. That fine Rose Jesse Colgel de Rousemon lik Baronne Pré Wiliam they are distinct. Sir J. Franklin seems a good deal like a moderate flower of Panl Dupuis. In my opinion Prince Lear is the best and most distinct Hybrid Per petual since the Géant. How beautiful and erect in habit, and what fine foliage. What a treat it would be
could our French neighbours send us over a shaped yellow or blue Hybrid Perpetual; those are the only two colours in which there is a good opening General Jacqueminot is brilliant in colour, is a strong grower, and has luxuriant foliage, but would be a more perfect flower if a little more double. Sometimes he Gloire de Rosomèmes. If amateurs were to make your columns the medium of occasionally comparing notes, hey might afford themselves and others mach amuse ment and instruction, and save themselvesimnoh disap pointment. Some Roses have their good and bad
years; La Reine and William Jesse have flowered remarkably well this season ; William Griffth 1 hav not had so good this year as last. Out of the 200 and
odd Hybrid Perpetnal Roses in the catalogues I think I could name 30 hard to improve upon. Paul Ricaut
Club.-The gardens which supply Montpellier with vegetables suffer much from what is called the "clubfoot." It is there believed to originate from an insect, and accordingly it is a regular practice with marke gardeners to examine the root previous to planting ont, invariably been found to suceeed. $M, S, B$ Bentham. Peashells.-In addition to the useful hints which M. J. B." has given respecting these at p. 354, allow me to add that economical French honsekeepers prepare
hein or winter use by frat diying them thoroughty under a sharper hent, and storing them in paper baen. A three-fingers' pinch of these batied peashells not only improves the flavour of any broth with which they ape the sbells of any ordinary pods will serve, thoush course the more sweetness they wontain the better peasholls the are served ay contain the better. The peacher with the Peas they in legetnble to be vate together with the Peas they inclose are produeed by are called Sans Parchemin, or skinleas, and Mavgetenem or eat-all ; there is the white-podded, the yellow-pothe the ram's-horn, the red-flowered, \&c. E. S. D.
Strauce rics.- I have some Strawberries in pots ea three fruit produced on each plant of havour but the remainder as they come small, vapid, and oftentimes disagreeable to the tele and numbers of them are rotten before they are quite sipe They are allowed to root in the prepared border, and have every appearance of healthy plants. I have watered them occasionally with guano water. Can yor form me what is the what I had hoped would have been a good crop of finely
flavoured fruit? G. H., Camden New Tovon, flaveured fruit ! G. H., Camden New Town. [Ramk
manure? Was your guano made with " Blue Billy !"]

Vild Bees.-Can you or any of your correspondent suggest a means for the extermination of wild ground bees? I am surrounded by them in such numbers that the Grass of my lawns is perfectly obliterated. O. \& [Will not rage dipped in turpentine and pashed into heir holes drive them away ?]
Elasting the Stumps of Trees.-On Monday Lent Captain Norton practically proved the efficiency of boi Percussion Blasting Cariridges" for blasting the Havin of rees, in a timber yard in Church siree half way dow ho wh stump, one of the cartridges having a wooden head wis inserted, and an iron bar of the same diameter as the auger, having a cavity or hollow in its lower end receive the small percussion appliance, was then put in over. the cartridge, so as to reach within shout tmo
inches of the head of the cartridge, the bar being tept in this position by a clip as well as by its fitting tiguty in the hollow bore of the stump; a long plank of tiate with one end on the ground and the other end held ove the bar by a long rope, was then allowed to fall on the upper end of the iron bar, and the cartridge whes instantly fired, and the stump rent asunder. This means have failed may be beneficially put in practiee for procuring fire-wood instead of allowing the stumps to go waste. The iron bar being of the same diameter as the auger, it decessarily fits air tight in the bellow above the cartridge and allows of no escape of the chas tic gas when the charge explodes, thus concentratipg the whole force of the explosion upon the solid stomp and no tamping is required, and the percussion applias ces obviate the necessity of any fuse. Captain Norten, therefore, very appropriately pronounces this meass blasting to be on the "Highest pressure, no safety wive, and as the exploding, gun-barrel isursting from the cartridge and only required, there can be no fear of any acciluatal stump shows The shattered appearance oercussion shell would be in the hull of a man of war, when fired from a 63 -pounder rifle cannon. Gravesend, July:26th.

## Bontitits.

Caledonian Hormcultural: July 5.-There.was or this occasion a marked improvement in the cultivation of specimen plants, and the number brought formal was greater than ordinary. Prizes were amarded ac follows :-Silver Medal to Mr. Sonith, Meiville Cumbe, for Tetratheca verticillata and Polygala Daimuiaian Stove or Greenhouse Plant, not shrubby: list, Falconer, Canonmills Cottage, with Oncidium puinn tum, traised in a balloon form ; 2d, Mr. Lockan, Arniston, with Gloxinia magniflora alba. Cape Heathe: lst, Mr. Smith, with Erica ventricosa and E. vemin cosa superba. Pelargoniums: Jst, Mr. Forrest, Glear tarkie, with Mochana; 2d, Mr. Henderson, Carginast. with Stlla. Dis, in anch pots: 1st, Hendemen, with Stella and Fair Ellen. Fancy Pelargoninnes. 1 st , Mr. Forrest, with Lady Hume Campbell ; 2d, Mr. Cameron, gr. to S. Hay, Esq., with Princess Marie Galitzin. Ditto in 6 -inch pots: 1 st, Mr. Forrest, witas
Othello and Bride 2 d , Mr. Henderson, with Celectis Othello and Bride ; 2d, Mr. Henderson, with
and Madame Van der Weyer. Fuchsias and Madame Van der Weyer. Fuchsias in \&ine pots: lst, Mr. Henderson, with Prinee Albert
Queen of Hanover ; $2 \mathrm{~d}, \mathrm{Mr}$. Walker, Rosehall, with well-grown plants of the same varieties. Roees Mr. Wemyss, Springwood Park, with the Madame :- Count de Mantease Molé, Madame Lafiys: Cloth of Gold, La Ville de Bruxelles, Elise Sannge, Napoleon, Géant des Batailles, Adam, and Duchess Sutherland ; 2d, Mr. Buist, Tyningbam, with Géant Batailles, Jules Margottin, Devoniensis, Baronne Proul vost, Mrs. Bosanquet, William Jesee, Adam, Pinots Ricaut, Duchess of Sutherland, Genlexal in pots: leth Mr. M•Farlane, Barnton, wihh Antagonist, Mastery
nd a Seedling named Rival; 2d, Mr. Mitchell, Ravel-:
ston, with Colonel Dundas, Antagonist, and Masterpiece. Herbaceous Plants, cut spikes : ist, Mr. Hally, Hermiston, with Aconitum uncinatum, Lilium bulbiferum var, umbellatum, Delphinium Barlowi, double Rocket, and an unnamed species of Salvia from CashSpirea Aruncus, Delphinium grandiflorum, Dictamnus, Fraxinella, Lychnis viscaria (double-flowered), and Large plants of Lygodium scandens, Asplenium viviparum, Aspidium exaltatum and dilatatum, Adiantum cuneatum and A. pubescens; 2d, Mr. Smith, with Adiantum formosum, cuneatum, and speciosum, Cyrtomium falcatum, Anemidictyon fraxinifolium, and Nipho-
bolus chinensis; 3d, Mr. Falconer, with Lygodium scandens, Osmunda regalis, Pteris rotundifolia, Asplenium septentrionale, Lastrea, Oreopteris, and Polypodium
Billardieri. Turnips: $] \mathrm{st}$, Mr, Porterfield, Upper Billardieri. Turnips: 3st, Mr. Porterfield, Upper
Hermitage, with Orane Jelly Tarip; 2d, Mr. Mitchell, with Early Dutch White. Fruit: 1st, Mr. Pender, who produced Black Hambargh and White Muscadine Grapes, Royal George Peaches, Stone Pippin Apples, in good preservation, and Murray Nectarines. The following prizes offered by office-bearers of the Fruit, One Sovereign, to Mr. Pender, for Peaches, Nectarines, Apples, Red Currants, White Muscadine and Black Hamburgh Grapes, and Melon, tastefully arranged in a round tray. Variegated Plants, One Sovereign, to Mr. Lockhart, for Cissus discolor, Coleus Greenhouse plants, Two Sovereigns, to Mr. Smith, for Erica elegans, ventricosa superba and minor, Savilleana, Erica elegans, ventricosa superba and minor, Savilieana,
Cavendishi, Bergiana, and spuris; Epacris miniata, Tetratheca floribunda, Polygala, Dalmaisiana and acuminata, and Aphelexis Barnsi ; 2d, One Sovereign,
to Mr. Blair, Mavisbank, for Gloxinia alba sanguinea, to Mr. Blair, Mavisbank, for Gloxinia alba sanguinea,
Epacris miuiata, Begonia Ingrami, Coleus Blumei, Epacris miniata, Begonia Ingrami, Coleus Blumei,
Achimenes Marguerita, Erica breviflora, cubica and tricolor dumosa; Stanhopes Wardi and oculata, Mitraria coccinea, Maranta bicolor, Allamanda neriifolia, Pimelea decussata and Hendersoni, Hoya bella, Leschenaultia formosa, and Stephanotis floribunda. Two Sovereigns to Mr. Reid, Broomfield, "for the following fancy Pelargoniums in 6 -inch pots, viz, Decora, and Lady Hume Campbell. Of extra productions, Messrs. J. Dickson \& Sons sent Gloxinias, Heaths, and Geraniums. From Messrs. Downie \& Laird came a
seedling Phlox named Addisoni, a variety of excellent form and substance, flowers white, with purple eye, for which a Certificate of Merit was granted; also, a promising seedling fancy Pelargonium, named Miss Trotter Hendersoni and decussata, Roses, and Pelargoniums, From Messrs. Dicksms \& C Co. Troproolum edule, Pelargoniums, Heaths, Gloxinias, Pansies, \&c. From Mr. odontites, Cenopteris vivipara, Platyloma ternifolia, Doriopteris pedata, Viola stipularis, Sce. From Mr. Douglas, Rosepark, the new Petunia imperialis, a fine double white variety. From Messrs. Cunningham,
Fraser, \& Co., Ranunculuses and Roses, which were Fraser, \& Co., Ranunculuses and Roses, which were there was one large tray. From Messrs. Ballantyne \& Sons a stand of Pelargonium blooms, including fine new French varieties.

The Englishwoman in America (8vo. Murray, pp. 464) expresses the opinions of an Finglish gentlewoman upon Whether it will meet with the entire United States friends on the other side the Atlantic is doubtful ; and yet it seems to us to do their undoubted merits justice, and to be blind enough to some of their peculiarities They must not expect travellers accustomed to the re finements and comforts of Europe to admire the insolence of domestic servants or the expectoration of
their masters. It must also be admitted that our their masters. It must also be admitted that our authoress shows,no favour to the sulky'pride of her own
ill-bred countrymen, we the following story proves:-
"The cars were very full, and were not able to meat all the passengers. Consequently, according to the usages of American etiquette, the gentlemen vacated the seats in favour of the ladies, who took possession of them in a very ungracious manner as I thought. The gentlemen stood in the passage down the centre. At ping at a station another lady entered. 'A seat for of the said the conductor, when he saw the crowded state tor a lady, repeated the man in a more imperious tone. Still no movement on the part of the gentlewan appealed to. 'A seat for a lady; don't you see there's a lady wating one?' now vociferated several woices at once, lady, said one balder than the rest, giving the stranger travelling cap travelling cap over his eyer, and doggedy refused to
stir. There was now a regular hubbub in the car; stir. There was now a regular hubbub in the car;
American blood was up, and several gentlemen Atried to induce the offender to move. 'I'm an
Englishman, and 1 tell you I won't be browbeat Finglishman, and I tell you I won'c be browbeat I y you beas:ly Yankees. I've paid for my seat, and
mean to keep ik,' savasely blouted the offender,
know it !-A regular John Bull tri

approving smile. I was so thoroughly ashamed of my countryman, and so afraid of my nationality being discovered, that, if any one spoke to me, I adopted $\quad$ We believe the which I could think of in rept
We believe the following picture to be very much more like truth tlan tales we have heard of A mexican adies doing nothing from morning to night, except "The ladies in the talked to
"The ladies in the United States appeared to me to be extremely domestic. However fond they may be of admiration as girls, after their early marriages they become dutiful wives, and affectionate, devoted mothers And in a country where there are few faithful at
tached servants, far more devolv, than English ladies have any idea of. Those amusements which would withdraw her from homie must be abandoned; however fond she may be of travelling she must abide in the nursery; and all those little attentions which in England are turned over to the nuree must be performed by herself, or under her superin tending eye. She must be the nurse of her childre alike by day and by night, in sickness and in bealth their husbands, their married life is by no means an idle one. Under these circumstances, the early fading of their bloom is not to be woidered at, and I canno but admire the manner in which many of them cheer-
fully conform to years of anxiety and comparative seclusion, after the homage and gaiety which seemed their natural atmosphere in their early youth."
Familiar as we all are with descriptions of Niagara and its wonders, the following adventure there wil probably excite surprise
"After depositing our purchases at the Clifton Honse, where the waiter warned us to put them under lock at last I should be able come to visit-the Falls of Niagara. But no ; I was to be victimised still further; I must 'go behind the great said their. and Mrs. Walrence would not go ; they Englishwoman, go I must. In America the capabilities En English ladies are very much overrated. It is sup-
 back. Yielding to 'the inexorable law of a stern necessity;' I went to the Rock House, and a very pleasing girl produced a suit of oiled calico. I took off my cloak, onnet, and dress. 'Oh,' she said, 'you must change everything, it's so very wet.' As, to save time, I kept
demurring to taking off various axticles of apparel, I always received the same reply, and finally abandoned myself to a complete change of attire. I lorked in the
mirror and belield as complete a tatterdemallion as one could see begging upon an Irish highway, though there was nothing about the dress which the most lively imagination could have tortured into the picturesque The externals of this strange equipment consisted of an oiled calico hood, a garment like a carter's frock, a pair of blue worsted stockings, and a.pair of India-rubber
shoes much too large for me. My appearance was so comic as to excite the laughter of my grave friends, and I had to reflect that numbers of persons had gone out in the same attire before I could make up my mind to run the gauntlet of the loiterers round the door. Here a negro guide of most repulsive appearance awaited me, and I waded through a perfect sea of mud to the shatt by which people go under Table Rock. My friends were evidently ashamed of my appearance, but they met me here to wish me a safe return, and, following the guide, I dived down a spiral staircase, very dark and very much out of repair. Leaving this staircase, I followed the guide along a narrow path covered with fragments of shale with Table Rock above and the deep abyss below. A
cold, damp wind blew against me, succeeded by a sharp pelting rain, and the path became more slippery and difficult, Still I was not near the sheet of water, and
felt not the slightest dizziness. I speedily arrived at felt not the slightest dizziness. I speedily arrived a
the difficult point of my progress: heavy gusts almos blew an pow of spray almost blinded me I was quite deafened and half-drowned; I wished to retreat, and essayed to nse my voice to stop the progress of my guide. I raised it to a scream, but was incertitude and extended his hand. I shuddered even there as I took hold of it, not quite free from the uvenile idea that 'the black comes off.' He seemed at that moment to wear the aspeet of a black imp leading me to destruction. The path is a narrow, slippery ledge of rock. I am blinded with spray, the darke $\operatorname{lng}$ sheet of water is before me. Shall I go on ? The spray beats against my face, driven by the contending month, and almost prevent my progress ; the narrowmoath, and almost prevent my progress, ing ledge is 70 feet below. Yet thousands have pursued this way before, so why should not I? I grasp tighter hold of the guide's hand, and pruceed step by step holding down my head. The water beats egainst me, the path
he guide to stop, bus my voice is drowned by the
Thunder of Waters." He guesses what I would say make a desperny ear, 'It's worse going baek. at the end of the ledempt: four steps more and I am at the end of the ledge; my breath is taken away, an ca drivin the whe inches from me, and, gasping for breath, and drencher inches from me, and, gasping for breath, and drenched
to the skin, I become conscions that I have resched Termination Rock.

And thus the lively anthoress tells the tale of her journey in N. America from Halifax to New Yorls, and back again by Halifax to Liverpool. Her work i something more than a counterpoise to the gossip of
Madame Ida Pfeiffer, who found merchants at St. Louis making molasses into refined sugar
The Stercoscope; its History, Theory, and Construction, Educationlicaron to che ne and useful Arts, and to Murray. Smali 8vo pp 235
The tille explaina sufficiently the olject of this treatise in which the student of optics, the artist, and genera reader will find every information relating to the find that the author has introduced a long and angry has endeavoure to convince the public that he is not entitled to the honour of the invention of the instrument in question Such disputes if - as is unfortunately the case here -carried on in an uneourteous manner, spoil books in the eyes of most readers, and redomid little to the ered of the writers.
Plain Instructions for the Management of the Aquathe i, Deann of Son, 12 mon , 13.) is an unsafe guide to the ignorant: frim some of its advice were taken The olject of the little contrivances called aquaria or aquavivaria is to preserve in health certaiu aquatic plants and animals, so that their habits, colours, and singular motions may be watched conveniently; for this purpoee everything introduced into them requires to be selected from the smallest of its race. One would hesitate before recommending a turbot, or a turtle, or a dolphin ns suitable objects for living in sueh places. No does the compiler of this guide do so ; but he does what amounts to the same thing. He telis his reades that among suitable plants may be selected the grea white Water Lily, the Anacharis, for which a Cambridge commot capacious enough, and stratiotes alouch, as a Pine Apple plant, and propagates twice as fast. Such all aquavivarium should be as broad as the Ser pentine. It is the more necessary that this should be pointel out, because if such plants are really selected inr these tanks a very pretty, interesting, and instruc No ornament will speedily lue cast aside and forgotten. Hottonia palustris should on any account be selected We dare say the instructions for managing aquaria are better than those for stocking them with plants.
The Joint Stock Compranies Act, 1856. By Edward W解 Es-ex Street, Strand. 12010 ; pp. 83.
This, we believe, is the first work on the above impor tant statute. The statute is given at length, with short observations as to the probable effect of its clausee.
a couvenient form, and is fally indexed.

## Garden IVemoranda.

GUnNERSBURY PAEK.-The improvement in the specimens of all the rarer and better kinds of Conifers has already been favourably alluded to in our columns. What we would now therefore more particularly direct attention $t n$ is the garden buildings, in which within the last few months great alterations have been effected. Instead of the low pits in which Pine Apples were號 for their accommodation. These are each 66 feet long 16 feet wide, and have what are termed hail-span roofs 10 feet in height. A shelf on the back wall affords accommodation for Vines and Strawberries in pots. In the centre of each house is a plunging bed supported by brick walls, and heated by means of hot water in 4 -ineh pipes. The latter are laid among brickbats, over which is placed a layer of coarse gravel, and above that is the soil, a good loam well enriched with manure, in which the fruiting Pines are planted outafter the lashion of those in the Royal Gardens at Frogmore. They are not managed on the Hamiltonian principle, and therefore when they have fruited they are removed and thrown away, and their places filled with the most promising plants from among those in the succession pits, where they are kept in pots. These Pine stoves, as well as two new span-roofed house devoted to the cultivation of Orchids and ordinary stove and greenhouse plants, were erected by Messrs. Gray and Ormson. A house here with brick walle which had fallen greatly out of repair has been made to look almost as well as new by plastering the walls with Roman cement, and then giving the latter a thin facing of Portland cement. The last, when properly set and dry, has a colour like that of grey btone and is almost as durable. Finally, an excellent range of new sheds, including rooms for the use of the young men employed in the gardens, and a mall room for making bouquets
in, is just heing eomplotd. The last is neatiy and con inenieutly fitted up with a table, or rather bench with
drawers in it, for keeping the appliances in for making and behind the table and running its whole length is a shallow tank which is to be covered over with open wirework through which the stalls of the bouquets and flowers will be kept in the water and thereby preserved fresh. The men's rooms also contain an unusual amount of accommodation both for cooking and sleeping, each maan being furnished with a good bed for himself and other improvements in this department which we should like to see universally adopted
As regards glass walls, if Mr. Ewing's have failed to become fashionable, to them at least must be ascribed the merit of having revolutionised our glass structures, and many an excellent contrivance for employing glass usefully and economically has been the result of their advent. An example confirmatory of this statement exists in the gardens now under notice, where Mr. Forsyth has faced 125 feet in length of ordinary wall with glass as follows. He made no expensive Peach borders, but merely took things as they originally stood. The piece of wall selected for expe-
riment was at the time well covered with Peach and Nectarine trees. The latter were unfastened; the wall-an old one-was faced with Portland cement and wired. The trees were then retrained and covered with glass in the shape of a case with upright front abjut 6 feet in height set 5 feet out from the wall, from the top of which to the top of the front was placed a sloping roof with sliding sashes. The lights in the fron secure at will abundant ventilation, and below that, in about a foot in height of trickwork, ventilators were fixed immediately opposite a flow and return hot-water pipe, with which the whole could be heated. These ven ilators, owing to their position, are found very useful in winter, the air from them getting partially warmed in passing over the pipes before it $\in \operatorname{nt}$ irs the house. Inside this long narrowPeach house, for so it may be called, have been ripened annually for the last two or three years fuil crops of finely coloured and well flavoured fruit which may be had in perfection early, and by dividing the range into compartments and having the pipes furnished with supply may be kept up till that on open walls is fit for table. This year immense crops have been ripened on every tree. The advantages of a contrivance of this Peaches and Nectarines are here obtained from trees grown in pots.
As regards the culture of Vines in pots Mr. Forsyth a acknowledged to stand pre-eminent, his plants managed in this way having invariably carried oft first
prizes at our different exhibitions botl this year and prizes at our different exhibitions both this year and
last. Those which bore the first erop are now being repotted and placed against a south wall to thoroughly ripen the wood. From these an early crop of
Grapes will be taken next year, and by means of a Grapes will be taken next year, and by means of a second and third batch of plants introduced into hea
in succession, ripe fruit may be had long before i could be got from the permanent plauts in Vineries.
We may mention in conclusion, that we ssw here an 3 feet in heeighen of Wellingtonia. it nueasures nearly with a stem 3 inches in circumference at the base. is in a pot, and has made a leader with offohoots 8 inches in length this season.
The plants out of doors in vases and in beds were very gay, the 1a
cellent condition.

## Calendar of Operations. <br> (For the ensuing week.)

plant department
Conshrvatory, \&c. - Carefully examine the stock of pot plants here, in order to see that none of them are necessary to assist them in making young wood for flowering next season. Also see that proper care is bestowed on late growing plants in the borders, for while in active growth more water will be necessary, and plunts that have completed their growth. Look after Laculias and keep them clear of their great enemy back thrips, giving them plenty of water at the root, old plunts that may not be growing freely, until they have made plenty of woud to ensure a good display of flower. Manure water must not, however, be given to
young specimens in vigorous healih, as it is apt to induce too gross a growth, a condition in which they seldom flower profusely. In order to secure fine heads of of comprom this piant it should be allowed a few weeks month, keeping the roots rather dry, and exposing injury to the foliage or the health of their neighbours. Brugmansia sanguinea is also a useful plant for winter and early spring flowering when managed so as to have it pruned, rested, and starting into growth about this
time. See that large specimens of Camellias are not allowed to get too dry at the root after they have set their buds; for shedding of the latter is often due to this cause. Young vigorous plants, however, frequently require to be watered rather sparingly at this period for early flowering should sew be growing freely and should be shilted when necessary; for if they are to
form large specimens for flowering in winter they must not be permitted to sustain any check; remove suckers
whenever they can be obtained and pot them for spring Whenever they can be obtained and pot them for spring
flowering. Calceolarias will now be beginning to demand attention ; get cuttings of favourite sorts rooted as soon as possible ; seed may also now be sown.

## forcing department.

Pineries.-Plants intended to furnish the winter and spring supply of fruit must be treated with conshowing at the proper time, or rather to do all that can
sho showing at the proper time, or rather to do all that can
be done to insure this, for the most experienced growers cannot always succeed in getting plants to fruit at the desired time. Attend to previous directions on this point, and continue to select the most promising plants, keeping them dry at the root, and fully exposed to light oas to check their growth, and induce a comparative vell-matured their growth, if wanted to fruit at once, should be kept close and warm, affording them a brisk bottom heat, and properly moistening the soil about the roots. Those intended to supply ripe fruit late in spring, if not considered sufficiently strong, may be encouraged to grow freely for some time yet, as if these can be got to show in November, they will be sufficiently early. Attend carefully to plants swelling their ruit, giving plenty of manure water at the root, and keeping the atmosphere warm and moist. Attend to he watering of recently potted stock, as if too much is given the fresh soil is apt to become sodden, and if too little the old ball becomes so dry that it is not easy to get it properly moist again, and in either case the check noto fruit prematurely Get all succession stock requiring more pot room shifted as soon as circumstances will allow, in order that they may be well eatablished in their pots before winter. Vixeriss. - Should the weather become cloudy or wet it will be unfavourable for Grapes that are ripe and expected to hang in good condition for a long time, and where the borders are of a strong adhesive nature, it will be advisable to cove with something to throw off heavy falls of rain; bu where the soil is of a light nature, and such that the sary. Use gentle fires where the fruit is colouring, with moderate circulation of air, and on fine days too much air can hardly be given at this stage. In dull weathe The wood will probably be well ripened in swe the ang house, and the foliage turning brown, and in this case it will be desirable here also to prevent the borde getting saturated with wet. If this house requires painting or any other repairs, this should be attended to while the house can be thrown open, and such work done more conveniently and much better than at any other season. Peaches.-The wood will probably be ripe in the early house by this time. Give therefore all the air possible. Give trees from which the fruit has ust been gathered a good washing with the engine to clear the foliage of dust, \&c. Melons,-Plants in dung frames will require considerable attention. Keep the bottom-heat as regular as possible, and endeavour to secure suffient warmth from the linings to allow of cautiously, and only when a fresh supply is absolutely necessary, and then give enough to moisten the whole mass of soil.

## flower Garden and shrubberies,

Propagation of stock for next season must now very soon be commenced and carried on with expedition, so as to secure strong well established plants before winter and without the necessity of keeping them so close or am as to induce weakly and watery growth. To be the cuttings should be put in sufficiently early in the the cuttings should be put in sufficiently early in the
autumn to allow of having them well established and fit to be exposed to the open air by the end of next month. Begin with such as are found to be the mos tedious to propagate and prepare for winter. Holly hocks are general favourites, but they do not afford cuttings freely, and are in general not over plentifu about most places. These should therefore be examined often for any cuttings which they may afford, as those rooted about this time will make strong plants for next season. Attend to the tying up of these and Dahlias, and go over the masses of Verbenas, \&c., frequently for the purpose of regulating the growth, so as to keep it orderly and neat. Sow Ten-w Stocks for spring flowering; transplant Brompton an Queen Stocks, and if the situations in which they are to allowing them plenty of space to prevent weakly alowing
hardy fruit and kitchen garden.
Winter Onions may now be sown, also Cauliflowers for the early crop next season, a small bed of pickling Cabbage, Brown Cos, and some hardier sorts of Lettuce to stand the winter. The tops of the main crop onions $d$ bolle be laid down if they are incline headed rolan, going over wha headed rake, and pressing the tops down sufficiently to check further growth. Plant out a good breadth of En dive on well enriched soil of a light dry nature; also see to providing a good supply of Lettuce, \&c., for autumn
use. Attend to Celery, keeping it well supplied with water in dry weather, giving it as much manure wate as can be spared for it, and keep the early crop rather closely earthed up. Vacant ground or that which can be cleared of early crops may still be planted with among growing crops. Cut Box edgings, and keep every corner clean and neat.
state of the weather at chisifick, near londoy.

## Notices to Correspondents.

Axrs: Edward Grifin. The adjective of this is axile, having 3 totally different meaning from axillary. The axis in botany
is the centre round which organs are arranged and therefore is the cenire round which organs are arranged, and therefore
axile signifies anything placed in or on that axis. Axil is the axile signifes anything placed in or on that axis. Axil is the
angle formed by a leaf or other organ and the part which angle tormed by a leaf or other organ and the part which
bears it; therefore axillary means that something grows
within or vear that angle. A bud is axillary to a leaf. bears it; therefore axillary means that something grows
winhin or uear that angle. A bud is axillary to a leaf.

## The Ggritultural gasette.

SATURDAY, AUGUST 2, 1856.

The influence of circumstances is necessarily always secondary to that of sort. In the feeding-stall and cattle-yard it is a commos thing to say that the half of what is called breed "goes in at the mouth ;" but let any sceptic as to the real cause of precocity of growth try his plan of two nurses to a mongrel calf, or see how Linseed in the milk and meal with Mangel Warzel afterwards tells upon the fatness of a calf bred anyhow, as compared with one, similarly treated, from any pure bred short-horn herd, and his experience will force him to admit that, in the explanation of it, sort comes first and circumstances afterwards in the order of their influence.
And this is just as true of plants as it is of animals. Good drainage, liberal manuring, and skilful tillage will induce ander an ordinary English sky abundant vegetable growth, but it depends upon the choice of seed whether this abundance be valuable or not. At any time. then, it is desirable to press upon our readers "the importance of preserving the purity of all our recognised species and varieties of agricultural plants," and such a subject is especially seasonable when our harvest fields and green crop fields themselves are eloquent apon it.
The address which Messrs. Lawson and Son have just issued on this sobject is thas exceedingly welltimed. Their advertisement demands more than ordinary attention. It announces an honour done to England through them for which, notwithstanding their modest disclaimer, England is greatly indebted to their exertions ; and, sanctioned as their statement is by the award of the Jury of Produce at the great international show at Paris, it is a most forcible greal to English cultivators and seedsmen
The difference to the former of mixed and impare as compared with true and well grown seed cannot be exaggerated. The one produces a crop all of the best and all ripe together; the other a crop of various quality, ripening at various times-and, in the very aspect of $2 t$, teaching a lesson of carelessnes and irregularity to every labourer upon the farm.
And as regards the latter, no one need look for a better lesson in true self-interest here than in the example set by Messrs. Lawson themselves, or in
that of Mr. Skirving, who we were told last week, knowing it to be of the utmost importance to the farmer and to the community at large that every acre in the kingdom that is cropped with corn, or Grass, or roots, should be cropped with the most valuable variety of its kind for quality and quantity. Every improvement gained in this way is clear gain; for it costs no more to grow the best sort than the worst, and between the one and the other there is often from 10 to 20 per cent. difference at least.

ONE of the most important papers in the carrent Number of the Quarterly Journal of Agriculture is that by Mr. Russell, of Kilwhiss, in which he criticises the contribations of Messrs. Lawks and Glibert to the recent controversy between Libbig and themselves on the growth and food of plants.
Mr. Russele has all along confidently worked out of the merely chemical track of research in his inquiries on this subject, and he is now gaining a hearing for his views on the meteorological conditions of the locality, and the physiological conditions of the plants, cultivated, as furnishing, in connection with the natural conditions of soil and air, the true explanation of arricultural experience as to natural and artificial fertility
We shall give our readers in this Paper a short account of his argument, leaving them, for the full understanding of it, to consult the article he has contributed to the current number of the Quarterly Journal. Mr. Russell states that the need of supplying ammonia to plants is, since Liebra's discovery of its presence in the air, practically limited by the degree of their ability to draw upon this natural storehonse of it, and he illustrates this position by "axioms" - "Nitrogen for Wheat and phosphorus for Turnips," justified according to the editor of ordinary agricultural experience, seem to be reversel by that of Mr. Smith, of Lois-Weedon. LoisWeedon is directly opposed to Rothamsted, for in
the former case all the manure is applied to Turnips and nothing is applied to Wheat. This contrariety, as stated thus by Mr. Russelie, is reconciled by considering the different conditions of growth imposed upon the plants by the plans of cultivation respectively adopted at the two places.
Mr. Ruserlu's statement on this head is as follows:-
"Mr. Smith, at Lois-Weedon, dresses his Turnips heavily with nitrogenous manures, and sows them in
5 foet rowr, and afterwards singles them out 9 inches 5. fset rown, and afterwards singles them out 9 inches
apart. This is scarcely $2 \frac{1}{2}$ plants to the square yard. But Mr. Lawes sows them in narrow drills, and even
when he dresses heavily with the richest manures, he When he dresses heavily with the richest manures, he
allows eight plants to the equare yard. To sow so allows eight plants to the equare yard. To sow so nitrogenous manures being theoretically, but not practically, unpopular as a dressing for Turnips in England. Those who condemn nitrogenous manures for Turnips should take a leaf out of Mr. Smith's book. This is the As to the subject.
discussed farther on; and we must give an extract or two from Mr. Russell's paper so that on this point he may speak for himself. He says :-
"The whole discussion centres itself in the questionshe atmy should amnoria crops, since 2d, Why should Turnips require phosphates whatities soil contains abundance for Wheat, while Wheat actuaily requires more phosphates for its growth than Turnips? The whole discussion, then, turns upon the mere facilities which plants have of obtaining phosphates from the soil and ammonia from the atmosphere."
Wheat can be raisell year after yenr at Rothamsted without ammonia or phosphates, only a few cwis. of Tornips could be got unless phosphates were added. These results show that Wheat can produce this amount without phosphates, but Turnips cannot do so ; and why cannot they do so, since the Wheat plant actually produce that amount of grain? Because Turnips have less facilities of abstracting the quantity of phosphates that are necessary for their growth.
flect for a mo the question will be very evident, if we reflect. Jor a moment on the different natures of the two The cond aratively large seeds of the Wheat are sown in autumn, and the plants grow little for six or seven montles. Duting this time there is no great demand for phosphates; and when the growing weather returns in spring, the roots of the Wh.eat, being in full possession of the soil, are able to thrive in a soil where the supply of these necessary substances is somewhat scanty. Wheat, simply because the vast number of rootlets in poseession of the soil can very readily extract phosphates from soils, in which they exist in comparatively gmall quantities.

Wrh a Tumip it is very different-its seeds are
very small, and its growth is very rapid. The munute
seed of the Turnip cannot suppy y the young rootlets seed of the Turnip cannot supply the young rootlets
which at sends into the ground with nuch nourishment; it is thus early thrown upon the soil for a supply of
matter to grow its roots as well as its leaves. For it must be borne in mind that no cells, either in the routs or the leaves, can be former without phoophates. See-
ing, then, that the Turnip must obtain a ready supply ing, then, that the Turnip must obtain a ready supply
of phosphates before it can prow at all need we wonder that there should be some truth in the recipe 'phosphorus for 'Turnips?
Our next extract makes use of passages from Mr. Lawes' writings in "Rendee's Farm Directory," and
from those of Mr. Putssert in our own columus, for the purpose of claiming the former as a convert to the views long urged by the latter. They illustrate Mr. Russelle's powers as a controversial writer, as well as his foresight and intelligence at a time when agricultural writers generally had their minds bent exclusively on the chemistry of vegetable
growth :growth :-
"In the same volume in which the perplexing and misleading exioms- Nitrogen for corn, phosphoris for Turnips'-are once more reiterated to the confusion regard as the herald of a brighter day for science. The following is the foot-note, which ought to have been honoured with a mare prominent place in Professor's Way's paper on the 'Value of Artificial Manures: (Mr. La mes and Dr. Gilbert) on Barley and Oats, induce them to believe that soluble phosphate of lime has, in some cases, a beneficial action on these crops.'
It is certainly ralher too bad to introduce this heretical doctrine without one word of comment. I was very much surprised to find a complete clue to the 'some cases' in which superphosphate of lime was beneficial to corn in another quarter-altogether. Some other writings on the same subject are given to show how antiquated 'the creed of the Britlsh farmer' must be who merely consults the Journal of the Royal "It think D. D.Doubeny slipg
reverses the princiyle

Mr. Russell goes on to say that the greatest increase he ever obtained in a cereal crop from the application of artificial manures was from super phosphate of lime applied to Barley sown as late as the middle of May on light sandy soil. With his fact, so corroborative of his doctrine that, in all speculations on the relations of manures to plants, regard ought to be had to the ability of the plant to forage for itself, and to the rapidity of growth for which, owing to climatic circumstances, provision has to be made, we must conclude.
We have not room for more at present, but our readers will see in the passages extracted a very important truth, very skilfully enunciated and illustrated, and one, too, which has never had that place n theoretical discussions of this subject which Mr Russele and its own importance have all along demanded for it.

FURTHER NOTES ON THE CHELMSFORD SHOW OF HORSES.
Horses.-The dray horse class by no means pre-
sented so many apecimens as might have been expected sented so many specimens as might have been expected
in a county in which heavy land so much prevails, and one so near the metropolis, where : market for dray

Thorses is always open. Ouly six ammals were ontered The prize was awarded to a dark irou grey horse, only
three years oll, hutof great weight, substance, and activity No. 327, belonging to Messers, Bastance, and actnity whilst his neighbuur belonging to Mr. Robert Whitefield a somewhat ligger horse and yet very active, cloed approached the prize winner in excellence. They were both capital specimens of a valuable breed. There was also a fine Suffolk shown in this class, No. 322 , wa mising horse, but rather too leggy. In the class for two year-old dray stallions only one horse was shown, but that a very useful animal. In addition to the foregeing lhere thich embraced no less than 130 horses and manme there were special prizes offered for lighter hors
money, we believe, proceeding from a local fund.

Class I. was tor thorough-bredstallions, of which there were however only eight exhibited. We presume it was understood, but if intended it should have been ex pressed, for thorough-bred stallions best calculated for getting hunters. The prize was awarded to a well known old Yorkshire bred horse belonging to Mesarg Moffat, near Carlisle. The horse possessed great mexit, having plenty of substance with good symmetry, and
his legs were very good for his age (16 years). No. a 5 -year old bay hurse belonging to Mr. Waller, wa highly conmended. There were several others of merit, as for instance No. 671, called the Lion.
Class IL., for hunting stallions, possessed more col lective merit than Class I., although the number was the same. As, however, there was a distinct class for thorough-bred stallions from which of course half-bred horses wuuld have heen excluded, so we think that i this class for hunter stalions thorough-breds ought to have been debarred from showing. The prize was taken hy $\mathrm{Nn} \cdot 673$, a thorough-bred 12 to 14 years old, called liom Moudy, a dark brown horse of great substance and excellence. We find he is the sire of the prize hackney
stallion No. 693 , also of 679 , stallion No. 693, also of 679, a very good and powerfu tranting stailion, deservedty commended. No 675, a fine grey horse, possessed much merit; as well as t-year old horse by Fire King.
Class III., coaching stallions, was by no means $n$ gead is, whether as regards excellency or numbers. Th a very good animal, against whom there was litile bred roan colt. We presume, as coaching 2 year old hatscarriage horse" would be a better understood term. We next come to a better filled class, having nice anumbals. The prize winuer No were some very nice aniurals. The prize wimuer, No. 693, Sebastopol he is 5 years old, and though a little short in the neck possessed a good deal of quality as well as substance. He belonged to Mr. Jax, of Suffolk, No. 695 was highly commended, and his merits well deserved the maxk of distinction, although there were several other
very clever hackneys shown, three of whom possessed very clever hackneys shown, three of whom possessed Phenomenon blood. Norfolk is still the best county in England for clever hackneys, and we hope it may long retain the unrivalled forehand and action which distinguishes the breed. Let the Nortolk breeders beware of the low action belonging to the thorough-bred. Wo the encouragement of the breeding of good hackneys. Prizes should invariably be given to this animal at hat is song the Royal Agricultural Society, for What is so necessary to farming comfortably, when hunting days are past and gone, as the possession of a
good liackney? If, in addition to this, prizes were given gor the heavier or stronger hackney, understood under the definition of a "cavalry horse," much would be done towards preserving an animal every year becoming more and more difficult to get. We would respectfully suggest to some of our cavalry officers now returned
from the Crimes, that if blessed with wealth they could from the Crimes, that if blessed with wealth they conld scarcely employ it more patriotically than by odarid for breeding cavalry horses.
Class $V$., for hunting mares, only afforded four animals, of which No. 699, a chesnut mare by the Colonel, gained the prize.
Class V1., hackuey mares, was much better filled, having 10 in number, and amongat them some capital animals. 707 , the prize mare belonging to the Rev. truer to her class if she had had more substance. Mr. A. Hammond's 12-year old roan trotter deserved s prize, as well as the Rev. W. H. Beever's No. 705, $n$ en of the best animals we have ever known under the
designation of a Welsh cob. Mr. Rose's Norfolk hacliney, No. 711, also possessed great merit; and a 4 -year oid mare belonging to Mr. George Creed was a very neal and compact little animal.
Class VII., for hunting geldings, was not numeronk, there being only six entered. Of these Mr. Barlow's in, a s-year old hunter, the son of a well knowa hork's in suffilk (Robinson) gained the prize. Mr. Bu
Claks VIII., for hunting geldings under 5 years o brought forward eight animals, No. 725 , a 2 -year old colt, by John o'Gaunt, gaining the proze ; and 724, is 3 -year old, by a British Yeoman, was highly con of
mended. The former was owned by the Earl of Darnley, and the latter by Sir Wilfred Lawson, Bart
Cinss 1X., for hackney geldings of any age, had on three animals entered, the prize horse being nest best was the Rev. C.J. James's student.

Class X ., backney geldings under 4 years old, ced
tained two animals of fair merit. We see no advantage in having four distinct classes for hackney geldings; one would have been we consider sufficient. If horsts ar doubt of sufficient merit to earn reputation as stallions, and if so the breeders deserve censure rather than reward for ruling it otherwise. We rave now gone through the 17 classes of horses exhibited at Chelmsford, embracing nearly 200 animals, of which no less than 130 belonged to the ngricultural breeds. Traking the show altogether and comparing it with previnus exhibitions, we should say that though it was much surpassed by the York show as regards the various kinds of lighter horses, it has never been excelled in the agricultural classes by any preceding exhibition, not so much on account of the individual merit of a few animals as by the great amount of excellence belonging to a large number. We find in the course of our inquiries that within the last few years the best class horses have greatly increased in value. As an illustration we may observe that the old mare, which with 1502 , prize at the Exeter show she would scarcely have realised half this sum. This fact speaks volumes in favour of the assertion as to the enhanced value of these horses, and which may in part be attributed to the meetings of the Society.

We cannot conclude without observing that, however excellent the arrangements might have been with regard to the transfer of stock and implements, the same praise cannot be bestowed on the arrangements with regard to the transmission of passengers. The writer wishing to go on to Colchester on Friday evening on lousiness, was obliged to stand the greater part of two hours in the open air incumbered with his luggage amidst a crowd of people having the same object in view the heat and pressure from which crowd were almos to this endarance. Many females were a so exposed pelled the officials to lift them over the barriers to the ample space within. The tickets were sold at a miserable box scarcely fit for a dog kennel, and after they were elansed admission was still refused tisher to the holders of tickets or their baggage ; and not only so but all in formation sas denied se the time would be given. It would be well if editors of news papers were to inform the managers of rait of news panies, for the comfort of those attending future meetings, that by refusing admission to their platform or premises after tickets have been sold and the time for the departure of the train has armived, they are acting illegaly as well as churlishly, and that if any for the consequences. It is to be hoped that at future meetings the managers of other railways will avoid the blundering arrangements of those of the Eastern Counties. W. C. S.

ON THE SHEEP SHOWN AT CHELMSFORD. Leicesters.-Class I. Shearling Rams,-The firs Pawlett, of Beeston, Beds, for two rams possegsio. E wide and deep frames, cood backs, outspringing chines good wool, fine hone and beautiful countenances; their sire was the prize sheep at Lincoln. Mr. R. W. Cress well, of Ravenstone, Leicestershire, showed some pretty tion. Those of Mr. G. Radmore, of Court Hayes, Devonshire, and Mr. J. Barton, of Barton House, York shire, comprised among them some superior and well formed rams ; and we more especially approved of the Devacter of sheep shown by Mr. S. Kingdom, of Lynch Devonshire, and Mr. F. Hannam, of North Deighton Yorkshire

Class II. Rams of any other age.-The first-prize sheep of Mr. Pawlett, 40 months old, has a beautiful back, full plaits, hanging cushion, a wide forequarter good serag, fine head and excellent wool. The second prize ram of Mr. Cresswell, 28 months old, is very symmetrical, of fine quality, with good neck, back, loin and rump, in fact a very superior animal. We did not much admire the sheep exhibited by Mr. W. Simpson, Kirby Grindalyih, Yorkshire, which, though large of the should of merits, had too tittle meat on shown in this class by Mr. F. Hannam is much more like the ideal form of excellence, and has besides a very good fleece.

Class III. Pens of five Shearling Ewes.-Mr. G Watkins, of Woodfilld Ombersley, Worcestershire, and the secon Pize a pen Barton, Devonshire, are very pretty, compactly formed, Barton, Devonshire, are very pretty, compactly formed,
and covered with curly wool.
Short-Woolled Sheep.-Class I. Shearling Rams. Short-Woolled Sheep.-Class I. Shearling Rams.-
This year we have an illustration of the saying that This year we have, an go by turns," fnrinstead of Jonas Webb, or Lord Walsingham, or even of Kigden or Sainsbury, we find a new first-? rize name- the highest honour being carried off by Mr. Henry Overman, of Weasenham, Norfolk. We admire the six rams exhibited by Mr. Overman in this class for their great size, beautitul form, and good feeding qualities; but we must be allowed to point outa defect in the first-prize animal which we think ought to have left the premium to be bestowed elsewhere. It has a large frame, great girth, chine and forequarter very uperior, and tine quality of bone and character of
countenance, but the hand carefully applied along the. propriety in every instance, and in most caes the a strai. back detects a very common defieiency, and for meat, we certainly prefer the second prize sheen, and meat, we certainly prefer the second prize sheep, and
indeed several beside. Mr. Jonas Welh, of Balpaham, obtains the second prize for a remarkably well-formed compact sheep, with beautfully straight back, out-
syringing ribs, thick neck, and very fine quality of heat and bone, and also a gaod fleace of superine wonl the other shearlings exhibited by Mr. Wtbl are so beantiful that the Judges must have lad considerable difficulty in selecting this one for distinction. The Duke of Richmond has some very fine specimens of his own breed, widely made, compact, and with plenty of wool.
The rams of Mr. Rigden, of Hove, Sussex, are straight wide, with good rumps and fine heads, certainly very superior animals, but having rather too much of that nsighily defect-a protruding body
Mr. Lugar, of Hengrave, Suffolk, shows some good sheep; but some of them have a little of the defect much worl on the shoulder and too little upon the loin Lord Wach wonl on the shoulder and too little upon the loin. Lord Walsingham's rams have some meritoriou points, but some of them are not at satisfactory West Lavington, Wilts, we much approved
Class II. Rams of any other age,-Lord Walsingham obtains both the prizes, the first-prize sheep, 27 months old, having very great substance, firm good meat, thick neck, good chine and loin, and a plentiful
fleece; the other of the same age, of great length, fleece; the other of the same age, of great length, esp, girth, and admirably this class a 40 month ald ram of superior excellence, symmetrical and beautiful quality. The 28 months' old rams shown by the Earl of Chichester are beautiful animals, compactly ormed, loins not too high, with good necks, rumps, and fine heads and bone. Mr. H. P. Hart, of Beddingham wool. The rams of Mr. H. Overman are plenty of wide, with goud necks, loins, and beautiful meat. A striking feature in this class was the presence of two pure Merinos, bred by Mr. F. Sturgenn, of the Elms, near Remford, which thoush of inferior form, and not ikely to win the favourable notice of breeders of mut ton, were admired for the wonderful fineness and eutiful quality of their fleece
Class III. Pers of Five Shearling Ewes.-Lord Wal singham's frrt-prize ewes are a very beautiful and level lot, very large and widely formed, with fine bone, and a superior quality of wool. The second prize is also warded to his lordship for a pen of very symmetrical and beatiful animals. The other lots which more pas ticularly struck us as very superior both in form, quality and wool, are the Duke of Richmond's and those of Mr. Overman. The Shropshire rams, shown by Mr. E. Holland, we hardly admired, because of their want of utton before the shoulder and their defective rumps. Long- Woolsheep. - Among these sheep we observed too many indications of uneven clipping, by which the defective points of the animals can only be detected by the hand-all appearing level or well thrown out to the eye

Class I. Shearling Rams.-Mr. J. Walker, of North each, Gloucestershire, takes the first prize for a ram o quarter, plaits and rump. The second prize to Mr. beale Bra, Hapen, Glow having a first-rate back, gond loin, chise, neck and fore Fletcher, of Shipton, Gloucestershire; Mr. W. Hewer of Northleach ; Mr. Lane, of Broadfield Farm, near the ame place and Mr. E. Hardy, exhibit some magnificent shearlings from flocks differing much in character from each other, but all of very superior meri
Class II. Rams of any other age. - Mr. W. Lane obtains the first prize for a ram 28 months old, of immense height and width, with remarkable nerk and chine and beautiful hand. The second prize to Mr. W.
Garne, jun., of Bibury, Gloucestershire, for a 39 months' Garne, jun., of Bibury, Gloucestershire, for a 39 months' lions, of very great leng quantity of offal and a good fleece. Mr. John Garne, of Filkins, Gloucestershire obtains a commendation for a 39 months' old ram, a very good animal with a particularly good loin and rump. Mr. Fletcher also receives a commendation for a 21 months' old ram, having a famous chine, neck, and good qusntity of curly woo
Class III. Pens of Five Shearling Ewes.-Mr. W. Lane takes both the first and second prizes; but we think other pens shown in this class are somewhat superior to the second prize lot, though these are very beautiful, and of good form and quality. Mr. Beale Brown's ewes are very good indeed, both for their ewes are very deservedly commended, their meat being irst-rate. The Cotswold sheep made altogether a very good show, though not equal to what they were at the famous Lincoln meeting.

HOME FARM MANAGEMENT.-No. VIII.
Anongst the very first duties devolving on manager appointed to the charge of a home farmery, the particular rotation course to be followed will demand attention. He ought to take a plan of the farm, and looking at the subject in its every aspect, fix on the order of copping which in the case aill be most hikely to give good owaresponsibility aloue. A little reflection may show the
propriety in every instance, and in most cases the absolute necessity of making the principal or his ageat
fully acquainted with the intentions of the overseer in regard to the management of the land under his care. comprise were the agent of a property to possess a comprehensive knowledge of agricultural matters theo retically and practically, he might himself give sound directions for the guidance of the person in charge of the proprietor's farm ; but unfortunately many agents or factors are mere counting-house men, and in practical details are wholly dependent on their subordinates Assuming that on first-class home farms the manager is a man nuf sttainments that the fixing of the rota tion of crops will be in a great measure left to himself there will still be advantages derived from his consultin his superior in every underiaking of importance. To give the latter a proper opportunity of judging of the propnsel modes of cropping brought under his notice, the steward nught to furnish him with vatious estimates of a practical nature. These would require to include a statement of the acreage of each species of crop-its probable value at harvest-the purchased manures necessary fo the whole farm under one system of cropping compared to another - the quantity of straw available for consump tion on the farm under each rotation gystem-and in most cases $n$ rough comparative estimate of the gros profits of the various modes of laying out the land in crop. With anticipatory calculations such as these
submitted at the beginning of every winter by the farm submitted at the beginning of every winter by the farm a favouratle position to give an intelligent consent to any judicious proposals that may be made on practical points. If a farm manager finds himself intrusted with important calculations of this kind he will naturally do his utmost, not only to select the course of cropping niost likely to prove profitable, but to carry out his own views at the least possible expense. Well, in aiming at these results there are certain general principles which according to circumstances should regulate his judg ment and control his practice. For example, on grow larce quat ticies of Wheat, while ou liuht land Barley will be the principal cereal crop. On medium soils fair proportion of both will be raised and if the climate is prop than either the than eith production of Potatoes, and a ready market is obtained for this root, of course it should bo extensively grown On the other hand, a farm situated inland, and not very accessib!e, ought perhaps to be more a Turnip than Potato growing one, even though the soil is suite for either crop. It is much easier to transport than in sny other mannar stock may prove more profitable than fattening beasts, just as a cut hay crop pray pasturage in these circumstances. Is a farm a Wheat a Barley, an Oat, a Bean, a Lotato, or a Turnip-growin occupancy ? Then it is the duty of the farmer to find out its properties and defects and to make the most o it accordingly. It would occupy too niuch space to enter fully into the question of rotation of crops, but may state one course of cropping suitable for medium and and another adapted for the clays.
For a green cropping and Wheat farm extending to say 360 acres, the following rotation system may be adopted with advantage :-

This will give annually of 'Turnips, 80 acres; Potatoes, 40 ; Wheat, 80 ; Barley, Grass, and Uass each, 40 20 acres. By making the Turnip hreak which begins the rotation a preparatory crop for Potatoes, the soil is not only ensily wrought for the latter but by the Turnips being partially eaten off with sheep only a ligh dressing of artificial manures is necessary to give wer fine yield. Then if the land happen to be fonl it is got roperly elaned ander this system, and is put best possible condition to produce superior crops during the remainder of the rotation. A nine-shift course may he thought rather too long for general adoption, bat it has very important advantages connected with it. l that crops are so extended over this series of year h the least possible expenditure-in manuse s. Labour-is required to give very large returns. Expe ronce has proved the fact, that with a given outh leaves the largest cropping being simply a modification of the eight-coura with a crop of Turnips taken before Potatoes it has at least all the excellencies of the latter if it is mot an improvement upon it.
For a clay farm which, though well adapted for the growth of Wheat, Beans, and Turuips, is seareely eo well fitted for Potatoes and Barley a different couree of wropping should be followed. A seven-course rotation of a farm of 350 acres will stand thas:

| Beant | 50 | cres |  | (Tarnips |  | 20) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| \{ Wheat... | 351 |  |  | Potatoes | 31 | 15 |
| \{ Barley ... | $15)$ | " |  | Mangel |  | 15) |
| 3. 'turnips | 15) 50 | " |  | Whert |  |  |
| $\left\{\begin{array}{l}\text { Wheat ... }\end{array}\right.$ | ${ }_{15}^{15}$-50 |  |  | Grass ${ }_{\text {Gats }}$ | $\cdots 4$ | 10 |
| \{ Uats | $20{ }^{1}$ |  |  |  |  |  |

The extent in scres of the different crops by this rotation course will annually be of Turnips, 70 ; Pota-
toea aud Mangel, 30; Whest, 100; Barley an
Oats each 30 ; Beans, 50 ; and of Grass, acres. According to this arrangement part of the Bean crop will be sown after Grass, but if the a very excellent yield. This saves the resources of the land to some extent by rendering it unnecessary the different crops under In laying out a farm or ther rotation system, great care should be taken to other rotation system, great care should be taken to
have the piece of land best adapted for a particular kind of crop put as far as may be practicable under that crop. For Potatoes or Barley the lightest parts of the farm will require to be selected; but this can be very easily done without the general rotation order being deranged. According to the state of the markets, as I have already indicated, a modification of any course of cropping may be made from year to year; but it is well to have a system which in the main will be adhered to. There are many farms no doubt on which neither the seven nor the nineshift course, as stated above, would be found altogether applicable. Yet there are very few home farms in the anited Kingdom for which these systems might not be peculiarities in soil and climate. J. Lockhart Morton, Lasswade, Mid-Lothian.

## Home Correspondence.

Boydell's Locomotive Steam-engine.-In your report of the Chelmsford Meeting of the Royal Agricultural
Society you allude to my traction engine, and as some parts of that allusion are not in accordance with facts, In the first place you say the engive is of 12 -horse power, and you call that used by Mr. Fowler 10-horse power. My engine has two cylinders of $6 \frac{1}{2}$ inches each, and is worked with 60 lbs . pressure of steam. Tha and when I saw it at work on the heavy land field it was worked with 95 lbs . pressure of steam. Thus if our engine is 12 -horse power, the one used by Mr. Fowler is 28 . In the nex place you say it is evident ,engine from hauling continually over arable land must prove a very heavy addition to the cost of the maprove a very heavy adhis I have to say that we have Worked one engine for six months on all descriptions of
land and over all kinds of obstacles, and we have never land and over all hinds of obstacles, and we have never
damaged the machinery or the boiler in the least, which damaged the mach nood now when they were made and the wheels and shoes show very littie wear-this engine can be seen here. In another part of the report, :speaking of the shoes, "under the circumstances of were of course for the most part merely a useless incumbrance." Without the shoes on the driving wheel We could not even have got on to the field, and upon not draw one-fifth part as much without the shoes as with, as the cycloidal bars attached to then form in effect a cogged railway. The last part of the report I have to observe on is the position of the pinion on which Mr. Boydeli insiats doubled to produce the same rate of movement onwards as if it were placed on a level with the axis of the wheel, and as much is lost as gained." This is certainly not the fact, and is very easily shown not to be so. The
driving wheel is driven by a pinion of 10 teeth working driving wheel is driven by a pinion of 10 teeth working the wheel the pinion works, whether on the leve of the axis or the apex, 10 teeth working on 96 the same time; and although the upper part of the wheel moves twice through the same space as the axland fulcrum on the ground, that is made up by the rectilinear motion of the wheel which is entirely independent of its rotary motion, carrying the pinion through the space it progresses, and this without reacting upon the forward movement, as the pressure upon the back of the cylinder counteracts the pressure
apon the carriage on which the sbaft of the pinion upon the carriage on which the shaft of the pinion
works. James Boydell, Camden Works, Camden Town works. James Boydell, Camden Works, Camden Town,
July 22, 1856. [In reference to this communication we at present only say that the "velocity of the pinion" referred to by our reporter, is not its angular velocity, but its velocity with reference to sny fixed point over which the machine may be passiog. Whether the of piston rod and pinion at the extreme end of that lever which is represented by the double radius of the driving wheel (its contact with the ground being then the fulcrum, and the tow-rope attached to the axie-tree representing the power and position of the resistance to be overcome), or be made by another position of the pinion to act as if pushing at a point on that lever
nearer to the resistance, and therefore less effectively, does not matter when the object is to produce movement. In the one position it correspouds in effect to gearing into a large spar-wheel, and in the other to double the force to work it; but in the former case doable the rate of movement will be needed to effect the "as much is loas work -so that, as our reporter blured matter as it at present appears to us.]

Whate Clover.-Can yon suggest any cause for the very unusual quantity of White Clover which appears
in all the pasture fields and on roaderides and places
where it caunot have been sowu? I have observed it au

## Eottettes.

We will resume aur wall ral of england. We will resume our walk round the stands of imple-
ments. Mr. Cornes at No. 45 exhibits his simple and well -known chaff-cutter, which has won many prizes. Gibson, of Newcastle-on-Tyne, at the next stand
hows several tillage implements, a revolving cultivator shows several tillage implements, a revolving cultivator cleaning the other-a principle originating with them, e believe, though now very generally adopted.
Mr. Huckvale, of Choice Hill, Chipping-Norton, shows his Turnip thinner and horse hoe at No. 60. It consists of a revolving circular edge which would clear the whole row as the machine proceeds were it not for The thin it by which untouched intervals are left. do not require thinning. The plants are left at regular distances, and singled by children where they require it. The great advantage of this implement is that the Turnips, \&c., can be cut out at the proper time, at a much cheaper rate than by hand, and the crop saved from injury by not being singled at the proper time
Price $5 \ell$. A patent horse-hoe for hill-sides, shown at this stand, exhibits an exceedingly ingenious contrivance for meeting the downward tendency of the implemen when working along the side of a hill.
At stand 62 Messrs. Reeves, of Bratton, near West bury, Wilts, exhibit Chandler's liquid manure drill.Spooner's water drill is shown at stand 71, by Messrs. Tasker and Fowle, of Andover.-Sparks, of Norwich exhibits steam-engines, circular saw bench, \&c.
Mesors. Garrett and Son have a large stand with threshing and other machinery, drill machines. We have already referred to Mr. Chambers' improvements in drills shown here.
An exceedingly ingenions bummelling machine by R. R. Holben, of Barton, Cambridge, is exlibited by
Barnard and Bishop, of Norwich. This machine consists of an elevating apparatus, which supplies the corn direct from the dressiuy machine without assistance and a breaker, which makes nearly 300 beats per minute, under which the Barley passes in a thin layer. It is perfectly efficient, delivering freely from 10 t 12 quarters per hour, and requiring but very little
power to work it. It can be used with any dressing machine, the quantity being regulated by four adjusting nuts; the arrangements being so extremely simple render it uearly an impossibility for it to get out of order. It occupies the space of one square yard only. Price 5l. 10s. At this stand, too, there is a good rasping machine for Turnips. This machine consists of a strong cast iron dise, to which are attached 10 indented steel plate cutters, which can be adjusted to cut Turnips, ing at pleasure from 1-16th to of an inch in thick ness, at the same time separating the dirt and small pieces of rind from the strips, which are delivered quite with dry food are found to These strips when mixed of feedin cattle or Mr . Bentall at 78 shows hice 4.108.
Mr . Bentall at 78 shows his celebrated broadshare, which however has this year had to divide the prize with Coleman's This implement has three shares, pre-
ceded by three points, arranged parallel with each other the centre point being so much longer than the side ones as to project beyond them in front, while the share connected with it is as much behind the side shares. This arrangement of the points before the shares is essential, as it is this that enables the implement to penetrate the hardest soils, and gives it a remarkable steadiness in its work, and a capacicy of adhering to the land in a degree not to be attained by other means. There are other advantages, too, in this peculiar construction. By means of the long point a share 18 inches wide can otten be used in hard ground, when without it even a 6 -inch share could not be used. The chance of weeds slipping by it is thereby greatly diminished ; and, fewer in foul land. It goes on three wheels, which are merely in foul land. It goes on three wheels, which are merely not require to be large. In the centre is a strong beam of wrought $T$ iron, to which is attached the frame. To the side arms are fixed two tines, one on each side which can be regulated either vertically or horizontally. The frame carries the centre-share and point, while the tines carry the side ones. The handles are convenient to enable the man to assist the plough round at the ends of the land. The head and hake are of the ordinary conploughs , allowing of adjustment when required, as in ploughs generally, to ensble the horses to walk in the rurrow. (as Gisually sent out) is 3 feet 6 inches; but can be altered to cover more or less.
Mr. Coleman's tool, on the other hand, is thus described:-A patent drag harrow, cultivator, or scarifier; invented and manufactured by the exhibitor This implement is known as the "Norfolk Prize Cultivator." It is admirably adapted for the various purposes of harrowing, culluvating, or paring land. ing from 10 to 2 inches wide, may be attached. These prongs are so arranged as to cut the land 8 inches apart. The depth of penetration is regulated by a lever,
and may with grear facility be accommodated to the required depth.

Holmes \& Sons, Norwich, at 86 show a large collece drills for corn and manure, $\delta c$. We extract their description of their manure distributor:-It has im. portant improvements in the delivery barrel, which is portant improvements in the delivery barrel, which is
entirely of wrought iron, is very light, and not liable to entirely of wrought iron, is very light, and not liable to
breakage or disarrangement; the deliverers are of such a form that a scraper is most conveniently made to pass over each one as it comes to its delivery point ; and
another important point is, that her above the delivering barrel, so that it is impossible that any manure can by any means get to them to prevent their working, as is the case with those which ame placed under the barrel; another advantage in these scrapers is, that being hung from the top, the deadweight of the whole scraper is rendered effective when acting on the deliverers, and by each scraper being made in length so as to scrape or clean four of the deliverers, each one separately has the whole weight of the scraper, thereby saving one-third the weight in iron that would otherwise be required. Small weights can be placed on each scraper when required. The whole machine is considerably lighter and of easier draught for the The The exhibitors' semi-lateral stirrer is found the most simple and practically useful, the lateral motion being given without any extra gear wheels or crank motion ;
the slides can be regulated as the machine is at worlk It can be fitted with the exhibitors' improvements for hill sides fitted with the exhibitors improvements for At stand 97 Mr Phillips 130 . Price 132.10 s. patent root pulping machine. The cutting principle of his machine is a beautiful adaptation of the circular saw ; a number of segment saws are fitted into a round cylinder, and bolted together so as to work in a perfect circle; on the spindle of the cylinder is a bevil wheel, driving another, which works an oscillating plate at the ack part of the hopper while the cylinder is revolving. The result of this is, that the teeth of every raw cut the oots in different lines and places; thus producing s perfect pulp without bruising or smashing the root and
destroying or losing the juice. One great feature of this machine is its indestructibility. The saws, being o tempered steel made expressly for the purpose, will last number of years without wearing up; and if from any ending to a machine maker, by a labourer at a without few pence. It is well known that for cutting wood no way is so economical as the circular saw, and that a saw constantly cutting hard wood will last a great many years ; it may then be easily understood how long the steel saw will last in pulping roots. It is superfluous to add that the employment of steel for cutting has a great advantage over the cast-iron plates used by other makers, which, although a trifle cheaper in the first cost, prove dearer before many months, from the great fendency to wear, and extreme brittleness in cold weather, when the machines are most required. This machine may be worked by one man or two lads. A reat recommendation in this machine is, that the state of the roots does not affect the cutting; their being rozen, or clung in the latter part of the season, no proving any obstacle to mincing them. Price 6l. $10 \%$ 。
At 99 Mr. Utting, of Wisbech, shows one of the many new contrivances in rollers. It consists of two sets of dises on two paraliel axles, the one set clearing the other, the one set narrow and the other wide, and the wo sets can be set relatively to one another in different positions, so that either the narrow or the broad edges of the land.
Mr. Carson, of Warminster, exhibits yet another form of roller, which he calls the Cross-cut Wheel Roler and Clod Crusher (No. 1). The wheels are 26 in . in diameter, and are of an improved form; having, in addition to the thin edge, a number of cross-cutting projections $t$ right angles to it, to give the implement greater facility in reducing clods, or in pressing Wheat, \&cc.; and these outer edges being all rounded, prevents any injury being done to the corn or plant over which they pas. The roller is made of a number of these wheels placed together on a round shaft, thus allowing them to revoive independently of each other; the frame is wrought and cast iron, and the shafts of wood. These shers are made of four different sizes, and of an ength suitable for the numerous purposes to which they re applied, a few of which may be thus mentioned: -Reducing clods to a fine soil suitable for receiving the seed. For roling Wheat in the spring after frost ; and thus, by strengthening the roots, to prevent the partial loss of the crop, and for putting a stop to the destructive effects of wireworm, grub, \&c. In a great measure to supersede harrowing, by being used before and aftes nowing, which ensures more equal and complete covering of the seed. For rolling Grass lands to destroy Moss improve the herbage, \&c. Price 161.
Messrs. Howard, of Bedford, have as usual a large and most interesting collection of ploughs and harrows, in the former of which arrangements for altering the position of the share relatively to the other parts have been patented. We may refer here to a curnip estroyer exhibited by Mr. Comins, of South Motan, Gardea which we suppose he obtained from inventardeners oroncle, for he describes it as the in about ton of Dr. Lindley. It is made of planed boari abor if foot wide and $4 \frac{1}{a}$ feet long, but it may be made longex be ordered; there are two wheels in front which may be set to any width required. The board can be raised a pass over ridges or lowered so the Turnips when sown on the flat. There
are two light handles to it so that a boy of 10 or
12 years of age can work it. The bottom of the board 12 years of age can work it. The bottom of the board
must be gasstarred as often as may be required ; the must be gas-tarred as often as may be required; the
shade of the board will cause the flies to jump, and in so doing they will stick to the tar.

Messrs. Hill \& Smith, of Brierley, Dudley, have a large collection of tools, and work in wire ; we describe one of their entries for fencing. The silver medal of the Royal Agricultural Society was awarded to these fences at the Southampton, and again at the Shrewsmany and decided advantages over iron hurdles, especially for permanent fencing, both as regards economy and strength. The set consists of eight kinds, as follows:-

These fences are, for pernanent fencing, far superior and cheaper to anything yet introduced. The deerpark fencing is much cheaper than anything that could be used for such a purpose, and has been much adopted. The exhibitors are now erecting about 10 miles of it for his Grace the Duke of Portland, for surrounding the deer park at Welbeck Abbey.

Tiptree Meeting.-A very excellent address was given at the gathering last week, by Mr. Mechi, for which we had not room in our report. We now give an extract from it
"The object I have in view is one connected with an impor-
tant purpose, embodving the great question whether the British tant purpose, embodying the great question, whether the Brititsh
stomach is to bo sufficiently gilled to enable it to maintain its stomach is to ba sufficiently filled to enabe it to maintain its
independence. It is a very serious affuir, that of the stomach.
 hollday to the British stomach. You laugh at the idea, but it is
a fact that every now and then you are on the verge of scarcity. fact that every now and then you are on the verge of scarcity.
You have wheat at 200 . \& load, and is not that a war price Yon have wheat at whis what, and is not that a war price?
And why in ft? Why is whis food dear when you
have open to you all parts of the world, and all the corn marlkets of the world? You go into those markets and bid the highest price, and you ought, it would be said, to command the
most ample supply. But still food is scarce , and dear. That is is
not to be denied. And why is it? It is beeause England has not to be denied. And why is it? It is because England has anything of myown, I am, prepared to toll you that fant the lands of England were cultivated in the manner that this farm,
and thousands of other farme are, you would not only have food enough to feed your owa people without the aid of forefgn im-
portations, but you would have some to spare. This will be proved if you take the acreage of the country, as far as we kow
It, though 1 am sorry to sag we do not know it correctly enough.
Thought when we called on the Hon. Mr. Cameron he would ave told you that while England has no agricultural statistics they have in the young and comparatively new colony of Canada
most correct statistics of every bushel of corn grown, and know What they are doing, for they have got over the old prejudice on mischief of disclosing their affairs is a perfect phantom and of England-you cannot do without them-you cannot keep them knowledge and intelligence-every day they are bringing the
resources of science to bear with greater effect upon the cultivation of the soil, and better means of communication are being
opened to them. Do not let us, then, be afraid of letting the Forld know that we are making a profit; for if we say we are ai bankrupt nobody will believe us. Now on looking round thi of doctors here, and I wish that amongst them I could get a ntend to imply that prejudice is connned to arriculture. I hope
ny aricultural friends will not think that I look on the singular in this respect, and as being the only class that entertain and cling to therr prejudices. I recollect that it was said that
steamboats would never do, and would never cross the Atlantic; that railways were impossible, and the electric telegraph was
hadness ynd these are all evidences that prejudice is not solely
an agricultural complaint."

## 7utbitws.

Proceedings of the Wakefild Farmers' Club for the year 1855, with the Report of the
The Wakefield Farmers' Club issues reports of its discussions and resolutions for the benefit of its members and of the general public, in this showing an example of public spirit and frankness which might be adopted ith advantage by more powerful institutions of the kind. Exclusiveness of any kind, such as some societies
present, can never tend to their prosperity. Some have present, can never tend to their prosperity. Some have excepting through a member. We cannot think of anything less likely to advance a club, either in public estimation or in that of its own members, than the operation of such a rule as this. Members join
professedly and really not to give but to receive professedly and really not to give but to receive
instruction, and when at any of their meetings a stranger who can give information on the subject that is being discussed finds himself silenced by such a rule as we The mentioned, every person present is injured by it, kind is by increasing its usefulness and activity-information should be welcome from whatever quarter, and when contributed, the more generally and permanently The circulated the better

agriculturists generally, and therefo
annual publication of its proceedings.
From the present annual report we extract an account of the discussion on mowing and reaping Mr. Hisl ear 1025 I .pened the debate. He said :-" In the Sir John Scott Douglas, Bart., of Springwood Farm Roxburghshire. Finding it to answer my expectations, I continued the use of the scythe, and for a great number of years past have practised no other mode of intendence. I may notice, by the way, that there are various sorts of scythes used for mowing grain ; there is the common scythe and bow in regular use in England ; the cradle scythe, used to a considerable exten and the county of Darious parts of Northumberlan its peculiar ty its peculiar handle, in use in Scotland; and the Hainaul scythe, used in Flanders, and which I have seen used in
Scotland by sons of Flemish farmers who were brought over for the purpose of exhibiting it (by the Highland Agricultural Society of Scotland) about 28 years ago. The above are all useful in the hands of those who are particularly acquainted with them, but few labourers
could use them all skilfully. I will in the first place could use them all skilfully. I will in the first place make a few observations relative to the expense
mowing and shearing; in the second place consider the advantages and disadvantages arising from either mode of reaping; and then sum up my observations by interests of ich mode will be morense of mowing and taking-up, binding, swathe-raking and heaping the rakings, of a fair average crop of Wheat, Barley, or Oats, upon a farm will cost other hand, the expense of shearing, bing differ-
stooking the same will be 15s. per acre, being ence of 5s. per acre in favour of the scythe. Second, the advantages derivable from mowing are the follow ing, viz. :- The farmer gets a greater quantity o the land, which is preferable to leaving it in the ground, especially on light soils; the saving in this case will be about 3s. per acre at least. The swathe
ought to be mown inward instead of outward, as it enables the mown lay it down betre, ne kis to take it up with less liability to injure the grain. also tends to the safer and more speedy harvesting the crop, as the corn does not stand so cowpact an closely compressed in the sheaf, and allows the wind to pass through with greater facility, and in most in stances it will be fit for carrying three or four days I rem, whic is of great importsice to the fawh shorn, being the sheaves formed a broad table-like top, and althoug well hooded, and would have been fit for carrying on the Monday, in the course of the Sunday, in consequence were very high wind, nearly the whole owing ornin being very wet, the rain so penetrated the sheaves that before they could dry through the Wheat sustained much injury from sprouting, which would not have been the case had they been mown, as it would have been certain objections are advanced against mowing, such as the grain being of an inferior quality, or rough in the hand in consequence of clods beiog collected by the swathe-rake; and also that, by mowing, the weeds are
all collected and the seeds get into the manure. To obviate the former objection keep the rakings separate and thresh them by themselves. My own experience that I can sell mown grain at as high a price as that which has been shorn, presuming the quality to hav been equal when growing. With respect to the latter objection, I have to observe that were the weeds not cleared from the ground along with the crop, the seeds would shake and grow in the soil, so that nothing would be gained by that mode; but as the seeds of weeds generally come from the threshing machine along with the grain, they can be burned up after being separated by the winnowing-machine, which would
objection also. Notwithstanding what I have gaid in favour of mowing standing crops, there are cases where shearing would be found advantageous, as will be found this year, as the crops are so much lodged by the continual rains; and by the use of the sickle crops of this description may be reaped with less loss than by the scythe. I have now to observe, in conclusion, tha by mowing the various grain crops there is a saving in
the expense of at least $5 s$. per acre; and where straw is the expense of at ieast $5 s$. per acre; and where straw is
valuable the incrensed quantity may be taken at 10 s . per cre, or where only avaulable to convert into manure, at 3s. per acre, which would be a saving of from 8 s . to
per acre-an
item of great importance to the farmer per acre-an item of great importance to the farmer.
I have also attempted to show that the quality of the grain is not deteriorated by taking the precaution have named ; and that I am of opinion there is a con siderable advantage to the farmer by adopting that mode of reaping without which the grain crops of the kingdom could not be cut down before
Mr. Scholey agreed with the former speaker that in dry weather the scythe would have the advantage over the sickile. He believed they were getting more acpore general use than the sickle. During an inclement season they ought to take the most speedy means to get the work done; and there was no doubt that more work could be done with the scythe. The scythe he
with the bow. For his part, if he had a quantity grain that wanted cutting, he would use the seythy he would get a greater amount of work done. He believed that a man accostomed to cut corn with a scythe would do it better with one without the bow.
Mr. Johnson was an advocate for mowing instead of shearing. When it was a thin crop it was much better to mow than to shear. Flour used for manufacturing purposes might be preferred harvested with the sickle ; but upon the whole he thought mowing the best. When being cut down with the scythe it was raised partially up again, the wind could get better through it, and it saved more stubble. He thought sufficient attention was not paid to raking. He thought the raking ought to be done every morning; but when the corn was mowed the raking was generally got altogether. When sickle it did very close and hard, as when cat by the sickle, it did not dry soon. Certainly corn cut by the sickle had the neatest look-mowing generally looked rather slovenly; but, notwithstanding, he would rather Mr .
Mr. Nicholson said he had mown some 10 or 12 years; but he considered it impossible to mow some crops, and in others there were a great many of the ans and Sometimes after mowng a strong lot it would be found that they had a short yield. He believed it took more power to mow with the longbladed scythe. When the corn was standing he believed the cse of the scythe was better than where it was laid; the ears were not so liable to be cut off. His pinn was upon the whole he strong heat he had ahing, He thought it possible to mow a strong crop of corn, but io must be with the short-bladed scythe. When he farmed in the south of England he had had the corn "fagged." It was not a sickle, but a heavy and widebladed hook that was used; it was struck into the standing corn, and very rood work it made. The farmers of the south of England prefer "fagging" to any other Strong - he cost pared, trong crops he sheared, and others he mowed.
Mr. Tweedale declared in favour of mowing. He believed there was more straw got by mowing, and that was of consequence when the straw had to be saved for cattlo. When the corn was mown the wind got through when was shorn, and by getting all the rahings together what oot spier was soen, and the sample of corn wae prodviled. By mowing finer samples of Wheat were to weed. Mr. Tweedale said he could not get hil men there were men whon could mow with it much easier than with the common scythe.
The Chairman said mowing did not look neat. But they might have neatness without economy. Certainly, as far as economy went, mowing was the best. He He did not think the one with better than a long one. the work well. It seemed out of the question that it should throw the corn ; it wanted something else to assist. He granted the wind would blow through it Unon He considered the therdeen scythe would do the work better than any other. Many men preferred having a long pull, which counterbalances the weight of the blade but mowing with the short blade did not require such a great swing. Work-people, however, had a prejudice against any new invention.

## Calendar of Operations.

## appearance of the Crofs

Rerrshire - The present appearance of the growing crops in RERKRHRE-The present appearance of the growing crops in
this neighborthod is good. Whet, Oats, and Barley all
promise to be dhove an average. Beans and Yeas about an
average The Turin
 litic. John Adanms, Matcham, Neuthery. Jht Barley, and Oats-in
 little damgane may have arisen to Wheat in very exposed situa-
tions from a heary storm of wind about a fortnight ago; but that
 capital condition, though along onr hill sides there are consider-
able quantities not yet cut, as the whil of this month has been very uncertain for haymaking. I apprehend there is a prospect
of Mangel being a good crop. Turnips are not promising; fles, wireworm, and weath-r have all been apaint them, and mang
lige been put in ton late. Potatoes begin othow di.ease in the
leaf thon an Benson, Truistork.
EssEx. - h have sent you a repprt of the crops in my im-
mediate neighbourliond. The Wheat I think is more than an
 to begin harvesting in 10 days. The Ralley is an average crop,
not more than tho-thirds the usual acreage sown. The Oasi
upon the mixed soils are good, upon the beavy lands very moderate. The 耳eans and peas are a great crop, and are very
henilly at ht this tire. Potatoes I lase beard no complaint of.
The hav crop is very large, and for the mont part well pot in

 are all looking rary well, but not so heavy as I have seen them
in this part of the country. The harvest under any circum-
stances, cannot commence before the middle of Augus. I see a
 $=-5=5=$ osecure them; Mangel good; SWedes, and Turnips backward,

Baans very good; Barley, of which the breadth sown is unusually
aman, a very heavy crop; and Wheat (as extensively planted ae Barley is the reverse) promising at least a full average crop: Tith a continumace of dry weather it will certainly exceed an
average; Oats and Peas can scarcely be said to be grown in this average; Oats and Peas can scarcely be said to be grown in this
neighbourbood. The healthy state of all crops, combined with the abandance of food for cattle of all kinds, will, should we be blesed with favenrable,weather for the harvest, mark 1856 as one
of the most propitious seasons we have knowno C. Randell, Chadof the most propitious se
$3 u r y$, Evesham, Juiy 28 . The crops in this county promise to be a
Húvinodonsmre. full average. Whent has improved mach since it came into ear, crop. Beass and Peas gemerally are very fine. Turnips have been sown two or three times, from the ravages of the fly, and are wie doedidedly agwinat themi Popatoes are splendid. Wresith avarage weatber we may expect general harvest by the middle of August. Bramplon, Frintingdon, July 25.
Tight; Oats, average crop; Beans, ano average crop; Barley, Tight; Oats, average crop; Beans, good; Potatoss, promising; looking well. The Wheat, where thin, is a good deal storm broken (not laid); Oats and Barley are unusually thin, but lueng all standing, and the ears pretty gond, we think they will prove an average crop. Harvest will not be general here untl Whent, gaod but blackened; Barley, very good; Oats, good; avesuge; Hay, heavy erop. T. Speweer, Knossinglon, Oakhana, Tuly 28.
Linculnshiee Feng.- A fow partial showers have been o Rervice to being nearly ready for the seytbe, and a good deal of Wheat has absumed a bright yellow tint. The Wheat is generally thin of plant, but the extremely favourable weather we
have had has filled the ears with weighty kernels, Bo that we may expect an avarage yield of unusually gond quality. The the dry hot weather induced it to ripen prematurely. Oats are
also good, excepting in the fens, where they suffered much from the spring frosts. Bemas and Peas will turn ont productive. Potatoes will. not be a heavy crop. Harvert is expected to be
geaeral about the 11 th of August. John Whitwell, Peterborough. Norfolk.-The Wheats in this district, which promised a by the Wheat midge; 日earcely an ear can be found but what is more or less affected. It would be difficult to form an estimate of the damage, but I fear alongr the sen coast we have suffered to the extent on one side boing complately whestroced crop, many o greater breadth of Wheat is however sown than usual, and the deficiency of yield will probably be counterbalanced by the extra number of acres. Barley and Oats promise to be a air crop, bu
a less acreage sown than usiual. Harvest will be ready in about a less acreage sown than usual. Harvest will he ready in abmut pretty good, and most of it secured in fine condition. The materially. They are now attacked by the black caterpillar, and whole fields are completely stripped of their leaves. R. Cubitt, Tell; Barleys stout, aad a.heavy crop; Oats, the same; Potatoes, at present free from disesse; Beets, doing unoommonly well; Turnips, very indiferent, having suffered much from the fly,
and are now in some places from the canker.-Rougham, July 28. Wester Rose, July 28.- After an unusually protracted rainy seavon we have now had a week of dry breezy woather, advan-
tageous alike to grain and green crops, and fortunately these fine days came when most needed, so that we liope the blouming semon has been got over without much damage. The greater pant of the Wheat that was laid has got up again, and should the-weather now continue dry less loss night be sustained than was some time ago anticipated. The small proportion of Barley
this year sown has also a promising appearance, and althougli some of it be now laid that has not yet resched its full length, thers is not the same danger of its filling as there is of Wheat. From its geareity it will in all likelihood be dearer comparatively than it has boen for many years. Oats, although by no means too riant appearance. Never perhaps in this quarter was the farmer's prospect of an sbundant crop better than at this moment. The catting and securing the hay crop, and mnch has been accomgreater part of it remains in cocks in the fields, and seldom have we seen the fields more thickly studded with them. Green erops of all descriptions have been making fatisfac
tory progress, and as Turnips have got a fair start we for an abundant crop. Docks and Thistles by dykesides What may, these certainly never do. Fir some time we have for a few weeks to come. Our men and horses are busy collect-
ing all the manure we can get for love or money, for next year's Wheat crop, as our desire is that never, in any coming year, now groan. For some time the price of cattle has been a shade lower. from the fears that were entertained of the rain damaging the Trumip crop. Dry weather has seldom been more needed. Worcestersaiee- Wheat on the gravel and loamy soils very good; on the clay and also on the very light land thin of plant,
and by no means so good as last jear; but I hope on the whole we shall come near, if not quite, an average. Barley ou the real barley soils very good; but on the clays and mixed soils very that it need; the coid and wet in May took such rn effect on it Svedes and Mangels good. Potatoes moderate Sata, fair crop. appearing. Hay crop great and never got better. Fruit litule or .
the crops in this neigbourhood may be thus classed:-Wheat look healthy, with a good ear, but generally thin on the ground; of heavy thick crop quite the exception; a very small propertion very full of black (or slane ears. The Wheat crop upon the lughter soils is very full of red Poppies. Barley a good crop, a spod deal lodged by the late rains, had a grear many black ears mang it. A small amount grown. Oats partially good, and and Mangela very promisiog Hay crop large and genernally mell secured. Potatoes not very viporous, but no appearance of diesase. The weather showery, but atill very fine. P. Stevenson, Aminsan, near Thirsin, July 29 .

## VALUABLE IMPROVEMENTS IN MOWING MACHINES. <br> BYROYAI <br>  <br> Letters Patent.

Under the Patronage of Her Majesty Queen Victoria, and His Majesty the Emperor of the French.

## 

A. SHANKS ABD SON, while soliciting the attention of the Nobility, Gentry, and Gavdeners to their athe same time respectfully s licit notice to their new HAND MACHINE, specially adapted for mowing small lawns, verges, as the cheapest as well as the which has now undergone a trial amply sufficient to enable the Patentees with all coufidence to offer it the machine to le worked with perfect ease by one person. It requires no change improvements effected by the Patentees enable close to the edge of Hower-beds; has great facilities for quick tuning, cutting and rolling at the same time: the length of the cut can be effectually regulated in a few seconds by merely turning a screw, and being simple as well as complete in its construction durability, and consequently not a $t$ all liable to get ont of order. The wors The nachines are fitted with due regard to strength and superior to mowing, with the soythe, Mhile the simulcactous operatious of rolling and close cutting greatly improve and beautfy
the turf. The Rolling and Mowing Machine is now in common use at all the Royal Gardens, Windsor, Kew, Buckingham Palece Illustrated Pirice Lists forvarded on application.
N.B. A. Shanks \& Sonf finding that their Patented Improvements are pirated, beg to cantion the public against purchacime Machiues with their improvements without their name and address marked on the Machines.
A. SHANEs \& Son also supply Fleming's SALTING MACHYNES, for destroying Weeds, \&co, on Gravel Walls, Court Yapis

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACZINES,

SOLE MANUFACTURER, iron and Wire works, NORTH STREET, LEEDS,

## REGISTERED JULY 24, 1855.-No. 3739.

THE ADVANTAGES OF THESE MACHINES supersede all others by having L a smail Wheel in front of the Grass Box, consequently will mow verges and round flower bede, Without any change wheels, or adding the old fashioned Roller, es in others; Will also cut either wet or dry, and by the simple adjustment of a thumb sarew, in. front, can be raised or lowered to cut
the Grass any length required; and having two Rollers behind, and a small one in front, they roll the width they cut; they will turn in very little room, and cut at the same time. All the working part made much stronger than the old machines. The bottom Blades are so constructed that they cannot taar up the rround:
consequently do not re
one person with ease; the two latter with a pony or donkey.
13 inches LIST OF PRICES (NET CASH):-

Testimonial from Joshuu Major, Esiq., Laudscape Gurdener, Fnostrop
To Mr Grerv, Lerps-Sir, As I almays apprecinte public and useful improvements, I mnst glady give my testimony to your highly improved Mowing and Rolling Machine. The one sent for my inspection and trial (cutting a breadth of 24 inches) was drawn ou fat ground with ease by one person, and although at the time of trial the lawn was wet, it was cut with the greatest
nicoty. So oomplete and simple is the invention, that amateur gentlemen, and even ladies, may work either the 16 or 20 -inch size with ease and pleasure, providing the Gnass is not too long. For extensive places $I$ should say the 24 inches would be most suitable; for even in undulating gronnd two persons may work it; but in flower gardens, when beds, \&c., are crowded, either of the smaller sizes would be best. I congratulate you on your very valuthle invention, which in my opinion, entirely
surpasses, and must eventually supersede all others, for it is not only free from intricacy and easy to the workman, bui extremely expeditious in its operations, and consequently must prove a great saving in the management of Grass lawns, and a great boon to
ther Testimonials may be had on application to the Manufacturer.
The above Machines are warranted to answer the purpose as described, or may be returned, and may be had of all principal Ironmongers, Nurserymen, and Seedsmen in England; also Mr. Charles Garrood, Superintendent of Agricultural Department, Crystal Palace, Sudenham
NEW PATENT INVENTIONS FOR STABLE REQUISITES.
Awarded a Prize at the Paris Exhibition, and Patronised by the English and French Governments.

## COTTAM AND HALLEN

THE Original INVENTORS of the PATENT ENAMELLED MANGER RACK and WATER TROL゙GH deseription and engraving,

A represents the Patent Halter Goide and Collar Rein, the ball or mixing with the food in the manger, is alone sufficient toclaim freedom up or down the guide har and is noiseless in in ease and tion, as also a sure preventative against the most restive horse being east in the stall
8 The Patent Portable Seed Box can be instantly detached from the Reok without disturbing the hay. The saving of the
seed in a clean and noefol state, either for agricultural purposes,
or mixing wita the food in the manger, is alone sumcientiochan $c \in$ The Seed Box detached, made of Galvanived Sheet Irven, light and durable. o The Patent Saddle and Harress Bracket combined, can be used with great advantage in Harness Rooms, where space is
object, as the long portion of the bracket eax be truened up out of

COTTAM'S MANGERS are constructed in the best possible manner, both as to form and atility, are cleanly in appearance, durable, and impervious to infection; manufactured Plain, Galvanised, or Enamelled.
Improved Stable Guttaring, with moveable safety covers, Sanitary Traps, stable Pumps, Double Corner Mangerts,
Hamess-room Appendages, and every article in Stable Purniture. Chaff Cutters and Out Bruisers, kept on show at
COTTAM \& HALLEN'S WORKS, 2, Winsley Street, Oxford Street, London. WARMING AND VENTILATING.-The New Illustrated Catalogue for 1856, and Retimates gratis on application.

GARN WATERPROOF PATHS. CATTLE SHED FLOORS.
THOSE who would enjoy their Gardens during the Winter months should construct their walks of PORTLAND gravel of which the path is at present made thom:- Screes is mixed with it, and to every partof clean gravel add one of shamt river sand. To five parts of such equal mixture add one of Port and Cement, and incorporate the while well in the dry state betion
applying the water. It may thens be laid on 2 inches thick. Ans labourer can mix and spread it. No tool is required heyond the spade, and in 48 hours it becomes as hard as a ruck. Vegetation cannot grow through or upon it, and it resists the action of it severest frost. It is necessary, of wa path rowards the sides. The same preparation makee first-rate paving for BARN CATTLE-SIIEUS, FARM-YARDS, and all other situriow Where a clean, bard bottom is a desideratum. May be Milbank Street, Wertminster.

## The Gavoeners" Chromitle SATURDAY, AUGUST 9, 1856.

A currous discovery is said to have been made by a French gentleman whose garden was most inconveniently invaded by ants. They swarmed at Rambouillet in his flower baskets and among his flower beds to such a degree that it was impossible to attack them with boiling water without killing the plants. M. du Rtbert therefore took another course. After stirning well up the ant heaps and removing the "eggs" he scattered over them a few handfuls of guano ; and with such success, as he states, that his whole garden was presently cleared.
This gentleman regards gaano as an ant poison, and he declares it to be his conviction that under all circumstances its action will be the same. He found it useful to water the guano slightly after having applied it, but it does not appear that this was of so much consequence to the ants as to the plants.
In order to test this statement we have made a few experiments with the following results :-

1. A nest of the small black ant, formed among a tuft of Aubrietia, was well stirred up, and the eggs exposed. A small handful of guano having been scattered over it, the ants were immediately thrown into confusion, the business of removing the eggs came to a stand still, and by degrees the ant disappeared. Water was added, and the nest onee more stirred up. At noon next day the eggs were found deserted, and the ants were gone.

The same with a smaller nest in the hard dry clay of a lawn. Same result.
3. A large hill of the small red ant, very strongly entrenched among Sedum popmlifolium, was distarbed, and a handful of guano thrown over it astonishment, commotion, confasion, scamper, helter skelter, immediately ensued ; eggs again abandoned the army of ants quickly disappeared. A pan was the army of ants quickiy disappeared. A pan was
then half filled with earth from the same ant hill, mixed with a swarm of ants and numberless eggs guano being applied the result was similar. The egns were instantly abandoned, and the ants endearoured to esclape. Water was added; and the earth and guano mixed with a trowel. Next day at noon there was no trace of life in the mixture. The eggs were untouched and becoming brown. Whether the ants had escaped or run away could not be ascertained.
4. At 3 p. M. a pint wide-monthed clear glass hottle was filled with some handreds of red ants, eggs, and the earth from another hill; guano was added, muslin was tied over the mouth of the bottle, and the proceedings watched. As before the eggs were abandoned, and the ants ran rapidly backwards and forwards as if in much distress The winged ones behaved like the others, making no attempt to fly away. The bottle was left all night in a warm room. At this moment, 10 A.M., the ground is strewed with ants motionless and apparently dead ; the eggs remain mixed confasedly apparently dead; the eggs remain mixed confasedly
with the earth, without an attempt having been
made by the insects to collect them. One winged and four wingless ants are crawling over the surface. Beyond this no signs of life are apparent.
Hence it seems that guano is fatal to the vitality of ants. How does it act? In the samples of guano employed the smell of ammonia was inconsiderable, owing to long keeping.

If we were to tell some of our gardening friends that the difierence between a Pfach and a Nectarine is little more than that which distinguishes a person with a Crimean beard from one to whom Nature has denied such an appendage, they would probably dombt the correctness of our statement, and be apt to infer from it that we knew little or nothing about the matter. But however incredible it may seem, the fact is no less certain that the Peach and the Nectarine are only varieties of one another, and were it possible to trace their origin we should very likely find that they themselves were merely different forms of the Sweet Almond improved by cultivation and the art of mans. The late Mr. Knigut, the distinguished President of the Horticultural Society, entertained the notion that the Common Almond and the Peach constituted only a single species, and that the Almond might by proper culture through many successive generations be ultimately converted into a Peach or Nectarine. So impressed was he with this idea that he determined to ascertain by actual experiment how far his opinion was borne out by facts. Accordingly he fertilised a Sweet Almond with the pollen of a Peach, and the result was a variety which produced fruit that retained the form and character of the Peach in every respect, with flesh perfectly soft and melting. (Trans. of Hort. Soc., Vol. in., P. I. From this it would appear as if we were justified in the conclusion that the Almond bears about the same relation to the Peach that the Crab bears to the cultivated Apple.

In the first volume of the Transactions of the Horticultural Society several instances are recorded of Nectarines having been produced on Peach trees, showing in a striking manner how closely the two kinds of fruit are allied. The earliest notice we have of this remarkable freak of Nature is contained in a letter from Pribr Colinnson to the great Linneus, dated April 3, 1741 . He says, "Lord Wilmington has a tree that produces Nectarines and Peaches without any art, but quite accidentally. The fruit does not mix together, but complete Peaches and Nectarines, both distinct, are on the same tree." (Corresp. of Linnewus, vol, i., p. 7.)
We have ourselves witnessed sume carious sports of this kind. We once saw at Carclew, in Cornwall, a fruit on a Nectarine tree that was half a Peach and half a Nectarine-that is to say, one side had the velvety coating of the Peach, while the other was perfectly smooth and shining like the Nectarine. The tree was raised from the stone about 20 years ago, and was never worked. It still exists, and is a delicions little early Nectarine deserving of being better known. On another occasion this identical tree produced a perfect Peach, a circumstance we believe to be of rare occurrence-the sport which is more frequently met with being that of a Peach tree producing a Nectarine. A beautiful example of this sort of transformation was lately commanicated to us by John Henry Lance, Esq., of the Holm Wood, Dorking. It was on the branch of a Têton de Vénus Peach, which contained a perfect fruit of that variety so remarkable for its prominent point, and a Nectarine rather smaller but well formed and quite round. It agreed so well in almost every particular with a similar production describad in one of Colinson's letters to Linneds, dated Sept. 25, 1766, and published in the worl already mentioned, that we think our readers will excuse us for making the following extract. "Some time ago," writes Mr. Collinson, "I saw what I think a surprising curiosity. On a large Peach tree full of fruit there was a branch which on one side had a Peach and on the other side a Nectarine. They grew so close together that they touched each other. I stood long with admiration viewng this wonder. The Nectarine had the shining smooth surface with a red complexion, the Peach was rough and downy as Peaches are. We have had two more remarlyable instances of Peach trees naturally and without art producing Nectarines; so I reasonably conclade the Peach is the mother of the Nectarine. Where this lusus naturee has happened, ingenious men have improved the accident by budding or with grafting from the Nectarine branch; and thus the race of Nectarines began.
Here a wide field opens up for inquiry. We know nothing for certain about the origin of the Nectarine, and although it is possible to have been obtained by budding in the way suggested above, still we think if the Peach and Nectarine are as closely related as we consider them to be, it is
quite as likely that the Nectarine may have come ing, and we now see that Tuscany is materially from the stone of an Almond or Peach, which would be no more wonderful than that the Ribston Pippin should have sprung from a Crab or some other variety of Apple. On this subject, however, facts are thought to be wanting, and we are curious to know whether there are any recent well authenticated instances of a Nectarine having been raised from the stone of a Peach-or a Peach from the stone of a Nectarine. $B$.

New evidence upon this subject has become the more interesting now that our learned friend M. Alphonse De Candolle has declared himself in favour of the specific diversity, not only of the Peach and the Almond, but even of the Nectarine itself. To the cases already on record of Nectarines being raised from Peach stones, such as the Boston Nectarine, and Mr. Calver's Peaches and Nectarines borne on the same seedling tree, M. De Candolle objects that such instances rest upon the recollections of gardeners, and not upon direct experiment carefully recorded. And he suggests that the trees which sport into Nectarines from Peaches may be hybrids between the Peach and the Nectarine, with the same tendency to throw sometimes one sort sometimes the other as happens in the common Cytisus Adami, which sometimes bears the flowers of the Laburnum, sometimes of the parple Cytisus, and sometimes of its own intermediate breed.

This is evidently mere hypothesis ; and it is also to be remarked that neither in the case of the Peach nor the Nectarine can any proof be adduced that they are found in a wild state. It does not indeed appear certain that Nectarines were known before the Middle Ages, when they were called Nucipersica, because of their resemblance to the fruit of the Nux or Walnut, whence came the modern Italian name Pescanoce; for M. De Candolle regards it as extremely quesionable whether the Tuberes of the Romans were Nectarines, as some have thought. Then as to the Peach itself, after examining critically all known anthorities which treat of supposed wild Peaches, M. De Candolle is driven to the conjecture that the native country of that fruit must be the North of China; which strikes us as seeking to pass from the known to the unknown. A more probable locality seems to be that mentioned by Pallas, who says that he found on the banks of the Terek apparently wild Peaches, of small stature, bearing velvety, austere fruits of little succulence, and not bigger than a Walnut, which the natives called Scheptala. (Dr. Royle says that Shuft-aloo is the Persian name of the Nectarine.) Pallas' account reads so like a description of Almonds in a state of transition into Peaches that we should so inter pret his evidence; and we own ourselves wholly unable to believe that the Peach has had any other origin. It is clear that the Almond has a great tendency to vary, as is proved by its varieties being sweet or bitter, hard-shelled or soft-shelled, and so on. It is also known that these peculiarities have now become so hereditary and fixed that the seeds of the Sweet Almond regularly produce Sweet Almonds, \&c. This fruit then has-1, a tendency to vary; and 2, the power to perpetuate its varieties by seed. That being so, the difficulty of understanding how a Peach can have been derived from the Almond by successive changes in the course of ages seems to vanish. Some Peaches indeed of the clingstone race are, in a bad climate little better than Almonds even now; the Italian melocotons, for example, which in this country are uneatable, although they acquire a tolerable degree of flavour and succulence in the hot climate of the Mediterranean. If we might be permitted to speculate upon this curious subject, we should say that the changes undergone by the Almond must have been of this kind:-

1. Almond became more fleshy $=\mathrm{Bad}$ clingstone
2. Bad clingstone became more fleshy = Good clingstone.
3. Good clingstone -became more pulpy $=$ Our soft Peaches.
4. Soft Peach sported, receding towards the original fleshy type and lost its wool = Nectarine

There is nothing more improbable in this than what we know must have occurred in the production of Canliflowers from the wild Cabbage of our English coast, or of Muscat Grapes from the smallruited wild Vine of Baidar, or of Wheat from Fgilops, which last case we presume may now be regarded as beyond reasonable contradiction.

Whiss the news from Portugal tells us that the Vine Mildew is producing more mischief than ever, and that from Spain is not much better, it is satis factory to find that in central Europe it is beginning to disappear. We had already heard that the "Currant" crop of the Ionian Islands was recover-
improved. According to Baron Mortemart DE
Borsse the disease had begun last year to exhibit unmistakable signs of disappearing, and he now reports it to have almost wholly ceased in the greater part of Tuscany. The vales of Arno, Chiuno, Serchio, and the slopes of Pietra-Santino now exhibit few traces of its presence. The leaves are not now in a sickly state, the white efflorescence is gone, there is no longer any offensive smell; all that remains is but a sort of languid vegetation. From the vast plain which commences at the lake of Porto, on the Modenese frontier, as far as Maremmes, the same happy change has manifested itself, especially on the hill sides where the cure first began to be perceptible.

On the other hand we learn from M. Montagne that near Montpellier a new disease has declared itself, and with such intensity as to threaten the loss of a third or even half the crop. This new affection, called Anthrachnosis, broke out between the 5 th and 15 th of June, and is described as a sort of smut (charbon). It is said to be caused by the action of cold dew and fogs followed by a hot sun. The same affection is reported to have appeared near Bordeaux.

## ENTOMOLOGY.

## Rose Sawfly Larve

A WEEK's absence from home during this hot weather has allowed the development of great numbers of the larve of the Rose sawfly, Hylotoma Rose, described in a leading article of this Journal on the 19th ult. Under these circumstances, supposing others will e suffering equally with myself from this cause. Thav thought it would be useful to publish a woodcut repre-
senting the transformations of the species, which is senting the transiormation
accordingly here supplied.

The cut represents a young Rose sprig with 16 swellings caused by the deposition of the egge, an en larged sketch being given of one of them showing the small dark slit on the upper edge where the egg was inserted; on the end of the twig several of the minute larve are feeding together with one nearly fullgrown all of the natural size. At the left hand side is one of the cocoons with the circular hole made by the perfect insect in effecting its escape. The fly represented magnified is a female, distinguished by the thickened ntenne, the natural size represented by the crossed ines. In the upper part of the cut one of the fringed antennse of the male is given. J. O. W.

PRACTICAL LESSONS IN BOTANY FOR
BEGINNERS OF ALL ${ }^{\dagger}$ CLASSES.-No. V.
By the Rev. J. S. Henblow, M.A., Rector of Hitcham, Suffolk [SUGGEsTion To THE EDITOR.-Any of your readers desirous commended can refer to such elementary works as your School Botany, \&c., for figures of the plants I propose
noticing. Still I would suggest your inserting a few of noticing. Still I would suggest your inserting a few of articles more generally useful.] With this suggestion we have endeavoured to comply.
Flowers.-Our vulgar notions do not qualify us for recoguizing either roots, stems, branches, leaves, flowers, fruits, or seeds, under the forms they assume in certain plants. As the parts of flowers are most important in systematic botany I begin by describing these.
So far as local opportunities and the seasons may permit, a teacher may commence with flowerg possessing a general resemblance to such as I shall presently notice, and he should introduce them (as nearly as possible) to his class in the order in which they are here described. This will assist in preventing a conusion of ideas not unfrequent in beginners as to the limitation of some of the terms employed.
N.B. After a lesson, the beginner may be required to detach for himself one part of each floral whorl, place it on a slate or paper, and write its name under it stating also the number of such parts in the whorl to which it belongs.
. The morphological considerations to which allusion will be made under the heads of a few N.B. may e omitted at first. When the technical terms have become a little familiar, and their application under-
stood, it will be advisable to show the difference between their merely descriptive uses, and their higher signi ficance in relation to structure. Ex.gr. When petal are described as "inserted on the calyx," the fact involved is the partial adhesion of two whorls of the perianth, leading possibly to the conclusion that in certain cases the perianth essentially consists of corolla and calyx combined.
Example 1. White Lily (Lilium candidum).

This is well adapted, from its size, for showing the essential parts " (pistils and stamens) of flowers, in contrast with the "perianth" surrounding them.

Pistil.-A green column in the centre is called a " pistil." The upper extremity of this is its "stigma." The lower portion (which contains three cells or cavities) is its " ovary"" On cutting the ovary transversely (directly across), a set of small flattish bodies ar seen attached along the inner angle of each cell. These are the "ovules," destined to become "seeds." The long solid portion of the pistil between the ovary and stigms is its "style."
N.B. In some plants the pistil has no style, and then the stigma is seated immediately on the ovary, and is said to be "seesta. In others the style is relatively very long He Pistiu compared with the ovary
Stamen.-At regular distances round the pistil are ranged six "stamens," each of which consists of two parts. The lower portion forms a sort of narrow stalk or support to the upper, and is called a "filament." The upper portion is an "anther," composed of two long cells filled with a very fine powder, the "pollen." When the anther is ripe, the two cells burst by a slit which opens longitudinally (lengthwise) down the middle of each, and the pollen escapes.
N.B. In some plants there is no filament to the stamens, and the anthers are then "sessile."
Perianth.-Six "leaves" of rather fleshy consistency and pure white, are placed at equal distances arow the stamens, and form the outermost parts of the flowe Collectively these leaves are called the "perianth."
Floral whorls.-Like parts disposed in a circle (or rearly so) worls. ${ }^{6}$ floral whorl" In the Lily, therefore con thee surch, rectoning from within ther outwards. Chese aro-1st, a pisti, 2 , sis the leave 3d, six leaves. Close inspection who show the of the perianth to be ranged in two whoris of (lying leaves each ; those in the inner whorl alternating (he six between) in position with those of the outer. The three stamens are similarly disposed in two whoris. The fin outermost are opposite the outermost leaves of perianth, and the three innermost opposite the inner three.
N.B. The three cells of the ovary indicate the pistil to be formed of three parts (carpels) combined. of 15 may therefore represent this flower as composed of corparts, symmetrically arranged in five circles, each cous taining three parts alternating with those in contiguos circles. In speaking of the different kinds of flo whorls, those of the same kind are often alluded collectively as forming a single whorl, with
the subordinate whorls of the same series.
N.B. The Common Tulip (Tulipa Gemeriana, and Crown-Imperial Fritillary (Fritillaria imperialion in the other Lilianths (Liliaceere) offer similar conditions in structure of their flowers.

The innermost floral whorls contain numerous small pistils ; numerous stamens surround them, and round these are six leaves forming the perianth.
N.B. Other species of Anemone, common Marsh Marigold (Caltha palustris), common Traveller's Joy (Clematis vitalba), and others of the same genus have more than one pistil, with numerous stamens, and a variable number of leaves to the perianth.
N.B. When there are more than one pistil in a Hower, each is regarded as a separate "carpel," the name given to the subordinate parts composing the innermost kind of floral whorl. In these cases, therefore, the terms pistil and carpel mean the same thing. But in flowers where the carpels are combined or grafted together (as in the Lily), they form the subordinate parts of a single (yet compound) pistil. A flower may, therefore, have a single and simple pistil, consisting of only one carpel; a single and compound pistil, consisting of two or more carpels; or it may have two or more simple pistils, each also a single carpel.

Ex. 3. Bulbous Crowfoot (Ranunculus bulbosus.) -

Many pistils-many stamens. Perianth composed of 2 kinds of leaves in 2 separate floral whorls of 5 leaves each. Corolla.-The five inner leaves, of a bright shinin yellow, are called "petals" (pronounced pettals), and collectively constitute perianth. Each has a little scale or gland at its base.
Calyx.-The five outer leaves, of a greenish yellow, alternating with the petals, and differing irom them in
form, are called "sepals" (pronounced
Petar or Crow- eeppals). Collectively they constitute a
roor. calyx.
N.B. The separation of a perianth into two whorls of
Petal of Crow- eeppals). Collectively they constitute a
roor. calyx.
N.B. The separation of a perianth into two whorls of
different kinds of leaves, is extremely common. In of the soil; and that in the case of sund the variation some cases the term perianth is employed where there is was $3^{\circ}$ greater and five days more rapid than in sandonly one kind of leaves present, whilst in others, for stone (terrain de grès). M. Quetelet, on comparing the reasons that will hereafter be mentioned, the term calyx is preferred. But in such cases the term corolla is never employed by modern botanists, though it was formerly used in a vague manner if the perianth happened to be highly coloured.

## BEURRE CLAIRGEAU.

## (Supplem 1854, p. 805. )

OF all the varieties of the Pear raised in our time, the Beurré Clairgeau appears to be the hardiest in its bearing. For five years this variety, which first produced fruit in 1846 or 1847 , has borne in my garden, not only on the Quince stock as a dwarf Quenouille and pyramid, but also on the Pear stock as a dwarf and tal pyramid. When flowers are seen it is a sure sign tha a superabundance of fruit will set. On the Pear stock, it is as a half standard pyramid and with the assistance of a moderate pruning that the finest and best fruit i abtained. Further it is on half standards that the best wood is produced. This variety is not particular as to soil, provided the latter is not too heavy and moist These facts have been proved in fifty gardens. An affinity is observed between this variety and the Beurré de Capiaumont, the relationship between which and an old variety of the Calebasse form, the one which is hardiest in our climate, is generally admitted. Being in possession of the original tree of the Beurré Clargeau, and having observed its good properties, in respect to bearing and the beauty of its fruit, I appeal to all amateurs who have possessed trees for three years to make known the results of their experience. Thus in less than ten years we shall obtain one of the most complete and best esta other meritorious varieties which have been in bearing for a quarter of a ceutury are still without such. J. D Jonghe, Brussels.

## ON THE HEAT OF THE SOIL

With reference to its effects upon vegetation. If rom Alph. De Candolle's Géographie Botanique.)
IT has been shown, both by observation and by expe much more energetically than by transmissiun from one part to another. The best proof of this is afforded by the fact that if a branch of a tree that is growing in the open air be protected, or introduced into a stove, it will develope its leaves before the other branches do. So also in the Polar regions the warmth of the air caus.s the plants to leaf and flower when the ground is still extremely cold. Nevertheless, since all plants pump up their sap from the ground, the temperature of the latter is an important element; during great heats it is coole than the air, during great cold it is warmer, and the more variable a climate is, the greater the importance of this phenomenon to the gardener. The heating or cooling effect of the soil will be most sensibly felt in those organs that are nearest the root, in those to which the sap flows rapidly and copiously, and in those which are bad conductors of heat. Thus the temperature o the interior of the Cocoa-nut probably differs little from that of the earth around its roots, because of the thick ness of the husk, which conducts heat bady ; whilst on the other haud the young shoots and flowers of trees acquire the temperature of the surrounding air. Plants whose roots penetrate deep into the soil will resis vicissitudes in the temperature of the surrounding air better than those whose roots are superficial, because the penetrate it.

Many interesting observations have been made on the temperature of the soil at various depths, but for our purposes it is sufficient to consider only such as exten to about 3 feet from the surface, for the roots of mos plants do not penetrate so deep as that. Those which do are chiefly plants that affect a very light soil, and even great trefs have more root-fibres near the surface than at the depth of 3 feet. It matters little to our in vestigations, that in our temperate climate a stratum of unvarying temperature occurs at from 20 to 30 feet deep, that this stratum is found as 3 feet beneath the surface in some very uniform climates, and at much greater depths in such excessive chimates as Siberia. Nor dnes it concern us that there is a thick stratum of perpetually frozen soil in some countries where the mean tempera ture is above $32^{\circ}$; we shall consider only the monthly variations of temperature in the upper 3 teet of the soil.
That the temperature of the soil at this depth is less variable than that of the air, is proved by M. Muncle's observations at Heidelberg, which show that the diurual variations are not propagated beyond 3 feet, the monthly variations beyond 5 feet. At Brussels M. Quetelet has shown that the annual variasions present the surface of the soil to a depth of 31 feet:-

$$
\begin{aligned}
& \text { Air in the shade at the murface } \\
& \text { at a depth of } 8 \text { inches }
\end{aligned}
$$

## 2 feet 24 feet 34 feet

$62^{\circ}$
$56^{\circ}$
$641^{\circ}$
$5810^{\circ}$
$511_{4}^{\circ}$
It further took 19 days for the maximum and minimum of the year to penetrate $3 \frac{1}{4}$ feet, or in other words the behind whit it her how meraidity of trangmission and amount of heat transmitted are modified by the nature
results obtained on the north and south sides of his observatory, found that the vicissitudes were greatest on the south side, where the thermometers were exposed to the sun and the rain.
The roots of most plants are found within a foot of the surface of the soil, and it is the temperatures at this depth that should becompared with those of the externa air. The Brussels observations supply us with the necessary data for every month of the year, and the following table exhibits the differences between two thermometers, one hung in the shade 21 feet above the surface of the soil, and the other sunk a foot below it both on the south side of the observatory.

|  |  | Degrees. |  |  | Degrees |

Mfan of the Year
Spring
Summer
Comparing in the table of oloservations taken on the north side of the observatory, the mean temperature o the air at ll feet above the surface of the soil with that taken at a depth of 8 inches and 1 foot, we find the following differences

Hence it appears that from the middle of autumn te the end of winter the temperature of the soil is warmer than that of the air at the mean depth attained by roots; and that, on the contrary, at the season when the plan is at its greatest vigour, it is colder than the air. In the one case the maximum difference between the air and oil occur in January, and in the other case during one f the summer months. In no case does it exceed At the end of winter and beginning of autumn period ccur when there is no difference between ture of the air and soil. This fact, combin what of the resuscitation of vegetable life in apris withdrawal in autumn, seems to indicato of adaptation of the cooler soil to the wants of plants at that season of the year. The difference is always greater in summer than in spring, and vegetation is not then more active than in April or May, in the latitude of Brussels. During winter a difference of 4 ? or 5 can have but very little influence in diminishing the effects of cold, for the sap scarcely moves at that season, and the effects of conduction from the roots to the branches must be extremely small. It night indeed be neglected altogether were it not that conn duction at riuht angles to the direction of the fibres of the wood being still less than conduction in the direction of their fibres, the joint effect of these causes is that the tree resiats the effects of external cold, and receives some little heat from the earth. Under any civersence howere in the case tree, or of long in the soil must be absolately insignificant.
On the other hand, during summer, a mean monthly difference of $5^{\circ}$ and even $6^{\circ}$ is of considerable importance; and even supposing it to be reduced to half that amount by the time the sap has reached the leaves, it still lowers very sensibly the temperature of the whole plant. This effect is increased by that evaporation from the leaves which resuits from the descent of the sap during the day, so that the hotter the air is the greater are the resources that the plant finds win the effect of the external heat.

Before, however, abandoning on this account the use of mean temperatures of the air, it is necessary to examine whether the disturbance due to the coolness of the soil in summer varies much in different chmates, or whether it varies slightly and according to the local conditions that occur in almost every country, as the mechanical and chemical composition of the soil, \&c. In the first case if proved, all the summer mean temperatures must be modified, and isotheral lines of another pind rust be constructed in order to apply the facts of the tomperature to the limits of species and to such pheme thowering and fruiting of trees such phenom countries. In the recond case we must an fores in an average soil select for comparison plants growiof conductibility, and posper theirvegetation with the temperatures expressed compare theirvegetation
by the common methoos. Comparing thus observations made at Upsala with others at Brussels, at 2 feet depth, it appears (1), that from October to March the earth gives (2), that the perature at Upsala than at Brossels; (2), that the months during which the earth is colder than the air are reduced to the three of April, May, and June, that during the months when the soil is coolest as com . pared with the air, the difference is less at Upsala than
at Brussels. Since the monthi included between April
and September are those whe temperature exereises most influence upnn the plant, it is less necessary in the latitude of Upsala to correct the mean teroperature of the air
During the winter the soil is warmer in proportion to the air at Upsala than at Brussels; but during the summer it is colder, amounting to
or double what it does at Brussels.
Peninsuia of India), it appears that in Peninsula of haia), it appears that in southern regions, Where the temperature varies but little, the tempera-
ture of the soil at $3 \frac{3}{4}$ feet is always $5^{\circ}$ to $7^{\circ}$ warmer ture of the soll at $3 \frac{1}{4}$ feet is always $5^{\circ}$ to $7^{\circ}$ warmer than that of the air;* a result opposed to all precon-
ceived ideas, for it might be supposed that the rail ceived ideas, temperature being below that of the air, during at leas some months of the year.
It is essential to distinguish between the two causes Which heat the tarth in summer, viz., the temperature of the air and the power of the sun's rays, and the article. J. D. HI.

## Home Correspondence.

Wellingtonia gigantea.-There must be somtthing wrong in the management of your correepondents who grow spindling, or die in places, or look otherwise badly. It is as hardy as an Oake, and as sturdy. This is my case; in 1854 I received from Messrs. Veitch one of or August, I forget which, it was planted on a heavy clay lawn, not aiany feet above the level of the Thamee, in a hole containing an inverted garden pot, and filled whith burnt clay, bits of charcoal left among the clay While burning, and leaf-mould. Over the bottom of the nicely arrnged 0 that the stem rested exactly cn few inches of mould lying over the hole in the fluwer pot. This secured complete drainage. In the winter 1854.5 , the plant was covered with a hand-glass as a protection against accidents, to which its smallness In 1855 it grew famously. In the winter of 1855.6 it had no shelter at all, having become big enough to take care of itself. This year it has dashed off onc this morning I find it has the following dimensions. From the ground to the print, 3 ft .6 i .2 ; from tip to tip of the lowest branches, 3 feet; it has this year alone grown 16 inches. How stiff it is will be seen from the
fact that it girths 4 is inches next the ground, and $2 \frac{1}{2}$ inches half way up. Your correspondents have coddled and spoiled their specimens. Acton, August 5

Permit me to inform you that two plants of Welling. (all from the same source) have suffered in a simila manner to those complained of by your correspondent not only have the ends of the laterals died, but in one cace the leader also. The soil in which they are they not have been over potted, or forced on in the first instance beyond their atrength! Your correspondent does not say whether his are in pots or not ours are bot not the sides, and appear in one instance to have lost the ends of their fibres. The height of the plants could be discovered and made known through your columns, others who may be so unfortunate as to get a touch of this disease (if such it be) might perhaps be able to save tli
stone Nursery.
The Pctato Disease.-Since we were visited with a thunderstorm accompanied by heavy rain ou the 15 th of July, the weather has been unusually dry and warm, and in this neighbourhood (Ealing) within the pasi week symptoms of disease are apparent among the several places, whilst on closer inspection the stems are found to be more or less covered with large black patches. The roots, however, do not seem affected, but re large and of excellent quality. W. B. B.
Gardeners' Bencvolent Inst tuition.- I have just read in Your columns a letter on this subject subscribed "An matters, the secretary of the Institution is charged with receiving "t the proxies of subscribers and using them as he pleases." This charge is made anonymously, and suerefore I have no hesitation in saying to your country subscribers, to whom this communication is more parwholly unworthy of credit. At the request of the secretary I attended the last dinner of the Institution charity; Lut I was prompted by my love for forts of the end a 1 and in helping those who at some time or other had contribu'ed to my pleasure, and who in their old age might require assistance from the funds of the Institution. I gave a small donation, and in a few days the names of candidates for election. A stranger to the * The seme reoult has been arrived at in our own country,
According o the tareful ubservations recorded by Mr. Thomp-
son, at chisick
 also in the mounthinm of Indik. See "Hopker's Himalayan
Journals."
to ask who was the most worthy object amongst the I potted in Norwood loam mixed with a little rotee
candidates, when he replied to my inquiry by saying
"that he never solicited a vote or in any way influenced the election of a candidate ; that he had aiways endeavoured to hold an independent pesition amongst the members; he believed all the candidates worthy support ;" but positively refused to assist me in my no reason to doubt this to be his usual practice.
correspone think he is in any way justified in making these personal attacks upon the secretary, although he is the paid
servant of the Institution. $\boldsymbol{H}$. Wiafield Crewe, 19, Buck ingham Street, Strand,-As the only paid servant this Institution, permit me to answer the allegations contained in a letter signed "An Old Member Committee," in your Paper of last week. I am not in the habit of answering or acknowledging anonymous correspondence ; but as that letter materially affects frat chacter, I depart from my usual rule. In the frst place I am accused of being the director and not as secretary it is committee; to this I reply, that as secretary it is my duty to put the committee
in possession of the facts of any subject under discussion, and to give my opinion when asked
without fear of offending either this or that party. without fear of offending either this or that party.
In the second place I am accused of receiving proxies and using them as I please; the last part I most emphatically deny. As secretary I receive such proxies as may be transmitted to me; I open, examine, and arrange them for the sorutineers on the day of election, but as to using them to my own purposes, this is impossible, as very few have not been previously filled up in favour of
some of the candidates ; and such as are not filled up some of the candidates; and such as are not filed up if request that they will exercise their privilege. During the time I have had the honour to hold offce, now 15 years, I can conscientiously assert that I have never in any one way influenced an election, and in all cases where I have been asked to assis interfere, and in this many subscribers will bear me out. When I have been asked which is the best clusion I beg to say that I have always endeavoured to discharge the duties required of me to the leest of $m y$ ability and to give satisfaction to the members at large, and I have every reason to believe that my services Chrysanthemums approval. E. R. Cutler, Sec.
Chrysanthemums.-Several gardeners have called and othere have written to me respecting their Chxysanthemums looking so sickly and bad ; they complain of them losing their bottom leaves and wish to be informed of the cause. In the squares and other little sumny spots about town they are all affected in the same manner. Now, the cause of the evil is no attending to the following rules:-When hot dry weather sets in the plants should be well mulched with what, provided it keeps the hot sun fro, ho matte the fibres that traverse the surface of the noil; for find that you cannot remove the smallent quanitity top-monld without meeting will roots, and when thes are exposed to the burning rays of the sur, the plant lag and lose their bottom foliage, and will, as may bo expected, flower indifferently; this is easily avoided by which keeps the plants growing, preserves their leaves and renders them ornaments to the garden as far as a healthy green is concerned, which in towns is looked upon as a boon where nothing else will places till pones in pots should be kept in miad times in the course of the season; they should also have a plentiful supply of water, taking cape if the mould hould opea or crack for fill up the gap with a fittie finely sifted eartl. If this is the soil and the pater when applied passes off between no sollow and roe pot and leaves the midade dry; also do not allow the plant to get too high before it is stopped, low enough to give it a geod bushy habit, with foliage down to the top of the pot. Mi dew, they tell me, is very prevalent this year ; this I easily manage to stop by sprinkling the plant with water, and then powdering and in lowers of sulphur. have in my borders of them has lost a single leaf, and they never looked better or healthier than they do at the present time The only pests with which I am annoyed are earwigs Edware I hope now to keep in check by means o Edwards' earwig traps. They eat out the heart of the have tried sulphur, tobacco-water, snuff, Deadly Nightshade, India rubber dissolved, oil, tar, and various other applications, but all without effect. Another circumstance appears to me worth mentioning. I had last year some Intermediate Stocks, which I purchased of IIr. Dancer, of Fulham. I sowed them on July 12 under two hand-glasses. As soon as they were ready for puttiug into potas I took them up, put five in a 6-inch pot market. They filled the pot with roots by December. kept them in a cold frame through the winter till the 1st of March, when they got so overgrown I was obliged to put them into the borders; to
my great disappointment nearly all came single. A portion of the same seed, the remainder of the packe

I potted in Norwood loam mixed with a little rotten
eaf-mould, and found some difficulty to keep them from damping off in the winter, although I never gave them drop of water from November till the beginning of February ; they were planted out the 2 d of April, grew. How is this difference in plants raised from the same seeds to be explained? Samuel Broome, Temple Gardens, August
Bees,-One of the species of fungus named in Mr. Byssus cellaris, always discolours the combs; from the other, the Great Puff Ball, the discoloration is very slight, and the unpleasant scent soon disappears on ex
posing the combs to the air. They are equally $\in \infty$. caciuus and safe in attaiuing the object desired where the combs are not required for use. It is not usuaily cecessary to stupify bees in order to unite swarms or milate readily when merely perfumed with s pufs two of tobacco smoke. A family of "driven bees" scented in this manner and placed in a hive, and then reversed under that to which they are to be joined, will similarly prepared for their reception. The previous removal of the queen will further insure an harmonious union.
Potato Disease and Electricity.-I earnestly request your readers to watch vigilantly the effect of the next tion has been steadily directed to the subject, and I now unhesitatingly declare my fixed conviction that the immediate cause of the Potato disease is electricity acting upon wet tubers. So certain of this have I been for a long time, that I have been able to predict again and aain the day of its appearance, sways within three days of a storm. If the weather continue damp, the now become extensively affected; if hot and dry, as to be convinced as well as myself; hence this appeal A curicus illustration occurred the last storm we had The haulm was struck diagonally across a plot I have about 50 feet long by 6 wide; all outside this space the corners of the ground, and connected them by wires The Potatoes so protected were none of them affected Ihave communicated my thoughts to Messrs. Mechi, think to be best obtained by pullishing them in your ournal. Supposing I am right, it has been asked, what benefit will accrue? I reply, knowledge is power; and although there is still an important question to solve, this malign influence before 1845 , yet it will be something to emancipate ourselves from a multitude of erroneous theories, and the first truth being established the second will probably soon follow. In the mean time, dry planting, dry manures, and lightning conductors are all indicated as likely in some measure to eon, Harw enden Hall, St. Alban's, Herts
Garden Mechanics (Mowing Machines). -The purpose labour, and as machines cannot reason or act arbitrarily in stopping, moving, or altering their process according to circumstances, they proeeed in a blind rontine whether right or wrong-mechanically as it is callednand every case less or more require the superimtendence of reasoning beings. A machine, by being unsucsed of inanimate matter destitute of feeling aind ssigned duty and gue, proceeds unswervingly task which it would be both inhuman and impolitic to demand from living creatures, and yet many human beings are employed as the moving force of yery ill-conatructed machines intended to lessen and aid human labour. We are told by those who have studied the subject hat the muscular energy of men forms the most insufficient or the weakest of all the prime moving forces Human labour is very limited in its compass, and is the least to be depended on for regularity. The powes nothed by one man is comparatively scoail, a large number on individuals to unite their powers in a continued or concerted effort. The mowing machines of the present day, intended to be worked by haman abour, I consider to be an accumulation of mechanica bunders, and ought to come under the cognisance of legislature or the Society for the Prevention of Craely to Animals. The contrivern of these maches to motion apparently collected uearly all the obstacles to motited
within their reach, combined them together, and offed within their reach, combined them together, and toys for
them to the gardening world as playthings, or ladies to work with. Those who use them will find that there is an abundance of friction connected with them and we learn from works on mechanics that frichion acts as a retarding influence in the action of mecbanical contrivances, and a due aliowance mues destroys on made for it. seldom destroys less than a thi d . However small may be, it sooner or liter canses the werring down and destruction of mechanism, and therefore forms an insurmountable obstacle to the lasting duration of bodies and the perpetuity of motion. Friction found to depend on the following circumstances. 1st, the degree of roughness of the surface. extent of surfaces in certain bodies presented to the action of
rubbing. ith, the nature of the bodies. 5th, the
degree of velocity of the motion. 6 tb , the manner of the motion. If these circumstances are properly examined, it will be found that there is much room yet
for the improvement of lawns as well as mowing machines. The following good advice has been for some time before the public, and may be repeated. One of the first considerations on the part of contrivers of mechanism should be how to provide for and
diminish the effects of friction in their machines. For want of forethought on this important point, thousands want of ingenious schemes which seemed perfect in the form of models and drawings on paper have been completely frustrated when attempted to be brought into use. When we bear in mind the weight of the mowing machine, set upon low broad wheels, its line of draught, he real travel with it at the rate of four miles an hour, it will be found in practice that a large quantity of muscular energy is necessary to work it, and that the convict on Castle, are less to be pitied than the gardeners and garden labourers who are condemned to work the mowing machines of the present day. P. Mackenzie, West Plean, Stirling.
Ground Temperature.-The following ground temperatures appear to me sufficiently remarkable to be worth recording. Thermometers sunk in a Peach border about 4 feet from the wall indicated at 1 foot, $72^{\circ}$; 2 feet, $71^{\circ} ; 3$ feet, $63 \frac{1}{2}^{\circ}$. The holes in which they are
sunk are covered over with tiles. The temperature during this fine weather does not vary perceptibly at night. To obviate any doubt of the instruments several Therent is the porous stratum of $r$ ontish some places as malm sock and in nown in of a very pale colour. The garden has been for very many years famous for the Peaches produced in it on the open walls, of which this ground temperature (which I have only lately begun to observe) seems to afford some explanation. The thermometer in the shade has been from $80^{\circ}$ to $87^{\circ}$ at its maximum. It would be interesting to know the temperature of borders similarly situated on other soils J. Rogers, River Hill, Sevenoaks, Aug. 4
Climate.-In your leading article on orchard houses occurs the following expression-" ${ }^{6}$ our deteriorated springs." This opens up a most important and interestchange of climate has taken place in this country? Many old persons declare that "in their young days when George the Third was king" winters were colder and springs milder than they now are. I generally find, on the subject, their recollections are very vague, and do not bear out their assertion of a change of climate. Improved cultivation, clearing of forests, and extensive drainage ought to have improved our climate. If they D. C. L. [This is a very difficult question. Barometers D. C. L. [This is a very difficult question. Barometers facts for several reasoas. But the continual loss of spring crops in the neighbourhood of London cannot be denied.]

## 马atietios.

Eivtomological, July 7.-W. W. Saunders, Esq., F.R.S., president, in the chair. This meetiag was a special one for the appointment of a seeretary in the place of Mr. Douglas, who had resigned, and upon ballot Mr. Janson was elected in his stead; a vote of thanks was thereupon passed to Mr. Douglas for his services during the past seveu years; as also another to the presiannual excursion to Reigate. A numerous list of donations to the library was announced, including the fine work on amber insects, by the late Dr. Berendt, of which an account was given by Mr. Westwood, who primeral insect world, so much more satisfactorily preserved ins amber than in stone ; and trusted, as the preserved ill amber than in stone ; and trusted, as the secured for the British Musefim, where it ought to form portion of the zoological rather than the palmontological eries. Mr. Douglas exhibited four new British species of minute moths belonging to the family Tineidee from Boxhill and Brighton. Mr. S. Stevens exhibited various interesting Coleoptera from Scotland and
Wales, collected by Mr. Foxeroft, including Uleiota flavipes and Chrysomela cerealis, also Lebia Crux minor alive, and Agdistes Bennetti (the plumeless plume) reared from the larver, and Limacodes Asellus from the New Forest; also full grown larvee of Notodonta carmelita and Perasia nubeculosa, and a box of beautiful Brazilian butterflies recently received from Mr. Bates, Mr. Augustus Shepherd exhibited a fine speeimen of the rare Gastropacha Ilicifolia, andother rare moths; and Mr. Westwood brought for distribution among the members Ppecimens of Porrectaria Laricella from the Lareh, and hibited some leaves of Whear. The latter also exbeen rolled up by the caterpillars of some species of Tortrix ; also a beautiful new species of Saturnia from Caiifornia, with its cocoons, which had been attempted White and Mr. for the production of silk. Mr. A. White and Mr. Bowring gave an account of various interesting and new insects collected by the latter at
Hong Kong, Siam, and Java. Mr. Willinsou exthibited number of living specimens of the splendid firefly
insects were in a weakly condition, having been brough from Havannah by the way of New York, which had occupied six weeks (during which time they had fed upon moistened sugar), they yet emitted a lovely pale greenish light, which became vivid on their being ex cited, both from the spots of the prothorax and the membrane at the base of the abdomen. Dr. Calver exhibited some larvee of Noctua cubicularis which had devouring the seeds in a growing state when nearly ripe. They were, however, very partial in their attacks as they would not touch one of the species of Festuch,
although they devorred the other. Mr. Stainton read a notice on the study of Microlepidoptera on the Continent.

The Language of Specifications of Letters Patent for In ventions. By John M'Gregor, Esq., Barris
Law. London: Butterworths. 8vo., pp. 133.
All who have been in the habit of watching the fate of patents when their validity is disputed in a court of justice are aware that the language of the specification and useful, and the patentee may be the true and first inventor, the infringement may be clearly made out and yet the patentee may fail simply because the title of his patent does not correspond with his real claim or because he has not performed the condition imposed upon him of particularty describing and ascertainiog the nature of his invention, and in what manner
the same is to be performed. The fact that judges have been, and may be in future, rather astute against a patentee than inclined to give him the benefi of any doubt, only renders it of greater importance to inventors to avoid those rocks and shoals which have so
often proved fatal to others. Mr. M6Gregor in the often proved fatal to others, Mr. M6Gregor in the worl. befrre us has done good service by pointing these been held collection of instancos where a patent ha shows how important it is for a patentee to be hones and full in his disclosures, and not to take for granted that because he understands his own description other found valuable surgestions for describing machinery those who propose to patent new agricultural implements of any degree of complexity will do well to make themselves acquainted with the methods shown by experience to be the best, and before preparing their specifications to study with care the principles which guide judges in construing those documents. For the attainment of these objects the learned author's essay will be found of considerable utility.

The Lost Solar System of th: Ancients Discovered. By John Wilson. 2 vols. 8 vo , Longmans.
What the ingenious author may have discovered w are unable to say; for ourselves we have found nothing in his volumes except a prodigious quantity of calcula tions, geometrical problems, and speculations founded upon what is kuown or reported respecting ohelisks,
needles, temples, castles, labyrinths, sculptured stones Druidical circles, pyramids, and similar ancient remains, The book seems to have no other begioning or end than such as pages give it, and if there is theory buried
amidst its figures we at least have not the sbill to disamidst its figures we at least have not the szil to dis-
inter it. Mr. Wilson has given birth to a great psychointer it. Mr. Wilson has given birth to a great psycho-
logical curiosity, and that is all we can glean from his volumes.
A twelfth edition of Black's Picturesque Townist in Scotland (Black, Edinb.) has appeared just in time for summer travellers. The reputation of the work as a minute, faithful, and well arranged guide-book is so firmly established that it is needless to say more of the present issue than that it is very considerably extended, and in many places wholly rewritten from the personal observations of the editor. Excellent maps, good woodcuts, and characteristie views of striking places in the in the foremost rank among travellers' manuals.

## Garden Memoranda.

Mr. Smith's Nursery, Dulwice.-Balsams, bean tiful varieties of all shades of colour, red, white, and mottled, and of unusual size, are most successfully has here, and every year about this time Mr. smith mode of cultivating them may therefore not be uninte resting. In sowing the seed he prefers the method of putting one seed in a 3 -inch pot, especially if the object anmed at is to exhibit at shows. This should be done July. Place them on a gentle howering in June or tank as near the glass as possible, and the latter should face the south, in order that the plants may be well exposed to light. The precaution of letting all superfluous moistare escape at the highest a quarter to half an inch on bright sunny days if the wind be not too cold or strong; a little more air may be given as soon as the plants have begun to form thei first leaves. When the latter have become fully deve loped the plants should be shifted into larger pots. If plenty of convenience exists greenhouses or interchosen for them, and if it is intended to grow the plants
to a large size, they may be shifted into 6 -inch pots at once and plunged half-way in a bottom-heat of from $50^{\circ}$ to $55^{\circ}$. Thus situated the roots soon appear at the sides of the pot, and before they turn half way round the ball the plants should be again shifted for the last time into 8 or 9 -inch pots, according to the size that may be desired. Thus far size of plant has been the oiject kept in view; but those who have not the above named conveniences must be content to sow a fortnight later; still, however, following the plan just laid down. In this case the first shift ought to be into 5 -inch pote, and if he help of a hot-bed can be obtained the plants may be planged in it, using, however, due precartion to ascerthan that heat at this stage is not too great. Another plan presente itself, and one which Mr. Smith frequently adopts: it is to plant in a pit heated at night from $60^{\circ}$ to $65^{\circ}$, by means of hot-water pipes, allowiog an increase should again be shifted into 8 -inch pots as before for the last time.
These matters as to raising and shifting being now settled, attention must be directed to protecting the plants from sudden chills, either from cold sir or falling off of bottom-heat ; for if once stunted by cold firstclass plants and flowers need hardly afterwards be expected. Plenty of light and air, however, judiciousiy taken to give them plenty of room; to do them justic they should as a rule stand as far apart as they are high. Having now stated the method of raising, potting, nd general management, there yet remains to be ex plained the kind of compost to be used. This should be of top spit about 4 inches thick from a meadow
of lich light loam a year old. If this is not o be had take the same quantity of fresh soil and after paring off the turf from the loam, char the former so as to reduce it to a state fit
for breaking up and mixing with the loam. Add to this an equal quantity of manure from a spent hot bed it be turned over to sweeten and dry before mixing so much the better. This compost should then be hrown together and well chopped and turned (not sifted), so that incorporation may be as complete as possible. In potting always endeavour to sink the plants low enough for the soil to reach the first leaves. lished cannot be done the first time it shousary in orde to obtain firmness in the pot, and also fresh surface of stem from whence to obtain more roots. The pots should be drained increasingly as the plants are shifted and over the drinage shonld be plaeed 1 op inches of fresh manure from the stable. This will be found very useful to the plants as they increase in size. As regards manuxe water the larger the plants are required to be, so in proportion should this be used ; but its application must be left to the discretion of the grower, who will be the best judge how often or how strong it ought to be given, for unskill fully administered it sometimes produces great mischief. In general Mr. Smith has found the compost above recommended and pure water to answer every purpose.保
The above results may also be obtained by sowing in the first or even as late as the third week in April on a slight or nearly spent hot bed, transterring the plants at once to pots of the last-named size, and placing them in a cold pit in the middle or end of May. These bloom in August and September, and will be found to well repay any trouble beatowed on them by an ex cellent display of finely coloured blossoms.

## Miscellaneous.

The l'se $^{\prime}$ of Looking at Plants Geographically-It renains to say a few words apon the general subject of Botanical Geography. It is no fault of M. de Candolle's work that we lay it down more impressed than ever with the vagueness of its principles, the inexactness of its methods, the puzzling complexity of its phenomena, and the purely speculative character o those hypotheses upon which all inquirers base their efforts to explain its facts and develope its laws Much stress is laid upon the value of meteorologica observations, but there is no method of tabulating these that offers a prospect of their being applied to the solution of any one general question in the distribution f species. Certain plants will not survive temperature bove or below a given number of degrees; or in other words, certain sums of temperatures are necessary to the filfilroent of their funetions: this is all the world nows ; but the tabulation of these temperatures has hitherto led to no general laws, for not every family of plants, nor every genus, nor even every species, but often every variety of race, mast have its own sum of degrees to ensure its continued existence. Nor in this al: the sum of degrees must extend annually over a certain definite peried of the year, and must be accompanied with so many favourable conditions of soil, light moisture, and parity of air, that the mere question of emperature becomes a very subordinate element however accurately ascertained. So far, then, as meteorvological observations are concerned, we must consider that, however accurate they be, they have hitherto admitted of no exact practical application with reference to the distribution of species, mor have they even indicated theoretical approximation to it. Next with regard to the limitation of species, genera, and families, within certain areas ; this again is subject
to no appreciable laws ; plants are no doubt governed
in their diffusion by conditons of climate and soil, and are dependent for their diffusion on their own powers of endurance, on the time that has elapsed since they first existed as species, on the elements, on the motions of
animals, and on geolozical changes; but we ant only animals, and on geolozical changes; but we ant only know nothing the geological changes they may hav survived, but all our attempts have failed to regulate their distribution in elevation or latitude or longitude, by clinate, or soil, or other external conditions. Species, genera, and orders stop, we see not why, and ofen reappear where we least expect them. Under of that recognizable relation between structure and function, or structure and external conditions, in the vegetabie kingdom that there is in the animal, and which often enables us to account for a fact in the distribution of an animal by another in that of a plant We see the limit of some aminal's distribution ding with that of the plant it lives upon or under, or that nourishes a third animal it preys upon; but we never see the plant stopped by or for the animal. There are comparatively few evidences of plants being structurally better suited to one situation than to another, with the exception of a few conspicuous classes, our power of accounting by physical causes for the facts of botanical geography is extremely limited. If, again, we turn from those branches of the subject, in reasoning upon which we make use of facts and observations however inexact or difficult of application, to the fundamental principles upon which the study is based, and from some of which we must start in all our investigations, we enter at once into the regions of pure speculation. Nor can there be better prouf of the facts and hypotheses advanced being insufficient to explain geographical distribution, than is afforded by the circumstance that even M. de Candolle, with all his philosophy and desire to arrive at exact conclusions, is compelled to resort to the unphilosnphical proceeding of demanding the operation of two laws to account for each of the two primary phenomena connected with the creation of species. Thus, with regard to their origin, he considers that most are special creations, but that some are the offsprings of transmutations; and with regard to the number created and place of creation, that some are created as solitary individuals or as a plurality of individuals in one place only; and that others are (simultaneously ?) created in several more o less distant localities. We are told that the majority of species were created such as they now exist, but there is not a shadow of a proof of this. No amount of scute observation or critical disquisition throws real light upon this subject, upon which men of science are completely at issue ; nor is there in the present state of devce any prospect of naturalists agreeing upon it. There are, as it appears to us, two broad facts, and only two, to which all naturalists must turn who seek some foundation for an opinion as to the origin of species, and these lead to diametrically oppusite conclusions. They are, on the one hand, that a great number of allows iorms are hereditary in as far as our experience number are extremely variable and that races with .characters as strongly murked as those of species are constantly being produced under our eyes. From 'Ilooker's Journal of Bctany.

Calendar of Operations.
(For the ensuing qeeek.)
plant department
Conservatory, \&e.-All hinds of soil used in potting should now be laid in without delay before the ground gets sodden with autumn rains. Store them up neatly in narrow ridges, so as to be safe from wet and yet exsuccess in plant growing very much depends upon having suitable soil for potting, no trouble or expense that may be necessary to procure this should be spared where well grown specimens are expected. Loam of moderately good quality may be obtained in most neighbourhoods, but good pent is not so easily got ; this is absolutely necessary, however, for the growth of choice hard-wooded plants, and should be procured at the proper season, so as to have it in a fit state for use
at the right time. Stove plants flowering in the conservatory will require attention, especially Achimenes and things of that sort, which should be gone over every day in cloudy weather, carefully picking off decayed flowers, \&c. Any of the twiners on the roof to prevent their shading the house too much, for after this season permanent shade should be avoided as much as possible. Young stock in cold pits intended to flower next season should be exposed to sunnght in order to ripen the wood, taking care, however, not do this so rashly as to injure the tolage.
FORCING DEPARTMENT.

> FORCING DEPARTMENT Those who incead comma

Pineries.-Those who intend enmmencing the culture of Pines on the open bed system cannot begin at a more from 18 inches to 2 feet deep, and should consist principally of good rich mellow turfy leam, well broken up, and carefully intermuxed with a liberal sprinkling of clean sand, and a small proportion of leaf soil or good rich fibry peat ; for when rough turfy soil is used and the bed is ever, from any cause, allowed to get thoroughly
dry it is very difficult to moisten it again, as the
water passes off through the lumps without pene-
trating them. But if the loam is well hroken up and trating them. But if the loam is well hroken up and
mixed with some leaf soil, or peat and sand, it will be found to take water freely enough, and the roots will be almost as much under command as when the plants are grown in pots. Persons commencing this method of growing Pines should also endeavour to avoid planting out pot-bound plants, for these, whether young or old, seldom strike freely into the fresh soil, and
are very apt to fruit prematurely ; but if such must be turned out, then care slould be used the soil firm about the balls, so as to prevent the water passing off without moistening the balls, Vineries, planted this spring where strong rods are expected. Let a vigorous root action be secured and endeavour to get fine wood well ripeneno. Give air freely and early foliage, but shut up early in the afternonn, sprimking the floors, \&e., so as to cause a genial moisture in the atmosphere, which will be of great service in strengthening the Vines. If plants are grown in the house, see that they are not infested with black thrips, and on no account be induced to regulate the temperature, $\& c$., of the house for the plants, but remove these to other quarters, or make them succumb) to the treatment most suitable for the Vines. Keep a sharp look-ont for the appearance of red spider in houses where the fruit is ripening, and coat the pipes or flues with sulphur on the first appearance of this enemy. Indeed it is well to do this occasionally by way of a preventive, which, in this case as in mostothers, is vastly preferable to a cure Vines in pots intended for early forcing will requir attention to get the wood properly ripened, and this should be effected by expusing them treely to light and air
flower garden and shrubberies.
In some neighbourhoods green fly has been troublesome to Verbenas, \&c. Where such is the case, tubacco water and soap suds may be used with success. The strength of the mixture should be tested by dipping some or the shonts worst affected into it, and used sufficieutiy the leaves. It should be applied in the evening when there is a prospect of a dry night, using a fine syringe or fine rosed watering-pot, and giving enough to moiste the whole of the foliage. Go over the beds frequently loss of time, for the bedding out plants are enjoyed but for a comparatively short season, and now that they ar in beauly every means should be used to render them as enjoyable as possible hy maintaining the most perfect order and neatness. Where the stock is clean, and growing vigorously, this will involve considerable labour, and it will be necessary to go over the bens frequently, pegging down where necessary, removing decayed flowers, and cutting back such of the shoots as may incline to encroach apon the edging of the beds. Keep herbaceous plants neatly tied up, and cut off the flower stems of any that are becoming unsightly. Take advantage of leisure hours to put in cuttings, and use every possible despatch with this work until there is \& good stock in a fair way for rooting of such things as are known to be difficult to winter, except in the shape well-established plants. Keep gravel walks perfectly
clean and smoth by weeding sweeniug, and may be necessary. Keep climbers on walls within due limits.

## hardy frut and kitchen garden

over luxuriant, and stop about half the shoots, beginning of course with the strongest, for a general stopping at this time would probably be of little farther service spray, wheres stopping the stronger shoots or those which incline to grossness will divert the sap into the weaker ones, which will be strengthened, while the buds on the shoots that have been stopped will become full and plump without starting into growth. The only effectual method, however, of curing a gross habit of growth when this is the case in ordinary seasons is rootpruning or keeping the roots within proper limits by means of shallow well drained borders. Should it be found that the shoots, after stopping, incline to start into growth, it will be advisable as soon as the fruit is gathered to open a trench at a moderate distance from the stem of the tree, cutting the stronger roots. This will be of the greatest service in cheching growth, and will probably do more to wards securing ripe wood than anything else that could be adopted. Get the Strawberry plantations intended to stand for next sesson trimmed as soon as convenient, cutting off and clearing away the runners, so as to afford the leaves plenty of room. Attend to providing plenty of Lettuce, Endive, $\& c$. . for winter salads; also see that there is a good bed
of Parsley provided in some sheltered spot where it can be readily protected in severe weather

## Cht Aoricultural Gastte <br> SATURDAY, AUGUST 9, 1856.

Mr. Carr, a manure dealer of Colchester, supplies Mr. Barnard, of Earl's Colne, with guano, and until the delivery of the last 50 cwts, ordered and received, the latter has been perfectly satisfied with the material sent to him by the former. As regards this last quantity, however, it appears that the men who sowed it knew it was not guano, but thought it was something else their master was trying. Mr. Barnard on finding out how different this "guano" was from the last received, sends a sample of it to Mr. Carr, who replies with regard to it, that there appears little reason to find fault with it, he has made experiments upon it and finds that it contains both phosphates and ammonia; he proposes, however, to pay for a full analysis provided Mr. Barnard will share the expense if the result should prove it to be genuine 「'eruvian. All this was in the month of March.

In May the guano is returned to the merchant who replies to his customer, "You have kept it two months and exposed it to the air, and the ammonia, its fertilising quality, has escaped-therefore I refuse to take it back." An action is accordingly brought by Mr. Carr against Mr. Barnard for the amount due, namely, "296." for $2 \frac{1}{2}$ tons of "best Peruvian guano." Mr. Barnard pays 9l. 3s. into court, and pleads that that is the full value of what was sent to him. To prove his case, the evidence of Professor Way and of Mr. Landelle is obtained. These gentlemen agree in their analyses, which prove that the sample they, received contained less than 2 per cent. of ammonia, less than 8 per cent. of phosphate of lime, more than 16 per cent. of gypsum, and more than 50 per cent. of sand and clay; in fact, that the material analysed was grossly adulterated guano.
On this Mr. Justice Erle sums up and says:-"If that sample represented the bulk it would settle the question; but the case on the part of Mr. Carr is that it was not an honest sample because the quano the 29 th of May, and in July this sample without any particulars as to how it had been kept was sent to Professor Way. The bulk was in Mr. Carr's yard, and if Professor Way had been sent there to obtain a sample for analysis it could have been decided to a dead certainty, hut this sample came from some part kept back, and how it had been used or where kept they had no information."

The jury, after a brief consultation, found a verdict for the plaintiff for 19l. 18s. beyond the sum paid into court.
Such is the history of a trial at the assizes last week at Chelmsford. The defence of Mr. Barnard imputation on the character of the latter It is suggested by the defendant that his misfortune has been altogether accidental; but he says he has not got the thing he bargained for; and it seems plain therefore that it is certainly his own fault that he has lost his cause. The defect in his case was the entire abrence of evidence to prove that the sample anslysed fairly represented the bulk complained of.

The lesson which his experience teaches must be plain to every one.
We are glad to say that in answer to our invitation, p. 457, we have received several sets of replies to the questions of the Agricultural Examiners at the late annual examination of the Society of Arts, We shall be able within a fortnight to name the anthor of the most perfect among them.

What is a Manure? -This question seems to puzzle those whose business it is to attach a meaning to the word as it occurs in various Turnpike Acts, The object of the exemption from toll which these confer upon "manure" certainly was to encourage every effort to obtain an increased produce from the land. And in this view, therefore, we must contend that the words "manure" and fertiliser are exactly alike in meaning.
This question was argued before the magistrates lately at Weston-super-Mare. Some farmers at cause why they did not pay toll for loads of sand hauled from Weston-super-Mare beach to be used as a fertiliser on the heavy lands of that district. It was then held that if used in its raw state for spreading on the land sand was not liable to toll,
but if first used as bedding for ca'tle and then put on the ground it was liable. This was not, however, satisfactory to the turnpike Joseph Bishop, the collector of the Worle turnpike toll, was summoned by Henry Welsa for unlawfully demanding a toll from him for a load of sand, which he was employed to hanl upon the lands of Mr. Moses Stabbins. Mr. Millard appeared on behalf of the collector. He contended that sand is not a manure at all. What is sand? Is it not a collection of small particles of stone? What is manure? It consists of any quantity of animal or vegetable matter used as a fertiliser of the soil. sand consists of small portions of rock which by no process could be changed. If you mix it with animal or vegetable matter it remains sand still Peace, which he said was regarded as an authority by magistrates, in which it is decided that sand is not a manure.

On the other hand Mr. Stararns, the complainant, stated that he and many of his neighbours had used sand as a manare, and had found it very efficacious on the heavy clay lands round Worle ; it served
to lighten the soil. He had ased it without any admixture, and it was sometimes used as bedding for cattle and then put upon the land.

The various Tarnpike Acts were referred to, and the magistrates were divided in their opinion.
It is plain, if the words of the Act are to be constıued in the spirit of it, that sand, used for the purpose to which Mr. Moses Stabbins was applying it, is a manure. It seems that the Act enumerates "dung, mould, marl, compost," and if Mr. Millard had confined himself to a discussion of the terms employed, "e should have no right to argue the matter with him; but his argument was not founded " "complost" being neither "dung, mould, marl," nor "compost," but apon its not seting as a manure. He was willing apparently that the spirit and not merely the letter of the Act should guide the decia fertiliser. To this it was a sufficient reply that Mr. Stabbins and his neighbours had used it as a manure, and had found it efficacions. But apart from actual experience in any particular instance it may be shown that sand is in every respec fitted to (1) in furnishing the building material of plants (2) in openiug the soil to the influences of air and moisture which tend to the activity of what fertilising material may already be present in the landit is on this ground that much of the difference and (3) in itself acting on material in the suil, Which if not so acted on is comparatively
of these particulars sea-sand may be operative as a
manure. Sand, according to Mr. Milcard, consists manure. Sand, according to Mr. Millard, consists
of "small particle" of rock which by no process can be changed." It is evident that Mr. Millard is no disciple of Tour; the thorongh tillage which measure thended owes its influence in very great measure to the changes which are thereby effected on the small particles of rock of which the soil
consists. Small particles of limestone rock, or what is their equivalent the particles which comminuted sea shells present, are soluble in rainwater, and thus (1) furnish in a soluble form matter which the plants require as food. But (2) sand on clay land such as Mr. Moses Stapeins cultivates confers porosity, and so enables the action of rain-water and of air on matters in the soil which if not so acted on would be useless to the growing plant. It is plain that even though sand were small particles of rock incapable of change, it would be an extremely fertilising agent when applied to stiff clays, whose fault as compared with fertile loam is very often simply a deficiency of the sand which Mr. Millard here condemns as aseless. And (3) we have little donbt that a calcareous sand such as that of Weston-super-Mare yields to rain water that which not only feeds the plant itself, but by its action on other matters in the soil provides food indirectlv.

In all these particulars sand is the fertiliser which Mr. Moses Stabbins has found it to be; and we hope therefore that the decision of the magistrates, much in the interest of agriculture as the Act intended it should, and as on the previous occasion it was, when the question was disenssed before them.

They write from Ronen that some losses have been sustained by feeding foals with Trifolium incarnatum in flower. In their stomach were found pellets, at first supposed to consist of hairs, but which than Trifolium blossoms on which the animals had been feeding. When out of flower (we presume before coming into flower) no such balls are caused by the plant.

## DIARY OF A DAIRY FARM.

This is a good time to commence making loaf or truckle cheeses, which are made from six to nine inches deep and about nine across. It being rather diffiealt to fill vats of this description, it has been found more convenient to have the vats made of rmall staves in the same manner as a pail or bucket with white hoops round them, and without bottoms, a piece of board rather larger than the vat being provided to place at the bottom when the cheeses are being made, and kept underneath until they are turned out; this being apart from the vat makes it much easier for taking the cheese out for the convenience of turning and salting, the shape of the cheese therefore will be mach improved by this plan. These cheeses if not made with great care are very apt to bulge in the sides, and thereby lose their besuty; and not only is the appearanee affected, but the quality also is inferior when the cheese do not retain ne proper shape of straightness on the sides, and flat-
ness on the top; the shape consequently mariss the quas on the top; the slape consequently maris the these cheeses for a time wheu first placed on the shelves to prevent their getting out of shape, but this is seldom necessary when the cheese is well made. When the
vat is about half full a small tablespoonful of fine alt should be put into the middle of the cheese, and well rubbed into the curd, taking care that it does not apread to the outside, which would cause it to separate and be of injury to the cheese. In making truckle cheeses the curd should be quite sweet, thoroughly crumbled, and made as dry as porsitle hefore filling the vats, and it should be pressed very firmly iu with the hauds, and allowed to remain in the press four or five days, turning them every day, and salting them three times.
Truckle cheeses alter being kept 12 months are fit for use, they always bring a higher price than other cheeses, and are recommended as the most convenient size for the table, and when the top is carefully cut off
in one piece, it caa be used as a cover to the cheese, which will keep it from becoming dry during the time of consumption ; exposure to the air invariably deprives all cheese of its original freshness of flavour. This form of cheese is in some dairies made throughout the are ever made. There is lowever a risk under ordinary management of their bulging and heaving during the extreme heat of the summer, owing to fermentation; and this difficuity does, therefore, in most dairies conmonths, when less heat interferes with the ripening of The fact is that tew people know how to niake good "truckles ;" the difficulty being, however connected with the quality of the pasture as well as with the skill of the dairy-maid. Wbereas on almost any pasture good thin cheese may be made, yet truckle cheeses seem to require a peculiar quality of Grass.

A word or two may be added on Devonshire cream :In making Devonshire cream for the table and also for butter, the method is to set up tins of milk for

12 hours, then place them either upon a stove or upoe an ironstand in a furnace of boiling water, tho milk should be heated until quite scalding and
skin appears to form over the surface of the cream; skin appears to form over the surface of the cream;
but it should not boil. It should then be care fully taken back to the dairy and allowed to stand 12 hours longer befure it is skinmed, when the cream will be found of great thickuess, atd can readily be made into butter by merely beating it in a bowl with the hand; half an hour is generally a sufficient time for this operation. This plan of course only allows of the milk being once skimmed; butter made thus is generally very sweet and good, and it is imagined there is no loss of cream, the extra thickuess quite making up for the loss of the second skimming of the milk. The Devonshire method of butter making may be practise with advantage in a small dairy, but would not be so serviceable as a churn in a large one.
Any of the herd of dairy cows no expeeted to calv next season should now be dried and turned off as
yrazers, as the flesh they will gain before winter is of more value than their mink for the remainder of the season ; and by giving them a good run of Grass, they will have made considerable advance towards fatness, so that when the keep in the Grass field becomen ahort,
they will be in euch condition as to be sold at once advantage, or by giving them so be sold at once to a little hay they would soon become very good beef if their room is required for other fattening stock, or pay for a greater consumption of winter food.

HOME FARM MANAGEMENT.-No.IX.
Nothing is more necessary in high farming than a correct knowledge of the natural peculiarities of culti-
vated plants, and an acquaintance with the general vated plants, and an acquaintance with the general
mode of treating them beat calculated to ensure mode of treating then best calculated to ensure a
maximum produce. The adaptation of particular plants to the soils on which they flourish with the greatest success, is always a point of much practica impurtance to the farmer. To render his discrimination as pertect and complete as possible he would require physiology, and should take evary means vegerabio the circumstances under which the various species of field plants are, or are not, predieposed to disease. It is not to be expected of course that a farm manager can have nuore than a general knowledge of scientific primition of plants, but if he is really possegsed of this he will be in a favourable position to lay hold on sound experimental facts, as they are brought before him from year to year in the course of his management. O practical experience the farmers of the United Kingdom
have already erected some of the noblest systems have already erected some of the noblest systems
of management of which the agricultural art can boast Step by meat of which the agricuitural art can boast practic step they have proved the actual value in recognised ev belonging of farming which is riew tural systems of the country. And if they have sometimes been over-cautious in admitting in to their favour improvements in farm management suggestoc by men of science, there can be no doubt that good as well as evil has been the result of this procedure. All farm practice is neeessarily founded on theoretieal primeiples. The latter may not be understood by the maxs practical man, even when he is from day to day uneome sciously dependent on their action for his success in hil calling. He takes care to sow his seeds at the time and in the way which experience dictates-apply manures
because he knows they do good though be cannot give because he knows they do good though be cannot give the exact reason why-and altogether the rules of good
farming common to the district keep him right in great measure in practice, while he is notwithstanding perfectly unable to give theoretical reasons in detai why they should do this. It is my intention in this and a future letter to refer to the best modes of rit be of advantage to state with the greatest possible brevity the leading principles which are called into action in the development of plant life.

Beginning with the germination of seeds, we shall find that here science bears a very intimate relation to practice. When a seed is deposited in the soil, its integuments and cells are softened by moisture, and part o its carbon being slowly converted into carbonic acid absorption of oxygan from the atmosphere, a sligh evolution of heat takes place. By this partial fermen of the a portion of the albuminous or azotised man and another po acid (either the acetic or lactic acid), which, acting on the starch and gum present, change them into sugar. On the sugar so prepared the embryo in ordinary cases is nourished until its rootlets are extended far enough to draw on the resources of the soil. Now it will be observed that this process can only be effected in a proper manner when the management of the farmer what it ought to be. The seed must be covered with muist soil; but if it is too far below the surface, or imbedded in wet plastic clay, the chemical agency of the sun's rays and the influence of the oxygen of the atmosphere will not have their due effect in promotigg speedy fermentation, and of necessity the germ will rin Or if the temperature of the soil is below a certing point germination cannot take place, and accorand winter. All these peculiarities indicate how necesse it is that the farmer should sow his more delicate need
only at the right time aud in the right way if he wish to have a promising braird. advantage we must know something of the nutrition of plants. When a plant sends out its roots it obtains nourishment from the soil, and in consequence
becomes larger in size. But how does this happen? Is becomes larger in size. But how does this happen? Is the roots, and affer undergoing a change are deposited in the interior of the vegetable structure? Well, what ever the means may be by which the revelopment of either our root or grain erops is effected, everything connected with it should be understood by the bailiff of a home farm, otherwise he is not likely to set an intelligent example to the numerous tenant farmers who are
watching his every movement. Of course a full notice here of the plysioloyy and nutrition of plants would open uptical farming, but I shall endeavour to conf to practical farming, but I shall endeavour to confine which relate to these important matters. It may be stated as an undoubted fuct that the soil of itself is as incapable of producing a crop, as either the sea or the atmosphere is. The elements supplied by even the richest soil are simply the dry bones from which the framework of plants is derived. The life, the vigour the colour, and the nourishing principles which they
contain are all to a large extent abtained from the contain are all to a large extent abtained from the
atmosphere. Yet, there is such an intimate conatmosphere. Yet, there is such an intimate con of nutrition that the farmer cannot add fertilising in gredients to the former without increasing the action of sider for a moment, that the ingredients which plant receive from the soil are only to a very small exten really nourishing in their nature, till they are exposed o atmospheric agency in the leaves of the plants. If the various inorganic substances which the roats assimi give an impetus to the in proper proportions, they iving an impetus to the from the carbonic acid of the atmosphere. But to do this with the greatest advantage the manures must be applied not only in the right quantities, but the bear a well proportioned relation to each other. uppose, for example, that a home farm manager is some light piece of land very heavy crop of Turuips on chemistry and vegetable nutrition he applies a large quantity of purely ammoniacal manures-well! what rould be the result in this case? Why, a very rapid growth would carry the young plants into full leaf at an early period - the organic or atmospheric elements routurally supplys due proportion unless the soil could the development of proportion of inorganic ingredients adeed. Talk of finger and would be very defective similarly hurtful diseases in other kinds of cultivated plants. But could suything be more likely to predis pose our field crops to disease than a disregard in this manures by which they ere to tortion in the prepariug of species of plant consists-in addition to its organic ing it with a manure we should subtances, and in provid position of comportion to that of the organic substances. Notwithstanding all that has been stated in the discussion between Baron Liebig and Mr. Lawes on the socalled "mineral theory," the principle always insisted upon by the former is a fact and will over remain one -that if soluble inoryanic substances are applied to the oots of plants in proper proportions, these plants will abtain from the atmotphere the ammonia and carbon necessary to give them a normal development. The we now apply them arises from the fact that e have not yet found out the right mode using inorganic mauurem, and that we wish extremely heavy crops within a given time. But Jethro ounduess of the great principles referred to It may be a question of expediency to apply ammoniacal manures to the soil instead of having recourae to thorough cultivation to draw out its latent resources, but certainly it is not one of necessity. What does a salt of position of then applied to the soil but effect a decomcontact with? In the absence of thorough pulverisstion and complete exposure to atmospheric air, it is the only agent capable of liberating sufficient inoryanic matters to afford nourishment to the crop about to be grown. Have we not in this fact a satisfactory explanaammonia is required in a manure practice far more Whan can afterwards be found in that crop? Professo Way considers that much ammonia is lost in supplying this may of a Wheat crop with its coating of silica, and probable possibly be the case. But it is also very manure remains locked up in the soil for years in the form of an insoluble double silicate. On this subject and a very cultivates it rightly is sure to reap a rich harvest.
should neve the thing which under any circumskances this-that the development by the agriculturiat, and it is directly dependent on the amount of solar influence the
which thick-sowing farmers wouli do well to ponder If they insist on growing luto plants where only 600 should be grown, then they must not exfect to they miuht haver agregate jield from the former than hey ought to be contented with produce of inferior quality. A full exposure to atmospheric agency is always uroductive of good renults in the elaboration of any of calivated crop, provided that that exposu J. Lockhart Moston.

## Home Correspondence.

Destructive Birds and Vermin.-As the time is again approaching when corn of all kinds is generally most evoured and destroyed by predatory birds and vermin f various descriptions, particularly by the sparrows, with guns and traps and bird-nets for their destruction. All mancouvres of chasiny them off or frightening them and other expedients of this kind, generally prove fruit less, thouuh very expensive. When once they become inured to noises and to strings with feathers attached, ce., all endeavours of this sort are of but little use. The best prevention we lave ever discovered of thi kind is to kill some and hang them up as examples, and as a terror to the living. Another is a suffed cat's skin which however will answer only for a time, as we have ourselves seen ohaffinches plucking off the fur to build heir neata with. We have also seen birds frequentl perching upon the head of a mawkin, though it ha body. We say townspeople should bestir themselves in this matter as well as farmers, for it is to the interest of he one as to the other-all must be fed. Supposing only one peck of corn per acre of Wheat, Barley, and
Oats (to say nothing of seeds), to be devoured aud ats to say nothing of seeds, to to evoured and
spoiled by those depredators in England, Sootland Ireland, and Wales it would amount to some millions of bushels more for our use of what we do really grow and if we would we might grow an inamense deal more Iust form the idea, which is a true one, that one sac Preas would starve a pair of pigeons in a year, were they allowed to feed upon them as they pleased. The writer has often seen many pigeons and $r 00 \mathrm{ks}$, the property of other people, feeding on corn with impunity belonging to himself and othert, when they were not a whelcome. As to the rooks, disputes often arise is quer they do us more good than harm. We answe arge rionegatively. A neighbour of ours who has caring for the circumstance thar $\therefore 0 l$. would not repay us and one of our other neighbours for damages done by rooks to various crops of garden Peas, which we have culti rooks this year only. He contends that were it not for could be grown. Our reply to him was, "Neither can there be as it is, as on one acre of spring Wheat sow least three-fourths of the seed corn was destroyed by his rooks; and had not 'thin seeding' been very much in our favour, at least i 0 l . loss must bav been incurred to us thereby, and as it is we really be lost is worth 12s. per bushel." This gentleman ha great notoriety for growing great abundance of crops of ail productions in his garder, and we asked him very politely and good humouredly if all this is occasioned by his gardener allowing all his rooks to enter his garden when they pleased to destroy the larva of iusects? Or a Surely not," be said " thourden do grow the fines crops imacinable." He felt confused at this reasoning and bowed respectfully to our remonatrances, and said that he did not wish to keep them to annoy his neigh bours. We contended that whoever kept rooks and pigeons ought to maintain them, as much as if they were omesticated poultry, \&cc. If any of our able statists will take the trouble to get a supposed estimate of what dess, pigeons, birds, rats, and mice consume and to unthiaking minds, and we trast will lead to a partial annihilation at least of such pests to the future wellbeing of not only ourselves but of our countrymen at larga, Hardy So Son, Seedyrowers, Maldon, Essex.
Crops in the North of England.--I have recently been aver a considerable portion of the counties of Durham and Lanesster, and of the North and West Ridinge of Yorkanie. I do not mean that I have performed a raiway journey through the districts, but, in the discharge of my professional engagements as land agent have been over a good deal of the land, and carefully examined the crops. The following is the opinion I have formed after this iospection. The hay harvest is now about, and in consequence of the dull weather up to last week, only just about over. The crop has not been a large one; but it has nearly all been secured in capital condition. Wheat- Upon good land, under air cultivation, Wheat has shot into ear better than was expected; in mome fields it is thinner on the ground, when you are among it, than it looks from the atide, soils, wet clays, and farms in bad cultivation, the crop considerably below an average. This summer, until very recently, has been a dull one, and for want of sunshine Weat on this sort of land has shot into ear very
slowly, and the ears are small. Barley is most promig-
g everywhere. I do not think I ever baw finer crops Barley the crops are magnificent, while on wet neglected soils many of them will never shoot into eare ; but I think on the whole the crop will be an sverace one. Beons are not a great length in the stalt, bat bloomed unusually well ; I find, however, on examination that no useful pods have been formed on the upper part of the stalk this is attributed to the effect of the frosty night we had last month. Turnips, -Swedes sowa early have done well, and now cover the ground; those intended to be well, and now cover the ground; those intended to be sown in the latter end of May met with a very wet season ; on much land Swedes could not then be got in, and Yellows had to be substituted. These and the Whites have brairded fairly, but they are late, and I do not consider the general crop of Turnips by any means safe yet. Potatoes have been planted to an unusually great extent this year; guano has been freely applitd, and thus far the crop is exceedingly promising. To show how expensively this crop is now prepared for, 1 may state that a gentleman of high standing and farming his own property in the West Riding told me that his Potato erop stocd him, on a moderate estimate, in manure, sets, and cultivation, to $13 l$. per acre; but he last year sold his whole crop at $21 l$. per acre, and the purchaser had so take up the Potatoes. This may be taken as a fair specimen of the high farming many of these spizited agriculturists are now following, and when it is added that not a weed is to be seen on the and, there can be little doubt of beautiful and abundant cops being the result. Roaldus
How to Preserve Turnips from the Fly, dec.-I have this year growing in a field of 10 acres a crop of dibbled Swedes that have come up very thickly, nol one plan, nor which appears to havo been attacked with the fy, nor have birds apparently moleated them, whereas in another field on the same farm, at some distance therefrom, these pests have done much mischief. Along the headiands of the former feld were deposited, about the end of April, in a heaped row, the weeds and other rubbish taken out in cleaning it. This heap, after being covered over with a layer of sods and earth, was ignited along its entire length, and it has kept smouldering ever since, emitting all the time a good deal of smoke, which, as the wind has been generally from that quarter, has almost constastly hovered over the field, so that to this circumstavee I have no doubt may be attributed the complete preservatiou of the plant from the ravagea above mentioned; and, moreover, instead of the smole doing any injury, it appears to have afforded benefit by causing the foliage of the plants to assume a darler colour, as well as their growth to be stronger. The land ed in the common way with farm-yard dung.

Monthly Councle, Aug. 6.-Lord Portman, Trustee ${ }_{2}$ the chair. Thirty-three new members were elected. Finances.-Mr. Raymond Barker, Chairman of the Finance Committee, reported that the current cashbalance in the hands of the Society's bankers in London was 2;81l. He laid before the meeting the usual quarterly statements connected with the different branches of income and expenditure. He reported best thanks of the Council should be given to Messrs Sparrow, Round \& Co for the great courtesy and xactness with which they had acted as the local bankers of the Society during the period of the Chelmsford meeting. This recommendation was unanimously adopted by the Council.
Housk-The report of the House Committee in reference to the repairs required in the Society's House, was read and adopted.
Reaping Maceines and Stram Cultivator-Reports having been read from the stewards and judges at Chelmsford, the following decisions were made:-
"The Council anthorise Sir Archibald Macdonald and Mr since the Cholmaford Meetrng to be made, befnre the trial at Boxtead Lodge, in the reaping machine of Messrs. Burgess \&
Key. The application of Messis. Dray \& Co. to remove an imenable their reaping machinc to work as intended, to be acceded the princupal works of the machine readered expedient in conse quence of the trial at Chelmstord.
13th and 14t days of for the adjourned trial at Boxtead Lodge be the "The Cormell consent

Protests and Recohmendutiors - Probests con nected with the Chelmsford Meeting, and recommenda ions in reference to points connected with future country meetings, were referred to the Stewards for repective repurts.
It is understood that the trials on the first day namely, on Wednesday, the 13th of August, will be engineer may have fullif and uninterrupted opportunity

0
Country Committee.-The general Country Committee for next year was duly appointed ; Lord PortMan being the
Comminications from the Earl of Clarendon on the progress of the Polish cattle murrain and the German wool fairs were announced as referred to the Journal Committee; Prof. Way laid before the Council his analysis of the bat guano forwarded on a previous occasion from the Foreign Office; his Excellency Lord
Cowley transmitted from France a work on the cultiCowley transmitted from France a work on the culti-
vation of Wheat; and Mr. Whiting, of Beaufor House, specimens of the new fish manure, manufacture by the London and West of Ireland Fishing and Fishmanure Company.
The Council having granted to the Secretary and the Clerks of the Society the usual vacations, aljourned over the a
November.

Highland Societr.-At the Inverness meeting this Society, which is too late in the week to enable us to give a report to-day, we understand that the entries of live stock, implements, \&c., are much larger than they were at the same place ten years ago $; 240$ cattle are
shown against 219 in $1846 ; 204$ sheep against 133 ; 331 implements against 59 . One thousand pounds are given away in prizes, and the complete management of
Mr. Fisher Hobbs, who is furnished with all the appliances that ample means and intelligence can supply furnish the materials of a very interesting paper, the substance of which we shall probably transfer to our columns another day.

Yorkshire Agricultural.- The annual meeting of this Society has taken place during the past week at Rotherham. A large show of live stock including no fewer than 170 entries in the horse class, a good show of poultry ( 300 pens), and an excellent coilection of implements, to which most of the agricultural machine
makers of the country contributed either directly or makers of the country contributed either directy or
through their agents, rendered the gathering particularly interesting and successful.

We have space for little more than the prize list, but must first allude to a very fair and excellent trial of the reaping-machine. Two only of the several forms of reaper competed for the Society's award-Hussey's by Deane and Dray, and Palmer's Union Reaper, with his patent side delivery. The trial was not so interesting as tions of all the respers now in use, but from being later in the season when the efficiency of the machine can le in the season when the efficiency of the machine can be The prize was awarded to Palmer's Union reaper. The prize was awarded to Palmer's Union reaper. that for horses is not made till later in the week.
SBore Horved Cartis.--Old Buls. 25\%. To Mr. Ambler,
Halifax, for Grand Turk; 101. to Loord Feversham, for 5th Duke

County of CORK.-At the late meeting of this society Sir Richard Kane made the following remarks on relations of selence to agricultural improvement :-
"The agriculture of this country must, like the other departments
 restits of our milid and favourable climate, and the exuberant
fertily of our soil, but in order to keep pace with agricultural improvement in other countries, in order to hold our place in a
finamcial and induatrial print of view with the farmers in other

$$ een carefully calcuvarious fertlisug ingredient mentionet an at present be obtained by farmers in this country, will afford the purchaser of manures the means of judying how iar the contain, is worth the price demanded for it. It will be perceived that the price which we have affixed to phosphate of lime rendered souble differs considerably from that which has been adopted in the excellent paper which Mr. Way some time ago published in the Journal of the Royal Agricultural Suciety of England,-viz $32 l$. $13 s .4 d$; but Dr. Ritchie, from his experience as a large purchaser of bones and manufacturer of mauures, ggrees with me that the value per ton which I have

given-viz., 25l. - fairly represents the price at which that substance could be prepared by the farmer from bones.
How Farmers may detect the Adulteration of Guano.As it may occasionally be useful that farmers should be enabled to test the qualities of guano, I have, from a careful consideration and examination of various methods proposed for this purpose, devised the fonowing facilities for a more extended chemical analysis, may be adopted :-1. Weigh 50 grains of the sample, and dry completelv, by placing it in a papar bire, or over the water bath (a simple apparatus for this purpose taining water on the fire, and inverting saucepan con- lid, upon which the suhstance to be dried spread on a piece of writing paper is to be supported and exposed to the heat of the water in the pan kept boiling untii it ceases to lose weight). The loss of weight which is produced by drying the sample, multiplied by 2 , will represent the amount of water present in 100 grains; of course, the less water present the better the sample. 2 . Weigh piece grains of the dried sample, and spead it upon from the botton of a Florence oil-flask, and support the glass by means of a piece of iron wire, bent so as to form a tripod over the flame of a spirit lamp, or when a spirit lamp cannot be obtained, place the guano in metal spoon, and expose it to the heat of a clear fire. Heat the specimen either over the lamp or fire until the blackness which is at first produced by the charred organic matter has entirely disappeared. If the residue, after being strongly heated for half-an-hour, is
greyish white, the greyish white, the quano is probably genuine ; if assumes a reddish colour, it has been nuxed with earthy
matters. Ascertain the loss of weight, which multiplied by 5 , will, after subtracting the amount of water found by operation No. 1 to be contained in 100 parts of the guano, represent the percentage of organic and ammoacal matiers. 3. Place a tea-poonful of the guano in made into a cream with a tablespoonlul of quick lime, observe the intensity of the ammoniacal odour. The stronger the smell of head salts produced, the better the guano. 4. Introduce the matter which is left on burning the sample of guano (operation 2) into a tumbler, and add to it a teaspnontul of spirit of salts, and about half a glass of water. If a brisk escape of gas, shown by the butbling up of the liquor, is observed, the guano is adulterated (by limestone, chalk, or marly earth). Pour the mixture upon a filter formed from a piece of blotting paper, or allow it to remain at rest for some minutes, and decant off the cear liquid portion, and wash it from the acid by pouring water over it two or three times. Dry the solid
residue thoroughly before the fire or on the water bath, and ascertain its weight, which, multiplited by $\overline{5}$, will represent the sand and earthy matters contained in the sample. By means of these simple operations, which any person of ordinary intelligence may successfully perform, the character of a sample of guano can readily that the manure sold to him as genuine be adulterated, he should at once forward a sample of it to a chemist, that its actual value may be ascertained. For this purthat its actual value may be ascertained.
pose about two ounces of the guano will be sufficient, pose about two ounces of the guano win be sumcient, paper, and forwarded by post. The cost, for a complete analysis, to a meniver of the society, is only ten shillinga Farmers should be aware that the sum paid to a merchant, beyond what the analysis shows the manure to be worth, may be readily recovered.

## Mancus.

Briclomaking. By Humphrey Chamberlain, Drainiag Engineer. Kempsey,
This is a pamphlet reprinted from the Journal of the Society of Arts, and it deserves a wider circulation than it has yet received. Any one about to erect kilns and machinery on his estate would do well to read the very full and detailed instructions which Mr. Chamberlain gives. His paper received one of the few honorary distinctions which the Society of Arts awards during their approval will be admitted by all its readers. The pamphlet contains two essays, in one of which the pamphlet contains two essays, in one of which the art of drying and of burning them. We shall refer shortly to a few of the facts which Mr. Chamberlain shortly to a ilew of the facts which
adduces in illustration of his subject.
"The quantity of bricks made per annum in this kingdom is about $1,800,060,000$. Of this quantity Manchester alone makes about $130,000,000$ per annum.
What are termed the London makers produce about the same quantity, but bricks are sent to the metropolis from a cercuit of 100 miles; it is, therefore, impossinle to give exactly the consumption. Taking trichis at the low in weigh 5 hree tons per 100, the capital employed mus be upwards of $2,000,000 \%$. sterling.
The process of brick-making near London is described as roush and imperfeect, so that it pays to purchase the better quality made elsewhere, so tar away as 100 miles,
The number of patents taken out comnected with the manufacture of bricks exceeds 200 , the main object of the machinery as patented being the imitation of the operation of mouldins
The art of the brickmaker, or moulder, is the knack with which he throws, or drops, the sott clay into the mould, so as to fill up every corner. This is apparently a very simple process, the accomplishing of which by
machunery has caused a vast ewpenditure of time and money, and occupied the attention of many leading mechanics for some years."
The description of brick clays, of the principal machines for working it-viz., the pug-mill, the wash mill, and the rolling mill-and that of the machinery employed in moulding, occupies the first of Mr. Chamberlain's papers. The object of this machinery is to manufacture "a rectangular block of clay about 10 inches lowg $4: 3$ inches wide, and $3!$ inches deep, containing some 154 cubic inches, into as compact, hard, and durable a material as a block of stone. There are four principles on which these machines effect this. lst. By moulding the dry clay (that is, clay containing only sufficient moisture to allow its particles to adhere when sulyected to considerable pressure) by powerfut maclinery; 2d, by imitating the old proceess of haud-mahing, filling moulds with soft-tempered clay like mud; 3d, by forcing clay in a stiff plastic state through dies or apertures the size of a brick, endways or edgeways (a die is a plate with a hole cut in it of the shape which is desired to be given to the clay); and, lastly, forming a stream of clay to the desired shape by roliers."

The difficulties which have attended all attempts hitherto to accomplish any of these operations are enumerated, and Mr. Chamberlain then describes his own machinery for the purpose :
"The clay is fed into a pug-mill, placed horizontally, which
works and amalcamates it, and then Works and amalgamates it, and then forces it on of through a
moulh -piece or die of about 65 square inches, or about half an

 an aperture thuls formed, but not thin ugh a keen angle.
After the clay has encaped from the mill it seized by four
rollers, covered with a porous fybric (mole-kin, driven at alike
surface speed from connection with the pig-nill. These rollers surface speed from connection with the pug-nitll. These rollers
are two horizontal and two vertical me, having a space of
45 inches between them; they take this larger stream of rough 45 inches between them; they take this larger stream of rough and shape of a hrick edgways, witn branturn sharp edges, for the
clay has no frictiom, being drawn throught by the rollers instead clay has no triction, heing drawin thrungl, by the rorken stream.
of frcing itself through, and is delivered in one unhrok
By hanging a series ot nandrill or core but By hanging a series of mandrills or cores bet meen these rollers.
on hy meryly changing the monthopice, we make hollow and
pertorated bricks, without any alteration in the machine. The perforated bricks, without any alteration in the machine
p,nilles which drives the belt working thene rollers is not of suf-
ficient diameter to be able to draw the clay away from the mouth-
 details of the machine stationary until more clay is fed into the
mall, whon it again immodiatly resmes its functions. The
botrom ruller carries an endless belt, on which the stream cf clay is delivered to the cutting frame. This carries a wire, which is consrantly traversing at a compensating angle, while the clay is in motion, and thereby makes a square cut. Afier it has ane at
 Yollers, which press the block of clay into the slape of $\mathfrak{a}$ brick, and
thereby acts with mechanical correctriess. For if the smallest thereby acts with mechanical correctress. For if the smallest
portion of clay esceapes from the mill, motion must be given to portion of clay escapes from the miil, Motion must be given to
the rollers or rotating die by the driving strap, and fromi them to to
the cutting wire. Tile bricks, as fuss as made, are patssed on by the cutting wire. The bicks, as fust as made, are passed on by
the machine to boys in aitendance, who receive then, on pallet
boards, and remove then to the drying floors or hacks."
The remainder of Mr. Chamberlain's paper is devoted to the consideration of the plans of drying and burning bricks, and we have not room for more than to say that the great source of economy in this department of the manufacture will be in using the heat from the cooling bricks in order to dry those that are unburnt.
The whole pamphlet is exceedingly interesting and instructive, and deserves publication in a separate form.

## Miscellaneous.

A. Plant needs Manure in Proportion to the Rapidity of its Growth.-"The greatest increase of cation of artificial manures was from superphos phate of lime to Barley that was sown mbout the middle of May on light sandy soil. A very considerable quanticy or supepy in Fife with the has results. I would 10 times rather trust my late-sown Barley with superphosphate of lime than I would my early-sown Swedes with the same substance. I hav therefore, no reverence for the recipe, phosphorus for Turnips, and nitrogen for corn. I shail have a few words afterwards on the ammonia question ; and in the meantime I think my readers will now perhaps concur as I do with Liebig, that 'it requires all the with the ain a wan intimato acquantance peculiarly fitted for grain, and phosphorus for Turnips, But the recommendation that Mr. Lawes has given in Rendle's Price Current, as to the manures sufficient for principle for which I bave long contended I importan fectly well the authors of the Rothamsted papers, wha really do know a thing or two about manures, were gradually drifting towards its recognition, although the current is still setting strongly in towards the soil Lawes has given in Rendle's Farm Directory are con tained in a table. The quantity of ammonia require by the Barley crop, according as it may be late or early sown, is curious. I extract his allowances for a crop of Barley from the first and last columns of his table :-

Barley (early sown) after a grain crop, of when the whole of
roots are taken off the land-3 cwt. of Pernvian ${ }_{\substack{\text { acre. } \\ \text { ". } \\ \text { Barley } \\ \text { sown very late in spring }-1 ~ c w t . ~ o f ~ P e r u v i a n ~ g u a n o ~}}$ and 2 cwt . of superphosphate of lime per acre.

These are the results of the 'recent experiments, and very curious they are. Mr. Nesbit, in his lectures on Agricultural Chemistry, tells us that the whole amount of ammonia and nitric acid which descends with a dressing of 2 cwt. of guano to the acre-just equal to the difference in the quantity of ammonia that a crop of Barley requires when it is sown very early no theory for this remarkable difference. The explanation of this important principle in the theory of rotations, One whuld be very naturally led to believe, that as Barley, in search of the minerals contained in the soil,' as Mr. in search of the minerals contained in the soll, as Mr. the ammonia contained in the soil. The early-sown Barley or autumn. Wheat has far more time to search for both ; but while it finds plenty of the one substance, phosphate, it fails to find the other. The facilities
which the Barley has of finding ammonia are vastly greater when it is sown late in spring. The objections are legion to the supposition that it has anything to do with the kind of soil with respect to its ammoniaabsorbing properties. After thinking a good deal over this question, I know of no objections to the supposition the atmosphere a murley can absorb, arec ammonia than what early-sown can do. I cannot yet give a better explanation of this, and hundreds of other parallel facts, than I gave years ago: 'When the phy siological characters of plants are somewhat similar the amount of ammonia required in manures is in the in the atmosphere during the time the primary organs of plants are developed. The higher the in the atmosphere, the greater facilities have the leaves of plants of absorbing ammonia from the air Less manure thus serves for late or summer sow crops. This law is a universal one. Wheat, Barley Oats, Rye, Turnips, Tares, Potatoes, can all be raise with less manure (ammonia) when sown late in the season, when the temperature is high. Thus many of the cereals alter their natures altogether when sown a roidsummer ; they will all put forth three or four leaves Indeed, it appear one they would put forth in March crops are increased by superphosphate of lime, white the soil contains a considerable quantity of phosphates it indicates a power on the part of the leaves to absurb ammonia from the air. There seems no other way of superphos he action of this substance. For example
litte or no benefit as a dressing fur early spring-sown
Turnips, Barley, Oats, or Tares, but it is so far an effective manure for all these crops when they are suwn ate in the season. In beautiful conformity with this principle, I learned while I was travelling through Almosta, that Maize, Millet, Buckwheat, although benefited by phosphates and ashes, from the fact that these crops are all sown in summer, and grown in summer. I should be glad if any one would sugges another theory fur these facts than that leaves have greater facilities during warm weather of fixing
ammonia from the atmusphere. I have lately found that a great observer distinctly states this principle and at the same time comprehends others also-
'Gardeners do with ordure hide those roots
That shall tirst spring, and be most delicate.'
Henry the Fijth.
t is almost neeedless to say that ordure signifies putrifying matters yielding ammonia. Shakespeare could not have selected a hetter word for the purpose of early and late spricion crops. Guaro is but Peruvian ordure." Mr. Russell in the Quarterly Jowrnal of Agri culture.
Red Sulphate of Ammonia--Under this name a dark red powder, smelling slightly of gas water, has come under my notice. It is acid to test paper, and gives of with lime. Its composition was

To name a substance which contains i4 per cent. o sulphate of ammonia as if it consisted entirely or mainly doubt compound, is an obvious deception, by which no worth more than $2 l$. 23. per ton. Professor Anderson in the Journal of Agriculture.

our hot weese nur heat twees of Whea level with the earth. We contemplate havinit Wheat readr to thresth in ten dass, and the opportunity
will not be lot. If the easther hoclds fine and hot as at present so as to brine the Wheat inter pood marching order, prices mast
recede greatly, but we contemplate Barler will min it will be a deticient crop in many districts and $a$ smats value onlv has been sown. Potatoes show ssmptoms of disath
sighty The pricsailiat presate of the weather is bere been found attacked and we consider that they will in a short time be out of danger
The green cre ps
generally with the excention of pank are deficient throughnut this district Forfancumbe GLexs, July 30 .-The crops are sll late, the Weatlier for the most part liaving been ungenial, wet and cold.
All the cereals bulk well on the ground the Batey bloom, Oats and Wheat are just showing the ear. A cold and rainy summer is not unfrequently followed by a dry and warm will be secured, but at this date it is about 14 days io arrear
and average spasons. Hay-making is progressing, the crop is a
fill nene, and the weather for the last 10 dasy not unfavourable. Turnip fields are in full plant, not early but equal; some distant Potatres are healthy and growine, but beemingly leses apparent. than last yearr, and indicate a midille produre per acte. lasture
Grass has been abundant throughout the season, and animals making satisfactory progress. Graziers calculate upon thetr part of the season for profit. The Angus Acriculturat Associa tron has this season, for the first time, awarded prizes for black
polled cattle bred in the riichland district of of the connt-
 as a separate class. Our glen farmers would do well to
atten to this fee of them may gain prizes, and still
fewer profit by them, but all are sure to profit by fewer pront by then, but all are sure to pront by
keeping prite the kind of stock best ssited to the sion and
climate of the district which they ocupy, a kind of stock which has always commanded the highest price in the market, and Which is now likely to be in greater demand than ever, both on
account of the high estimate in which the breed is held, per se, and also for its ralue as a crnss with the short- orns. with whit which
it has generally county. An averaze welght of superior tol has been shorn and
 both ass to numbers and quality. The flocks are anl now dispersed
through thir native plens, in the full cring yenent fof fredom and asture, and hre progreessing accordinperature bery suited to their neration, and the natire poor are well cared for and do not need to beg fron dor to dor, but during every summer and nutumn we
have an influx of vagrants, which come in streams from the town have an inthux of vagrants, which come in streams from the towns
and spread through the glens, avoiding as far as possible the
los partly and clitiefly because they meet a more kindly recepption
among the hills, where the benevolent feeling has not yet been petrififed by the influence of a legal assessment.
GLorcessprrumpe-The follow int observ
 - good and well got up on my own property and in the immediate netghbourhood in the first week of July. Some farmers cut late
and have not ret finished carting. My Barley is short in the
and abow-a midding crop, but rinening fast ; will be ready to cut in of every description have made a mood plant, but are much in Want of rain, from the absence of which we are also very short of to ass; the absorption upon the sandstone soil which prevails here ol a great extent is so rapid and complete that we seldom com-
plain of having too much rain, and the present season has been
 and shows little fluctuation in the 24 hours, either night or day At a lower level 1 have no doubt the fluctuation would be many
degrees. Thermumeter to day $74^{\circ}$. highest point it has reached this summer. SS. Shiviruets. Aug. 1 . ILAACAMHRE, - I cannot pive Yon any reliable information
respecting the crons in this neizhbourhod for at least two or of strae in the white crops, hut from the supless sumper have had, I am afraid the Whean and Barless will turn out
deficient in grain. The Oat crop I expect will be pood. The hay crop is a fair a average, but has been a very expensive one to
save. great many diseased ones. Early sown Swedes and there are a great many bunchy tops wenong them. Late sown
commou Turnips look well. We have had two days rain, with commou Turnips look well. We have had two days rain, with
the barometer rising. $G$. Dreory, Holker, July 30 . NoRTH HANTB, July 31.-The present beautiful weather is
 Wheat cutting will commence on Monday next, and, with a con tinuation of fine weather, by the following Monday, harvest wil
be general. With the exception of partial blight-rotted
 yield, the number of acres being also above the averase of years Barley is very heary upon the ground, and with a fine batrest be mustuly productive atd of fair quality. Oats also are locking
fairly, although the breadth of both these crops have this seasen been fneroached upon by a great breadth of Wheat. An abun-
dant hay crop has been well secured. Potatoes are in some places showing the disease, but not to the same extent as in former the fly, and many fields have been re-sown. The black caterpillar is now showing itself very destructively on some farms, and this, combined with dry weather, renders the prospect for a
Turnip crop an indifferent one. The chief animal produce of this Tistrict, sheep and lambs, have however sold at very remuneraNorthamprosume - I think that the whole of the corn crops
in this nelghhmrinat are quite an average, and, witll fine
weather, I think the prospect of the coming harvent is a favournot a ceneral one. Wm. Gray, Courth $n$ Hall, Nort hampiton,
Subrey. Wheat: favourable, backward, much affected by
Wheat midge. 13aripy: a large crop, forward, every way favourable. Oats: a average, short straw. Peas: unusualiy wry favourt
plenty of haulm, no disease. Beans: mean crop, well podded, short straw. Potatoes - large crop, great breadth, no appearance
of disease. Hay: heary cut, well got up. E. J. Lance, Erimley,
July 25 .

Notices to Correspondents.
of Bricks: Whrcester. Mr. Chambertain gives the following answer to jour question:- "To attempt to give the cost of mann-
facturing would ouly mislead. The largest item is lebour, the
cost of which varies so much cost of which varies so much between manufacturing and a.gri-
cultural districts. The next is coal or fuel for burning. which country. Again, one clay requires a large expenditure of unel
to be used, in order to attain the most intense heat; while annther will burn sufficiently hard at ahout $10^{\circ}$ Wedgwood The consumption of coal for burning bricks varies with the
clays, Irom 3 to 20 cwt per 1000 .
Early layb: $E A$. Where there is a good market it is probably
the most profitable of all management. Large sums have been
made thls yaar in this way. Take as an illustration a case
mentioned last week in the Dublin Farmers' Gazette:- "During
the present year Mr. Atkinson has realised more money for the present year Mr. Atkinson has realised more money for
his lambs than we ever heard of being done under the circumstance. From 48 ewes purchased in Bahs. These were lambed sent 59 to Liverpool, which realised the grosh amount of
1093 7s, or an average of say 1 l. 17s. 1 d. each. The sales were made between March 20 th and April 24 .h. Noith. Aales were
 ever fully his experience of gas water may have corroborated that of many others during many years as to its fertilising effect, it cannot be properly urged as a recommendation to the
use of gas tar. The two things are of course enticely different, as use of gas tar. The two things are of course entirely different, as
any will find who shall try them. Gas tar has, nevertheless, been nsed with good effect ultimately (though injurinus at first) on
Grass land, but it must be applied with great caution, and if at all as part of old compost.
Influrnce of Maceinery on Working Men: Fis. One imcharacter of work done by machinery. Hand labour is in mave a flush of work and a flush of means, alternating with Sdleness and starvation. Their improvidence leads to misery.
Machinery, which enables work in all weathers, provides uniMachinery, which enables work in all weathers, provides uni-
form employment, and induces uniform industry and constant comfort. Take brickmaking as an illustration. Mr. Chamberlain in his paper before the Society of Arts referred to this very point. He says, "I cannot refrain here from mentioning whet an injurioas effect the presentsystem of hand-making has on the habits
of the men. The brickmakers (that is the moulderg and their attendants) men and lads, are throughout the kingdom employed at their trade only during six or seven months in the year, except where bricks are artificially dried, in the neigh-
bourhond of collieries. In the winter season the bourhond of collieries. In the winter season the bricks would be destroyed by frost, neither could they then be dried. They
therefore work early and late; and from their having rio winter occupation, and on account of their dirty and laborious Work, they have such a price per thousand as to compensate
them. The result is generally, among this class of men, that them. The result is generally, among this class of men, that
although they are so well off in the summer time, they spend all they earn, leaving the winter to provide for itself. At selves and their families, as well as fuel, they have nothing to fall back upon, and in too many instances no employment; for as they earn so good wages in the summer, they do not Willingly come down to the price of ordinary labour. These Tine: T T. If you apply it, it should not be left exposed for plonghed then ploughed under. It should be slaked and plonghed in at once. We think that 80 bushels of hot lime Wheat is a good dressing applied just at the right is to be in patches of dead corn are a mystery. If they are over the clay advantage. But they are more likely where the soil is ligh and moory, and in that case a dressing of clay will be Mruriva Cows:
imagine they have taken some deleterious substance in their Grass or other food. I should recommend their bowels to be Telieved by means of Linseed oil and Linseed gruel. If. C. S. progress of Ireiand: Michael. Facts illustrative of this are
given tersely and forcibly by Lord Fermoy at a given tersely and forcibly by Lord Fermoy at a recent
meeting in the South of Ireland. He says that $2,000,000$. of Government money, and probably $10,000,000$. besides caltural improvements in Ireland; and thanks to the system of Agricultural Statistices, he conld say that in 1841 there creased to $3,497,901$. In sheep, there were in 1841, 2, 166,189, In 1854 they had increased to $3,722,219$; so that, in point or Let them now take the Balinasloe fair. In 1849 the number of sheep sold was 60,256 ; in 1855 it was 79,311 . of cattle, there increase of mold in than double. and in 1855, 18,533; that was an wethers at Ballinasion in 1819 was average price of first-class 18. 14r. in 1855 it was $3!$ In 1849 the price of first-elass wa price obtained for first-class heifers in 1849 was 137.10 . The in number 211 . As to the stock, whilst they had nearly doubled Falue of each beast. And was he not justified in saryine the they were getting prosperity in the land? They had now a for a fair day's wages. ${ }^{\circ}$. The following is the plan which Mr Kelly adopts in the cultivation of green crops:-"The ground is Wurzel, or Turnips are intended to be sown: then marked out into beds or ridges (for Carrots or Parsnipi) of 3 feet 6 inches Wide, with farrows 15 or 18 inches wide, accordiag to the depth of the soil, always making the furrows wider in shallow soils, the be is are marked 4 feet 6 inches wide with fagel Warzel 20 incres wide. The dung if then spread evenly on the ridges, and the furrows dug and shovelled on the dung. The Thang fir Carrots and Parsnips should be applied in winter Then the ground was being trenched or digged; but if not, and that it must be applied at sowing time, it must be well prosurface of the beds must be made fine by a garden rake, ard the sweds then dibbled in-three rows lengthways in each bed, viz., one rnW in the middle and a row within 4 inches of the edkes of the beds on both sides, or the beds may be made
wider and the seeds dibbled in rows across the bed 18 inches asander. The Mangel Wurzel ard Turnips wust be dibhled in lines lengthways in the beds, three rows in each bed, and at the same distance in the rows as already recommended for drits.
Sprngg Fefd for Sheep: MG $\mathrm{F}^{\prime}$. Rye is the earliest spring food.
St. John's Day Rye is the earliest sort of Rye. "Rowe" is properly, we believe, the aftermath of Clover. It is bad man agement to leave an aftermath unstocked till spring. If you sow Rye early enough, or Italian Rye-grass, you will have Wurzels and straw chaff during winter on the Grass fields, and then Rye or Italian Rye-grass, with gnd C'lover-hay after Waltoman Propagativg Case : A porsible. it is a small portable whe-hght glass case. the heat and moist air derived from a
small lamp beneath a shallow tank undurnurth the flon on Which the pots are arranged. The whole affar is something it answers ver mell and 2 feet or 30 inches high. We believe Wramorre: FF. If the land is heavy clay we would try burming a gond deal of it. The ashes being spread the land should and in February try Beans in preference to Wheat and Mangel Werzel among romt crops : the principle of this advice being that strong sind vigorous : growtha should be ased after such menns an mere tillage affords. Pressure is said to be useful ** Au nsual, many communications have been received too late, We must also beg the indul the necesory inquifies can be made. insertion of whote coutaibationa is attll delayed.

## IMPROVED MOWING MACHINES

J A M E S F ERRABEE \& CO., Phœnix Iron Works, near Stroud, Gloucestershire.

HORSE MACHINE-Half-inch Scale.
J. FERRABEE AND "CO. and their predecessors have manufactured and sold between 5000 and 6000 of theme their construction which originally introduced them; and they have from time to time made all the important fiuprovements in be worked by a stout pony or a horse. They are made very strong and durable, and will cut the longest and coarsest Grass usually met with on lawns and pteasure grounds, executing their work in an expeditious and superior manner, producing a more even and uniform surface than the most skifful mower- they will foll w the inequalities of the surface without cuiting intt, the soil, and can pulled by nuskilled labourers with equal facility on lawns, hedges, between flower beds, bowling greens, cricket and pleasure proands pulled by nuskulled labourers with equal facility on lawne, hed ges, between flower beds, bowling greens, cricket and pleasure grounds.
The Price List below includes the carriage to any Railway station in England and Wales; and for a small additional sum they are sent carriage fivee to any Railway Station in Scolland or Ireland.

This day is published, in one vol. 8vo, with нumerous woodeuts, M EDICAL AND CECONOMICAL BOTANY; or An Accrunt of th
extract from the author's preface.
The Vegetable Kingdom contains, among a large quantity of plants of no known importance to man, various usetul species
employed in medicine the arts, or in, the many branches of employed ceonomy. TTe principal part of those which cau be
domestic cone
brought by teachers in Enrope under the notice of students, or brought by teachers in Europe under the notice of students, or
Which, from their great importance, deserve to be among the

 made in such a way that all teachers who possess reasonably
extensive means of illustratiting their lectures, and all Botanic Gardens, may furnish the larger part of the specips which are
mentioned. A small selection was indispensable: firstly, because a greater work would have been beyond the reach of the majurity
of purchasers: : and seendly, because experience slinws us that those who have to studr a science of observation, such as Botany,
require to concentrate their attention, in the first instauce, upon a limited number of objects."

## HORTICULTURAL BUILDING, AND HEATING BY HOT WATER.

HEATING EXTENSIVELY BY ONE BOILER, COMMONLY CALLED
"WEEKS' ONE-BOILER SYSTEM."
 diameter.

Buildings of every description, Dwelling Houses, Churcles, Warehouses, Horticultural Buildings, \&e., separately or combiued, and to any extent, can be effectually heated by one nolleb.
J. Weexs \& Co. refer to their own extensive Establishment, the whole of which is heated by one boiler, and may be seen in constant operation, warming Hothnuses, Greenhnuses, Conserpetories, \&ece, upwards of 1000 feet in length, the water in the various honses circulating through upwardy of 5000 feet of pipe, and the whole so fixed and regulated that any one of the houses can be heated separately, or the whole together, and any part regolated at pleasure.
J. Weers \& Co. have also great pleasure in referfing to the extensive Nursery of Messrs. Edward Henderson \& Co., Wellingtou Romd, St. John's Wood.

We will here quote Mr. Henderson's own words, expressing his approval of our ons boileze The Nobility and Gentry abnut to prect Horticultural Buildings or to fix Hot-Water Apparatun SYSTEM. He says:-
 done for me in hating a great number of mur hot-houses from "NE BOILER. It is almost impossible for
me to express my satisfaction sufficiently strongly. The efffet and great saving produced is truly ucon me to express muy satisfaction sufficiontly strongly. The effcct and great saving produced is truly whn 900 feet in length, and these various houses are to some extent widely separated, as 300 feet stant in one direction, 150 feet in another, 200 feed in another, and so on, including our large nevoly laid-out winter gardion?
Messrs. John Weeks \& Co, can also refer: to numernits seats of the Nobiltty and Gentry in various parts of the country where one Boifer has been fixed to warm a great number of houses, sc., In some instances our one Boiler is doing the work formerly done by 20 , so that in these cases the great number of fires, stokehnles, and chimneys, are entirely dispensed with.
At his Grace the Duke of Leeds'. Hornby Castle, Yorkshire, one of J. Weeks \& Co.'s Boilers is heating 10,000 feet of 4 -inch pipe, and one of the houses, a large Conservatory 190 feet long, is
J. Werks \& Co. make their Tubnlar Boilers of all sizes on the same economical principles : nariy 4000 of which of different sizes are in operation at the seats of the Nobility and Gentry
extensive at minty of cielserrates tion, combming all modern improvements in the various brariches of ihe Horticultural sciencerathat a lady or gentleman can select the description of house best adapted to the purpose tor which As an Horficulturnl Establishment it is also an unlimited source of attraction, containing Nem and Rare Plants in great variety.
The Collretions of STOVE and GREFNHOUSE PLANTS, in ell the various stages of growth and in endest varlety, incluide every novelty that is worth cultivating.
A large stock of GRAPE VINES, struck from eyes, very strong for Planting and Forcing in pots. FRUIT TREES and SHRUBS of every kind.
The SEED BUSINESS is conducted upon an extensive scale, every article warranted true to its kind, and of gemine good quality.
GARDEN TOOLS, and Horticultural Implements of every description, all of the best make, no CAST-IRON VA
CAST WIREWORK for all Ornamental Ganden purposes.

> JOHN WEEKS \& CO., Horticultural Builders and Hot-Water Apparatus Manufacturers, KING'S ROAD, CHELSEA.

Thothouses, Greenhouses, Conservitorits, Forcing Pits, sur, Burir upon the most scientific principles, combining all the improvements of the day. Hoarrculrukar Works of every deecription malla any extent, erected in any part of the Kingdom, manufnctured of the best materials of every description.

See our Ilhstrated Catalogues; also Plans, Models, and Estimates of Horticultural Buildings and Heating by Hot-Water; also of Cast-iron Vases and Fountains; also Catalogues of Dines, Pruit Trees, Stove and Greenhouse Plants, Seeds, dec.

GRAY and ORMSON, Danvers Street, Chelsea, having had considerable ex$G$ periences in the construction of Horticultural Erections, which, for elegance of design, gond materials, and workmanship, combined with economy and practical laptation, cannot be surpassed by anything of the kind in the country, are in a position to execute orders on the lowest possible terms.
G. \& 0 . have been extensively employed by the Nobility, Gentry, and London Nurserymen ; and they can with the greatest confidence give the most satisfactory references to all by whom they have been favoured with orders. Their Hot water Apparatus is also constructed on the most approved and scientific principles, for rab purposes to which the application of Heating by Hot Water can be made availabla.

## Cht Gavidutge Chromitle. <br> SATURDAY, AUGUST 16, 1856.

By the side of a country road not very far from London is a row of paling inclosing a plantation of some 20 years' growth, and pierced by a narrow gate of similar naterials. You may ride past the place repeatedly without observing that a neat paved footpath winds away into the interior of the plantation. In winter a few ornamental chimneys may perhaps be seen peeping over the tops of the branches. Follow the footpath; you will soon find yourself at the back of a charming Swiss cottage, mantled with Ivy and embowered in trees. Roses, Clematis, and gay climbers strugule over the columns and hang in festoons from the sides; a very small lawn, trim as velvet and brilliant with richly coloured flowers, separates you from a rustic flight of steps; to the left is a wide opening among the trees, through which there is a glimpse of green
wooded meadows bordered with gay shrubs, and wooded meadows bordered with gay shrubs, and forming the slope of a gentle valley.

Passing through this opening, the end of the cottage is seen defended by boxes and hives of bees, sheltered by the overhanging roof, and still profusely decorated with flowers until you reach the front. At your feet is then revealed a broad lawn, separated from the meadows by a raised terrace walk. Gladioli, Fuchsias, Geraniums, and other gaudy races on the one hand flank the walls of the cottage, while a rough bank of stones closely covered with Acanthus, variegated Coltsfoot, Lilies, and plants with striking foliage, conceals from riew for a moment a charming flower garden, on which the eye of a Turner would have dwelt with deli,ht. Here purples and scarlets, and yellows, and whites, and blues, are tastefully intermixed in skilful confusion. A high wall covered with handsome climbing plants shuts it in from the north from the south it receives the whole influence of the sun, while it is screened on the west by plantations, and on the east by the cottage and its accessories. It is a kaleidoscopic flora in a niche of verdure.
In all this there is no apparent attempt at display. The trees and the flowers, the parterre, and the bees, and the rockwork, and the festoons of climbing plants all fall into their places with so much ease that Nature herself might be thought to have that Nature herself might be thought to have
planned the scene; especially since there is no trace of greenhouse or conserratory such as is usually found in a garden like this. Not indeed that the materials by which so much brilliancy is reflected are either rare or costly. Verbenas, Petunias, Calceolarias, Lobelias, Geraniums, and the like, give the principal colours with which the artist has worked; the only unusual material on her palette being Liatris spicata, whose peculiar purple and
erect mode of growth are here introduced with good
A peep within the cottage does not diminish the desire to know from what hidden sources all this floral brilliancy is derived; for in the drawing room we see Orchids and tropical Ferns, and in the housekeeper's room certain dishes of handsome Peaches and Grapes, which cannot ripen without glass by the beginning of August. The mine from which so much is extracted must be sought for at a short distance. Passing along a shrubbery path, bordered by plants remarkable for their good foliage, among which are especially notable the parple-leaved Berberry and the purple-leaved Filbert, whose husks of the same rich colour are so beneath overarching trees, with quantities of Ferns on either side. From this you suddenly emerge into a kitchen garden, along whose edge are thousands of Sedum rupestre for the pasturage of bees. Here, amidst roughly kept ground are two or three glasshouses, patched up with weather boards and asphalte hedge carpenter. Nothing can be more unpromising than their exterior. Inside you find a good hotwater apparatus, earthen floors on which water stands in puddles, ramshackle stages, and Spruce Fir poles to keep a low span-roof from tumbling down. trellis with 50 or 60 dozens of fruit, skilfachly trained and perfectly ripened; in another a crowd of Orchids in beautiful health, Scitamineous plants worthy of an Indian jungle, cashions of the greenest, most feathery and most elastic Lycopods, glorious Ferns, and over all a canopy of faultess Grapes, which would have beaten Glendinninc's (see p. 499 had they contended with them. Heaps of Vandas, Cattleyas, Epidendrums, one of which (rhizophorum) has been two years in blossom, Bromeliads, Onci diums, Calanthes, and a swarm of other Epiphytes crowd the shelves. The Grapes belong to Vines planted in a border 1 foot only deep, and little more than twice as broad, at the back of this Orchid house, and within it, so that the roots are never exposed to chills or drought. Other places as nnsightly have other uses, and especially that of shelter.
This is the magazine of beauty. Rickety unsightly places which a fastidious gardener would pull down, and which it requires some care to keep np, form the mine from which a master of his art raises house and pleasure grounds. He is not frightened by damp and red spider; ne:ther is he ashamed of his tumbledown apparatus. Nor need he be. On the contrary, he may be proud of extracting so much value out of such unpromising materials.

After all the important question to be asked of mere garden buildings is-do they answer the purpose? It matters nothing how they look, or in what clumsy manner they are put together, pro-
vided they do the work required of them. Nor can there be a greater mistake than to suppose that in order to render a forcing house serviceable it must be constructed with the elegance and skilful workmanship demanded in a drawing-room. If it is wanted as an elegant object, or a place of resort,
then indeed the architect and workman must combine their efforts to produce the best effect they can; but if it is merely required to do gardeners' work it is of no sort of consequence how rude its construction or inelegant its form. It is only necessary to keep it out of sight.
Let no one inquire where the scene of our little sketch is to be found. Some know. Others will guess. Suffice it to say that the facts are more striking than our description, and that we must not expose privacy to the invasion of the curious, or even of the enthusiastic. Enough indeed may be
learned without a visit; and especially this-that resalts are sometimes in an inverse proportion to means. We all know how little may be accomplished by much in gardening as well as other occupations; and our present sketch will serve to show how much may come from little. Skill has wonderful power over materials; taste is but another form of skill. With their aid the most modest retreat may become a scene of more real beanty than a palace with its statues and terraces and fountains. And this is no small consolation for those who imagine that nothing great can be effected without enormous cost. The most sagacious of modern statesmen pronounced him to be the best farmer who made the greatest profit out of the least capital. That principle we apply to gardening.

Sous years since there appeared in some meadows in Berkshire an extraordinary quantity Flannel a substance which gained the name of Water Flannel. It overlaid the Grass to the thickness o some inches, was white on its ander side, green on
its upper, and was said to grow 80 rapidly that
people were alarmed lest their meadows should be ruined. It was soon ascertained to be nothing more than a Conferva (C. crispa) which had formed with great rapidity while the meadows in question were inundated, and went on growing as long as the soil continued to be damp enough. As the land dried the Conferva perished, and soon disappeared. We believe it was removed by harrows. (See our volume for 1843, p. 735.

We learn from the Moniteur des Comices that the same plant has taken possession of the districts in France lately overwhelmed by water. The other day M. PAYEN laid before the Central Agricultural Society of Paris specimens that he had received from Châlon-sur-Saône of this vegetable matter deposited in the form of an immense felt cloth which threatened to suffocate the meadows if not removed. He reported that the plant was so rich in nitrogen, containing by analysis 0.883 when dry, that it must make a good manure, either when mixed with farm-yard matters or soaked with urine. Where however it was inconvenient to carry it off the land he advised it to be thrown in heaps and burnt
Such Confervas are common everywhere, and contribute to, or wholly cause, the green filamentous scum which often renders ponds and similar places unsightly. When raked out or otherwise removed it will be as well to recollect the advice given by M. Payen, and not to waste them as is often done.

## New Plants

181. Rhododendron Blandfordifflorum. Hooker Bot. Mag., t. 4930.
We wish this beautiful plant had received a better name; for aix-syllable words, in sn uncouth form, take our breath away. Not that the name is uncharac teristic ; on the contrary, the flowers of this Rhodo-
dendron are like those of a Blandfordia; we only dendron are like those of a Blandfordia; we only
object to it because it is unpronounceable. In the object to it because it is unpronounceable. in the the cold pits in the garden of the Horticultural Society upon a Rhododendron which had been raised from Dr. Hooker's Sikkim collections under the name of . cinnabarinum var.? They were long, tubular,

scarlet with a yellow edge and interior, and being pendulous had much the appearance of a Clivia or Blandfordia. The plant was a scrubby bush, with leaves like those of $R$. cinnamomeum; but its brilliant flowers quite concealed the faults of habit. We now learn from the Botanical Magazine that it is one of Dr Hooker's discoveries in the Sikkim Himalaya and Eastern Nepal, "where it is not uncommon at elevations of 10,000 to 12,000 feet, both in valleys and on the mountain tops and ridges. It forms a slender rather ugly sparingly leafy twiggy bush, with often very ornamental flowers, which are extremely variable, and even wholly dissimilar in colour and often in formo," It therefore behoves cultivators to take care that in propagating this species they provide themseives with dulous, and deep scarlet bordcred with bright yellow.

This is perhaps the only unobjectionable series of observations upon record. M. Dove quotes another by
M. Stark of Augsburg, butit was deduced from common
thermometers, not blackened, observed at 7 A.M., 2 P.M., servations upon record. M. Dove quotes another by
M. Stark of Augsburg, butit was deduced from common
thermometers, not blackened, observed at 7 A.M., 2 P.M., thermometers, not blackened, observed at 7 A.M., 2 P.M.,
and 9 A.M., and at 35 feet above the surface of the thermometers, not blackened, observed at 7 A.M., 2 P.M., ground, and they hence neither give the maximum of arradiation, nor minimum of terrestrial. There are also other series of observations made by Gasparin at Mount Peissenberg, and by Quetelet ; but - $\quad$ a $\begin{aligned} & \text { all are open to the same or to } \\ & \text { similar objections. } \\ & \text { M. Dove states that if similar }\end{aligned}$ $\sqrt{\text { and }} \begin{aligned} & \text { all are open to the same or to } \\ & \text { similar objections. } \\ & \text { M. Dove states that if similar }\end{aligned}$ observations to those of Chiswicl were made in a continental climate the differences would be greater. If by this he means that the extremes between solar and terrestrial radiation would be greater, there can be no doubt that he is right, for the atmosphere of London is much more charged with vapour and clouds than that of a central, and especially an eastern locality in Europe. If on the other hand he supposes that the mean deduced from the extremes between the thermometers exposed to solar and terrestrial radiation is greater than those between thermometers hung in the shade, his opinion appears to me open to doubt. The exeess of heat indicated by the thermometer exposed to solar radiation arisoos y suppos, from the fact that the days are loss cloudy than the nights, and that hence terrestrial radiation does nocompensate for solar, as it would do were the atmsphere uniformly clear. Thus in maritime localities the differences between the purity of the air by day and by night is greater than in continental localities. Goad observations are however wanting upon this poin, ad in such a case it is best to be cautious. Under ien temcumstances I doubt the hypothesis that the mean erresperature deduced from the ext in shates the trial radiation is proportioned in all climates the mean deduced from the maxima and minias which air in the shade. In other words that the places which fall under the same isothermic* line are the same as those which fall under lines following the mean the extremes between solar and terrestrial radation.
Be this as it may, the question of far greater prac
II.-ON THE DIRECT EFFECTS OF THE SUN'S RAYS AND OF EXPOSURE UPON PLANTS. (From Alph. De Caxdolle's Géographie Botanique.) N.B, The temperatures are invariably expre:sed in degrees of
Fshrenheit's thermometer, except when otherwise stated, the elevations in English feet, - Transl.
Plants are usually exposed more or less completely the sun's rays, and observations on temperature phenomena of vegetation.
M. de Gasparin, to whom this objection appeared a very forcible one, remarks that Humboldt often insists upon the necessity of measuring the direct effects of the sun's rays upon plants and the soil they grow in, and he has himself recorded observations made with thermometers covered with a layer of earth $3 \frac{1}{4}$ feet thick at
Orange and at Paris. Comparing these with others taken Orange and at Paris. Comparing these with others takea in A.D. 1786 at Mt. Peissenberg (alt. 3000 feet) he con-
cludes that the sun's rays heat solid bodies in spring $71^{\circ}$ at Paris, $13^{\circ}$ at Orange, and $20^{\circ}$ at M . Peissenberg. aud that the sun's rays raise the mean temperature of the year $6^{\circ}$ at Paris, $12^{\circ}$ at Orange, and $7^{\circ}$ at Mt . Piessenberg. He adds that these figures are considerably reduced if the thermometer be also exposed to the rain, dew, and evaporation.
Similar very exact observations have been recorded at the Horticultural Society's Garden at Chiswick, with three thermometers, one covered with black wool and exposed to the sun to give the maximum effect of solar radiation, one similarly covered exposed to the sky at night to give the lowest temperature produced by nocturnal radiation, and the third hung in the shade.
These cbservations have been studied by Prof. Dore, These cbservations have been stud
and the following are the results :-

Mean of year
Winter
Winter
Spring
Sinmer
Spring
Summer
Autumn
Autumn

|  | Mean deduced from max. solar, and min nocturnel rad. | Mean temp, in shade. | Differences. |
| :---: | :---: | :---: | :---: |

| Mav to September | $68{ }^{\circ}$ | $59{ }^{\text {c }}$ | $+7^{\frac{2}{0}}$ |

 other series of observations made by Gasparin at Mount bservations to those of Chiswicl be this as it may, the question of far gretables are scted upon by solar radiation in the same manner as are a basin of copper or the bulb of a thermometer, whether empty or foll of water, or quicksilver, or spirits of wine, empty or full of water, or quicksiver, or spirits or coneanWhether free or covered with a black or a non the earth's surface which have equal temperatures during the same period of time, in contradistinction to the isotherial hints of Humboldt, which pass through point
It appears to us that the fact quoted in a previous article from M. De Candolle's work, namely quat the temperature of the soil is in many places permanently above that of the air, is in insell proof that the isothermic lines projected from observations of from air taken in the shade cannot coincide with those dedar and terthe mean between the extremes of observations of sollary the the direct resalt of radistion, and
ducting substance, \&c. Another question is, how and it is but litcle larger than the ordinary grains, and some-
to what extent is the action of the sun's ray upon times occupies the same grain with Bunt. plants comparable with its action upon a thermometer Is the thermometer a true exponent of the action of the sun's rays on a plant? Of these two questions the first relates to physical science, the second to pure physiology and to physiology of a very abstract nature. J.D. H.
(To be continued.)

## VEGETABLE PATHOLOGY.-No. CXXXIII.

541. Parasite (Cordyceps.* Ergot).-The seeds of many Grasses and some Cyperacece are subject to a very curious affection, which has long been distinguished under the name of Ergot. One form is famithe affection is scarcely less common in Wheat or Barley. Various causes have been assigned for this production, and various names given, but it is only within the last eight or ten years that its real nature has been ascertained.
542. The older observers looked upon it as a mere diseased state of the corn, without much inquiry into its cause. In Sowerby's Fungi the species varieties are figured under the name of Parinaria (tab. 326, figs. 4, 6). Later writers referred it Solerotium, a genus formed to receive all fungi of it was separated under the generic name of Spermoedia by Fries, under a notion that it was not
truly a fungus. Leveillé considered the essential part of the fungus to consist in a wrinkled porpart of the fungus to consist in a wrinkled porfirmed by later writers. Queckett attributed it to a firmed by later writers. Queckett attributed it to a
minute parasitic mould to which he gave the name of minute pa
543. Meanwhile a curious Sphceria, now assigned to the genus Cordyceps, had been figured in the Flora Danica as springing from what was there called a seed, but which was evidently an Ergot. This species was published in Klotzsch's Herbarium Mycologicum, as growing on Ergot, together with another also on Ergot. Cesati, however, who communicated the specimens did not boldy assert the fact of the Ergot being a condition of the Cordyceps, but remained more or less in a state of to his observations, early as 1848. Corda had also in the CEkonomische Neuigkeiten figured a sort of hymenium in Ergot, which induced him to refer it to the genus Hymenulc. Tulasne's observations were published in 1853, and if a knowledge of Corda's and Cesati's memoirs, the merit of placing the real nature of the substance beyond doubt. If the Ergot is sowed like common seeds, with proper attention, it uniformly produces a Cordyceps distinguished by perfect ascigerous fruit, while at an earlier
stage the surface of the Ergot exhibits a quantity of stage the surface of the Ergot exhibis a quantity of
stylospores resembling closely the spores of Hymenulu. The only doubt that has been thrown upon the matter is that Cesati has seen the same Ergot pro-
ducing two species of ducing two species of Cordyceps, a fact which
lias been confirmed by Mr. F. Currey, from whom I have lately received an illustrative ever, does not seem to me to militate against Tulasne's doctrine for it is possible that the sporidia of two species equally capable of affecting the grain of the ame Grass, though the ergoted grains arising
from the action of the two species may not be distinguishable; and even supposing that at one and the same time the Ergot might produce Cordyceps purpurea and microcephala, no reason can be adduced why the sporidia of either species should not concur in the production of the Ergot, and consequently when the Ergot is committed to the ground either species or both masy spring from its surface.
544. One step towards the eradication of any disease is cleariy a knowledge of its cause. If, then, the intimate tissues of the plants are not infested with the parasite, it may be hoped that by steeping the grains of those secies as Rye ala may be prevented Should however the Ergot have fallen, and the Cordyceps have in consequence been produced, if two white crops follow each other in succession, the latter may be affected even hough the seeds have been steeped. Besides the might take them to almost any distance, for they would not readily fall wher once wafted upwards, except arried down by rain.
545. It is a great mistake to suppose that Wheat is very rarely affected. Ergot sometimes forms a large portion of bad samples of Wheat, though its nature is little known to our English farmers. In Barley it
attains a large size and is very conspicuous. In Wheat

From $x$ og $\delta \nu \lambda \eta$, a club, and $x i p a \lambda \eta$, a head. For this Claviceps is substituted by some authors as more regolarly formed. The
546. Rye is solittle grown in this country for food, that we seldom if ever hear the same complaints of the evi ever of bread into the composition of which a large quantity of Ergot enters, is followed by the mos distressing and fatal gangrene. Its medical uses in the contraction of the uterus are well known, and there is no doubt that ewes and heifers often slip their calves when it abounds in a pasture. Farmers therefore should on no account turn in breeding stock where Ergot abounds. It is often very common on bents of Rye-grass in autumn 547. Though the accounts of the action of Ergo when used for a continuance upon the human frame are
beyond doubt, its oceasional use may pass off with imbeyond doubt, its occasional use may pass off with im-
punity. Children on the Baltic coasts often eat it under the name of St . John's bread without experiencing any evil consequences. Our figure represents at a an ergoted grain with Cordyceps purpurea growing from it

Ants and Guano.-It affords me pleasure to be able to confirm all you say upon this subject. Some eight or nine years ago in which Peaches and Nectarines were cultivated. The plants were grown in turfy maiden loam, and the ants were evidently introduced with the soil. However during the early part of the season, when a mois condition of the soil and atmosphere was maintained to induce rapid growth, the ants made but little pro-
gress ; but as the fruit approached maturity, and a gress ; but as the fruit approached maturity, and a drier soil and atmosphere were preserved to faciliate ants increased so rs and conduce to hig to disfigure i not destroy the entire crop. Various plans of trapping were resorted to, but all were very tedious and none very successful. Toads, upon the whole, proved the best traps, but they do not enjoy ants as they atmosphere. Besides, few ladies like their appearauce especially so contiguous to luscious fruit, and worse than all the ants got the mastery of them. The idea then occurred to me of trying to make the ant homes so nauseous as to compel them to be off. With this object in view I had several strong infusions of cow horse, and sheep manure made to water the tubs with The ants did not relish these applications; still they reasoned like lawyers upon the advantages of possession,
and stayed where they were. They even legan to retaliate, for while the surface was wet with the manure water they kept more than once on the trees, and consequently did more damage to the fruit. But no sooner did the soil become partially dry than they returned to their old quarters, and appeared as happy as ever. Last of all I sprinkled some very strong guano all over the surface of the tub, and immoediately gave them a gentle watering. The consternation and discomfiture if not entire destruction of the ants was complete. The sudden bursting of a steam boiler in a crowded factory could produced in the ant homes. Their first anxiety, as i always the case with these interesting insects, was about their young, and a few efforts were made to secure and drag off the eggs. But they were alnos scramble for personal safety ensued. Many, however, perished before they reached the sides of the tubs, and the others were found half-dead upon the floors in the morning. A second application over tubs, floors, \&c. cleared the houses, and the fruit ripened in great per-
fection. I have frequently applied the same remedy since and always with success, more or less speedy accord ing to the strength of the guano. The ants generally writhed under it as if hot water were applied to them and I have always attributed its destructive properties to the larye quantity of very volatile ammonia it con my . This may be the reason why I bave observed alarmed experiments that the ants were not so wate administered dry guano, but became intense. I wa under the impression that I bad communicated these facts to some of the garden periodicals, but now presume that I have been mistaken. Of this however I am quite sure, that such facts cannot be too generally corroborated or too widely known, more especially as all fruite, as tar as I am aware, and most flowers thrive amazingly under the guano regimen ; and thus most fortuna ely we are enabled to destroy a troublesome peat, and to improve the health, beauty, and productiveness of our flowers and fruit by one and the same agen
Fish, Harduick Gardens, Bury St. Edmund's.
Bethunia.-I beg to submit for your inspection the leaf and flower of a plant which grew up in a Musk pot. The leaf you will observe partakes of the form of the Convolvulus, Thanbergia, and Pharbitis, but the flower is entirely different. The plant has but one
stem now about two feet high, and whenever a leaf
sprours a stem shoots out bearing a flower which resta gran the anterior part of the leaf. It would highly its name and my friens entivating the plant. In the absence of its proper designation it has been called Bethunia, and it requires much water. J. D. B., Wandsucoth Common. [It is some Polygonaceous plant, too imperfect for identification. The flowers are all males. It is apparently related to Polygonum nepaby the females.]

Bees.-There is now to be seen in the shop window of Mr. Cory, grocer, of Trumpington Street, Cambridge, a glass of honey containing the extraordinary feet 0 . reet 1 Mgh , and the diameter or a common cottage hive. The empty glass was placed upon the the finest virgin stock, and it was filled perfectly with he finest virgin honey in seven weekis. Not a speck or blemish is visible in the combs from top to bottom. Mr. Lamplugh, chemist, of Chatteris, in the Isle of Ely, is the person who produced this immense mass of honey worked from a single hive. He has once before produced a glass containing above a hundredweight. Mr. Lamplugh seems somewhat shy in answering questions, but he says he can do this by his method of management, and that no trick or subterfuge is resorted to. Surely he ought to publish his system for the benefit of the public. There is no denying the simple fact that this huge mass of the purest honey was taken from the top of an ordinary cottage hive. I under stand that $\mathrm{Mr}^{2}$

Early Peas.-For the purpose of ascertaining which among the Conquerors, Emperors, and Champions is really the best Yea for a first crop, I this season sowed riet 1 S oug No l; Sutt' Enty Champion ; 3, Warner's Conqueror ; 4, Warner's Emperor ; 5, Waite's Daniel O'Rourke. No. 1 I have reason to believe is the true kind, and it is the eariea and best Pea of the whole lot. Nos 2 and 3 I could not distinguish from each other in any poink Both No. 1. I am told that Warner's Conqueror is only nother name for Warner's Emperor. If so, and it my No. 3 is true, then Sutton's Early Champion and Warner's Emperor are one and the same Pea. No. is evidently false; it appears to be a very inferio strain of the old Chariton. I cannot say whether or not my No. 5 is correct. If it is so, Daniel 0 'Rourke only rauks third in point of earliness. As this is a of Peas, it some importance both to buyers and sell he result of their experience on the subject We want but one sort of Pea for a first crop, and if by comparing notes we ascertain beyond all doubt which保 tained in the seedmen's lista, all the others might with advantage be consigned to oblivinn. J. B. Whiting
On the Practical Advantages of introducing Botany into ? iools.-In the valuable series of articles contributed to your jourual upon this important subject by the Rev. Professor Henslow, I see that allusion is made to the inconvenience that attends the absence of systematical information from the collectors of valuable articles sent to Europe from our colonies. Now this is a point to which my attention has been particurarly drawn, both in foreign countries and at home, and $t$ to time more frequently than during the Exhibition of 851. It is a fact noturious to the jurors of most, if not all he departments that were concerned with raw products, that countless numbers of reputed valuable substances rom the animal and vegetable lingdoms were sent or brought to England by men of activity and intelligence, but who were utteriy ulable either to give themselves, $r$ to obtain from others in the country whence they were procured, any intelligible account of their origin. Supposing it to have been a vegetable product, they might ell wh more, intelligible hint as to nature of its flowers, leaves, or ruit. Comparisns with plantsof our own country (with Which, as al , for the questioning afinity, were always to be had when the questioning application and no meaning, and English colonial names ound of alse analogies and mistaken resemblances . but en allige analogies and miat that required nothing beyond ordinary powers of accurate observation was extremely rare. Now, though early training in the elements of botany will not make grown up men botanists, I do believe that it will have so schooled the aculties of observation of every man subjected to it as a child, that his powers to form correct comparisons will remain latent through life, even when men will habitually exercise that faculty through life; for when once it is known and felt to be present and capable of being called up, the desire to lastly, I believe theve irresistible will exercise it in obtaining a knowledge of the plants which surround them, that there will be no colony or dependency of Great Britain, which will not contain many persons able to give such a description of any plant that may be brought to them as will guide a proficient in botany its affinities and uves. J. D. H.
Putato Lisease and Electricity. -The theory advanced in last_week's Number by "J. Q. Rumball," viz, that
the Potato disense is cuused by the action of electriciry on wet tubers, appears to me the one days after a thunderthe disease should appear tiree days after a thunder
storm is no proof that lightning produced it, for it might be a mere coinendence, or it might arise from
other attendmnt circumstances. Your correspondent other attendnnt circumstances. Your correspondent
makes no attempts to support his theory by known factmakes no astempts to support his theory by known factit has many) seem to look upon electricity as another "Ariel," playing all sorts of odd pranks, and setting all laws at defiance. Now this is not the are subject to certain fixed laws, which never vary. For the benefit of your non-seientific readers I will trespass a litie on your space to explain the phenomena which take place during such storms. All thunderEither, lst, by the passage of the electrical fluid from one cloud to another; or, 2 d , from the earth to the clouds; or, 3 d , from the clouds to the earth. This takes place, however, only under the following circum-
stances-the olund, or part of the earth from which it passes, must be in a positive state of electricity; and the cloud, or part of the earth to which it does pass, in a negative state of electricity; the exchange goes on
till both are reduced to the same condition. Another important law of electricity is, that it moves by conduction, i.e., as some substances, such as metals, water, \&ce, are conductors it will pass along them; but glass, fur, atroospherie air, \&ce, being pon-conductors, first causes of thunderstormas epumerated above cannot influesco come to the third-the passage of the electric fluid from the clouds to the earth, which takes place in the following manner :- A cloud highly charged with positive eleetricity, being surrounded by air which is a bad con-
ductor, cannot discharge its excess of electricity till is is ductor, cannot discharge its excess of electricity till it is in the vicinity of some good conductor, such as a church, a house, a tree, or any other high object, to which in
immediately passes (generally in a zigzag direction, owing to the resistance of the air), and is conducted to the earth, where it is distributed in a thousand different directions. Now with these few simple though well established laws before us, what are we to make of Mr. Rumball's theory? The only data he advances in support of ot are :-18t, he has trequently
observed that the Potato disease made its appearobserved that the Potato disease made its appear-
ance three days after a thunderstorm, it the ance three days after a thunderstorm, if the
weather continued wet or damp, but if the weather was fine, very little disease appeared.
If this is a fact that can be borne out by general observation it wonld lead me to suppose that excessive wet, afiter dry hot weather, had produced disease and not electricity. Second, the "illustration" which your correspondent quotes in support of his theory is worthy of notice ; that the disease attacked his plot of Potatoes in a dingonal direction is to me no illustration whatever,
for it appears to be at variance with all the known laws of electrical phenomena. The electrical current could not have been confined within the space he describes unless there was a more highly conducting medium running in that direction, which is improbable ; and if so,
ander such circumstances it could not have injured the nnder such circumstances it could not have injured the
Potatoes. It could not have been in the air, for if it had been so near the earth as to affeet Potatoes, it musi have at once passed into the earth, as the earth is a good conductor, and the air a non-conductor. This fact is, I think, a "curious illustration" of the fallacy of his theory. Lastly, the erection of the iron rods proves nothing, for they could only act by concentrating the electric fluid in that part of the earth which
he wished to be most free from it. A great deal of he wished to be most free from it. A great deal of
space might he wasted in the refutation of these and other data brought in support of this and other theories respecting the Potato disease, but I forbear; I would merely suggest that such theorists would do well to parsue their observations in a more systematic manner, and instead of being lawgivers let each be, what I am, a Student of Nature.

Twenty-Sixth Meeting of the Baitigh Association for tee Advancement of Scierce, Chelfenham, August 6.- Under a summer sun, Italian more than English in its warmoth, the members of the British Asso-
ciation gathered at Cheltenlam to commence their Twenty -sixth Annual Session. The beanty of the town and neighbourhood and the magnificent weather did not fail to draw together a large company, though the scientific attractions were not expected to receive any gained during the war from the discussion of questions bearing more or less of political interest. The first general meeting of the members took place in the evening at eight o'clock. The Duke of Argyll resigned the chair to Professur Daubeny, who rose and addressed the meeting in an elaborate speech for which we much regret our inability to find room, except so far as one

Itis well is concerned
"Itis well kriown," observed the President, "that a controversy has been going on for some time past between this distinguished foreigner, and certain experimental agriculturists of our own country, with regard to the principles upon which the manuring of our land ought to
be regulated. In this dispute, however, you will not expect me to take part, for it would he obvionsly improper on the present occasion that I should avail
myself of a little brief authority to influence the public on any other, it might be deemed an act of presumption in any other, it might be deemed an act of presumption extensive practical experience of the one, or to the high scientific eminence of the other, to tahe upon him self to adjudicate between two such conflicting parties.
But I may be permitted to remark, that whilst some But I may be permitted to remark, that whulst some
points of difference between them still remain open for further investigation, a much nearer correspondence o opinion exists with respect to others than the public in general, or even perhaps the disputants themselves, are inclined to allow. In so far, indeed, as concerns the relative advantages of mineral and ammoniacal manures, I presume there is. littie room for controversy; for inorganic constituents required by the crop, it by no means follows that the latter are always in an available condition in which land has been long under cultivation, the former class of manures becomes, as Baron Liebig assorts, a matter of paramcunt necessity. Now, that the same necessity exists for the addition of ammoniacal
manures can hardly be contended, when we reflect, that manures can hardly be contended, when we reflect, that at the first commencemeut of vegetable life, every
existing species of plant must have obtained its nourish ment solely from the gaseous constituents of the atmowhich it vegetated. The only divergence of opinion therefore that can arise relates to the degree of their respective utility in the existing state of our agricultare, and to the soundness of Baron Liebig's position, that a plant mineral ingredients, and is all other respects in a condition calculated to allow of healthy vegetation, may sooner or later be able to draw from the atmosphere whatever else is required for its full development. And does not, I would ask, this latter position derive some support from the luxuriant vegetation of the tropics, where art certainly contributes nothing towards the result? and is it not also favoured by such experiments as those carried on at Lois Weeuon, in orthamptonshire, where the most luxuriant Wheat years without manure of any kind, simply by following out the Tullian system of stirring up and pulverising the soil? How, too, are we to explain that capacity of sub Mrising without any artificial supply of ammonia, which
Mres is led by bis experiments to attribute to Turnips and other plants of similar organisation, unless we assume that the power residing in the leaves of absorbing ammonia from the air may render plants, in some cases at least, independent of any extraneous aid? Be this, however, as it may, there is at least a wide distinction between this opinion and the one attributed to Baron Liebig by many, who would seem to imagine hat, according to his viewe, ammomia, if derived from As if it could be a matter of any moment, whether the substance which in both cases afforded the supply of aitrogen, and which in both cases also was primarily derived from the decomposition of organic substances, had been assimilated by plants direerly upon its being thus generated, or had been received into their system atmosphere! To suppose that Baron Liebig should have attached any moment to this distinction seems although the paramount importance of mineral manures may be insisted upon, and the success which had in certain cases attended the use of one compounded only of mineral ingredients may be put forward as a motive for further trials, the utility of ammoniacal substances in all their several forms is at the same time distinctly admitted. Still the practical ques' ion remains, whether admitting the theoretical truth of Baron Liebig's posi-
tion, a larger expenditure of capital will not be required tion, a larger expenditure of capital will not be required with agmoniact farm into a cond proeuring those materials which contain that ingredient ready for use. And here experimental researches, such as those conducted on so extended and liberal a scale by Mr. Lawes and Dr. Golbert, come in sid of theory. They stand; as it were, midway between the abstract principles which science points out to the furmer and the traditional usages with respect to his art which have been handed down to him from one generation to another. They bear the same relation to the farmer which the records
of the clinical practice in a large infirmary do to the general principles of medicine expounded by the modern physiologist. It is true that the experience of a particular hospital may not at all times coincide with the anticipations which science holds ont; but this discrepancy only suggests to us the imperfection of our confide knowledge, and is not allowed to dilu the lished on incontrovertible evidence. On the contrary, whilst he modifies his practice from time to time by the experience he has gained by actual observation, he feels at the same time the fullest conviction, that these results will be found eventually reconcileable with the general principles, which a still more extended series of induction may have established."
In concluding a moes interesting apeech Dr. Daubeny added-
"We are told, that in a future and higher state that of praising and worshipping the Almiuhty. But is not the contamplation of the works of the Creator, and the study of the ordinancer of the Grest Lawgiver of the
aniverse, in itself an act of praise and adoration ? and, if so, may not one at least of the sources of happiness one of the rewards for a single-minded and reverential pursuit after truth in our present state of trial, consiast in a development of our faculties, and in the power of comprehending those laws and provisions of nature with which our finite reason does not enable us at pre-
sent to become cognisant? Such are a few of the reflections which the stady of physical science, cultivated in a rigbt spixit, naturally suggests; and I ask you, whether they are not more calculated to inspire deeply conscious how much of the vast field of knowledge must evar lie concesled from our view-how small a portion of the veil of Isis it is given us to lift up-and, ting faith the knowledge vouchsafed from on high on subjects which our own unassisted reason is incapable of fathoming. 'Let us not therefore,' to ase the language of a living prelate, 'think scorn of the plea-
sant land.'- 'That land is the field of ancient and modern literature-of philosophy in almost all its departments -of the arts of reasoniug and persuasion. Every part of it may be cultivated with advantage, as the land of Cauaan when bestowed upon God's peculiar people. They were not commanded to let it lie waste, as ncurably polluted by the abominations of its firs inhabitants ; but to cultivate it and dwell in it, living in obedience to the divine laws, and dedicating its choicest fru:ts to the Lord their God.

Next week we shall commence our reports of such parts of the sectional business as we think likely to ie: terest our readers.

## flotites of Books.

Descriptive Dictionary of the Indian Idtands and Adjacent Countries. By Johu Crawfurd, F.R.S. 8vo Bradbury \& Evans. Pp. 459.
No one knows so much of the Indian and Philippine Archipelagoes as Mr. Crawfurd, whose "History," pubhished above thiuty years ago, is still a book of the highest authority in adl that relates to the trade, history betore us the learned author has recast his materiale, reducing them to the form of a dictionary or rather gavetteer, by which plan a reader can find the subjects he seeks for more readily than in a continuous narrative even if well indexed. There is no satisfactory way of describing how such a work is executed except by extracts, of which we produce two only. The first relates to the Cocos nut tree, serving to correct the absurd exaggerations current respecting that most useful plant.

Cooo-Palm (Cocos-nncifera).* This Palm, so gensrally diffused over the tropical world, old and new, would appear to be a native of several of the islands of the Asiatic Archipelago, while to othersit seems to have been conveyed by currents or by man. The two mort frequent names for it are, the Malay, nur, and the Javanese, kâlapa. These, with some corruptions, have a very wide circulation, especially the firsk, The
Javanese name extends to the lunguages of Colebs, Javanese name extends to the languages of Colacen Sea, but the Malay, to the Philippine tongues, to the language of the South Sea Islands, and oven to that ef Madagascar.

The Coco-Palm is in a good measure a littonal plant, attaining earliest maturity, greatest size, and most fruittulness close to the sea, although growing also and yielding fruit at a considerable distance from it. natives are well aware of this fact, according to the
following apt quotation from Marsden's Suwatra. 'Here, said a countryman at Laye, 'if I plant a Coco-Nut, I may expect to reap the fruit of it, but in Labun (an iuland distriet) I should only plant for my great grandchildren.' Many uninhabited islets, on the weatern coast of Sumatra, afford examples of the mode in which the Coco-Palm has been conveyed by currente, and of the partiality of the plant for the immediate neighbourhood of the sea 'Ihis island, Triste,'says Dampier, 'is not a mile round, and so low, hat foll of Coconuts clear overik. nute are sut small, yet sweet enough, full, and more ponderons than I ever felt any of that bigness, notwithstanding that at every spring. tide the salt water goes clear p. 474. The island thus referred to is the Pulo-Mega, or 'Cloud Island' of the natives, a name taken from Sanserit, and is distant from the shore of Sumatra 15 leaguts. From this account, it is evident that the nut may be conveyed a long way by sea without losing its vitality. The same judicious observer narrates the following fact in illustration. 'The 10th day, being in latitude $5^{\circ} 10^{\prime}$, and about 7 or 8 leagues from the island of Sumatra, on the west side of it, we saw abundasce of Coco-nuts swimming in the sea, and we hoisted out our boats and took some of them, as also a small hutech or scuttle, rather belonging to some bark. The nuts were very sound, and the kernel sweet, and in somes, the milk or water in them was yet swoet and good. Vol. i. p. 474. The Coeo-nuts, in this case, were no oubt the produce of a wreck.

By far the best account of this important
We regret to be oblified to notion some typographical errory
suoh as thil wectiers for meife
nalis for officinarum, and mo ori
that I have seen is to te found in the 4th vol. of the Journal of the Tndian Archipelago, written by Mr. J.
T. Thomson. 'The habit of this tree,' says this expe-
rienced and intelligent writer, 'is on the sea slurre rienced and intelligent writer, ' is on the sea shirire
fringing the beach. In such a position, should the sorl fringing the beach. In such a position, should the soll be lion, such as sea-sand and shells, it grows luxuriantly without the concomitant sids of cultivation, manure, or the proximity of inhabited houses; but this only bending stem inclined towards the sea, causing its fruic to be received into the bosom of that element, appears to have peculiarly fitted it for extension to the various islands and atolls of the Indian and Pacific Oceans, to whose inhabitants it affords both sheiter and fond. whose inhabitants it affurds both sheiter and fond.
When planted in other localities than these, it neither When planted in other localities than these, it neither
grows well nor affords fruit, unless it be on rich still or in the proximity of dwellings, and in average soils it requires both considerable manuring and cultivation. good Cocos-nut tree when in full bearing will yield 140 to 150 nuts per annum. for commences to in sandy soils of middling height in the sixth and seveuth year, and on high ridges in the ninth aud tenth year, and the last, though slow in growth, are wholesome goo elapse before the formation of the fruit, and the fruit requires six months more to come to full growth, three monthe more to ripen, and it will remain other two months before it drops. Thus 14 months elapse between the blossoming and the falling of the ripe fruit.'

The accounts usually given of the almost innumerable uses to which only parts essentially valuable are the albumen of the only parts essentially valuable are the albumen of the
nut for its oil, and its husk for a textile material. In the Asiatic Archipelago the wood, the leaver, the sap, and the pith of other Palms are either better in quality or cheaper. In whatever manner the first inhabitants of other regions of the earth may have obtained their earliest subsistence, it is certain that those of which the Coco-Palm is a native had at once from it a spontaneous
supply both of food and drink. Its presence on the coast probably contribuled, with the easy supply of fish, to determine, from the first, that maritime character which still belongs to so many of the tribes of the Archipelago. called Sago.
"Sago, in Malay, Javanese, and all the other languages of the Archipelago, sagu, most probably a word of one name of the farina or meal, for each species of the genus of Palms producing it has its own specific name Of these there are supposed to be five, the moast frequently cultivated of which are the Rambiya, Sagus leovis. Alt the species much resemble eacl other, and all yield an immense quantity of farina, the wood being all yield an immense quantity of farina, the wood being
a mere shell, containing a mass of medulla. Sago trees a mere shell, containing a mass of medulia. Sago trees Philippines, as far as Mindano, wherever there is genial soil for them, and this soil consists of a marsh or bog, composed of decayed land vegetables, near the sea, but excluding tidal action. They are most abundant in the eastern parts of the Malay Archipelago, as
the Moluceas and neighbouring iolands, with New the Moluccas and neighbouring iolands, with New
Guinea and Borneo, and in the Philippines, Mindano. In all these they are more or less the bread of the in habitants. From these countries they are believed to have been introduced into Sumatra and the Malay Peninsula.

The Sagos differ from all other Palms in two important particulars. They propagate themselves by they die after producing truit. From the first of these properties, a Sago plantation once formed is perpetual. The trees are cultivated in small patches, and a man and his family are thought, without nuch care, to be equal to the management of a plantation of 100 square fat down immediately before bearing fruit, which is usuaily about the age of 15 years. 'When,' says Mr. Logan, who has given by far the best and fullest account of the culture aud manufacture that has ever been published, 'a plantation has once arrived at maturity, there will be a constant harvest, because the natural
mode of growth secures a continued succession of new plants frum the time those first planted have begun to extend their roots, and this succession can be regulated by the knife in any manner the planter desires. The Sago tree whr in cut down and the top severed from 15 to 20 feet in height. Assuming 20 inches as the diameter and 15 feet as the height of the trees, the contents will be nearly 26 bushels, and allowing one half which wody fibre there will remain 13 busbels of starch of 700 lbs . for each tree or $12 \frac{1}{\frac{1}{3}}$ bushels. It way ive some idea of the enormous rate of this produce if it be considered that three trees yield more nutritive matter than an acre of Wheat, and six trees more than an acre of Potatoes. An acre of Sago if cut down at one
harvest will yield 5220 bushels, or as much as 163 harest of Wheat, so that according as we allow 7 or 15 years for the growth of a tree, an acre of Sago is equal in annual produce to 23 or to 10 acres of W
Journal of the Indian Archipelago, vol 3 , p. 312 ."

Sago is the sole bread of the inhabitauts of th

Spice Islands and of New Guinea, and its neizhbouring islands, but of no other part of the Arclipelago. In the
Malay countries it is the only food of the wild tribes, and is hardly used by the Naalays themselves. In Mindano it is consumed only by the poorer classes, and in Java, Bali, and Lombloc, fertile in Rice, it is
altogether unknown as an article of fond. It is far from being either so palatable or nutritious as it is prolific, and is never preferred, even where it is most abundant, to Rice. It has the obvious dizadvantage of on which it is impossihle to fall back on any other. In this respect it is like the Potato or the Banana, although over the first of these it possesses the advantale of the
crop being less liable to failure; if, indeed, liable to at all. One thing is certain, that no nation of the Archipelago, of whom it has been the chief vegetable diet, has ever acquired any respectable amount of civilisation. Those doing so, who had attained the greatest of it, were the inhabitants of the small islands producing spices, and they owed their advancement to the trade they carried on in these commodities, but even
these had neither a calendar nor a written language, and received the useful metals and their clothing from the nati. ns of the west.

The granulated farina of Sago, of a dirty brown colour, used to be exported fiom the Archipelago in smull quantities, under the old system of monopoly, but
about the time when the trade with Europe was first thrown open in 1814, the Chinese of Malacca began to prepare a much superior article, known in commerce under the name of Pearl Sazo. Of this and of Sage sent the chief place of manufscture and principal mart the Chinese being the sole manufacturers, and the raw material being brought from various neighbouring countries, but chiefly from the north-western coast of Borneo, and the north-eastern of Sumatra with its adjacent islands from Siak to Indragiri. In the year 1847-48 the quantity of Sago exported from Singapore was about
$45,000 l^{4}$

A more difficult task than thus to record the most important facts relating to the vast region over which Mr. Crawfurds work extends coald hardy have been undertaken. We therefore must not be surprised a such subjects as Gutta percha, Cotton, Satia wood, China Grass, Caoutchouc, dc., having been omitted. plement while we have a most valuable book of reference, indispensable to all good libraries.

The Stepping Stone to Natural History (Longmans, 12 mos , pp. 191,) is upon a good plan, but its field is much too extensive for the little people who are to use its name stepping stone tountain. What can childre want to know about Simiuclce and Cebidce, or Spring boks, Koodoos and Nylghaus, or Chondropterygian, is quite beyond all possible utility. The apology, that it is upon the good old spelling book plan, wilh hardly be accepted in these days of common sense. Teach children all the important facts about such natura history as they come in contact with; tell them all abou horses and cows and sheep, and sticklebacks and pike, and blackbirds and poultry and toads and froge, but in mercy do not perplex and disgust them with a catechism concerning narwhals, Mastodons, Babyroussas and Geckos While the little volume before us must be condemned for the purpose its author seems to have contemplated, we can recommend it to adults unacquainted with natural history, and who have access to museums Even for them, however, it is not
have been, from want of an index

## Garden Memoranda.

Messrs. Wood \& Son's Nurskry, Maresprild, Sussex.-After a pleasant journey of some 13 miles railway, we arrived at this celebrated hose nursery, which is delightfully situated on rising ground, with Ashdown Forest on the one hand, and a deep valley through which runs a stresm well stocked with fish and overhung with woods that thickly clothe the neighbouring heights on the other. Here Mr. Wood, soon after the termination of the battle of Waterloo and after many years of active service on the Continent, quietly settled down to cultivate the Queen of Flowers, and
from that time to the present, by means of energy from that time to the present, by means of energy in importance. He began with 14 acres, which have now increased to 60 . As may be imagined, these are not all covered with Roses; on the contrary, many acres are occupied with general nursery stock. The Queen of Flowers may nevertheless with justice be said to form the most prominent feature of the establishthe first staudard Roses in Sussex; Mr. Wood having seen them growing in a private garden on the Continent seen soth their beauty and effect ; immediately, therefore, the war with France had ended, he obtained fow and sent them home to his brother-in-law, but owing to their being too long out of the ground they did not grow. Others were, however, afterwards imported and planted in this nursery, in which a good stock was soon got together; and now it not only pro-
standards and dwarfs in equal abundance. It is stated that
Of the brilliant Geant des Batailes we saw in the shape of standards and half-standards no fewer than
7000 plants, and of that fine new Rose General Jacqueminot there were certainly as many as 2000 specimens. These two Rosee were growing side by side, and although the unusual amount of sun we have lately experienced had greatly impaired the brightness of their colours, such large plantations of them made a display more easy to conceive than describe. The latter certainly wants more doubleness to be perfect ; but its glorious colour and large size make it a great acquisition. Duchess of Norfolk, another high-coloured nearly spineless Rose, is well worth attention. This is a profuse flowerer, grows very vigorously in autumn, and makes an excellent pillar Rose. It can hardly be termed a climber. Of Jules Margotin we have on former oceasions spoken in the most favourable terms; it is one of the most free flowering Roses with which we are acquainted, and here it seemed to be unusually well coloured. As a bedding variety it cannot tail to be extremely effective. Col. Rougemont is a noble Rose Imost as large as Baronne Prevost, which it resembles evemes into bloom after that variety has don flowering, and therefore becomes a useful successor to that favourite sort. Lonise Odier, rosy peach, is one o the best of its class, and the same may be said of
Prince Leon, a compact brilliant crimson; Gloire de Dijon is a fine Tea-scented Rose with a Noisette habit and Melanie Willermoz is a good hardy white shadec with buff. Madame Cambaceres is a fragrant, very iree flowering, finely cupped variety, and Emperor Napoleon and Baronne Laray are both good new Rose and worthy addutions to the class to which they belong Revei and Vorace are two good Bourbons ; Souveni de Leveson Gower though not quite new is an excel lent free flowering and compact Rose. Duchesse de Orleans, deep rose, is large and durable and finely formed. General Castellane, bright carmine, is an excellent variety, and Gloire de France is a good excellent in shape; Le Lion des Combats is a large double crimson, and Madame Place, pink with a rich satin-like gloss on it, is well worth growing. Among tripes, Panache d'Orleans is one of the best, and of Docteur Julliard is a very free flowerer. Madame Theodore Martell, a blush pink, is very double and carries its flowers up well above the foliage; La Ville de St. Denis is a bright rose, large and showy; Lord Raglan is small, but brilliant and so free that it has six or eight flowers on a truss.
Alexandriue Bachmeteff is a good new Rose with the Alexandrine Bachmeteff is a good new Rose with the
colour of Robin Hood. Of light Hybrid Perpetnals few colour of Robin Hood. Of light Hybrid Perpetnals few beat Mrs. Rivers and Madame Vidot, both excelient flowers of their class ; a new light kind celled
Josephine Ledechaux is said to be good, but this we did not see in flowe
Of Standard Roses worked high so as to cover unsightly objects quickly, and also for forming weeping or fountain Hoses, we remarked some excellent examples. Some Mosses and Hybrid Perpetuals worked on were very fine, having made remarkably large heads for the time they have had to form them in. They are worked so near the ground that in addition to the support derived from the stock they send out roots of their own, and therefore as it were have a double chance of succeeding. Some kinds take freely on this stock; others do not ; therefore both judgment and exworked on it
Tea Roses in pots are grown here extensively, and form a prominent feature in the business of this establishment. A new span-roofed house is being erected wide, and 12 feet high ; it is to be glazed with Hartley's rough plate glass, and heated by means of hot water in tanks and pipes. Of other houses two were filled with Tea Roses, and out of doors beds bave been formed for them as follows. The bottom consists of faggots over which bot dung is laid to the dep h of heet, and then $\tan$, in which the pots are plunged. Thus placed in the open air without covering of any kind their wood gets well hardened, and they are thus more easily kept ree from mildew while growing, These Roses are a brick tank built in a corner of the stable-yard ; into this are put from time to time quantities of horse droppings; these are mixed wilh rain water collected from the roofs of houses and conveyed there, where after standing for a time it is fit for use, and Bkifuly applied forms an excellest are reported to be growing here in pots.
Manures, it may be mentioned, are scarce and dear in this locality; all sorts of expedients are therefore resorted to to auply their place. One of the best substitutes for them isp charred turf and other garden refuse To get this 10 feet in len,th, 6 feet deep, and 12 feet wide these sre hid 30 loads of turf from the forest, mixed with Lerrel leaves and other regetable retuse. These when Laurel leaves and other vegetable retse. These when dry are set on fire and covered eresping, and ao vent as much smoke as possible from escaping, and s. In thested until the whole mass has become chaure is obtained, whicls when applied to Roses and other crops has been found to be productive of the very best results.

Amoug hardy hervaceous plauts Phlux Countess of
Home is one of the finest things in its way we have white with a crimson eye, well formed, and compactly set on the spike. Col. Dundas is another capital Phlox, rosy pink in colour, and, like that just noticed, remains long in beauty. King Leopold is an excellent striped variety. These are kinds which should be in every garden. Another Phlox called Madame Fontaine, white with a bold crimson centre, is also good. Lyth rum "speciosum roseum " is an extremely gay plant, and would make an effective bed; it throws up numerous spikes covered with purple blossoms quite 15 inches in length ; this and the dark-red Monarda didyma are plants which should not be lost sight of ; they are much gayer than many new things which are more costly plant which is quite hardy and las's long in bloom.
Holiyhocks are cultivated here in considerabl numbers, and among them were some first class kinds It is only lately that this noble autumnal plant would grow here. It has always been eaten up with mildew but by means of careful attention to dusting the leave with hot lime and sulphur this pest has nearly disap peared.
Forest and ornamental trees and shrubs are grown here extensively. Weeping trees, both Ashes, Thorns Hollies, and Larches, are also plentiful, as are Standard Portugal Laurels, among which were some promising speci mens with straight clean stems from 8 to 10 feet in height Of Laurel hedges we noticed some good examples, 10 and 12 feet iu height, and ar useful both for shade an helter. Fruit trees, especially Peaches, Nectarines and Cherries, both trained and otherwise, grow remar ably well in the light sandy soil of this locality.
Thirteen acres of very unpromising land attached to this nursery have lately been converted into an American garden. We say unpromising because it consisted mostly of sandy rock, over which was a thin layer of peat. The rock was chipped away by degrees, broken
up fine, and mixed with the soil, aud now it is found up fine, and mixed with the soil, aud now it is found
that Rliododendrons, Kalmias, and other peat-loving plants thrive in it perlectly. This is a good example of what may be done with land of the worst description. We may mentio: that Potatoes both here and in loam
showed disease in their tups; the tubers appeared to be unaffected
The growth of Conifers is not neglected here; amon them we remarked a Cryptomeria said to be 30 feet in height. Its stem I foot from the ground measured $2 \frac{1}{4}$ feet in circumference, and it is beautifully branched from bottom to top, altogether forming one of the fines trees of the bind we bave seen. Of Abies Douglasi there was a thriving specimen ; also Libocedrus chilensis 5 feet high and quite hardy, having stood ou of doors several wiuters; Araucaria imbricata, and eral kinds of Pinus.
Finally, it may be worth recording that this nursery is open at all times to respectable parties, whether they come to buy or for pleasure. To be able to see the Rosee when in full bloom is to many who have other wise no chance of seeing such a collection a real treat, and fur retirement from he heat of the day a commo dious Rose-covered summer huuse has been provided in which a leisure hour may not be unprofitably spent.

## Miscellaneous.

The Tansy and its value.-M. de Morogues announces that this plant, dried, is excellent sheep food, and that when fresh it makes capital litter for domestic animals. Its peculiar balsamic odour most effectually drives away fleas. A lapdog sleeping on a bed of fresh Tansy is immediately treed from these vermin. It should be renewed when the leaves are quite dry. This seems a better application of the plant than following the xample of our grandmothers and making it into cakeo. Destruction to House Bugs. - The French Acadeny of Sciences is assured by Baron Thénard that boiling soap and water, consisting of two parts of common sosp, and 100 parts of water by weight, infallibly destroys bugs nd their eggs. It is enough to wash walls, woodwork, \&c., with the hoiling solution to be entirely relieved from this horrid p: st.

## Calendar of Operations. <br> (For the enssuing week.)

## PLANT DEPARTMENT

Conservatory, \&cc. - The cifferent varieties of Japan Lilies will soou be coming into bloom and will require attention in the way of staking. When remnved to the conservatory they should be placed in a cool airy part
of the house shaded from bright sunshine, and afforded liberal supply of water. Every care should be paid to prestrving the beauty of their flowers, and having as active war against insects; the best remedy for ants is guano (ste pp. 531 and 549 of our last and present numbers. Any repairs which must; be dune to plant houses should now be fini-hed as quickly as Cosid Pirs.-The fine wea hrr which we have been experiencing will be highly serviceable to the inmates of these structures, and while bright sunshine continues plants to rip-n their wood to allow then ge late growing plants to rip-n their wood; allow them plenty of air,
removing the sashes altogether on tine nights. Shake out and repot Pelargonuma which are sufficiently
in a cold frame until they have made fresh roots When fairly established after repotting they can hardly be too freely exposed to air or kept too cool. Attend carefully to Chrysanthemums ; see that the shoots are sezure from accidents, to which they will be liable eft unstaked after this time. Give them plenty of rich manure water and let them be set wide apart i they open airy situation, removing suckers as soon as they make their appearance. Cinerarias for earl
blooming should be kept cool and moist ; endeavour t seep them free of thrips and mildew. Repot Primula and encourage them to make rapid growth, especiall the double varieties which are particularly useful fo winter decoration. Calceolarias for spring flowering hould be sown at once if not already done; but we have now so many fine varieties of shrubby kinds, and these so hardy and easily managed that for mere decorative purposes the herbaceous sorts are hardly worth the trouble of growing. Cuttings of the shrubby sorts, such as King of Yellows and Orange Boven put in now will make useful plants for flowering nex pring, and with very little attention they will form spec Violets clear of red spider by liberal washings with the yyringe, and give them plenty of manure water; also attend to tree Mignonette for winter flowering, keeping
the plants well supplied with pot room and in the mos vigorous health possiole ; pinch off all the flowers a they make their appearance.

## FORCING DEPARTMENT

Pinerirs.-Plants growing in dung pits must be freely upplied with air to prevent their getting drawn, and hey should also be kept near the glass and not allowed to stand too closely together, for strong robust plants need hardly be expected unless this is attended to, an weakly drawn ones seldom or never yield fine fruit Give careful attention to such as are swelling ; afford them plenty of warmth and moisture, and as much manure-water at the root as the soil will bear. Remove useless suckers and gills as soon as they are perceived, which, if lef, only rob the fruit aud wenker the sucker for keeping up the stock. Do not allow young stock in free growth in the succession pits to stand too closely together, nor to sustain any check through neglect in watering, or the want of pot room Plants growing in beds of soil must also be carefully attended to with water, keeping the soil in a nice mois tate Where rapid growth is required keep as warm and moist as can be done without drawing the foliage and give plenty of strong clear manure water at the root, and the plants will make rapid progress for the next two months. Vineries,-See that Vines from Which the fruit has just been cut are free from insects, giving the foliage an occasional washing with the engine if red spider is at all troublesome; and use every precaution to keep the leaves in health as long as possible. Prevent the growth of laterals, which only shade and injure the principal foliage. Late Grapes colouring should be assisted with slight fires in cloudy where they are noscats, which, atter this seasuir gentle fires, unless the westher should prove un usually fine. Thrips are frequently very trouble some in lite Vireries where plants have been grown under the Vines, and where there is any quently examined closely; giving the house a heavy smoking as soon as they are perceived, and repeating this for two or three times at intervals of about a weel shading the house the day after smoking, where it can be done so as to be able to keep it rather close, will render the cure more effectual ; and if the pest is taken before it gets quite established, it will be easily got rid of by two or three smokings, but unless taken in time it is very difficult to eradicate. Peaches.-Give every attention to getting the wood well ripened, as next year's uccess will very much depend upon this being properly effected. Keep the foliage clean and free from insects, and endeavour to preserve it in health as long as posroots as dry as can both day and night, but keep the roots as dry as can conveniently be done, therefor guard the inside borders from heavy fulls of rain, shut ting up the sashes at night when there is reasou to apprehend much wet. Any gross shoots that may still incline to grow should be stopped, as if left they encourage the action of the roots, and cause a greater tendency to growth than would otherwise be the case. Loosen the surface of the border where this is at all close, in order to admit air and warmth

FLOWER GARDEN AND SHRUBBERIES
Timely attention should be given to the propagation of variegated leaved Geraniums, such as Flower of the day, Mountain of Light, and Golden Chain, which we need scarcely say are first-rate sorts for bedding out. Turner's Alma will make a capital addition to this class of plants. Most of the kinds are unfortuately shy growers except when planted out in rich light soil, and gross wond does not readily emit roots. Cuttings will strike freely, however, if planted where there is a little dry bottom heat, under the shelter of a hand glass in the open border or in a cold frame; but they are very iable to damp off in the moist atmosphere of an ord nary propagating pit. Look over the beds and see it
their appearance can be improved by any means, and spare no attention at the present time which is calculated to render the effect more satisfactory. Go over Rose beds frequently, removing decayed Flowers, \&c., and
keep down mildew by dusting the parts affected with the fungus is perceived. Any
hardy fruit and kitchen garden.
Keep the young shoots of Peaches, \&c., closely nailed in , and thin in order that they may be fully exposed to the influence of the sum. Protect the fruit from waspe by the use of a thin net if it cannot be done otherwise but shade the trees as little as possible. If not pre viously done cut off Strawberry runners, and trim and clean the beds so as to expose the plants for bearing next season to light and air, in order that they may be strong and well ripened. Lettuces to stand the winter hould now be sown ; choose for the purpose a bit of light dry soil. Also sow a small bed of Cauliflowers and some Cabbage to succeed the August sowing. Attend to providing a good supply of salad for late use. Plant out Lettuce and Endive on light rich soil. Attend to taking up, drying, and storing Onions. Destroy weeds and stir the surface of the soil among growing crops.

THE DORSETSHIRE POULTRY IMPROVEMENT ASSOCIATION.-The Annual Exhibition of this
ociation Will be held in Dorchester on WEDNESDAY and Association wil be held in Dorchester on w EDNESDAY and
THURSDAY, September 17th and 18th, when several valuable
Silver Cups the Silver Cups, the gittito of noblemen and entlemen of
in addition to the Society's Prizes, will be awarded.
All Entries must be made (on the Forms only) with the Honorary Secretary on or before Monday, september 1 st , after Prize Lists, Forms of Eutry, , ind the Rules of the Association
will be forwarded to any applicant on stamped Will be forwarded to apy applicant on a stamped enve

## SATURDAY, AUGUST 16, 1856.

We give in an adjoining page reports of the Wheat crop from 207 districts scattered over the United Kingdom, 196 reports of the Barley crop, 200 reports of the Oat crop, 137 and 112 respectively of Beans and Peas, and 209 reports of the green crops
Of the Wheat, Barley, and Oat harvest-reports 78,68 , and 78 renctively state the crop to be an average one; $1 \quad 98$, and 96 respectively put it at above an average, and 15,30 , and 26 respectively at below an areage. Rut this term "average" requires a word of explanation A reporter may have honestly returned his crop as "average" for a long series of years, while every succeeding year has been an improvement on the last. An "average crop" in 1856 means a good 1840. The "average" of 10 years ending 1846 was a good deal under that of those which have since elapsed-and when, therefore, 78 aut of 207 re porters state the present harvest to promise an "average" return of Wheat, we must take their opinion of the present crop to be only that it does not promise a greater advance upon pregress hitherto would lead us to expect. This of course enhances the meaning of all the more favourable reports as well. And here we may Whtion that among the 114 reports of the Wheat harvest which we have said return it on above an average, all those are classed which ase such terms as "good" and "very good," course in immense, the injustice is done of making a return for instance from Dumfries-shire or from Denbigh of equal value with one from Lincolnshire or Norfolk; but our readers will not be satisfied with this mere resume of results, and on examining the list themselves they will find that all our great Wheat growing districts are represented at the least quite as favourably as the others. Thus in Lincolnshine the crop is said to be "average, good average, good average, average, heavy, over nverage, cood, great breadth;"
and in Norfolk and Suffolk as "full average, average, hurt by midge, various, average, great breadth, average, good, talk of midge, full average, full crop, quite average, average, good average." We think, then, that taking into account the extent of land under Wheat, which is undoubtedly much beyond an average, along with the generially favourable opinion of the crop, we may be satisfied that there is now as large a quantity of home-grown Wheat within the country as there ever yet has been. To be sure it is not all harvested yet, and the weather of the last few days has not been first-rate harvest weather. The corn, too, is very much of it deadripe, and there is a difficulty in finding hands to reap it fast enough. It has ripened all so fast that we have little doubt the opinions as to harvest time which are given by our correspondents would all be put at 4 to 10 days earlier than they are printed here if they were given again. The hot dry weather of July and August has, however, heen favourable to the crop, and the rains which have fallen latterly have done more good than harm to the country generally as yet. We quite believe, therefore, that the yield of Wheat will prove an unusually productive one.
As to the other crops we may shortly say that of the returns of the Barley crop 30 put it as an average, 98 at over average, and 68 as under average ; of the Oat crop reports, 26 put it at average, 96 as over average, and averaye. The acreable produce of the Barley crop is thus at least as much above an average-and we believe them both to he unusually good -as that of Oats ; but to the former must be added the consideration that so few acres of the Barley crop probably never have been grown as has been the ase this year.
The Pulse crops are generally gond, especially hose of Peas. And on the green crop returns we may just add that they refer exclusively to Turnips, Mangel Warzel, \&c., not to Grass and hay nor to Potatoes. They are generally, it will be seen, un-
cut of Clover, it has been unprecedently well got and abundant. The opinions we have had given us of the Potato crop are generally favourable. The disease is spoken of in a few places, bat by no means generally.
Ws have received from Mr. Donnelly, of the Agricultural Statistics Office, Dublin, a copy of a very useful circular, addressed by him to County Surveyors, Chairnien of Railways, Canals, \&c., on the extirpation of roadside weeds. "It is," he says, "universally admitted that great injury arises to the farming classes in Ireland from the growth of weeds along the sides of public roads, railways, and canals, and the shedding of their seeds over the adjoining lands," and he requests therefore that the authority of the grand jury at the present assizes may be obtained in order that a special covenant may be introduced into all road contracts, requiring the destruction of weeds on the sides of highways The Lord Lieutenant, he says, considered the remoral of weeds not only from farms, hut also from the sides of all public roads, of so much general importance that his Excellency was pleased to refer to the subject at a recent agricultural meeting of the Royal Dublin Society.
The following table in illustration of the growth of this evil is taken from Mr. Donnelly's reports for 1853 and 1854 on Irish Agricultural Statistics He gives it as enforcing his appeal upon the subject.
The degree in which weeds prevailed on the sides of roads, railways, and canals is shown in four classes: in the first, the proportion kept generally free from weeds is given; the second shows the proportion in which the removal of weeds was only partially attended to ; the third, the proportion in which this useful labour was almost entirely omitted; and the fourth class that in which it was wholly neglected.

The evil complained of seems from the above table largely to have increased.

We promised last year to try what the produce would be of the chlorotized Oats described in the Agricultural Gazette, 1855, p. 569 and p. 586 . A piece of ground was selected for this purpose, consisting of good sandy loam free from any admixture of coarse new manure, hut in good heart, so as neither to force unnaturally nor to starve, either of which circumsłances would have materially affected the result. The first appearance of the plant was most unfavourable. It had a streaked unhealthy look, and the shoots which soon came from its base in great number were peculiarly flattened. At this time matters appeared in such a condition that it was verv doubtful whether the plants would ever have sufficient strength to throw up flowering stems. They were however well weeded, and the soil carefully loosened, insomuch that after a time, on the occurrence of more genial weather than when they were in an early stage of growth, they rapidly a good crop, that we felt half inclined to think that we should have to retract our notions of the absolute
necessity of good healthy seed to produce a heilthy, then a disease propagated by seed in the second peculiarity attendant on its growth. We have onr
crop. All continued well till the panicles had got quite free of their sheaths. The upper spikelets were tolerably healthy, or at most only slightly variegated, but the lower were completely chlorotized as in the previous year. There were indeed both stamens and pistils in the chlorotized flowers, but neither had arrived at perfection, and not a particle of chlorophyll was visible. The mischief did not indeed on the whole exist to the same extent as in the parent plants, but the loss would still vary from a fourth to a third, or as in a specimen now before us, to a half; and the comparative amendment is due most probably to favourable circumstances which would not exist in field culture.
However this may be, we have at least a certain proof that disease may be propagated by seed, a fact which reason anticipates and our experience in animal pathology renders more than probable. It was indeed pretty clear that the Lancashire Oats, which originally came from Scotland, were derived from a diseased stock, because portions of the same field which produced them when sowed with other seed was free, while on the contrary distant fields sowed with the
generation, with every attendant symptom reproduced.

The inference is clear, that a great desideraom in modern farming is a more careful selection , or the procuring of it from quarters worthy except worldy cunning, we have known the proft of implicit credit. It is quite clear that a person of of such an undertaking to be considerable.
intelligence and character might attain not only an The present season has been remarkable for the honourable reputation, but substantial profit, who peculiar prevalence of smut. The loss in some cases should make it his business to grow the best agri- has been a third, and not only Barley but Oats have cultural seeds possible for the market. He could suffered materially. Smut is in general so rare as command almost any price he pleased if he conld to cause little uneasiness to the farmer, and unlike once inspire faith in his judgment and probity. For bunt, it does not affect the produce when reaped, such a purpose a rich farm is by no means wanted, It may however be worth the farmer's while to conmuch less forcing manure : but the place of manure sider, from the present year's experience, whether must in great measure be supplied by the most care- he should not steep his Oats and Barley as well as ful cultivation and the exclusion of weeds. Above his Wheat. In such a case perhaps sulphate of all, he must not allow a single grain to which any copper is the safest remedy. At lezst it is so in the suspicion might reasonably be attached to pass out cave of Wheat, which does not lose its powers of of his premises as seed corn. The better plan, germination if the weather after steeping should indeed, would be to consume exclusively on the prove unfavourable to sowing, as is the case with premises produce which could not be warranted. some other preparations. Almost every one is aware It need scarcely be added that to insure success the that he canuot insure a crop of Wheat without very strictest accuracy must attend every operation, steeping, and we have now a case at hand where and a regular journal be kept noting the sources that process was neglected, and at least half the and a regular journal be kept noting the sources | that process was neglected,
from whence the parent seed came, and every produce is bunts. M. J. B.

## Home Correspondence.

The Cradle Scythe.-Referring to the discussion on mowing crops in the annual report of the Wakefield Farmers' Club, it may be interesting to some of your readers to know that in Canada and the United States,
where time is one of the elements of harvesting to an extent totally unknown in England, owing to the scarcity of labourers, the cradle seythe is the only article used; but it is, I think, of quite a different description from with a light frame consisting of an upright post and four fingers the length and curve of the blade, the upper one about 2 feet from the scythe, and all set so that when at work they shall be about perpendicular to the old sort is nearly straight, but a new one with a very curved handle is said to do excellent work. There is but one rib on it, the left hand grasping the top of the snaith, and by a peculiar but easy push at the end
of the stroke laying the cut grain in a long regular swath. With this tool a good man if the grain stands well will cut from 2 acres upwards a day, more if the grain stands very light, less if it is very heavy. A
neighbour of mine told me he cut once 5 acres of heavy Oats in a day, and from seeing what work he could do on his farm, which was next to mine, I believe it to be true. The scythe and sickle are only used when grain pick it up with the cradle; one man following to rake and tie completes each band of harvesters. It is perhaps owing to the straw being laid rather loosely in the sheaf that rapid carrying can be put in pro-
gress; for if a field of Wheat takes more than two gress; for if a field of Wheat takes more than two
days to cut, the instant the last sheaf is bound, the lhands fetch the waggons and begin carrying the
first cut Wheat, the sun being so powerful and the air so dry that not only is it fit to carry in so short a time but it would be injured by standing longer I do not point out this in the hope of showing farmers how to do with fewer labourers, but it is of course of great advantage to be able to get in a field of grain, and there is always plenty of other
on a farm. A Canadian Farmer.
Po ato Tops.-Early dwarf frame, or short blade varieties of Potatoes, are generally saved from the preblight sets in, scorching or starving the fungus or conblight sets in, scorching or starving the fungus or con-
tamated sap in the leaves and stalks, and such we think we may venture to say are safest left to chance.
It is, however, well known that our practice is to cut off It is, however, well known that our practice is to cut off
(not pull up) the Potato stalks when luxuriant crops are attacked with blight, in order to bleed, as it were, the roors, and to save the tubers from further decay To pull them up is to kill the plants instantaneously, shutting in disease, and subjecting the tubers to decay,
unfitting them for human food. As some persons are averse to this practice, and as it stops the growth of the tubers, 'we will not press it any further, and only remind our readers that, whether they have recourse to it or not, the blight itself in strong crops stops all forther progress of growth in the roots, and it all amounts to the same often in the tubers when left to chance, whereas if the ronts were tapped by cutting off the stalks it would not unless such decomposition had really taken place before tops, however, we have taken into consideration this season. Off 1 rod of a luxuriant crop it will be found
that 1 cwt. at least of tops may be cut, or 8 tons per acre, which if not eaten may be trodden into a very rich manure, and if taken into account with the chance of a fall crop of Savoys, or Cabbages, or Mangels, or Swedes, to be transplanted between the rows as soon as the
haulm is removed from the Potato roots, this renders it of no material loss even if the Potatoes at Michaelmas should prove to be small, for let it be recollected they will be only small, and small they must be if left to chance after they are blighted, and then they may and will be decayed, and no chance offered of Savoys, Cabwould be of little use and value. By forking up the Potatoes at Michaelmas we cultivate the land, and prepare it well for the next year's crop, and if a slight dressing of guano is applied before forking up the Potatoes, the green crops then advancing to maturity
will be very much improved, and but little if any loss will be very much improved, and but little if any loss HardydeSon, Seedgrowers, Maldon, Essex.-P.S. Twenty Whars of our best improved selected and prolific red each'ear, w. 11 weigh 10 oz , and if cut off at the joint of the straw $\frac{3}{4}$ of a pound, which, if compared with the weight of 20 ordinary osr readers what our thin seeding will do with judicions management, $A . H$.
White Clover.-A writer inquires the cause of White Clover appearing in the pasture fields and roadsides. I
always considered it must have proceeded from the manure, but a residence of many years in America altered my opinion, for I always observed that wherever a clearance was atfected in the forest, no matter how although no seeds of any kind had been sown and the surface of the ground burnt nearly all over the previous considered there the best sheep pasture in America. I shall be happy if any of your valued correspondents varied opinions on, the sulbject._George_S._Rogers,_Red
received the following:-The White Clover growing on road sides and places where it cannot have been sown, respecting which your correspondent " $R$ " inquires, is
the true Perennial White Clover. It grows wild in many the true Perennial White Clover. It grows wild in many
parts of Britain, and we have large quantities of seed saved for us annually, as we find it more productive and more permanent than the common white or Dutch Nons leating
Black Catervillar.-A letter addressed to me this day (July 31) from a farmer of great experience, renotice at the time, and was, I perceive, alluded to in the Mark Lane Express of the 28 th inst. 1 must quote a few lines of the article in order to introduce the remarks which I have to offer. "I recollect above 20 years ago
when I had 50 acres of Turnips destroyed in less than a week, many of which had been hoed twice, after the scourge had left, it was found by those more fortunate that the Turnips which had escaped were attacked by a large brown grub later in the season, which ate the tap root of the Turnips after they had arrived at full growth." By this extract it appears that two insects perceive that my friend refers to a black insect that preys upon the leaves, and which "had not been seen for the last five or six years." The destruction that came ander my own notice while I resided near Maidenhead must have been produced by the brown grub mentioned by the writer in question. This caterpillar first attracted
my notice when I lived at St. Peter's, Isle of Thanet, in my notice when I lived at St. Peter's, Isle of Thanet, in
1821 , for I found plants of the Cabbage family, such as the Savoy, Borecole, and Broccoli that had been perfectly healthy over-night, flaceid and drooping on the following morning. Another circumstance excited particular attention, as when one plant so drooped its immediate neighbour was the next to fail. For a time no solution of the problem suggested itself; but upon carefully moving the earth around the stems of a diseased plant, a large dingy grey grub was seen coiled into a sort of ring. As in every instance the same grub "guilty" was pronounced against posture, sentence offender thus deguilty" was pronounced against the offender thus de-
tected, as it were, in the very fact. 1 lost sight of this marauder till the period referred to in the Mark Lane Express. I do not retrace the exact dates, but I enter-
tain little doubt that the fearful destruction of the Tuin little doubt that the fearful destruction of the 1834 or 1835 . Then scarcely a Turnip escaped, and
this not only round Maidenhead but far into Buckingthis not only round Maidenhead but far into Bucking-
hamshire. I was in the habit of inspecting the crops nd gardens about Marlow, High W ycomb, Missenden, \&c. In the latter place the able gardener at The Abbey adopted every means at his command to ascertain the family of Lepidoptera to which the grub belonged. He kept several of the grey caterpillars in soil, placed the vessels well secured in a warm forcing house, and in due ime had the satisfaction to witness the changes as they took place, terminating in the development of several in print that they belonged to a species termed Eyrostis, or by some 历igrotus. I have not data to which I can now refer in respect to the previous assault of the black but well remember that the ravages of the grub were horribly extensive ; insomuch that a person had nothing more to do than just to disturb the ground with the hand or a stick when he would see the remains of a bulb riddled into numerous holes, with perhaps ten or re those ugly larve busily atwors on the remainypocritical coil. J. Tuvers, Croydon.

## Sorietios.

Highland and Agricultural Socibty.-The meeting at Inverness has been successful in bringing out for xhioition some of the best animals in scotland and the north of England, notwithstanding the difficulties in
transmitting stock beyond the railway region of the country. About 70 shorthorns competed for the Society's prizes. The first and second prizes for old bulls were given for animals bred in Aberdeenshire those for young bulls were given to Mr. Willis, of
Bedale, and Mr. Tod.
Highland stock was present in good numbers and quality, the prizes being given to Mr. M'Rae and the Right Honourable Duncan M•Neill, the Duke of Sutherland, and Mr. Malcolm, of Poltalloch. Mr. M'Combie takes the first prize for the polled Angus breed of cattle which excited so much attention at Paris. It is won by an animal that has carried off the prizes at Berwick, Aberdeen, Carlisle, and Paris, never having The show
The show of sheep was very fair, Leicesters were well represented, and Chevints and black faced sheep
are a good show. The implement show was not a large one. A discussion on short-horn breeding took plac
during the meeting, which we shall next week report.

The Rofal Agricultural Society of Ireland held their annual show at Athlone this week. The exhibition of stock is unusually fine. The first prize in short-horned bulls is awarded to Grand Turk, belong-
ing to Mr. Henry Ambler, of Watkinson Hail, Halifax Lord Clancarty's short-horned roan bull, Pro Bono Publico, has taken the second prize. We are
unable owing to the crowded state of our columns so

## do so next weel.

Boxted Lodge, Colchester: Trial of Reaping Machines.-Mr. Fisher Hobbs having in the most pablie-
spirited manner offered his crops and grounds to the spirited manner offered his crops and grounds to the
English Agricultural Society as the arena of the adjourned trial of reaping machines, a large number of those interested in reaping by machinery, as well as in steam ploughing, were gathered together there last Wednesday and Thursday. A more agreeable agrienltural holiday was never spent. The thoroughly prac. tical, systematic, and successful farm manage ment exhibited, and the hearty hospitality enjoyed were security for this. The farms occupied by Mr. Fisher Hobbs are somewhat scattered and unconnected,
but this, which would in ordinary hands have been fatal to good management, seems to have had no injurious fffect at Boxted. We saw there clean, level, and well drilled corn and green crops; the Wheat, Oats, and Barley were first-rate as to yield, the last being however
laid; and the Swedes, Turnips, and Mangel Wurzel covered the ground perfectly. First-rate flocks of Downs were on the pastures, and herds of Mr. Hobbs's breed of pigs were in the yards. Successful cultivation of Italian Rye-Grass was providing food for cattle and or horses-the effects of well managed drainage, harvest work was in busy operation, and there was bright weather over all.
On Wednesday the trials were in the presence of the udges only. On Thursday the public were admitted. Key's M'Cormick, Dean and Dray's Hussey and Key's M'Cormick, Dean and Dray's Hussey with their tipping platform, and Hussey with Palmer's side delivery. Where the corn was standing they all worted well, and would travel in any direction-where it wu
laid or bending they could none of them cut it well except by going rightagainst the lay of the corn; and then, returning empty, they also all worked well. Where Bell's laid, and required to go across the lay of the corn, Burgess failed both to well ; but Dean a Dray and arvid cutting the ears. When working on ridged land Hussey, with the tipping platform, worked best of all. The price of the machines in the order we have named them is $42 l ., 40 l$., $32 l$., and $25 l$. respectively. The told he charges 7l, royalty apiece, sum which we venture to predict will end in their disuse altogether. Hussey's knife, especially the skeleton form of it, seemed to us equally well fitted for its work-and
the greater cheapness of the implements which use it is reatly in their favour. The tipping platform delivers the corn intermittently in the wake of the machine, the sheaves needing to be tied, or at least lifted aside at once. Palmer's radiating rollers which deliver it intermittently on one side did not send off the sheaves so cleverly as the other. M'Cormick's, with the screw wathe, did not, except whe corn off in a conding well, make quite so good work as Bell; and Bell, again, which came out well under difficultits which spoiled the work of the others-charging a laid crop, and leaving in its wake a clean jane of short stubble, with corn laid, ears together, on one side-failed on the ridged land to do its work so well as Hussey. The award of the judges is not yet published. It will, we Bell and Dean and Dray's Hussey with the tipping platform.
Mr. Fowler exhibited his steam-plough at work will great success and promise of future usefulness, bat to is we must refer another week. Mr. Amoss power employed, en*bles us to say that $]_{\frac{1}{20}}$ acre of land was ploughed by it in one hour, 8 horse power only of the ploughed by it in one hour, 8 horse power
It is difficult to overrate the value of Mr. Fisher Hobbs' services in thus inviting public attention to the two great sources of economy agricultural labour which for promised to us. The substitution of steam power
that of horses in cultivation, but especially that of horse power for hands during larvest time, which Fowler's steam-plough and the reaping machines now promise, are the two great agricultural problems of the day.
The latter subject is especially pressing and more portant now, when every year we are suffering more and more from difficulty in finding hands al greater puble, and we have to thank Mr. Hubbs for ar it than it has ever yet attained in England.

## nintotw.

A. Letter on Steam Cultivation to E. Greaves, Esq, of Haversham. By William Smith, of Woo
This is a very sensible and well written letter, degcribing in as aimple a manner as possible the differences between plough and spade culure, the propriety of eopying the latter rather than the former in a tillage copying the latter ratheam, the alternative of the locomplement drawn by steam, applying steam power in cultivation, and lastly the author's own experience as a cultivator of land by steam pow
extracts on all these subjeets.
The difference between the plough and spade. " "The
absolutely turn over the soil, placing the former surface from four to six inches below, and bringing up the smoothed surface of the under soil to the top. By this process all the seeds, weeds, and roots are deposted od from roots or layers-such as Couch Grass, Water Grass, Crowfoot, Coltsfoot, and others, and which really are the plagues of the farmer-being divided by he plough, are indefinitely muitiplied; and do, in fact, extent, as to render it absolutely necessary for the farmer to leave his land partially barren for the purpose of removing these obnoxious weeds; to do which the plough entirely fails him, and he is driven to the scuffler, cultivator, or other implement which he has invented for this purpose
"In spade husbandry, which has been advocated as the best system of all, the soil is not turned over to anything like the extent that it is by the use of the plough. This system consists mainly of a complete breaking up of the soil, and an admixture of it with the manure; at the same time accompanied with a separa-
tion of the permanent Grasses, \&c., from the annuals, tion of the permanent Grasses, \&c., from the annuals,
the former being carefully removed by the hand, and the latter deposited beneath the earth to decompose, and perhaps, to some extent, to provide food for the next crop. But how little food they furnish may be inferred from the fact that, the more free the soil is even o these, the better will be the crop produced. In short, may be laid down as an axiom in farming, that, his Wheat he ought to grow Wheat, and, at least as far is is practicable, nothing but Wheat, and when Beans, pothing but Beans, \&c."

Another marked difference between spade hus bandry and cultivation by the plough is in the depth From four to six inches is the ordinary depth o cultivation with the plough, and it is a question whether it would be generaily advantageous to culti-
vate to a greater depth if the subsoil were to be laid upon the top, as is commonly the case in ploughing. Now a spade is from 10 to 12 inches deep, and to this depth in good spade husbandry it is usually thrust. But when we carefully observe the whole of the operation, we shall see that the spade does not upturn the whole of this; but that when the leverage is applied, the lower part is siattered by the violence that is offered, and the upper part is all mixed together and broken. But how different is the turning over of the spade from that of the plough, may be inferred from the care which the gardener is constantly obliged to use, after the operation of the spade, to draw into the next trench the weeds which the first operation consolidated either by the transit of heavy implement or by the padding of horses, either of which seem very ijkely to impair the success of our agricultural opera tion. The passage of a heavy and unwieldy implement over the land cannot but have the effect orporing considerable consolidation, and rende percolation of the water and the action of the atmos phere less free than they otherwise would be, isut of more detrimental to the success of our operations than even the passage of a heavy implement. For the horses continually tread on a lower surface which has been smoothed over by the under-side of the share, and a crust or pan is thus formed through which the water will not freely percolate till after the application of a good subsoil plough, which in its turn again introduces the padding of the horses. Thus in all our agricultural operations with the plough there is not only a great loss, but there is an enormous waste of power. By portion power as distinguished from tually applied to counteract the poffect which we desire to produce, The power which a horse exerts to carry himself across a field is simply power lost; but the weight arising from gravitation and non-effective effort is all entirely wasted or exerted in producing a consolidation or the soil and subsoil, which previous to seed-time is generally fland is completely cultivated at once. It is true there are two or three operations,-the breaking up, the are two or three operations,--the breaking up, the
mixing of the soil, and the separation of the weeds, are mixing of the soil, and the separation of
all performed at one and the Bame time.

The locomotive and the traction plans of applying stam power.-"The success of the locomotive on our rail ways seemed to turn almost all attention to that means of applying steam; aud even now it is not despaired that success may attend the ingenious combinations of some
of our engineers. But when we consider the enormous of our engineers. But when we consider the enormous loss of power even of a team of horses (a weight of
from two to three tons) in carrying themselves across from two to three tons) in carrying themselves across
field, as well as the waste of power in connteracting their own exertions, by consolidating that which they are employed to render porous, I was led to believe that the loss of power in a locomotive engine, weighing probably from seven to nine tons, would be considerably greater even in proportion, when it was moving itself across a ploughed field or up even a sligh opposing its own object would of course depend upan the manner of its movement and the mode of ite application. But by adopting the traction system, the power lost would be only that which was required to overcome the weight of the ropes and the friction over overcome the weight of the ropes and the friction over
the soil, which would be much less than that required to earry the locomotive engine ; and little or no powe
would be wasted in counteracting its own efforts.

Besides this, there would be a great advantage in usin an engine which could be applied to many other agricultural purposes, such as threshing, grinding, chaff catting, \&e."
Mr. Smith's ovon experience.-"On my own farm, which, as you know, is clay and gravelly clay, I have as far as I could consistently with the use of horses, for some years past avoided the turning over of the soild and more especially on that part of it which has been under my own management without the intervention of bailiff : the chief implements I have used being my Registered Subsoil Plough and my Patent Culivator This mode of cultivation has been attended with the most beneficial results. I can give accurately only the result of the last year. On my home farm I had an average produce of $46 \frac{1}{5}$ bushels of Wheat per acre while the produce of the rest of $m y$ land, where the plough had been used in the ordinary manner, was so much less, that it reduced my total average, over acres, to 42 z bushels. Allowing that the eye of the master does secure sonething, still this is a result which at all events shows that the turning over of the soil not a matter of positive necessity, and that at least as good a crop can be secured by well mixing the soils as there can be by turning them over ; and my own experience shows a better. It is almost premalure to refer to growing crops; yet the present state of mine, where the principle has been carried out by steam power, when compared with those growing on simila soils does not lose by the comparison."
"I have nsed steam power over 100 acres of land this season. Some of this on my own farm is under crop, Beans, Peas, and Oats, all of which look very promising."

## Calendar of Operations.

S. E. CAarbradar, August 9.-On our light and chalky soils the Wheat and Barleys bave ripened veryr rapidily ; a great breath of
the former hat been cut; linnds have been numerous, at least sufthe former has been cut; hands have been numerous, at least suff

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACHINES,

## sole manufacturer, iron and wire works, north street, leeds.

 REGISTERED JULY 24, 1855.-No. 3739.THE ADVANTAGES OF THESE MACHINES supersede all others by having Without anall Wheol in frout of the Grase Box, consequantly will mow verges and round flower beds, without any change of Wheels, or addung the old fashioned Roller, as in others; will also cut either
wet or dry, and by the simple adjustment of a thunb serew, in front, can he raised or lowered the Grasss any length required ; sad having two Rollers bellud, and a small one in front, wey roll the widht they cut; they will turn un very little roonn, and cut at the same time. All the working parts
made much strunger than the old machines. The botton klades are so constructed that thes cinnot made much stringer than the old machines. The botton Mlades are so constructed that they cannot
tear up the ground; they are only drawn, and not pushed and drawn as in other machines, tear up the gruund; they are only drawn, and not pushed and drawn as in other machines,
consequently do not require haif the power to work them. The three first sizes can be worked by consequently do not require haif the power to work then.
one pervon with ease; the two latier with a pony or donkey.
LIST OF PRICES (NET CASH):-

To Mr. Gresis, Legs - Srr, An I always appreciate public and useful improvements, I most gladly give my testimong to your highly improved Mowing and Rolling Machine. The one sent for my inspection and trial (cutting a breadth of 24 inches) was drawn on flat ground with ease by one person, and although at the time of trial the lawn was wet, it was cut with the greatest
nicety. So complete and simple is the invention, that amateur gentlemen, and even ladies, may work either the 16 or 20 -inch size with ease and pleasure, providing the Grass is not ton hng. For extensive places I should say the 24 inches would be most suitable; for even in undulatng ground two persons may work it; but in flower gardens, when beds, \&c.. are erowded, either of the smaller sizes would be best. I congratulate you "n your very valuable invention, which in my opinion, entirely
surpasses, and muat eventually supersude all others, for it is not only free from intricacy and easy to the worksan but extremels surpasses, and must eventually supers-de all others, for it is not only free from intricacy and easy to the workman, but extremely ex
peditious in its operations, and consequently must prove a great saving in the management of Grass lawns, and a great boon to peditious in its operations, and consequently munt prove a great sa
the public.- I am, Sir, your mostobedient servant, Josmua Masor.

The above Machines are warranted to answer the purpose as described, or may he returned, and may be had of all principal Ironmongers, Nurserymen, and Seedsmen in England; also Mr. Charles Garrood, Superiatendent of Agricultural Department. Crystal Prace. Svienham.

VALUABLE IMPROVEMENTS IN MOWING MACHINES.
BYROYAL
LETTERS PATENT.
Under the Patronage of Her Majesty Queen Victoria, and His Majesty the Emperor of the French.

## ALEXANDER SHANKS AND SON, arbroath, forfarshire.--PATENTEES.

A. SHANKS and SiN, while soliciting the attention of the Nobility, Gentry, and Gardeners to their A. Horse and Pony MOWING and ROLLING MACHINES, the Completeness and superiority of which are now well known
 as the cheavest as wrll as the most efflctent and complete machine extant. The improvements effected by the Patentees enable the machine to be worked with perfect ease by one person. It tequires no change of wheels or rollers in nowing verges ; will cut close to the edge of flower-beds; has great facilities for quick turning, cutting and rolling at the same time; the length of the cut can be effectualy resplated in a few seconds by merely turring a screw, and baing simple as well as complete in its constraction
the machine can be ensily worked and managed bo a common labourer. The machines are fited with due regard to strength and the machine can be easily worked and managed by a common labourer. The machines are fitted with due regard to strength and
durablity, and conseguently not $p \mathrm{tall}$ liable to get nut of order. The work is executed with great rapidity and in a manner pastly durabitity, and consequently not
superior to mow ming with the scythe. while the simullanenus operations of rolling and close outting greatly improve and beautify superior to Thowing with the scythe. White the simbitanenus operations of rolling and close cutting greatly improve and besuary
the turf. The Rolling and Mowing Machine so now in common use at all the Royal Gardens, Windsor, Kew, Buckingham Palaed and Osborne. Illustrated Price Lists forvarded on application.
N.b. A. Shangs \& Son finding that their Patented Improvements are pirated, beg to caution the pablic against purchasing

## NEW PATENT INVENTIONS FOR STABLE REQUISITES.

Awarded a Prize at the Paris Exhibition, and Patronised by the English and French Governments

## COTTAM AND HALLEN,

THE Original INVENTORS of the PATENT ENAMELLED MANGER RACK and WATER TROUGH I AS ONE FIXTURE, to which they have made important additions, the main features of the same being explainod in the description and engraving.
A represemes the Patent Halter Guide and Collar Rein, the ball or mizing with the food in the manger, is alone sufficient tocluim of which is taken to the buck of the manger, works with, ease and froedom up or down the guide bar, and is noiseless in itso pera-
tion, as also a sure preveutative against the most restive horse tion, as also a sure preveutative against the most restive horse
being cast in the stall. B The Patent Portable Seed Box can be instantly detached general notice from the Rack withunt disturbing the hay. The saving of the light and Box detached, made of Galvanised Sheet Iron light and durable.
$\mathbf{0}$ The Patent Sadle and Harness Bracket combined, can be used with great advantage in Harness Rooms, where space is object, as the long prriou of the bracket can be tarned up out o
COTTAM'S MANGERS are constructed in the best possible manner, both as to form and atility, are cleanly in appearance, durable, and impervious to infection; mannfactured Plain, Galvanised, or Enamelled.

## Che Garuentrg Chronitle.

SATURDA Y, AUGUST 23, 1856.
It is to be feared that speculations upon the geographical distribution of plants are not the only innocents which the acquisition of facts will compel us to slanghter. There is an ingenious notion relating to the distribution of colours, which once gained disciples everywhere, but which seems to be in no better plight. This being a gardeners question has been occasionally adverted to in our columns, and a fresh and most startling case of interference with theory leads us to introduce it once more.
One of the best digested accounts of the theory in question is that of Prof. Balfortr, from whom we borrow the following statement.
"In reference to their colours, flowers are divided by De Candolle into two series-1. Those having yellow for their type, and which are capable of passing into red and white, and never into blue. 2. Those having blue for their type, and capable of passing into red and white, but never into yellow. The first series is called Xanthic, the second Cyanic. The following is a tabular view of the two series, green being considered as an intermediate state of equilibrium between the two :Red
Orange-red
Orange
Yellow-Orange

- Xanthic series

Yellow
Green. Colour of Leaves.
Blue-green
Blue
Blue-violet

| Violet | Cyanic Sories |
| :--- | :--- |
| Violet-red |  | Violet-red Red

Or the table may be given thus:Green.

## Red.

Green, which is made up of blue and yellow, is the centre whence the two series diverge, and they meet again in red. It would appear that all tlowers capable of changing colour, do so in general by rising or falling in the series to which they
belong. Thus in the Xanthic series, the flowers of the Marvel of Peru may be yellow, orange-yellow, or red ; those of the Austrian Rose, orange-yellow or orange-red; those of the Indian Cress vary from yeilow to orange or orange-red; those of the garden Ranunculus pass through every gradation in the series from red to green. In the Cyanic series, the Anemone varies from blue to violet and red the Hyacinth from green to red, through all the gradations; Lithospermum purpuro-cæruleum, and many Boraginacere, from blue to violet-red; the Hydrangea from rose colour to blue; and the ligulate flowers of the China Aster from violet-blue to vielet-red and red.
"These rules cannot be said perhaps to be universally applicable. They appear, however, to be very general, and they are useful in enabling us to predict the possible varieties of colour in the flowers of the same species. To the Xanthic series belong Adonis, Aloe, Cactus, Camellia, Cytisus, Dahlia, Lysimachia, Mesembryanthemum, Enothera, Oxalis, Potentilla, Ranunculus, Rose, Tulip, Verbascum, \&c. As examples of the Cyanic series may be mentioned Anagallis, Campanula, Epilo bium, Geranium, Globularia, Hyacinth, Phlox, Polemonium, Nenophila, Scilla, Vinca, \&c. Some exceptions occur to the rule laid down; thus, while Hyacinths are in general blue, red, or white, some varieties assume a pale yellowish hue; the yellow Aaricula of the Alps, although it does not become pure blue, exhibits occasionally a violet hue; the flowers of Myosotis versicolor change from yellow to pale hlue.

The original colour of the Tulip is yellow, and although by cultivation it is made to assume all the varieties of colour in the yellow series, we do not find it becoming blue. Such is also the case with the common Dahlia and the Rose. No one has succeeded in getting a blue variety of either of the latter. The Geranium, on the other hand, although it presents all shades of blue, red, and although it presents all shades of blue, red, and to be a certain limit in the range of colour which a species can be made to assume. These remarks apply only to the change of colour in a given species. They will not apply in all cases to every species of a genus. Thas, whilst most of the Gentians belong to the blue series, and do not become yellow by cultivation, there is a yellow species of the genus (Gentiana lutea) which never changes into blue. Such is also the case in the genera Aconitum, Linum, Sonchus, \&c. Again, we find certain plants exhibiting in the same flower blue and yellow colours. This is seen in Dendrobium sanguinolentum ; also in Pansies, and in many other parti-coloured flowers, as in Convolvulus tricolor, and in species of Myosotis, which have yellow zone round the corolline tube, while the upper part is blue. In these last-mentioned case each of the coloured portions of the flower vary in general only in their proper series-the part which is yellow never becoming truly blue, nor the blue yellow. The florets of the ray of Composite plants often exhibit blue colours, while those of the disc are vellow. The law by which the changes of colour are regulated has not heen ascertained, and it is impossible, in the present state of our knowledge, to predict what colour a florist's flower will assume."
It is impossible in the present state of our Knowledge to predict uchat colour a florist's flower will assume. That is the point. Were the cyanic theory true we should always be able to say with some tolerable certainty within what limits change of colour is produceable. For example the blue series might run into red and violet, but never into yellow orange or scarlet; and rice versâ. That would be something to foresee. But as matters now stand we know of no reason why Camellias should not become yellow or Dahlias and Azaleas blue. Such a change is just as likely as that which we are now about to describe. If there is a genus more pre-eminently blue than any other cjanic race it is surely the Delphinium or Larkspur. Among this genus we have blues of all degrees of intensily, violets, reds, pinks, whites and greens, but nowhere a trace of yellow-not even in the stamens. Delphiniam therefore should, according to theory, be fixed irrevocably to the standard of blue, and a scarlet or yellow species was no more to be expected in the cyanic Larkspur than a blue species in the xanthic Azalea. But the scarlet Larkspur has come to us unmistakeably ; golden yellow in the petals, scarlet as a soldier's jacket everywhere else. This occurs in the beautiful Delphinium cardinale, one of the last of Messrs. Verrcu's fine Californian introductions. In this flower there is no sign of blue, except in the green spot at the tip of the sepals, a tint that is common to both series of colours, as is above explained.
Whence comes the yellow which, mixed with red,
has produced the brilliant scarlet of Delphinium in the presence of which scarlet could not be formed ? To he sure we have such colours in the Columbines (Aquilegia), which are first cousins of out in $A$. canadensis and its allies. We have yellow too in Aconites. Are we then to infer that some future Lobs will bring home a scarlet Aconitum. Why not? We think it extremely probable. all events the cyanic and xanthic speculations philosophers must now be laid up in the limbo pleasant dreams.

We have already reported that the Vine dispase disappearing in Tuscany, and we have reason to believe that even in Portugal the worst is over. That the disease in that country was not actually incurable has been shown by the case of a variety called the Souzão, of which a highly diseased plant was sent three years ago to the Horticultural Society, by Mr. Forrester, and which is now healthy and bearing ripe bunches in the Garden at Chiswick.

This may seem to be a rash opinion in the face of the intelligence from Portugal which has lately appeared in the columns of the Times, in whose city article it is stated that "the accounts from Oporto regarding the prospects of the coming vintage in the Douro are discouraging. The American from any bad signs, had suddenly manifested the blight to an extent which had destroyed the hopes entertained from the introduction of those descriptions. This year the disease is said to have attacked the fine vineyards beyond the factory demarcation, and an instance is quoted of one on the frontiers of Spain which last season yielded 60 pipes of the
best wine, and which will now not produce six pipes.'
We do not know what was expected from the introduction of American Vines, if by that term is meant, as we believe to be the case, European Vines cultivated in the United States, for the Vine disease exists there, as well as here, as we lately showed upon the authority of Mr. Chorlton (see p. 516). At all events we know that the American Vines were grafted on Portuguese stocks. Even here the resalt was perhaps not quite so unsatisfactory as would appear from the Times; at least it does not correspond, as we are informed, with the experience of one of the great wine growers, who this year grafted in Portugal a thousand Vines with cuttings obtained from English hothouses. Of this number about 900 took, and until June were green and beautiful. But, what was very curious, wherever among them indications of fruit appeared it was speedily stopped by
the Oidium, which, however, did not extend to the Oidium

It has also been remarked this year that in the Douro wine districts, although the Oidium appeared in Jone, and apparently "paralysed the Vines," yet after the fourth day they recovered and vegetation
proceeded with renewed vigour, "leaves and wood proceeded with renewed vigour, "leaves and wood the Grapes withered and dropped off."

It is impossible not to regard these as favourable symptoms, indicating that the virulence of the Vine disease is passing away even from the west of
Earope. In the meanwhile the condition of the Europe. In the meanwhile the condition of the
inhabitants of the Douro wine districts is lamentable in the extreme. For two years past the cultivation of the vineyards in many instances has been abandoned-the labourer has no employment-the proprietor no produce. Next year most of the Vines from this neglect alone, and not from disease, will be well-nigh ruined.
As to the wine itself we learn that as there were few Grapes produced in Portugal last year capable of being made into wine, the most prejudicial adulterations were resorted to in order to produce a beverage of vinous appearance for the use of the Portuguese
people. The wine, therefore, as it is called, and at prepeople. The wine, therefore, as it is called, and at pre-
sent is sold at the tendas or public-houses at Oporto, is of infamous quality, and much sickness has already being traced to its use. According to present appearances the production of wine in the north of Portugal will be even less than that of either of the two past years. On this account and in spite of the
Government restrictions to the contrary large Government restrictions to the contrary large
qnantities of common wine will be smuggled from Salamanca, or from the interior of the province of Beira, and be introduced into the Alto Douro districts and thence admitted into Oporto for consumption or exportation. Among other contrivances
which have been resorted to in order to save somewhich have been resorted to in order to save some-
thing from the vineyards, it is understood that the thing from the vineyards, it is understood that the wine growers have been pressing such Grapes as they to the juice in order to prevent the putrid fermentation to which it is now so liable. This brandy-
syrup, or cherupiga, containing probably 50 per
so-called Port wine manufactured for sale in the English market

VINES IN THE VALLEY OF THE THAMES.
YoUr remarks in a recent leading article relative to Mr. Glendinning's splendid Grapes will no doubt excite considerable interest, especially among that class of gardeners and amateurs who have incurred great trouble aud expense in preparing Vine borders and planting will be all but nil. It will, I think, be admitted by all who have studied vegetable phenomena, more especially in relation to the culture of plants, that the more we deviate from the simplicity of nature, the more proportion do our chances of doing what is not righ increase. Earth, air, and water, with their natural concomitant, light, supply all the requisites of plant manufacture, and though we may go to Peru for guano, quite certain that we shall experience much difficulty in discovering any foreign substance equal to what every country gentleman can find upon his own estate. Plants, like animals, may be fed to a very plethoric state, and like chem too that very plethora will injure the constitution, and by bringing on premature old age, so impair the vital energy of the plant as to render it of little or no value. Thus it is that one man prepares a Vine border, using all manner of foreign substances, mixing
fish, flesh, and fowl, the refuse of the currier, the sugarboiler, the butcher, the kennel, and the slaughterman, in most incongruous confusion. He plants his Vines, and they grow with a vigour reasonably to be expected from such a preparation. But does the wood ripen ? Does it become of that hard and indurated character which would result from slower and smaller growth? No ! but the Vines produce magnificent foliage, and no doubt next year they will produce some splendid bunches of fruit. Yes, they do so, but somehow or ond Muscats Black Hamburghs are red, the Frontignans be the reason of it? Oh! the border is too dry, it has had too mucl water, or the stupid gardener has given so much air as to chill the bunches, or the house has not had sufficient air. But never mind, they will
do better next year; they are making nice wood, and the foliage is unusually grass green and watery Next year comes; the rich border has had a good soaking of winter snow, and an additional soaking of manure water cold from the tank of farm yard; the Vines start irregularly and weak, the few bunches they show take a gpiral growth and result in teudrils, and all is over. What ever can be the cause? The border was rich and had plenty of manure water, and it was also well drained. Surely something must have destroyed the roots; well, let us see; but oh horror of horrors! the which (it was so light and porous) you could thrust your waiking cane without an effort, is now one soapy mass, cold and inert as so much recent cow dung. But see the roots ; are not they fine? Yes, thick, soft, and
spongy, as those of Asparagus or Bindweed, and with spongy, as those of Asparagus or bindreed, and wiference, that they have not a fibre or spongele upon them. Such then is the result of an over-rich border ; it may be an extreme case, but not more extreme than many that have been seen. It is the effect his companions, "what an enormous quantity of sack for such a small quantity of bread."
This brings me to the subject of the present paper "llustrated by Mr. Glendinning's "Grapes it appears as other cases which I may mention shortly. Prepared Vine borders are not only unnecessary, but if made are useless. For something like 20 years or more, firstrate Grapes both in quality and quantity have
been shown at Chiswick and other London horticultural exhibitions from the garden of Mr. Beaufoy of South Lambeth. These Vines were planted for the most part by Mr. R. Atlee, who for many fourteen years ago, I conoratulated Mr A upon the success which had attended the planting of the Vines. "Yes," said he, " you may do that, but my border had nothing to do with the production of these Grapes, for the roots as soon as planted went perpendicularly down and I believe there is not a Vine root in the border." and I believe there is not a Vine root in the border."
As an illustration of this fact Mr. A. took me to a Pine stove where he had that season planted a Muscat Vine, and that with just sufficient fresh soil to plant in had made such a growth as is only seen when the
roots of a plant are quite in their natural element. roots of a plant are quite in their natural element.
Now the subsoil in the neighbourhood of Vauxhall is a reddish gravelly loam, poor to appearance but open and porous, and hence well suited to the habits of the think, in Mr. Glendinning's neighbourho prevails, doubt the Vines have taken the same course. In the vale of the Thames, from its rise in Berkshire down to Gravesend and Tilbury Fort, and ou both sides of the water good Grapes will be found, I will not say without prepared borders, but I doubt not in many instances plants than those I have previously enumerated. To commence, take for example the celebrated Champion
Hamburgh Vine at Sunning Hill, those wonderful Vines at Cumberland Lodge and Hampton Court.

Richmond, Kew, Mortlake, Barnes, Patney Vingston Bermondsey to Deptford, and so on to Graves end, and in all these places you find excellent Grapes and certainly in several places where no preparation has been made for planting them. Perhaps for quality persons have produced better fruit in Covent Garden than Breffett, of Barnes, and the various growers a Vauxhall or South Lambeth, especially Chapman, while Stones, of Deptford, was famous for his Grapes lons before the writer of this was born. Start again from Hampton Court, and proceed by Teddington, Twickenham Isleworth, Brentford, Chiswick, Fulham, and Chelsea and we find Vines of great excellence. The late My, Willmot's extempore way of making a Vine border by describing it as a hole made with a pickaxe into which a little soil was put to cover the roots will be familine to many of your readers; and his description is iiterally true, for I have reason to know that nothing more was done when the Vines which produced fon crops in two years were planted, than to take ap thio a bushel or 80 Vauh they made no Vine borders beyond merely trenchin they made no Vine borders beyond merely trenching
and manuring the ground intended to be planted. That Vines in the vale of the Thames generally speaking send their roots deep into the soil and beyond the influence of ordinary atmospheric changes is evident from the manner in which market gardeners dig and crop their borders, and from their forcing the Vines in the depth of winter almost without any protective material, and certainly without any fermenting material to impar heat to the roots. If the roots were near the surface of the soil such practices could not be persisted in, and hence think it reasonable to infer that Mr. Atlee's theory of will in fuoting in the subsoil is just, and now explaind will in future be more fully appreciated. Hence the reason of Mr. Glendinning's success, and hence also the upon similar success by employing similar means. Bua the most remarkable thing in connection with Mr. G.'s Vines is, that they are not what would generaily be
regarded as fine Vines, that is, they have not girth or strength of stem usually considered necessary to produce a crop of Grapes of first-rate quality. According to the theory of the late Mr.Clement Hoare noVine is fit to carry a bunch of Grapesuntil its stem at the base girths 3 inches and then only a few pounds, but most of Mr. Glesdinning's which have carried such splendid Grapes do not girth that much at the present time, and hence if by good judge filage were of would be regaraded even fact struck me upwards of 20 years ago, when fresh from the fine Vines at Welbeck, I called to see the forcing establishment of Mr. Breffett at Barnes, $h$ was in November, and the first house of Vines was jest beginning to swell, but they were so weak in the stem and the wood so small that I could not resist ${ }^{\text {an }}$ involuntary exclamation of surprise that they should
consider such Vines worth the trouble, not to my expense, of forcing so early in the season. Well do I recollect the smile that passed over Co Breffet's countenance as he sarcasicaly remarked
 Park) being with me, and there on those poor Vines were certainly the most compact and beet colourad early Hamburghs I had, at that time, ever zeen. fine Breffett's Grapes were always celebrated for fine colour, thin stem and compact form, and they Thus it the same characteristics to the present time. .
appears that mere girth of stem is not a criterion of the appears that mere girth of stem is nor a especially if the fitness of a Vine to carry a crop, more especialy has Vine has been grown slowly, but if the grown inesbeen rapid, and the roots are soft and spongy, thenpes. haps girth of stem should be taken into consith matery In an over-rich border a Vine will make loced in a moist roots something resembling those prodacat without fibre but in fibrous loam and other porous material, a large quantity of fibrous roots will be produced, the growth will be slower and of moderate strength, and the organization of the plant of the most mature and perfect descrin Such a Vine, though apparently not so atrong as on planted in a rich border, has the maturing principle, I may be allowed the term, more fully developed, ath has its vessels full of highly elaborated instead the rich
crude and watery material which results from border.
Hence the renson of Mr. Glendinning's succesa, and hence also the reason why rich borders suonimo a. P. W.

VEGETABLE PATHOLOGY.-No. CXXXIV. 548. Parasite (Antennaria Capnodium ${ }^{*}$ ). -The genus Erysiphe, which has been shown our indigenous of many of the affections to which both our to extend and culinary plants are subject, does not sees its place is
to very warm climates. In such localities to very warm climates. In such localities
taken by the closely allied genus Meliola, which of producing a white mycelium has one which is jet black and the fulcra which surround the po the thicker of the same sooty tint. It is principally on the thus is leaves, but by no means exclusively that this g of the * The first from antronne, alluding to the resembisice

produced. The species are principally tropical, but
they oceur in Chili, New Zealand, and the United States. 549. There are, however, other black mildews which have a similar habit, and are indeed scarcely distinguishable without the use of a lens, which are far more widely and copiously diffused, and in consequence more destructive. These are not to be confounded with the olivaceous smokelike fungi which are so common in antumn on the leaves of trees which have produced honeydew. They belong to quite another category, and have a less pure black than those which are at presen before us, aud a very different structure.
550. The first which require attention are those cases in which the parasite on examination presents the characters of Antennaric, consisting of branched moniliform often echinulate articulations, some of which swell out into a sporangium, which either contains minute spores, as in the accompanying figures of Antennaria Stephensit, Berk., or young plants in miniature (see Gai'p. 851 ), which are 1844 , p. 851), which are at once developed under favourable circumstances on the rupture of the walls.
These are not very common in our own country, but in some countries
they abound to an excessive degree, and nowhere more than in New Zealand, the Auckland and Campbell Islands, and other localities in the southern hemisphere. In one species (A. scoriadea, Berk.), the threads project so much from the matrix and are so intricately branched and compacted as to look like cinders, and approximate to the American genus Scorias which covers various vegetable substances with a moist black spongy crust two or three inches in thickness.

551. These Antennarice are the pests of the Coffee and Orange plantaticns in Ceylon and the Azores, and as the common Fumago generally accompanies honeydew, whether arising from Aphides or other causes, so these affections seem generaliy to wait upon the attacks of a species of Coccus. They have extended so widely of late years as to make cultivation very precarious, and at present no effectual remedy has been discovered, though it is probable that sulphur may have the same effect on them as on other epiphytous fungi.
552. Though the characters of the genus Antennaria appear so strongly marked, as appears from the figures given above of $\boldsymbol{A}$. Stephensii, it is now pretty generally acknowledged that the genus is not autonomous, but merely a condition of the genus Capnodium, which in mexely a condition of the genus Capnodium, which in attends or follows the Antennaria, and this under such attends or follows the Antennaria, and this under such the one is merely a form of the other. In Capoodium perfect perithecia are formed by the matting together of the component threads of the matrix, or at least they run up and are incorporated with them. These are generally very much elongated, and often strangely branched, and in several cases perfect asci and sporidia appear, as is the case also with the closely allied genus Scorius. The geographical distribution, as might be expected, is almost identical with that of Antennaria. The true fruit is not, however, invariably produced where the Antennaria stage is perfected. In this country, for example, Antennavia occurs occasionally without progressing to the stage of Camodiun, but there is a little species which is common on Laurels and other evergreens which constantly perfects its perithecia.
553 . On the continent the species, when in the form of Antennaria or Capnodium or both united, are far more common. One of these, $A$. Stephensii or familiar an object to our fruit dealers. It is no unusual thing, on opening a box just imported, to find the greater part of the fruit covered with a dense velvety coat, exhibiting in parts the characters of Antennaria, in parts those of Capnodium, which must have grown principally on the royage, as it is scarcely conceivable that the fruit could been packed in such an unsaleable endition. The loss however in consequence is not absolute, as a portion of the fruit when", brushed looks tolerably well, but it is evident that its" keeping qualities must be much impaired by such a process.
554. In stoves where Cannodium is most likely to occur, extreme cleanliness and timely sponging will
prevent the accomulation of these very unsightly
plagues. I have not however met with any instance of plagues. I have not however met with any instance of abundant figures, will be found ins the fourth volume of the Journal of the Horticultural Society of London. M. J. B.

PRACTICAL LESSONS IN BOTANY FOR BEGINNERS OF ALL CLASSES.-No. VI. By the Rev. J. S. Hevslow, M.A., Rector of Hitcham, Suffolk. Ex. 4. Common Primrose (Primula vulgaris). The Cowslip and a Polyanthus have the same structure.
Coherion.-There are five sepals in the calyx, but hey are united or grafted together by their edges throughout a considerable portion of their length. The calyx consequently becomes a sort of cup-like tube surrounding the other floral whorls. Whenever similar parts in a flower are thus more or less grafted together they are said to "cohere."
There are five petals to the corolla, but these also colsere, and form a narrow tube below, which expands above into a border with five lobes, indicating that cohesion is not complete to the summit of the petals.
N.B. According to old notions this calyx would be considered as composed of one sepal (monoscpalous) partially divided into five segments. The corolla would also be regarded as of one petal (monopetalous) slightly cut into five lobes.

Adhesion.-There are five stamens attached to the tube of the corolla at the part where it begins to widen. This position of the stamens is owing to the greater portion of their filaments being united or grafted with the corolla. If the tube of the corolla is split open and held up to the light, the attached or cohering portions of the filaments are easily traced to the bottom. When dissimilar parts belonging to different floral whorls are thus grafted together they are said to "adhere."
N.B. This convenient mode of distinguishing the grafting together of similar parts by the term "cohe sion," from that of dissimilar farts by the term "adhesion," is seldom noticed by descriptive botanists, though long since suggested by De Candolle.
N.B. Simple inspection of the solitary pistil, with its one-celled ovary, would not enable us to determine whether it were composed of one or more earpels. Other considerations, which need nol yet be noticed, have shown it to be composed of 5 open carpels cohering by their edges.
Ex. 5. Common Cherry (Piunus cerasus).

## Cumbry.

Calyx of 5 sepals cohering below into a tube
Corolla of 5 petals inserted (ie. seated) on the ube of the calyx
Stamens numerous ( $\infty$ ) also inserted on the calyx. N.B. As in the last example we observed the inser tion of the stamens on the corolla was owing to the partial adhesion of their filaments with it, so here we
have both petals and stamens partially adhering to the calyx, and thus producing the appearance of originating rom it.
N.B. Like instances of adhesion between the three outer floral whorls (calyx, corolla, and stamens) occur in the Peach (Amygdalus Persica), Purple Loosestrife (Lythrum salicaria), \&c. Where adhesion takes place between all the floral whorls, a marked peculiarity of structure is the result, and will be explained in the nex example.
Ex. 6. Round-leaved Bell flower (Cumparula rotundifolia) or any other species of this genus.

Superior and Inferior (orary and perianth).
The calyx of 5 cohering sepsls, the corolla of 5 cohering petals, and the 5 stamens, all adhere together, and with the ovary of the single compound pistil. The result produced is an appearance as if the parts of the outer floral whorls grew from the top of the ovary. In such cases the ovary is said to be "Inferior" and the perianth "Superior." Whereas in the other 5 examples because the pistils were free from adhes:on with the other floral whorls, they would be styled "Superior," the perianths originating below them would be called "Inferior."
N.B. Numerous flowers possess a like structure, as the common Snowdrop (Galanthus nivalis), all Currante and Gonseberries (Ribes), all Honeysuckles (Lonicera), \&c. Floral Recfptacle.- The parts of whicha flower consis!s are seated on the "Floral Receptacle," which is the summit, more or less swollen, of a short the floral receptacle may be exposed by removing
with an inferior ovary the floml whorls are so combined with the floral receptacle that they cannot be detached 80 as to expose it uninjured.
Inconpletr Flowers.-There are many flowers in which No only one kind of the essential parts is present The other kind will then be found in other then be found in other flowers either on the
same plant, as in the same plant, as in the common Hazel (Corylus avellana, or on a dif erent individual of the same kind of plant, as in Willows (salix). The perianth is sometimes entirely wanting, and the essential parts of the flower are then generally protected by a lesf-like scale, and are often crowded together into a dense mass. As an example we may refer to the flowers of a Willow or Poplar, but without further comment than is required to show they consist of either stamens only, or of a pistil only.
Heads or Flowers - A very large number of plants, especially one particular group, Composites (Composito), bear very small flowers (florets) closely aggregated into a mass termed a "head" (capitulum). This was formerly

regarded as a "compound flower," and is still so con sidered popularly. The common Daisy (Bellis perennis) Dandelion (Leontodon taraxacum), Dahlia, Sunflower (Helianthemum), Oxeye Daisy, Sic., are familiar examples. Such heads of flowens are surrounded by small, generally green, leafy scales, looking somewhat ike the sepals of a calyx. Beginners must be cautioned against mistaking them for single flowers. Every little hower in such a "head" possesses its own floral whorls, the peculiarities in whose structure need not now detain us, but will be explained as we proceed.
Schedule Lessons on the Floral Whorls.-Particular places in the school are assigned to the children 80 far apart as to prevent any copying. As only botanical volunteers stop after the rest have been dis missed, this arrangement, though our school is small, suffices. Each child receives a specimen and then rules for itself the following blank form of schedule on a late wherein to record the result of its own observations on the flower, and to enter the conclusions to be drawn from them.

| P. L. |  |  | Cl. |
| :--- | :--- | :--- | :--- |
| C.S. |  |  | Di. |
| C. P. |  |  | Sec. |
| St. |  |  |  |
| $\mathbf{P}$ |  |  | Or. |
| $\mathbf{U}$ |  |  | Gen. |
|  |  | Sp. |  |

The merest beginners, from six years upwards, comose the 30 class, and confine themselves to the first biank column, with sundry more or less perfect tempts at completing the second. The 2 d class fill in the two first columns, with such attempts at the
remainder of the schedule as they can muster resolution to make. The first class are expected to fill up the whole schedule. In the first blank column are to be inserted the actual number of parts entering into the composition of the
P. L. implies perianth leaves, only noticed in cases where it is doubtiul whether a calyx and corolla are present. C. S. stands for calyx-sepals; C. P. for corolla petals; St. .orstamens ; P. for pisti, and the C. below it for the number of carpels, where these can
out by inspection, otherwise a ( $)$ ) is inserted.
In my next communication I will give a few examples of the manner in which this first blank column would most probably be filled up by the children of the first class, with a few comments on the mode of correcting the not improbable errors of those in classes 2 and 3
(To be continued.)

## A RECENT STORM.

A violsnt storm occurred on the afternoon of Wednesday, July 23d, which merits careful investigation. Having examined its phenomens in this neighbourhood, with a view to determine the cause of hail, I am enabled to furnish some particulars which will probably be of Ackworth on the N.W., through Badsworth to the S.E., thence through Thorpe to Wentbridge, N.E.
At Wakefield we had lightning of a peculiar redpurple colour, which was reflected from the ground as thunder. There was some very heavy rain, but no hail. The circumstances appear to have been the same from
Wakefield to Ackworth Moor Top, there being traces of Wakefield to Ackworth Moor Top, there being traces
heary rain along the whole road, but none of hail. am informed that no hail fell at Ackworth, but a smart fall of hail occurred at Moor House, which is situsted on the N.E. boundary of the parish of Badsworth. The hail here beat against the east windows of the houses. The succeeding rain was extrem tree a limb as thick as man's thigh. Mr. Moore's crops sustained no damage, howing that the place was situated beyond the limit laterally some distance from the place of its formation. The centre of the parish of Badsworth was nearly the centre of the storm in this districk. Here hailstones, or rather masses of ice, fell, some of which, after being carried a distance, weighed $3 \frac{1}{2}$ oz. each, and
measured between 6 and 7 inches in circumference. Almost every house had a large quantity of glass broken carefully cultivated gardens presented a spectucle of destruction which must be seen to be believed; and in they will hardly return seed to the cultivator. A field of Wheat belonging to Mr. Jones, of Badsworth Hall, ing to a widow woman, afford good illustrations. and the whole scene afforded a terrible instance of the desolating effects of a few minutes' hail such as happily is seldom seen in this country. A field of
Wheat near the toll-bar, on the right-hand side of the road from Wakefield to Doncaster, affords an excel lent illustration of the law of hailstones. The bulk of the field is unaffected by the storm, showing clearly that
it was beyond the limit of the hail in that direction, but it was beyond the limit of the hail in that direction, but
the corner pointing towards Badsworth Clurch happened to be within the limit, and the effect of the hail across that corner is distinctly visible. The Wheat is damaged for 20 or 30 yards into the field. The injury of the centre of the storm, causes which I have discussed elsewhere. The breadth of the storm at Badsworth was about a mile and a tenth. From Badsworth to Thorpe ravages of the starm are everywhere visible. Corn crops are threshed in the field, and the ears cat off from the stalks; an for a minute or two in a sheet of flame, and large branches are torn off in all directions. From Thorpe to Wentbridge the desolation continues, and as an illustration of its extent I was told that a poor man, who occupies 19 acres of land, had nut as mach corn left upon it as would keep himself, his wife, and a pig during the winter. yet it was no uncommon thing to hear the damage done by the hail on particular farms estimated at from 2000 . to 400 l . In one case nearly 300 l . was paid by an insurance company, and in two others valuers werd called in, who estimated the damage at nearly 4000 . Two brothers, nained Kitson, residing at Birkin, have
suffered damage to the amount of 750 l . A gentleman sumed Seaton, residing at Wentbridge, was sitting with his family at table when the storm came on. In a few moments most of the glass in the front of his house was broken; masses of ice went through the panes with such rapidity as not even to splinter them, cutting out holes as cleanly as rifte bullets. A decanter three-parts
full of wine was knocked off the table, the wine glasses broken, and the table indented in many places. The stone walls of this gentleman's buildings are pitted all over with holes made by the hail, for the most part larger Shan would be made by firing swan shot at them. Mr. Seaton informed me that five or six buckets of ice
were gathered up in his dining-room, and that he were gathered up in his dining-room, and that he
saw some ice which had lain in a hedge-botrom from Wednesday afternoon until Saturday night. The latter statement is corroborated in the following manner.
pridge, named Friend Taylor, living at Wentbridge, was about a mile and a quarter from home, at
right angles to the storm's path, when the storm right angles to the storm's path, when the storm
occurred. With two or three other persons he took shelter in a Turnip field from the rain. There was no hail where he was, but so strong a wind set in, blowing at right angles to the storm-path, that the
Turnips were lifted up out of the ground above an inch The storm began about 35 minutes past 4 p.m., and continued until two or three minutes past 5 p.m. The hail beganat 45 minutes past 4 p.m.,and lasted for 7 or 8 minutes, Some of the hailstones were angular, as if fractures of a sheet of ice ; others closely resembled Peach stones by the fact of there being no perceptible interval between the flash of lightning and the thunder. The gardener at Badsworth Hall and another person observed the lightning descend from the clouds to the earth, and then instantly return from the earth to the clouds. During the storm the barometer fell very little in comparison to its fall for the high winds the week before. Marvellous as some of these facts appear, the accuracy of the report will be borne out by Mr. M. E. Naylor, who was good enough to accompany me during the inquiries. My thanks are specially due to Mr. Moor, of Hall ; to Mr. Milnthorp and Mr. Harrison, of Badsworth, for the trouble which they kindly took in furnishing me with the information.
On Thursday last, at a few minntes past 12, a curious electrical phenomenon was seen close to St. Andrew's
Church. Instead of an ordinary lightning flash a globe of fire, similar to the sun, with a hole in the centre, was perceived, having two long tails projecting downwards

and outwards. This appeared poised for an instant, and then descended to the earth in a neighbouring field with its points downwards. The Potatoes in that field appear Wance to have become diseat Journal, Aug. 15 .
III.-ON THE DIRECT EFFECT OF THE SUN'S RAYS AND OF EXPOSURE UPON PLANTS.

## Continued from p. 849. )

IT is admitted that the mere fact of the different parts of plants being differently coloured prevents our measuring the effects of the sun upon them by the indications of its action on a black-bulb thermometer. Its effects are much modified by this cause, and there are also many others scarcely recognised by meteorologists. A solid body, such as a leaf or branch, cannot be treated as a liquid in a bulb is, especially when the solid is a bad conductor, and the liquid (mercury) is a mobile and good conductor. Vegetable tissues are cooled by day by the ascent of sap and by evaporation ; during night these movements cease, and radiation proceeds unim-
peded. The transport of the sap during the day determines a considerable amount of evaporation which further modifies the heating power of the sun's rays. The stem, and often the leaves also, of a tree are vertical, and in general a plant presents but a limited area of its surface to the whole effeets of radiation; further, the several parts shade one another. In a forest or on a prairie it is only certain parts of eachindividual branch that are exposed directly to the rays of the sun ; the others are turned to the north, or are more or less completely sheltered. When an isolated tree is tufted, it is not more than a tenth or twentieth part of its surface that more than a tenth or twentieth part of itt surface that
receives the solar action, and radiates freely into space, and again, the more it evaporates the further cools its green parts.
From all these causes combined, it appears that, supposing the difference between the mean temperature of a thermometer hang in the shade during a fine season and one exposed to solar radiation to amount to
$3 \rho$ effect of this difference upon vegetation to reduce it considerably. It will, in as far as we can judge, not exceed a fraction of a degree (Centigrade), and hence the differences due to radiation between a maritime and continental climare situated under the same latitude may be very trifing. Hence also observations made in the shade may be supposed to represent very
well the shaded surfaces of a plant, and owing to the well the shaded surfaces of a plant, and owi
effects of evaporation the exposed parts also.

Common observation confirms this view in temperate climates. Did solar radiation influence vegetation to
the amount of $4^{\circ}$ or $6^{\circ}$ we should not have the notithen the amount of $4^{\circ}$ or $6^{\circ}$ we should not have the nowthern sides of isolated trees flowering and fruiting till long
after the sonthern. In lanes rumning east and wit should find one side lanes running east and weat we the other in many natural phenomena (for a difference of several degrees of temperature is often the equiralent of many degrees of latitude), which is not the case at all.
The operations of agriculture are equally unfavourable to the hypothesis of the action of radiation on plant Thus, in the harvesting Cherries, Apples and Grapes there are not two gatherings, one for the north and the other for the south sides of the trees. The difference is so small that it may be neglected, whilst did it
amount to 4 or $5^{\circ}$ of mean temperature its effect amount to 4 or $5^{\circ}$ of mean temperature its effect would be to hasten the maturation of some parts and retard
that of others by many weeks. With us the Vin that of others by many weeks. With us the Vine posed to the vineyards at all exposures, some even ex have more thorth, but they do not find it necesary observe in harvesting is to take the ripest Vines first.
The observations of meteorologists are entitled to less confidence in my opinion than are the facts of vegetable life. :A thermometer cannot be compared with the tissues of a plant in a physical point of view. Plants demonstrate the chemical effects of solar rays that are unappreciated by the thermometer ; and lastly there is a great difference between the kind of effect produced by the sun's rays upon a thermometer and a plant ; in the thermometer it simply causes a fluid to dilate, in a plant it sets a complicated piece of machinery in
motion. The best way of appreoiating the effect of radiation is not by observing the thermometer, but by watching the effect of sun and shade upon different specimens of the same species planted in the same soil.
There are two classes of facts which require study ander this point of view. 1. The influence of a nort plants to affect different elevations; a differeice easily expressed in terms of the thermometric scale. Thus, on a mountain the mean annual tomperature of which diminishes at the rate of $1 \frac{30}{4}$ for 500 feet, a of which diminishes at the rate of
species which ascends 1000 feet higher on the south species which ascends 1000 feet higher on the sou
side than on the 'north is influenced to the amount of $3 \frac{1}{3}$ by the exposure. It is true that the dryness of southern exposures and the humidity of norther have some effect independently of temperature,
but when many species are under observation such sources of error are eliminated. It may be objected to this method that the northern slopes receive some sun, and that the southern are sheltered from the northern blasts, that the latter have two ad vantages, more sun and shelter; but to diminish the effects of shelter it is better not to include the lowes parts of the mountain, which are always the noest sheltered. On elevated and isolated summits the north winds are almost equally felt on all sides.

Observations on the date of leafing, flowering and fruiting of plants belonging to the same species in the same country, \&c., in the same year, but differenty exposed to the sun and shade. Those exposed will be so many days in advance of the others. During these days a register of the mean temperature in the shade is kept, and thus one has a measure of the effect of the
sun's rays expressed in terms of the time elapsed and sun's rays expressed in terms of the time elapsed and in degrees of the thermometer hung in results which differ in different countries and vary with the season and with the year, but the means of which will give sufficiently good approximate estimates countries. J. D.

(To be continued.)

## Home Correspondence.

Budding Pear Trees.-I should like to ask why M. de Joughe in his paper of the 14th July recammends Par trees to be budded 2,3 , or 4 feet from the ground? Al over the American continent, where there is a sun M. do Jonghe never could conceive as it could not exist in it full clear brightness in Belgium, it is the invariable custom to bud all fruit trees as near the ground a possible. To say this is done through ignoranco simply absurd. All arguments point to the commo sense of such a course, as it enables the purchaser bo do what he likes with his trees, instead of what the nurseryman chooses to allow him to do. $\boldsymbol{A}$ Canadian Farmer.

Orchard House Trees,-The following hinta 'may be interesting to some of your readers. About ten day since I removed some of my Apricot trees in pots from the orchard house to a sunny gheltered place to ripen their fruit in the open air; this retarded the ripeem
period some eight or ten days, and the flavour of theis fruit has been beyond anything I ever tasted in Apricots so piquant and yet so juicy and luscions; some are sur on the trees ripening slowly. If they had been remered from the orchard house in July, before they commend o to colour, they would not have ripened till the anrees August, or even till September. If Apricot from to produce late fruit are placed under a north wand the the middle of July till the middle of September, and aspect removed and placed under a wall with a southern asp or, if the autumn be cool, to the orchard hoase, they ripen fruit of fine flavour as late as October. This suctise method of retarding Apricots may always be pract the
with the most agreeable results. I am now trying
same experinent with Peaches and Nectarines, by re-
noving from my orchard house
a Noblesse and one on wo wod placiug them under a wall will a southern aspect, vithin 2 feet of it $;$ I $I$ expeet that $I$ shall have Noblesee Peaches sith a fiue piquant flavour three weeks after Phoaes in the orehard hooces and on wallis haveripened. The trees should be prepared for removal by lifting them a week or so previously, and if trees are fixed deeply into the borders, all the better. I may, perhaps, mention that I have just gathered from a tree in my orchard house and eaten some fruit of the Early York Peach-an American variety with serrated leaves and Early Ann, is larger, of a fine colour, and decidedly the finest early Peach yet known. When the orchard-house system was first broached it was most confidently given out by some of our best gardeners that it would be found utterly impossible to keep fruit trees in pots in a state of health, and then when it was found that the trees ground was taken aud my system of not re-potting the trees for a number of years was condernned as quite un-
tonable. I have at this moment only the pleasant fact to state in reply to these melancholy croakers-my tree that have been in the same 13-inch pots some five, and some six years, are more fruitful and more luxuriant
in their growth than they have ever yet been. Thomas Rivers.
Wellingtonia.-I received from the United States Wate last autumn and in the winter some 600 or 700 were potted in the usual compost, sand and loam, and placed in a house well ventilated. They grew healthily and well all the spring, and were removed to the open they seemed to be in most vigorous health and growth occasional shoots turned brown and died off; these were removed and not much noticed. During the months of June and July past the disease has progres the great extent, so that perhaps one-third of the young
trees are affected; they do not all die, but after losing trees are affected; they do not all die, but after losing root. I have never before seen any disease like among Conifers, and I must confess I was at first ex ceedingly disturbed at its appearance and its origin Being however at Mr. Young's nursery at Milford in June last, I learned from Mr. Young, jun., that out of a dozen plants they had had from Messrs. Veitch, they had lost half by the same disease. It seems therefore peculiar to the tree, at least in its young state in this climate. Whether age will make it exempt is yet to be seen. I enclose a plant for your inspection. Thomas
Rivers. [So many of the roots were dead and brown that we can hardly doubt that the soil contained some ingredient which disagrees with Wellingtonia. appears to $u s$ that the roots perish first, and then the his soil by our correspondent Acton ( $p .534$, col a) for whosel accuracy we vouch. Perhaps Wellingtonia does not like potting. The roots of the specimen sent us were already corkscrewed. The Acton plant never had pportunity of being spoiled by "pot-cramping."]
Figs.- The following appears in the Independanc Belge, 12th August, 1856 :-A process forhastening the ripening of Figs is, according to the Journal de Tarn et onsists in the epplication of a small drop of Olive oil to he centre of the eye of the Fig; the oil is applied with straw sc as to touch only the centre. This operation should be performed as soon as the eye of the Fig sliows
a decided red tint, and in the evening after sunset. The Fig which was green, small, and hard, becomes on the gext day swollen, soft, and with a yellow tinge. The eye s open, the flowering commences, and the fruit is gathered on the morning of the fourth day, when the seeds are about to be formed. By this means the fruit which is obtained has more perfume and sweetness than by the ordinary ripening, and is free from the presence question is well known. seds. Nhows that the advantages attending it are more imaginary than real.]

## surieties

Britism Association for the Advancement op The business of the Section commenced by the reading of a paper, "Notes on Experiments in the Botanica Garden of the Royal Agricultural College," by Prof. Buckman, of the Agricultural College, Cirencester.-In
this paper the author first described the soil and situathis paper the author first described the soil and situa-
tion of the locale occupied as his garden, which, from tion of the locale occupied as his garden, which, from
being situate on forest marble clay, is of a somewhat being situate on forest marble clay, is of a somewhat
sterile character. The experimental portion is divided into 200 plots, most of which are $2 \frac{1}{2}$ yards square, some double that size, and a few still larger, now engaged in experiments with various manures. The plots are employed at the present time with crops mostly experimental, in the following classes:-Grasses, 82; Papilionsceous feeding-plants, 25 ; crops for green food, 12 , Wheat, 6 ; garden vegetables, 5 ; Turnips, experiments ornamental plants, $40:$ total, 197. For the Grasses many observations were given tending to show that varieties-instances of which were given in the follow-
ing genera: Bromus, Festuca, and Agrostis, one case in particular and the three following forms of Festucs,
F. Ioliacea, F. pratensis, and F. elatior, were shown to have been produced from the same seed by the gradual change of the first two into the latter. In the Paph-
lionaceer the author pointed out the production of the lionacese the author pointed out the production of the
spring and winter varieties of Vetch from the $V$. angusifolia. In the genus Trifolium he made the followin remarks on T. pratense and T. medium. The T. pra ense occurs wild in all good and rich meadows and pas trea; its place, however, in poor sandy soils is supplica by the T. medium, on which account the latter plan was some few years since introduced into agriculture to ensure a crop when the former usually failed. The seedsmen used to supply it under its botanical name of T. medium ; but it is a curious circumstance that al he samples of $T$ pratense, and lence, at present the best-informed seedsmen no longer send it out under the riginal botanical desiguation of T . medium, but under hat of T. pratense pereune-the fact being well established that we have two varieties of broad Clover cultivation, whilst the true T. medium has been eatirely lost to agriculture; and the whole evidenc with respect to this subject showed that it has not been lost from neglect, but that it has merged into T. praense; and if so, it remains as a most interesting matter for experiment, especialiy when it is considere that no doubt has been entertained by botanists of their istinction as species. Many experiments of a like
ind were described, and their practical utility clearly pointed out
The President called attention to Prof. Buckman paper on account of the question it raised as to the perMr. Manee of specific characters in plamis which he had made on the hybridization of Wheat, showing to what exent the characters of the permanent varieties of Whea may be changed.-Dr. Daubeny thought Prof. Buckman's paper valuable both in an economical and taxological iew ; for whilst it showed how external circumstances could change the characters of specific forms, it showed how certain forms could be produced which yielded larger amount of profit to the farmer. There was a general impression among botanists that the specific names to new forms of plants had been to give specific names to new orms or piants saiked to carried too far, and Prof. Buckman's paper seemed to indicate the way in which new forms had the for
duced. The Rev. L. Jenyns referred to the fact that duced, - The Rev. L. Jenyns referred to the fact Sym two plants formerly thought to be distinct, the Symphytum officinale and the S. asperrimum, were growing together near Bath, and that it was now impossible to distinguish one from the other. Mr. Bentham stated that by taking a single"isolated Flora like that of Great species ; but if the British species were compare with those of the Continent of Europe, it would be found that certain forms which were regarded a distinct quite evidently run into others. He re ferred to several species of Trifolium as confact that not a single phenogamous plant was peculiar to the British Islands, but all were connected with peeuliar Floras on the continent of Europe. Experiments har been made by Vilmorin on the conversion of wild plants into the cultivated forms, and he had perfectly succeed with the Carrot and some others; but th wild Parsnip, which Prof. Buckman had successfull cultivated, had resisted all his experiments.-Dr. Gilber referred to his own and Mr. Lawes's experiments, an stated that certain inorganic substances, arowth of many agricultural plants, producing considerable changes in the characters of their roots, leaves, and stems.- Mr

Babington stated that with regard to the grea majority of British plants which had been called species, Many of these grew constantly together and under ever possible variety of circumstances, but always presente the characters by which they were distinguished. H protested against the doctrine, that because plants re sembled each other therefore they were not distinct. He did not believe in the identity of Eyilops and Triticum, were the result of hybridiastion.

Entomological, Aug. 4.-J. O. Westwood, Esq., V.P. the chair. Donations to the library from the Roya and other societies, Messrs. Kolenati, Guerin-Menevill Nylander, \&c., were announced. Mr. Douglas exhibited a specimen of the very rare moth Drepana Sicula, which a single example only had been previously tured in this country, in Leigh Wood, near Bristol, Mr. Bolt. Mr. Hunter exhibited Erispos Latreim, beautiful moth belonging to the family Noctuidæ, quite from the country, which he had succeeded palealis, Trochilium chrysidiforme, from Folkestone. Mr. Weir exhibited a number of specimens of Macaria notata, all of which were more or less deformed, wanting one or other of the wings, a circumstance to which this species seems especially liable. Mr. Samuel Stevens exhibited several specimens of Trochillum chrysidiorme, and a new species of Pbycita, from Galli from the sandhills at Deal, and other rare moths. Other rare species of moths were exhibited by Messrs. F. Bond and Tomkins, and Mr. Waterhouse exhibited some interesting minute Coleoptera from the New Forest,
including five species of Myrmidonia found in the nests
of biack ants, uxypodia vitrata, and Urchegia vittata; the atter had been reared from the larva. Mr. Wollasto so extibited a number or rare Coleoptera from Leicester hire, including Soraptia fusca, and a Galeruca wib houstruus antenue, that on the 1 a eparate branches. A paper by Mr. Newman was rea on the effect on insects of the poisonous effluvia arising from bruised Laurel leaves.
Tardebigg Horticultural-On Friday the Right Hon, the Baroness Windsor threw open the parls an gardens of Hewell Hall to the visiors to the Tardebigg
Horticultural Society's Show, which was held in th park. The object of this society is to encuurage a tast or horticulture arnong the cottagers of the parish, an udging from the display they made of fowers, frui, nd regetables on this occasiou, the efforts of the committee met their due reward. But the beauty of th exnibition was mainly attributable to the splendia collection of plants and fruits extribited by Mr Markham, gardener to Lady Windsor, which were sufficient to establish that genteman's shl as a cativator. The visitors to the gardens had a great treat bing allowed to inspect every part of lhew. The French garden is truly magnificent, and withics gente lopes, noble terraces, and richly filled fower beda, is judicious, judiciously, can effect. The Dutch garden, in quite different syle this, wh
 walks, and clipped arboreta tiedes, attraction. The conservatory and Camellia house contain some most beautiful and and of them measuring more than twenty feet. The gardens and lawns are all in the highest state of seeping ; any one might ofer a presuo tor a ded wor risk; and the whole mangement of credit upon the gardener. Birmingham Journal

## Shotites of 6ooks.

The Secrets of French Ccokery. By A. Gogué. (Les Secrets, \&c.) Paris. Hothelte. 12mo. It gives the This intele volame does no belie mysteries of a French reader a complete hog who reson why all middle cilche, alis bithose class Engish gists say that cookigg is only a prelinh ary gestion, for the purpose of en. complete the process. Experience tells us hat wey are quite mistaken ; and that among the middle classes in England cooking has been expreas contived to render food more difficuit to digest laan il is in its natural state. M. Gogue explains this in his litue book, win more over enters into many useful details concerning French invitations, guests, servans, and entertainments, no omitting the daily cares of housekeeping. About eight and-twenty pages are occopied with the cooking of vege tables, among which we find, what is rare in works of this kind, the treatment of Tomatoes and Aubergines Let us translate what is said of the latter. "The Aubergine is a fruit of southern regions. In Provenco and Languedoc it is greatly esteemed, and is cooked in varius ways. In Paris it is difficult to obtain good ones sufficiently ripe. Choice should always be made f $u$ eh are very violet.-Stuffed Aubragings Cut them in two lengthwise; remove a part of the les' mince it and add an equal quantity of mince Mue mince it and ada equal much crumb of bread soaked in broth Take a piece of butter as big as an egr, as nely minced bacon-fat, some olive oil, a littl Parsley, two cloves of Garlic, and six and the flesh
 add a quarier as much stuffing, mix them all thoroughly, and fill the inside of the Aubergine, finish off with the stuffing, sprinkle with bread crumbs, and put in the ove, Cont half an hour at most.-Fried Auberginss. in four lengthwise; duest them win sal, er them stand for an hour. Pat into a pan three table spoonfuls of Oive oil, and fry hom, hang first arais them and wiped them with a cloti. Mix a little chopped Garlic and Parsley with the oil.-Gricle Aubergines: Cut them in two, and after having well scored the flesh season them with pepper, salt, oll, and little minced Garlic. Grill them over hot ashes, or on very gentle fire, taking care to turn them.
We suppose that Aubergines ripe and good, not half ripe and nauseous, as they are in this country, will soon become a Covent Garden import from the South of France. In that case these recipes will be useful, for English cookery books know nothing of such esculents. And yet they are among the nicest of delicacies Even Mrs. Acton

## Garden Memoranda

urnham Grken -To many it may be gratifying to know that notwith standing the diminished expenditure to which this establishment has of late been subjected, the condition of everything both outdoors and in is highly satisfactory. In the arboretum the Grass is short and trim, the walks smooth and clean, and had it not been for the heavy rainfalls which we have lately experienced the
possibly been desired. Even now they are extremely gay, and should fine weather soon return the temporary injury they have rectived will doubtless be but shortlived. The finer kinds of Conifers planterd on the east side of this department of the garden have acquired beauty, and now thder them objects of muchingerest and established and their true characters nore fully developed they are well worth inspection. On deciduous rees the "ear and yellow leaf" has scarcely yet ventured to appear; everything therefore looks green and healthy, and notwithstanding the dry warm weather Und lave had bears the stamp of luxuriance and beauty Aebimenes and plants of that descrintion, and the coith oner with Geraniums-scarlet, variegated, and sweet scertel, Cockscombs, and Balsams, and last but not least with that charming buibous plant Tritonia aurea This flowers most profusely, and when planted tolerably wick, the large masses of bright ornat produces are most striking. It is a plant whic succeed anywhere just free from frost, and few things for autumn decorecent introduction are so valuable greenhougeg we il the Greeninmses we noticed the Australian Passiffora cinnaCoccocrpselum win ruit, which is said to be eatable. cococpselum repens, in the propagating house, was in beaunul condition, with its pendant shonts loaded with the most brilliant Lapis lazuli berries. It succeeds pereetly when the pot is suspend drom a roof, but is apt o damp off if placed on a shelf.
Among rovelties and plants not yet sufficiently from Mr. Skinner there are cousiderable numbers, chiefly
kind of scarlet Composite. way of fulgens; an Antigonum, reported to be a very Tiae stove climber; the large orange Cassia beavery Poites viciefolia ; a double variety of Clitoria grandis and Cæsalpinia exostema, a crimson. flowered shrab Rondeletia anomala was plentiful, lorions Tecoma velutina. Among Rhododendrons wa n Indian one called lancifolium, presented by the East undia Company. Its foliage is small and liairy some hing like that of Rhod. ciliatum. Of the " Burnin oush," Eutonymus americanus, raised from seeds brough from the United States by Mr. Rowe, there are number of plants, and the same may be said of American Oaks, among which there appear to be some curious things, more especially one with striped acorns.
Of supposed new Conifers we olserved a new Pinus from Erzeroum as bright a green as P. insignis. This doubtless prove hardy and a useful addition.
In the large conservatory the huge Brugmansias in the bed have just been pruned "hard in," leaving nothing but bare stumps, which have been washed with a mixture of clay, soft soap, and sulphur to keep
down red spider. In a week or ten days these down red spider. In a week or ten days these
will push again, and may be expected to be in ful beaty about Christmas. The handsome Orange Cestrum is just opening great bunches of blossoms. The side sheives are gay with Hydrangeas, the white variety of Tracheiium corveum, a useful annual for autumn work, and a mirvellous plant of Platycodon at this season well worth a place under glase, where its numerous large blue blossims forcibly remind one a those of the handsome Lisianthus lussellianus. The specimen of Lucul:a which has stood and flowered fo so many years in this house bids fair this season to he
as fine as ever. New soil having been applied to ito as fine as ever. New soil having been applied to its
roots in spring has caused it to make good growths, every one of which promises to furnish a bunch of fragrant blossons. Baeckia peniula is well worth attention, not only because it is covered every year about this time with myriads of how of snowy whiteness, but also because it has a graceful weeping habit
which always makes it interestiug.
The Rose house, as our readers have already been informed (see p. 403), has been in great beauty. The autumn has scarcely commenced. After they had done blooming the flowering tops were removed, the plants made new growth and have again formed plenty of buds, some of which are just beginning to open.

The Orchard house is now worth a visit. Plums, Peaches, and Pears are all good. Of the last we of large size, and this in a year like the present when Pears everywhere are scarce, is a point gained of some importance. The Jeffer:on, one of our best Plums, is nearly ripe ; the Early York, a small P'eaclı possessing fine flavour, is now fit for table, and the same may be ssid of the little Nectarine called Fairchild's Early, a variety which when ripe has a colour not unlike that of a small Apricot. Several new linds of Vines trained up the rafters are fruiting here this year for the first time. They are, however, not yet far enough advanced
to warrant any opinion being offered as to their merits. In another house we noticed plants of the wild GrapeVine of the valley of Baidar
there is this year an excellent crop of Peaches on the protected trellis, brought first into notice by Mr. Bellenden Ker and Mr. Rivers. The Acton Scott Peach in particnlar is quite loaded with fruit, which is of fair Ond well coloured.
Orchard fruit here, as in most other places this year, is scarce, except on walls, where ou some of the Pear dant. None are however quite ripe. Jargonelle Pear

I maggot
The Dioscorea Batatas planted withnut having been previously raised in heat is being tried here again this year, and so far with perfect success. Large whole roote, cut sets, and small tubers about the size of Peas, have all been planted. The plants from the whole roots are considerably the largest, those from the cut sets next, and the smallest of all are those from the
Pea sized sets. All of them are tops are not staked, but are allowed to ramble about as they please.
It may be mentioned that seeds of Acacia and other hings steeped in glycerine for 10 days, and others of the same kind not so treated were all sown at the same time, and in the same kind of soil ; the object being $t$ o ascertain which would succeed the best. The experi
ii:ent loas scarcely been under trial long enough to wient has scarcely been under trial long enough to present, howtver, no difference exists betwrom it ; present, howtver, no difference exists between the two p quite as well and regularly as those to which it wa pplied.
We understand that the Council are actively engaged in remodelling the whole garden establishment with The to reduce expenditure without impairing utility The great conservatory is to be converted into a winter sheter for fine specimen-plants that can be used in sammer to decorate the arboretum. The consequence of this will be the sale of a large number of fine greenhouse plants no longer wanted. The orchard is
al-o undergoing a thorough examination, and many old apse duplicate tres, as well as worthless sorts Apples and Pears, are condemned, is order to make room for other things.

## Calendar of Operations.

 (For the ensuing woek.)
## plant department

Consenvatary, ece-Continue to trim and requlate the growth of twiners, cutting out any shoots that have done flowering, which will tend to strengthen those left he case them to bloom fater than would otherwise must be done this season, fininheng, \&e., which possible. See that Chrysanthemums are liberally supphed with water, and do not atlow them to be injure
for the want of staling. Stove.-Specimens of such things as Echites splendens, Stephanotis, Allamandlas removed to a cooler and drier house, which will be a more suitable situation for them while ripening their wood than a moist warm stove, but if this cannot be
done theu they should be placed in the conlest end of the stove, keeping them rather sparingly supplied with wate at the root, and exposing them as freely to air as circumstances will permit. Take advantage of every leisure hour to wash the foliage of such things as require it looking carefully for and destroying mealy bug and scale xoras and many hard-wooded stove plants are ver subject to the latter, and in most cases require to be fre quently looked over to keep them clean. Keep the shoot of young specimens nicely tied out, and give timely attention to training, so as to secure the desired form of rowth. Lonk well to the stock of things for winter keeping such as have made their wood and require pexiod of comparative rest to bloom well rather dry and con, and encourage any that may be backward in FORCING DEPARTMENT
Pineries.-Endeavour to afford plants swelling their fruit a high temperature with as little assistance from tmospliere dry is not conducive tonus to render the finely swelled fruit. Therefore economise the sun' warmth as much as possible, shutting up early on the afternoons of bright days after syringing the plants and moistening every available surface, and maintain a high temperature during the day, giving air sparingly. Bu ruit approaching maturity will be improved in flavou by a moderate use of fire-heat, a freer circulation of air and a dry atmosphere, and where there are no means of avoiding having plants swelling their fruit and those ripening it in the same compartment, then it will be advisable to keep the atmosphere rather dry and airy while fruit is colouring, as size is of little importance unless combined with quality ; but this will be bes decided by employers' tastes, \&c. Give careful attention to securing a fair supply of fruit for winter and spring use. Look over stock in pots frequently to make sure that it is properly supplied with water at the root, and give a liberal supply of clear strong manurearer where free vigorous growth is desired. Vineries Where the fruit is ripening all iavourable opportunities when the weatlo ripening, ueing fire-heat rather freely When the weather is damp and cloudy, and be careful is recure a dry state of the atmorphere where the fruit using a little fire-heat when necessary to dispel damp See that ripe fruit is secure from the depredations of wasps, if these are at all troublesome.

FLOWER GARDEN AND SURCDberies
The earliest struck cuttings should be potted off as oon as they are sufficiently rocted to bear the operation, placing them in a close pit or frame until they have hecome fairly established in their pota, when they should
be freely exposed to air, in order to induce shortjointed firm growth, which, with ordinary care, will be
enaly canked dyer the winter, whereas, plants got in every care and attention, to atmoaphere will, despit spring. Push forward the striking of cuttings, and get the autumn propacation ont of hand as sped aly possible. Where alterations involving the remoral arge trees or shrubs are in view for the autumn the necessary arrangements for commencing them canino be made too soon; for although many things mayy be eno successfully at almost any season of the jear failure, be done more cheaply, and with less righ and ailure, in September than at any other period.

## hariny freit and kitchen gamden.

ood trees will have already made as mach younc Where this is the much clance of getting ripened. stop a portion of the shonts, beginning of course with he strongest. See that Strawberry piauts tor forcing are properly looked after, as nothing but attention in preparing the plants wiil insure a good crop. lieep them regularly supplied witls water, expose them fully oo the sun, pinch off runners immedrately they are per. eived, and use every means to secure fine strong plants with bold crowns early in autnmn, with which there will be no risk of failure next sprin_. Cover Morello Cherries with thin nets, to protect them from birds without excluding the air ; also, if not already done, net up some of the latest keeping Gooseberries, to afford a late supply. The Red Warringson is one of the best to hang late on the trees, and is also of good quality: Gather early Appies and Pears as they becnuee ripe, and before the greater portion is blown down and injured. Tomatoes must be kept thin of wood, cheeting sun's ats, and exposing the fruit to the action of the sun's rays as much as possible. Take advantage of dry
days to earth up early Celery, sprinkling a good dustiur days to earth up early Celery, sprinkling a good dusting
of quivivlime or soot about the plants in the rows, ani over the surface of the ground for some distance on eaeh side, to destroy glugs, which generally do considerable damage to Celery, especially in wet seasons. Wiuter Onions should be sown at once, also Caaliflowers.

SATURDAY, AUGUST 23, 1856.

$W_{\text {F }}$ are now writing on the fifth day of an almost continuous rainfall. Over the whole of the south of England the corn had been ripe some days before the rain lesan, and one of the finest crops that Eugland ever saw has been spoiling eve since. There were not hands enough to cut it as i ripened, and machintry for the purpose is unfortuunately to be met with only here and there at distant intervals. There was time enough, had there been the means, to have harvested many hundred thousand acres before the weather changed, and the produce of those acres woold probably have been worth one-fifth more, both in money value and as food, than aiter five days' rain upon it in the field it can be supposed to be.
When the scarcity of labourers had become bions, the lommended the The practical man who wrote the harvest field. and men who had been accustumer food spoiling saving it forbidien to do other than look idly on. He recommended, therefore, that those who could not get their harvestmen elsewhere should be allowed to hire assistance here. And ever sincethe grain meanwhile sprouting in the sheaf-have we had to listen to the warnings of political economists against the danger of Government interference in the labour market! But why are these warnings, which no man ever heard when Government was taking these men out of our fields, reserved for the time when it is proposed to send them for a few political economy surely requires that every effort be put forth to place the vear's supply of food in safety? What red-tape stickler for routine, do you suppose, should stand lower on the list of incapable obstructives than the theorist who at such a time would interfere between the men who own the nation's food and any means hy possibility within their reach for saving it? As well protest against the employment of the soldier when men are wanted for the fire-engine at a conflagration, as protest when corn is dead-ripe stan ing in the fields uncut, and liable, as the past week proves, to scrious injury by weather-
auainst the use of any means whatever to get it under cover. The agiculturist may rest assured that he best serves his country then, and acts most ruly in accordance with a sound political economy, who by whatever means he can command secures his crons most rapidly.
At Boxted Lodge last week, where, although the corn was ripe, the fields had been left uncut because
they had most liberally been placed at the disposa of the Agricultural Society's judges of reaping machines, we were rejoiced to hear Mr. Fishen Hobrs declare that he had but to speak a word, and if he nee led them he could obtain 150 of "those Gernan fellows" (there is a portion of the Foreign Legion encamped at Colchester), and ther would clear his fields at once. liut there were four machines a work upon his farm, and he therefore had not need of them. The case to which Sir Morton Peto's etter to the Times referred is that of the thousands who have no machines, and who would gladly employ more labourers if they were obtaimable. We hope that when harvest weather shall revisit as once more militiamen, as well as any others who can wield the sickle, will be set to work with eners, leaving all these writings on the theory involved for perusa after harvest-home.
We must, however, hefore leaving the subject, point out the importance to the country as well as to the farmer of a more general use of the reaping machines another year. In the excellent new number of the Agricultural Society's Journal, there is testimony given to the entirely successful and practical character of this implement, which ought now everywhere to be introduced. Mr. Hammond cnts down 150 acres per annum with Dpan \& Dray's Husery's machine with the tipping platform-the amount of an average day's work beiug nine or 10 acres; Mr. Parrington, of Ruicar, cuts down $1 \frac{1}{-}$ to $1 \frac{1}{2}$ acre per hour with Burcias of Ker's form of M'Comacr's machine, and Baln's form which Croserill makes has this year received the largest share of the Society's prize which has been divided amongst all three. In fact it is unrquestionable that for ordinary harvest work any one of the machines will beat the bagging hook or scythe for the cheapness and the quality of its per formance. If then Crosskile, Bungfss, and Dean could only distribute 10,000 reapers before another harvest, it would be equivalent to more than letting loose all England's standing army on our corn fields, even supposing every man of them to use the sickle as well as he can wield the sword. This would be an interference with the labour market certainly - but who with the past fortnight's experience before him would not hail it as of great national service? Had we had such means at our command this year we should not now have had to complain of one half our crop leing five days in the raill. Supposing these machines to have been a week at work, 500,000 acres would have yielded $2,(100,000$ quarters of grain, worth noore both in money and as food, by much more than the value of the machine, than it now will prove to be. And the ground would have been cleared a fortnight earlier than it will for autumn cultivation and the other sources of employment which energetic agriculture furnishes.

In last week's number of the Society of Aits Journal there is an article on what are called negative Artesian wells" hy Dr. Brucrmann, of Stuttgard, in which he describes the process of digging wells in Germany for draining purposes, and offers his services in superintending engineering works of that description here.
Dr. Brectrmans's" negative Artesian wells " are What we have naturally in many a locality in Eugland, though we do not use such fine words in naming them. We call them "swallow holes." They are to be found wherever on elevated land a watercourse or ravine cuts through the diluvial clay ying between the surface soil and a porous rock below. Soil over such a rock is continually drained over its whole surface and throughout its whole shistance by the operation of the same principle which Nature exhibits more obviously in operation in these swallow holes, and which is efficient in Dr. Bruckmann's negative Artesian wells. And there is no doubt that this natural drainage may often be facilitated by the artificial passages by which Dr. Bruckmann proposes to render mor direct the connection between the supply grownd where the water falls and the npenings through which the porous rock receiving that supply delivers it again at a lower level.
Wherever impervious beds intervene between the soil or spot requiring drainage and a porous rock which would convey its water naturally away, then it simply becomes a question whether a well sunk through these water-holding beds, or a surface channel cut, it may be, a long distance to obtain the requisite fall be or be not the cheaper artificial exit for the drainage water.
Dr. Breckmann has in great detail described his success in Germany, and he has stated his qualifi cations for ensuring similar success elsewhere. These qualifications do not need to be of a very high order a very little experience in geological inquiry wil suffice to determine whether there exist in any
locality the circumstances necessary to the success of
an artificial swallow hole．And any piactical land drainer can say whether under such circum－ stances that be the cheapest method of obtaining an outfall for the drainage water．

In reference to the essays we have received giving replies to the agricultural examination paper of the Society of Arts，we have to state that the answer given hy Mr．Henry Cox，Longford，Minchin－ hampton，appear to $u_{\psi}$ the fullest and completest of the number．Any of them would，however，have perfectly deserved the award of＂excellence＂at the hands of the Society＇s Examiners．We shall publich Mr．Cox＇s paper in successive numbers of this journal，and refer more fully to them all next week．

## LOCUSTS．

When in London lately I was informed by a friend that he had just seen in Mark Lane a sack of podded somethinga，bearing this name，and which，from their pleasant flavour and general appearance，he considered likely to form an useful and agreeable variety of cattle food．The question was，from what plant they were derived，and whence the seemingly inappropriate name of locusts，a name，one would imagine，rather indicative of the insect than the vegetable world．In answer to my inquiries，I obtained the following information， which I here subjoin，for the benefit of those whu，like myself，may feel interested on a subject of no little importance both to the naturalist and the agriculturist．
Locust Tree－The Robinis pseudacacia of botanists，a North Amertean forest tree．The same name has also been given to
the Ceratonia Silliqua or Carob，or Algaroba tree，which inhabits the Ceratonis Siliqua or Carob，or Algaroba tree，Which inhabit
the Levant，and bears large pode，filled with nutritious pulp．－ the Levant，and bears large pode，filled with naus）Carob tree．－
Pexy Cyclopadia．
Ceratonia Siliqua（Keras，a horn；hornlike pods）．

 Hortus Brilannicus，p． 414.
Oeratonia Siligua
Bread，or Locnst tren），is a Jarge leguminous tree，inhabifing Syria and Egypt，and cultivated all over the warmer partto of the Mediterranean．It is valuable on account of its pods，which are $50 r 6$ inches long，deep brow，and filled with a succulent pulp， highly nutritions to cattle，and also used by man．Its name of its pods were the＂locunts＂on which St．John fed white in the wilderness．In consequence of the well－known value of these pods for cattle food，an attempt was made by the late Lord Spencer to obtain them from the Mediterranean．Some tons were actually received，but we are not aware that the result of their use has
beem published．It is understood that，as food，they quite an－ swered the expectations entertained of them，but cost too much to be worth employing．They must not be confounded with the Locust tree of the United States，which is the Acacia of nursery men，the Robinia psendacacia of botanists，for an account Carol tree，hotanically Ceratonia．－A small evergreen tree the Cassia division of the leguminous order．It constitutes a genus of itself，and takes for its speoific name Siliqua．It abound in Spain，Italy，and the Levant，and was introduced to Britain in the 1 atter part of the $16 t h$ century．Its stem usinally grows to
the height of about 15 feet；its leaves are differently shaped from those of most other evergreens，and render it an agreeable variety among Orange trees，Myrtles，and other greenhouse arborescent September and October，but are seldom produced in Britain in its pods are lnge，fab，horn－shaped，and brown coloured，and con－ to be the Locust tree of Scripture，and is generally known in Spain under the name of St．John＇s Bread．The shells of the tiful parable of the prodigal son．The seeds are imported from－ Ards of native prowth the name of Algaroba Beans，and the pods of native growth are eaten in times of scarcity by the cosalry drring the Peninsular War，－The Rural Cyclopadia，Rev．
Such is the information I have been enabled to obtain on this somewhat obscure subject；obscure because the term Locust is applied to three different articles having no connection whatever with each other，namely，the Robinia，or common Acacia；the destructive insect of might name，and which in my ignorance I usea to faney lastly the Carob，or Algaroba Bean，which I have no doubt，as its Spanish name of St．John＇s Bread implies， was the actual article on which he did subsist．I under－ in Gloucester corn market last Sacusts were exhibited in Gloucester corn market last Saturday，but at what price per ton I cannot exactly say．The experience of any of your readers on the subject will be both interest－ ing and acceptable．Samuel Taylor，Wotton Parade， Gloucester．

We have also received the following：－I procured a bushel of the＂Locusts＂for experiment．The seeds within the pod are as hard as gravel，and are rejected by the horse，while he eats the pod．His teeth grind against the bean，and he gets rid of it．If injury is seem to be objectionable．Probably when imported the seed becomes dry and hard．I picked them out of the manger after the horse had eaten his feed of Oats，chaff， manger after the horse had eaten his feed of Oats，chaff，
and Locusts chopped up with chaff．How is this objec－
tion，if it be one，answered？C．Easton，Aug． 16.

## SOME PAROCHIAL STATISTICS

Br Martin Doyle．
Tue parish in Ireland of which I propose to give some details respecting its rural economy presents a fair specimen of the agricultural condition of a con－ siderable district in the south－east portion of the province of Leinster，a district which ean boast of
farmers and peapantry superior in their habits of rural
economy，unremitting industry，strict integrity，orderl tenths of the kingdom south and west of the metropolis Ecclesiastically the parish about to be noticed may be distinguished as the rectory of $\mathbf{M}$ united to the rectcries of $B$ and $C$ and the vicarage of $D$ ．The total tithe rent amounts to ahout $600 l$ ．a year，of which 110 l is payable to the lay rector of D ，and $490 l$ ．to the incumbent．

The table No．l，compiled from constabulary investi gations in the present year，shows the apportionment among the occupiers and the almost exclusively agri cultural character of the population which is irregularly cattered over the whole area，there being but three very small villages，of which the largest contains only 30 habitations．

Assuming that each of the 574 families contains on the average five individuals，the aggregate is 2870，a little more than its numerical strength 20 years ago The last disastrous famine scarcely increased the ordi－ nary rate of mortality though great privations were endured by the poor，and the non－increase of the popu－ lation beyond about 4 per cent．is attributable to the voluntary emigration of some families．The great dis－ proportion between the acreage and the number of tenants is obvious．Deducting the portions farmed by three gentlemen（who are the proprietors of these and of adjoining properties）and those farms which are held by a few comparatively large class tenant farmers， 7500 acres are in the occupancy of 200 families，of whom 70 acres are in the occupancy of 200 families，of whom 70
hold between 5 and 50 acres．In fact there are many others who occupy even smaller holdings than 5 acree， and are classed in the constabulary returns rather as farmers than labourers；but to avoid needless compli－ cations I have excluded them from the columns of land occupiers，and placed them in column 9．To the 245 families at foot of this column may be fairly added the 49 families in col．8；they are chiefly dependent on their stipendiary labour，because they do not till their fields in the garden style，with spade or digging fork（by which in some cases they might acquire more income than by hiring out their services），nor obtain so many crops as their land would produce under a more careful system ；and I must state，in justice to a very deserving and laborious class，that their soil in many localitien is poor shallow clay，on the fertility of which no de－ pendence can be placed，even with much toil and care ＊Several hundred acres of alluvial land，reclaimed from the
incursions of tidal water，will soon be assigned to these two deno－ minations of the parochial area．
$\dagger$ These chiefly inhabit a tract of very poor soill，which was a by its owner to the occupying families at little more than a nominal rent．
nominal
$\ddagger$
countyis
count．Man ． num in this and the four followivg columns 50 scres．
the humble occupier，therefore，alraid to trust the maintenance of his family to what might be yielded by his land，seets emp！oyment elsewhere for himseif or his sons，as the case may be，as a source of certain ncome．There is to be added also to the class of operatives upon the land a great number of young men paid by the quarter or the year．The labourers of this ascription do not appear in the tubular details，yet there cannot be fewer on an average than two farm men servants domesticated in each of the 96 families（in columns 4,5 ，and 6 ）；and even the families in column 5 ，in most instances，labour in some manner on their farms，the fathers，sons，or nephews hold the plough， drive the harrow，sow seed，lead their carts，or dis charge other sorts of work．Thus a very large amount of human labour is actually available if not always fully employed．

## The aggregate number of labourers is produced from there tributaries，viz．， 245 families（col．9），supplying Individuals who labour，cols． 7 and 8 Domestic servants，cols． $4,5,6$

Now，if so many hands be considered as far beyond he legitimate requirements of near 10,000 acres，how much more will the redundancy of labourers appear when it is shown that the quantity of land in actual culture is leas than 5000．Some constabulary investi－ gations for the present year enable me to demoustrate the correctness of this statement．

Thus it appears that only 4838 acres（about half the productive area，after deducting the waste）are pro－ ducing crops on which routine labour $\|^{\|}$is expended， and 727 acres of the foregoing number are under Clove and meadow，which require but a very inconsiderable amount of labour

The cereal crops are obviously in too high proportion，and the Clover very disproportionately low． Turnips，Mangels，and Cabbage constitute less than one seventh；but Beans are considered an ameliorating crop，preceding Barley with the best results，and though usually tilled in the most slovenly manner and often but poorly manured the abundantly manured subordinately with those crops that are beneficial to the soil．Many farmers apply for Beans dung abundantly，and others use composts of sea weed，sea－sand，some farm－yard manure，and vegetable soil，well mixed and frequently turned．Some indeel are so poor and hard run to accumulate fertiliag materials that they have recourse to the roads and lay． bounding their fields for mould，which they cut sway in a shameful manner from the sides，contracting originaly wide roads，made and repaired at the public expense， narrow causeways with deep dykes，of which the outer sides dangerously decline from the remnant of road way left．Even on important highways inspectors road contracts have difficulty in preventing such spoliation or in having the tresspass repaired， 80 sucl the legal breadth of road may be attaived again．Such injuries are committed in winter or the early pap in spring to obtain fertilising mould，for the Bean crop particular．This is now one of the most profita if they readily raiged crops for the petty farmers，and in or any of the cultivators shall be led to adopt the
I Some trivial amount of labour，however，is employed on top dressing

English or Scotch methods of sowing（by dibbling or
drilling the seed with the plough instead of ploughing drilling the seed with the plough instead of ploughing
seed broadcast and so thickly into the ground that the stalks become slim and feeble，and the plants so crowded as to render hand－hoeing impossible），the Bean crop would be decided ly ameliorative，and of the inferio soils especialy．The breadth of land under Potatoes is much greater this year than it was last year；and though a tarms it promises well．I see fields of Potatoes around farms it promises well．I see fields of Potatoes around me in a very luxuriant state，and apparently past danger
of blight or any disease．Yet I have every hope that of blight or any disease．Yet I have every hope that
the advantage of having Swedish Turnips for cows，pigs， and horses has been so fully established that the extent of their culture will not be diminished．For cattle feeding the Potato is not likely to be used here again in preference to Swedes，which seldom or never fail it fairly treated．It is but now indeed that any of the common farmers are beginning to think of hoeing the
Turnip crop；seeing，however，the beneficial results of Turnip crop；seeing，however，the beneficial results of
the practice in a few instances，it will be adopted by all the intelligent cultivators within a few years．
I have yet to state the amount of brute animal acres，or in some manner acting within the parochial limits．
There are 381 agricultural horses of working age， 21 mules，and 148 asses．There are therefore more than eight horses for each hundred acres under the plough gether），which is at least double the number of draught animals required on the same extent of land in Great work imposed upon them not ordinarily called for by work impssed upon them not ordinarily called for by in particular ；and as the number of families in occu－ pation of the farms is so vastly greater in M—ut than on an equal space of land in any strictly agricultural
part of Great Britain，much allowance must be made for the various demands for animal labour by so many families having unavoidable intercourse with the market town．There they frequently must go to dispose of agricultural produce，though it may be small in bulk or value，and for the purpose of bringing home coals， town manure，or whatever they may want．Again， though many of the large farmers have capital horses，
and feed them well，the petty cultivators who constitute a great majority of the agriculturists have only small slim animals，unequal to heavy draught，and consuming but little fodder，very little expensive fodder，grazing during eight months of the year，and kept during rate supply of indifferent hay．The man who holds rate supply of indifferent hay．The man who holds similarly circumstanced；these unite their horses for similarly circumstanced；these unite their horses for
ploughing and harrowing，and thus both parties are ploughing and harrowing，and thus both parties are they effect by co－operation．Quarries of limestone are within the parish，and many horses are employed in drawing calcined lime to the farms．Individual farmers also have limekilns and draw the stone unburnt to them from the quarries just referred to，or from a little quay to which a tidal canal bears it，and boat－loads of sea
sand．The drawing of culm and coals also is to be added to the animal labour．
A glance at Table 3 shows the number of other sorts of live stock．

| $\underset{\substack{\text { Milch } \\ \text { Cows．}}}{ }$ | Two years old and upward |  | One year old，and yearr． |  | Under one year． | Total of $=$ Cattle． |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 655 | 37 | 73 | 31 |  | 295 |  | 1675 |  |
| Sheer． |  |  |  | pigs． |  |  | 域 | 年 |
| One year and upwards． |  | $\begin{aligned} & \text { Cnder } \\ & \text { one } \\ & \text { onear. } \end{aligned}$ | Total． | $\begin{gathered} \text { One } \\ \text { year } \\ \text { and } \\ \text { upwards } \end{gathered}$ |  | Total． |  |  |
| Ewes． | $\begin{gathered} \text { Tups } \\ \text { and } \\ \text { aethers } \end{gathered}$ |  |  |  |  |  |  |  |
| 746 | 420 | 715 | 1881 | 102 | 782 | 884 |  | 6907 |

When the horses，mules，and donkeys（all of which are principally grazed）are added to the foregoing stock， it will appear that the Grass land is sufficiently stocked． Many of the cattle are very large and handsome dairy stock，which would appear to advantage in any fair in the United Kingdom，and some of the sheep breeders have a heavy stock．In no particulars has progress been more marked in degree than in the improvement of all sorts of live stock，The breed of swine has been ospecially improved，and the prices obtained for them this year have been very high．The labourer alone remains stationary．He is still insufficiently paid for his labour，and consequently insofficiently housed，elothed，and fed．
1 must devote a future page to the distinct considera－ tion of his condition．

## Home Correspondence

The Meaning of an＂Average．＂－Observing in your leading article of the 18 th August a very shrewd
meant something very different froni the average crops our crops，\＆cc．，since the latter date＂［All we stated referred to the positive meaning of the word＂average．＂ －on this we drew no inference whatever．The conclu－ sions drawn below as to an＂average＂meaning Mr．Grant＇s，not ours］，and that consequently may very fairly be inferred by the mase of our speculators，capitalists，and consumers that average crops in 1856 meant a much greater surplus of food
than average crops in 1840 ，and that of course greatly decreased prices slould be insisted on，for the excess of supply would be sure to bear out the demand for lese rices in the end．Now this policy I think is erroneons in principle and practice，and must have a tendency to
wasteful consumption and decreased production．I have Wasteful consumption and decreased production．I have
no desire to impeach your veracity or motives in the statements you have made public，but I feel impelled to remind you of the one side statement you have made which if not corrected may lead to much misapprehen－ sion and injustice．I offer no opinion at present as to the result of the forthcoming harvest．We have no yel＂caught our hare，for anid these continuous we what is quite certain，and what I feel quite certain your candour will induce you to lay before your readers nex week，is，that you omitted a very important adjunct namely，that the average of population has increased in a full ratio with the average food production or rather over，and conse quently if your anticipation of a great increase of surplus food．And further you omitted to state what the for the advantage of increased employment and wages has given the means of procuring the necessaries of life in an increased degree ；ay，and the comforts，too，ar much more within the command of the mass of con－ they will，and ought to avail themselves of it，and rejoice ；long may all classes of our countrymen，in cluding the hard－working and honest producers of abundance，rejoice together and be thankful．Let me be rightly understood．I do not quarrel with your state－ ments； 1 only wish to draw the attention of jour reader to facts，and what should，in my humble opinion，accom－ pany your elever remarks，namely，that even if we secure an increased average in food，we have also an blest in an increased degree with the power and means for consuming it John Grant，Blackawoton，Totres，

Vitality．－Some years ago a Mr．Bickes professed to have found out a stimulgnt in which he proposed to steep seed Wheat and other cereal grains，and which he said communicated such an energetic vitality to the plan that the field in which it was sowed required no othe manure．This was a good deal ridiculed at the time the idea than the public are willing to admit？I don＇t mean to say that either Mr．Bickes or any one else knows how to communicate such a stimulus，but if the possibility of such an operation be denied，allow me to ask how it is that flowers raised from seed grown in the United States（the Sunflower and some or the Mallows for instance）grow to two or three times the size of plants raised from English seed in the same garden， even if that English seed has been raised from plants grown from American reed．For instance，the Sunflower grew 10 feet and the Mallow 15 fee high in my father＇s garden when raised from American seed；but when these robust plants ripened their seed， generation did not sowe main，than 5 feet high．If thi robust growth was not owing to a stimulas communi－ cated to the seed－to what was it owing ？This is a question I have asked two or three times in your although I think it a most important subject，and one that does not deserve to be pooh！poohed！For even supposing such a stimulus cannot be artificially com municated（which has yet to be proved）it shows the municated（which has ebting seed raised in the very great inportance of getting seed raised in the most suitable co mates hay be desirable to get our seed Wheat from America
I have heard of an Australian Turnip weighing 84 lbs．May it not be desirable to grow our Turnip seed in Australia ：If function reacts on organisation，is size，quality，and early maturity become hereditary，
who can tell whether by so doing we shall not have Turnips averaging 30 or 40 lbs ，a－piece through a field T．Go，Clitheroe．
The Harrest．－Observing your reports of the Wheat crops over 207 districts scattered over the Unite Kingdom，we are surprised that only in four counties， namely，Surrey，Kent，Denbigh in Wales，and by your ＂blighted，＂＂rather blighted，＂＂light in ear，＂\＆c． wheress in our own county，Essex，if our own report were worth a fig，we could not now（August 16）fairl described it in York，and as he has noted it in his No． 3 marginal references，namely，＂Quarter under average，Wheat looks like a full average crop，but when the ears are examined they are found to contain fewer grains by nearly one－third than they ought to have．＂
The fact is that blights are chiefly occasioned by sudden
atmospheric chanyes from a temperature of cold to heat， or from damp and lurid weather to sudden bright sun－ shine in the summer months This has been truly exemplified this last fortnight or three weeks，which has brought all the varions descriptions of corn here abouts，and seeds we cultivate，especinlly such crops as have been planted We adverted to this a fortnight back，and it is now fully substantiated by an abundance of straw，though no more than an average of 20 grains in each ear ot ver wany plots of＂rough chaffed＂Wheat will be realised，and not half the produce of one ordinary perfect ear from each grain of seed sown；in other words there will not be say 12 bushels of crop from every bushel of seed Whent practiod wo whe for the practised．We cannot forbear to mention that for the suddenly interrupted by thunderstorms and cold wind， which is blowing the fully ripened corn out sadly，so which is blowing the fully ripened corn out sady，so fear that those sudden changes of weather，so contrary in regard to heat and cold and wet and drought，
at this juncture of time will have a bad effect on the crops in the north of England，bringing their late crops on too prematurely，as such changes of weather now generally have a worse effect on late crops Our experience has proved to us that when such brigh weather has not occurred till September and October the crops have often been spoken of in far north as very satisfactory．It is presumptuous，however，to attemp to battle with the elements ；but it is no reason we should not do all we can devise in providing against the worst，leaving the rest submissively to the Almighty giver of all events．Hardy \＆e Scn，Seed Groverr，Maldon

## Exace：

Boydell＇s Steam Locomotive．－In your report of Mr． Boydell＇s machine it is correctly stated that the advan－ tage gained by the position of the pinion at the top of the driving wheel is not real．But the reason given，

 of the pinion and the driving wheel move with the same relocity velocity，and this without referlocity there of the positions of their axes．The velocity thererore of we the whel regulates that of the dher the pinion be the velocity of the machine，whether at any interme－ placed at the top，or at the side，or at any believe，as diate position．The true explanation is，I believi， follows ：－The power of traction of the machine is
measured by and is equal to the friction or bite on the ground of its driving wheels．This friction is pro duced by（and is equal to it for all practical purposes） the force excited by the pinion on the circumierence of the driving wheel，by means of a lever ；the radin of the wheel beingite arme，and the axis ite fulcrum．Now so long as the arms of the lever are equal，which，in the case of this wheel，is always the case，it does not matter whether they are in a straight line（as when the pinion acts on the top of the wheel），or whether they are bent（as when the pinion acts at any other point）－ The effect of the pinion at the top of the driving wheel would be the double leverage attributed to it， if the pinion were unconnected with the machine，but its xis being connected with it，pressures exist（e．g．，the ressure of the axis of the pinion on the frame of the nachine，which tends to retard it）which counteract this apparent gain．It is a dangerous thing to reason co sidered，all rule．G．P．S．—I snw this most extraordinary affie t work in the show ground at Chelmsford－that is， the engine was moving itself over a piece of dry and the conclusion I came to was that if steam plough－ ing has to depend for its success on this it never will succeed．Since then I have been led to look over the various notices of this engine which have appeared in the Gardeners＇Chronicle．In Number 16，p．267，there are some dimensions given；the cylinders are $6 \frac{1}{2}$ inches diameter $=33$ inches area，the length of stroke 10 inches， but the important olement，the number of strokes，nol given．The weight of the engine is stated by＂W．B．（any relation of Mr．Boydell＇s？）［No．］to be 9 tons．Mr．Boy－ dell in his letter at p． 524 does not give the power of the engine，neither does he deny the statement made by Mr． Mechi at p．290，that the engine is 16 H ． P ．，and that one－half the power is required to keep the engine moving！I believe that when the experiment is fairly tried the result will prove even worse than this．It never will pay to drag a ubeless weight miles an hour．There is no need for it，and the sooner Mr．Bor號 purse．Bu ply position of the pinion（whel gears into the driving wheels at the upper part of their circumference，on which Mr．Boydell insista wimk much con this mould be real after all．＂I should think not elee this would be ＂a new proposition in mechanics，＂as＂W．B．＂tries to prove at p．507，in a way which it is utterly impossible where you place the pinion which communicates motion from the crank－shaft to the driving wheel；and that ＂the upper part of the wheel moves twice tirough the same space as the axie and fulerum on the ground，＂ （p．524）is as great a mare＇s nest as I believe the wheels with the endless railway are．A point in the circum－ ference of the pinion，or in the circumference of the
the same speed as the axle of the carriace, or as the carriage itself travels alung the ground when the car riage wheel and the driving wheel are the same diameter. "W. B." gives the following dimensions of the wheels, $p$ 257: The carriage wheel, 6 feet diameter, or 18.85 feet circumference ; and the 26 -toothed wheel, 5 feet diameter or 1.5. 7 circumference; and therefore the pinion of 10 teeth must be 1.63 feet in circumference, and 1.6 :3 by 150 strokes by 60 minutes $=14,670$ feet per hour as the speed of the driving wheel, to which add one-fifth, and we have 17,604 feet, or $3 \frac{3}{3}$ miles as the speet of the circumference of the carriage wheels, or the speed of the
carriage. Of course the speed will vary in proportion to the number of strokes per minute. maschine he had better pocket the loss and try something less complicated and more likely to succeed. What advan-
tage have his endless railway wheels over common wheels of the same diameter and the same breadth except in complication? R. S. $\overline{\text {. }}$, Guteshead-on-Tyne, $A$ ug.
I think a few words will alter your Mr. Boydell:difference of the velocities of pinions working at the apex of the spur-wheel, or below it; I take the liberty of en deavouring to do.so. Whether the pinion is geared into from the axle ow the centre round which it, its distance same; but at the apex it gives the leverage as you describe it, and on a level with the axis it acts simsply as a bell-crank does, the legs of which are equal to each the boiler is the same, and likewise the velocities. On Wednesday last, in the presence of many scientific men a traction-engine at Woolwich with 2400 lbs . effective make that 2400 lbs . draw 4080 lbs . over a pulley inclination of 1 fot in 10 fep at inclination of 1 foot in 10 feet at that speed; the dead traction on this alone must be 4480 lbs. besides the traction on the level, which I calculate at least 2000 lbs that increased power is got ; and where wan prove that increased power is got; and where can it be driving-wheel by a pinion
Boydell, Canden Works.

## Cow Parsnip.—With

Heracleums as serviceable for or settling the point of may rest assured that cattle will not eat it freoly a whatever stage of its growth it may be cut, and why is designated Cow Parsnip baftles our understanding as well as his own. For ornsment, however, it is not grow both sorts. H. sphondillium, though indigenous able for cows climate, we repaat it, is very serviceshele for cows, pigs, and rabbits, if not for horses and sheep, with a small portion of corn or bran, and may we cut three times a year, and whether green in May, or at seeding time July, it may be used with safety and advantage; but neither of the two varieties ought to be allowed to ripen seed in the garden compartments, as mately become a may be watce alloisition. When boys, we can well remember that, searching for Heracleam sphondilium, or "cow-mumble" (for this is sides of vuigarly calsed, for pigs and rabbits by the spring destroyed scores of partridges' nests with their oggs, either intentionally or accidentaliy frightening their eggs. Cultivating this plant in the garden or waste would prevent all this, and the circumstance destroying those partridges and pheasants be prevented, Which is of more consequence to gentlemen sportsmen notice. Havdy d Son, Seedgroners, nevertheless worthy of We have also received the following:-Mr. Taylor of Wotton Parade, Gloucester, writes so touchingly about the Heracleum in this week's Paper that I cannot sefrain from attempting to offer him some comfort, though it be from a humble quarter. Our late revered father was an active energetic experimentalist; he tried vaious sorts of gigantic Heracleums from Siberia, broad-leaved and cut-leaved, and persevered for more
that 20 years in feeding sheep, cows, and horses upon it, mixed with other green meat. The sheep generally family objected to the cows eating where it grew. The family objected to the cows eating it on account of the apring became scabby or broke out in humours. It thus ell into disuse and it has been of late attempted to extirpate it from the pastures and aralle fields, but alas ! it defies all the efforts of the plough and spade, and overruns us more and more. It makes a noble ornament in must rob the trees of yet its large strong deep roots there an enemy. A Novice.-I have had, as I expected, many applications for seed of this plant; which, so far as I have been able, I have had great pleasure in supplythis ; but I regret to say that I have been unable to do reasons, which I hope will plead my apology with my various correspondents. I was out on a tour when their them on my return to Gloucester time in attending to I found the seed much forwarder than I expected ; and what I did not expect, a great deal of it eaten and carried away by birds-a satisfactory answer to the theory of Mescrs. Hardy as to the poisonous nature of the plant! Of coarse they are too good judges, either
sound seed, The rogues had, therefore, not only po loined much of my good seed, hut left mot only purthan bad, or at most doubtful. However, I have done the hest I could. Still, of the small quantities sent should the proportions germinating be smaller still, I trust the explanailon 1 have given will exonerate me
from anything like wilful neglect. Samuel Taylor

## ク/e $P$, Aught 6.

The Pof cto Discase, has made its appearance with us o a greater extent than last year. The crup is going lighted, symptoms are as usual. Wheat is also a little ichle; and we shall have harvest earlier than we thought by a week or 10 days. Ahout the middle of next week most people will begin hereabout. Barley and Turnips do better, though we have not had rain enough to moisten the earth; but not far off there have ,een some heavy thunderstorms. Mangel does well where thick enough, but it is of ten too thin. What can in before the ground gets warm, and so dies of cold ! Or is it not all ripened sufficiently, and some comes up quickly, while the weakly ones take half the summer to ring them up ? I rather incline to think this last is bown away in preparing the seed for markht to be West Su: sex.
Three Years Crops.- Perhaps the underneath statistics of the crops on my farm may be interesting to some of your readers.

Cercular Tillage.-Without prejudice to any one went now Chelmasford to see the steam ploughing, and am fuite satisfied inventors think there are no conditions whereas it is a problem to be complied with, sa social they, mechanical, and agricultural. The only condition hall study is this, namely, that the power of steam tillage, without change armern. I method of surprised at this mistake on the part of the engineer and mechanist when they have a precedent in point so recent as the introduction of steam to an improved method of travelling. For ten years I have made this problem of steam-tillage my especial study, and for nearly that period of time have been linocking at the ack door of British agriculture ; often wondering when I shall be asked round to the front by those who happen to have the means of paying for admission:-this can dy have arisen from my not uttering all I know, and confess (out of regard to others' sentiments) I have concealed some startling facts which have come to my since I know the igure of this investigation. However fields will be profitable to the farmer and highly beneficial to the labourer and the country at large, and also to the agricultural mechanist in the long run, and its unexpected reaults before the read Agricultural Gazette, leaving them Aerdict thereon. The first unexpected anonouncement "mave to make is, that steam cultivation is not a mechanical "problem after all; it is a "manual" one ! This assertion will appear most paradoxical to some, yet such is the fact, and steam cultivation will prove itself a paradox-the real modera paradox. Ten years ago, being cast amongst farming in Norfolk, and the in inventive turn, I was particularly attracted with the idea of tilling land by steam power, and was more especially moved by reading some spirit-stirring appeals modestly signed "C W H" the "H" I bumbers of then my task con amore. "This is a mechanical problem of a high order," I said, "and doubtless will require much So I So I got out my saw, planes, chisels, hammer and nails all ready for action; but with these I also pulled out Lord Bacon's Novum Organon Scientiarum, or "Art of conducting a Research and inquiring into the causes of things, and eliciting the Truth in either matters of Practice, or matters of Experiment, \&c.". I first read then proceeded to investionte this problem of steam cultivation. As in duty bound, I first inquired what the mechanist had done for farming ; and 1 found that, as compared with the days of no machinery, he had done wonders in the homestead ; corn could be threshed out in immense quantity and in a very short time, and infinitely cheaper than before the use of mechanism Straw could be cut into chaff and steamed, cake and ands bruised as food for animals; Beans, Peas, Wheat and Barey ground in vast quantity ; in fact, the power wer increased production was only limited by the executed at a much cheaper rate than before. "All
righthere,"I sam. "The usual characterisuce nt the righ employment of mechanism are evidenced-this is per fectly correct in principle. I will now exa ine the their efforts to introducen they are unceasing in have already got a great machinery into the field coming; hence, judging from anal fom analogy under which of course they are acting I shal see the same result, the same nower I shal creased production. I shall see at least 100 tons of 'Turnips 'manufactured' on an acre of land, where without machinery there were formerly of land, where tons; and 50 coomhs of Wheat manufactured on land where there were only 10 coombs made before on land where there were only 10 coombs made before, and all
will be done at a less cost." When I got into the field will be done at a less cost." When I got into the field I
found I was quite mistaken. Somelow or other the productive and economical power of machinery seeme brought to a dead stop; and its shortcoming had to be argely assisted by expensive stimulants or manures, to arrived at when executed without mechanism or it had at all! ! when executed without mechanism or manure at all In fact I could not discover any of the usual results of the right employment of machinery. "What is the cause of this ?" I asked. "This is "tillage," was the answer. "What is tillage?" I again asked. "It is the means employed to obtain a fruitful plant." "What is practice is a "life manufacture, not a "dead" material manufacture, and tillage, is only one of the material manufacture, and tillage is only one of the
means which lead to it." Then I saw why the field does not afford scope for a high degree of "mechanic evelopment, it is a field for "man development." Why sleam cultivation cannot be rencered into a "mechanical" problem (in chief)-it is evidently a "manual" problem (in chief). What they want here in this department is a rabour assisting, not a labour saving or labour superseding machinery. Our agricultural philosophers are evidently striving to put the wrong "element" in the wrong place. Their conclusions and heir practice are based on a false analogy; they act and argue upon a resemblance which does not exist; here is one comparing 'the growing of a sack of corn to the But this is evidently not a question of how to lat but how to make a cotton plant; not how to make the sails and ropes of a ship, but how to make a Flax plant; not how to
make the silken garment, but how to make the Mulberry tree; not how to grind or thresh com, but how to make a Wheat plant; in fact, not of how to manufacture dead material, but of how to make things of life. Thinking only of the means the mechaniat disregards the eud of tillage, making no provision for , hence the contrivances in the field lead to no result mared with his effective and cheapening processes in homeatead. I see the reason. Never having had to eal with anything but the manufacture of dead objects nalogy, steam-driven machinery, impelled by alse same laws and rules. There are three elements necessary for the field, to lead to increased and chenp production, viz. : Steam, men, and mechanism. Our production, viz: Steam, men, and mechanism. Our
mechanists neither know how to combine these agenti, mechanists neither know how to combine these agent,
nor which of the three to advance to the front rank, soas nor which of the three to advance to the front rank, soas
to lead to cheap and successiul steam cultivation. $C$. Burcham, Londor.

ROYAL AGRICULTURAL OF ENGLAND.
Adjourned Trial of Reaping Machines, at Boxted Lodge, Aug. 13 and 14,1856.-The judges awarded to Mr. Alfred Crosskill the sum of $20 l$. for his "Improvel Bell's
Reaping Machine." To Messrs. Burgess and Key the Reaping Machine." To Messrs. Burgess and Key the
sum of $15 l$, for their "Smproved M'Cormick's Reaping sum of $15 l$., for their "Improved M'Cormick's Reaping
Machine." To Mr. Wm. Dray the sum of J $5 l_{\text {o, for his }}$ "Improved Hussey's Reaper." From the result of these trials, the judges regret to observe that very little improvement has been made in this class of muchines since last year. They consider that for general harvest purposes, the machines of Mr. Crosskill and Messrs. Burgess and Key are to be preferred; but for reaping only, they think Mr. Dray's decidedly the best machine.
H. B. Caldwall.

Boxted Lodge, August 14, 1856.
Royal Agricultural Improvement Society of Irs and.-At the annual meeting last week of this society the Lord Lieuteuant made the following remarks:"Within the last 20 years more than a million of Irish acres hare been reclaimed from the waste. In 1811, to 8 millions of
people there were 13 millins of cmitivated acres in Ireland. Now.
perhaps more than a million has been subtracted from the popl-

The following is the award of prizes by the society's judges of stock:-
Short-horiss.-Sec. 1: 1st, Mr. Henry Ambler's bull Grand
Turk; 2d, Lord Clancarty's Pro Bono Publico Turk; 2d, Lord Clancarty's Pro Bono Publico. Sec. 2: 1st, Mr. 1st, Mr. M. Ambler's yearling bull General Jackson; $2 d$, the
Ho. L. I. King, Harman's Lord Ragan. Sec. \& 1st, Mr. Rowland Campion's cow Lady-like; 2d, Lord Monck's Lady
Colingwood. Sect. 5: 18t, Mr. Campion's helfer Jenny ren ceiving for the second time the Purcell Challenge Cup; 2d, the
Hon. I. .I. King Harman's Merino. Sec. 6: 1st and 2d, Mr.
J. J. Turner's white heifer Lily Grey and roan heifer Ace of
Hearts. Sec. 7: 1st, Mr. Campion's Rosalie; 2d, Mr. Ambler's Lady Mary.
OtaEr Breeds.-Best Devon bult, Earl of Chartemont's Lord
Devon. Best polled Angus or Galloway bull, 'Lord Largan's Devon. Best polled Angus or Galloway bull, 'Lord Lurgan's Best Kerry bull, the Larl of Charlemont's Black Knight. Best the Earl of Challemont's Young Ruby. Best polled Angus or
Galloway cow, Mr. Fi. Atkinsou's Indian Qurech. Mest polled
Angus or Gallowar heiter, Lord Tylbot de Mainide's Angus or Gallowar heifer, Lord Talbot de Maiahide's Maid of
Angus. Best lot of two polled Angus or Galloway heifers, Lord Talbot de Malahide's Duchess and Fanny. Best Ayrshire cow,
the Earl of Clancarty's Scotchl. Best Arshire heifer, Mr. W. Boyle's Fanny. Best lot of two Ayrshire heifers, Mr. Allan
Pollock, of Fairfield, Creggs. Best Highland cow, Allan Pollock, of Frenchar Rest of ter West Hichlat heien Allau Pollock. Best Kerry cow, Lesd Taibot de Mallahid.
Best Kerry heifer, the Earl of Clancartr. Best of all bulls, the Gold Medal, Mr. H. Ambler's Grand Turk. To the breeder the best prize bull, the Gold Medal, J. E. Bolden, Esq., Spring
field Hall, Lancastar. Best of all the prize cows or heifer exlibited at the slow, Rowland Campion, Esq. To the breeder
of the best prize cow or heifer, the medal, J. H. Cameron, Esq. of the best prize cow or heifer, the medal, J. H. Cameron, Esq., Horses.- Best old stallior: : 1 st, Mr. Archbold Molloy's
Clydesdale stallion Diamond; $2 \mathrm{~d}, \mathrm{Mr}$. Sylvester Rait's Glancer Best young, stallion: 1st, Mr. Allau Pollock's Redmond; 2 d ,
Miss Morris's Blue Ball. Best draught mare in foal ; 1st, Mr. Rait's Bay-bill ; 2d, Mr. W. S. Featherstonhaugh's Clydesdale eray cart mare. Best 2-year old draught filly, A. Pollock, Esq Ballinasloe. Rest yeariirg draught filly, Mr. A. Chalmers,
Dalkey. Best draught filly: 1st, Sylvester Rait, Esq. $2 \mathrm{Ad}, \mathbf{M r}$. A. Chalm LLicesprfs.-Best slearling ram: 1st, Mr. Rntland Campion; 2d, Mr. Reybell. Best two shear rann, ist and 2d, Mr.
R. Campion. Beat old ram. $18 t$, Mr. Carter, Yorkshire; $2 \mathrm{~d}, \mathrm{Mr}$.
Owens, Blessington. Best pen of five shearlung ewes: Clonbrock; 2d, Mr. R.. Canhpion, Best pen of ewes : nnder fiv years old, Mr. Owen. Best pen of pen ewe lambs, Mr. J.
Latouche, of Harristown. Oteer Losg-Woolled Sheep.-Best shearling tam : 1bt, Mr.
N. W. Roche, of Eernoy; 2d, Mr, B. Browne. Best two shear N. Wh, Mr. N. W. Roche. Best old Mam, Mr. N. W. Roche. Best
pen of five shearling ewes: 1st, Mr. T. Browne; 2d. Hon. L. H. pen of Give shearling ewes: 1st, Mr. T. Browne; 2d, Hon. L. H.
King ITarman. Mest pen of five old ewes: 1st, Mr. Ambiose
Bole; 2d, Mr. David Kerr, Edenderry. Best pen of fire ewe lambe, Mr. Ambrose Bole.
Cheviots. - Best old ram, 1st and 2d, Marquis of Conyngham. Best pen of five shearling ewen, 1 st and 2d, Marquis of Conyng-
ham. Best pen of five old ewes, 1st and 2d, Marquis of Conyng-
Sourndowy-Best shearling ram, Mr. T. Roberts, Strokestown. Best id ram, Mr. T. Roberts. Best pen of five shearling
ewes, Mr. T. Morris. Rest pen of old ewes, Mr. T. Morris. Other Short-W onlled SmpFr. - Best old ram. Mr. Lambert,
Slane. Bhest pen of tive shearling ewes, Mr. J. Kearvey. Best pen of old ewes, Mr. E. Atkinson, jun., Malahide. Best ram in
classes, the medal, R, wland Canopion, E.q. Swise - Best buar under 18 months old : 1 st, Lord Castle-
maine; $2 \mathrm{~d}, \mathrm{Mr}$. A. D. Chaigneau's (Athlone). Best old boar: breedmg sow under 15 months: 1st, Rev. Mr Wathone). Bes Kildare; 2 d, Sir K . Paul, Wateriord. Best old breeding sow:
1st, 1I. Carvil, E-q. Ballymore ; 2d, Lord Cast 1st, II. Carrell, E- (f, Ballymore; 2d, Lord Castlemaine.
ExTRA Premecais fur best breeding bows, Mr. Matthias Hart-
ford, of Moate.

## Hiviéms.

## The Journal of the Royal Agricultural Society of England.

 Vol. XVII. Part IThe current number of this periodical is written almust wholly by men of science. We have essays on Vegetable Physiology, on the Natural History of Pasture Grasses, on the Roots of the Wheat plant, on the Com-
position of Farin-yard Manure, and ou the Cunyosition
of Drainage Water by such men as It nfrey, Buekman, Voelcerer, Way. In addition to these liebig comtributes a vigorous rejoinder to the controversy between
himself and Lawes, Mr. Denison publishes his report on the agricultural department of the Paris Exhibition, Dr. Bell describes Durham farning, and Mr. Horsfall A gives us in detail his experience on dairy management A distinctive feature of the present issue of the journa appendipearance of a number of shorter papers as an Parrington, and Moore contribute
The whole volume contains a great deal that is clear addition to our hnowledge, much that is descriptive of existing knowledge, besides sone that tends to upset it maintains the high character as an agricultural periodical which bas hitherto belonged to the series.
periodical which bas hitberto belonged to the series.
We must be satisfied at preseut with this descripti notice of its contents, leaving to future numbers of the Paper the task of discussing some of the essays it contains.

## Miscellaneous.

The Mixing of Ealt vith Liquid Manure.-In a former Number of the Journal we directed attention to an satisfactorily that common salt was a fiser proved mos We have also more than once alluded to the important place it is yet likely to nccupy among the saline substances used by the farmer. In Switzerlund it is now almost the universal practice to mix it with liquid manure. It value here is supposed to be derived from its propert which ing ammonia ; and the discoly quite accidental, and deserves to be mentioned in this place. The important duty on salt in Switzerland is very high and oppressive-so much so, as in all such cases to lead to many attempts of evading the vigilance of the custom-house officers. A peasant having tried to
defraud the authorities by carrying off a bag of salt, was defraud the authorities by carrying off a bag of salt, was punishment which would be inflicted on him if the bag Were discovered about his premises, he threw it into his liquid manure tank, where he was sure there would be covering it. Thinking he had destroyed his liquid manure before using it he diluted it with water, 50 as to diminisha a much as possible the bad effects which he thought would be derived from the salt. Grear, however, was his surprise, when he found that the Grass on that part of the meadow watered with the liquid manure in which the salt was dissolved, was both mure luxuriant in its growth, and was preferred by the cattle to all other forage. On perceiving this, the experiment was repeated with the same result. Government, aloo, having become aware of it, allows unpurified salt to the refuse of the salt works, containing from 75 to 30 per cent. of salt. About $1 \frac{1}{10} \mathrm{lb}$. of salt is used for every $\because 2$ gallons of liquid manure; in gravelly dry soils a larger proportion of salt is employed, and in soils naturally damp a smaller proportion. In soils liable to suffer from drought on dry hill sides, salt is employed, after being first mixed with earth. Its effects are most apparent on Peas and leguminous plants of every kind, on roots, Potatoes Carrots, and Ruta-bagas. It has little effect on clay
soils, excepting when drained. In some districts it is soils, excepling when drained. in some districis it is used for improving the quality of the dung. The salt is first mixed with earth, and this mixture is spread on every layer of dung. These derails on the use of sait, communicated by M. Fellenberg, are worthy of a care fui consideration from farmers of all counmes. We do not say that the application of salt directly to soils in this country will be always attended with as Leneficial results as in switzerland; but we cannot help expressing our opinion, that the value of salt as an ingredient in a compost heap is not sufficiently appreciated in this country. And the practice, alluded to by M. Fellenberg, the mixing salt with earth, and then working this up with experience of the farm, agrees 80 well with our own Professor Anderso. 2 in the Joumal of Ayriculture.

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACHINES,

sole manufacturer, iron and wire worhs, norti street, leeds. =

## REGISTERED JULY 24, 1855.-No. 3739.

THE ADVANTAGES OF THESE MACHINES supergede all others by having a small Wheel in front of the Grass Box, consequently will mow verges and round flower beds, without any change of Wheels, or addmg the old fashinned linller, as in others; will also cut either
wet or dry, and by the simple adjustment of a thumb screw, in front, can be raised or lowered to cut the Grass any length required; and having two Rollers behiud, and a small one in front, they roll the width they citt; they will turn in very little room, and cut at the same time. All the working parts made much strunger than the old machines. The bottom Blades are so constructed that they cannot tear up the ground; they are only drawn, and not pushed and drawn as in other machines,
consequently do not require half the power to work them. The three first sizes can be worked by

THE ELEMENTS OF BOTANY, Structural and numerous Illustrations. 12s, cloth. by Professor LINDLEY, of which "School Botany," and "The Vegetable Kingdoms", form the othor parts.
The first two Parts of
The first two Parts of The Eleyents of Botany, comprising Struectural and Physiological Botany, and a Glossary of T
nical Terms, are published in one octavo volume, price 12s. These three parts form a complete mananal of Botany for
Medical and other Students who have made themselves cequainted with the anthor's "School Botany.

- Bradbury \& Efans, 11, Bouverie Street.

This day is published, in one vol. 8vo, with numerous woodcuts, M EDICAL AND GECONOMICAL BOTANY; or Domestic Ceconomy.
"The Vegetable Kingdom contains, among a large quantity of
plants of no known importance to man, virinus nseful species plants of no known importance to man, virimes nsetur spceie
 earliest subjects of study, , are mentioned in the following pages,
where they are arranged in the manner proposed in the 'VEGETable Kivedon' of the anthor, with the sequence of matte convenience of younger students would be consulted by doing so.
The author trusts that this selection will be found to have been made in such a way that all teachers who possess reasonably extensive means of illustrating their lectures, ancl all Botanic mentioned. A small selection was indispensable; firstly, becanse e greater work would have been beyond the reachi of the majority
of purchasers; and secondly, because experience slows us that those who have to study a science of observation, such as Botany require to concentrate their
a limited number of objects.

## The ©ardentrs＂Chromicle．

STURDAY，AUGUST 30， 1856.

The reappearance of the Potato disease，and the storms which have here and there accompanied it have revived the old speculation that this affection is caused hy the action of electricity．We see the question raised in the country newspapers，and our own correvpondents are engaging in the discussion．
It is uged that the disease continually breaks out after thunderstorms，as was confidently asserted in Ireland in numerons places in the year 1845，when fi hermen reported that they had seen from the sea lightming plaving over healthy Potato fields which immediately became rotten．Of this a very extra－ ordinary instance was pointed out in the parish of Skerries，near Dublin．Without going back to those days we are assured that similar instances have just occurred．A correspondent mentions the following cases as having come within his own knowledge：－

A severe storm occurred at B－＿，during which the exchange of electricity between the earth
and the s＇orm－cloud was seen by more，than one and the s $^{\text {torm－cloud was }}$ seen by more，than one
observer．From that time the early Potatoes become diseased，and on the Saturday week after the storm were half rotten．An electrical discharge was seen to take place from a cloud into a field on Thursday， August 7．Prior to that time no trace of disease appeared；now there can hardly be found a root
withont one or two stems nearly rotten，and the
damage done was rlearly visible on the Saturday morning after the storm．Enquiry of those who get their living by buying crops of Potatoes on the land and selling them again，and whose experience is of course the largest in this case，shows that frequently a corner of a field is taken；sometimes a strip along a hedge side；sometimes a belt across the middle，and commonly a limit to the malady may be＂traced in some one or more fields in the district in which it prevails．An old man，a market gardener，was going with his cart to Bradford market from Wakefield four years ago in the month of July．It was very close and hot．At a particular pot on the road it became＇suddenly as cold as Christmas，fit to take the face off you．＇This lasted for about 50 yards，when＇all on a sudden it was as hot as going into a stove．＇That night the Potatoes became diseased which had previously been per－ fectly healthy，and this poor man was rumed by the loss．He now works as a labourer in the public streets．I think，＂adds our correspondent，＂that in all these（probably in all other）cases electricity is the cause，the sole cause of the evil，and that fungi，\＆c．，are but results which mostly accompany the decay of nitrogenised regetable matter．The stem of the plant forms the medium through which electric discharge takes place：the obstruction to the passage of the electricity developes heat which converts the fluids of the stalk into steam， thus rupturing the cells and giving rise to decay． The circulation of sap，altered in its chemical con－ dition by passing through the disrupted part，causes the decay of the tubers．It is also probable that a chemical decomposition of the fluids in the plant takes place by the electricity in its passage，and that part of the effects known as Potato disease are due to this．＂
But it is to be remembered that the Potato disease breaks out in the absence of thunderstorms；as， for instance，in the spring，when Potatoes are forced for an early crop．Nor can we admit it ever to be so sudden in its appearance as is alleged．On the contrary，it is invariably preceded，for some days or even weeks，by the well known brown dis－ colouration of the stem near the old set，a symptom which，being underground，is not observed．More－ over it is necessary for the advocates of electrical agency to show why that agency failed to manifest itself before the year 1845 in Great Britain．These are facts for which theory must account satisfac－ torily before we can give our assent to the electrical notion．We forbear to remark upon our corre－ spondent＇s hypothesis that the fluids of the stem are converted intosteam（！），which ruptures the tissues and thus causes decay；nor is the sapposition con－ sistent with facts of another kind．The Potato disease is first manifested on the skin of the stem next the old set．Sume time afterwards blotches，accom－ panied by the mildew plant（Botrytis），appear on the leaves at or near the edjes．Afterwards the decay spreads，connecting the base of the stem with the leaves and invading the lateral tubers This is the invariable course of the disease as far we have observed it，even when it has spread with the greatest rapidity，and in some instances a few hours have sufficed to complete the operation．
We wholly coneur with our experienced friend Mr．Berkeley in regarding the phænomenon as due to the action of the microscopic spawn（mycelium）of the Botrytis，which after a time sets up a putrid fermentation of the juices of the Potato．All facts at present known to us are consistent with this view ；which nevertheless is not without its diffi－ culties．Why，it must be asked，did not the Botrytis attack the Potato before 1845，in these islands？Or if its attacks were in reality mach earlier，as is probable，how was it that they became so virulent from 1845？To that we have no answer to give．The same question is also applicable to the Vine mildew，and remains equally without reply
It is probable that the spread of these pests may be owing to a greater alundance than usual of nitrogenous matter in the tissues of the Potato and that direction and we know that nitrogenous matter is most especially the nutriment of fungi．If that be so the sudden application of nitrates formed in thunderstorms，dissolved in the rain that accom panies them，and rapidly absorbed by the roots of the Potato，may give such an impe＇us to the de velopment of fungi as will account fir their sudden excessive manifestation in connection with electrical discharges in the atmosphere．Nor would this be inconsistent with the presence of disease in forcing houses，although thunderstorms do not occar there because in such places carbonate of ammonia which is always in excess，may furnish the nitrogen required．This is a very different，and，we ventare to think，more plausible interpretation of the sup－ posed connection between lightning and Botrytis，
that what is ginerally offered. But even if true it by no means exhausts the question; for it still fails to explain why nitro

Mr. John Shaw, of 40, Princes Street, Manchester, has sent ns a sample of a shading matbrial which promises to supply a real want in gardening. The fabrics at present in use for that purpose are either too opaque or too perishable, or too heavy, or too costly, or they have, like Frigi Domo, the great fault of shrinking excessively. That before us seems to be free from such objections. When drawn over a glass roof the effect is that of a white cloud reflected on the glass; it does little more than diffuse light without obstructing it. Of its durability we cannot judge, but some trials we have made with it in wet windy weather are satisfactory as regards its strength. Nothing can well be less heavy, even when soaked with rain, for the threads are too far apart to allow water to be detained among them Its price is $5 s$. for a piece 20 yards long by 38 inches wide; 3d. a yard for such a width is as little as any good material can cost. Finally, as to shrinking, we do not at present see that it possesses that bad quality in any appreciable degree.

Time is, of course, the only test of the true value of articles like this "Tiffany," for so it is called ; and that test we have not been able to apply. We know however, that it is in use at Trentham, where Mr. Fleming finds it extremely useful. In a note before as he says:-"The new material for shadin answers perfectly. It is stout and yet open enough to admit sufficient light to plants in flower, under its genial shade. Pine Apples are much benefited by being shaded by it during bright sunshine, and so are Melons and Cucumbers." He proposes to fix it permanently during summer over the Camellia house at Trentham, in order to preserve the healthy green foliage from being browned by the sun. He is also of opinion that the fruit, and to protect wall trees from frost in spring.
We advise a trial to be made of it at once, as a
nard against the swarms of wasps which the late guard against the swarms of wasps
dog-days so abundantly engendered.

IT is said that Wellingtonia, the noblest of Coniferous plants, is afflicted with an alarming disease. Our correspondents describe the disease in various ways; but chiefly as a dying away of the limbs without any assignable cause. To a small extent this seems to be constitutional ; and so far it resembles what is so common in Cryptomeria Juniperas squamosa, and a few other plants of the same group among Conifers, and may be regarded as unimportant. But in some cases the mischief goes farther, the whole top turning brown and perishing Is that really a disease? Or is it not rather the consequence of some management which the plants dislike? We incline to the latter opinion

If Wellingtonia, while very young, is planted out of doors in burnt clay and fragments of charred roots or leaves, it grows with great rapidity, presents the appearance of robust health, and becomes in a few months the sturdy bush described at p. 534 by a correspondent at Acton. No cold touches it. No wet affects it; for the place in which it has grown ever since its infancy is as wet and cold as could be found in the county of Middlesex. We ascribe this vigorous health in some measure to the soil which perfectly agrees with it, but more especially to the perfect freedom of its roots. On the other hand, all the unhealthy specimens we have seen o heard of had been nursed under shelter, and cramped in little flower-pots. The effect has been to pro duce a weakly growth at a season when the plant should have been at rest and the production of wood and leaves in places where they are imperfectly exposed to that action of sun, wind, and air which is indispensable to all plants, but most especially to Conifers. Moreover the roots crowded and twisted within the narrow space of a flower-pot were quite incapable of obtaining such a supply of food as was demanded for their own organisation, as well as for the nutriment of the branches. The inevitable result would be the death of something. In a specimen sent us by Mr. Rivers both top and bottom were perishing equally
Should this reasoning be correct the remedy will be obvious. The plants should be fully exposed to the weather in all seasons, and never be cramped in pots. It would seem as if the treatment of Sprace and Larch was that which they would prefer. If for a plant of so much value that rough management is thought objectionable, then we would suggest the basket potting so successfully employed where the situation a plant is to occupy finally cannot be decided. This basket potting, which is far too little known, is managed as follows:-A seedling is
planted in a small coarse wicker basket plunged in
the ground. After a time its roots find their way the ground. After a time its roots find their way
through the sides of the basket into the surrounding earth. The basket is then carefully lifted and placed in a similar plunged basket of much larger dimensions, the first being left to rot. In time its roots find their way to the open sides of the second basket, when the shifting must be repeated; and this must be continued till the station of the specimen is finally determined upon, when it is planted along with the basket or baskets into which it may have been transferred from time to time.

In this way "corkscrewing," as the spiral direction of the roots is called, becomes impossible; whereas in a garden pot it is as impossible to prevent it. he roots of a Conifer once become corkscrewed

nothing will afterwards overcome the spiral tendency; and atthough the plant may not actually all over or be blown out of the gromnd, it acquires ncurable debility, as may be seen anywhere in the case of Cedars of Lebanon and others which have been long kept in pots for the convenience of transplantation; and of the condition of whose roots the annexed cut is no exaggeration.

## IVew Plants.

## 182. Biota Meldensis

This new Arbor vite is named from having been raised at Meaux, by a Mr. Quetier of that city, so famous for its Roses. It is said to be a hybrid between the common Arbor vitæ and a Red Cedar. It has, however, the cone of a Thuja. Its pyramidal habit makes peculiar interest as being the only hybrid yet known among evergreen trees. Monitcur des Com. There is a Thuja pendula with a weeping habit and long flagelliform branches which is aiko supposed to be a hybrid, as is hybrid Oak between Qu. pedunculata and Ilex ; and donbtless other cases could be named

## GLASS-HOUSES FOR GARDENING

 PURPOSESYove remarks upon the triumphs of good cultivation in make-shift houses have induced me to offer a few observations upon garden structures in general. In no department of gardening have more errors been committed or more expense contracted than in this, and no other has furnished so many sources of vexation to gardeners or disappointment to their employers. believe one chief reason of this arises from the fact that houses are frequently erected without any very definite idea of the purpose they are intended to serve Almost every country tradesman, be he carpenter bricklayer, plumber, or ironmonger-for all these, and and dabble in such matters-feels himse quained to give estimates for and erect such buildgrowers or learned lawyers, are generally prepared to give their opinion on the subject; and ranges without those who are to use them having been consulted about the matter at all. Hence, expensive houses are frequently built without any proper means of heating or ventilating, their facilities for successful cultivation being in an inverse ratio to their cost. I have seen many instances of this description, and in the arrangements for heating alone have observed as much ot-water pipe used in an Orangery as would suffice for Orchid house; whereas in a plant stove I have seen he pipes for heating the atmosphere so buried up as if atmospleric heat, to weep the foundations of the build-
ing comfortable instead of economically securing genial temperature by placing every inch of the warning apparatus in the best possible position for conducting
and radiating heat. But I will not multiply instune and radiating heat. But I will not multiply instances, as such anomalies are common to most gardeners, unleas indeed it be those whose plant houses have all bee erected and heated by some of the large London provincial firms, who generally execute their work to their own credit and the satisfaction of all parties concerned.
While I perfectly agree with you that very much may be accomplished, and is, by most good gardeners with very unpromising materials, I am still of opinion that all glass structures for gardening purpose should be distinguished by strength, durability, effi with , and beauty, and hat all this is compatible with a due regard to enlightened economy. They should be strong to give that security and safety to our protegeses which their fragility and our sympathy and love for them so imperatively demand ; also tha we may be able to visit them at all times, to adnire their beauty, and miaister to their wants without any fear for our personal safety. This can hardly be the case with the makeshift houses so graphically described at p. 34\& They should also be strong, to protect them from accident. About three years ago I was awoke one morning by a terrific hurricane and the crash of breaking glass; three minutes sufficed for dressing and calling up my young men, and I sallied forth to examine the range of houses. I shali never forget the scene. The lights of dancing solka house and a cold pit hard by were dancigg a polka together, to the rough wild music of lofty greenhonse that swayed about with the wind and threatened every moment to add its light half rotten amidst the serious havoc and deafening uproar of the storm, a vow that I will legibly imprint upon every glass house that I design, or cause to be erected--that they shall all be strong. But glass houses should also be durable, and this implies that they should be constructed of the best materials. Also that these materials should be 8 formed and placed as to be kept as dry as possible. have frequently seen the finest beams of Deal forming throush by having a level top or a alioht inclination bwag by having levelin a hit inclinatio inwaros. sometimes even mouldings are fixed on above water. Such beams ought invariably to bese of retaining the centre to the sides, so that a drop of water cannot lodge upon them. Attention to such matters, securing good workmanship in the glazing, and giving them a coat of paint just when, and not a year or two after, they require it, will enable good materials to withstand the severe tests to which they are exposed for years. Iron, though more durable than wood, cannot be recommended for general purposes. Its use involves the quantity of such frequent ioside painting, and he und cof glass destroyed by its powesful expmer than counterbalance the advantages it possesses on the score of durability. Above all glass houses must be efficient, that is, they must answer the purpose for which they were desinned. The roofs should be impervious to moisture, and thongh strong not heavy to obstruct the free ingress of light. Ventilation should be abundant, skilfully arranged to avoid draughts, simple, easily and speedily regulated; a copious supply of water at the temperature of the house should be provided, and atmospheric moisture easily at command. The heating apparatus must be sufficiently strong, clean, and under perfect control ; and, in fine, the whole arrangements made with the view of producing the largest quantity of perfect fruit or flowers the shortest period of time, at the least cost, in the mallest space. With such houses a common man may ucceed, while a good gardener is sure to excel.
Garden structures ought also to be ornamental. It is bad policy to keep them ont of sight, and in most places it is simply impossible. Ladies and gentlemen in the present day are not satisfied with results. They mast see the entire process by which such results are obtained. Hence, for one lady or gentleman now who is satishied with seeing their gardens in their house or on thein table, hundreds are almost daily visiting every part them, from the imposing highly finished conservator, that has become a necessary appendage to the drawnid room, to the rade contrivances that are run up to bedding plants from the withering breath of a in March, or the pelting hailstorm of laughing Apru. many establishments, too, the entire range of glass becomes a promenade for the family in cold or wet weather. By such means the taste for gardening pursuits is doubtless strengthened and extended. The gardener who by erecting ugly houses or keeping them untidy would check this taste is blind to fostering it as mas profesion. I? woud structures and their ccupants still more beantiful. Much may done by beauty of design-more perhaps by sit arrangement-and a good deal by destroying the some monotony of our roofs, and indeed the whole inside of our houses by introducing chaste and pleasing colours of paint. The charm of good culture and cleanliness isupe to he always present. But it wim leannes 1 suppose to be with economy I think Strength and durability constitute the very keyton surength or or half a century ; compare the expense of the balance will be in favour of the latter. There are many ex-
ceptional cases, but as a general rule it holds good in this, as in all other matters-that what is worth doing at all is worth doing well. Besides well-built houses are
generally more efficient. Great masters of our or generally more efficient. Great masters of our or
indeed of any other art are comparatively rare, and it requires such to achieve triumphs over great difficulties. Much beauty too may be secured at but little additional cost, and I know of no department of art in which more can be obtsined for a less sum than in garden architecture. However, I freely admit that if garden buildings are to be richly adorned, a strict economy cannot be adhered to, for I agree with you, in one of your articles upon the Horticultural Society's garcen at Chiswick, that ornamental gargardening is a high style of art ; and who can say that gardening is a high style of art; and who can say that
its practice involves more expense than the pursuit of its practice involves more expense than the pursuit of
sculpture or of painting, or that the pleasures it confers sculpture or of painting, or that the pleasures it confers? D. T. Fish, Hardwick Gardens, Bury St. Edmunds.

## GHUZNI VINEYARDS.

The perusal of a leading article in your issue of the 2 d inst., in which you advert to a Transatlantic publication on the growth of the Vine, induces me to trouble you with a suggestion gathered from my Eastern experience, and which I think it probable may prove useful to the cultivators of the Vine in the United States, and more especially to those resident in Canada.
I served for four years, 1839 to 1842 inclusive, in
SECTION OF A GHUZNI VINEYARD.

## B. General level of the ground. C. Earth excavated from D.

table land, the highest portions of which, having an altitude of 6000 to 8000 feet above the sea, are around Ghuzni and Cabool ; from thence the plateau slopes gently towards the south-west, until at Candahar the barometer indicates an elevation of about 4000 feet only above the sea level. The climate of the northern districts appears to me greatly to resemble that of Canada. The air is pure and exceedingly dry; the
summer short but intensely hot; whilst the winter is long and extremely severe. I have seen the thermometer stand at $112^{\circ}$ Fahr. in my tent on the banks of the Helmurd in August, and in the following winter witnessed the quicksilver fall to $14^{\circ}$ below zero in the citadel of Ghuzni. Yet Affghanistan is celebrated for its vineyards; indeed, Grapes may be called the staple production of the country, and although many of the species are valuable only for their abundant bearing,
others, especially the small golden Bedana (seedless) others, especially the small golden Bèdana (seedless)
possess a richness of flavour that would render them pasourites even in England. The system of cultivation pursued, and under which alone in such a climate and with limited means the husbandman could hope to see his Vines ripen both fruit and wood, is briefly this :-
The site of the vineyard is selected, if possible, on the slope of a hill with a southere aspect. The ground is then dug in trenches (running north and south) at intervals of about 12 feet, and from 3 to 4 feet deep, the soil excavated being deposited between the trenches, thus torming intermediate mounds, the whole finally
det in B. ganglioniformis thery short and of a pure wimt which also tioniformis, the peat of Lettuces, but the threads, instead of being regularly forked, swell into ganglion-like processes, from which little spicule project, each of which is surmounted by a spore. O the Anemone the fertile threads are still shorter than in the Botrytis of Rhinanthus, and are very slightly divided, so as to bear only four or five spores.
558. The threads of the Botrytis are injurions in two ways, first by diverting and appropristing the nutriment
which was elaborated by the plant on which they grow, principally as it should seem by endosmose through the walls, though the threads are capable of penetrating the cavities of the cells, and secondly when they themselves decay, by acting like a putrefactive ferment on the tissues with which they aro in contact. It is manifest that if this be the case it is not necessary that the Botrytis should penetrate to every part where decay exists, for when the tissues are once affected at a particular point they can communicate the taint as well as the fungus. The Botrytis which attends the Potato murrain is so important as to require a separate article. Our figure represents Botrytis macrospora, Unger, pecies coly allied to $B$, umbelliferarum, in whieh Caspary has found his sporidangia. M. J.B.

## Home Correspondence.

Diseased Lobelia.- May I talse the liberty of requesting you to examine the enclosed specimen of Lobelia It is the weli-known for dwarf blue beds and also for extensively used here for dwarf blue beds and also for margins to beds. Mately observed that beds of it wero-
less brilliant in colour than usual, and after closely exless brilliant in colour thsn usual, and after closely ex-
amining the plants I found that they were elighty spoted. I attempted to save the beds by cutting a little from the tops of the plants, and afterwards shading them with boughs. They however would not revive, but were in the space of three or four days entirely gone, leaving not the slightest trace of their former beauty-they became one putrid mass some of the beds in distant parts of the garden begin to get gradually affected in a similar manner; but the evil is confined to this varioty. spring are not at all affected, though growing in the same compartment of the garden. This variety of Lobelia I have kept up from cuttings made in autumn and spring, the ay weather has been very dry and warm for several weeks, but during that time the beds of Lobelia were well supplied with water. Their decay has been so rapid and unusual that I am sure you will not consider me obtrusive in laying the matter before you. Robert Gordon Foggo, Shrublend Park. [We have examined very carefuly the specimen of Lobelia which you have kindly transmitted, without arriving at any satisfactory conclusion as to the cause of the affection. The root is singularly healthy for so diseased a plant. There is no fungus about the plant to account for the decay, which commences at isolated spots an oner the play, even as high as the calyx and petals, and then rapidly extends in every direction. Upon the moister portions are imperfect specimens of Botrytis grisca mixed with Macrosporium Chciranthi. These, however, are merely a consequence of decay and not a cause. There is a minute Phoma on the peduncles, but in too small quantities to make it of any consequence. The only peculiarity about the tissues is that the walls of the external cells are strongly plicate, a condition dependent upon their having become more flaccid than in health. The whole history of the complaint, and especially the circumstance of its being confined to a single variety, indicates one of those constitutional disorders against which no one can guard, and ayainst which it is often hopeless to contend. Even in the animal kingoom, where there is more time for the application of remedies, such maladies often admit of no relief. About fifteen years since an excellent breeder of short-horns, notwithstanding the atmost skill and attention, found his stock attacked by cancer. It was not at all known how it was generated, nor why it became almost universal. Every possible means were employed almost universal. its increase but in vain, and at last it to guard againative to get rid of the breed altogetber. It is exactly the same with the gardener, to whom it is is exactly the same with the gardener, extremely mortifying, because his employer, if unacquainted with the subject, is apt to attribute failure to want of skill, but wherever plant liable to diso from cuttings the stock is peculiarly liable to diso ease, because the peculiarities of constitution are under the most favourable circumstances handed down, and if there is any weakness it is often exaggerated, added to which from the very moode of increase, the tissues are liable to taint from dead matter about the scar, and though the taint may not be sufficient to produce apparent disease at once, it may impair the constitution. The only effectual plan is to get a new stock from some distant quarter, or to try what may be done by seed. The latter resource is, however, a very precarious one, as the seed of thoroughiy diseased plants, if they are vigorous enough to produce seed, is very apt to give rise to a diseased stock ${ }^{\text {seed, }}{ }^{\text {M. J. B.] }}$

Victoria Regia.-My Vietoria Regia, described at p. 518 , is now furnishisg remarkably fine flowers; its boom in its perfect stage measured $11 \frac{1}{4}$ inches in of which there are in all 12 , and new Hower buds are
appearing every day. It is considered the finest plant
in this part of the country. $W$. $M a y$, $a r$. to Josiah Spcde, in this part of the country. IV. May,
Early Peas.-I qui.e agree with Mr. Whiting that it is a matter of some importance both to buyers and
sellers to ascertain whicl is really the best Pea for a sellers to ascertain which is really the best Pea for a
first crop; and like him I have this season been proving a few surts for my own satisfaction. They day:-1. Sangster's No. 1; 2, Prince Albert ; 3, Auvergne. Nus. 1 and 2 were equal in regard earliness, but No. 2 is such a poor bearer and so very tender, that I consider it not worth growing; No. 3 was a few days later, more prolific, but inferior in flavour to No. 1 ; No. 4 was eight days later; No. 5 I found to be only a second early, but fur inferior to Fairbeard's a second sowing, being an abundant bearer, and possessing an excellent flavour. II. Y'etrie, Elsham Hall, Lincoln. I beg to add that of "Rendle's First Early Green." After several trials with this Pea I have proved it (except in one instance) to be "Danecroft Rival ;" the exception alluded to was last year, when it turned out to be identical with "Warner"s Emperor." The seed Beta.
Locust of Tartary.-On Monday, the 11th inst., as one of the bailiffs was passing into the county court at Mansfield he took off the Town Hall railing what he called a large grasshopper, and gave it to the clerk of the Court. It appeared much exhausted, but recovered itself on being fed ; it died last Friday. It is the larger species of the locust of Tartary. How it could have got to Mansfield must be explained by those more conersant widh such matters than 1 am . J. 0
Proposal for a Metropolitan Botanic and Flower Garden.-If you will find room for a few lines explanacarrying out the above objects in a practieal way I shall feel obliged. My plan is to institute a garden where botany (that of our own land especially) may be studied, and lovers of gardening may see those flowers, plants, and shrubs which are in use for garden ornament observe their habits, and learn all information about
obtaining and keeping them. I believe such a thing is not in existence, certainly we have nothing of the sort near London. The beautiful gardens at Kew afford no facility for study, and as regards indigenous botany they
are generally considered a failure. The Regent's Park Gare generally cousidered a failure. The Regent's Park service to the general public ; the Medical Botanic Garden at Chelsea I need not mention, and at the Crystal Palace ornament and not instruction is the rule, and in garden and home adornment get at the name, nature, and cost of the useful aud beautiful vegetation which enehants his eye. In two paragraphs I will briefly state how I would pursue this object of instructing in science and taste. The garden sbould be as near town as amoke and the price of land would allow-not beyond gardening should take a central position, the shrubs and named beine and clearly named. Outside this division in a contanuos tine or circle would be placed our indigenous plants, ordered learning theirnedical and other properties. Exotic plant should be similarly managed, so that the visitor might learn the country, habits, and uses of what he is looking at. I would also as far as practicable allow botanic students to obtain small specimens, as at Versailles and elsewhere, and an arranged propagating department, so the ground there should be a light structure containing reading-room, where botanic and gardening periodical might be seen, and a select library of reference. Ther hould also be the names of all the seedsmen and floriste, and the catalogues of those who publish them ; secondly, museum, where specimens, scientific and economic could be easily referred to, and gardening implements and contrivances exbibited. It may be said all this would costa fine sum, for most undertakings in this country must be done expensively, but having had the idea in my mind for some months I could show that the expense would not be very great, not more than a person of comhould suggest a public subseription own grounds. grounds in the first instance, and purchase and collect a ew thousand plasts/; and public gardens, private goodill, and Alorists would no doubt The rarer plants and the herbarium (which could start with about 2000 species) might be collected by degrees. For current expenses, I calculate a nominal entrance charge of $2 d$. , florists' special advertisements in the reading-room, shows, and the sale of redundant seeds and specimens among the trade, would defray the expenses of gardeners, \&c. Having been an amateur gardener for some years, and a botanic student for many, feel much interest in the idea, and should be happy to give any assistance in $m y$ power flowers. G. Finden Warr, 5, Elizabeth Cottages, South Road, Yilington.
Change in the Seasons.- Something has lately been said in your columns about the change in the seasons that appears to have taken place of late years; and I have ago indeed, but perhape none the worse on that account

It forms part of the eesay "Ot Vicissitudes of Things," by Lord Verulam, commonly called Lord Bacon. "There is a toy which I have heard, and I would not
have it given over, but waited upon a little. They say it is observed in the Low Countreys (I know not in what part), that every five-and-thirty years the sane kind great frosts, great wet, great droughts, warn int as summers with little heat, and the like; and they call i the Prime. It is a thing I do rather mention becaucomputing backwards I have found some concurrence.' This passage may not be familiar to some of your readers, and whatever they may think as to the ex istence of the "Prime," will probably interest them a showing that irregularity in the seasons was experienced to some extent, at least, by the subjects of Queen
Elizabeth as well as by those of Queen Victoria, and as showing moreover that the subject excited some attention then as now. One of juur correspondents says that the testimony of old people to the change of climate since their youth is found to be very vague when sifted. Not always I think. In 1851 an old man told me that he thought it rush to build such a large flat-roofed edi. fice as the Crystal Palace. "To be sure Paxton ha'n a lived so long, nur seed sich snow as I've a done." He then told me precisely the year and the duration of a great snow that happened in his youth, but I have forgotten both. Again, I remember a very old gardener saying that in his youth a particular sort of Plum used
to ripen well at Frampton, in Dorset, on standards, to ripen well at Frampton, in Dorset, on standards,
which is now never the case there. In both these cases the evidence was as clear as could be. Has the question as to the existence of Vineyards in England in old times
ever been settled? In Normandy there is no doubt of their laving formerly existed in parts where they are not to be found at present. H. J. Moule, st. Germain-en. Laye. [And so they did in England. The reason of their cultivation being discontinued was the gradaal introduction of good wine at low prices, as we long since explained.

Hedge Plant.-It has been stated that this is admirably adapted for covering rocky banks and walls. AB, however, I do not remember ev that purpose except by myself, I may state that few, any, plants are so well adapted for an ornamental and efficient fence. Ten years ago I planted a hedge of it at
the bottom of a sloping garden about 60 yards long $y$ the the bottom of a sloping garden about 60 yards long by the side of a road, and about $3 \frac{1}{2}$ feet above its level; and
for the last four years it has proved a sufficient protection against cattle without rails. The only care quired is to keep the plants clean and their branches as they extend in the line of the fence for a few years, with an annual dressing with the shears or switchingknife when it has obtained the required size. My hedge is much admired by all who have seen it, being at all times a deep green, and enlivened in the depth of winter and spring with a profusion of scarlet berries, until it again becomes as white as a sheet with its innumerable with bees. Besides forming day are literally covered with bees. Besides forming a good and neat fence the
branches hang down above the bank and completely brauches hang down above the bank and completely cover it to the level of the road. Mice store the berries
ap in winter ; but the Mistletoe thrush is the only bird up in winter ; but the Mistletoe thrush is the only bird
I have seen attracted by them, J. Gaitskell, CumberI have
Large Puff:balls.-I found a puff-ball (as it is commonly called) of such gigantic dimensions to-day that I longated human skull. It measured in ehape of an 2 feet 11 inches by 2 feet 4 inches, and weighed 5 ounces. Cavanensis. [This is not very large for Bovista.]

## societios.

British Assoclation for the Advancement Science, Aug. 7.-Section D.-Zoology and Botany (Continued).-Dr. Lankester read a paper from Prof. ing Plants." In this paper Prof. Henfrey anounce that Prof. Schleiden and Dr. Schacht had given up their opinion that the end of the pollen-tube produced the embryo in the seeds of flowering plants; and had come to the conclusion that the embryo is formed from a distinct protein mass, contained in the embryo sac. He also pointed out that the embry mass does not become a regular cell covered with cellu lose till after the pollen-tube has come in contact with Frmbryo sac.
Friday. - "On the Variation of Species," by the Rev L. Jenyns.- Having referred to Prof. Buckman's paper, o-day would refer illustrations were animals, and not plants. He then proceeded to refer to the fact that a large number of varieties of animals, more especially birds, had been put down as distinct species, which were undoubtedly the same bird. Whilst he was convinced of the existence of species, he felt sure that there was a tendency to regard as dist:nct many animals which were not so.

On the Triticoidal Forms of Æyilops, and on th pecific Identity of Centaurea nigra aud C. nigrescens, by Prof. Henslow.-In this paper the professor recorded the result of his own experiments, in which he had so far succeeded in changing the character of 1 yilops squar rosa as to lead him to conclude that M. Fabre's origina statement that A. ovata was the origin of Wheat Triticum sativum, was not altogether without foundation. He exhibited sp:cimens, in which the form

Ægilops squarrosa had undergone considerable change but he had not yet succeeded in obtaining the character of Triticum sativum. Prof. Henslow then exhitited foras of Centaurea nigra and C. nigrescens, in which it wo seen that these plants had completely passed ove int he other. He then referred to instances of the specie Rosa, Primula, and Anagalis, passing one int the ther. Mr. Bentham stated that when he first began study botany, he thought permanent characters ought e regarded as distinctive of species. He now, howere believed that permanent characters might be given plants by locality and clinute, which had no right to b
egarded as distinct species. He then regarded as distinct species. He then proceeddd A sia, and Africa, as contrasted with that of the Brius slands. He instanced more particularly Bellis ptren nis and B. sylvestris as the same plant, and Taraxscum obovatum and 'T. levigatum. He thought that all the forms of Rubus, with the exception perhaps
arsius, ought to be referred to R. fruticosus.-Sir W. Jardine referred to iustances of birds in which extern ircumstances changed the colour of their plumase and ther points of their structure.-Prof. Balfour referre to instances of plants which varied very much in thei characters, according to the circumstances in which the vere placed. He mentioned the case of Pontederia
crassipes, which assumed, according to its treatment, crassipes, which assumed, according to its treatment,
quite different characters. Accidental changes in form quite different characters. Accidental changes in form
frequently became permanent, of which he related an instance in a Fern at the Edinburgh Botanic Gardens. -Dr. J. E. Gray referred to the great influence which depth, age, and other circumstances had upon the cha racter of shells. He believed the multiplication of 8 , ecies was a great evil, and calculated to deter persons from the study of natural history.-Prof. Busk drew attention to the importance of distinguishing the characters which constituted a species from those which might charac terise the individual. In the lower forms of both animal and plants, the individual exhibited itself as compose of hundreds and thousands of parts, each resembling the other.

Metropolitan Hollyhock and Dahlia Exhibimon This took place at Cremorne on Tuesday and Wednee day, the 19th and 20 th inst. One hundred and sixty
spilies of Holly hocks were staged, all nearly 3 feet ii height, and closely set with bloom, the flowers giving an average diameter of 5 inches. The Dablia as a whole were not first-rate. Roses were shown by
Messrs. Yaul. Messrs. E. G. Henderson contributed van-load of Coniferous plants, which, tastetully grouped, formed an admirable centre for the display of the Hollyhock spikes staged round them. Messrs. Smith of Dulwich also sent 30 specimen Bals ms, Of Hollyhocks Messrs. Bircham \& Ward sent Solfat: rre Souvenir, Pourpre de Tyre, Lemonade, Purple Petfec tion, Brennus, Seeulling, Fireball Superb, Standard Vesta, and Hon. Mrs. Ashley ; Mr. Chater-Lady Middleton, Walden Masterpiece, Saturn, Resplendens, Canary, Autocrat, Beauty of Walden (one of the bes varieties shown), Empress (best buff or yellow), Géant
des Batailles, Fanny, and Mont Blanc ; Messrg, Paul produced Primany, and Mont Blane ; Messro 'Tyre, Narcissus, Mrs. Oakes, Hedenham Rival, Beauty of Cheshunt, Solfaterre, White Globe (best white spike), Glory, and Hon. Mrs. Ashley. Nine spikes: the Rer. C. Feilowes showed Solfaterre Improved (best yellow spike, as also the best spike in the exhibition), Superb, Purpurea elegans (best purple or plum spike), Hon. Mrs. Ashley, Mrs. ©ak , Dique, Brenof Yellows, Eva, Pourpre de Tyre, Beauty Souvenir, Solfaterre, Yellow Model, Seedling, and Hon. Mrs. Ashley; H. Bowler, Esq., furnished Atropurpurea, Hon. Mrs. Ashley, Unique, Joseph Clarke, (is H. Bowler, Lilac Model, Queen, Solfaterre, and a Seed ling; Fourth, Mr. C. J. Perry. In twenty-four blooms, the best varieties were for the most part bloom shown in spikes. In the class Mesars. Paul showed (olloctions Of these, the best varieties were Exquisite, Nil Desperandum, Sulphur Queen, Ceres Atrosanguines, Rosy Morn, Lilacina, Grandis, Masterpiece, Queen of Buffs, Ruby Queen, Canary, Purple King, Leonora, Lady Middleton, Lilac Queen, Beauld Walden, Autocrat, Sceptre d'Or, Ignea, Walden Rival, Lord Jocelyn, Pourpre de Tyre, Mrs, Oakes, Memnon, Purple Perfection, Mr. Adams, Waite Globe, Beauty of Cheshunt, Eclipse, Hon. Ashley, Blushing Bride, Solfaterre, Charles Baron Improved, Criterion, Rosy Morn, and Omar Pacha. Of Dabliqs (24), Mr. Charles Turner sent sir John Franklin, Colonel Windham, Malvina, Captain ingram, Incomparable, Sir F. Bathurst, Bessie, Lulins Harbinger, Grand Sultan, Amazon, Kachel Espasero, Sir R Whittington, and Duchess of Cambridge Mr. H. Legge had Admiral, Sir C. Napier, Crimed King, Amazon, Mr. Seldon, Duchess of Kent, Glenlyon
Beauty of the Grove, Mrs. Legge, Robert Bruce, Beauty of the Grove, Mrs. Legge, Robert Bruce,
Rachel Rawlins, Duke of Wellington, Magnet, Le Phare, Louisa, Glenny, Port Wine, Roundhead, aud Julien Mr. Keynes furnished Lord Paimerston, Lollipop, Sin, F. Bathurst, Lady Folkestone, Coour de Lion, Mai Sir J. Franklin, Rachel Rawlins, Dr. Gully, Bessie, ReLord Bath Sir Chap or In the private growers' class ( 24 blooms), Mr. C. Gran
sent Miss Caroline, Pre-eminent, Lord Palmeistou,
Fanny Keynes, Malvina, Robert Bruce, Cossack, Amazon, Lady Mary Labouchere, Lilac King, Lord Bath, Yellow Beauty, Sir C. Napier, Lollipop, The Nigger, Sir J. Franklin, Bessie, Miss Burdett Coutts, and
Duchess of Wellington. In the class of 12 Dahlias, J. Cook, Esq., showed Salvator Rosa, Lollipop, Rachel Rawlins, Constancy, Beauty of the Grove, Beauty of Slough, Duchers of Kent, Miss Caroline, Empress, Sir
F Bathurst, Colonel Windham, and Essex Triumpl ; Mr. Holmes : Lord Palmerston, Caroline, Sir C Sir J. Franklin, Cherub, Diadem, Yellow Beauty, Sir F Bathurst, Miss Burdett Coutts, Bijou, The Nigger, and Lollipop; the Rev. C. Fellowes: Fanny Keynes, Miss Lord Bath, Marion, Amazon, Miss Burdett Coutts, The Lord Bath, Marion, Amazon, Miss Burdett Coutts, The
Nigger, Lollipop, and Duchess of Wellington ; C. J. Perry Esq., had Miss Caroline, Beauty of Slough, Archbishop o Canterbury, Rachel Rawlins, "Ringleader, Lollipop, Annie Salter, Magnet, Yellow Beauty, Mrr. Rawlins,
Annie, and Bessie. Fancy Dahlias (24 blooms): Annie, and Bessie. Fancy Dahlias (24 blooms) :
these Mr. Keynes exhibited Charles Perry, Conque these Mr. Keynes exhibited Charles Perry, Conqueror, Polyphemus, Carnation, Lady Grenville, Jonas, Empe-
reur de Maroc, Mrs. Hansard, Miss Frampton, Duchess reur de Maroc, Mrs. Hansard, Miss Frampton, Duchess
of Kent, Mrs. Spary, Pigeon, Model, and some unnamed seedlings ; Mr. C. Turner: Fugenie, Butterfly, Marvel, Pigeon, La Vogue, Inimitable, Enchantress, Duchesse Admiration, Miquette, Kossuth, Laura Lavington Phaeton, and Gloire de Kain ; Mr. H. Legge : Butterfly, Triomphe de Roubaix, Vaseo de Gama, Baron
d'Arme, Malvina, Attraction, Mrs. Hansard, Annie Miquet, Duchess, Ktraction, Mrs. Hansard, Annie Laura Lavington, Gloire de Kain, Phaeton, Pigeon, Juliana, Lady Greville, Liliput von Branduth, and some seedlings. Twelve Fancies.-The Rev..C. Fellowes had Enchantress, Topsy, Triomphe de Roubaix, Inimitable, Eugenie, Miss Ward, Lady Grenville, Comet, Pigeon, and Kossuth; C. J. Perry, Esq.: Triomphe de Rous baix, Pigeon, Marvel, Gloire de Kain, Jonas, Butterfly,
Reine dea Belges, Uncle Tom, and Comet ; Mr. C. Reine des Belges, Uncle Tom, and Comet; Mr. C.
Grant: Enchantress, Triomphe de Roubaix, Empereur Grant: Enchantress, Triomphe de Roubaix, Empereur
de Maroc, Duchess of Kent, Reine des Fleurs, Wonde Maroc, Duchess of Kent, Reine des Fleurs, Won-
derful, Gloire de Kain, Cockatoo, and Comet. Firstclass Certificates were awarded to Fancy Dahlia Polyphemus (Keynes), flaked rose and purple ; to Fancy Dahlia Model (Keynes), also flaked rose and purple,
but of distinct shades; and to Dablia Mrs. Legge (Legge), orange ground, with red or cherry tips. Lady Popham (Turner), white, with chaste tip of purple, seems of first-rate merit, a single flower only was staged Fenella (Holmes) is a small flower in the way Amazon, Unique (Turner) is a good orange and red.

Botanical of Edinburge : July 10th. Prof. Balfour in the chair.-The Chairman stated that the painful duty devolved upou him of recording the death
of the President, Colonel Madden, which tonk place suddenly and unexpectedly from rupture of the aorta soon after last meeting of the Society
sure, (he said) deeply deplore the loss of one who took a warm interest iu our proceedings, and with whom we have had much pleasant intercourse. For my own
part, I cannot easily give expression to the sad feelings with which I contemplate this bereavement. He had been a constant visitor at the Garden during the summer while engaged in preparing his elaborate paper on the Indian plants in Dr. Buchanan Hamilton's herbarium ; and I had looked forward to the pleasure of spending many a happy day with him in the prosecution
of botanical science. His amiable deportment and of botanical science. His amiable deportment and gentlemanly manner endeared him to all of us, and we all rejoiced to see one who had spent a large portion
of his life in the active service of the East India Company now devoting his time and leisure to the prosecution of science. During his residence in India he was a careful observer, and made many interesting remarks on the flora of the country. He sent home the seeds of many valuable plants which have flowered in Glasnevin and other gardens. When he came to settle Societies, in both of which he became a very active member. He was elected a councillor of the Royal Society, and took a marked interest in its proceedings. He particularly took charge of the scientific additions
which it was agreed to make to its library. To the which it was agreed to make to its library. To the
Transactions of the Botanical Society he contributed an Transactions of the Botanical Society he contributed an boos high on the Himalaya, and it is to be hoped that the paper which was read from him at our last meeting will be in such a state as to allow of its publication. Most
sincerely, I am sure, do the Society condole with his afflicted widow. Such events call on us to be ready, seeing we know not what a day may bring forth. I have also to report the death of Mr. William Gourlie, the local secretary of the Society in Glasyow, who was connected with our Society from its commencement, and who aided it much by his exertions. He was a zealous of plants, which it is hoped will not be lost to science. From his mercantile position in Glasgow he was able to render important service to the Society and to botanists on many occasions, and he was always ready and willing to do everything in his power for the promotion of of botany I was my residence in Glasgow as professor mens now in the museumebted to him, and many specimens now in the museum here I owe to his kindness. western metropolis, and his labours promised to be inatrumental in infusing a taste for science among the

British Association took place in Glasgow in September last he acted as chief local secretary. The labour which he underwent, not merely during the meeting, but for months before, was extraordinary. He spared no pains to render the meeting creditable to Glaggow, and the arrangements which he made called for commendation from all. He was publicly thanked by the Duke of Argyll for his services. About the time of the meeting symptoms of disease of the bones in the face appeared, and tle malady went on insidiously and unobserved for many mouths, till at length it appeared as a fungous growth. He endured at first great suffering, which he
bore with much fortitude and resiynation; and after a bore with much fortitude and resignation; and after a
protracted illness he sunk in the course of last week. He has been taken away in the midst of his usefulness, He has been taken away in the midst of his usefulness,
and at the very time when he seemed to be gaining the highest eminence in his native city. The place which he occupied will not be easily supplied. Let us hope that his $\in$ thusiastic love of science, and his noble exertions in the cause of botany, will be means of
stimulating his townsmen to follow his steps; and that, stimulating his townsmen to follow his steps; and that, while they are prosecuting their commercial speculations, they will not think it beneath their notice to
devote some of their time to science, which was to him in his season of recreation a source of high enjoyment and which secured for him many friends in all parts o the world. Though dead, may he yet speak to them.

Ferny Combes. A Ramble after Ferns in the Glens and Valleys of Devonshire. By Charlote Chanter. Reeve, 12 mo , pp. 118.
Under this name we have a very pleasing guide to the most beantiful of our English counties; not in the formal manner of a Murray, and free from the dull watiousness of the forces, but as fresh and enjoyable sold at Watering places, but as fresh and enjoyable as the
rich scenery to which it introduces the reader "Combe" we are told signifies in Somerset and Devon "Combe" we are told signifies in Somerset and Devon a hollow or glen with its rivulet running down to the
sea. "The Combes of North Devon, with one or two sea, "The Combes of North Devon, with one or two exceptions, ara rarely above two or three miles long, we should see that the land within three or four miles of the sea is ser that the land winin three or four miles of of which, when cultivated, prove rich and fertile ; but for the most part they are poorly farmed, or still covered with a tangled mass of Briars, Ferns, and Golden Gorse. Now and then you find woods, but not of any very great extent. The Combes are very rich in Ferns; but the best places for hunting are the loose only to the bare white walls of our oolitic districts will be surplised to hear that they must look on walle for most of our most beautiful and curious Ferns. But a North Devon ' wail' is a thing by Itself. The rotten shatey slates, placed edgeways, are but he outer
covering of deep banks ; and through this coating spring tasselled Athyriums, never-ending varieties of Scolopen-
drium, and numerous forms of Filix-mas, not forgetting the many states of Lastrea dilatata, rangiog from four feet high to an inch and a half.
To these wild scenes Mrs. Chanter introduces her readers with all the zeal of an enthusiastic admirer of Nature, and especially of those charming forms in
which the vegetable world is pre-eminent. Her book not written to while sway a weary hour, but to be used not written to while a fay a weary hour, but to betas
on the spot; it is a field book of Devonshire botany its pages have all the verve and eager dash of a Forbes In a scramble after plants local difficulties are tossed aside, to rough it is the word, and the discovery of a Feru new to the traveller is ample compensation for
fatigue and inconvenience, to say nothing of something like danger
Listen to the spirit with which Dartmoor is deseribed the words seem to come from the mouth of a buglehorn.
hills out upon the hills ! the glorious, granite capped acres free froor, breezy and Nesture has put her own seal upon them. Ages, ages ago were those huge blocks of granite strewn about, defying man to intrude on Nature's solitude ; for who could remove all those countless myriads of stones, to till the ground that lies beneath? Yet centuries ago this wild region, and the wildest parts of it, now deserted by man, were the abodes of a curious, wonderful people. Dartmoor was one of the strongholds of the Druids; and the many 'hut circles,' 'stone avenues,' tolmens, and cromlechs, show them to have been a numerous people, maryec-
lously attached to stones. Their peculiarly pet place, lously attached to stones. Their peculiarly pet place,
Wistman's Wood, is unique. Gigantic blocks of granite, so piled one on the other that the only way to get along is to jump from stone to stone. Woe betide you if you put your foot on a nice tempting piece of Sedge or Grass ! l'he thin crust speedily gives way, and you may chance to get wedged in between Druidical remains. From amoug the rocks spring ancient Oaks, known as ancients even in ancient days, gnarled and stunted, clothed with hoary Mosses and parasitical plants. Not long ago we rees Do naturalists record the fact that rabbit frequent trees; or is it peculiar to those in Wistman's Wood? Wise people say that Wistman's Wood ought to be 'Wise Man's Wood,' in honour of the very clever and intellectual people who once resided here. Hevaring we
signifies borrowful to suggest that 'whist' or 'wist' visited Wistman's Wood can hardly fail to have been struck with the doleful moans and sighing which assai him on all sides (added to his own if he have a tumble, no unlikely thing), making him fancy that a regiment of Arch-Druids and Bards are bewailing the overthrow of their altars, the desecration of their circles, the standing still of their rocking stones,"

But we must not detain the reader from a volume so attractive as this, further than to enable the authorese o deseribe her own true feelinga concerning the pleasures of a botanical ramble
"Some indeed may inquire, ' What is the advantage of knowing the names of a set of weeds which are of re use to any one !' 'Of no use!' That is a question not for us to solve.

At any rate, are many of your employments more useful? Are all so innocent? Ask the worn-out, heart-wearied man yonder, who has escaperd for one short month from his stool in a city office ; ask him, if there be not a use in the exquisite and various forms and colours of the seaweeds he is turnin, over on the beach. He will answer, 'It does me good to look at them; it refreshes my soul ; it makes mo young again !' Of no use ? That is too easily assumed, and implies surely a forgetfulness of Him that made them. It does not necessarily follow that a thing is useless because we happen to be ignorant of 'its us? We ought to believe, we ought to be sure, that the lowliest flower or insect has, though it may be unknown to us, a real use in God's cconomy 'Behold the Lilies of the field, how they grow I' These gaily dressed flowers thed their use It was their miseso (could they have a higher !) to ( God for meat, drink, and clothing. Who will deny the God for meat, rink, and cho fascination which flowers or the choicer kind exercis custly greenhouse, the highly paid gardener, are requisite for their possession, bur what do the wild flowers cost? Only the trouble of picking them; and
they, if people take the pains of looking for and examining them, have quite as many, though more humble charms than their more aristocratic relations. Here smell this bunch of Butterfly Orchis. Did ever 'But where did you find it? I never saw it before. Good friend, $I$ plucked it by the side of a road you have passed a huadred times. Look at these Daffodils -where will you find colour more brimant, texture mose delicate?' 'But they are such vulgar flowers they are so common!' 'My friend, I fear you are very valgar,
The heart of manyoa weary soul will respond to this, especially just now when the dreary streets of cities are emptied into the lanes and fields of green delightful England. We should add that the little volume is illustrated with eight coloured figures of Ferns, the only fault of which is that they are stuck between every page except that to which they belong.

## Garden Memoranda.

The Modern Structures in the Botanical Garden, Carlsbuhe.-The botanical gaiden of Carlsrube is one of the oldest, if not in Errope, at least in Germany Caspar Bauhinus, the great botanist of the 16 H residence of the Grand Dukes of Baden, the treasures of which were subsequently transferred to Carlaruhe. When the present Regent assumed the reins of the nen country, he resolved new buildings, which, besides their practical adaptation, should be architectural works of art. Baudireetor Hübsch, a gentleman known by theoretical and practical worss, was entrusted with the endection of
these structures. On the borders of the gardens of the these structures. On the borders of the gardens of the
castle stands the new greenhouse (Orangerie Haus). castle stands the new greenhouse (Orangerie Hans).
As the Orange trees of the establishment are numerous As the Orange trees of the establishment are aired. The and high grown, a large space was required. The building is 250 feet long, 50 feet broad, and of an adequate height. The side which turns towards Stephanie Street is ornamented by the principal elevawhich is a hall for festivals (Festsaal). The other part of the greenhouse is connected under a right angle with the whole remainder of the buildings, and ends at the palace, so that the passage from the palace to the end of the houses is uninterrupted, in a leng th of 1,400 pavilion, through which passes the road from the pavilion, through which garden to the pleasure grounds (Englische Aniagen !) of the gardens of the palace, above which is a salon affording a fine view over the town and gardens. A residence for the director, a Palm-house, and a caldarium for exotic water-plants lie also in this and a caldarium or exition of the building forms an arcuated gallery. In front of the gallery is a wintergarden, which torms one of the pleasantest parts of the whole. We find here trees protection during winter, but now stand quite free as in their native land. The length of this winter-garden is
400 feet by 40 in breadth. The great advantage of this 400 feet by 40 in breadth. The great advantage of this arrangement of M. Hübsch is, that he has known how to manage things so that not even a vestige of the beams and spars of the winter protection is to be seen in summer, which was accomplished by the winter-garden having in its rear the long gallery, in the walls of which winter-garden could be immitted without leaving any
vestike vemad wien not required. Builder.

## Miscellaneous.

Agrimony Tea. - The following recipe is given in a late number of the Moniteur cles $C$. Put fresli gathered leaves into a coffee roaster along with three pebbles to act as stirrers. At the end of a quarter of an hour a native tea is produced which to drink, and possessed of all the tonic or astringent qualities of greea tea. This beverage is particularly adapted to people who live poorly, and imper fectly digest their bad food; it is also recommended fectly
against dysentery.

American Vine Mildew.-The first indication of the disease is shown by the leaves having brown spots upon them, and which permeate quite through the tissue. Afterwards, are seen small white patches of the soft and
delicate fungus attached to the under side of the leaf, delicate fungus attached to the under side of the lear, the fruit stalks, penetrate to the berries by the rhizoma or spawn, and make them in appearance like a diseased Potato in the first stage of infection, stopping their will fall off after a short time, and the whole plant become seriously injured. These white patches are the fructification of the parasite; when viewed under the microscope, there is exhibited a mullitudinous congregation of little mushroom-looking substances, and if suddenly jerked, the tiny sporules sayy be seen detached and floating in the atmosphere, so minute and subtle and in
such countless numbers, that it is not unreasonable to suppose (beside the immediate development and rapid vegetation of thousands of them under favourable influences) many are absorbed by the stomata or breathing pores on the under surface of the leaver, and conveyed into the interior, simply by the descending movement of the elaborated sap, which is afterwards converted into woody fibre, and in its turn becomes the organised medium by which the ascending sap, in the following spring, flows with greater velocity to the unfolaing upwards, and conveyed onwards to the foliage, and there remain dormant, until the favourable circumatances oceur for their germination, when they spring into reaewed iffe, and speedily produce another crop of seeds
for a future generation. This kind of mildew seldom does any mischief after the growth approaches towards ripeness, or the fruit is in the last swell, and as it generally begins to appear about the early part of July,
during damp and close weather, those planit which during damp and close weather, those plants which have almost free from its attacks; but in the Cold Grapery or Retarding House we should be on our guard, and the floor of the house, in the proportion of one pound to each 15 or 20 square yards, and withhold water for the time being, keeping the house quite close, if cloudy, and allowing the temperature to rise somewhat higher for off fumes which are readily perceptible to the smell, and will check the further progress of the pest if present, or prevent its appearance if not 80 . We have used all the supposed remedies that we could collect a knowledge of, by way of experiment, without being able to discover anything more than temporary relief, while the fumes of immediately check, and if water be withheld during the continuance, to finally overcome it. There need be no fear of sulphur doing harm to the foliage ; so long as ignition does not take place, it may be used with contidence. Herein lies the secret. If allowed to burn, which in its then gaseous form will speedily destroy all foliage with which it comes in contact. Chortton's American Grape Growers' Guide.
An Ancient Oak,-One of the oldest trees in Europe was atruck by lightning in the month of July last. This tree, an Oak, had been planted near Châtillon-sur-Seine (Côte d'Or), in 1070, by a Count of Champagne. The Oak, which had therefore existed 786 yeare, measured seven and a half metres in circumference, and had produced acorns up to 1830. Morning Paper:

## Calendar of Operations.

## (For the ensuing week,

PLANT DEPARTMENT
Conserfatory, \&c. - Hyacinths and other Dutch bulls should be procured and potted for early forcing as soon as they can be obtained, and even where early forcing is not intended there will be a better chance of getting first-rate bulbs early than some months hence. Small Orange trees ia pots for forcing in winter for the decoration of this house should now be fully exposed to the sun and air, in order to get their wood well ripened, The Mandarin being a free grower, with a dwarf bushy habit and small foliage, and a most abundant bloomer, is probably the best for this purpose, but any of the
varieties flower profusely provided the wood is thoroughly rarieties flower profusely provided the wood is thoroughly
ripened in auturn. These and Daphnes should be largely grown wherever sweet-scented flowers are in demand in winter. Also see to having plenty of Salvia gesneriflora, which is an exceedingly gay plant and very useful Should mildew appear on any of the soft-wooded Heaths, dress with sulphur at once. These will, however, be maostly
they must be zuarded against getting too wet at the root Get Azaleas that have set their buds tiel into form order to give them a neat appearance. Also attend to orcier to give them a neat appearance. Also attend to
the staking and training of other things as leisure time the staking and training of other things as leisure time
can be found. Look carefully after red spider on anything found to be liable to this pest, and see that it is
eradicated before the plants get disfigured. It is easily eradicated before the plants get disfigured. It is easily
got rid of by laying the affected plant on its side, and got rid of by laying the affected plant on its side, and
well washing the under sides of the leaves with the engine, applying the water with as much force as the foliage will bear. Shake out and repot Pelargoniums that are sufficiently advanced after having been cut back, keeping them rather close and moist until they strike into the soil. Plants, however, that are fairly exposed to air or kept too cool. Also keep Cinerarias cool and moist, and attend to repotting such as require

Primulas must also be carefully attended to, in order to encourage them to make rapid growth, particularly the double varieties. Keep Tree Violets clear
of red spider by liberal syringings, and give them of red spider by liberal syringings, and give them
plenty of manure water, which will assist in beeping them in vigorous health.
Pineries. - Where the pot system of cultivation is practised, any of the stock whicl may appear to require repotting should be examined and shifted at once, if
this is found necessary, in order that the roots may get hold of the fresh soil before dull cloudy weather sets in, when it will not be safe to encourage free growth. And any necessary re-arrangement of plants growing in the with a little care in shading on bright days and keeping the atmosphere moist, this can be effected at present with very little risk of checking the plants, so as to throw them into fruit, and there is also plenty of time to get them well established after removal before the dormant season. Encourage plants expected to show fruit next January to make vigorous growth, for these
should be sufficiently advanced by the middle or end of October to allow of keeping them rather cool and dry through November and December, so as to chech nnd thoroughly mature their growth, as unless this is
attended to there will be considerable risk about getting attended to there will be considerable risk about getting
them to show fruit at that season. Plants which have been prepared for fruiting, and which it is desired to get up at once, should be encouraged with a moist warm atmosphere, keeping the soil about their roots in a healthy state as to moisture. Some dislike to apply water at the root in the case of plants that have hold it until the fruit is perceptible; but this is a mistake, causing loss of time as well as injuring the plants, as unless root action is encouraged, plauts cannot be expected to start freely. If artificial treatment must be resorted to in order to get the plants to fruit at the desired time, there is no method so certain or so little injurious to the plants as keeping them cool and dry for a month, exposing them to as much sunshine as the foliage will bear without scorching, and then affording them a moist warm temperature and a brisk bottom-heat, giving sufficient water at the root to properly moisten the soil. Take off and pot, or plant out suckers at short intervals as they can be obtained of sufficient strength, for having a regular succession of plants is the most likely way to secure a regular supply to give air freely in houses where the ripening of the wood is the object aimed at, and if a little fire heat is used, with air, this will be much more efficacious now
than later in the season, when the sun will be lesa powerfal. Except however in the case of young Vines with a very gross habit it will hardly be necessary to use fire heat if the weather is dry and sunny. Keep the surface of the border in a free open state, so as to encourage evaporation, for keeping the roots too wet is the main cause generally of the wood being backwhere the second crop is ripenisg keep the atmosphere as dry as can couveniently be done, and also let the trees be on the side of dryness at the root, but avoid such a degree of it as would be likely to injure the foliage or the bearing wood for next crop.

The flower garden and shrubbertes.
The stock of cuttings should be carefully looked over to see that nothing has been omitted, and that a sufflcient quantity of everything is in a promising state for making nice stocky plants before winter, and if it is
fouad that the stock of anything is in-uficient not a day fouad that the stock of auything is in-ufficient not a day
must be lost in getting in cuutings. If however there is must be lost in getting in cuttings. If however there is practice where there is a large quantity of bedding stuff required, and proper convenience for growing them and propagating in spring, these will furnish a large quantity of cuttings next March which will form equally good plants by turning out time as cuttings put in now In the case of such things as Ageratunas, Heliotropes, and dwarf Lobelias, it is useless wintering young stock, as these grow so freely in heat and are so easily propagated from soft cuttings that a few good-sized old plants which require but little room or attention in winter will furnish a very large quantity of plants by turning out time. See, however, where there are not plants to furnish spring cuttings, that plenty are got in at once, of being short of stock at turning out time. Attend to the poting of such cuttingsl as are sufficiently rooted, and give every after attention to these in order to get
them well established before winter. Sow hardy annual in the reserve ground for transplanting to assist in fur. nishing an early display next season, for which they ar exceedingly useful. Persevere with mowing and othe outine work, and go over the beds frequently, remor ing dead flowers, \&c., and while the garden is in foll beauty spare no effort to have everything in and about t in the best possible state of keeping.

HARDY Fruit and kitchen garden. Take advantage of dry days to get Celery earthed up,
first thoroughly soaking the lines with manure water, also apply quicklime where slugs are troublesome. 0 heavy soils it is sometimes necessary to surround the plants with sand or sifted ashes to prevent their rotiting off in winter, which they are apt to do if surrounded with soil that holds much water. Where anything of this kind is necessary it will be advisable to defer earthing up till later in the season, as frequent soilings of this sort would be very troublesome. Also pull up Thin young crops of Turnips, Spinach, \&c., before the Thin young crops of Turnips, Spinach, \&c., before they
l,ecome weakly and drawn, through standing too closely together. Stir the surface of the soil deeply amoon growing crops, to admit air to the roots, and keep down weeds. Recently plauted Strawberries will be benefted by liberal applications of manure-water. Get spare ground manured and dug or trenched for another crop
whenever time can be spared for this kind of work.

SATURDAX, AUGUST $30,1856$.
Mr. Boydelu, whose endless railway or slippercarrying locomotive has now for two seasons occupied the attention of agriculturists, supposes that the power of his engine is doubled by gearing it on to the driving-wheel of the machine at the top of its circumference. Our correspondent "G.P. S." has, we believe, exposed the fallacy on which this idea rests by pointing out that the pinion, whose "leaves" pressing against the "cogs" of the driving-wheel convey the power in question, is a part of the machine itself. If it were not connected in this way then, pushing as it does at the end of a diameter o the wheel whose other end, in contact with the ground, is the fulcrum, while the weight to be overcome is the strain upon the draught chain attached to the axle, it is evident that it would have all the advantage contended for it. A force of 10 lbs . where the pinion presses would balance a strain of 20 lbs pulling at the axle: but the pinion is part of the machine itself, and exerts a pressure in its bearings
as well as on the cogs into which it gears. It is just in the position in which a man would be who should push the machine along as he rode upon it by pressure applied at the end of the spokes of the driving wheel. He pushes forward with a thrust of 10 lbs . we will say, but this forward thrust by hand is accompanied by a corresponding backward thrust by foot, if he be-standing, of just as much. The former may indeed be equivalent to a pull of 20 lbs , upon a rope attached to the axle of
the machine, but from this the latter has to be deducted, and thas the apparent gain derived frem the advantageous position of the thrust is destroyed
W. Bo." who contends for all the advantages claimed on this ground by Mr. Boydeli, speaks of the "saving of space which the motor-force gains by translation," i.e., by the forward movement of the machine as it is operating; but apart from any direct attempt to meet the claim pat thas we must remember that the machine has to start before it can be in motion, and the efficiency of the power which it carries must be tested in the first place therefore while it is at rest.

Or all the pests in the shape of weeds by which the farmer is harassed, there is none so mischievous in its effects or so difficult of eradication as the Crow Garlic (Allium vineale); it is, therefore, not surprising that enquiries should be repeatedly made as to the best methods to be adopted in getting nid of it, and as it is in reality one of the exceptional cases that cannot be included in any general weed treatment it is proposed to consider its separate history here.

1. The Crow Garlic is a liliaceous plant, the scape or flower stem of which is as much as from 2 to 3 feet high, rising from a bulb which, especially in non-llowering examples, will be
surrounded by from four to eight smaller bulbe or bulblets. The original intention of the scape is to bear the flowers, of which it would thus present a bear the flowers, of which it would the manner of the Garlic and Onion of our gardens; but it curiously happens that instead of flowers the scape is surmounted by from one to three compacted heads of minute bulbs possessing the structure and characters of those at the base of the plant, and endowed with such a power of vitality as to be in most cases viriparous, that is growing or sending out leaves before they fall from the pareut sten. These are sometimes, but very rarely, mixed with flowers, and as they readily and singly separate from the parent, as its stem becomes dry, so then each little bulb as their mass becomes scattered around is in the condition to take possession of the soil where it falls, which it does like a clove of Garlic, by sending out roots from its base, and thus a whole colony in one season results from a single plant.
The power of propagation possessed by this plant may be gathered from an estimation of three examples collected during the present week, July 1856.

Here then we see that the Crow Garlic if allowed to seed has a prodigious method of increase, and we must recollect that its increase is not, like the majority of weed plants, by seeds which are for the most part agreeable to birds and insects, by which means many much more productive plants are kept in check; on the contrary, it would appear to be avoided by all classes of these creatures, whils the bulbels themselves, which are seldom abortive, possess such wonderful powers of vitality that they may be kept like Onionsor the ordinary flowering bulbs for months and perhaps even years, and still maintain their germinating power. It however fortunately happens that only a tithe of the plants of a season send up flowering heads, as they are liable to be interfered with in their growth in corn, seeds, and the like by the exuberance of the respective crops in which they occur ; but the farmer must be made aware of the important fact that it then increases by bulblets or smaller bulbs which bud out around the larger, and hence we have in the Crow Garlic a pest which, if it matures itself, results in the production of hundreds of others, but, if not, still the original bulb is increased in strength, whilst a colony may insidionsly arise from the bulbel of a former year even though the flowering process has not been brought about

The great anxiety manifested by farmers with respect to the plant under review is easily accounted for, when we consider that its favourite habitat is that of the corn field, and usually the best Wheatproducing land on calcareous formations. Such for example, as the great oolite of the Cotteswolds, and the chalk marl of the Wiltshire hills, are peculiarly liable to it ; indeed, the more plastic soils on these usually light lands are peculiarly liable to it. Its injurious effects, anlike most other weeds, cannot be traced in any considerable degree either to a robbery of plant food from the soil or to its incommoding the plants amongst which it grows by any particular overshadowing, as it seldom grows in such quantity as to affect the crop in either way, and is besides possessed of small fistular leaves with a straight flower-scape, taking up even in its most perfect shape very inconsiderable space. Besides, its herbage even in hay (for it sometimes affects the hay as well as the seed field) possesses but little of the offensive Garlic odour which characterises it in the dried form. Did the plant usually seed, its seeds would be so small as to produce no mischief beyond its power of reproduction, as they could readily be separated from the grain; but it is in the production of its bulbels that its injurious character resides. These are so near the size and weight of a grain of corn that they can be separated from the grain only with the greatest difficulty, and sach is the offensive smell and taste of these which are peculiarly rich in the Garlic odour, that a few pulbels crushed in threshing much injures the sample for the market, whilst if ground with the corn it most effectually damages the flour
3. From these consideratious our third inquiry resolves itself into the two following heads :-
a. The freeing the sample from the bulbels when present in the crop.
b. The eradication of the plant by which the bulblets and bulbels are produced.
a. In any ripe crop where Crow Garlic is known - Throughout this articie the term bulbel is used to axpress the smaller buds, of Which the conginmerated head if composed
buibets, the smaller bulbs which rrow abour the principil bulb
at the bese of the plent, and which are called the smaller cloves of the garden Garlic.
to exist care should be taken in harvesting to handpick it as closely as possible, to which end the best plan we can devise is to have each ridge before taken possession of by the hand reaper or the reaping machine, as the case may be, carefully examined by women or boys, who should precede the reapers. and so carefulily pick out each of the heads of balbels ; this should be done quietly, as if ripe the bulbels will readily become scattered over the ground, and thus he prepared for propagating the evil at a future time ; the plan's so collected should be brought together, not with the notion of rotting for manure, but in order to be burnt, as this precaation, usually the only safe one in the destuction
of weeds in general, is incomparably so in the of weeds in general, is
case of the Crow Garlic.
But with every precaution some of the Garlic heads will escape observation; it will therefore be necessary to overlook every sheaf of Wheat preparatory to threshing.
It however frequtently happens that a sample of Wheat is so foul that these plans, however carefully conducted, are unavailing in preventing an ill flavour to the samples of grain, in which case there is often no safeguard except letting the crop stop in the rick for a period of from two to three years,
when the Garlic cloves, whether in the form of when the Garlic cloves, whether in the form of
bulbels or bulbets, become dried up, in which state they are lighter than the grains, and can then be removed from the sample by winnowing.
b. The avoidance of these processes, which are a constant source of trouble and expense, should be an important object with the farmer, to which end we would recommend the colonies of the Garlic-for they generally grow in clusters where the heavy bulbels fall when undisturbed-to be well overhanled with the fork, and if the bulbs are thus forked up in spring they will then not have made their bulblets, and if caried away to weed or rubbish heaps and burned there will be an effectual stop to the 240 -fold increase which might otherwise be developed.
Later this increase may be prevented by pulling, but by this process the bulhs are almost certain to be left in the soil and then they at once begin throwing out root buds or hulblets, and in increased quantity, when propagation hy bulbels is denied. Sometimes the reapers avoid the plant in their work and then the heads are left slanding, and so the bulbels are scattered under the impression of killing it in the fallows-and it is quite true that much of it is got, together with weeds and Couch, by the barrows in preparing the land for the next crop becoming entangled by the long viviparous growing leaves-but at the same time it should be rementbered that this very operation tends to spread a far greater proportion more evenly over the surface of cession is amply provided for. But as regards that taken off with Couch by harrowing, a practical cantion will not be out of place. We have in our mind's eye a large heap of Couch which was taken from a field greatly infested with Crow Garlic; this Couch * was deposited on a bit of waste ground to rot, a result which ensued; but be it observed the rotten Couch only afforded a soil for the prowth and development of the accompanying Crow Garlic, and at this noment its surface is green with the leaves of unseeded plants, whilst a sprinkling of mature heads enough to sow a large field have reared their tall forms between; and indeed the specimens enumerated in this article were derived rom this source.
Here then we see the curious and unusual powers of propagation of this plant; we have noted its great vitality which, unlike Couch, cannot be destroyed by drought and exposure to the sun, nor even by rotting in a heap: its history teaches us that wherever present it should be rooted out in the best manner that can be devised. Its balbels should never be left to the chance of being scattered abroad, but being collected, all power of vitality should be destroyed by as speedy and effectual a burning as can be performed, for useless indeed will it be to fork out Crow Garlic from one crop if we sow it in the supposed rotted weeds or spread with the manure for its successor.

The following table, being the first contribution to the Agricultural Statistics of 1856, shows in statute acres the extent under Flax in Ireland in 1855 and 1856 , compiled from returns collected by the Constabulary. It is expected that, on the further
revision of the Agricultural Returns of 1856, no revision of the Agricultoral Returns of 1856, no
difference of any importance will be fonnd between the extent of land under Flax here given for the present year, and that which will appear in the more detailed Tables now in course of compilation.

- This Couch consisted of a mixture of the three following

## ON DRYING GRASS ARTIFICIALLY.

A PEW weeks past I was pleased to see the eubject of drying Grass by artificial heat described in your journal. Living as I do in a wet climate, where on the average I think we lose one-third of our hay crops, I have naturally been led to consider how that loss could
be avoided, and amongst other remedies that of artificial be avoi
drying.

I believe that in some localities and under certain conditions, this mode of operation might be conducted without its cost interfering so much as to obviate the advantage to be derived from it.

The land ought to be sufficiently flat, so that the hallage, a main point, might be easily effected, and the meadows situate immediately adjacent to the dryinghouse ; also manure ought to be liberally applied to provide a great quantity of Grass in a small compass, so that the operation be carried on over as limited an area as possible, to assist which, as the work could bo carried on at any season early or late independent of weather, each meadow might be mown twice or even three times. I have no doubt either but that superior fattening qualities might be given to the Grass by the judicious use of certain manures, such as bones, lime, guano, \&c., and that the Grass, undergoing no alteration by the process except being deprived of its moisture, would retain the properties it held in its natural state, and be as useful in fattening animals in the stall in the winter time when meat is dearer, as it is in the field in summer.
The difficulties to be met are the expense of the dryinghouse and apparatus, the cost of the coal, and the carriage of the Grass. The manual labcur required would not be far short of that necescary for saving the crop in the common way, for although a great saving would be accomplished in the diminished labour required to turn and dry it, the gathering, loading, and unloading, would cost much more than that required in maling hay, the carriage would be as four to one, and the loading and unloading, as the pitchfork would raise very small quantities at once, would be increased in the same propartion.
From some experiment mado in a draining pipe drying-shed heated by flues, I found that 20 lb . of hay cut on a rainy day were sufficiently dried in the course of 24 hours at a temperature of $80^{\circ}$ or thereabouts, and that they lost 15 lbs in weight by the operation.
In this shed the draining pipes could be sufficieatly dried for burning in about three days, half a day more with less, according to the weather. The result agreed With what I should naturally have expected, viz., that
the drying of Grass would be accomplished in one-third the drying of Grass would be accomplished in one-third
of the time required to dry clay, the substance being
much more pervious to heat in cousequence of the par ticles being not so iutimately connected.
Clay in the shape of draining pipes when dried ready for the kiln lumes as near as may be one-fifth of its weight in the three days at a temperature of $80^{\circ}$ in the drying shed alluded to above, whilst the Grass lost three-fourthg of its weight, so that I think with a temperature of $120^{\circ}$ it may be safely presumed that the Grass would be sufficiently dried in 12 hours with a heat of $120^{\circ}$.

Now as to the modus operandi. To render the opera-
ion pracisally useful a bulding of large dimensions comparatively speaking would be required, and I should say that it ou_ht to be large enough to admit of a ton of dried Grass being turned out every 24 hours.
Now from experiments I made with a view to ascertain the room required to spread the Grass produced from an acre of ground producing one ton of hay per acre, I found that a superficies of 100 square feet duce $22 \frac{1}{2}$ pounds of dried Grass. On the meadow the crop when spread the second day stood caly 3 inches deep, but on the heated floor, where there would be no evaporation rising from the earth to interfere with the drying process, I conceive 7 inches in depth, as indeed I proved by actual
experiment, would not be too much. I think it would experiment, would not be too much. I think it would probably be found that it would dry spread 8 inches deep; taking the depth, however, at 7 inches, a floor 107 feet long by 30 teet wide would take Grass sufficient to turn out half a ton of dried Grass, whilst a second floor immediately over the first in the same building would take the other half ton, thus drying an acre a day. The lower floor might be conveniently male of the perforated maltsters' tiles reating upon iron rafters, supported on pigeon-hole brickwork; six hot-water pipes, 4 inches diameter, supplied with boiling witer kept in quick circulation, would furnish the heat underneath the quick circ
The building to be 12 feet high to the square, so as to allow of a second Huor of open lattice work of wood being placed above the ground floor with a height of 6 feet 6 inches between the two. The slope of the roof would allow sufficient kead room for the workmen on the upper floor. Four planks 9 inches broad to be placed longitudinally upon the upper floor for the men to tread upon as they turn the Grass. Trap doors in the upper floor to be provided to let down the Grass fresh placed there for 6 hours to be finished on the lower floor. A hay-house or perhaps two, at convenient distances from each other, abutting upon the drying shed at right angles to receive the hay as it becomes dry.

An objection might here be raised that the steam rising from the Grass on the lower floor would moisten that upon the upper, but heat rises to such a degree that this apparent disadvantage would not interfere in practice, at least it does not do so in drying draining pipes, where I find the pipes on the higher shelves of the racks dry twice as fast as those on the lower ones,
though subjected to all the steam rising from the shelves below them.
After the hay harvest was over the building might be usefully devoted to drying corn in the sheaf, and after September the lower floor would make an excellent granary, where corn might be kept 3 feet deep, drying it gently and turning it until it was fit for market.

As to fuel, I believe that half a ton of coal would keep up a temperature of $126^{\circ}$ of heat in a house of these dimensions during the space of 24 hours.

It appears to me that if fire bricks can bear the expense of drying by artificial heat that hay ought to pay for it. By way of comparison-fire bricks are sold here at 30 s. 4 d . per 1000 :-
Coal, labour, digging, hallage, royalty, moulding and
burning ... ... Coal (at
Profits

Now, on the average, hay is sold here at abou 47. The cost would be as follows :-

Rent of land producing 1 ton per acre
Tithes and parochial rates covered by after Grass
Mowing and haymaking, the same as if made in
the field ... ... ... .... ... ...
Half a ton of coal, at the price in this country
may 153 .
Interest on building supposed to cost 5001 ., at 7 per
ecent... to cover wear and tear, and assuming it to
cent... to cover wear
dry 60 tons a year
Profits
2192

One intelligent agriculturist auggested to me that the Grass might be only three parts dried by fire-heat, and that the remainder of the moisture should be expelled by heating in the rick; but inasmuch as I conceive the superior quality of dried Grass to common hay due to its undergoing no change but that caused by the expul sion of its moisture, I consider heating in the rick inadmissible. Agricola.

## POTATO DISEASE

The Potato epidemic which contrary to all precedent has been Jate in its general attack, indeed some week later than it has been accustomed to be in even yean has since the thunderstorms of the 14 th and 15 th " brought up its lee way with a wet sail." The leave are blackening rapidly everywhere, and there already much appearance of disease in the the crop
and the nearly full growth of it, we have every reason to expect a very great plenty of Potatoes this year,
indeed confidence has so returned in them that conacres of them have again become common and this alone has been enough to expand their production. The thunderstorms were accompanied and followed by heasy and continued rain, and, so far, Mr. Rumball's
dream of electric influence has been read. He has however been so ably and cleverly refuted by "A Student of Nature" in the Ohronicle of the 16 th that it is scarcely worth saying more about it; on this side of the water by the despised peasantry of the country for a very long time and even by many more enlightened men, indeed it is the general
belief that lightning is the cause of the disease, although belief that l.ghtning is the cause of the disease, although beofore in this destructive way. But we have other and even stranger theories very confidently put forth here; some persons have found, no doubt in favourable
situations for them, slugs and snails, not some but numerous, legions, infesting the diseased Potato leaves, hence they are the cause. Indeed nothing has given so much room for imagination in supposed causes as this
Potato blight, and yet there does appear a very simple and effective one, and often asserted in the Chronicle, in a pest that not only prevails with our Potatoes but extends its baneful influence over every product of the earth, a simple vegetable parasite sufficient to produce all the phenomena which the Potato exhibits.
Very shortly after the appearance of the desolating Potato disease unmistakeable mildew seized upon almost every green thing; the Currants of Zante were destroyed, garden products suffered from it, the very Hawthornis of ur hedges escaped not, indeed it has been a veritable period of mildew throughout the world. In Ireland, under our moist climate, Wheat suffered so severely by Hopes, in the most promising crops, were so much blighted that only bushels were reaped where quarters were expected; the rust was so heavy on it that in going through it one was covered as thickly with a red powder as a miller is with a white one. The general confidence has for the last two or three years been restored, not only in the Potato, but in the Wheat, the tillage of which has therefore also progressively increased to a very great extent.
"If," says Mr. Rumball after a thunderstorm, " the weather continue damp, the tubers become extensively affected; if hot and dry, as now, then only a few are
touched." Did it never occur to him to remark whether touched. Did it never occur to him to remarl whether
such were not the case in damp weather, whether there such were not the case in damp weather, whether there
were a thuiderstorm or not. Very generally a thunderstorm is preceded by hot dry weather, which is unfavourable to the spread of mildew; if no rain attends or follows the thunderstorm the growth of mildew is
still stayed, if it is attended or followed by rain the mildew spreads rapidly, supposing it to be the period of its attack, for the weather in such case is most favourable for its rank growth, and then also most other vegetable products also feel the same influences and become subject to its attacks. The present year very strongly exemplifies this: the hot dry weather which prevailed this summer at the time that, according to all precedents, the Potatoes ought to have felt the effects of mildew, so checked and delayed its growth that it made no senaible appearance till the storms occurred and the growth been most rapid among the Potatoes, but the Peas are also covered with it, which were not before affected. If, according to Mr. Rumball, "the immediate canse of the Potato disease is electricily acting upon the wet tabers, the rain ought to precede the electric shock, and the tubers ought to be affected for long before the electric stormes, even in dry weather, the leaves become slightly affected, so long before that a fow blackened leaves are, I believe I may say invariably, seen a month cr more before general observation detects the visitation, and very long before the mildew
spreads; the fact is it exists apparently irrespective of spreads; the fact is it exists apparently irrespective of
the state of the atmosphere, and certainly some time before the tubers become diseased.
With respect to our Irish discovery, the slugs or snails naturally infest sheltered and moist places, which all the arguments urged by the agriculturist of the Esher model sehool in favour of his slugs or snails are equally cogent with mildew, each deprives the plant of its juices and causes death in the parts that have been so deprived-both are parasites-but I think the mildewed edge that borders the blackened spot of the leaf is a very decided proof of the presence and action
of the vegetable parasite. I would call the attention of those who doubt the disease being a mildew to this indication :-the under side of the blackened part of a leaf of the Potato plant is found edged to the breadth of perhaps half an inch with a white mildew; it would I think appear patent to any one that the death of the blackened part has been caused by the drinking up of its juices by this fungus, the precursor of its death.
The life of leaves is destroyed by many accidents, and, where a black leaf appears, the cry of Potato disease is raised, but unless the mildew edge is seen I am ever slow to attrinure it to our fell foe. It is rather curions,
made by a Longford man who is a sincere has been the slug or snail mand who is a sincere believer in nator of it years ago; he has opened some of these delicate insects with his penknife and found them fully charged with the green (juice of) Potato foliage they had so lately devoured; bad he opened a eaterpillar he fuid it have found it "fully charged" with the gree J. M. Goodiff.

ON THE SOCALLED TRANSFORMATION OF eGILOPS OVATA INTO WHEAT
When a fer years ago the late M. Dunal introduced Agde, respecting the socalled transformation of Fabre at Agde, respecting the so-called transformation of Legiops
ovata into Wheat, the greas body of European which found the most adherents in England, implicitly believed in the exact letter of M. Fabre's conclusion li.e, What hy a successiul cultivation alone a mere weed which, found the most in Germany and France, rejected which, found the most in Germany and France, rejected M. Fabre's conclusions and endeavoured to explain the
change that had evidently taken place, by assuming that it had been brought about by crossing \&gilops ovata with Wheat, a process by which, if repeated, any hybric would ultimately revert to its parent stock, as is the case for instance in a mule, which in the course of a few generations will, by means of crossing, become either a donkey or a horse. Although I have had no opportunity of mating any experiments with the plants alluded to, I to assist the good cause by reprinting in the botanical periodical edited by me (The Bonplandia) all the which liad appeared German arries and pamphet as were best calculated to keep the subject alive, and guard it from being disposed of by weak and illogical arguments. Being so much interested in this question I was agreeably surprised on hearing some weeks ago that one of Prof. Henslow's Egilops plants had pro Henslow's flants were so hybrids, but only well-grown specimens of 㢈ilops ovata, it was likely to be demonstrated by this "sport" that the views of M. Fabre, quently those of the other party incorrect. Like many others I have ever since then looked forward with great interest to the publication of Professor Henslow's
report on his singular production, and my interest has if possible been heightened since the receipt of a letter from St. Petersburg, dated July 15 th, $185 t$, in which
my esteemed friend Dr. Regel, the director of the Imperial Botanical Gardens of that place, informs me that he has succeeded in answering the Egilops question, not ex cathedra, but by experiment, and that his own only take place by a repeated process of hybridization) have been confirmed. I have produced this letter in ectenso in the "Bonplandia," vol. iv., p. 243 , and will Dr. Regel justice, I must preface with the remark that it was he, who, long ere Godron published to the same effect, started in his "Gartenflora" the hypothesis, now confirmed by his experimests, and that to him belong whatever merits or demerits it may have.
The following is the abstract alluded to :-"St. Petersburg, July 15th, 1856. My experiments, made during the last few years of fecundizing Egilops ovata
with the pollen of Wheat have been successful ; the hybrid iteelf now stands before me. There is nothing of a gradual transition from one plant into the other, but we have obtained at onee from the seeds of Kgilops ovata a plant which shows a much greater resemblance
to Wheat than to Ægilops. The individuals to Wheat than to Ngilops. The individuals raised (about 10) do not differ in the least from each other, all are perfectly alike. The thin prostrate stems have changed into strong robust ones, which, though they may still i.e prostrate at the base, soon become rigid, erect, and $1 \frac{1}{2}$ to 2 feet high, bearing an ear from $1 \frac{1}{2}$ to 2 inches long, which resembles more that of Wheat than that of Egilops. In the few instances in which I have succeeded in raising a hybrid between two genera, the hybrid always bore the generic type of the plant en the hybrid, Egilops triticoides, is really no Egilops but a Triticum; for its glumes and palew are not, as in the glomes, whichencompass each spikelet, terminate in 2-4 ariste, and have equally thiek parallel veins Moreover these glumes quite envelope the spikelet, which consists of two perfect and one imperfect florets. In Triticum vulgare these two glumes are laterally carinate on the bacis, have unequally thick veins, are
pointed, or terminate a little below the apex in a mucro or a long arista. (For the process of fecundation the beardless form of Wheat was selected.) These glumes are placed at the base of a spikelet with three or more florets, which they do not quite envelope. The hybrid produced by the two plants bears a spikelet with from three to five florets, our the base of which are two glumes which only sarround the spikelet when it is young; but afterwards not at an. On the back we through which they end in an arista, much shorter than the glumes themselves. The tendency which the hybrid shows to EEgilopg consists in the numerous veins of the
gl
w
p
is
lo
a
ar
th
to
glumes running parallel with the keel, and one or two o palere is in Kgilopa not unlike the clumes ; in Wheat it is either obtuse or, in the bearded forms, and ends in a long arista; on the back it is carinated. The hybrid ha a lower palea carinated at the back and ending in an rista many times shorter than the paleze; moreover tooth.
"From this description it will be seen that myjexperio ment has confirmed that Egilops triticoides is a hybrid between Egilops ovata and the Wheat, and that the concusions respecting the transition of the two plant which I deduced from analogous cases have proved correct. Opposed to them are reports of other ransition forms between the hybrid and the two parental lants, leading us to the consideration of three questions in.: whether there are really any other trasition frms ? whether, if there are, they have been produced by a returning of the hybrid to one of its parents ? or Whether they have to be explained by a repeated fecundation of the bybrid with one of its parents ? have already declared in favour of the iatter view, it is troe myself have not seen these later transition-forms, but have also no reason to doubt their existence. That hybrid, when it is a perennial plant, cannot return to ts parents by esexual propagation we know from ex perience, but it is different with the sexual propaga ion, where experiments with newly raised hybride ertile even in their pollen, must decide and cm only prove the question. Experiments to tha effeet have yet to be made. I know from personal experience only one instance of the latter. Respecting our hy brid between the Wheat and Egilopa I have ie
 Egilops, and again some with the common bearded heat. How far these experiments may succeed the future will show. In other respects we have still to onver a question mooted by Dr. Lindley in the started by Dr. Klotzsch, expressed the opinion that is Egilops triticoides had fertile pollen it would prove that Egilops ovata and Triticum vulgare were extrem frms of one species. But this view does $n$ since my hybrid has pol'en, which is entirely sterine The question, therefore, whether Egilops triticoides is thus answered in the affirmative; we have, however, till to learn whether our plant may not fecundate itsel by means of its own pollen. This latter question no theory, only experience, can decide. $E d$. Regel."
Since the above was writen, I have seen in the Athenceum a brief abstract of Prof. Henslow's paper on the Exilops question read before the British A ssociation Cheltenham, in which it is stated that Prof. Henslow had so far succeeded in changing the character of Etgilops ovata as to lead him to conclude that M. Fabre's original statement, that it was the origin of the domestic Wheat (Triticum sativum) was not altogether without foundation. He exhibited specimens, in which the form of Ægilops ovata had undergone considerable change; but he had not yet succeeded in obtaining will reader great service to systematic botany if h ill ${ }^{2}$ g cone hithero, viz, to by means of cultivation to the rank of Wheat, though he may only obtain, as I have little doubt he will, positive fact by a negative result. Berthold Seenann
We believe the plant which was the subjeet of Prof. Henslow's experiments was $\mathbb{E}$. squarroma, not ovata.]

ANSWERS TO AGRICULTURAL QUESTIONS.
By Mr. Hena
In your Paper of July 5 you invite answers to the questions put by the Society of Arts. The farm to which Wherer Beand the presumption the Wheat and Beand. I start on the prosumptona he farm is in good heart and properly drained, and the larm buildings in good repair and nesrly centra, and land is much more expensive to manage than when it approaches nearer to a level.

## farm practice.

In answering the following quesicis manasement of farm, you will make your replies throughont consibtent with
the scheme of culturation which you lis down for yourself in the first of them. The farm in question is 320 acres in
extent-70 acres being in meadow-land and pasture; the soil
is an adhesive losis extent-7 acres being in its quality may be indicated by its
is an ahesive loom, and
rent and rates, which amount in all to 22 , 5 , per acre. Stato the mode in which you will erop this farm, supposing acreage under the several crops your name-and bening in $\operatorname{mind}$ (in ruference to jour cir
requirements of your live stock may be
I would, for the sake of round numbers, cut off 1 acres of the arable land lying pearest the standing, and apply it to grow Italian Rye-grass, Rye, Potatoes, way of experiment. We should then have six equal proportions of 40 acres each-
Two portions, or 80 aeres, wonld be Wheat.
One portion, or 40 seres, would be Benns.
One portion, or 40 scres, would be Mengel Wurzel, Smeden , One portion, or 40 acres, would be bechover.
We should then have Wheat twice in six years ; Oats, Clover, and Beans, once in six years; Mangel Wurzel
once in 12 years; and Vetehes and Turnips onee in

12 yearso Then I would shift in every rotation the
Mangel Wurzel on to the Turnip land of the preceding six years, and vice versd. I would endeavour to manure every other year in some way; thus I would use a small portion of farm-yard manure, and 2 to 3 cwt . saperphosphate, wha a helle salt, for the root or fallow crop; a fair dressing of dresm-yard manure alone for ashes or screened earth, as a top-dressing for the Clover ashop. We should then have bone earth once in six years, and guano ouce in six years. Perhaps you will say, why grow Oats on this land at all? I have many reasons. rotation. 2d, They may be sown in spring, and there fore more equally divide the labour, because it will no always be convenient to get all the roots off the fallow land in time for Wheat. 3d, Oat straw is capital fodder, and Oats will be required in rather large quantities for feeding the farm horses, \&c. Certainly, in a tine of scarcity, and when Wheat brings such prices as the last two years, there may be a deviation in its favour, but on an average of years I should consider it right to admit Oats into the rotation. So mucla depends on seasons a regards the requirements of stock food, that I think this question a difficult one; but suppose we set down as an 15 tons per acre. I am fully aware that very much larger crops have been produced, but I think this is quite as much as we can consider an average, taking seasons into consideration, and likewise the fact that we must begin with the Clovers, Vetches, Rye and Talian we shall have much of it spoiled before it is half housed.

The Rye and Rye and Vetches would be off in time for Vetches (early) would be off in time for Yellow Turnips, and come between the first and second cut of Clover; an the late Vetches would be off in time for White Tarnips, and would serve to help out with the young Clover of the second cutting. This would serve the horses and about 30 head of cattle, with the addition of a little dry food, from the middle of April till the end of September.

State the quantity of seed you will need upon the farm for
each of the crops you grow,

| Seeds. |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Potatoes |  | ... | 3 | " | 30 |  |  | 90 | " | Estimate the produce of the farm in bnshels of the several

seed crops grown: and state the sura foin will realise for each
according to what you consider an ordinary price for each per bushel.
80 acres Wheat, 30 bushels per scre, 2400
40 acres Beans, 32 bushels per acre, 1280 bushels ...fis 5ited
Sis. 90
Say how many horses you will need to work the farm, and name the operations in which they will be engaged during
If the farm is clean, level, and convenient to the steading, I could work it with 7 horses, i. e. 3 pairs and one odd, which would be nearly always engaged in drawing food for horses and cattle, drawing stones to
repair roads, \&c. \&c.; but as stock must be bought for repair roads, \&c. \&ce; but as stock must be bought for
this farm, I should buy annually 4 or 8 yood old working bullocks, say in August. They might help through the Wheat ploughing and sowing if required, and be good for feeding afterwards; this would make us sure of our work being done in fair time. The chief operation in which the horses will be engaged in June is preparing drawing hay from meadow land, and drawing food (green) for live stock. In October (we will suppose the harvest to be finished in September) they will require to be lept with all vigilance preparing the Bean stubbles
for Wheat, and sowing Wheat ou the Clover stubble for Wheat, and sowing Wheat ou the Clover stubble
(which we suppose to be nearly finished ploughing I September); towards the last week, if the Bean stubbles are finished, they may be engaged in drawing n some of the earliest Mangels, as this operation should be finished before the middle of next month, or serious consequences may oceur from frost.
6. Relate the several operations after Wheat luarvest in the

As soon as the Wheat is off I would
grubber or Bentall's broadshare through the Coleman' grubber or Bentall's broadshare through the land, say two or three inches deep; the harrow should follow, and would have it picked off; it might then Jie two or three weeks to allow all seeds to germinate, when the barrow hould be again passed over the ground to kill such as had germinated. As soon as the Wheat sowing is
would give it double ploughing; these two ploughs
other without, the deptl being regulated by circum stances, that is, I would only break a small portion of the subsoil that had not been previously worked This operation finished, in a fortnight opportunity served, I would put through it crossway the Ducie drag or Coleman's scarifier withl chisel points as deep as botls ploughs; this would mix in some degre the under soil with the top without causing sterility for a time. The next operation would be to ridge it up
either with the double breast plough or single plough either with the double breast plough or single plough
going twice in one place; the plough without board should be again passed down bew win and the whole may then lio for frost and air to pulverise till we can find time to draw on the manure, which may be done any time in the winter when the land is in a fit state. 'This I would put in the bouts between the ridges and split the ridge back on it, and the subsoiler should again be passed down the furrows. It will then be fit to remain till April, when if weeds make thei appearance it may be advisable to run the horse hoe up and down the furrows, and a pair of jight harrows the follow crossways. Mangels are very fond of salt therefore if three or four cwt. per acre be ground fine and strewn over the whole before this last operation it will be of much service, not only as food to the plants, but in killing insects, slugs, \&ce. If superphosphate or guano is used, it is best to mix this with the salt before sowing. The double breast plough may again be passed between the ridges lightly, and after a light roller have passed over them with pieces nailed on to mark the spot where the seeds are to be deposited, the seeds may be planted with a dibble at the rate of about five pounds per acre, or they may be deposited with the drill on the top of the ridges. As soon as the plants are fairly up in rows the borse hoe may be put to work between the rows, and men and women to
clean the rows and single the plants, leaving of course clean the rows and single the plants, leaving of course
the best plants in the ridges, after which they will only require a constant attention with horse and hand hoe till October, when they may be drawn aud carted off the land and laid in long narrow heaps well secured with straw or nther protecting material till required for use.
6. Estimate the cost of each of these nperations per acre
and give all the other titems which make up the cost per

The cost per acre of the preceding operations

| Scarifying with Coleman's cultivator |  |  |  |  | ... £0 |  | 2s.6al |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Harrowing two tines | ... |  |  |  | ... 0 | 1 | 1 |
| Double ploughing | ... | ... |  | ... | ... 0 | 2 | 2 |
| Second searifying |  |  |  |  | ... 0 | 2 | 2 |
| Ridging up |  |  |  | $\ldots$ | ... 0 | 2 | 2 |
| Subsoiling between ridges twice |  |  |  | ... | ... 0 | 4 | 4 |
| Filling 15 loads manure |  |  |  | ... | ... | 1 | 13 |
| Hauling ditto |  |  |  |  | ... 0 | 5 | 5 |
| Spreading ditto Covering ditto |  |  |  |  | ... | 1 | 16 |
|  |  |  |  |  | ... 0 | 2 | 20 |
| Horse hoeing and hoeing and again ridging up |  |  |  |  |  |  |  |
| 3 cwt . superphosphats | ... | ... |  | .... | ... 1 |  | 10 |
| 3 cmt . saltDrilling or dibbling |  |  |  | ... | ... 0 |  | 36 |
|  |  |  |  |  | ... 0 |  | 20 |
| 3 horses hoeing between plants |  |  |  | ... | ... |  | 3 |
| Singling and horse hoeing 1st time |  |  |  |  | ... 0 |  | 3 |
| 2 after-hoeings |  |  |  | ... | ... 0 |  | 30 |
| Pulling and filling Drawing home |  |  |  | ... | .. 0 |  |  |
|  |  |  |  |  |  |  |  |
| Stacking and covering with straw |  |  |  |  |  |  |  |

These items must vary much under different circum tances, and it is not to be understood that any person a farm had been overrun with weeds. For instance a farm had been overrun with weeds. For instance
land has fallen in and come under my management that for hand-hoeing alone has cost above 20 s. per acre.
(To be continued.)

## Home Correspondence.

Seed.-"T. G., Clithero," asks if it may not be desirable to get our seed Wheat from America, or to this negatively. Most kinds of seeds, if not all, grown iu warmer climates than our own, certainly degenerate both in point of earliness, healthfulness, and fineness of growth after the first year of planting in this cool climate of ours; and many do so even the first year, though they grow very fine plants and flower well, yet they prove cmly abortive. The Scrivet Runner, for instance, is remarkable for this; two years ago an from America, extraordinarily large and good, far beyond any grown at home, and both being sown side by side and treated in every way alike, the English nearly all but abortire, though they blossomed most profusely, and this was a geueral remark amongst our neighbouring seed growers. After becoming inured, however, to the climate, the next year very little difference was observed. Of some Mazagan Beans from France and some of home growth, planted the same day and treated both alike, the Frenchmen were fit to gather a fortnight before the English; both were left for seed the next jesr, however, both were again sowed together, and no difference in ripening was observed.
This oceurred 30 years ago. Many nurserymen and amateurs no doubt, if they will speak truthfully in the matter, will pronounce it to have been the same with Ten Week Stocks, Balsams, \&c., from abroad. But to be candid however, a contrary effect has been observed when they had been cultivated and brought from cooler climates than our own; they generally then become improved in earliness, quality,
hese remarks apply not only to countries, but even different districts at home from N. to S. or from S . to N We could advise nothing better than to grow ow Wheats and seeds saved from home growth, and from arliest selected stocke, or well cultivared land withou timulants or manure of any kind; although the seed may prove to be somewhat smailer than that raised rom precocities reared by strong manures. All we want from abroad is what we cannot grow and supply at home. This we think requires to be better under stood in commercial trausactions abroad and at home for we may rest assured they are studying their ow interests, and will soon know their business as well ourselves, and we may safely take it for grauted they will require to buy no more of us than their own real necessities require. Let us also study our own interest and maintain our independence as well as we can by growing all we possibly can at home. Hardy and Som Detue; Muldon, Esscx.
Destruction of Wecds in Ireland.-Mr. Donnelly has sent us the following letter. [The pupi's taught a National Schools exceed lialf a million.

## Srr,-We have had the honour of laying hefore the Cons missioners of National Educatinn your letters of the 10t July missioners of National Education your letters of the 10 th July and 18 ith inst., relative to the great importance of the destruction

 of weeds along the sides of highways.We are directed to state in reply, that the Commissioners
cordially approve of the suggestion you have made, that the
chidren attendurg the National Schools should be instructed by
their respective teachers as to the necessity of destryning a il their respective
weeds f(nind on
adjaceut thereto.
The Commissioners will, therefore, have much satisfaction pointing out to their Inspectors the steps necessary to be take or carrying your suggestion into effect

## Agricultural Statistics Office, 5, Henrietta Street, Dublin.

Memoranda on the Breaking lip of Grass Land (Con inued from $p .427$ ). - Let us take 100 acres of land in old pasture, being good meadow or grazing ground of equal value with that already named, which we propose to bring into cultivation. In the first place I believe it is allowe by the majority of good furmers that the best mode o reducing Grass land of nearly every description into arable is by paring and burning. Suffice it to say tha the land ought to be pared with the paring spade in February, as you then have it in readiness to bur as soon as the weather will permit. Of course it an advantage to burn the turf as early as possible, at you then do not lose the season for sowing your seed or corn. I propose to farm this 100 acres on the fou field system, viz., Wheat, roots, Barley, and Clove or Italian Rye-grass. We shall consequently have 25 acres of each of the above mentioned crops. I shall now endeavour to show the probable value of each of these crops, and the cost of producing them. It is impossible to fix in what way your land shall be cropped the first year, so much depends on the nature cropped the first year, so much cipends on the nature
of season. On land of the description I have mentioned we may calculate on growing $4 \frac{1}{2}$ quarters of Wheat pes acre, on an average of years. Of the probable value of this crop per bushel it is rather difficult to calculate but we shall certainly be within bounds in reckoniog at 6s. per bushel. The other corn crop, viz. Barley, w will put at 5 quarters per acre, and allow 32s. pe quarter as its value. I now come to speak of the two remaining crops, namely Routs and Clover. Of the root crop, whether Mangel Wurzel, Swedes, or Carrot are preferred, I do not hesitate to say that 20 tons per acre ought to be produced, and in fact that weight is produced by good farmers from land of the value we have been treating of. And while I am on this subject it may not be out of place to say that certain quantitie of each of the roots I have mentioned should be growith I would propose that half the land should be sown with Swedish Turnips, one quarter to Carrots, and the remaining quarter to Mangel Wurzel ; so that you mas commence feeding your cattle on Swedes which for the first three months are decidedly the best roots, atter wards the Carrots, and lastly the Mangel Wurze, which root if properly stored and not allowed to shoot wil retain the preater portion of its nutritive propertie through the whale pring and even summer. I hav frequently seen ath on this valuable root, and shiving as mus as of the root, and thriving as much as at an weros of corn year. I have spoken of the value of the two crops 25 acres 0 I will now endeavour to frove the value of a 5 . In thu roots to be applied to stall feeding of cattle. Barley doing I will add to the roots the straw of the Barey crop, which shall be eaten by the cattle, and actual ob of the Wheat shall be used as litter. From actual observation I have come to the conclusion that low either of the roots of which I have spoken is sumcie? for an ox per day. Now supposing 25 acres wis is 500 tons, and that the Barley straw of 25 acres sufficient quantity of dry food for a given number
 food will maintain 37 oxen or cows during six montin Lastly, let us consider in what way the remainio field of the course is to be consumed, viz, clove th Italian Rye-grass. Of this crop I propose in stalls or whole of it be mown and consumed by cattle in slan Rye yards. The number of times Clover or Italian on the grass can be cut in the geason depends chieny to say, good or bad managensent of the land. Suffice it to that the same number of cartle can be maintained the remaining mouths on this crop of Clover as fed on the roots and Barley straw. For the sake comparing the relative merits of these two syatem
farming, let us suppose that each animal will pay $1 l$.
per month for feeding, and that under each mode of management the cattle thrive in equal proportions, although I am fully convinced that roots and straw in the winter, and green Clover in the summer, very far exceeds hay alone and Grass alone. E. H.

## גitutcus.

The Journal of the Royal Agricultural Society of England. Vol XVII., Part I.
We refer to this volume now merely to call attention to Dr. Voelcker's valuable report upon the management results of a leugthened chemical research; and the conclusions arrived at are of the greatest possible practical value. In some particulars they are opposed to the generally prevailing opinions on the subject, as will be seen rom the article concludes. the article concludes.

1 Perfectly fresh farmyard manure contains but a small proportion of free ammonia. 2. The nitrogen in fresh dung exists principally in the state of insoluble nitrogenised matters. 3 . The soluble organic and
mineral constituents of dung are much more valuable mineral constituents of dung are much more valuable
fertilisers than the insoluble. Particular care, therefore, should be bestowed upon the preservation of the liquid excrements of animals, and for the same reason the manure should be kept in perfectly waterproof pits, of sufficent capacity to render the setting up of dung heaps in the corner of fields, as much as it is possible, unnecessary. 4. Farmyard manure, eveu in quite a fresh state, contains phosphate of lime, which is much more soluble than has hitherto been suspected. 5. The urine of the horse, cow, and pig, does not contain any appreciable quantity of phosphate of lime, whilst the this raluab fertiliser. The drainings of dungheaps, partly for this reason, are more valuable than the uriue of our domestic animals, and therefore ought to be prevented by all availsble means from running to waste

The most effectual means of preventing loss in fertilising matters is to cart the manure directly on the field whenever circumstances allow this to be done On all soils with a moderate proportion of clay no fea needs to be entertained of raluable fertilising substances needs to be entertained of raluable fertilising substances
becoming wasted if the manure cannot be ploughed in at once. Fresh, and even well-rotten, dung contains very little free ammonia; and since active fermentation and with it the further evolution of free ammonia, is stopped by spreading out the manure on the field, the valuable volatile manuring matters cannot escape into the air by adopting this plan.
"As all soils with a moderate proportion of clay possess in a remarkable degree the power of absorband soluble organic constituents are wasted even by heavy fall of rain. It may, indeed, be questioned whether it is more advisable to plough in the manure at once, or to let it lie for some time on the surface, and to It appears to me a matter of the greatest importance to regulate the application of manure to our fields so that its constituents may become properly diluted and uniformly distributed amongst a large mass of soil. By ploughing in the manure at once, it appears to me, this desirable end cannot be reached so perfectly as by allowing the rain to wash in gradually the manure evenly spread on the surface of the field. by adopting firm my theoretical reasoning the objection could no fonger be maintained that the land is not ready for longer be maintained that the land is not ready for
carting manure on it. I ann much inclined to recomcarting manure on it. I ain much incined to recommend as a general rule : Cart the manure on the fiel, spread it at once, and wait for a favourable opportunity
to plough it in. In the case of clay soils, I have no hesitation to say the manure may be spread even six months before it is ploughed in, without losing any appreciable quantity of manuring matters. I am per-
fectly aware that, on stiff clay land, farmyard manure, fectly aware that, on stiff clay land, farmyard manure,
more especially long dung, when ploughed in before the more especially long dung, when ploughed in before the
frost sets in, exercises a most beneficial action by keepfrost sets in, exercises a most beneficial action by keep-
ing the soil loose and admitting the free access of frost, which pulverises the land-and would therefore by no means recommend to leave the manure spread on the surface without ploughing it in. All I wish to enforce is, that when no other choice is left but either to set up the manure in a heap in a corner of the field, or to spread it on the field, without ploughing it in directly, to adopt the latter plan. In the case of very light sandy soils it may perhaps not be advisable to spread out the manure a long time before it is ploughed in, since such soils do not possess the power of retaining manuring matters in any marked degree. On light sandy soils I would suggest to manure with well-
fermented dung shortly belore the crop intended to be fermented dung
grown is sown.
"8. Well-rotten dung contains likewise little free ammonia, but a very much larger proportion of soluble organic and saline mineral matters than fresh manure. 9 . Rotten dung is richer in nitrogen than fresh. 10 . Weight for weight, rotten dung is more valuable than fresh. 11. In the fermentatiou of dung a very considerable proportion of the organic matters in fresis manure is dissipated into the air in the form of carbonic acid and other gases. 12. Properly regulated, however, the fermentation of dung is not attended with any great loss of nitrogen nor of saline mineral
humic, and other organic acids are formed, as well as decom, which fix the ammonia generated in the 14. During the nitrogenised constituents lime which it contains is rendered more soluble than in fresh manure. 15. In the isterior and heated portions of manure-heaps ammonia is given off; but, on passing into the external and cold layers of dungheaps, the froe ammouia is retained in the heap. 16. Ammonis is not given off from the surface of well-compressed dungheaps, but on turning manure-heaps it is wasted in appreciable quantities. Dungheaps for this reason appreciable quantities. Dungheaps should not be turned more frequeatly than absolutely necessary. 17. No advantage appears to result from carrying on the fermentation of dung too far, but every disadvantage. 18. Farmyard manure becomes deteriorated in value, when lept in heaps exposed to the weather; the more the longer it is kept. 19. The loss in manuring matters, which is incurred in keeping manure-heaps exposed to the weather, is not so much due to the volatilisation of ammonia as to the removal of ammoniacal salts, soluble nitrogenised organic matters, and valuable mineral matters, by the zain which falls in the period during which the manure is kept. 20. If rain is excluded from dung-heaps, or little rain falls at a time, the loss in ammonia is trifling, and no saline matters of course are removed; but, if much rain falls, especially if it descends in heavy showers upon the dungheap, a serious loss in ammonia, soluble organic matters, phosphate of lime, and salts of potash is incurred, and the manure becomes rapidly deteriorated in value, whilst at the same time it is diminished in weight. 21. Well-rotten dung is more readily affected by the deteriorating influence o rain than fresh manure. 22. Practically speaking, all the essentially valuable manuring constituents are preserved by keeping farmyard manure 0 ditar 23. If the animals have been supplied with plenty o litter, fresh dung contains an insufficient quantity of water to induce an active fermentation. In this case fresh dung cannot be properly fermented under cover except water or liquid manure is pumped over the heap from time to time. Where much straw is used in the manufacture of dung, and no provision is made to supply the manure in the pit at any time with the requisite amount of moisture, it may not be advisable to put up a roof over the dung-pit. On the other hand, on farms where there is deficiency of straw, so that the moisture of the excrements of our domestic animals is barely absorbed by the litter, the advantage of erecting a roof over the dung-pit will be found very great. the worst method of making manure is to produce it by animals kept in open yards, since a large proportion and after a fertising matters is wasted wo-thirds of the substance of the manure is wasted, and only one third inferior in quality to $n$ weight of fresh dung is left manure in 25. . manur in heap appearst me that adoped by length in Morton's 'Crelopædia of Agriculture,' under the head of "Manure."

## Notices to Correspondents.

Answers to Agniccetcrale Questrons: We are unable this week to compare and तisclus, as we had proposed, the papers Writers. MEAT: FRS. Tha rpport lately prbilehed gives the Healch. "Snch meat is hebitually oftered for sale" The ficers of ing are among the marks by which it may be known: -Its ing are among the marks by which it may be known:-Its
colour is generally either dingy or too bright; the smell is peculiarly sour and sickening even when such meat is fresh; also soft, flabby, and not set; there is often blnod in the veins, Which has crraled there, and not run out as it does when sound of the paper.]. VALUABLE IMPROVEMENTS IN MOWING MACHINES.
BYROXAL
Letters patent.

Under the Patronage of "Her Majesty Queen Victoria, and His Najesty the Emperor of the French.

## ALEXANDER SIIANKS AND SON,

 ARBROATH, FORFARSHIRE.-PATENTEES.A. SHANKS AND SON, while soliciting the attention of the Nobility, Gentry, and Gardeners to their at the same time respectiuly solich and ROLLING MACMIINES, the conpleteness and superiority of which are now well known around flower beds, \&c., and which has now undergone a trial amply sufficient to enable the Patentees with all confidence to ormart as the cheapest as well as the most efficient and complete machine extant. The improvements effected by the Patentees ennble close to the edge of flower-beds; has great facilities for quick turning, cuttirg and rolling at the same time; the length of the cut can be effectually regulated in a few seconds by merely turning a screw, and being simple as well as complete in its construction durability can be easily worked and managed by a common labourer. The machines are fitted with due regard to strength and superior to and consequentiy not at all liable to get nut of order. The work is exccuted with great rapidity, and in a manner vantly the turf. The Rolling and Mowing Machine is now and Osborne. Illustrated Price Lists forwarded on application.
N.B. A. SuAnks \& Sox finding that their Patented Improvements are pirated, beg to caution the public against purchasing Machines with tbeir improvements without their name and address marked on the Machines.

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACHINES,

SOLE MANUFACTURER, IRON AND WIRE WORKS, NORTH STREET, LEEDS
REGISTERED JULY 24, 1855.-No. 3739.
THE ADVANTAGES OF THESE MACHINES supersede all others by having 1 a small Wheel in front of the Grass Box, consequently will mow verges and round flower beds, Without any chaage of Wheels, or adding the old fashioned Roller, as in others; will also cut either
wet or dry, and by the simple adjustment of a thnmb screw, in front, can be raised or lowered to cut the Grass, any length required; and having two Rollers behind, and a small one in front, they roll the width they cut; they will turn in very little room, and cut at the same time. All the working parts made much stronger than the old machines. The botom Blades are so constructed that they cannot ear up the ground; they are only drawn, and not pushed and drawn as in other machines, one person with ease; the two latter witl a pony or donkey. The three tirst sizes can be worked by

ATURDAY, SEPTEMBER 6, 185
grtivas por the ensuing week

The Adelteration or Food is a suhject which has engaged the attention of a Select Committee of the Ho flow before us. Upon the whole they theire with a difficalt subject as snccessfull ave dell wis been as could have been expected from persons guided not possessing any personal practical knowledge of the matters brought before them. The existenc of adulteration, or what is called so, is stated to prevail widely, not only among articles prepared in this country, but in foreign products before they are imported; and a long list of both classes of articles is enumerated by the Committee. Without disputing the truth of the information collected on this point, we mast observe that it has very much the appearance of exaggeration, including, as it does, articles in which adulteration can scarcely be said to be procsised now, or at least to such an extent as to all for lecislative interference. For instance, the frauds in chicory and tobacco have been rendered so dangerous to the dealers by the vigorous action of the Board of Inland Revenue as to be no longer of mportance.

In dealing with these various adulterations," the Committee say, "it is necessary to distinguish between the pecuniary fraud practised on the public, and the injury to public health. If, as regards the adulteration of articles with substances of cheaper and innocuous character, the mublic derive the full benefit of this cheapness in a lonoer price, it
would be difficult, if not umoise, for the Legislature to interfere, unless it conld do so by requiring that every such article be sold as a mixture, as distinyuished from the article in its pure state. This the aw already requires as to the article of coffee, and also as to the article of bread, which, unless made of Wheat flour alone, must be distinctly marked with the letter ' $M$.' Bat, whenever an article is so adulterated as to involve pecuniary frand or injury to health, it appears to your Committee to be the

This extraordinary paragraph very much shakes our confidence in the judgment of the Committee. According to this, a man is not guilty of fraud if he sells starch for sugar, provided he charges no more than the value of the mixture of the two articles ; thus a pound of sugar being worth $4 d$., and of starch $\frac{1}{2} d$., a grocer who sells his so-called sogar at $2 \frac{1}{4} d$. a pound commits no wrong; and the poor man who cannot tell the one from the other has no claim to legislative protection. There is no fraud, say the Committee in selling a customer what is useless and not wanted, under the pretence of its being useful and what is wanted, provided only the fair market value of the adulteration is charged. So that the shopkeeper who sells rice instead of pepper, only charging the price of rice, does no harm, although he spoils his customers provinons ; and the manare dealer who supplies loam instead of guano commits no wrong. (although he mins his castomers' crops, provided his article is sufficiently low priced. This is surely free trade run mad. It is clear that the Committee are unacquainted with the practical working of these frauds, or they would not have introduced into their report such a sentence as that we have quoted. In their own households the evils of adulteration are scarcely known. Upon such a point they should have taken the opinion of a jury of farmers, gardeners, or artisans, whose good sense would have ensured a verdict that all articles when adulterated involve pecuniary fraud; even after hearing the ingenious Mr. Robrrt Archer Walling ton, solicitor, Leamington, who thiuks it quite proper to sell gelaine under the name of isinglass. Here however two distinctions must be drawn. The first between those thinus whose nature requires them to be mixed with other substances in order to render them fit for commercial purpuses, and such as demand no such preparation. Thus pure Arnotto will not keep, and must be artificially prepared for the parpose of the dairywoman, although Dr. Has all did not know it, till his menorable discom fiture by the Pharmacentical Society. A second ough to be made in those artificial preparations which like marmalades, pickles, and similar articles, have no known composition, but are prepared so as to suit the taste or pocket of the buyer. The Commit tee indeed say that marmalade is adulterated when containing Apples in its compo-ition. Bat what is the meaning of the word marmalade? Some think that Quince marmalade is improved by Oranges, that Orance marmalade is better when made in part from Cranberries or from Apples; that Raspberry marmalade (or jam) is the better for Red Currants. To call such mixtures adulterations is absurd.
To remedy the state of things which to the Committee appears to exist, the Board of Inland Revenue, armed with new powers, would be perfectly competent. The Committee however object to this, on account of its centralising action. What they propose is "to empower municipal or other local or district anthorities to appoint an officer, or officers, who, on complaint made, or in cases of reasonable suspicion, shall procure portions of any article supposed to be adulterated, with a view to their examination or analysis by some duly qualified person appointed for that purpose. On the report of such persons, if it confirm the suspicion of dulteration, a summons shall be issued and the case be investigated before the justices, who shall have power to inflict summary punishment, by fine or imprisonment, in every case where pecuniary fraud or danger to health shall have been proved. The justices should also be empowered to publish the names of offenders."
If it should be practicable to obtain in country places such evidence as would be required to support the informations brought before the justices, we should see no objection to this part of the ecom mendation of the Committee. But the doings lately at Wakefield, at the instigation of amateur chemists, are calculated to throw serions donbt pon the possibility of relying upon local evidence; and unless persons of unquestionable knowledge could be found to support the informations great injustice might be committed. The detection of frauds of this nature is a very delicate matter; chemical investigation and microscopical examin tion may be made o prove anything in the presence of magistrates unacquanted with the difficult sciences to which they belong. Partizan witnesses are moreover able to find or see almost anything they wish to find. So hat prosecutions for fraud require to be conducted with more discretion than is always locally to be secured. It would be the more especially necessary that dealers should be ensured against wrong convictions if justices were to be empowered to publish the names of offenders." For although public exposure would be far more effectaal in suppressing the offences in question than private fines,
yet on the other hand it would be a far more serions wrong if resulting from magisterial mistakes. Such a power might be safely intrusted to a central board, but it is very questionable whether it could be
intrusted to a bench of justices who might beconie intrusted to a bench of justices who misht becone
unconsciously mere instruments of oppression. We have always been of opinion that the exposure of dealers by the so-called sanitary commission of the Lancct was wholly unjustifiable, and deserved severe punishment. No such objection would exist to the power of exposure being placed in the hands of a board like that of the Inland Revenue, which would be free from local prejudices, and above all suspicion as to the fairness of its proceedings
To our minds the adulteration of food forms only a part of the inquiry to which Parliamentary at-
tention might be directed. Frauds of all kinds, quite as serious, surround us; the farmer who is victimised by the rascally guano-mixer; the gardener who is sold a piece of iron hoop under the name of a knife, or a mixture of Poa annua, Cocksfoot, and Cow-grass instead of Poa pratensis, Rye-grass and White Clover; the traveller who gets only half a pint of wine or beer for a pint; and his wife who purchases a mixture of wool and cotton under the name of flannel, or fast-coloured clothes which lose their colour after the first shower, are all alike victims of fraud, and are equally in need of legislative protection. And that being so, it may be doubted whether after all people must not be left to protect themselves.
$W_{\text {F }}$ have just had our attention called to a magnificent specimen of Lilium giganteum-the "Prince of Lilies" as it has been justly styled by Sir Willian Hooker-that has recently flowered in the garden of the Hon. J. Townshend Boscawen, Lamorran Rectory, near Truro, Cornwall. From the drawing and account with which we have been favoured, it would appear to be the finest specimen of the kind that has yet been produced in this country, or perhaps in Europe.
The first knowledge that botanists had of this majestic Lily was derived from a figure and description of it given by its discoverer, Dr. Wallich in his "Tentamen Floræ Nepalensis Illustratæ," printed at Calcutta in 1824; but the honour of introducing it is due to the late Colonel Madden, who sent home seeds of it in 1846 or 1847, and from these, as well as the more recent importations that have been made by Messrs. Veitch and Son of Exeter and Chelsea, we believe all the plants of it now in cultivation originated. The first that Howered in Europe was a plant in the collection of Messrs. Cunningham, Nurserymen, Comely Bank, near Edinburgh, from which a drawing was made in July, 1852, and subsequently published in the Botanical Magazine, fol. 4673. We are there informed on the authority of Colonel Madden that "the plant is common in the damp Kumaon, Gurwhal, and Bushur. It grows in rich black mould, the bulb close to the surface, at from 7500 to 9000 feet above the level of the sea, where it is covered with snow from November to April. The hollow stems are commonly from six to nin
The Lamorran plant, we learn from Mrs. Bo catwen, was one of four which were offsets taken in November, 1854, from a plant that flowered out of doors in July of the same year. The bulb was unprotected through the severe winter of 1854-5, when the thermometer was down as low as $10^{\circ}$ (Fabrenheit) at Truro; and it has also borne the two last trying springs of 1855 and 1856 without protection. With these facts before us there cannot now be any doubt about the hardiness of this noble Lily, and of its being able to endure without injury the usual severity of an English winter, even in places which have not the advantage of possessing the soft and balmy air of a Curnish climate. The height which the flower stem attains in the course of a season is most unusual for any of the Lily tribe. Dr. Wallich's specimen is stated to have been 10 feet high, which was also the height of that of Messrs. Cunningham, the flowering portion at the top measuring 20 inches and bearing 12 flowers. The Lamorran Lily, however, considerably exceeded these, and must 12 feet high with a raceme of 18 large white drooping flowers, somewhat resembling those of the common white Lily, excepting that they had a deep purplish tinge along the inner edge of each division of the perianth. When in perfection they measured five and a half inches across the mouth of the tube, and were no doubt similar to those described by Dr. Wallicr "delightfully fragrant."
We congratulate Mr. Boscawen on the success which has attended his experiment of cultivating this fine plant in the open air, and trust it may be
ng means of induciag him to continue the interest in Cornwall is better adapted for experiments in this way than Lamorran, nor could a more beautiful family of plants have been named for such a purpose than the one Mr. Boscawen has selected. Let us hope that it will not be long before we are made acquainted with the comparative hardiness of other East Indian Lilies, as well as of those lovely kinds from China and Japan with which our gardens were enriched some years ago, and which now form the most attractive ornaments of our conservatories during the latter part of summer and autumn. $\boldsymbol{B}$.

PRACTICAL LESSONS IN BOTANY FOR BEGINNERS OF ALL CLASSES.-No. VII.
By the Rev. J. S. Hengrow, M.A., Rector of Hitcham, Suffolk.
Floral Schedule, column 1 st.-As filling up floral schedules forms a principal feature in these practical lessons, I trust I may be excused if I dilate a little upon be somethope to convert those who fancy there must master, in the meaning and application of the more important words employed in a strictly scientific and efficient botanical terminology.
Number of parts in each Floral. Whorl. - The following examples will suffice to show how the first columns of these schedules should be filled up; and a few comments will explain some of the niceties to which attention may
be directed. be directed.

9, Papaver Rheas; 10, Cleieiranthus Cheiri ; 11, Viola odorata; 12, Lychnis dioica; 13, Hypericum perforatum; 14, Ulex euro-
 rialis perennis; 21, Orc.is maculata, 22, Iris pseudacorus; 23,
Agraphis nutans: 24, Arum maculatum,
When the parts composing a floral-whorl are "free" (not cohering), their number is evident. When they cohere, more or less, their number may generally be readily ascertained by the upper portions of the several parts projecting beyond the lower cohering portions But there are cases in which the cohesion between
some or all is complete, or very nearly so. It is then sometimes difficult, sometimes impossible, to recognise the precise number of parts in a whorl,
without taking into consideration the peculiar without taking into consideration the peculiar laws of defined that "seeing is not always believing" in botany any more than in other sciences.
N.B. "Seeing not beliexing." I cannot refrain from insisting on the better recognition of this important aphorism than the
public generally seem disposed to admit. Some of may remember the manner in which my scepticism was asailed
in the Gardeners' Chronicl ei in the Gardeners Chromicle eight years ago, when I quastioned
the accuracy of those who declare they have seen a mother viper allow her Joung to run down her throat for shelter. I Ihen
asserted that whether such a vision were fact ocular delusion, science required better evidence than had
oitherto been hitherto been produceed, before so remarkeble an an anomanaly could
be admitted as an undeniable marvel. Ail believers in the swailowing thenry were chatlenged to secure an example b whick the fact (if sych it were) might be scientifically demon-
strated by some competent anthority as I amm aware) in which anch opportunity has hitherto ocen (so far
to regard as most prob
Chromicl for 1848 , p. 600 .)

A beginner, in filling up the first column of a floral sched A beginner, in filling up the first column of a floral schedule for
our example 14, the "common Furze," wonld almost certainly our example 14, the "common Furze," would almost certainly
record two sepals to this flower. I should allow him some credit
for his imper for his imperfect observation, and then show him a minute notec at the summit of one, and two notches at the snmmit of the other
divisions of the calyz; this will probably satisfy ling the divisions of the calyx; this will probably satisfy hin that the
number of sepals are really five. This exanuple would further
afford me an afford me an opportunity of stating that five sepals ara
constantly present in flowers constructed on the same plan as those of the "common Furze." Now, as all flower's thus con belong to a very large section (Papilionaceece) of an eztensir
natural order (Lequminoser he will hardy natural order (Leguminoser), he will hardly be again deceived if
some Lupin, with apparently only two sepals, were next offered
to some Lupin, with apparently only two sepals, were next offered
to his inspection. He would at once suppose there must probucu'y be five sepals to its calyx. Close examination would show hinu bo had judged rightly. This ambignity, it may be remarked, is confined to very few such (papilionaceons) fowers; the true number of sepals is sufficiently distinct. There are
certain generalities implied in the structure of the more tant natural groups which soon become impressed impor memory. These serve as checks to imperfect observation wher memory. These serve as checks to imperfect observation wher-
ever tbers may happen to be (apparently or actually) some
deviation from the more ordinary characteristics by which such deriation from the more ordinary characteristics by which such
groups are recognised. To return from this N.B. digression to our 16 exam
schedules.
P. L. (i. c. Perianth Lcaves). -Where a subdivision of the perianth. into calyx and corolla is sufficiently marked (as in Examples 9 to 18) the number of it leaves need not be noticed; since it would only be the
B. In Examples 12, 20 and 24 we have two kids of flowers : one kind to be examined for the stamens and the other kind for the pistils. In 12 and 20 these are on different plants (Dicecious) ; in 24 they are on the same plant (Moncecious). This last example is sure to puzzle beginners, and no wonder, as its real structure was unknown to the great master, Linnæus. It, or some such, may be early introduced for the sale of showing them how to avoid confounding an aggregation of flowers (an inflorcscence) with a single flower, as in the case of composites already noticed, Ex. 8 "Oxeyedaisy."
Mem. From my not having seen a proof of No. 6 a little omis
sion has occurred. The paragraph to the "Willow" should havs been headed Ex. 7\% and that to the "Heads of Flowers" by have connected the words in "Oxeye-daisy" (Chrysanthenum
as this is a generic name, and beginners might be apt to regar it as only a genecies of "Daisy" (Bellis). This sort of confusion
it is not uncommon.
(Tobe continued.)

VEGETABLE PATHOLOGY.-No. CXXXVI.
559. Parasitee (Botrytis. Potato Murrain). It is now so universally acknowledged that the Vine disease is due to the attacks of a parasitic fungus, that there ought to be no difficulty about the reception of the cognate theory as regards the Potato murrain, a theory respecting the justice of which I have never entertained a doubt. The only theory which at the present day can at all compete with it, is that maintained by Schleiden and others, that it is the result of high cultivation, a theory which shall be fairly stated at the end of this article.
560 . In considering the Potato murrain it must be borne in mind that there are two distinct diseases of the Potato, each characterised by the presence of a fungus, which may and often do occur separately, but which may also simultaneously attack the plant. These diseases are distinguished by the Germans under the name of nassefäule and trockenjäule, the wet and dry rot. They are in some respects antagonistic to each other, though both concur in the final destruction of the tubers.
561. The last is called the disease of Martius, from its having been described by him in 1842. It is characterised by the presence in some of its forms of Fusisporium Solani. The affected tubers are traversed tissues to such an y hard, the such an extent that they become excese they hard, so as to require many heavy blows before they give way. The degree of hardness is not always equal, and in some cases, at least in this country, the Fusispormu. taay exist alone on the Potatoes while the tissues are moist. According to the degree of dryness the parasite assumes many distinct forms, and has been described under several generic names. This disease had exised in Germany for many years, and had become so pre the lent at the time when Martius wrote as to maernany a matter of doubt.
562. Just as the disesse of Martius had attained its height another malady, characterised by the more speedy dissolution of the tubers and the presence 0 Botrytis infestans, made its appearance. It was ex tremely destructive in some part of the Unite the Conin 1844, and was noticed in England and on the Cob tinent in that and the preceding year, but in lortance became almost universal, and from the great importance
of the subject attracted general notice, though scarcely
any one anticipated the horrors of the consequent
famine, or the enormous political changes to which it gave rise. The disease in most cases, and with most varieties, commenced in the haulm and leaves. Little patches of Botrytis were observed which soon reduced the tissues with which their mycelium was in contact crops of the Botrytis sprang up like Fairy Rings in a Grass field on the circumference of the exhausted soil. The tissues of the stem were rapidly involved, and finally the more superficial porticns of the tuber. Where there was no superabundant moisture the decay of the tubers was not so rapid as that of the green parts of the plant, but under less favourable circumstance a few hours produced an extraordinary effect, and in some cases which were witnessed by the Goverument Commissioners in Ireland, in four-and-twenty
hours large heaps were reduced to a loathsome putrescent mass. According as the Botvylis existed alone or in cent mass. According as the Botrylis existed alone or in
combination with the Fusisporiunu, the decay under the combination with the Fusisporiunt, the decay under the
least pressure of unpropitious atmospleric influences least pressure of unpropitious atm
xhibited a greater or less intensity.
563. Multitudes of remedies were proposed, but for the most part with very little success, nor is the crop such as to admit of very expensive chemical applications at the cost of additional labour and expenditure. The most effectual, perhaps, was the cutting off of the haulm before the fungus was established. From the low growth, and the occurrence of the fungus principally on the lower surface of the leaf, it is almost impossible to get sulphur fairly in contact with the parasites. Where the air is naturally impregnated with salt, in the neighbourhood of the sea, or artificially with chemical vapours, as dear copper works, the disease has been wholly absent or far less virulent. The whole surface is there accessible, a condition not very easy to realise in practice. There is much reason to suppose that the disease is gradually dying out, though virulent attacks, as at this present moment, have occasionally occurred in almost every district without intermission since its first prevalence.
564. The Schleidenian theory rests on the fact that and partly of proteinous matter in partly of cellulose and partly of proteinous matter in contact with starch, fermentation or chemical change, are easily deranged under any alteration of their normal ingredients. then, an increased dose of nitrogen be taken up from then, an increased dose of nitrogen be taken up from
the soil in consequence of the use of highly nitrogenous manures, the balance as a necessary con sequence is deranged and putrefactive fermentation ensues. The difficulties in the way of this theory are guite as great as in the other, and when ouce the prejudice is removed that fungi can only grow on decaying or decayed vegetable matter, a notion which is opposed by a host of facts, there is little objection Fo be brought against what is commonly called the Fungal theory. The one cause, however, may greatiy aggravate the other, and the cultivator should be instructed that he cannot farm very highly without the prospect of danger. His direction sim be turn and the thorough extirpation of all obnoxious weeds. Under such a system he will insure a good return, and at the same time have a healthy vegetation, while ample work is provided for the labouring ponr, to the general comfort of himself and neighbours.* M.J.B.

NEW GARDEN FERNS.-No. XIII. 24. Gymnogramma pulchella.

Fronds ovate, irregularly ramose, tripinnate or quadripinnate; pinnæ alternate, the lower primary ones unequally ovate-
lanceolate, largest on the posterior side, elongately narrowed franco the broad base, pinnules, all alternate, recondary oned
ovate, about half an incli long, deeply pinnatifid often pinnate
ore below, the ullimate divisions oblong, incibo-lobate, the tinneses spore-cases protruding from the white pulverulous coating
the uoder surface rachis and otipes dark purut
thes laris purple brown.
An elegant Fern introduced from the continental which, however, we lave not seen published. It has some affinity with G. rosea, Desv., of which the G. couspersa,

rue., appears to be a less developed state, but is a larger growing plant, with smaller divisions. It is a stove Fern, and is supposed to be a native of South America, young plants of what were probably the same apecies (which we *Further views on this subject will be found in my article in the first volume of the "Journal of the Horticultural Society of
Iondon, and under the word Potato in "Morton"s Encyclopedia
of Agricalture"
vated $F$ erne), grown a year or two since at the W ellington Nursery, having been obtained from Mr. Linden. The fronds grow 2 feet, perhaps more, in length, and are nearly from whe across the base. Their form is very irregular the race varying size and length of the pinnæ, and from are more finely divided and elezant in cutting than the accompanying figure, otherwise correct, indicates. The fronds are quadripinuate at the base, tripinnate above the secondary pimules being ovate, with their oblong lobes quite separate in the one case, and divided nearly to the midrib in the other ; these ultimate finnules or lobes are themselves inciso-lobste, and their large lobes are generally bifid. The upper surface is of a dull but deepish green, rendered grey by the shedding of the white powder, which thickly clothes the lower surface, and through which the sori, consisting, as in
the allied pulverulent Gymiograms, of but few sporecases, protrude, forming indistinct lines beveath, The stipes and rachides are of a deep purplish brown colour.
It is an elegant slender Fern of considerable size and very graceful arching habit, and grows freely in a stove temperature ; increasing, moreover, readily from the spores.
25. Hymenophyllum dilatatum, Swartz. Lepto clonium soromies, Presl.
Fronds erect, decurved at the points, ovate-acuminate, quitt
smooth, tripinnatifid ; primary divisions ovate-lanceolate; ultismooth, tripinnatifidi ; primary divisions ovate-a anceolate, quitti-
mate segments broaly linear, often elongated or subcaindate mate segments broady linear. often elongated or subcaudate,
dropongm, entire; involucres sunk in the apex of the s. gments ornoping, enire; involucres sunk in the apex of the s. sments
orbicular and somewhat wedge-shaped below, the nalves obtuse
entire recentacles clavate, included ; stipes and rachis green entire ; receptacles clavate, inc
and winged almost to the base,
One of the most beautiful Ferns of New Zealand, where it is very abundant. It also occurs in Lord Auckland's Island, and in Java. The fronds often attain a foot and a half in height, with the ir stipes erect, and their branches gracefully decurved. The fronds consist, as it were, of several series of branchings or forkings of the rachis and veins, these being throughout and as well as the stipas, bordered with a green leafy natifid on each sic. In other words they are tripin deflexed ; their narrow sub-divisions are also tailed, and

these are again branched into short linear lobes. Each of the ultimate segments has a single vein or rib passing along its centre. The fructification is borne towards the apex of the fronds ; the sori situated at the apices of the ultimate lobes, in which the somewhat wedge-shaped base of the involucre is sunk, its free portion being rounded, entire, broader than the segment, and contacle. The fronds are of a deep olivaceous green, aud tacle, the fronds are the a deep oivaceous green, aud
peculiarly smooth, the texture as in others of this peculiarly suooin, ue texture as in others of this evergreen species requiring abundance of atmospheric moisture. T. M.

DEGENERATION OF VARIETIES OF THE pear tree.
Is a variety of the Pear tree capable of degenerating in its vigour, hardiness, and bearing, as well as in the
form, size, and flavour of the fruit? In general we believe that this question may be answered in the negaive, provided always that in propagating the variety by scions on the Pear stock it is planted in a suitable condition as regards soil, climate, and situation. If all these conditions are insured, a variety, whatever it may
be, ought to be reproduced, by budding or grafting, be, ought to be reproduced, by budding or grafting,
with little or no variation from the original type. Some varieties are less subject to vary than others. Some improve, others lose in certain respects. It is important to know correctly the locality in which a new variety has been obtained from seed, and in what favourable situation it has shown itself in full perfection. It is the cullivator can get acquainted with these practical details, unless, indeed, he make very long and expensive experiments for hinself. Let us add some examples to make ourselves better understood. La Fortunée, a seeiling which fruited for the first time in 1829, is a tree of moderate vigour, and bears in the open ground, either as a pyramid or a standard; but the fruit is not larger than a small Bergamot. In a gravelly soil the frut is larger, and ripens earlier, but the flavour is not improved. Worked on Quince at half-standard height, and planted against a wall with a south-west aspect, in a light, free, moist soil, it will produce fruit as large as
the Bergamotte de Paques, or as the Ne Plus Meurisse. $\dagger$ The Beurré d'Hardeupont (Glou Morcean) does not succeed on the best Pear stock in a light deep soil

When cultivated as a standard. Neverthelest the seeu ling tree is stated by many of the amateurs of Mons to D'Harde perfect fruit in the garden of the lat We have seen trees of the soil was of a gravelly nature We have seen trees of it, on the Pear stock, in the old experimental [private] garden of the Messrs. Lee, of Hammersmith, and according to Mr. Salter, the presen possessor, these trees bear well-formed fruit of excellen quality.
The Beurré Diel requires a rather compact but rich soil, and the Passe Colmar, the Poire Legipont or Mer veille de Charneux (the name of a village in the province of Liege), a light deep soil to yield perfect ruit as a standard on the free stock. Planted against o wall these varieties yield fruits more perfect in form but not so high favoured. Against a wall the Beurre Rance becomes enormous, and assumes the Bon Chrétien form; but as a standard, in light, free, and deep soil, the flavour is better.
In general a good variety of Pear raised in a cold climate, or in a cold heary soil, succeeds very well when transplanted into a warmer situation. The fruit raised in a warmer climate than that of England and Belgium does not generally succeed elsewhere than against a wall with a good aspect, like some of the varieties which have been obtained in our latitudes, and varieties which have been obtained in our latitudes, and
which absolutely rezuire the protection of a wall to which absolutely require the protection of a wall to yied fruits perfect in every respect; and further, the
trees must be trained in the form most suitable to them. Worked on the Pear stock certain suriaties must be grown as dwarfs some as half standards, others again as standards. The branches of some may occupy horizontal position, whilst those of others nay diverge at angles more or less acute. It is only on this con dition, all others being observed, that the trees produce iruits perfect in form and flavour, and without being tion anded in any of their characters. The constit cultivate it properly in the open ground, as well a against a wall.
The Easter Beurrét worked on a strong wilding, at 7 feet from the ground, and planted in a free, deep, warm soll, forms long, nearly upright shoots, and bear Bergamot excellent iruits of the form of a shoots being inclined to a more horizontal position, and bears perfect fruit of the Doyenné forms.
These examples will be sufficient to render intelligible my ideas on the necessity of having monographic notices, stating the soil and aspect in which a variety of the Pear ought to be planted in order to produce fruits possessing all their qualities, so that its non-success may not be attributed to degeneration.
Coutrary to a resolution taken in consequence of observations made in the cultures of Van Mons, at Brussels and Louvain, we, about 15 years ago, admitted into our collection about 50 varieties of Pears of French origin, or said to be such. Cultivated as standards, without shelter, 15 successively died off, barren, and suffering from various diseases. Those Which survived were, for the most part, recognised as name had been given. The remainder are still on trial not yet having borne fruit. The Duchesse d'Angoulême has occasionally produced some fruit on the Quince stock, and a few on the Pear stock. -Beurré and Dojenné Gouboult have succeeded better. Belie de Clerc yields Feron soon decay. The only variety, native of Nantes, which has exceeded our expectation, is the Beurré Clairgeau. If I had not received the seedling tree of this variety, which I do not cease to admire, from a reliable source, I should indeed be inclined to believe that it is the result of a seed from our country, and sprung from a race several times regenecountry, and sprung fr
rated in our latitudes.
The varieties of English origin, of which 21 have likewise been introduced in our cultures, present, in peneral, as vigorous an appearance as the varieties of Belgian origin obtained in the end of the last century; but the trees are far from having that fine form and good habit of growth possessed by the varieties lust raised by Van
Mons, to which preference must be given for reasons Mons, to which preference must be given for reasons previously stated. The varieties received from Germany likewise succeed well with us; but, with the varieties of Belgian origin to which new names have been given.
From what has been already stated it will be understood that varieties cultivated in climates analogous to that in which they were raised will, in general, retain suitable soil and treated in a proper manner.
If the canses of degeneration are to be ascertained, they may be sought and found
affinity with use graft.
2. In the use of grafts badly selected, either taken from the lower part of very young trees, or from others weak and affected with various diseases.

4. In a mode of cultivation unsuited to the nature of the variety.
This variety is known in France by the name of Doyenné
ditiver. It was raised in the garden of the Capucing ar Lognt

5. In planting a varyety in soil whech is either
poor and too shallow, or ten heavy, cold and moi-t. 6. In want of attention, in consequence of igno.
of the first eements of a rational mode of culture. With respect to the first three causes, we ha touched upn the principal points connected with them on several occasions in previous articles, and it would fourth, it is evident to every practical man that a formal derree of vi_our, and consequently a good crop, of perfect fruit, can only he obtained by allowing the
tree to take that form which is must in conformity with tree to take that form which is must in con is constantiy
its mode of vegetation. If that form tion restricted by remature pinching or by too severe
pruning, the tree bears a few small, cracked, gritty pruaing, the treemes barren, and is eventually destroyyd. This is nut owing to degeneration, but to a want of still on the part of the cultivator. Nor can we attribute the cause to degeneration, when l,a,l fruit is gathered from a tree planed in a suil which is too strong, compact,
and moist. It is not reasonable to seek from the soil that which it cannot give.

We have seen a plantation of more than 100 Pear trees, comprising about 80 of the best varieties of Pears, an able cultivator. They were all trained in the same an able cuitivator. They were all trained in the same and upon the Quince. Un the 15th of June, $185^{\prime \prime}$, the 100 trees had not 200 P ears on them. The premature
pinching, performed in a season different from the pinching, performed in a season different from the
ordinary run, had caused a disordered vegetation, from which, of course, the treas suffered, and in consequence
of which they were not able to set their fruit. Moreof which they were not able to set their fruit. Moreover, the ground where the trees were planted was
covered with a rather thick layer of horseduns, and this preventing the action of the air and sun upon the soil which covered the ronts, the trees were unalide to profit by the beneficial tffects of the solar rays upon barren, is that result to be attrihuted to the circumbarren, is that resuties treaterl in this way having stance of the variefies treatent in
reached the perind of degeneration?

On visiting lately one of the finest gardens in Belgium, I ohserved that part only of the trees planted against a wall bore fruit. On seeking for the cause of
the sterility, I found it was this-the soil of the burder in front of the wall had been dug to a considerable depth for cropping with vegetables. By this unintelligent operation the fibrous roots, and the sponginles
with which they were furnished, were destroyed. The organs of fructification previnusly formed had produced flowers, but could not set the fruit, or if any did set it mostly dropped. These rrees bore bund had not been dug bore, on the contrary, a large quantity.

It was supposed that the season was unfavourable, and that the trees were bad. The proprietor was even inclined to think that the Pear trees against the wall had no linger the vigour and hardiness requisite for bearing fruit, and attrihuted this bad resul
degeneration of the varieties of the Pear tree.
Between Chelsee and Fulham several plantations of fruit trees, about 50 years old, and of fine appearance may be seen. It may be observed that between these trees vegetables, the culture of which disturbs the fibrous roots near the surface of the soil, and thus renders it impossible for the tres to produce fruit. In fact, When a tree is transplanted hefure the winter solstice
into a lighter snil, it will be found in the monti of March that the ends of the cut roots have formed callosities, and small fibrous ronts. On leaving a tree in is place without $r$ moval it will be seen on the
rising of the sap that the wood-buds along the shoots become fruit spurs, and it is by the action of the fibrous ronts and spongioles that this result is obtained. When
the tap-roots strike downwards, the stem and shoots the tap-roots strike downwards, the stem and shoots
again push upwards; and as long as the fibrous roots at the surface of the soil are not destroyed, and whilst manure suited to the nature of the ground is given at fibrous roots upon the organs of fructification will continue to exercise a favouralle influence on the bearing of trees properly planted and duly attended to.

In conclusion, fruit trees, like all living things, are capable of improvement, either by chance or by the
mind of man, and of reproducing themselves in the mind of man, and of reproducing themselves in the
course of time more or less identical, and more or less perfect, according to circumstances and skilfulness treatment. But as to the opinion that varieties of the time they have been in existence we do not believ in it. J. De Jonghe, Brussels.

## Home Correspondence.

Lindsayon Lichens.-The account you gave of this book (see p. 502) induced me to purchase it. I cannot say that finding it much less well done than it might have been. The author 18 doubtless a learned man, and his book is full interesting and valuable information; but he seems to have no notion of the mode of enabling others to gain the knowledge they seek for. He puts all his plates in the wrong places, and forgets to refer to them from the
main text. He produces fine-looking figures of the minute parts of these plants, but is quite mysterioue as to the manner in which one unskilled in microscopical observation is to find them. He produces a "synopsis"
with a grand dressing of fine words, tut he tells nothing
about the meaning of those words. What is an inexperienced student to make of Gymnocarpi and Angiocarpi, words whose value must be ascertained liefore one step further can he taken? As to how his Usneacte, Cornicu-
lariacte, and all the other acese are to be recoznised lariacte, and all the other accese are to be recozmised
the sy nopsis is dumb. To be sure this last matter is explained as Dr. Lindsay proceeds, hy technical drss, iptions of his acce, but what the reader wants to know is
their diatinclions in the fewtst prssible words. That is what he should have told us, and that being all left out his brok seems to me like a country signuost consulted in a pitel dark night. I can forgive him for the hard little trouble that "corticolous" means urowing on bark, and so on ; but I really cannot excuse his having hept
 perienced student most wants to know, $R_{0} E_{\text {. }}$ have been folli_ed to curtail this letter, which no doubt expresses the sentiments of many reiders. The omissions to which "R. E." alludes have been adverted to hy our
selves, and we do lope that the learned author will selves, and we do linpe that the learned author
adopt the course we formerly presumed to suggest. he does not it is impossible that his volume, with all it merits, can ever become popular.]
Bees are sometimes united without destroying either of the queens ; but as every cause of irritation sinould be ing bees. As to the result of introducing a stranger queen into a hive, Huber made many experiments ; in some instances the stranger was smothered, in others she was permitted to encounter the reigning queen, and the rivals contended for the sovereignty by royal duel in the same manner as the succession to the throne is contested when there is a plurality of princesses. Such of proceeding, however, appears at varianc with the loyalty and devotion of the bees towards queen, once ackuowledged as sucb. Being desirous of testing their fidelity, I introduced a queen into the centre of an observatory hive, which contained a fertile queen. The moment the stranger entered she was seized, prisoner till slie died. Stie was probably suffocated hut not without offering a desperate resistance, as many This scene lasted three hours and a half, during whic time the queen of the hive pursued her ordinary avocations with perfect composure, but the closing act was very remariable. When the stranger becane lial other bees, finding her no longer imprisoned, trembled for the safety of their sovereign, for she was instantly surrounded by a dense mass of bees, and retained in the midst of her faithful guards till the removal of her riva from the hive assured all of her anfety. As the per
fuming the hees with smoke destroys the power of recognition among the workers, it is possible the effect on the queen may be similar, and that her own suijects might not have power to identify her or a strange queen, interestis a nice point which it would be extremely difficult A. Your correspondent "Apiarian" does not need to give himself any trouble about there being two queens in a joined hive; the bees will regulate that for themselves. The following is the method I adopt to swarnss: on the evening of the day that the second swarm is thrown off, and when all the bees are quiet, 1 litt the hive where I intend the bees to remain very carefully off the stand where they have been placed, and putting an imp (rim) on the spot, I take the new swarm, and placing the hive upon the imp, I give it a smart blow, which shakes down all the bees into the imp. I then replace the other hive upon the imp, and united and agreeing well together, unless I have so mismanaged as to shake or disturb the bees in the first hive; if I have done so, they begin to fight with and kill the others, and often the whole swarm is destroyed Of course it must be understood that the second swarm has been hived as soon as it was thrown off. If I wish
to unite two old hives, I stupefy the bees in one hive by to unite two old hives, I stupefy the bees in one hive by means of the large fungus, putting my fumigating box in the bottom of an empty hive, of which the mouth is upwards, and those bees which do not fall down into the empty hive are carefully swept into it with a feather from the combs, as they are removed from the hive then the same process is resorted to as above described for swarms, and the union is complete the next morning if care has been taken not to disturb the other bees, T. G., Clitheroe.

Sulthur--Before the occurrence of the Vine disease gardeners had been in the habit of using sulphur in various forms either as a wash or a furnigating agent but since the period of that attack which reduced the elusters of Grapes upon the open walls to objects of deformity, many have devoted their exclusive attention to means of applying sulphur to the Vines as a certain the ravages of the funges on almost every Vine in and near Croydon, my attention has been aroused to the subject, and having had a very favourable opportunity to experimentise upon two young Vines planted by myseif, I have either prevented or enarely warded off the evil by the use of sulphar in a form now to be described. The levigated stonebrimstone is with greater facility mixed with water
than the common flowers of sulphur, but it is not often met with, and therefore taking any required
quantity of the later it can be rendertd mixable wit water by only trituratiug it with a twentieth part , powdered tragacanth (gum dragom), both dry, alding in that state, by increasing the guantity of water sulphur can be easily and thoroughly mixed and iucorporated with the fluid without one particle of it flosting at the top. Thus, if required, the syringe masy be at the top. Thus, if required, the syringe may be
employed, or the mixture may be laid on the wood as a paste with a painter's brush. My Vines have been so treated in the early part of the year, the old woo and young shoots being covered by the bruth. The sulphur was thus fixed by the tragacanth; and as a
consequence not one symptom of disease has been consequence not one symptom of disease has been observed in either foliage or fruit. On the latter :aim sulphur ouly to obviate adhesion, and every shower ciull then wash it off. Gardeners used to complain that hey could not blend flowers of brimstone with water: I then published the result of my process, and its applicability is certain either in the (inery, plant stove, or to trees on the open wall. Jolen Towers, Croydon.

## 今urleties.

British Association for the Advancement of Science, Aug., 1856.-Section B.-Chemical Scie:ce."On the Products and Composition of Wheat Grain," tained the results of a large number of experiments made by him and Mr. Lawes during a period of several years, upon Wheat grown in this country as well as abroad. Dr. Gilbert subjected the various coarse and fine varieties of flour to analysis, and showed that the nitrogen increased in proportion as the sample was coarser and contained more bran. The flour that contained least nitrogen was that which took up least water in the process of bread-making, and an interesting question arose as to the nutritive value of bread containing much or no bran-Dr. Gilbert's opinion being in favour of the latter, as far as working meu are con cerned, notwithstanding the theoretical higher fact stated by Dr. Gilbert was, that the B'ark Sea Wheat in Eurone and the Southern States Wheat in America were far richer in gluten than those from more northern latitudes, those from Dantzic containing least gluten, while they stood highest among bread-making grain. The character of the gluten stemed dependent in some degree on its oily constituent, and therefore the quality of the bread depends on the maturation of the seed. miglit depend on the state of hydration of the starch and gluten, but was doubtful as to the value assigned to the nutritious qualities of starch, as the French chem'sts proved that the starch was often left undigested.-Dr. Voelcker stated that he had arrived at sinilar experimental conclusions to Dr. Gilbert, but while he acknomledged that starchy bread was mechanically the best, he combated Dr. Gilbert's view, that this was the most wholesome kind of bread for the working man. He traced the phosphoric acid found by Dr. Gilbert in the bran to phosphorus contained as such in the gluten, legumine.

## Section D.-Zoology and Botany, including Pat-

 siology.- Prof. Henslow gave the results of the labours nimals, and Pee on Typical Forms of lists which nimals, and Plants for . Wsenms. The list in the had at present been obtained had been printed inlast volume of the Transactions. They were still inlast volume of the Transactions.
complete, but Prof. Henslow hoped they would be comlete for every department before the next meeting He exhibited some specimens of a new method of mounting, more especially mineral specimens. Th consisted in placing them on a small stand of clas which being at first soft gradually hardened and becam a firm support to the object.-DDr. Wright, of Chelten ham, thought that the lists of objects would have keell nore useful if references to good figures of then. E. Gray known works had been appended.-Dr. J. Eapeciall poke to the importance of local museums, alies of plan necommende that the classes and frecimens from the and animals should be illustrated by specimens fron that ocality in which the museum existed. He luplicate speci local museums might be supplied with dup. Duplicate mens from the government mu-eums. , but these could the Treasury. He made no doubt that by a proper application the duplicate specimens from all nurgoue said ment museums might be obtrined.-Prof. Tennficiently that the labels in our museums were not suffe of communicative. It was not enough that the gamerness, mineral was given. Its composition, colour, specific gravity, and other qualities might be give collec label with as much ease as the name. In all thr teach tions too little attention was paid to making of placing He especially drew attention to the necessical Gardens, London, on those cages where three, four, even more species of animals are kept. A mere evel under these circumstances was no guide, Bell exmischievous where it was a wrong one.-Prors bums for pressed his conviction of the importance of nus one had the purpose of teaching natural science. as Profes50. done so much and so ably on this subject as was Pre Henslow. The Ipswich Museum, of which sum ought to
sident, was a perfect model of what a museum
 the school of this village Prof. Henslow had demonstrated that it was quite possible to teach natural history in combination with other branches of knowledge. account of these interesting experiments had been given by Prof. Henslow in the late numbers of the Gardeners' Chronicle.
"Recent Researches on the Cause of the Fluidity of the Blood," hy Dr. B. W. Richardson. - The
point of Dr. Richardson's researches consisted in point of D. Richardson's researches consisted in stituent of the living blood, and its escape from blood abstracted from the body. The author related a long series of demonstrative experiments, all proving not only that ammonis was present in the blood, but that upon its presence the solubility of the fibrine, and therefore the
fluidity of blood, depended. The peculiarity of this fluidity of blood, depended. The peculiarity of this
demonstration of the cause of the fluidity of the blood is, demonstration on the cause of the fluidity of the blood is,
that it explains the different hypotheses which have previously been offered on this question, and shows in how far these hypotheses have approached or fell short of the truth. In concluding his paper, Dr. Richardson pointed out that ammonia, in combination with carbonic acid gas, is a constant constituent of the air expired in the breath. The presence of ammonia in the animal economy, and its evolution in respiration, was of interest
in that it connected more closely the limit that exists between the animal and vegetable worlds. But the subject was of the greatest importance in relation to the causes, the nature and the treatment of various diseases. Prof. Bell complimented Dr. Richardson on the ver laborious series of experiments by which he had arrived at his conclusions, with regard to the cause of the coagulation of the thood. He had seldom heard of an investigation conducted with more regard to the principles of
sound induction. [The power of ammonia in preserving the fluidity of caoutchoue seems to be counected with he action of the former substance on the blood. Ed. $]$ Dr. Lankester exhithited some water taken from a well
Cirencester. The water from this well had been the at Cirencester. The water from this well had been the
cause of illness in a family which had partaken of it. cause of illness in a family which had partaken of it.
Although at first clear, after standing a little time it exhibited the mycelium of a fungus. This water had been sent to him for examination, and he had been struck with the resemblance of the fungus to that of one which he had found in the well-water of Broad Street,
Golden Square, the drinking of whicl had been undoubtGolden Square, the drinking of whicls had been undoubtedly connected with the outbreak of cholera in that oo have received into it the contents of house drainage. He had now discovered that the well at Cirencester had also received into it a certain amount of house drainings. He related other cases in which fungi appeared in contaminated water. None of the water mentioned exhibited any injurious constituents that could be discovered by chemical analysis. Before chemistry could detect them they had lost their injurious properties, and the microscope alone could realise their presence.
Mr. M. Masters exhibited a specimen of an abnorma growth in a Rosewood tree. The specimen consisted o two root-like organs which had been found in the hollow having descended from the upper part of the cavity in the trunk, and descended and penetrated into the bottom of it. Mr. Masters also exhibited a series of microscopic photographs by Mr. Delves.
Dr. Lankester read a description of a new crustacean Monimia Whiteana, from Mr. S. Bate, of Plymouth also an instance of instinct in a caterpillar from Sir
Thomas Phillips. [The iutroduction of Monimia into Zoology as a generic name might surely have been avoided. It has long been used in Botany. Ed ]

## 敌ctutciay.

The Social History of the People of the Southern Counties of England in past centuries, \&c. By Geo. Roberts. $8 \mathbf{v o}$. Longmans. pp. 572.
In nothing have historians committed a graver error than in supposing that the interest of the world is Kimited to wars, politics, and religion; to the acts o Kings and Emperors, or the violent outbreaks of
popular masses. It is wonderful that the social condipopuar masses. It is wonderful hat should not have more attracted the attention of the antiquary, and that domestic matters, which come home to the feelings of everybody, should have been in a manner passed by
in favour of striking events which, however great in in favour or strisults, cants find no sympathy with the bulk of mankind. Probably no single chapter in the romances of Walter Scott has more strongly interested his readers than that with which Ivanhoe opens, although the personages are no higher than Gurth the swineherd, and Wambs the jester; and the reason we take to be that the former condition of men of that
class is too little known. The present volume of Mr. Roberts is an important contribution to the popular literature of our early social history : it may be doubted indeed whether any volume, since the days of Strutt throws more light upon that of which we know so little and we most especially recommend it to the study o days of Geva, which may "perhaps discover that "the good old English gentleman," are phrases which bear a very different interpretation from what is generally supposed. The thuth that like other people we hav ascended by slow degrees from the lowest depths

Victoria must prefer a pigstye to a palace. It is curions indeed to see how much the practices of our forefathers resembled those of a Red Indian in some respecte, If a $e$ enly in the indispensable propitiation by presents. anythinger or great country bquire was solicited to do Gascong, says Mr. Roberts, "a pottle of wine from Gascony, some broad fish, and shrimpis from the south
coast might prove a courteous offering proper and effective." In like manner when the Mohawks, and Cherokees, and Choctaws were to be propitiated, a botte of rum, half a pound of tobacco, or a string
glass beads were necessary to secure their good will.
Although there is scarcely a subject of domestic interest, from punishing a scold to the laws which regulated dress and expenditure, which is not more or less illustrated in these pages, yet Ruch as concern rural
affairs will most incerest our reade.s. In the matter of affairs will most interest our reade.s. In the matter of Oak timber, for instance, we have some curious parieulars, which explain how it is that the country has gradually become converted from close forest into open arable helds. Its value was extremely small, its use universal and extravaiant. "It is recorded that in an ace " acres of timber were worth in Sussex 21. 13s. 4t, writer of that day complained that "women carry manors and thousands of Oak trees on their necks." In 1545 , in the ancient accounts of the mayors of Lyme, are entries of 20 Okis (Oaks) bought for 6s. $8 d$. ., inr $2 s$., as they stood. Hewing, sawing, and delivery at the sea-side was in addition and cost $4 d$. a day, exclusive of meat and driuk, for which $3 d$. extra was allowed; so that a woodman's day's wages were more than an Oak tree. Altorether, as Mr. Roberts observes these Oaks finally cost (on an average) 29. $5 d$. each, "showing that the expense of carrinse, meat, and
drink, was ninety-fuur times more than the origimal cost." drink, was ninety-fur times more than the original cost. War trees cost the Corporation of Lyme 7. 14s. We are not however to iufer that the price of Oak or other
timber in Dorsetshire was the game all over the kingdom. On the contrary it varied excessively accord ing to locality and other circumstances. Thus:
"The celebrated round table at Windsor was made about the year 1356. The prior of Merton sold from his wood near Reading 52 Oaks for 26. I 3s. 4d., or nt the rate of 10 s .3 d . each. In 1394, 42 Oaks in the park of Combe sold for 9 l .19 s . 1 d ., or 43.8 ? $d$. each while 467 Maples brought 19\%.13s., or 10 d . each. In W oond belonging to there sold for 20 s . Cotham cording to the practice of that and later eras. In the reigu of Edward VI. 200 large trees, 'gnossos arbores, near Drogheda in Ireland, were valued at lifi., i.e 18.7d. each. Most of the houses in narrow streets were constructed of Oak framework, Oak heams, and Oak flooring. The latter were lail lengthways, and not across the floor joists, as in the present day. There was no reiling to the under rooms. The bearas, joists, and flooring were whitewashed. Oak wainscoting, tables, chests, and furniture were universal. Much of this ha been bought up and made its appearance ss an ingre
dient in modern fittings up of rooms affer the old style Very little lime was used. Oak came much cheaper than Ashlar stone. Laths were not in use. The daubers, afterwards plasterers, spread their mortar apon Spear Grass."
The reckless consumption of timber, as thu described, and in iron smelting and chareoal burning did not fail to bring forth its fruits in the shape of scarcity and dearness. We find that "So early as the year 1563 is an item of 40 s 。 in the constable's account of Lewes about preferring a bill for the pre servation of great timber. Wood was becoming scarce in many parts, and the want of if, as there was no sen coal for general use, was much felt. Tusser, like many other writers, took occasion to complain of some grea of wood for fuel, and its immediate bad consequences:-

## Some burreth a lode at a tyme in his ball. <br> Some never leave burning till hurnt they have al <br> Make many poore soules without fier to sit.'

The iron furnaces near the Downs by Brighton had caused timber and wood to be so scarce and dear laa rom 3s. 4 d. a ton it had risen to 138.4 d ; from 25.60 d a e. charoad to $78 . ;$ and from 68.0 . 14. hundred billo or tale wood to 8 s .; and ship board from 168 . the hundred to 50 s. the hundred.". "Apropos of fuel. ditizens of York by his introduction of the domeatic citizens of York by his intruduction of The bellows of the Minster organ liad been there probably from the time of the Anglo-Saxons.
The growing scarcity of fuel-wood by degrees led to he introduction of laws for the protection of timber :The scarcity of fuel, before coai began to be reguarty supplied to the inhabitants of the south-western parts, more than that, fuel for calinary purposes, must hav stimulated the poor to sally out into the fields an supply in an illegal manner their necessities. We are smith, that each woman went
were the regular wood-stealers, hedge-tearers There were the regular to crown all, the pollers of or spoilers of hedges, and, to crown al, the pollers of
trees. Ranulph Hocket was appointed iu 1578 , beside
his ottice of plygerd, "to have aud take all the wowd
from the hedge-earers that they shall bring into the Comb Street from over Gosling's Bridge, and therewith to take their ropes and hooks. Fifteen common wootCalers and spoilers of hedpes were presented by name in 1597. The number is sufficient to account for great an in the neighbourhood, and these trespassers and spoilers acted in defiance of an order in the Court -Hedge-tearing or breaking. - Persons fivund with wood to have two days and one mipht in the cacch house, and during that time to have brown bread and water Second offence. To be set in the stocks two days in the open street, with the wood stolen before them, and one pight in the darls house, with bro"n bread and water. Third offence. - To he whipped about the town, as such persons ought to be who commit peekery and petty larceny. Fum"lo offince.' (Pase torn (uut)." "A precept from the manor of Castle Combe in 1.5.57, against har bouring a hedse-tearer, proves that this hathit prevailed extensively. Preceptum est quoi nullus infra dominium istud hospitat Elenam Otes, neque aliam personam in dominiis suis que frangit sepes vel spolist boscum sub poona foris faciendi domino, xs. In the same nanor, in 1586, it was ordered that the tenants shall put away those uniler them that stelithe woon, breke hedges, or are common scolders, under a penaly witnessed in some parishes in South-east Devon at the decline of spuggling. The 'helps' that is those who were hived to ol . not having siven up nialt wark for bonest lubur, were not having given up night work for habor, were fiinured in the landscape lost its poll or head in the night, and the stump alone remained
These extracts show how full of interest are Mr . Roberts's payes. With one more passage concerning beer we must close the voume :- The invaluable entries in the arclinves of the Scrope family, horus o
the manor of Castle Combe, Wiltshire, ematule us to add the manor of Castle Combe, Wiltshire, emable us to add much to our previous knowledge. These entries of
orders about beer date from so early as 1456 , the reign of Henry VI. The ale-tasters presented Thomas Coke sale for refusing to sell ale to his neighbours while he had some on sale, and even while the $\operatorname{sic} \leq \boldsymbol{n}$, the ale stake] was out. He was fined 4त. In 1461, one Lautroppe was presented for having, contrary to the order brewed three rimes under one display of the siga or ale-stake. For this he harl to pay 6 d . We understand that upon setting out the sign that beer was on sale, the ale-tasters (tastatores cercvisice) proceeded to perform their antice. - his man offended by brewing three times, and only making the usual signal for one brewing. This, had it not been detected, would have enabled him to sell two brewings without the liquor having been tasted by the proper officers, and the public might have had ale sold to them 'not sufficiently mighty of the corn, o wholesome for man's body.' To meet this perhaps growing evil practice, in 1590 ( 22 Eliz.) it was ordered hat innkeeper, common brewer, or typler slaa which shall a ho of the ub, čnâ, xxs. This order was made against the langer of fire, and to prevent tipplers from having the means of condacting these furtive brewings. Here the public good was aimed at. No one was to brewin 140 at the sams time as the churchwardens were bre win the church-ale for the profit of the church, unde
pain of $138.4 d$, nor (A.D. 1464) to lorew or sell till pain of $138.4 d$. ; nor (4.D. 1464) to lorew or sell tild all the ale brewed for the chureh was eatirely sold. This was brewed for the benent of the common fund for the relief of the poor, A.D. 1590. When the Archbishop of Canterbury shonld visit his land at Faring (near W orthing, in sussex, in 127, four gat The or the bes beer were to tee chargen only ld. If bad it was to be staved, and a $\frac{1}{2} d$. or $1 d$. charged for the versel. Th price of beer at Castie Combe in 1464 was, for-

## Best ale, 12 gallons This rose to OUd. in i53z. <br> One thurindole

In the reign of Henry VIII ( 35 th year), Isabella Staneby and another, common brevers at hyme, were presented for brewing ale not highy at corn, but, on the conurary, too wfin measures, for which each was fined $6 d$. (serevis' brassicav' nimis tenue et insalubre et vend' per mens'illicit.') 'The orders for brewers are net afew, no legs than for tipplers, or those who sold tipule or drink. The ale-tasters had an important duty to pertorm. In 1572 it was ordered that none of the ale brusters do from henceforth brue but with fewell, and not with har wood or faggot-wood, upon paiu for every time of so
doing of $5 \%$. 15 is curious that in London the "read of
fire caused a law to be made at an assize of beer in 1212 , that ano baker sbould bake, or ale-wife trew by night, or with reed, straw, or stubble, only of wood."

## Garden Memoranda.

A. J. Doxat's, Ese, Putney Heath.-This is one of the most delightful of the multitude of beautiful suburban residences which now everywhere encompass our metropolis. It is pleasantly situated on high ground in the middle of Putney Heath, and although scarcely
beyond the smoke of London the house is so secluded beyond the smoke of London the house is so secluded
and skilfully gurrounded with shrubs and trees that it and skilfully surrounded with shrubs and trees that it lawn are clumps of Rhododendrons, several nobl specimens of Portugal Laurels, Cedars of Lebanon, and some of the rarer kinds of Conifers, while near the mansion is a charming bed of Petunias edged with variegated Alyssum and a basket of red and white Verbenas, the latter consisting chiefly of the fine variety called Mrs. Ho'ford. In front of the house are some fine old Elms, and surrounding the whole is a double row of Lime irees, between which a cool shady walk offers an agreeable retreat during the heat of summer.
The flower garden, which is small, is cut off from the Lawn ky means of a Laurel fence and a strip of green walk. It contains beds of Verlenas, scarlet and other
Geraniums, and borders of annual and herbaceous plants. Maurandya Barclayana planted out in spring covered a wire trellis beautifully with foliage and flowers, and a ohort distance from it we observed a pretty specimen of Fuchsia corallina. Attached to side of it. At present the greenhouse is gay with Fuchsias, Japan Lilies, and Pelargnniums, which are Kept back in spring by picking off their blossoms so as not to allow them to flower early. By this means they may be had in good condition abont this season long after the early kinds have been cut down. A shelf along the ront was occupied by Fucbsias, the shoots of whicl were trained up the roof, and being beautifully in
flower they had a very gay appearance. On the bask flower they had a very gay appearance. On the baok
wall a large Plumbago capenisis planted in a slate Wall a large Plumbago capensis planted in a slate an elegant lacesground to a fine stageful of plants in front of it. In one of the Vineries was an excellent crop of bout 400 bunches. The other is a later house to which no fire heat is applied, except the weather about this time becomes danp and cold. This house is ventilated at top aud front-in the latter by means of lights swong by their middle on pivots. For many years the crop in considered was induced by opening the front lights from which a strong current of air was admitted among the leaves. He therefore some four years ago tried the effect of keeping them shut ever after the fruit had set and since that time he has never been troubled with that pest. The soil in this locality being only a very thin
stratum overlying gravcl the lawn got cliolefull stratum overlying gravel the lawn got chokefull of
Moss and burnt up in summer. With a view to improve it the turf was taken up and relaid with a layer of blue mari under it, and since that has been done the Moas has disappeared, and now even after the unusual amount of hot weather we have had it looks as green and nice a it could possibly be desired to do.
On the walls of the kitchen garden is a capital cro of Peaches, Nectarines, and Plums. Apricots have also an excellent crop, especially on the Chesnut, a large and comparatively scarce variety which is now ripe. When Figs were wont to be covered here in winter the result was no crop; but during the last two seasons
.when they have received no protection whatever they When they have received no protection whatever they
have borne well. Even on the most exposed side of the wall they are this year covered with fruit. Ridge Cucumbers are here, as in most other places, rendiseased both in top and root, a remarkable circun stance on a soil so dry, warm, and gravelly.
An American Aloe bloomed here magnificently last year in October. The candelabra-like stem still stands green on the plant

## Calendar of Operations.

## PLANT DEPARTMENT

Cosserfatory, \&c.-Lucnlias and other winter flowering things growing in the border must be freely exposed to light and air, in order to get the growth well ripened and to insure a fine di-play of blonm. Also see that all plants are clear of black thrips, for this pest is particularly active at this geason wherever it is allowed to gain a fonting. especially on Luculias and such things as are house for the accommodation of tropical plants, considerable care and attention are necessary t) properly
manage these at this season, as some having completed manaye these at this season, as some haryg completed dry, in order to ripen the wood, while others in free growth requirs to be encouraged with warm:h sud
moisture. If there is no convenience for remuving to a cooler house such things as have made their arowth, these should be placed together at one end of the stove, Keepin: them : paring! supplied with water at the root, and giving air ratherireely, which will generally serve to provent any atteupt at a second growth; and those requiring to be lept warm and moist should also be
placed together at the opposite end of the house, where very littie air shouid be given, using every care to keep Clerodendrons, \&ce, which have done blooming, may be removed to a Vinery where the Grapes are ripe or
ripening, for as these will require very little water, they ripening, for as these will require very little water, they
will not do much mischief in the way of causin damp and their room in the stove will be found very useful for other things. See that everything is free from insects, and keep the foliage of such things as Ixoras, \&cc., clean by washing with a sponge and soapy water when necessary

Pineries.-Take advantage of bright weather while continues to encourage free growth where this is desirable, giving the plants a liberal supply of water at the root, using manure water for such as are moderately well rooted, and keeping the atmosphere warm and moist. Shading will of course be dispensed with by this time-at least it should be, as growing plants will require exposure to all the light possible, in order to See that the succession stock is properly supplied with water at the root, as any neglect in this respect while the weather continues bright would be liable to cause aome of the plants to fruit prematurely. Also keep the atmosphere moist by frequently sprinkling the paths, early in the afternoon, so as to husbaud the solar up as much as possible: be careful, however, in syringin to spare plants in flower, as syringing these over-head would probably cause deformed fruit. Give plants swelling their fruit plenty of clear strong manure water and young plants growing in open beds will enjoy an sccasional soaking of the same. Vineries.- If brigh that is thoroughly ripe and expected to to shade fruit in to hang for a con may may be rather improved by warmth, \&c., some sort soon lose their fresh plump appearance. Give air freely and keep the house as coul and dry as circumstance will admit. Stop laterals in the late house, and keep the foliage reguarly exposed to light, an as to have it to colour should be encouraged with plenty of warmt and air, as Grapes ripened during this fine weather will be very superior in quality, and more likely to hang means late in the season, when there will be artificia tively little sunshine. Keep thrips in check where at all roublesome by repeated fumigations, and use every means " preserve the foliage from red spider. Vines planted his sexson, and which are growing freely, may soo this is discovered to be the case, if it is desirable to ncourage free growth for some time longer, give the the surface roots, but by no meang give it a soaking.

FLOWER GARDEN AND SHRUBBERIES.
That the present month is a favourable time for transplanting large sized shrubs and trees is seldom disputed; nevertheless, it more or less annually bappens that a great amount of this kind of work is put off until so late that the plants have no chance of push drying winds of March: and there are doubtless many of our readers purposing to shift large shrubs and tree this season who have hardly thought of commencing soon as circumstances will admit, and they will find that things shifted during this month will require but littl attention in the way of watering next spring and and spring Also with young things from the nursery turned up as soon as possible, especially in the case of strong adiesive soils, which are quite unfit for plantiog until they have been scme considerable time exposed to the mellowing influence of the sun and air. Give diligent attention to the propagation of bedding out stock, and get cutting that are sufficiently rooted potted off at once, keeping mond untit they become established. established in their pots should be grad time and have got established in their pots should be gradually inured to exposure to the open sir, stopping the shoots to keep them dwarf and stocky. But plants that are not very strong should be shaded from bright sunshine for a few hours in the middle of the day, or placed in a shady situation ou of doors; let them have the benefit of the night dews however if kept under glass, and guard them from cold drying winds if removed from under shelter. If any of the beds appear to be suffering from the want of water, give them a good soaking at once, and see that late Hollyhocks are affurded a liberal supply, which will greatly assist us in prolonging their beauty. We may fron have indications of the near approach o frosty uights, and it will be well to be prepared with be injured by sight trost, such as Heliotroves, \&c., and the varie, readily injured by frost.

HARDY FRUIT AND KITCCHEN GARDEN
Any of the Peach or Nectarine trees which are observed to be growing too freely slould be gone over, stopping all the stronger shoots, and thuse that were treated in this way a few weeks ago should a!so be looked over again, stopping a further portion of the shonts if this appears necessary, to prevent the formation of gross strong wood. Pear, and indeed, all trained fruit trees
should also be gone over, removing all superfuous wood,

80 as to expose the trees to sun and air as fully m pos sible, which will be of service towards getting the fruit
spurs and bearing wood well matured before Where mulching lias been used for Peach and Nectarin. trees, this should be removed at once, if not already done for the fruit is seldom well flavoured if the roots are eas cluded from the action of the sun and air during the period of ripening. See that Strawberries in pots for forcing next season are well cared for, placing them in an opea sunny situation where they will have all the light possible and do not allow them to suffer through the wapt of moisture at the root. Exhausted crops, as Peas, \&ic should be cleared away as soon after they are done with as possible, and the ground manured and trenebed when it will be in readiness for plauting with Cabbage, \&c., and will look fresh and clean if not wanted for immediate planting. Tie up Endive to blanch, and plant out the late crop in a warm sheltered situation. Attend to Tomatoes, keeping the shoots closely stopped in order to prevent useless growth, and expose the trait
fully to the sun, for these are backward generally, and are hardly likely to ripen unless well exposed to the sun, \&ic.

Camelinas: Sub., Cond and imperfect drainage often cause
the buds of these to drop off, and even a scarcity of witer after the buds of these to drop off, and even a scarcity of water after
they are formed will produce the same effect. Another reason Why Camellias drop their buds is leaving too many on the
plant. Some rarieties produce twice as many, as they bave
strength to expand, the consequence of which is if they are not picked off at any early period they will drop off, and those that remain will offen be deformed and small. If, theretore, you Decased Trmber: Templeoque. It is eaten by some Coleopterous insect, probably an Anobium, or Ptinus Fur.

The system of stadies pursued in the College comprises every Eracineerlng, Mining Manufath for the pursaits of Agricaltur and Military, Services, and for the Universities.
Analyses and AEsays of every description are promptly and
accurately exeunted at the College. The terms and other par-
ticher ticulars may he had on application to the Principal.
the . ovesirs a is prepared to make engageraents to deliver in
Che number of Lectures on Agricultura
$\mathbf{M}^{\mathrm{R}}$. MORTON has a few quarters of healthily grown and perfectly rinened Seed to dispose nf. It is of
our sorts: (1), The Whitield Red Straw, and (2), the Fenton-
ooth white Wheats of buther a hite heats of good quality and great productiveness, the
neal shorier strawed than the former.
niter Browick ; and (4), the so-called "Tiney's Success"--both produc-
tive varieties of Red Wheat, the former yielding rather the hnlkier, though at the same time the somewhat coarser produce
of the two. They have all been srown cn a lisht biausly soil in every case it has been a standing crop of bright
straw. Price 60 . per 4 bushels, including the sack
Post-office orders to be made payable at Kingston-on-Thames

## The agricultutal Gasette. SA TUIRDAY, SEPTEMBER 6, 1856.

Evarything connected with so important a plan as Wheat is interesting, and the most trifling observations may lead to investigations of great value We make no apology, therefore, for calling attention to a curious appearance which is presented this year by some of the Wheat which has beea prematurely ripened and not subsequently exposed to wet; at least such is the history of the phenomenon as it has occurred to ourselves. The whole grain, or that portion of it more especially which is near to the embryo, exhibits a pure rosy tint, of different degrees of intensity. On the application of mois ture the tint vanishes entirely. Under the micro scope the tissues sometimes appear entirely un altered, while on other occasions there are abundant threads of mycelium. We are inclined, however, to consider these as accidental, and to attribate the appearance to purely chemical causes. The tint is so precisely like that which proteinous) mat:ers assume when treated with sugar and sulphuric acid, that we cannot help suspecting that it arises from some chemical action between the starch converted partially into sugar and the sulphates contained in the outer coats, upon the gluten contained in the superficial cells. This is indeed mere conjecture, and we throw it out as nothing more, but at least there is nothing improbable about it. The tint, it should be observed, is not confined to a few scattered grains, but exists in a vast proportion of a sample. It is, occurs, or in other words in those which have ripened before their time. If any of our readers have any experience of the pheriomenon, or any better explana tion to offer, we should thankfully receive it. M.J.B.

We must postpone for a week the full publication of the tables containing the agricultural statistics of Sentland, which, thanks to Mr. Maxwell's energy, and the unanimous acquiescence of Scottish agricul turists in his plans, have heen thus early presented to the public. Among the principal facts which they illustrate are the great increase in the extent nader Wheat, 260,000 acres being in Wheat this year, while 168,000 only were in Wheat in 1854 , and the diminished extent under bare fallow, which
is this year only 16,000 , while in 1854 and 1850 it
was 26,000 and 22,000 acres. It appears that the returns have been given by the tenants without a single instance of refusal, a fact which must ultimately affect the opinions of agriculturists in England as to the tendency of such inquiries and such

The value of the Carob Bean, or rather of the pods containing it, as food for cattle, has occupied the attention lately of several of our correspondents, and we are therefore exceedingly oblived to Dr. Voelcker, of the Royal Agricultural College, and to Mr. E. T. Kensineton, his pupil, for valuable information on this subject. The latter writes to us as follows:-

Although cargoes of the Carob Bean have been imported from time to time into Eugland, it would appear that only lately have they become generally known as a useful food for cattle. With the exception of an evidently defective analysis published in 1845, by Professor Johnson, in the Proceedings of the Agricaltaral Chemistry Association of Scotland,' no analysis of the Carob pods appears to have been published. It was therefor suggested to me by Dr. Vorlcerer to ascertain carefully the composition of this article of food. The following are the results obtained:-

"In the foregoing analysis, the large amount of sugar deserves to be especially noticed. It will be seen that in the state in which this food is imported into this conntry it contains more than half its weight of sugar ; in addition to this large amonnt of sugar it contains about 17 per cent. of other respiratory and fat-producing principles, and about 1 per cent. of ready made fat. For these reasons the Carob Bean appears to be especially well adapted for fattening parposes. The amount of flesh-forming constituents, it will be observed, is comparatively
small, and is exceeded in the case of Barley-meal, Oats, and grain in general. This would indicate that it is not so well adapted for young stock or milk cows as more nitroyenous fond would be, since such food, according to Mr. Horsfall's experience, is highly conducive to the abundant secretion of rich milk. The inorganic matters consist principally of alkaline salts, containing a good deal of phosphoric acid.

The Bean pod contains dark brown and extremely hard seeds, which are rejected by the animals. A
direct determination has shown that they constitute about 131 per cent of the whole weight of the Bean as imported into this country. It is of importance to bear this in mind, for the intrinsic value of this food is considerably lowered by this aseless matter. A comparison of the foregoing analysis with the subjoined analysis of Barley-meal would seem to show that there is no saving in using the Locust Bean in preference to Barley-meal :-

"It will be seen that Barley-meal and Locus Beans contain about the same quantity of moisture and indigestible fibre, and that taking together the amount of sugar and other respiratory principles, we have 71 per cent. in Locust Beans and 68 per cent. in Barley-meal. The deficiency in these prin ciples, however, is made up by a larger amount of flesh-forming constituents in the case of Barleymeal. On the whole, therefore, we may say that as far as the theoretical composition of the two articles of food is concerned, both possess about equal value." Our correspondent goes on to say that the deduction on account of the hard indigestible seeds in the pods, being about one-eighth of the whole, is equivalent to about 30 s . per ton, since Locust Beans were bought at Cirencester at the rate of $12 l$. per ton at a time when Barley-meal was about 11l. per ton; and he adds the particulars of an experiment at the College Farm, in which the two foods were tried against one another. Two Scotch ozen were supplied with 4 lbs . of pods and 4 lbs . of Barley-meal each per day, and other two of the same breed and condition with 8 lbs . of pods each per day, and at the end of two months no perceptible difference in the condition of the animals was observed. It would thus appear that the 4 lhs. of Barley-meal produced an equal effect with the 4 lbs of Locust Beans rith
which each animal was suppli-d. Still, however, it is desinahle that a mure extensive senses of prac-
tical feeding experinn-nis should be undertaken before we can arrive at trustworthy conclu ions. And we are exctedingly oblized, therefore, to Dr. Voflerer, and our correspondent, his pupil, for giving such information as will no doubt lead to further tial of this foot. We must add that the
Carob pods can be imported at a much less cont Carob pods can be imported at a much less co-t
than that at which they seem to have been bought at Cirencester.

## SWALLOW HOLES.

The following is extracted from a report on the drainage of a
estate in Yorkshire, writen so long ago as 1844 , by $J$. Baile

 report is isteresturg from its riference at so early a date to
what is still one of the coming object to bearrived at in estate

## REPORT \&

I Have been over the above property in order to advise upon its capability of drainage, and upon any advantage its surface may possess for the collection ob purposes. I will first state a few facts relating to the eological and physical form of soil and surface, with hich my observations have suptlied me, and which have very materially induced the conclusion arrived at The estate comprises 878 acres, 3 roods, 27 perches, an its area is remarkably compaet, having only one ema property, the workhouse, within its boundary (the figure of which is nearly square). The surface is undulatory, mainly inclining with the dip of the strata from the north-west to the snuth-enst corner, intersected lateral valleys, whereby much the ureater part of the land gives its face to the south. The soil itself offers the several varieties for which the millstone grit is remarkable ; the heavy clay alternativg on the surface with a shaly rubble, and composing together four-fifths of the estate, while the remaining one-fitth is peat. The averaging in size 5 acres, and the plantations, though for the most part judiciously disposed, occupy a larger I estimate thistent with the profit due from the land I estimate the quantity of land undrained and requiring under-dra youg that quantity already there are about 100 acres beyond tliat quantity already drained,
though imperfectly, by your late father and the tenants. If we take as peat 120 or 130 acres, we shall leave to the lighter land about 300 acres, Then as to fall surface, I find there is an area of abnut 320 acres which has an inclination favourable to the concentration of its surface and spring waters, but owing to the frequent and sudden change of soil from the tenacinus clay to the porous rubble, 1 doubt if I can assume any data enabling rain thermine how much of militat. against such a profitable conservation of those waters as I am anxious to propose.
of the tenants showed me a very npposite illustration of this sudden change of soil, and the spot upon fields through which the main l have projected would pass.
he upper part of Town field, perhaps for two or three chaing wide under Town field plantation, was a year or two back wet and quaggy, while the remainler
of the field was dry and well fit for the growth of of the field was dry and well fit for the growth of
Barley. In order that the teinant might treat and crop the whole alike, he drained the wet land. The drains were cut southward down the land, equ distant, but instead of conducting their water by a receiving drain into the field-side ditch, he caused holes to be dug in the porous soil, into which he collecter a quantity of wet land to enupty themselves into them, so that in heavy rains they overflowed and swamped the growing whel "was not
[Mr. Denton then goes into details upon the sources of sapply, and the direction of carrying channels by which the drainage and spring water of the estate might be conveyed to the best site upon it for a water power mill.

Thus several small springs at the north-west corner of the estate, which have never been known dry in the it is right I should say that the contour of surface in duces me to think that were an effective drainage adopted on the estate, the water of these springs would be considerably curtailed. I could not even estimate the quantity of water each spring would supply, as the water as soon as emitted was partially absorbed to be again discharged at a lower level.

Much water is now retained by the clay lands, to be exhaled by the atmosphere. Much, very much, is away in surface streames, and much remains stagnant in the peat. The water retained by the first would be callected by under draining; a considerahle part of that
which is received by the stcond would be intercepted that carried off hy the third by division would be re claireed, and that stagnating in the last would be gained by open drainage. Doubtless all the water fallugg on except those which present a porous surface and absorb the rain as it falls, might be concentrated and brouyh to the point selected ; but as these pous porough
alternate with the non-purous, and that tur within such extra expense of cutting the main receivor and makin? the reservoir (beyond the cost of an uniform and effec should be minutely ascertained

I am impelled to urge upon you a further examina cion into the capability of the estate to originate within itself a water power, in considerat on of its rear locality
$t$, Leeds, Bradford, and Otley, the heart of the weaving district; and in consideration of the fact that although distant but seven miles fiom Leeds, the heavy cost o land carriage brings up the price of coals to 12 s. per ton J. Bailey Denton, Gray's Inn, London, Feb. 16, 1844.

## OAE IIUNDRED AND NINE TONS, TEN OH MANGEL WURZEL PER ACRE

The Agricultural Society of Rochelle lately inserted in its Transactions a note in which M. Auguste de kilogrammes per hectare, or upwards of 409 tons of Hangel Wurzel per acre. This account appeared exage erater to the Central Society of Agriculture o the Seine Inférieure, seeing that the most productive and best cultivated soils had never been known and it requested the Society of Rochelle to confirm the above statements. M. de Gasparin was accordingly again consulted respecting his previous
"I know," said he, "in the first place, that the Without however Gascons aire somewhat distrusted Whout however raking notice of the diference of the natural fertility of the soil. From (1000 square métres) 39 perches, 16 yaris, or very nearly a quarter of an acre, a space which I ueually devote to my ex periments, I actually obtained 27 tons, $7 \frac{1}{\frac{1}{c}}$ cwt. ; but attain this result, eight conditions must be fulfilled.

1st. The ground must be deeply trenched. 3d. Tha plants must be $12 \frac{2}{2}$ to 1,3 inches apart, every way. 4 th Irrigation must be resorted to every fortnight when it does not rain. 5th. A hoeing, if nossible, must be mence running to seed must he topped, 7 th. The leaves must not be stripped off, 8th. The crop must no be taken up till the end of November, when vegetation has ceaced.
He then enters into some details relative to these propositions, which we give in full. "1st. The trenching permits the plant to make greater length of root an 2 d . My ground, about a quarter of an acre, is manured with 26 cubie yards of good dung, and 220 lbs of Colz cake. 3d. The seed was sown on a hotbed, under glass, on the first of January ; I planted with plants as thick as the finger in April, when others sow the seeds. This early sowing is essential to success. The roots ha then nine months' growth when I took them up at the end of November ; and as they form a concentric circle every 15 days, they had 18 by that period, or period ; and as the last six waysel sown at the the others the size of the roots was more than doubled 4th. The fibrous roots of the Mangel Wurzel do not spread far. It may therefore be planted rather closely have remarked, in my seed bed, that plants which came up by the side of each other were, notwithstanding heir proximity, as good as the rest. 5th. Irrigation iadispensable with us. Circumstances having prevented me from irrigating in the two last seasons,
the produce in them lias not reached the figur have stated to you. Care however must be taken not to give water in excess, otherwise the roots will be apt to hecome hollow. 6th. Hoeing is necessary atter irrigation, for when the water becomes crusted. Huwever in this close and luxuriant crop the ground is sonn covered by the foliage, and after the third hoeing it is difficult to give a fourth but neither sun nor wind can then dry the roots; and doubtless, under the shade of the leaves, combinations of gases are formel whel accelerate the vegetation the plant. Mangel Wurzel plants which are lrought forwardnoearly, are apt to run to seed, but by cutting back
the stem when it commences to run, the root then grows like the others. 7th. By stripping off the leaves, especially in the dog-days, the growth of the plant is stopped. 8th. Do not take up the roots till November, when regetation has wholly ceased. In October and weather is warm.

In short, to obtain a result like that in question, warm climate, abundance of manure, irriga

If the plants have not 9 months of vegetation heat and moisture, these great ageuts of vegetation re deficient; if a frequently clouded sky renders the sun'srays lessefficacious, doubtless the amount of produce would be different
The figure which I attained, and which appeared extraordinary to the Central Society of the Seine Inférieure, is certainly not the ultimatum. On the banks of the Canal de Saint-Gilles, in the soils that yield so prodigious a vintage, a Mangel Wurzel has been grown which weighed 132 lbs . How many of such would be required to weigh 100 tons ? and can we no study, and afterwards realise the conditions under which
this phenomenon has been produced ? 'There are some persons in Enpland," says II Auguste de Gaaparin, in of Italimn Rise.Grass. The cultivators of Timothy Grass cannot accuunt for this production of 10 tons per aere But when [ see all the care that is given, the showers a liquid manure drainage, and steam coming to the assistance of man, I, for my part, am ston easily con
vinced of the assertions of the English. They have vinced of the assertions of the English. They have
sought for the plant in the extremity of Italy; they have laid und they have united it to the active industry of the north. And we too have our part to play; we will search the tropica we will seize upon thee shoots exceed our underwood in height. The Panicums the Arundos and Echinops will cover our fields, and shall not be long, I hope, in making some interesting communications upon the subject.

ANSWERS TO AGRICULTURAL QUESTIONS.

## Continued from $p .588$ <br> Describe as concisely as you can the culture of Sainfoin and Trifolium incaratua, among forage crops- of the Carrot

sinfoin requires but very little culture, merely to drilled in on a young Barley or Wheat plant in the month of April, at the rate of 3 bushels per acre. Some people mix a little Trefoil with the seed, in order to cut nore forage the following year; but I do not consider a goou practice. saiufon in alk the first year by fter 80 wing, and what we gain in bulk the first year by
 weakerhg in al , forage plant on the Cotswold hills, and few sheep breeders an affurd to be without it. If, however, it is allowed to stay and wear itself out, it is a very long time before die and will again produce it in perfection.-Trifolium incarnatum is an annual plant, and is best sown on firm ground amongst a very clean Wheat stubble in the autumn. In favourable situations it produces an early and excellent forage, but slugs and pigeons are exceed ingly fond of it, and sometimes play sad havoc amongs Carrot to 25 ibse of seed per acre is sufncienc. th the one we set out with, its natural soil being a deep rich sandy 10 . I should cultivate it much in the same way a sand Writh the excep tion of ridging and farm-yard manure. There is no cro know of so fond of guano as the Carrot, and I would ow broadcast 4 to 5 cwt per acre over the land abou a month before sowing, and well harrow it in to preven the escape of ammonia, the seed sha be mixd ind rather damp sand the first week in April, and drille about the second week, about 18 or 20 inches apart. Car should be taken not to cover the seed too deep, or it wil not vegetate freely. If put in with the Suffulk drill th weight should be taken off and a very light roller passe over after, butit is necessary that the ground should be made pretty firm before drilling. A portion of Radis seed would be well drilled with the seed, as it would indicate the rows earlier and render the first hoeing les tedions. There is no crop on which there has been more writing and discussion than the Potato, and ther is no crop more accommodating and more grateful for good management $\qquad$ the Carrot its best home is rich sandy soil ; in it it will luxuriate in all its glory, but it will yield good crops in strong clay, light grave o brown on the twolntter descriptions of soil then it may be planted in Octobe or November, that is, if the tog wave bod quite dry by drainage, but in in the two former descrip tions of soil, then March and April is the proper time plant them. If planted on a large scale the double mould broad plough may open the drills in the sam manner as for receiving the dung. For Swedes Mangel the sets may bedropped in by women or children and by splitting the ridges they are covered; they ma be hoed with the horsehoe and earthed up again with the double broad plough, and when ripe may be dug either with the plough or with the three-prong forb. They should be stored in long narrow heaps to prevent the from fermenting, and a good plan is to cover them with the soil without allowing straw between it and the Potatoes. Many people have said, do not cut yout Potatoes before planting, but since the disease has been prevalent I have been more particular to cut them thil before, and for this reason, that a whole Potato throw up a greater quantity of staks than a cal of consequently there is a denser mass and less chance or air circulating amongst them to seep themury and heald and likewise there is a greater amount of amall tuber atruggling for the nutriment the plant is enabled obtain, and as a matter of course the produce cannot fine I have cultivated them very successfal between rows of Turnius 3 feet apart. The Pola and when up horse-hoed and arthed, and the Turnip geed drilled in in June or Jal. The baulm of the Poratoes dies off about August September, allowing plenty of time for the Turaip swell, and affording some excellent keep in the follow, spring ; and if some of the Potathes chan them gith tie the roots of the Turnips will devour greatest avidity. I have not deviated mach A criculrecommendation in the Journal of the Royal Age-to tural Society at the commencement of the for the air
to circulate about the foliage and plant such variecies as
come early to perfection; by those rules I have not yet come early to perfection; by those rules I have not yet
failed to secure penty of sound and wholesome Potatioes. -The Bean is fond of strong adhesive loam, and will even grow well in clay; it is a very deep feeder, and will penetrate a long distance into the soil ; and before draining became the rule, that is, when very few pieces were drained, it was very nearly the only plant that would thrive on this description of land; but it thrives much better now that it is drained, picking its food in some cases out of the drain irself, and leaving plenty of little pipes to convey air and water through the once impervious subsoil. Its proper place is between two white straw crops, and many instances could be named where Wheat and Beans have followed each other a great number of yeare, and the land has even improved ff so great an amount of excrement as the Bean off so grear an ammen ox This may be good manure for the succeeding Wheat
crop, while it tmay be poison to Legumes, and likewise crop, whe equires very little silica or alkaline salts, and it is very probable that the Bean plant raises more of these salts from the subsoll than it requires, and thus in some dergree assists the Wheat plant, which
requires to be largely furnished with these ingredients. The only culture it would get under the system of manawensent I should pursue on this farm would be, that as soon after harvest as convenient, the Uat stubbles would get a good scarifying with Coleman's calivator, or some other of that class of implements, would draw on 12 or 15 cart-loads of manure, and spread equally over the prece, and plough down with one deep furrow; the only other culture it would get would be a harrowing on two before planting, which should take place in February or beginning of March drills or dibble. I think it a good plan to plant them in doulle rows, leaving a sufficient space for the hurse-hoe to work freely amongst the rows, and by horse and hand-hoeing keep them clean till harvest, when they may be cut and bound with straw bands, and stooked in the eame manner as Wheat, and ricked as convenient--
Oats in the Scotch practice are generally cultivated after old "lay" or two or three years seeds, but on the farm we are treating of $I t^{1}$ ink they should come after roots as I have found Wheat after ronts does not fill well, and is more apt to got blighted. A single ploughing after roots, and deposits with the drill in February or March at the rate of 4 bushels per acre, will yield a first-rate When ; it may be either mown or reaped and stooked as tmosphere than must other grains, and is not so par ticular about soils. It is at home on the bog and peat soils of Ireland and Scotland, as well as on the chalk of tershire, and the brash of the Cotswolds in Gloucesalluvial soils of Worcestershire and Hereford.
8. Say what quantity of purchased inauure may be reasonably
applied during the fear upon the farm, enumerating the
applied during the jear upon the farm,
kinds and stating the application of each.
The purchased manure would be of three kinds. The first of small amount, viz., salt-about 3 tons to the Mangel Wurzel crop. This should be sown broadcas along with the superphosphate of lime os bone earth. I would apply always bone earth with the root crop. As this is a salt that goes to supply the building material of the bones of animals, we are continually losing it from the soil, and this is the only manner in which we can phosphate would cost atout $42 l$., and should be confined to phato woun and contains some phosphate, it is best applied to the Clover crop in April, at the rate of about 2 to 3 cwt . per acre, but it should be previously mixed with double its weight of screened soil or clay ashes to fix the volatile principle of the ammonia. Five tons of guano may be reasouably expended on this farm :6 tons of superphospbate
5 tons of guano

The guano should be applied, if possible, when the glass is falling towards "rain."
9. Give the number and kinds of the several agricultural cost of euch, and say what implements you would have silbstituted tor any on your list had the soil of your farm Common heavy land plough
Double meaky land ploug
Coleman's cultivato plough
Scoth carts with harvest frames:
Clord crus, 3 sets of 3 each, different weights

## racks tor young beasts in yards

4 sets of harmesis

If the land had been light we should have substituted light land ploughs, and the heavy roller for the clent crusher. We should have to get hurdles and racks for sheep feeding on the ground. I have assumed from the rent of the land that there is already a steam engine and threshing machine on the farm ; if not, circumstances should guide us in the outlay ; as portable engines and machines are now very numerous for hire, it may be better to hire than expend a large sum in this way. An efficient apparatus of this sort could not be got mueh under $380 l$. to 4002 ., which would be a great tax on the farmer's capital.
10. Estimate the expenditure in wages on the farm, and name

Wemann to atond hos, $15 s$. per week
Hoeing and thinning 41 acres ronts at 6 ss, per acre

(a), 3s. to $5 \mathrm{~s} . ;(b), 2 s .6 d$. to $3 \mathrm{~s} .6 \mathrm{~d} . ;$ (c), 21s. to 28 s . (d), 2s. 6 d . on light land to 4 s . on strong land. Some of the farmers on the Cotswold Hills pay from 1s. 6 d . to 1 s .8 d ., and give aboui 3 quarts of table beer per acre beides for mowing their crops of mixed Rye-grass and Clover, hut here a man can cut with ease about 2 acres per day. (c), from is. per acre, where the crop is light; on light lands to 118 . or 12s. In the rich alluvial soils I heard of one instance last year thefused,
farmer nffered to give 15 s. per acre and the men ref farmer offered to give $15 s$. per acre and the men refusent, but here the crop was and down in exceedingly bad and twisted condition.
(To be continued.)

## HOME FARM MANAGEMENT.-No. X.

It is obvious, from what has been stated in these etters, that there are so many theoretical principles involved in the conducting and successful carrying out of practical farming that it is necesqualified for their duties, and unite as far as quasible in themselves "practice with science" in its various forms. Example farms are more likely now than at any previnus period to exercise a stimclation and if they are to be exemplary they should be managed an the first principles of the art. But apart altogether
from the example set by judicious home farm
management, there is good reason for alleging that they might be made remunerative if only properly
taken care of. The successful care and treatment of root cros io. The suceessonected in a very intimats way with successful farm management altogether, and here I shall notice the way in which these should be managed on a home farm so as to secure this end. The rotation-whatever it may be-is usually begun by either a naked fallow or a green crop break. In respect to summer fallowing, it may only be said nas be heard of on a hone farm, and if these defects in the soil render it neceseary to prefer a bare fallow to Beans or Turnips in cleansing it, the sooner it is thoroughly drained and permanently improved the better will it be for both the landlord's and the tenant's profit account. In preparing the soil for the varinus species of green crops there are certain modes of culspecies of green crops therem all, and it may be well, ture equally suitable for them all, and
therefore, to treat of the working of the land for these purposes by itself hefore going further.
The first prepayatory op-ration fur the cleansing crop of any year should be undertaken immediately after the harvent of the provious season. On light soils this first work may consist of a thorough grubbing of the stutble land, first up and down, and then across the ridges (stitches or breaks). By using the broad share or grubber drawn by two horses abreast, the soil may be quite easily loosened to the depth of 8 or 10 inches. But on rather strong soils there is no implement in the present state of cur agricultural mechanism equal to the deepsuil swing plough. The way in which the work should be done hy it may be described as fullows. As anon as the crop is removed from the field if other circumstances are favourable-and while the ground is yet comparatively dry, this plough drawn by three horses yoked abreast, either with equalising draught bars or with a cmmen in motion. In most cases it is of advantage to plough across the ridges, and if the horses are powerful enough, and are equally matched, a depth of from 10 to 12 inches may easily be attained. A plough team of this kind is not only three horses in any other way, but the ploughman is quite able to manage it without a driver. Of course a is quite able to manage inghout a driver. proper performance of the work, and the ploughairons should be so prepared as to ensure the complete inversion of the furrow if the ploughman will only do his part aright. Unless this deep ploughing is given when the soil is tolerably dry it will not be produetive of all the advantages which in reality belong to it in many instances. When clayey ground happens to be in this favourable state, such deep cuiture opens it up and effectually prevents it from again becoming consolidated for many years thereafter. It also leaves the land in the best possible state to be acted on by froast and atmospheric air, and though an wech or more of clay is brought to the surface, no evil, but great good, from its being intermixed with the preparatory sulcess of green cropping depends on to the depth of the stirred soil must immensely increase its inorganic resources, and of consequence its fertility also. After strong land has been once wrought by a soil plough, and it is thought desirable that a still greater depth should be attained, the use of Cotgreave's plough drawn by four horses will effect this end in a satisfactory mauner.

I have now described the best mode of working the soil in the autumn previous to the season in which root crops which calls for a passing next preparatory operation wher cor pasing notice is that, of spring pulverisation-a work very easily accompinhed on sharp light eoos, If the land difficult undertaking on refractory clays. Irubber and is friable in its nature, a turn or two of a grubber and a pair of rank harrows bring it almost at once form suitable tilth. On such land as this a home farmo manager requires very little skill in carrying out the cultivating processes, but on strong clays the case is land is the watchful skill and prudent promptitude necessary to get it wrought just at the right time that the farmer's task is by no means an easy one. If in his determinstion to push forward the field labour he acts ras the soil in a prudently the chances are that in workis taking most effective measures to sour and toughen it for many years to come. One half of the skill of the clay land farmer is required to keep him from committing blunders like this. Should he be wholly unable to exercise patience and wait till the sun and wind have dried the ground sufficiently to permit of its being properly worked, then he ough al once to look or some other farm the ards heavy land farms I am well aware that the stewards of heavy land farms which happen to be in the proprietor's occupation are likely in many cases to be misunderstood by their employers, when they exercise caution in the way fhave indicated. Because Lord Mingary's farm bailiff is working his Potato or Turnip rand on a certain day, therefore Mr. Springleethie's bailiff may on the same day be doing likewise. But if the one farm is a light loam and the other a dense bibulous clay, any skilful farmer knows that they cannot both be ready for spring

Carry forward
imagines, in waitiog till the ground is tolerably well dried. Now, while too much cannot be said against the thoughtless sluggishness which will permit an hournot to say a day-to pass by unimproved when the soil is in a suitable state to be wrought, it is a very great
mistake to compel a steward to push forward the pul. verising work before the proper time. In patiently waiting till a clay soil is sufficiently dried to be effectually reduced to a tilth, means are really being taken to ally reduced to a tilth, means are really being taken to
ensare its pulverisation in the easiest way and on the ensure its pulverisation in the easiest way and on the
most satisfactory basis. Though the farm horses should be standing half the day idle, it is better to submit to this evil than to have them doing work ooly calcu-
lated to increase the after labour connected with the management of the soil. A judicious farm manager will take care that the worl is not herun till the right time, but he will also do everything in his power to press it forward when once it can be the fact satisfactory manner. of need scarcely notice increased by their being ploughed during the winter in months months great care is necessary in selecting the time
when they are to be tilled, The prudent farmer will when they are to be tilled, The prudent farmer will
certainly do as little as possible to strong clays when they are wet, and the necessity for this caution just makes it the more imperative that he should, as far as may be practicable, push forward at least the preparatory operations for a green crop as soon as possible after the harLothian.

## Home Correspondence.

## Locusts.-In an articie in your Gazette lately

 you invite information on the subject of this species of food. I will give you such as I at present have. was recommended to me about two months since as a character, a desirable food for fattening sheep. I purchased half a ton at the price of $8 l_{\text {. per ton, and I }}$ have now for about a month given it to fattening sheep some of which I have killed for my own table. The quantity which I give is half a pint a day to each sheep this costs for each about one farthing. Although and thrive abundantly. Those that I have killed have been unusually fat ; they have nothing but this food and the attermath pasture of a rather poor sandy park. Thave not yet been able to persuade horses to take it. Pigs devour it voraciously. Considerable quantities were, I understand, produced at the Exhibition at Paris from Catalonia; the reputed price was $2 l$ a ton in the country. It is no dobbt easily procureable in the Mediterranean, and is I believe a very valuable article of food, and will well repay the importer if sold at a price far below the present price of 81 . a ton. In Locust tree ${ }^{2}$ large spreading tree, in shape resembling the Beech, the end of branches and produced in loose spikes at brown pods, shaped like those of the byarden Bean, about 6 inches long and $2 \frac{1}{4}$ broad. I enclose you one of these to show the accuracy of the above description Late Peas, Staronly a single pod of Peas or Beans is allowed to reans.- 1 or grow old, whether casually or purposely on each plant, it prevents any more pods being formed worth she plants standing for. Every one pod therefore attaining age, whether required for the home table or cheap rate or given away. The plants being thus deprived of their first fruits will the same hour make an effort to produce more young and fit for table, like a swarm of bees when deprived of their honey, instine teaching them to replenish a fresh store. If in dry veather a drenching with the watering pot (avoiding the will be observed the very next day. Thus if care is persisted in, not tearing the straw or leaves or tendrils, by gathering the young pods, in most iustance five o ten times the quantity young and fit for table may be procared. Hardy di Sons, Seed Grovers, Maldon, Essex. Blight.-Since the blight attacked the Potato tops montin ago, we have had very little rain here in Essex, and up to this date, August 26 , the tubers though small are quite sound and free from disease. The corn here about is very much blighted; but it has been secured 18 yet without any harm from wet, but we may say it has been benefited thereby, the fearful storms of late having passed by or around this neighbourhood. Seed of many kinds have also sadly partaken of the prevailing Lettuces. Fruit ish are especially the Brassicas and parts, although it can only be fairly spoken of as very leficient. Hardy \& Son, Seed Grovers, Maldon, Essex. old zurgeon, who has practised in a rural district for many years, who has had preased in a rural district for many years, and has had great opportunity of observasudied their habits and administered to their wang both in health and disease, to say a few words on the practice of giving stimulating drinks to labourers in them in Engla harvest. The drinks usually given to the last it can only be for its stimulating properties from the alcohol it contains, or as a refreshing aceseent drink,
as to the nourishment it contains-that is almost nil ;
and from the former propertits I have often seen it roluce very serious symptums.
very small portion of gluten still undecomposed must be moutliful of good bread will contain more nourishment than a quart of strong ale : and I couclude, therefore that this also is taken mainly for its stimulating qualities, just as gin or whiskey are taiken, to give a temporary
lift to the animal spirits, to be followed sy a rapid depression. All these stimulants, however, do not act in the same manner; some, as Champagne, \&c., produce their effects rapidly, and these as rapidly go leave less debility as their consequence ; while others (and beer may be classed among these) are slower in exerting their influence, which, as well as the longer unless the state of excitement is again produced and continued from day to day. At length pay day comes, and a thorough debauch at harvest hom linishes what the daily excitement has been gradually paving the way for. Hear what our great chemist total abstinence. In his Letters on Chemistry, p. for when speaking of the spirit drinker, he says: "Spirits by their action on the nerves enable him to make up the deficient power at the expense of his body, to consume to-day that quantity which ought naturally to have been employed a day later. He draws, so to speak, a bill on his health, which must be always renewed, because for want of means he cannot take
up; he consumes his capital instead of his interest and the result is the inevitable bankruptcy of his body. Exacily the same results follow the stimulation and exhaustion of the system by heer or cider. The common idea aiter drinking stimulating liquors is, "I am stronger now than I was before; I can work much better:" but let us examine whether there is really a
healthy increase of strength, or if the idea contains an healthy increase of strength, or if the idea contains an hill ; he wants horse dragging his load slowly up the it-the vigorous strokes reanimate the dumb brute, and now he pulls harder, the load moves quicker; a little more whipping and more hard tugging and the victory is obtained: the cart has reached the top of the hill and a free breathing time has come. Well, is the horse the stronger you not been drawing a bill on his health? if Have member Liebig's result. Thus also does the slave driver ncrease the strength of his human animals, by the nip. Now, what the whip is to the poor horse and their energy is increased temporarily by robbing them of future strength, with this difference, that in the latter case the stimulus is made to please, not to isting. and this difference, paradoxical as it may appear, is all' to the disadvantage of our husbandmen. Neither the horse nor the slave desires a repetition of the stimulus; fear alone being the motive for extra exertion, they will therefore do all in their power to avoid the painful process; but the drink is felt to be a pleasure, the repetition of it is eageriy sought, and if denied the labourer becomes dull and illttempered; if granted, he runs a great risk of becoming a confirmed drunkard. My only man working out of doors, and thus enjoying the healthy stimulus of fresh air, and having thereby a good appetite stimulating drinks than with them. I have purposely avoided any discussion of the immense train of evil dependent on drunkennes, though another aspect of the subject is intimately connected with agricultural inte rests, viz., the increased rates caused by the effects of
drunkenness. What, then, can you do to strengthen your labourers? I answer-give them plenty of nourish ing food: to use the words of an excellent reviewer The substitution of solid aliment, containing the mate rials of muscular tissue, for a liquid which contains but producing substance (never less wanted than when aborious exertion is being made under the summer sun) is attended with the very result which the physiologist would predict, namely, an increase in the amount of muscular substance, and consequently in muscular vigour." M. R.

Reaping Machines.-Your article lately upon the ex pediency of using reapers for cutting corn being so much to the point, and having used them rather exten-
sively for three years past, allow me through your sively for three years past, allow me through your
colums to give some practical results. Although the columas to give some practical results. Although the hem, I see them with a widely different eye-there $i$ improvement. You admit the necessity of extra labour there we all agree. To come to the point: I had a large harvest to let; I let it in my usual way to a company rusion to a few contingencies which alas! never came, reaper which I had previously ordered, but knowing the extensive number required by Mesers. Burgess Key, I began to despair of my dumb friend; but Brentwood on Monday, Angust 4 . Brentwood on Monday, August $4^{4}$; a new one had to be put together, which was done; set to work just at
o'clock in a 13 -acre field large measure. By o'clock, "military time," there was just one acre let neut, the work perfectly satisfactory. Women and boys on the 15 th and 16 th without a drop of rain. I could
not have doue 18 willrout a reaper; it woulu have been
this moment in the field, and added to this the feld ploughed. Again, two pieces of Wheat, one north and one south, have fallen under the same destructive process. Again, a piece of Oats, averaging 6 feet height, I thought must be its master ; the machine set to whrk, 8 acres down in as many hours, and just now women 4s. per acre to tie them, 15. demanded of me per acre to cut besides beer. The same machine is now in Scotland, 1 have no doubt you will soon hear of its fame. I am not afraid of wearyin you upon this important implement. Messrs. Burgess Stanford-le-Hope, "narsow power to my farm a already let his corn to a company; but regardless already let his corn to a company; but regardless chine to work, cut down half their Wheat, and the time which would have been taken up in cutting wa most judiciously made use of in carting. Upwards of 60 acres of Wheat was secured in firstrate condition without a drop of rain, being the whole of the Whea grown on a farm of 211 acres. Let practical men put
to figures 60 acres of $W$ heat got up in this manner and 60 acres blundered up, as I have seen much mnner and the last few days-the labourers being gainers at the same time, likewise the public. These few remarks convey their own lesson-those that run may read ; all the scouring paper in the world will never rub out prejudice, nor all man's reasoning root it up, but no one be bold enough to fight against truth. Reapers wil supersede like steam brute physical strength, and rejoiced shall I be to see it, for the working man's sake, made often by intemperance in the harvest field, throug a series of years, at 50 years of age what he should b min. I will just add one remark from a labourer of mine of 23 years' standing, a giant in strength, "I neve ment, as I do your leading axticle o I never saw such work, so quick your leading article; I never saw such more, but a word to the wise is sufficient. William Eve, Manor Farm, North Ackcrdon, Romford, Essex, August 27.
Questions on Farming.-Having seen a copy of the Questions put by the Society of Arts in your Gazette have on the table of the Mechanics Institution here, of agriculture, but being up my ideas on the theor eannot say much about the practice. 1. The causes f the increased fertility of land just drained may of the increased fertility of land just drained may
be gathered from the following. The surplus water is be gathered from the following. The surplus water is lst, by cooling it by evaporation ; 2d, by preventing the ree access of air to the soil ; and 3d, by holding the soil in an unfit state for working.-2. By fallow 2 d , the 1 st , injurious weeds are des air by this means ered lighter to the soil and decomposes it, setting at liberty its mineral constituents for the use of the crop; and 4th, if the crop to the roots of the crop whition the crop, in one way supplying it with a larger amount of ammonia. - 3. A dung-heap should be lept under cover as the rain falling on the heap would wash some of the soluble parts away, (yet stable manure should not be kept too dry, as it is subject when so to dry rot); an son, clay burnt or unburnt (but generally better whe ammonia should be mixed with the manure heap in orderto prevent the escape of ammonia,-4. Lime is a fertiliser st, by supplying some amount of nourishment to thecrop and $2 d$, by decomposing (when applied in a canstic state) the vegetable matter of the soil, thereby rendering it fit for food for the crop, and when the vegetable matter is pexcos, reducing that excess.-5. As to the manure specified 1 know very little about the price of manures, but having seen advertisements of superphosphate o lime, from 7\%. to $12 l$. per ton, and as this seemen to be s manure of that description, though not one of the best, might guess near the higher price, but this is only in acid is explained thus:-1st, the phones by solutime is rendered easier of assimilation to the crop and $2 d$, the crop being thus assisted in its early growth, it forms leaves and roots quicker, which give the crop greater power of assimilating food from the air and soil,-7. The greater value of the manure from full-grown animals appears from the following:-Young animals retain a larger portion of the phosphate of lime which is in their food than full grown animals do, hence their excrements are nof 80 poorer for manure, and besides, their food When cattle are kept warm, less of their food is required fors combustion to support the heat of the body; and 2 d , bing kept quiet they will waste less muscular tissue. R. T. Redmayne, Warper, Dule Street Milh Blackburn. Employment of Soldiers in Harvest Work.-I agree entirely in the principle of "turning swords into ploughshares, and spears into pruning hooks," so far at
least as the emergencies of the case call for such transmutation, and I really ean conceive no emergency more urgent than that of a fickle harvest, heavy crops, and a scarcity of hands to do the work of harvest, whilst, as you justly observe, those who could help are suffered to look idly on. What danger can arise from Government interference in the labour market, allowing a certain number of soldiers to turn harves
eenomists to solve. But a case just now occurs to me, which though not exple that the military may occasionally estabimployed in farm work, not only without detriment be employed but with advantage both to the community ro the serne men themselves. When many years ago I assisted in the management of the late Mr. Rocos harms near Liverpool, there chanced town. It go hap of Suffolk militia quartered in the town. It so happened that Mr. Roscoe and not unfrequently directed to farming subjects; amongst others that of hoeing Tursips, a matter in which, to say truth, the labourers of of this, the colonel very kindly and considerately offered us any required number of his men to assist in the work, an offer of which we gladly availed oure. They gave us a cood crop of Turnips, with some advantage to the men, Who if they did not show the natives "how fields were won," showed them (vastly more to our purpose) "how folds were hoed." Where was the interference with abour in this case ? And is not the harvest a far more mportant object than Turnip hoeing? Agreeing gene ally in what you have said on the subject, there is one poiat on which I may be allowed to differ. I do not for moment question the superiority of reaping machines over manual labour as to expedition. Thousands of acres may be got down by them for scores by the sickle and reap-hook; but unfortuaately getting down is not getting up. Of the immense breadth of Wheat cut this year on the early lands, how small a proportion was secured when the rain set in , compared with what there might and ought to have been. I have no doubt that there was a carcity of hands, that the farmers wanted soldiers, but of what was fit than to spend time and labour in inreasing the quantity already down, adding so much to the risk in case of bad weather? Mind, I have nothing to say against reaping-machines, only that of themselves they are powerless, nay worse than powerless, as a
security against bad weather. They will cut down an security against bad weather. They will cut down an
immense space in a little time, but unless the quantity 50 cut is harvested in as little a time, which of course implies a proportionate increase of manual labour, of what advautage is their boasted expedition? I am glad to see the subject of Locusts as cattle food attracting the public attention. The hard stone-like seeds mentioaed injure the teeth of the animals eating the pods, but if desirable in other respects, especially as to price, I have considerable faith in the ingenuity of our agricultural machinists to devise ways and means of overcoming gruiter
$4 u j_{6} 25$.
Boydell's Steam Locomotive - Both "G. P. S." and "R. S. N." in a late Paper fall into the same error of taking movements round the axle as the fulcrum instead of the bottom of the wheel when it rests on the ground ; such being the fact, all their reasonings fall to the ground as fallacious. Again, I was hardly propared to find that any of your readers did not know double that of the bottom. [The bottom of a wheel rolling along the ground is stationary.] Lastly, there nothing new in the proposition that a force applied to applied at the axle. The new proposition to which I refered is the saving of space which the motor force gains by translation when thas applied to the top of the hod. W. B
Circular Tillage.-Some people once started off in quest of the philosopher's stone : they did not find that, but in the search they stumbled upon certain pebbles, which laid the foundation for sciences most useful to Fitse ;" Others went off in search of the "Elixir cience of medicine, which has served to alleviate the ains and pangs of suffering humanity. Others went iter perpetual motion ; however they did not discove What they were immediately in search of, but they reatly advanced the knowledge of mechanics. Somehat like the above cases will this problem of steam fill surpass it. It it will disappoint expectation, for it doing the worl. It will be found that instead of stean work. Some years man, I started in search of steam tillage ; my expectation (like that of most other persons) till land I shall find out some plan whereby we can pard without men or horses, and thus remove an long investigeavy tax upon bread production. After the readergation, it now remains for me to lay before discovered of the Agricultural Gazette what I have anouthfols. At first, acting on the principle that soal form of my agricultural or field investigation in the that thespopositions, with the distinct understanding driventill doctrines will be exemplified a seans of field-practice, and that, therefore, it is life production. 2. That on this account the farmer's field
practice ence. 3. differs from all other business arts in existmaterial That there is no analogy between the dead material in the field. 4. Hence it follows that that may of proceeding which is right in the homestead practice wrong in the field. 5. That our present field error of judgment in a mistake, based on an original perpetuated through and that this error is and has been
to be aimed at in tillage. 6. That the error in principle arises from the fact that field-practice is the art of
manufacturing live objects, which demand more of "attention" than of any other agency-that this element "attention" is not now provided for-the means for tillage practice being solely
of field-practice wholly disregarded homestead machinery is anefit 3 . That in the machinery is an evil or an alloy only to be tolerated because it can never be wholly dispensed with. Here the real question is-whether we can by steam-power so assist man as to render him equal to two montas hard labour in the field; so that at the end of that time We may possess him in full force to fill his true office as
affording care and attention to the nurture of that plant affording care and attention to the nurture of that plant
which to him and us is the staff of life? C. Burcham, London.

## Calendar of Operationa.

SEPTEMBER.
Fabm neab Hexians, Aug. 29.-Previous to the 8th instant we had a fortnight of very wa
crops nade rapid progress.
Which laid the crops very. much, and from that heame uaiti8 fel
the weather has, with little change, been cold, cloud nid now the weather has, with little change, been cold, cloudy, and wet,
and little progress has been made witl harvest work. To-day and little progress has been made with harvest wor of sumshing har west will be quite general in this valley next week; on the
higher wiund the crop is still very far back. So far as we have gone our crops cut up better than we expected
vers much damaged. but much will depent
September. Turnips have improved greatly
september.
being a good crop on Turnip soils. Hay was ne now look like
better condition. In the Potato crop there are some cases of
disease in the district but it is by no means general, and the crop is good. Stock is doing well.
Wrstrr Ross, Sept. 2.-The crops have made very slow pro-
gress for mome weeks. The weather has been cold and showery and the sun's countenance has been pretty mucla s stranger to us. has been blowing from all points of the compass, and showers
have heen falling bundantly; and so twirled are some of our have been falling abundantly; and so twirled are some of our heavier fields of Wheat that an on-looker would be apt to sup-
pose that they had been stooked. And besides the colour is any pose the that golden colour which we so much like to see. Not only bave those fields that are laid got this dark, leaden colour, but those also that are yet eract have got mucho of the same napromising appearance. A few pieces of early Oats have been cut,
but at the present step general harvest will not be reached for but at the present step general harvest will not be reached
some 10 days. Oats are not no heavy as Whent, but will, 1 doubt some 10 days. Oats are not to heavy as hean, not, y year grown will not be sufficient to neet the requirements of
this yistrict. Barley is also a superior crop, but will be very
the dist scarce from the small breadth sown. Turnips have been thriving wonderfully; indeed the progress has been such that we question
whetlier, at this season, they ever looked better. they already in many fields that it would be difficult to tell in fur Turnips, at fully previous prices, for wintering of hoggs. for this purpose. The Potato disease has been at tork Even if the disease should not have visited us this seaen the Yield would have been under an average; but as it is, their
growth is prematurely stopped, and few of them will reach the size of marketable Potatoes. Harvest people are by no means
scarce in this quarter, althnugh wage are rradually lnoking up. scarce in this quarter, althnugh wages are gradualy hooking up.
A few days ago, a farmer intimated that be wanted hauds to cut
down a few acres of $\Theta$ ats, and, on the morning appointed a band of nearly 100 appeared and offered their services, and speedily
the whole was into the stook. Whele Sussint, Sept. 3.-Since our last report we have got chrough the most important season of the year, amidst many
hopes and fears. Before the rain came there was not much Wheat secured, and perhaps rather more than half of it was cut, and as there were a good many of the shocks blown down and
got more wet than if standing, some few sheaves soon began to sprout, but still there is not so much of this as to do much harm We should hardly think enough to make it perceptible in the bread, as most of the sprouted corns blow away in the
dressing. There is not much difference between what was cut and what was not, as mnch of the latter was laid pre-
viously, and of course was more or less aprouted. But by dress ing a little harder we shall get a good quantity of fair cut before the rain: it is altogether unifit tor the maltster, and what
nas not cut is very much damaged, so that we shall have the was not cut is very much damaged, so that we shall have the
uality very various, and Barley fit for malting dear, while for feeding purposes it, will be in good supply; and the consequence crop does not grow so rapidly there is nct much harm done to it; the chief, loss is by shaking out, as they have had to be turned
so often, and the rain made them tender. The Potato disease which seemed for several weeks to be confined to the tops, now shows itself in the roots to a great extent, bu ane the altogether if the quality is not all that we could wish, the quantity is well up very high so that harvest will be finished this week and in the best order, and there will be uo want of dry corn for the millers The rains have ilune good to the Turnip crops where they had not altogether filen, and perhaps so where it is good and liberally
mavure recommended itself more, for whep: some have spent extra
used there is seldom much fear of a crop labour this year emnugh to have supplied them with abundance of
it, and they would have now had the satisfaction of looking at a
俍 good crop instead of naked fieids. Our work wheat stubbles.
Rye, Vetches, and Tritolium sown ous the Wheat
have always preferred ploughing for Trifolum, more for the have of being better prepared for the succeeding crop of Turnips
sute as it does not do nearly so well as when harrowed in upon the Wheat stubule we must give up ploughing. $G$.

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACHINES,

SOLE MANUFACTURER, IRON AND WIRE WORKS, NORTH STREET, LEEDS.

## REGISTERED JULY 24, 1855.-No. 3739.

THE ADVANTAGES OF THESE MACHINES supersede all others by having 1 a small Wheel in front of the Grass Box, consequently will nlow verges and round flower beds, Without any change of Wheels, or adding the old fashioned Roller, as in others; will also cut either
wet or dry, and by the simple adjustment of a thumb serew, in front, can be raised or lowered to cat the Grass any length required; and having two Rollers belind, and a small one in front, they roll the width they cut; they will tura in very littie room, and cut at the same time. All the working parts made much stronger than the old machines. The bottom Bindes are so constructed that they cannot tanr up the ground; they are only drawn, and not pashed and drawn 28 in other machines,
tonsequently
do not require half the power to work them. The three first sizes can be worked by eonsequently do not require half the power to work them. The three first sizes can be worked by
one person with ease; the two latter with a pony or donkey.

LIST OF PRICES (NET CASH):-

## Testimonial from Joshaua Major, Eisq, Landscrpe Gardener, Fnostrop

To Me. Greme, Lebds.-Sir, As I always appreciate public and useful improvements, I mast gladly give my testimony to your higbly improved Mowing and Rolinng Machine. The ne sent or my inspection and trial (cutting a breadth of 44 inches) wa drawn on flat ground with ease by one person, and although at the time of trial the lawn was wet, it was cut with the greates nith ease and pleassure, providing the Grass is not too long. For extensive places I should say the 24 inches would be moest guitable; for even in undulating ground two persons raay work it; but in flower gardens, when beds, dec., are crowded either of the smaller sizes would be best. I congratulate you on your very valuable invention, which in my opinion, entirely surpasese, and must eventually supersode all others, for it is not only free from intricacy and easy to the workman, but extremeiy expeditions in its operations, and consequently mingt prove a great sa
the public. -1 am, Sir, your mostobedient servant, Joshra MAjos.

Other Testimonials may be had on application to the Manufacturer.
The above Machines are warranted to answer the purpose as described, or may be returned, and may be had of all principal Imnmongers, Nurserymen, and Seedsmen in England; also Mr. Charles Garrood, Superintendent of Agricultural Department, Crystal Palace, Sydenham.

## Che Garwentsi Chromicle. <br> SATURDAY, SEPTEMBER 13, 1856.

If the tide of Mormons now flowing with increasing force towards the United States is to be stopped, it is more likely to be influenced by a knowledge of the difficulties such emigrants have to encounter than by considerations of any other nature. We therefore avail ourselves of a favourable opportunity for the parpose of pointing ont the true nature of the Salt Lake district, whither Mormons are directing their steps, in the hope that the perils which beset their path may deter some at least from blindly rushing to destruction. Our information is derived from the narrative of M. Julus Rémy, a distinguished French naturalist, who visited Utah last year, and whose statements are oot open to contradiction.
This traveller, with one companion, quitted San Francisco on the 30th July, 1855. The early part of their journey through what is called the Sierra Nevada of California, was agreeable enough. There the dense forests of Coniferous plants recalled the Alps of Savoy; in the meadows, on the rocks, everywhere, appeared a prodigions multitude of gay flowers, which filled the air with their fragrance. Eriogonums in endless variety gave a peculiar feature to this vegetation. A Pyrola with variegated eaves grew beneath the Fir trees, and rested on a ittle forest of musk-scented Rubus. The highest point they reached in these mountains was 9600 feet according to the anerïid. A day, by Carson Valley, took them into the plain, wheie they learned the road to the Salt Lake. Hereabouts they found the hottest springs known, the water indicating a temperature of $82^{\circ}$ Centigrade, or $179^{\circ}$ Fahr Nevertheless even here vegetation maintained an existence, Confervæ flourishing in the almost boiling fluid.

Here a total change came over the scene, and all was desolate. The luxuriant vegetation, the en amelled meadows, the cooling shade, the limpid streams disappeared. On the banks of the river whose course they followed nothing better appeared than stunted Willows and Poplars. Now began the deserts: the soil was covered with a sal crast, amidst which a few miserable bushe (shrubby Chenopods) sprang up. The mountains which formed a sort of frame to the horrid scene,
were themselves naked and barren; the river
swarmed with serpents. At Ragtown, the first place they reached, the water became so salt that it was almost impossible to drink it. All around the place lay the carcases of cattle. A day's rest for their animals enabled the travellers to attempt the passage of a desert for 40 miles. They started at 6 o'clock in the evening of Aug. 15, and by 6 in the morning of the 16 th they had struck the river Humboldt, whose waters, at that point, they found maddy, stinking, full of dead fish and soda, and consequently undrinkable as well as unwholesome. Great quantities of fishing birds and huge mosk rats abounded. The vegetation consisted of Grasses, Sedges, Docks, \&c. The great desert was at hand. At this charming place the horses broke loose, and one of the travellers had to follow them. The first desert had again to be passed, but on foot, without food or water; and it was three days before he returned with the cattle, having his nose broken by a kick from one of the beasts, and being "almost dead of a fever brought on by fatigue among the burning sand. Deserts like this must be seen to be appreciated ; without personal experience no one can form an idea of the misery endured in such places. The thermometer stood at $40^{\circ}$ and $45^{\circ}$
Centigrade (104 and 113 Fahr.) at 2 p.m., and at night rain fell in torrents. Such a position was dangerous to the last degree. Remy himself was attacked with fever; and to add to his discomfort his tent was surrounded by savage Indians and still more savage whites, and his best mule died "killed no doubt by the alkali." The big-tailed foxes soon came down from the mountains and devoared him.

For many a weary mile our travellers followed he course of the Humboldt, a river that runs along the bottom of an immense gulley, which prevents it's being seen from the plain. In this gulley it always necessary to encamp, in order to find pasture for the cattle ; a great nuisance, because it brings you immediately under the fire of Indians concealed On the edge of the cliff. On the $22 d$ August M. Rémy fell in with a body of emigrants, from the Choctonés, an Indian tribe into whose territory he was about to enter. Notwithstanding the assurance of the emigrants that he must inevitably experience the same fate, he and his companion persevered in their journey, travelling only by night for a whole week, in order to escape the Indians,
who were on their track and occasionally sent some arrows after them. Luckily Remy's companion was well acquainted with the Indian habits, and to this circamstance the little party undoubtedly owed their lives. At last they reached a Mormon post, the residence of a strange fellow named Prtrr Haws, who to his other peculiarities added that of a belief in the transmigration of souls.
With some trouble an Indian chief was here found who agreed to guard the travellers as far as the Salt Lake. Their way over mountains and plains was indicated only by the compass. A little snow
fell, and one night after a heavy rain they found themselves frozen in their blankets. The vegetation now changed. Pines and Junipers appeared in abundance, but of no height. One of these Junipers, 18 feet high, and about a foot in the diameter of its trunk, was found to be 509 years old. At last they came within 90 miles of the Salt Lake, at a hideous region wholly desert, without a trace of man or by the light reflected from the snow-white salted soil. In two days they passed through this frightful solitude; and in a few days more, over a rather better country, they reached Grantsville, a settlement still 40 miles south-east of the lake, after having been a day and a half without any kind of provisions.
The lake itself is described as extending so far into the mountains that it resembles a vast sea, and seems to lose itself among them. Its waters are of the deepest azure, and so dense that the human body will not sink in them. Its edges, especially on the north, are formed entirely of a deep bed of the most beautiful salt.
Such is the way to Mormonland by way of California; from the Eastern states the dangers we believe are greater and the road longer. If a couple of strong experienced resolate travellers only just succeeded in reaching it at the peril of their lives, what must be the fate of old men, women, and children, whose mere numbers enormonsly increase the inevitable dangers of the journey? Let us hope that those who have influence over the
ignorant peasants believing in Jos Smith and his ignorant peasants believing in Joe Smith and his
successor Brighass Young, will make them acquainted with the facts here related; for when nothing else will stop them in their mad career a recital of dangers and hardships such as these mav snatch at least a few of them from utter ruin.
The Salt Lake City itself is situated between the
river Jordan and the Wahsatch Mountains, against
which it rises like an amphitheatre. M. Remy and his companion entered it on the 25 th of September, after 58 days of hard travelling from Sacramento. They found it unlike any other city in the world it may be described as a vast assemblage of houses rather than a town according to European ideas. The streets are 40 yards wide, and run north and south, or east and west. They are watered by streams ingeniously brought from the neighbouring mountains, and bordered by rows of Cotton-wood trees (Willows). The diameter of the city is six miles. With the exception of the palace of the Governor the houses are all constructed of wood and plaster, stand a little way off the street, and are surrounded hy a plantation. The Mormon Pope or president is Mr. Brigham Young, who is also Seer and High priest. This worthy gentleman has 17 wives of different ages; the number of his children is unknown; all that the travellers could learn upon that interesting subject was that nine were born in the week they were there; and that preparation was made for the reception of 30 sultanas in his new palace.

The Imperial and Central Horticultural Society of Paris have just announced exhibitions of flowers, fruits, and esculents to he held at their house, No. 3, Quai Malaquais, Paris, on the following days, viz:-

## 11 and 25 September. <br> 9 and 25 October.

13 and 27 November
The objects of exhibition are to be new reedlings, or such as have not received prizes at previous exhibitions; they are to be delivered, carcfully named, before 9 oclock in each morning and to be removed the next day in the morning. Exhibitors, visitors, and members of the Society are to have admission on each day from 10 in the morning to 5 in the afternoon.

## the potato disease.

IT is now 11 years since I first directed attention to this remarkable disease, and notwithstanding all that has been written upon the
subject, and the numerous experiments that have subject, and the numerous experiments that have
been made throughout the country with the view of been made throughout the country with the view of
ascertaining whether some means could not be devised to act as a preventative or arrest its progress, I believe every plan and mode of treatment that akill or science could suggest has been unattended with any satisfactory result, and we are at the present moment not only without a remedy against the inroad which this mysterious visitnr annually makes on our Potato crops, but are even little better acquainted with its habits, or the cause which produces it at a particular season of the year, than we were at the time when it first made its appearance. On this subject, as on every other of a questionable nature, we have had opinions innumerable, and almost as various as the persons who have given them. Some have attributed its origin to the efrects of soil,
over manuring, the attacks of aphides and other insects, over maluring, the attacks ot aphidas and otaer insects, a few with more probability, I think, have ascribed it to atmospherical causes, axising from the electrical cbanges that are continually taking place, producing a certain condition in the air unfavourable to the health of the bring on disease and hasten its decay. In so far as my experience enables me to judge, I am inclined to believe groundsospherical theory is the right one, and the grounds memoranda of the state of the weather both before and after the appearance of the disease in the west of England during a series of years from 1845 to 1853 , which may probably interest some of the readers of the Gardeners' Chronicle who have made similar observations.
1845, August 13.-The disease first noticed among eome early frame Potatoes. The previous week was became sunny and warm. The brittleness and burn appearance of the leaves induced me to suppose it bring me effects of cold, although I could scarcely early in the season. In a short time the disease spread with great rapidity, stems, leaves, and roots being all very much affected, especially the latter, many of them being nothing but a pulpy mass emitting a most offensive smell.
184
1846, July 4.-Symptoms of disease beginning to and in exposed situations the leaves and stems of Potatoes were much damaged by the wind. The early part of July proved warm and dry. The injured portions soon became affected with disease, and the crop was found nearly as bad as in 1845
1847, July 17.-During the greater part of this Much rein fell on was remarkaby which day and the 17 th it was very close and sultry, with occasional dense fogs. Disease very general, but considered not quite so destruclive as in the two preceding years.
1848, July 1. -Throughout the month of June the

During July it was unusually warm and sultry. On several days the thermometer stood at $80^{\circ}$ and $82^{\circ}$, and
on the 15 th it reached as high as $86^{\circ}$. The Potato crop hree-fifths of the produce b actual measurement being found wholly unfit for use

1849, June 18.- The beginuing of the month sultry and wet, but warm and fine during the week before the disease appeared. Coming as it did so early in the season I began to think it perfectly useless to persist in cultivating the Potato. Crop indifferent and muah disessed. Besides the Potato, other plants auch a Heliotrones. Cucumbers, and Melons in frames, Cucum bers and Vegetsble Marrow on ridges, as well Jerusalem Artichokes, were all serionsly injured by this disease

1850, July 19.-Weather very fine both before and after the disease was seeu. The crop indifferent, bu the roots tolerably sound and apparently isoproved in quality

1851, July 13.-The disease just appearing. Weather previous to this date very fine and seasouable, after this yearm and wet. The crop not soulm having bee destroyed rather early in the season.
1852, July 2.-Weather daring June sunless and wet, with occasional storms of wind. On a sudden change to close sultry weather in July symptoms of den were soon apparent, and as it spread most rapidy great fears were entertained about the crop he usual.
1853̂, July 10. -The latter part of June very wet The beginning of July fine and warm, with dense foge occasionally, which appeared to favour the spread of the disease, for although not observed until the loth the crops generally were all more or less affected by the end of the month. A large portion of the root injured, but by no means so bad as formerly, and thero are now some hopes that the cultivation of Potatoes will be resumed, the disesse having run its course and lost much of the destructive character it had on it first appearance.
Now to whatever cause this singular malady may be owing, I think it will be evident from the preceding remarks that the state of the weather has much to do with it-a sudden change from wet to dryness, or the reverse, accompanied by a rise or fall in the tempera ture such as uzually follow the thunderstorms that occur about Midsummer, being almost a certain fore runner of the disease; while a sultry, humid atmo sphere is found to be alike favourable to its develope ment and dissemination the moment it comes into existence.
On these points we have yet much to learn, and although we have failed in our attempts to dizcover remedy for this epidemic, we must not be discouraged from continuing our inquiries. The mildew was at one time looked upon by gardeners as a similar pest; but now it is no longer dreaded, recent discoveries having made us acquainted with a substance that is a perfect antidote against its attacks, and which proves to be both simple and easy of application. Such being the case, it is but reasonable to hope that by connecting together the remarks and observations of the gardeners and meteorologist we may in time obtain some insight into the nature of this scourge which has for som years past so seriously injured the Potato crop; and having done so, we may probably discover a remedy that shall be as effectual as in the instance of mildew above mentioned. $B$.

VEGETABLE PATHOLOGY.-No.CXXXVII. 565. Parasite (Stemphylium, Macrosporium, Sporio desmium, Helminthosporium*). The two firss of these genera may perhaps be safely reduced to one; the third is distinguished by the almost total absenco of sporophores, while the fourth has in general very dart and well developed fertile threads and spores with numerous horizontal but no vertical articulations, which are normal in the two first, and are not alien to aporin desmium. In the present notice I shall consider proe cipaly those species which decidedly belong to the threefirst, reserving the last for
566 . It is only of late years that anything bas been said of the destructive powers of any of the species on living tissues. The species, like so many other fang?, were supposed to attack dead or dying parts of vege tables ; but it was not imagined that they could establin. themselves on sound and healthy tissues. It was hore ever shown by De Bary that plants of Heath a attacked by a little Stemphylium, which runs over to tender foliage and soon reduces the healthiest plants the dry sticks. This has been especially noted Prossin, and actions of the Horticaltaral Sotributed by Raben aple the name of Stemphylium ericoctownm horster published. I have nal numerous examples myser by thongs other matters pary. The plant is remarikable amongaracters of Verfor exhibiting in different stagos it assumes its perfect form
567. More recently two papers have appeared in the Botanische Zeitung, 1856, illustrative of a fungus caused in Rape seed and Carrot by a referred by Amtmann Kühl to the genus Sporidesmiun - From cricpuran pressed olives; $\mu$ wass long ava urase see
bat which appears more properly to be merely som
Macrosporium. The details are far too lengthy to reproduce here, and they do not admit of much abbreviafion. It appears, however, that the mycelium penetrates deeply into the substance of the mother plant and soon causes more or less complete ruin. The dis coloured spots are at first punctiform on the pods, bu trieform on the stem pown, and at length rot spread; the leaves hang down, and at length rot off without however beeng aways atily propagated, not only between slips of glass in water or a damp atmosphere, but on parts of the Rape plant. Spore3 sprinkled over the pods produce a new crop in less than four days. The black specks soon apperr as in other cases, and the delicate mycelial threads penetrate by means of the stomates into the subjacent tissue. The spores are very tenacious of life, and are readily propagated after they bave been kept a twelvemonth, a fact which probably is equally true of a great variety of moulds, and which accounis for their ubiquity. When the crops were still unaffected, in the beginning of June, the fungus was easily reproduced by sprinkting spores which had been saved from the preceding year ; and in nature these are preserved on the dry stems and leaves, and perhaps in various other situations, for the fungus s not confined to Rape, but affects equally Carrots and Charlock.
568. The roots themselves are often infested with another parasite referred to Helminthosporium. This pablished in the twentieth number of Klotzsch's Herbarium Mycologicum ; but unfortunately I have not yet received the number. It is published under the name of Helwinthosporium rhizoctonum, Rabenhorst. The base of the root, and sometimes the middle but The top of the Carrot is sound, but the base is soft The top of the Carrot is sound, but the base is soft the soil other parasitic fungi establish themselves on the suriace. It first appears in the guise of little cattered black specks. These soon become confuent, and throw out a quantity of mycelium, which is of lighter colour than the fertile threads, insomuch that various tints may be traced from white and rose soloared up to violet black. The mycelium does not penetrate beyond the subepidermal stratum, but the calls which are infested change their colour by a converion of the contained matters into ulmates and humates. The leaves are at the same time affected with the same pould as the Rape, but distinguished from it as a variety yithe greater development of the sporophores. In both plates, and are either strongly clavate or acuminate. a the parasite of the Rape the spores sometimes produce new spores from their surface, or at their apices, and the process is repeated till we have the structure of ellernaria. In some again two or three are joined at The base, in which case we have a close approach to Triposporium. Unfortunately, though the species is rery carefully described, the author is unable to suggest any remedy. The mycelium is to deeply seated to be easily affected by sulphur, a remedy which can scarcely ver be applied in such a case till it is too late. The best practice probably would be to give a good topreessing of lime and sulphur, though the action of these unhappily is not permanent, since it affects only those parts of the plant which are already fully expanded. $\lambda$ fresh crop of the parasite will necessitate therefore a fresh dressing, the cost of which may exceed the probable return. M. J. B.

THE DESTRUCTION OF DODDER.
The means which till now have been employed for ho destruction of the Dodder were either difficult or cious to apply, or his parasitical plant has mach have endeavoured to find an easy, sure, and cheap means of destroying it ; for in order to be available to the cultivator these conditions are required. After any unsuccessin a mple fis the guditure to fectly well. It is the sulphate of iron. The mode of roceeding is this
I dissolve in 220 gallons of water abouk 220 lbs . of alphate of iron. With this solution I water the parts of artificial meadows that are attacked by the Dodder; wet the plants thoroughly with the liquid. It is necessary to perform the operation in fair weather in forder it is is to the oxidation that I atribute the resulte or is is to the oxidation that I attribute the results becomes black and friable. If performed in rainy weather the rain-water must inevitably carry off portions of the solution which adhere to the plant. I cannot tate exactly the number of quarts which should be given to each square yard of surface, for the quantity muat vary according as the plant is more or less affected. In two or three days after the application of the tolation, the Dodder is completely destroyed. I then mow the forage and carry away the portions affected by the parasite, and which have been acted upon by the sulphate. When the remedy is applied in time, that is to stroyed by the Lucerne has not ber conely deoualy after the application, and the leaves assume a dart hue, indicating good health.
The action of sulphate of iron is two-fold; on the $186 e$. Feb. 15. Ueber das Erkränken der Mölhren, in Bot. Zeit
restores the vitality of the plant which has been exhausted. It might be supposed that the sulphate of iron applied in such quantity would act as a poison upon the Lucerne ; but this is not the case. The calcareous soils upon which I have operated proteet the Lucerne completely, because the sulphate of iron is de composed where lime is present. But these are not the only soils on which I have operated; I have also destroyed the Dodder on allovial soils, which contain but little lime; the Lucerne has not been affected by the sulphate of iron on these soils any more than on the
A poison being only taken into the system of vege tables by the roots, and the spongioles of the Lucern being very deep in the earth, the sulphate of iron reaches them only in small portions, and in consequence of rain which may occur after the application. If a of iron would doubtless destroy it but in our artificia pastures of Clover, Sainfoin, and Lucerne, this result is not to be feared. Ponsard in Mon. des Com.

## NEW GARDEN FERNS.-No. XIV

## 26.

Thyrsopteris elegans, Kunze. Paniculari Bertert, Colla,
Fronds large decompound, the sterile and fertile portions soparate sterile with cuneatelanceolate obtusely serrated ultimate seg
ments; fertile consisting only of the rachis or veins bearin ments; fortile consisting only of the rachis or veins bearing
stipitate subsecund sori, which have an oblique cup-shaped or subglobular involucre, and form a thyrsoidal race cup-shaped subglobular involucre, and form a thyroidal r
stipes stout, clothed below with deciduous wool
This is a very remarkable Fern, both on account its size and peculiar structure, and scarcely less so for its geographical position-the island of Juan Fernandez The native fronds gathered by Bridges, which we possese are upwards of 8 feet in length, with a smooth stipes of 5 feet long, roundish in the upper part and measuring half an inch in diameter, flatter near the base, where is thickly clothed with deciduous wood, and there measur ing an inch and a quarter in its broadest diameter. The leafy portion is about $3 \frac{1}{2}$ feet long, and nearly as much across the bawe, the lower pinne or branches being a least a foot and a half long; supradecompound, with nearly triangular outline, smooth, shining, and coria ceous. The lower pinnæ or branches have several fertil quadripinnate pinnules at their base, and are sterile towards the apex; white the upper pinnæ, also with quadripinnate pinnules, and the apex of the frond, are entirely barren. The tertiary divisions of the sterile portions, one of which is shown on the left hand in the ate, more or less acuminate; they are

lanceolate, entire, or with one or two shallow teeth, and corresponding free veins. The fertile parts of the frond are exactly analogous to the barren in their mode of division, as is shown on the right hand in the figure, they consist only of taked clusters of spore-cases, th veins only, tipped by the sori, being developed, and the parenchymatous matter of the sterile parts being altogether wanting ; each venule or vein bears one ot these clusters, so that the entire, or two or three-toothed barren segmenta are replaced by one, two, or three sori res pectively. The involucre is a semi-globular or cup-shaped body, somawhat contracted and oblique at the mouth and contains sessile compressed spore-cases like those of the Cyatheas, to which family, no doubt, this plant belongs. It has been said to have a caudex as thick a a walking-stick, and hence it has been called an arbores cent Fern, but as the stipes fully answers this description there has no doubt been some error in the terms employed, and the Fern appears to be rather a dwarf stemmed plant with gigantic fronds. The involucre are comparatively larger than shown in the figure. The plant forms a desirable evergreen Fern for a warm greenhouse. It was intreduced a year or two since by Mr. Bridges, to the nursery of Mr. Low, of Clapton. T. M.

PRACTICAL LESSONS IN BOTANY FOR BEGINNERS OF ALL CLASSES.-No. VIII. By the Rev. J. S. Hexslow, M.A., Rector of Hitcham, Suffolk. Column Ist, continued.-C. S. (i.e. Calyx-Sepals.) In Ex. 9, "common red Poppy," it is necessary to observe
the number of sepals in the flower-bud, because they the number of sepals in the flower-bud, because they
fall off as the flower expands. In Ex. 15, wood
exawberry," a gardeu specimen anay be cunsulteu, or more flowers have coalesced, and the parts of the floral whorls are in consequence multiplied. The calyx in this plant is generally described as "double," i.e. as composed of two whorls, each consisting of five sepals, all of which cohere. I'he significance of the five outer sepals will be better appreciated after a morphological esson on the relationship which subsists between one part and another in the different floral whorls.
C. P. (i.e. Corolla-Petals.) In Ex. 17, "white Deadnettle," five petals cohere to form the tubular corolla. The same structure occurs in "common white Horehound" or in any other of the very natural order Labiates (Labiatce). Two petals cohere almost to their summit, and thus form the upper portion (upper lip), whilst three cohere almost as extensively and form the lower portion (lower lip) of the corolla. Such a corolla is termed "lipped" (labiate) from its affecting someWhat the appearance of an animal's mouth with the lips apart.
St. (i. e. Stamens).-In:general the number of the stamens, whetherfree or cohering, is readily ascertained. If they exceed 12 they are recorded as numerous ( $\infty$ ). In Ex. 21 "spotted palmate Orchis," and in others (as Herminium monorchis) of the numerons and remarkable order to which it belongs, the flower is peculiarly modified. In this and most others of the order there is only one stamen consisting of sessile anther composed of two lobes or cells, which stand more or less apart. Beginners will follow the example of Linneus in mistaking these two obes for distinct stamens. It has already been noticed that some of the flowers of Ex. 24, "spotted Arurn," consist of only one staunen, and it may be further remarted that the two hobs of the anther are seated back to back and not side by side, as is more usual. In the earlier state they are yellow, and gradually turn purple.
(i. e. Pistils and Carpels).-There is sometimes difficulty in determining the number of carpels. When there are more than one they frequently cohere, ither partially by their ovaries only, or further atil by he lower portion of their styles, leaviog the upper considered "single" and branched, each branch bearing a stigma. The cohesion may be continued throughout the entire length of the styles, leaving the stigmas only ree. Or the cohesion these a and the character of the compound ig. .iorer indicated by the number of lobes or projections which tally but not aiways) with the number of the carpels. There is only one carpel to a pistil in Example 14, "Canmon Furze "and other Legumens), in 19," In these cares, Laurel," and in 24, "spotted Arum. "simple." In Ex. 5. "wood Strawberry" the carpels are numerous and free, and the pistils (being identical with them) are "numerous" and "simple. In the other examples the pistil is "single" and "compound.
To Ex. 9, "common rcd Poppy" a (?) has been placed, because the number of the somewhat $\infty$ carpels which compose its pistil is variable. This may be ascer without divid. a the
 To Ex. 17, "white Dead-nettle," another (?) denote difficulty, which botaing havo wher celled ovary originates in the cohesion of four carpels or two.

To Ex. 18, "common Primrose," there is a third (?) because it is impossible by inspection and transverse section of the pistil to decide whether it consists of one carpel or more. When its ovary has become matured into a fruit, there are sufficiently clear indications that five carpels are present, but wo should be forestalling what ought first to be shown in regard to the general structure of fruits, if we were to proceed with these remarks.
In Ex. 24, "common Arum," one kind of flower consists of a single In Ex. 24 " "common Arum," one kind of flower consiats of a single
simple pistil, composed of an ovary capped by a sessile stigua.
Several of these are ranged round the lower part of the stall on Several of these are ranged round the lower part of the stalk on
Which they are seated. They have no perianth, and are packed
close together. The other kind of flower, which consists of a close together. The other kind of flower, which consists of a
single sessile anther, is also without perianth. These arre
packed close together round the stalk, a little above the flowers

 N.B. When the beginned finds that professed botanists are
sometimes at falt, he will feel satistied there is an unexhausted
mine of discovery before him, in which he may soon al npen up some fresh vein of inquiry and assist in the axcumula-
opion of facts tion of facts tending to elucidate the laws by which thie structure
of plants is defined. The more clearly these laws are appre-
hended, and as seeming anomalie disappear the more surely do
年 they testify to the su
they were ordained.
I would earnestly caution all who are inclined to take up
botany as a special pursuit, never to hivten to the misapprehen-
sions under which even some nuturalists seem to labour sions under which even some nituralists seem to labour in regard
to the comparative importance or uon-importance of its several
branches, and still more in respect of the supposed rudimentary and unsatisfactory state of the entire science. The prygress
hitherto wade roay possibly be a mere forshadowing of what we
have to expect: but it has bfen great. It onght not to be under have to expect: but it has been great. It onght not tu be under-
ralued. Men of sound learning, of philosphic minds, of most
accurate habits of investigation, have devoted their lives to this They have placed it at least upon a par with any other great
branch of natural history: in some respects they have carried it beyoud all. In every subordinate deparment of the science the
progress has been so satiafactory that the mereas tyro to whom it

## Home Correspondence

Litium giganteum in North Staffordshire.-This ox raordinary plant flowered splendidly in July last a Biddulph Grange. It was planted in the open border and has borne the three last severe winters without
any other protection than a wooden shutter, intended to any other protection than $a$ wooden shutter, intended to
throw off superfluous moisture ; and even this precaution was probably superfluous. The flowering stem made its appearance in A pril, and rose to the height of 8 or 9 feet crowned by a truss of 15 blossoms, which continued fully 10 days in perfection. They were ex quisitely fragrant and first expanded in the eveniug, a circumstance that might have escaped notice had not the delicious odour-perceptible at the distance of 30 yards -attracted attention to the spot where the plant grew The flower-stem meabured 3 inches in circumference a
the height of a yard from the ground, and was stiff as a the height of a yard fom the ground, and was stiff as a fresh, but instead of flowers is now surmounted hy seed pods as large as those of the common Bean. The plan had been received from Mesers. Veitch, of Chelsea.
Fine as was this specimen, it seems to have been inferior to the one that flowered in Mr. Boseawen's garden, near Truro, in Cornwall ; but this was probably owing in a great measure to the circumstance of the Staffordshire plant having been removed last autumn, which of course dot be done without great injury to its rof our article on this subject at p. 563 . We have another your article on this subject at p. Delphiniums, of lilac and scarlet being met with in the same genus, but certainly you are perfectly correct in stating that no instance has yet occurred where these two colours have been blended by hybridizing. I mention Salvias because I have tried in rain over and over again to produce in them a red and blue striped variety. Subscriber.
Diseased Lobelias.- I regret to find the disease noticed by your correspondent Mr. Foggo as affecting Lobelia ramosoides is by far too common this season, and I suspect in many instances will be attributed to some neglect on the part of the gardener. A neighbour of mine had several of his plants die off rather suddenly without any apparent cause, while the plants in my three months, continue healthy without having exhibited any symptoms of disease in a single instance. Almost every one who has visited the Royal Gardens at Kewthe place above all others in the neighbourhood of London for healthful recreation and rational amusement -must have been struck with the beaution appearance the principal walk leading to the great conservatory; and yet when there a short time ago I was surprised to find the beds that had been the objects of general admiration were occupied with Verbenas, \&c., that seemed by their appear ance to have only been recently planted. On inquiring the reaso:l for this being done so late in the season, was informed that the blue Lobelias with which the were previously filled had been all suddenly attacked with a sort of "blight," and so seriously injured as t render it necessary to have the whole of them removed.
If such has been the case elsewhere I fear the effect of If such has been the case elsewhere I fear the effect of many a gay parterre will have been greatly marred for blue Lobelia occupied. $B$.
Exhibitions.-If prizes are offered for fruit and vege tables in collections of 12 distinct kinds, can parties take the prize if they exhibit in their collections three Grapes, two dishes of Peas, three of Potatoes? Do you term those distinct sorts of fruit and vegetables? Also would it disqualify a party, provided he staged more
dishes than the 12? By answering these questions you would greatly oblige George Taylor. [We apprehend that if there are three really distinct sorts of Grapes, \&c., A person who stages either more or fewer than 12 dishes is undoubtedly disqualified by such an act, and his Mawning Fhould be treated as if not present.]
Mawnring Forest Trees.-I send you two leaves of two Lime trees of the sameage-I suppose 140 yearg-
and whose soil was exhansted by two such large vegeand whose soil was exhausted by two such large vegeables sueking the substance out of it for 140 years. good earth round the stem, and extending as far as the branches, a diameter of about 45 feet. The large leaf is from this tree, and the others on every branch are tree which got nothing (this is 10 inches round). I think this shows how a limited number of ornamenta trees may be dealt with and invigorated, and made to prolong their lives. The labour and cost might prevent it being done to a large extent, and earth might becone
scarce. It has occurred to me whether some more conscarce. It has occurred to me whether some more con-
densed and portable nutriment might not be given, mixed probably with a litule earth or ashes and left to be worked into the roots, in caatious quantity. Perbaps
produce of trees by incineration. Is it not therefore probable that its effect on the roots of trees might be to nourish them ! I mean to try it in a cautious way, and one of the shapes in which I mean to make the experiment is by applying out wonds. I have been burning a good deal of stuff, out wonds. I have been burning a good deal of stuff,
and I mean to apply the residuum in this way. I find and I mean to apply the residuum in this way. I find
also that coarse sulphate of potasss can be purchased at 6s. 6 d . per cwt., and 1 cwt . will do a great many trees, sowing it on the surface and leaving it to be washed in by the rains, of which we have abundance.
I live in the belief that there would be a good result. $K$. I live in the belief that there would be a good resuit. $K$. [We cannot entertain a doubt that the method here pated. The difference in the leaves of the two Lime trees sent us was most striking.]

## Borieties.

Crystal Palace Horticultural Exhibition.-The ast of the great cisplays of Fruits and Flowers held this year under the auspices of the Crystal Palace Company took place on Wednesday, Thursday, and Friday las, was perfectly successful. The park and terrace gardens were in excellent condition, the beds well furnished with flowers, and the vases, which are wholly filled with Scarlet Geraniums, were a perfect blaze of beauty Indoors the plants were also extremely healthy. up pill rowi at least 12 feet in height. Two remarki or their opposite the Sheffield Court were remarkable ess than 12 feet in beauty; hey couldion measure Water Lilies were blooming profasely in the aquaria. The number of visitors during the three days, we understand, was upwards of 50,000 .
The display of Stove and Greenhouse Plants contri uted on this occasion was comparatively limited; but what were produced were well flowered. They consisted chiefly of Plumbago capensis, Heaths, Allamandas, Dipladenias, Ixoras, Stephanotis, Clerodendrons, Vero iras, Cyrtoceras reflexum, and Pleroma elegans. Japan Lilies, of every shade of colour from pure white to the richly-spotted rubrum, were shown in abundance. Some of the intermediate varieties were extremely handsome especially one in a group contributed by Messars. Jackson,
Of Verbenas there were several collections, the best which was furnished by Mr. Shrimpton, gr. to A. Doxat, Esq. These were trained over flat circular wir rellises, and were beautifully in flower. To crimson sorts Geant des Batailles promises to be a good addi-
tion. Among scarlets Mrs. Woodruff and Lord Raglan tion. Among scarlets Mrs. Woodruff and Lord Raglan is Wonderful. These sorts all possess white eyee, which serve to set their respective colours off to excellent
beat.
Cockscombs and Balsams were exhibited; but the former were not good, and the latter, with the exception of a collection from Mr. Smith of Dulwich, were past rest. Mr. Smith's were however beautifuly fown and flowered. The way in which he manages sent year's volume.
The exhibition of Scarlet Geraniums, three stage deep, was quite 14 yards in ltngth. The best of them were Frogmore, Tom Thumb, Lady Middleton (which is not distinguishable from 'Trentham Rose), Rubens, and Le Tititn. The last is a very fine kind with beautifully compact heads of flower. Among sorts with horse-shoe leaves were Baron Hugel, Masterpiece, snd
Brighton Hero ; and of variegated sorts beautiful plant of Brilliant, Attraction, Silver King, Golden Chain, and Flower of the Day. We also noticed variegated and ther kinds gratted standard high.
Fuchsias occupied a piece of stage at least 24 yards in length, and among them were some well grown plants. Of light kinds we remarked Queen of Hanover, Venus de Medici, Pearl of England, Duchess of Lan caster, pure white with rose coloured corolla, Enyland' Glory, a good bold flower, Clio, and the small purple orolla'd Snowball. Among dark kinds were Autocrat Prince Albert, Orion, Duke of Wellington, Banks Glory, Alpha, and General Williams. There was also good dark kind with a double corolla.
Achimenes were exhibited in tolerable abundance Among the sorts were gigantea, a variety in the way of picta, Chelsoni, rosea, the blue and white varieties o ongiffora, the white Marguenitre, venusta, Backmanni good purple, and Edmond Bossier, white, prettily treaked round the eye with rays of lilac
Of Lycopods there were several well grown eollec nequalifula were beautiful plants of Danielsianum nequalifolium, Mertensi, lepidophyllum, Casium arbo ream, Galle otti, stoloniferum, denticulatum, flexuosum umbrosum, viticulosum, Wildenovi and apodum. The lively green comp
tion of everybody.
Of Ferns there was a large bank of handsome speci mens here and there mixed with Orchids and Pitcher Plants. Of Gymonogramma there were as usual some beautiful species; aiso Cheilanthes lendigera, Asplenium beautiful, Pteris geranifolia, Gleichenia dicarp?,
and Sagean alata. Adiantums, Aspidiums, and otheis commonly met with were also abundsint.
Pitcher Plants came from Messrs. Veitch and Gedney The sorts we
Orchids were scarce. They were funithed by Woolley, Carson, and Gedney. Among them were the pretty Eria densiflora, Miltonia spectabilis, Aerides suavissimum, Odontoglossum grande, Peristeria elati, the blue Vanda, Epidendrum vitellinum, with blosome of unusual brilliancy, and two Angreecums.
Heaths were in good condition, but not plentifol. Among the sorts were Clowesiana, Lrbyana, Massoni Austeniana, and retorta major.

Plants remarkable for fine foliage were shown extee sively. The best group as usual came from Messra Veitch. It consisted of noble plants beautifully arranged of Livistonia borbonica, Philodendron pertusum (a species with large and handsome leaves), Dracena Draco and indivisa, the beautiful Aralia pulchra, Pleetocomia elongata, Pandanus utilis, Dion edule, Cyce revcluta, and Sabal umbraculifera. The same firm contributed a very fine group of Variegated plants, and contributed a very fine group of Variegated plants, and
collections of the latter were also shown largely by collections of the latter were also shown largely by
other growers. Among the different kinds were Mum other growers. Among the different kinds were Mum
zebrina, Maranta Warczewiczi, Croton pictum, Diefienbachia picta, the beautiful Cissus discolor, Croto variegatum, and C. discolor, the latter with leaves red underneath and green above, Pandanus argenteus varie gatus, Coleus Blumei and pectinatus, the former blotched, the latter streaked and mottled with brown the red and brown Dracæna terminalis and ferrea Ananassa sativata variegata, a variegated variety o the Aloe-leaved Yucca, a Hydrangea with green and white leaves, the variegated Aspidistra lurida, Cals dium pictum bicolor, and the red hairy-leaved Begonis plendida So large an assemblage of these and other beautifully variegated plants was perhaps never before rought together ; their effect en masse was admirable.
Fruit, it need scarcely be remarked, formed one of
e most important features of the show. It was very the most important features of the show. It was very
plentiful ; but with one or two exceptions it did not plentiful; but with one or two exceptions it did not the same may be said of Plums, which on the whole were very good. Pears were not very plentiful, but there was a good display of Apples
The best collections of 12 dishes of 10 distinet hinds of fruit were contributed by Mr. Fleming, gr. to the Duke of Sutherland, and Mr. Tillyard, gr, to the Rt Honourable the Speaker at Heckfield. Mr. Fleming' exhibition contained a Black Prince and Moscow Quee Pine Apple, both good, but the latter a little over ripe Muscat and other Grapes, Trentham Hybrid and Hybric Cashmere Melons, Violette Hâtive and Red Roman Nectarines, very fine Walburton Admirable Peaches, Moorpars Apricots, Morello Cherries, and Jargonello Pears. Mr. Tillyard had a good Black Jamaica Pine Apple, two Melons, very nice Violette Hative Nectarines and Nobleese Peaches, Re Magnum Bonum and Washington Plums, White Ischis Figs, excellent Black Hamburgh and White Nice Grapes, Morello Cherries, and White Carrants. third collection from Mr. Page, gr. to W. Leaf, Esq., of Streatham, contained Sharpe's Emperor and Jefferson Plume, Yellow Ingestrie Apples, Brown Turkey Figs Elruge Nectarines and Noblesse Peaches, Black Ham burgh Grapes, two Queen Pine Apples, Jargonelle Morlo and Of collections of eight dishes of 6 distinct kinds o fruit the best came from Mr. Frost, gr. to E. L. Betts Esq. It contained a Queen Pine Apple, Muscat an Black Hamburgh Grapes, King's Green-fleshed Melon Grosse Mignonne Peaches, Violette Hative Necta rines, Jefferson Plums and Morello Cherries. Nex in point of merit was a collection from Mr. Robinson, gr., Warnford Park. It contained a Black Jamaica Pine Apple, Muscat and West's St. Peter's Grapec Nectorio Brunswick Figs, and Melon. A thir collection came from Mr. T'aylor, gr. to J. Coster, Esq.z of Streatham : it contained a Golden Perfection Melon, a Queen Pine Apple, Black Hamburgh and Muscadine Grapes, Brown 'Turkey Figs, Noblesse Peaches, Jeffer son Plums, and Morello Cherries. Other collections came from Mr. Kaile and Mr. Martin, gr. Selwood Park, Sunning Hill.
Of Providence Pine Apples noble specimens eame from Mr. Bray, gr. to J. B. Lousada, Esq ; and from the Duke of Devonshire's garden at Chatsworth Queens large and beautifully formed came from Mr Barnes, of Bicton. These, we should think, could not weigh less than 6 lbs each. Mr. Bray had also sod handsome specimens of this kind of Pine Apple, andso had Mr. Page, gr. to W. Leaf, Esq. Mr. Dand some Pan frit Schreiber, Dowlais House Glamorganshire
Three excellent dishes of Grapes came from Mr Fleming of Trentham ; the sorts Muscat and Black Hamburgh. Mr. Ewing, of Bodorgan Hall, also Bur nished very fine bunches of Barbarosss and Blace Hamburgh, both of which had, however, suktained sols little injury from travelling. Mr. Alborough, of Brou Museat, and Back Hamburgh. In the elass of tw dishes, Mr. Snow, gr. to Eari de Grey, had some wel grown and beautifully ripened Muscats ; Mr. Flemide Muscadines and Museats, and Mr. Robing 12 lhe
Frontignan and Muscats. Boxes containing
of Black Hamburgh beautifully coloured and covered with bloom were furnished by Mr. Harrison of
lands, Mr. Kay of Finchley, and - Mr. Clarke of Manchester. The last appeared to be Mill Hill Hambursh. The largest bunch of Grapes shown was one of Muscat of Alexandria, coarse and green. This came from Mr . Young, gro to C. Bailey, Esq., Aberdare. The
next largest, a beautifully ripened bunch of Mitchell's next largest, a beautifully ripened bunch of Mitchells seading, a kind Mr. Vare sent a noble bunch of Black Hamburgh.
Peaches and Nectarines were well ripened, but small. In the class of 6 dishes of 3 kinds, the best came from Mr. Frost, gr. to E. L. Betts, Esq. The varieties were Grosse Mignonne, Gallande, and Barrington Peaches, and Elruge, Newington, and Hunt's Tawney Nectarines. In 4 dishes Mr. Dawson had Grosse Mignonne, and Violette Hative Peaches, and beautiful specimens of dishes, Mr. Lane, gr. to J. H. Palmer, Esq., of Fulham, had excellent Elruge Nectarines and Violette Hâtive Panohes Fine fruit of the last-named variety and of Pitmaston Nectarine also came from Mr. Dawson.
Pitmaston Nectarine also came from Mr. Dawson.
Which were however composed of very small fruit. The Which were however composed of very small fruit. The
best came from Mr. Ewing, gr. to O. F. Meyrick, Esq., Bodorgan Hall, Anglesea.
Melons were not very plentiful. The best Greenfleshed came from Mr. Munro, gr. to Mrs. Oddie, of Colney House, East Barnet. The sort was the Bromham Hall, sometimes called Pine Apple. Mr.
Whiting of the Deepdene furnished the best Scarletfeeshod.
Figs: the best were contributed by Mr. Bousie, Marseilles. Excellent fruit of the Brown Turkey came from Mr. Robinson of Warnford.
Cherries were chiefly confined to Morellos, of which there was some beautiful fruit. The best two dishes came from Mr. Dawson; one was the Florence, the from Mesers. Hudson and Betteridge.
of Plums, remarkably fine specimens of Jefferson, Kirk's and Greengage were shown by Mr. Snow, gr. to Earl de Grey, and nearly equally good
fruit of the Jefferson, Kirk's, and Washington, came from Mr. Bousie. We also noticed good specimens of Magnum Bonum.
Dessert Apples, beautifully ripened and well coloured, were shown by Mr. Mitchell of Brighton. The sorts were Nonesuch, King Pippin, Summer Golden Pippin,
Court Pendu Plat, and Margil. Of kitchen varieties the best carme from Mr. Munro, gr. to Mrs。 Oddie. The ${ }^{3}$ orts were Norfolk Beaufin, Emperor Alexander, White Quaranden, Hawthornden, Alfriston, and Keswick Codlin.
Of Pears the best flavonred dish was furnished by Mr. Whiting ; the sort Jargonelle. Mr. Taylor, gr. to J. Coster, also showed fine fruit of this variety.

Of Fruit trees in pots Messrs. Kaile, Lee, and Lane Plums, collections containing Peaches, Nectarines, and Nectarines large and well coloured.
Cat flowers in the shape of Dahlias, Hollyhocks, China Asters, and Pansies were shown in great abundCamee, and for the most part in excellent condition. Nothing in their way could possibly be finer than the collection of Dahlias contributed by Mr. Turner, of
Slough. Mr. Keynes also showed very good blooms. Slough. Mr. Keynes also thowed very good blooms.
Among the Dahlias shown by Mr. Turner were Sir Among the Dahlias shown by Mr. Turner were sir staney, Sir C. Napier, Captain Ingram, Bessie,
Cossack, Lady Popham, Earl of Carlisle, Yellow Beauty, Cossack, Lady Popham, Earl of Carlisle, Yeliow Beauty,
Shadel, Lord Palmerston, Rosea elegans, Tyrian Prince, Satirist, Beauty of the Grove, Salvator
Rosa, Edmond Foster, Sir F. Bathurst, Fenella, Model, King of Autumn, Fame, Grande Sultan, Miss Burdett Contts, Butterfly, Lollipop, Essex Triumph, Rachel Rawlings, Richard Cobden, Perfection, Eclipse, Lord Ragian, Colonel Wyndham, Deita, Ruby Queen, Sir Chance, Mr. Seldon, Exquisite, Amazon, and Admiral Dundas. Among Mr. Keynes' flowers, Dulse of Devonshire, Morning Star, Lord Cardigan, Negro, Evening Star, Chameleon, Miss Nightingale, Lady Paxton, Omar Pacha, Marshal Pelissier, Hamden Beauty, and Chrysalis. Fancy varieties differed but Beauty, and Chrysalis. Fancy varieties differed but
little from those recorded at p. 583. Several seedlings were shown, and some received prizes of these we hope to give some account hereafter.
 Chater's were Sir W. Middleton, salmon; White Globe (Paul's), Mr. J. Clarke; Purple Perfection; Jabez Chater, rosy salmon; ignea, rich orange; Sulphur
Queen Improved; Alexandrina and Lady Middleton, darl rosy salmon. Mr. Paul had Queen of Whites, beautiful variety with none of that green tinge which whites generally have; also Primrose Perfection,
Rosy Morn, a lively looking bright pink Lind; and a eream coloured sort called Pearl. Several collectious condition, and individually very beautiful; but Holly hocks to be seen in perfection should be shown in the shape of spikes.
do, atoser were abundant, and formed, as they always nished by Mr. Mireat attraction. The best were furAnong the varieties we remarked beautifal blooms of

Dijon, General Jacqueminot, Lord Raglan (which de Dijon, General Jacqueminot, Lord Raglan (which pro
mises to be one of the very best of our new Roses) Acidalie, and Mrs. Bosanquet. Mr. Cranston had a fine Acidalie, and Mrs. Bosanquet. Mr. Cranston had a fine
boxful of Gloire de Dijon, which is one of our best and hardiest of Tea Roses. He also showed good blooms of Cloth of Gold, and of that fine Rese Jules Margottin From A. Rowland, Esq., also came some fine blooms. Vegetables were not very abundantly contributed, and
what did come were not first-rate, with the exception of what did come were not first-rate, with the exception of
one dish of Potatoes called Bradley's Kidney, which was greatly admired. They were very regular in shape, and quite smooth and polished in the skin. Many larger varieties were shown, but they were coarse were good.

Entomoloeical, Sept. 1.- W. W. Saunders, Esq. F.R.S., President, in the chair. The President before entering upon the business of the evening communicated to the Society the great loss which natural history had taken place suddenly on the morning of the meetiog at taken place suddenly on the morning of the meeting at
Yarmouth. As one of the most profound British naturalists, and one of the most amiable of men, Mr. Yarrell's loss would be long felt. He had taken a warm interest in the welfare of the Society from its first establish ment, and had for many years acted as its treasurer.
Donations of works upon natural history presented to the Society by the Royal Agricaltural Society, the Zoological Society, Society of Arta, \&c., were an nounced. Mr. Weatwood called attention to the modi fication in respect to the distinction of species and
local varieties which was attempted to be estahlished in local varieties which was attempted to be established in Dr. Schaum's new work on the Coleoptera of Germany, in which a great number of insects hitherto regarded
as distinct species were sunk into local varieties : point of view which was recently gaining ground to a
considerable extent in this country. Mr. Wallace ex hibited specimens rarity, recently captured in the Isle of Wight, namely Caradrina exigua, hitherto unique, and Botys silacealis known only by a specimen in the old collection Francillon, which had consequently been regarded as a doubtful native species. Mr. Janson exhibited the London, hitherto of very great rarity-Dinarda den tata, a single specimen in the British Museum recorded as captured by Leach in Devonshire had been doubted as British ; Dendrophilus pygmzeus (D. Sheppardi Curtis); Dorcatoma rubens in an old Oa tree ; and Cryphalus binodulus, a genus of Bostrichide new to this country. The species of this family are gene rally found under the bark of Conifers, but the present
species was found under the bark of Aspen. Mr. species was found under the bark of Aspen. Mr
Douglas stated that he had observed Apate capucinu in the staves of casks of Currants imported from the Ionian Islands. Mr. S. Stevens stated that he had reared a beautiful species of Plusia and a Pyralis which had fed on the leaves of plants imported by him from Madeira, which he noticed as an instance of the facility with which foreign species might be accidentally introduced into our native lists. Mr. Hunter stated the circumstances under which he hitreill ported specimen. Mr. Turner exhibited a new Depressaria from the neighbourhood of Worthing Mr. Newman exhibited specimens of a curious white woolly insect found on leaves of Grass, which the pre sident recognised as a species of Coccus. Mr. West wood gave an account of several masses of eggs of a Phryganea inclosed in gelatinous masses Greun exhibited Cleora Lichenaria reared from the larva feeding upon an orange-coloured Lichen. Mr. S. Stevens exhibite the larver of Agrotis Ashworthii and Macrogiossa Stellatarum. Messrs. Dutton and Moore also exhibited
numerous insects recently captured ; and a paper by Mr. Bates, containing the capcrion of a new species of Myrmecilla (one of the Cicindelidæ), was read.

## Garden Memoranda.

Mr. Wilkins' Exprrimental Garden, Readimg. The supplying growing erops with liquid manure underground has long occupied Mr. Wilkuns' attention, and the practical value of the plan on a smali scale has for the success which we had heard had attended his efforts we were induced to pay his experimental garden a visit in 1854, and the result of our inspection on that oceasion will be found at p. 536 of our volume for that yeur. We again inspected his crops the other day, achan and and condition. They are growing in beds botomed the hin tile or brick which aha encioses them at the ends and sides to the height of 4 inches, and down the middle of each bed a drain-pipe is laid, which conduets and diffuses the manure-water over the whole of the bottom of the bed. At one end of this underground drain is placed an upright pipe which is fed by a series of smail gutta perwha pipes connected with a reservoir in which the manure-water is made, and from which by turning a tap all the beds can be supplied with liquid manure at one and the same time, and when enough has been furnished them, which is known by the height at which the water stands in the upright pipe, the tap is gain turned and the supply cat of. Wuch is Mr. Wilkins present plan of preparing the beds and sapply-
describing are others formed in the usuul mauner have each the old and another on the new system the eam been planted at the same thase and with ference between the one and the other can be seen at a glance. The first bed we inspected consisted of French Beans in a state of maturity. The pods of those on the new system were much more plentiful than those on the old plan; they were aloo individually longer and contained Beans of larger size. In German Greens on the new and old plan there was a marked difference in favour of those to which manure water had been applied. Rhubarb both on the new and old systems had been good, but that on the new especially so, the flower stem rising 7 feet in height; both had manure water had been applied had pushed fresh stems fit for use, while on the bed not so treated there was not a stalk longer than the finger. Hemp on the new system had made stems 7 feet 4 inches high, and strong in proportion, while that on the old plan was only 4 feet 5 inches in height, Emall, and spindly.
Sutton's Early Six Weeks" Turnip, sown three weeks ago, warl but on the old plan they had entirely failed, the fly having attacked and ruined them before they had got into rough leaf. White Globe Mangel Wurzel on the new plan was a perfect crop, while on the old system it measured 2 feet 3 inches in girth. Swedes were greatly in advance of those in a neighbouring field where the highest class tillage is pursued, some of the roots on the new system girthing $23 \frac{1}{2}$ inches round, while those in the field and on the old syatem had scarcely half that circumference. The difference between the growih of Carrots and Parsnips on the new and old systems wha also equally remarkable, those on the new being much the largest.
In Potatoes the difference was not so great; both were good and apparently free from disease. Some in pure sand and sawdust, but fed with liquid manure, were both growing vigorously. Brussels sprouts on the Hops both manured and otherwise were good and bearing heavy crops. A pole raised from a cutting planted in the spring of this year was 11 feet in height and full of fine Hops from top to bottom. The yield of Wheat, doubl that grow on the plars of Whast were much finer, and the individual grains larger. Marsh Mallow grown for its fibre was equally as good Marsh Mallow grown for its nore was equally as good on the old system as on thew. It win that Mr. Winkios plan of reeding crops in active gew with liquid manure an the root has been productive of the best resalts, and small gardens allotment holders and others possessing smal gardens it will be found invaluable. By its adoption they may which their gardens at present yield them, and that at little trouble to themselves. We understand indeed that a company is being formed to carry out the plan in regard to small gardens at a very emall expense, which the cottager will be permitted to repay in such a way as his means will allow him. As we have said, boofore, to small hulders the plan may become great large scale remains to be proved. The preat obstacle to its universal adoption is its expense. That, however the patentee thinks may yet be overcome.
We may mention, in conelusion, that Mr. Wilkins has made capital bread of half Mangel Wurzel and half Wheat flour; its taste is good and its colour equal to that of second-rate bakers' bread. He has also made wine from Mangel Wurzel, which he says might be sold for $6 d$. per quart bottle. We tasted some of it after it had been three weeks bottied; it was, of course, not in perfection, but it promised to be excellent after it had been longer in the bottle

## Miscellaneous

Bunya-Bunyd.-The finest cone of Bunya-Bunya A raucaria Bidwilli) that has perthaps ever been sent to Europe, formed part of the collection of the Australian products in the Exposition Universelle at Paris, 1855, and was exhibited by Chas F. D. Parkinson, Esq., of Moreton Bay, son of Col. Parkinson. Through the mediom of Col. J. Sidney North, M.P., this has been presented to the Museum of the Royal Gardens of Kew, and it is accompanied by the following interestiog particulars, from the pen of Mr. Parkinson himself :"This tree is deserving of more notice than any other growing in the northern districts of New South Wales ; not perhaps because the quality of the wood may be superior to the other kinds of Yine, but because each tree belongs to some one individual of the Aborigiees The Bunya-Bunys is of the Pine kind, and grows in scruhe or ranges of hills or monntaina. growing in a wild state furcher to the soath than the range dividing thrett ; but in the Wide Bay District, Brisbane and Burnett ; but in the Wide Bay District, in the 27 th parallel, it grows very thiekly over an extent of country, about 30 miles by 12 , which is in
consequence called the 'Bunya-Bunya country.' The tree is easily distinguished, as it far outtops every other kind of tree in the scrubs; and instead of the branches pointing downwards as in the Moreton Bay Pine (Araucaria Cunniughami), they grow straight out from the tree, or rather with a curve or inclunation
upwards. In beight is immense ; Leichardt mention
the r being 160 feet high betore there were any
branches; for in its wild state the branches only grow near the top of the tree, owing to the want of light in the scrub, but if planted out in an open space they feather same purposes as Pine, and is rather more durable : it makes excellent sheep-luurdles. The leaves are of a rich dark green, and sharp-pointed, so much so as to be prickly. The cone, or fruit, is very large, and grows on the extreme tip of the tree. This fruit is only plentiful every third year. In appearance it is like an
immense Fir cone, and is, hefore it is quite ripe, of a beautiful green colour. Measurement of the cone sent to the great French Exhibition:-12 inches in length 22 inches round the broadest part, transversely; 19 . globe. When the proper season arrives, the native assemble in great numbers from very great distances all around, for the purpose of eating the fruit, which they generally roast. Each tribe has its own peculiar set of trees, and each family its own allotment among them. These are hauded down from generation to generation tree not belonging to him, a fight, or 'pullen pullen,' is the inevitable consequence. This is believed to be the the inevitable consequence. This is believed to be the
only hereditary personal property possessed by the Aborigines, and $i t$ is therefore geverally respected, and this makes the 'Bunya-Bunya' interesting." Hooker's Journal of Botany.
American Apple Orchards.-In America they have rchards, but they ${ }^{\text {and season of rest in neglected }}$ spring frost. Downing, in his work, the "Fruits and Fruit Trees of America," treating on orchard culture, 3ays, "The bearing year of the Apple, in common the excessive crop which it usually produces, by which they exhaust most of the organisable matter laid up by the tree, which then requires another season to recover Wh collect a sufficient supply a avain to form fruit buds. When har the fruit is thinned out in a young state, leaving only a moderate crop, the Apple, like other fruit
trees, will bear every year, as it will also if the soil is trees, will bear every year, as it will also if the soil is
kept in high condition." He adds in a note, "One of the finest orchards in America is that of Pellham Farm at Esopus, on the Hudson. It is no less remarkable for the beauty and high flavour of its fruit, than the constant productiveness of the trees. The proprietor, C. J. his esq., has kindly furnished us with some notes of following highly in teresting one on the Apple:-'F For several years past I have been experimenting on the Apple, Iaving an orehard of 2000 bearing Newtown Pippin trees. Ifound it very unprofitable to wait for what is termed
the 'bearing year,' and it has been my aim to assist Nature, so as to enable the trees to bear every year. I have noticed that from the excessive productiveness of this tree, it requires the intermediate year to recover itsel - to extract from the earth and the atmosphere the materials to enable it to produce again. This it is not able to do, unassisted by art, while it is loaded with fruit, and the intervening year is lost. If, however, the tree is upplied with proper food it will bear every year ; at least such has been the result of my experiments. Three years several thousand traped in my orchard, and washed all the trunks and stems within reach with soft soap; trimmed out all the branches that crossed each other, early in Juve, and painted the wounded part with whitelead, to exclude moisture and prevent decay. I then, in the later part of the same month, slit the bark by run-
ning a sharp pointed knife from the ground to the first set of limbs, which prevents the trees from becoming bark-bound, and gives the young wood an opportunity of expanding. In July I placed one peck of oyster shell lime under each tree, and left it piled round the trunk urtil November, during which time the drought was excessive. In November the lime was dug in thoroughly. The following year I collected from these trees 1700 barrels of fruit, part of which was sold in New York for four and others in London for nine dollars per barrel. The cider made of the refuse, delivered at the mill two days after its manufacture, I sold for 3 dollars per barrel of 32 gallons, exclusive of the barrel. In October I manured these trees with atable manure in which the ammonia had been fixed, and covered this immediately with earth. The succeeding autumn they were literally bending to the ground with the finest fruit I ever saw, while the other trees in iny orchard not so treated are quite barren, the last season having been their' bearing season.' I am now placing round each tree one peck of charcoal dust, and propose in the spring to cover it from the compost more extracts from this work to show that in America orchards, when neglected, bear crops every alternate year only, but where under proper culture they bear perseverance of this American gentleman, who takes so much pains with his Newtown Pippin trees, then may we hope to hear no more outcries as to the failure of our crops. M. Saul, in Turner and Spencer's Florist, Fruitist, and Garden Miscellany.

## Calendar of Operations.

(For the ensuing week.)
PLANT DEPARTMENT.
Comespratomy, dc.- Where valuable stove plants
have to be kept here while in bloom, they will require
areful management to prevent their being injured by stove plants are soon injured in a low temperature if kept too wet underground. Give air freely on bright days, but if the house contains many stove plants it will as to retain a little warmth for the night ; and in the event of wet cloudy weather setting in, it will probably be found necessary to use a little fire-heat, to dispe damp and preserve the blossoms of tender things, and
this should be seen to before handsome specimens get disfigured or ruined for the season ; for these in bloot are not over plentiful about most places at this season of the year, and are therefore worth caring for Keep everything in this house as clean and neat as possible, removing decaying flowers and leaves, \&c, mmediately they are perceived, and examine pot specimens frequently, particularly such as may not round in order to expose all their sides equally to light and air.

## forcing department

Pineries-A rather dry state of the scil about the roots and also of the atmosphere is essential during the ripening of the fruit where high flavour is an object, the fruit is approaching maturity water plants on which the fruit is approaching maturity, and it will be adviaable sufficient air to prevent a staguant state of the atmosphere, for fruit of first-rate quality canot be expected from plants growing in a sodden soil or a damp unhealthy atmosphere. Endeavour to afford growing stock steady bottom-heat of about $85^{\circ}$, and keep it well supplied with manure-water at the root, but avoid getting considerably. As fire-heat will now eo necesa case during the summer, care must be exercised to secure a properly moist state of the atmosphere, keeping the evaporating pans or troughs regularly supplied with water, and moistebing the floors, \&c., frequently, as any
svdden change from a moist to a dry state of the atmo svdden change from a moist to a dry state of the atmoalso to plants swelling their fruit. Be as sparing fire-leat, however, as circumstances will allow, and shut up early on the afternoons of bright days, so as to Where young sock is crow in dung-pits care must b exercised after this season not to get the plants wedily through keeping too close and warm, giving air freely on every favourable opportunity, and sufficient comman warmth should be secured from the linings to allow giving a little air at night and on cloudy days in houses where the fruit is ripe; but only just suf n houses where the fruit is ripe; but only just suf
ficient to keep the atmosphere dry, and look over the bunches, frequently removing any tainted berries inmediately they can be perceived, for these if left in the it to spread much faster than would otherwise be the case. It is still a too common would otherwise be the Vines to the weather immediately the fruit is cut, and somes persons deem this practice essential to the ripening of the wood. When the weather happens to be warm and dry, such treatment may answer very well, but to expose Vines in wet, cloudy weather, when the object is the ripening of the wood, is sure to result in disappointment; therefore, where the wood is not properly ripened, keep the atmosphere dry and moderately warm, and use sufficient fire-heat to allow giving air fieely both day and night. Use brisk fires houses where the fruit is not yet ripe, giving air freely, and be careful to guard the foliage from insects particularly where the fruit has to be kept for
any length of time after it is ripe. Peaches.-As the trees will now be freely exposed to the air day and night, very little attention will be required here for the present. The foliage should, however, be kept clear of red spider, by an occasional washing with the engine where necessary, so as to preserve it in health until has performed its functions and decays naturally. any trees have to be removed here from the open wall this may be done immediately the present crop o ruit is gathered, as the removal very caretully will not and tho thee propery anded therwards will not prevent the wood ripening, and there will be
plenty of time for the trees to make fresh roots and get sufficiently established to carry a crop of fruit next season if not forced too early.
fLOWER GARDEN and SIIRUBBERIES.
If previous directions have been attended to, the propagation of next season's bedding stock will by this time be well advanced, and where, from the pressure of other work or other causes, this is not the case every possible dispatch must be used while the weather is favourable for such work. Where cuttings of Ver benas and such like things have yet to be put in they should be inserted rather thinly in deep pans or shallow pots, in which they can be wintered, as they will be got
established sooner in this way than would be the case if they were to be potted off before winter, and we have requently found late cuttings managed in this way to winter fully as well as stronger plants; and, except plants intended to furnish cuttings in spring, before winter provid small bedang plad with out having been got up in a close warm atmophere to render them sappy and tender. Many parties, through anxiety to secure large plants, kee and frequently in frames on dung beds, where size is
soon obtained, but plants treated in this way are neces sarily so scft and tender that it is almost impossible to Therefore avoid keeping such things too warm after this season, and if they are placed in bottom heat give air at night and whenever it can be done withou the cuttings flagging, so as to prevent weakly growth.
hardy fruit and kitchen garden.
Where wasps are troublesome means must be taken to preserve ripe fruit from their depredations, and Plums and Peaches had better be netted up, as wasps, if at all numerous, sonn do serious damage to these Also look frequently over any varieties of Pears ripening, and gather those that are fit, for if allowed to han after they are ripe the wasps are sure to find them, and will attack the fruit before it is fit for gathering, so that the crop will probably be spoiled unless it can be netted up. Where Currants are covered with mats, which, by the bye, are very inferior to close nets for this purpose, and much more expensive, the trees should be un covered occasionally on fine dry days, so as to expose the fruits thoroughly to the air, in order to prevent their being injured by damp, \&c. Trim and dreas Srawberry plantations, and be careful to injure the leaves of the plants as intte as possible, and avoid deep digging between the rows which is of no farther use than to injure the roots, as the Strawberry rather prefers a somewhat firm soil.

## Notices to Correspondents

QUEEN'S COLLEGE, CALWAY
THE COLDEGE SESSION for HE COLLEGE SESSION for 1856-57 will commence on TUESDAY, Oetober 218t, when the Suplemental down in the Prospectus.
The First Matriculation Examination for the Session will take place on FRIDAY, October 24th.
Additional Matriculation Examinations will take place before the close of the tirst term. In the department of $A$ griculture four Scholerships of the value
 and two to Students of the second year.
empowered to award at the same examination two prizes of 122 . second year.
N.B.-In addition to the Scientific Education given in the Lecture Rooms of the College, the most auplo means are now possegsed for giving practizal instruction to students in Agricul-
ture. The Professor will exhibt on his own farm as well as on large property of which he has the management the best examples laf land improverment, and superinr cropping on waste worn out
of and
bon and mountain lend, with specimens of the crops raised thereon. bog and mountain lend, with specimens of the crops raised thereon.
Further information may be had on application elter personally or by letter to the Registrar, Queen's College, Gaiway
from whom also copies of the Proopectur may be obtained.-By order of the President, Wriciax Lurtos, A.M, Registrar.

R. MORTON has a few quarters of healthily grown and perfoctly ripened Seed to dispose of. It is of both white Wheats of gond quality and great proviuctiveness, the Browick; and (4), the so-called "Tiney's success" - both produc tive varieties of Red Wheat, the former yielding rather the bulkier, though at the same time the some what coarser produce of the two. They have all been grown on a light Eandy sili; and
in every case it has been a standing crop of brikht unmildewed Post-opfice ordera to to mate in to Johr C. Morrox, West Moulseg, Surrey

## The Agritultural Gajette.

SATURDA Y, SEPTEMBER 13, 1856.
The use of dry antumn weather in the cultivativation of our stabbles is well insisted on and described by our excellent correspondents Messrg.
HARDY in the following commanication, with which we have been favoured by them :-

Now that harvest is past is the time to set about the burning of the stubbles. No employment of horses and men pays better or does more good on the farm. As soon as the corn is cleared off the fields a Bentalu's or other broadshare, and a large rake, fork, and shovel for each man employed are required to effect the purpose, myriads of seedling weeds to spring up before myrnads be ploeghed and sown, such as would other-
it is to be wise not have germinated for years. We would just observe that whoever is not supplied with the efficient implement made by Mr. Bentall ought to be, and our distant correspondents who have no knowledge of it will do well to take our recommendation of it as a first-rate article for expeditiously and cheaply cleaning the aurface of the land
"The process of paring and burning is simple, cheap, and efficacious. First, the broadshare, three horses, one man, and a boy, will pare twice over 3 acres in a day, say at 58. per acre. Three men then follow whilst all is dry, with large-sizrd atrong rakes, raking up all the stubble and weeds in their green state before they shed any seeds, taking five common-sized ridges at a time, forming fires on the middle ridge at about every 2 to 3 rods; then with a four-pronged fork they form and light the fires as they go along at three places on opposite sides. When these are about half burned through they rake all the clods up towards the fire and bury up at night by heaping all the earth over them that can be shovelled up around them. The next morning most
of them, and all, if properly managed, will be arrive at that maxioum of produce which our burned or scorched throush sufficiently to kill all vegetable and animal life of which they contain the germs. The fires will then require but little trimming and tucking up, and the work is completed, leaving about a load of burnt earth at each fire, and at about 40 loads at least on an acre, valued at $2 s$ s. per load. We say on, for it is already on, and this makes it so valuable, as all cartage is on, and this makes iave valuable, as all cartage is
spared, and on heary lands no manure will be required for the next crop of corn."
The expense of these operations need not exceed $10 s$. or $12 s$. an acre, and the result, independently of the fertilising dressing thus obtained, is worth far more than this in the diminished cost of keeping clean the green erops of the following year. What land can be manured in autumn should have its dressing carted on after this fallow operation is completed, and being ploughed up and left till spring is in the best possible condition for such early spring culture as may be needed to prepare it either for the Bean crop or the Mangel Warzel.
The agricultural statistics of Scotland for 1854 were published in February 1855: those for 1855 were published in December of the same year: the statistics of 1856 , so far as the acreage of the crops and the number of the live stock are concerned, were pablished on Sept. 1. There is progress here in a very important point-the quickness with which we are all informed of the results of Mr. Hasu's inquiries. It was of little service to inform us in February, when half the produce of the land had already been consumed, how much food had been produced, and even in December such information would have had comparatively little influence on the food trade of the country. It is of the very greatest importance to safe trade that we should have, just as the consumption of the new year's food begins, certain data laid before us from which the year's supplies may with tolerable certainty be calculated. And for this, so far as Scotland is concerned, we have to thank the agriculturists of Scotland, the Highland Society, and its energetic secretary. These all receive the thanks of those interested in the attainment of such information from the whole country, and who see the earnest of success elsewhere in the remarkable success which has attended the inquiry in the north.
But the tables themselves, as well as the time of their appearance, indicate remarkable progress. The quantity of land in Wheat has amounted this year to 261,842 acres against 191,300 in 1855, an increase of one-fourth in a single year ! In Barley the extent is diminished, being 165,663 acres this year against 186,082 in 1855. In Oats the average is 918,258 in 1856 against 933,662
in the previous year. In Rye we have this year 4754 acres against 3692 in 1855. In Bere there are 15,385 acres against 17,263 in 1855. Of Beans there are 40,488 acres against 37,338 in the previons year. And to take the more important of the green crops, we have 459.741 acres of turnips nowgrowing while there were 449,404 acres last year. Potatoes are grown on about the same extent of land-viz, 148,930 acres this year, and 146,969 last year. Mangel Wurzel is rather on the increase: there are 3642 acres in 1856 agqinst 2299 in 1856 . Carrots and Cabbages are both grown in increased quantity; and of Rape, for which there is now a separate place in the schedule, we learn there is about the same extent grown in Scotland as of the other two, vizz, 1400 acres. It is interesting to learn in addition to these particulars that the extent in bare fallow in Scotland has this year diminished about one-seventh, being 17,715 acres against 22,462 acres in 1855 .
The number of live stock seems to vary but little from year to year. The total number of horses returned was 172.229 in 1855, and 179,904 in 1856; of cattle, 974,816 in 1855, and 967,311 in 1856; of sheep and lambs, $5,694,900$ in 1855, and $5,822,478$ in 1856; of swine, 134,350 in 1855, and 126,944 in 1856 ; of all live stock, $6,981,295$ in 1855, and 7,096,637 in 1856.
It is satisfactory to know that these returns are made by men competent and willing, and that the scheme both as regards the inquiry and the numeration of its results is in the hands of so able and now so experienced a man as Mr. Hall Mazwrle. No such criticism is possible of the Scottish statistical nquiry as Mr. Carronl makes of that conducted in

Twar the produce of our corn fields is dependent on the quantity and quality of the grain we use as seed is known to every one. The formation of a proper seed bed has to be followed by the right deposit of a properly selected seed, and that by the due cultivation of the plant, before we can
climate will allow us.
There is, however, one of these particulars which has occupied less of our attention as cultivators than it deserves. We have looked carefully to the tillage of our fields; there has been discussion enough on the position of the plant with respect to its neighbours - thick and thin seeding have occupied the attention of our correspondents quite sufficiently; but the importance of a due selection of the seed with regard to purity of sort and with regard to perfect healthiness of growth has not been put so prominently before our readers as it deserves. Mr. Berkeley has indeed lately given his experience on the hereditary character of a disease in Oats, and Mr. Lawson has urged on cultivators the need of care in choosing unmixed and pure varieties; but there has not been such general interest in the subject as it ought to receive. This is more especially the case with reference to the former of these considerations. The latter has commanded more general attention, and Mr. Lawson speaks not more for himself than for a large body of experimenters and observers to whom with himself the farmer is indebled. Drummond, Rendle, Skirving, Sutton, every seedsman indeed of any note, gives his name to one or other of the many sorts which every agricultural plant presents. These sorts have been reared from single seeds, carefully tended and accurately compared with others, and found to possess merits such as in the opinion of its cultivator or originator give it a claim to general cultivation. There is not a seedsman in the country whose professions, nor, let us say, one of any note whose actual operations do not prove the general estimation in which the subject of purity of seed is held by cultivators.

It is the importance of perfectly formed and thoroughly ripened and completely healthy seed to which we need now to call attention. No one who has travelled through the country in July and August, even in a season like the present, when a hot season has ripencd grain more perfectly than in this country it generally is, has failed to notice in the Wheat fields patches of dead or prematurely ripened corn with bleached or dusky, empty ears,
which puzzle the cultivator quite as much as they do the passers by. He knows the past history of the land, but that does not explain them-and he knows the several processes which during its growth and cultivation the crop has undergone ; but these throw no light upon them. The probability is that the phenomenon, common enough in every arable district in the conntry, is due, like the somewhat similar case to which Mr. Berkeley called attention in the Oat, to defective seed.
It is certainly within the experience of the farmer as well as of the gardener that the produce of a seed is dependent upon something besides the treatment it receives from the caltivator. It grows not only according to the soil in which
deposited, but according to the force or character of the vitality which it has inherited. The faulty plants which die off before the rest are but the lower illustrations of the same scale whose higher places present such specimens as our correspondent from Clinheroe refers to in his recent communication on the importation of seed from other climates. Of course, then, it is of the highest importance that our seed should be taken from plants making some approsch to such specimens as more congenial climates yield, and should be ripened as perfectly and as healthily as in such climates they more generally are.
If diseases are hereditary, healthy plants alone should yield the seed we use, and if, as the facts which "T. G." quotes would indicate, vigour of growth as well as weakliness is handed down, the importance becomes more obvious still of choosing the seed of next year's crop from the best and healthiest crops which this year has provided.
Happily there is no lack this autumn of well
pened and prolific Wheat. An unusually hot ripened and prolific Wheat. An unusually hot
summer and a spring time such as, on well-drained soils at least, induced a strong and vigorous growth, have united to produce an unusually abundant yield, and wherever this has been well harvested seed of the best quality is to be had: and it may be added that the occurrence of harvest all together, by which mach became dead ripe before it could be cut, was not unfavourable to the character of the grain as seed however much it may thus have suffered as food.

ANSWERS TO AGRICULTURAL QUESTIONS.
 ('Onntimed from po. 608.)
11. Give a rough estimate of the capitnl reeded during a year's
tenancy of the farm, speeifying the amounts required res pretively for rent and taxes, labour, horses, tmplemiente, live preck, teed, mennure; and say if there is any other pricicipal

Besides 35 acres lattermath and 35 acres to be grazed

## 13. Say

Two relays of 30 full grown beasti, calculated with the roots and meal, and cake and Clover, and Vetches and Rye, to clear 8l. each beast and feeding; or one lot of younger beasts to begin with the Rye and finish with Mangel, Beans, and cake, and calculated by growth and fatting to realise $16 l$. each in the 52 weeks. On the meadow land, and to be fed with straw, roots, and hay and which may be assisted with Italian Rye, \&c., \&ce, and which may be assisted with Itaian Rye, \&c., \&c., two or three farrow sows, and young pigs as may happen.
14. How long do the mare, the cow, the ewe the sow, go with
young? Name the months when you would wish then to Foung? Name the months when you wonld wish them
Mare, about 11 months; cow, 9 ditto ; ewe, 21 or 22 weeks; sow, 16 weeks. The mare should foal in April or May, as then she can be best sparedlfrom work; the Grass is springy and will afford plen!y of milk, and the
foal will get strong before winter. The cow should calve about February or March, as the milk is not good for cheese-making until the cow has calved some weeks. There will be time to wean the calves before cheese making commences, and theywill get strong before winter. The ewe should bring forth in warm districts as early as February or March; there will be time to wean the. lambs and the ewe to again get fresh for the tup. The Grass will be springy when the lambs are beginning to Teed, and they will get strong before the time to go fot In thes, and the draught ewes can be got early fats grown, the lambs should not be born before April, the Grass will not be grown sufficient to produce mill, and they may get starved. The sow should farrow in March or April, as then the skim milk will much assist them. They will get a good size by cheese-making time and will thrive well on whey and Peas, or if no whey they may thrive on roots, \&c., till after harvert, when they will be in good place to fatten on smail cosm and mall Potatoes.
15. Give the probable annual consumption of a full-sized fanna horse in full work, and sufficiently fed on Oets, Beans, and hay in winter, and on Oats and green food consumption an any other scheme of feeding,
91 bubels Oats, 22 ditto Benng, 22 cwh hay, 9 tons green fued, 22 cwt. Oat-straw, 45 bushels Oats, 45 ow. 22 cwt. Sainfoin hay, eut straw ad lib. Or 45 buhhels Oats, 91 awt but straw ad lib. Or when homes Oata, $w 1$ cw hard and many hours on the road, \&ce, 45 bushery hard ands Beans, 91 cwt bran, 45 cuto old hay. I know a roadster team worked (thoy say)
"16 hours" per clay fur the 6 days each
working remarkably well on this food.
16. Say how yon would manage as to food, \&ce, during its first

The first four or five weeks it would have full meal of whole milk, and would alter be gradually worked
down to half new and half skim, till it began to feed down to on Mangel Wurzel and hay, or Grass, as the would gradually add Linseed and hay tea. I have known would gradually add Linseed and hay tea. I have known a farmer wean 20 calves cownes milk by adding this. Towards the latter part of May it ahould be turned on the best pastures, and as
winter approached should be full fed on chopped hay winter approached should be fulf fed on chapped hay
and roots sliced and mixed; or if the Oat straw is very good, and cut a little before ripe, it will be an excellen sobstitute for hay. In this case I would add a little Linseed-cake, say 1 lb . per day.
17. Give the routine of operations in the cattie feening house
daring asy in Februarr,
datating the times of feeding, the and the quantities of esch kind of food sapplied per hend.
$60^{\prime}$ clock, a.m., a feed of mixed chaff and sliced roots, and cleaned out or fresh littered, as the case may be $70^{\text {celocks, a a.m., the same as above, with a little Bean }}$ meal or Linseed cake mixed with it. 12 noon, a feed of sootain littered ; 5 $5 \frac{1}{2}$, the same, with Linseed or Bean meal ; 6 , a few handfuls of hay, and left for the night. During this time it is calculated that each beast will Boan meal, 2 lbs. Linseed cake, and 7 lbs . meadow hay I am fully aware that this ration is not such as is rocommended by many feeders, but my object is, lst, to prevent the animals being choked, by being too eager
for their food in the morning; 2d, to induce them to lie down as much as possible; and, $3 d$, to render them satisfied for the night hy a few handfuls of meadow hay,
which, after all, is their natural food. I have been astonished at the ease and contentment they will exhibit anter this feed, and they will rarely rise till feeding time the next morning.
18. Suppose an ox feeding to 60 or 70 imperial stone, to be
ready for the butcher towards the end of its third year; state
the kinds and quantitles of food it wilk consaman during ita
last nine months, from June till March.
We should suppose that by Juve the green food, such 28 Rye, Clover, and Vetches, will be sufficiently hard to be given without much or any dry food; but if soiling is practised, I hold it to be good to give a little dry food with all green food, until the stalks become hard or the seeds are formed; thus an ox would consume in four months, at $1 \frac{1}{2} \mathrm{cwt}$. per day, 180 cwt . Clover, Vetches, Oat straw ; the next 10 weeks it would consume about 105 cwt common and yellow Turnips, and about 7 cwt . chopped Oat straw ; the last 10 weeks the roots would and 2 lbs . Linseed in place of it; the straw may be slightly reduced, and about 7 lbs . hay substituted. Thus Vetches, and Rye-grass ; 105 cwt. common and yellow Tetches, and Rye-grass; 105 ewt . common and yellow neadow hay ; 26 ewt. Oat straw; 140 lbs. Bean meal 140 lbs Linseed.cake. If less roots and more straw, then I would add more Liuseed; if less straw and more roots, then more Bean meal. Bean meal should be used more largely too with Mangel Wurzel than with Swedes, because it tends to correct the laxative qualitiea of the
Mangel Wurzel. I have seen some very exeellent beeves fatten with cut Swedes and English hay ad. lib. ouly.
19. Deaseribe the operations of eheose-makidg, and say what
quantity should be made from good meanow land in a diry
of 50 cows of $a$ productive Elind during the month of May.

The operations of cheese-making in Gloucestershire are very simple. The cows are milked about 5 a.m., and 3 to $4 \mathrm{p} . \mathrm{m}$. If the dairy is large, it is made twice The milk is brought and put into a large tub, and reduced or increased in temperature as the case may be, to 80,85 , or $90^{\circ}$ of heat. A quantity of rennet, half a put to 50 gallons, is then added, and left about an
hour. The curd is then cut across with the cheese knife, and the whey strained from it; the caneese knife , and the whey strained from it; the
curd is then cut very smail with the cheese knife, (rometimes through a mill lately invented for the purpose, which saves much trouble, and is said to mix the fatty matter more intimately with the cheese), and as auch as possible of the serous matter allowed to pass off. The cheese cloth is then put into the vat," and is
filled with the broken up curd, the ends of the cloth turned over the curd, and the whole put into the press where it is aubjected to gentle pressure for about a couple of hours; it is then taken out of the rat, a

Pheese and rubbed over the out-1de of the new formed cheese, and returned to the vat with a fresh cloth ; it is then taken out twice each day for four or five days, hen gallue more salt the few first turnings ; they are when put on the sheif to dry in a rather dry warm place, cheese-room and tur two they are convered month or so. There are many "whims" in vaxious dairies, such as scalding the curd, pouring hot whey ou the outsides of the cheeses, washing with hot whey, rubbing the cheeses with herbs or the floor on which they liebut to enumerate all would be tedious. About $1 \frac{1}{\mathrm{~d}} \mathrm{cwt}$ believe, be a fair yield for 50 cows.
20. If the firm we have supposed had been in Fifeshire instead
of Kent or Surrey, what changes in the mode of cropping
I believe it is pretty generally considered that the Oat crop is the most suited to the climate of Scotland but the county of Fife being a populous district, and dear the sea coast, Wheat should enter into the rotation of crops only in a diminished ratio, say only after Beans,
and the Oat should follow the Clover. Potatoes would enter largely into the fallow crops, and Mangel would only be grown in smaller quantities. As thi Swede and yellow Turnip would require to be sown earlier, and Vetches, Sce, would only be fit to cut later, we could not manage crops, but it is probable the Swede crop would be heavier, the climate being more humid and better adapted to the requirements of the Swede.

## IRISH PAROCHIAL STATISTICS.

## By Martin Duyle.

The labourers kept in farmers houses are sufficiently well maintained, and if unmarried they possess ample means for providing comfortable clothing and even saving some porion of their wages, which they some
times invest in the purchase of two or three sheep that cost them a very trifling sum for pasturing. But labourers who have families and live at home are geverally in very pitiable circumstances. I ought rather to ase the past tense, because I am considexing what the rates of wages and prices of fond have been during the abundance and anticipated fall in the prices of Potatoes and meal.

The ordinary rate of wages is 6s, a week; it neither rises nor falls as in England, according to the price of are fixed except in the actual period of harvest, when a pressing demand fer 1.bourers of necessity causes increased wages. But how stands the case during months in the you-working days, and the severity rigidly observed as noli-working daya, and the severity half-day ; 5 s. 9 d. therefore may be stated as the full average weekly earnings of an able-bodied labouring man. The respective conditions of worknen in ny ow employment may be taken as accurate illustrations of our labourers circumstances. Two+ active young men, not busy at home they are glad to work with me, such extra labour renders their domestic state extremely favourable; they have perpetual occapation of some sort; they possess in their little establishment a horse, two cows, a calf, donkey, pigs, and poultry; their land is well cultivated, and their homentead is respectable, not unlike a Belgian tenement. Another man, who lives a least a mile from the place where he brings a piece of Barley bread every day with him for breakfast and dinner, and my dairymaid gives him milk when she has got it to spare, and this is the diet of the man generally The cost of food for his whole family per week is-

$$
\begin{aligned}
& \text { Three stone of Barley or Indian meal } \\
& \text { Salt, soap, and candles } \\
& \text { Meal, treacle, or cocos }
\end{aligned}
$$

$48.6 d$.
0.6
0
0

When Barley-meal could have been bought for ls. and Potatoes for 2 d . per stone, the wages were from 10 d . to 1. a day, and so they remain though the price of food is onethird more. Here is one of our Iriah anomaties, marke prices do not regulate the rates of rural labour; how ever high the price of food may be there are lahourers always ready to take the place of any dismissed workman, and the selfish principle leada employers to accept the services offered, withous duly considering whether the employed have the means of obtaining the food on which the evertion of their physical strength depends. In the foregoing instance the wife and a child of the man work in barvest, though not with me. Otherwise withont beging this family could not pay 158 . a jear for the ront of their cabin, or provide soy clothing. Ther is not even a Cabbage garden attached to the babitako nor bave they the privilege of rearing poultry. They have not possessed a pig since the firat failure of Pota toes, and while the food of the family consiats of Barley meal or of Indian meal, it is obvious that there can be any refuse from the tabie to fill a pig's stomach
A nother man works with me at the same rare of wages, but being childless and having only a wite to + August 18. - Thia day, howt var, unquestionable evidences of + August 18. - This day, howt var, unquestionable evidences of

ost
with a good garden at a moderate reut, he is in com sows eircumstances. Another man who ploughs, turuine , cc, and acts as a working farm baing with the earnings of his two little eons los. a weeh, cottage rent free, with a rood of ground for Potatoe and Cabbages, and facilities for rearing and fattening poultry. Yet this family can barely suboist, being five in number.

One person more remains to be noticed, to complete the types of our labouring class. A man about 75 years old works in my garden; his wages are 10d. a day; tre has an aged wife to support and house rent to pay Persons unacquainted with the details of the lrish Poor law system may imagine that the condition of our poor is much ameliorared through its agency; this is not e0 in reality. We have union houses with poor rates as it England, and medical aid is provided in every paris for the sick poor; but what a difference in the appliea tion of the provisions and modes for affording relief in England and here! When the labourer there is worn out by toil and years he receives a weekly allowance according to the number and circumstances of his family, dies in the cottage in which he has perhaps lived all his days among friends and neighbours, and is buried with decency at the expense of his parish. A labourer widow with a helpless family has a regular allowance of bread and a little money wbile she continues in want but in neither of these urgent and pitiable cases, nor in any, are the Irish poor aided from the poor rates uniess within their district poor-house. No
Probably less than one-twentieth of the 52,872 indi-
Probably the 33 lectoral divisions of (including a very considerable town population) receive (inchar ref (externally none) and only 12 persong participate in it of the parochisl division under my participate in of the parochial division under my derive little benefit from the rates imposed. While it is possible to avoid it, neither destitute nor infirm poor will enter the poor-house; they look upon a suggestion to go there as unkind, if not insulting, or as a death warrant; their feelings revolt from the notion of
abiding there; they greatly prefer to beg, and some would even starve and die at home than become its inmates.
The old gardener and his wife (the latter a faithful and respected servant in some families in which she formerly lived) have been always of irreproachable conduct, but having had a family to bring up and provide for, they had no opportunity of reserving a fund for old age and infirmity ; they may soon be destitute of the means of living, and yet I am sure that they will not avail themselves of the really good accommodation afforded to the aged and infirm in the union-house, with which in their minds are associated the ideas of shame and imprisonment,
A short time ago I endeavoured to persuade a abourg widow, who has four young children, to exchange destitution and the habit of living upon warm th which she and her children might receive in the poor-house, instead of remaining in a damp cabin, strug-poor-house, instead of remaining in a damp cabin, struggling against cold, hunger, and naredness; but this pauper sobbed and cried, and would not for a moment admit the expediency of leaving the miserable den in which she lived; and there she remains and is likely to continue subsisting on private charities, a burden on me and others. I think her case is one that loudly calls for out-door relief. Her objections to the confinement and order observed in a poor-house are perhaps to a pauper in ber circumstances quite unreasonable, yet the repugnance is insuperable. Less than the expense of maintenance there for her children
It is saddening to reflect upon the destitution in old age of persons who have honeatly and industriously laboured until their physical powers are exhausted by servitude, especially if, as in the instance of the aged gardener and his wife, they have habits and dispositions which elevate them above the classes of paupers that chiefly occupy the poor-houses. Financislly considered, the cost to our parish of out-door relief in all such cases as the two preceding ones would be much less than the amount contributed in rates, from which at present very little sensible benefit is now derived in return.
Guardians are so afraid, even where rates are very moderate, that the wedye of out-door relief, if once inserted, would be pushed to extremity, that they will not allow its small end to enter at all into their system of relief. They will not act upon the humane principle which is operative in England, that the feelings of the poplications for out-door relief.
The result is that our parochial poor are not relieved from the ratee levied for the poor (the rare exceptions do not disprove the proposition, and, what is a serious evil, vagrant mendicancy is not suppressed. The police, indeed, have authority to take persons charged with the offence of begging before a magistrate, who may will incur the unpopularity of making complaints in such cases, or the responsibility of sending comparatively innocent persons to associate with thieves and robbers in a gaol, from which they may come out grievously demoralised, and ready to plunder the farmer's dairy, tore-room, or poultry-house in dark winter ninhta, when parposes. . The trouble and annoyance also of going to
a magistrate, and the disinclination to oceasion to the: wheel of the traction engine, as you have brought the
police the fatigue of marching 10 miles with beggars here. Besides, many of the farmers give alms (in meal or Potatnes) as a moral daty, or from a generous impulse (but mischievously in effeet) to the groups of pulse (but mischievously in effect) to the geir doors tramping beggars that frequently pass by their doors; and thus the rambling paupers who ought to be confine poor-rate paying population. The clearing of roads and treets of professional beggars, many of whom are sturdy and insolent, might, I think, be rendered obligatory on the police, without the intervention of private individuals.

## Home Correspondence.

Chambers's Drop Drill.-An impression having gone abroad that the drop drill invented by Mr. Chsmbers and exhibited by Messrs. Garrett at the recent Chelms ford show, introduces a new feature in the agricultora world, I feel it only due to myself, though far from wishing to detract from the credit due to Mr. Chambers for his useful and efficient implement, to lay my claim to the prior introduction of such a drill before the public. At the Glasgow meeting of the Royal Highland Agricultural Society a drop drill on the principle invented by me was exhibited, and in addition to the nigh encominms of the judges received a prize medal st best drop drill. I also supplied that zealous patron of agriculture, the late Mr. Pusey, with a imilar implement to the one exhibited, and have lately received from his steward the assurances of Mr. Pusey's entire approval of its working. To all connected with the science of agriculture the development of mechanism 0 meet its requirements cannot fail to be a subject of interest, and is is rather in the light of a fellow labourer than a rival I regard Mr. Chambers; but I am, I think by no means disparaging the merits of that gentleman's roduction when $I$ venture to question its title to originality. Thomas Chardler. [Drop drills have been nowa many years-the question to be answered is whether the principle has been before applied to water drills.]
30 I igour of Fegetable Growth. -In your Paper of August 30 I observe a reply from Messrs. Hardy \& Son to m
letter of the previous week, in which I endeavoured
call the attention of the public to the curious fact in vegetable physiology that seeds ripened under favourban other seeds of the same kind in the same soil, and 1 auggested the institution of a series of experiments for the purpose of ascertaining what seeds are improved by this process; I also asked if this fact of increased igour could be accounted for on any known principle of vegetable physiology. I think Messrs. Hardy \& Son quite confirm my view of the question, and in these ays of half our wot half wet from them half our read, half oux wool, half our hax, all our hemp, all oux silk, and all our cotton (to say nothing of sugar, coffee, tobacco, \&c., ) it is too late to talk of being independent of foreigners. If we can get Turnip seed that will
produce twice the weight of English seed on the same produce twice the weight of English seed on the same
anil, if we can get Whent that will produce a quarter more per acre than our own seed, it is surely very desirable to sow such seed. I do not say we shall be able to do this, but the facts mentioned in my former tetter lead me to infer that it is very probable we shall be able to do this, and if my life be spared the experi ments will be tried; but I again repeat the inquiry is there any explanation of the facts I before mentioned to be found in any English or foreign book with which you are acquainted! If there is no notice of this to be found, will some of your scientific correspondents endeavour to Wi.Wat beo. G., Clithero

What becomes of the Reaper?-Many persons may tee the present but not the future. I have just been reading Mr. Eve's letter on reapers ; what we most want him to inform us is what is to become of his reaper and the 10,000 others at 30 l. apiece, when the emporary operation of corn eatting is completed : There is such a science as mechanical economics. We have had his fair practical statement respecting this contrivance ; let as hope he will favour us with an economical one, $C, B$ Condon. Is not the economical aspect of this question most eatisfactory to the purchaser, who has by laying out his 30 l. in this way saved in a single harvest more than 30l. in the quality of his corn?]
Grown Barley.-Here as elsewhere the Barley both cat and standing sprouted very much during the late rains. I selected some grains which had thrown ont roots, but of which the spear had not appeared; they ready for the kiln. They were taken from the mow, having been carried, and the rcots were rubbed off. When placed in the folds of wet flaunel they all grew again, first throwing out fresh roots, and then, as you will see by the sample enclosed, the spear, showing that the vegetating power was not lost. As this is contrary to the generally received notion, it notice. Can any of your scientific readers tell me what portion of its strength Barley so grown would lose as Wittenham, Seept. 8 purposes!? J. C. Clutterbuck, Long Wittenham, Sept. 8
Mr. Boydell's Locomotive Steam Engine. - I have great reason to be obliged to you for the candid and explanatory way in which you have given your opinion respecting the question at issue between myself and (as I mast admit) many scientific men, relating to the pinion at the top of the circumference of the road
question into a small compass, all other points being motor force upon the carriage itself, independentiy of motor force upon the carriage itself, independently of
the action upon the wheel-that question is at once set rest by the fact that the pinion when worked as s for stationary purposes, has no effect whatever upon the progressive movement of the carriage. worked by means of the steam power turning a shaft the pressure of that shait in one direction being equa to the force of the steam the other, and not at all the samo thing as a inan pushing directly at the whee When the thrust of the foot is in opposition to the for I am sure you will at once concede, and will, I fee satisfied, promulgate your acquiescence in it as prom nently as you have the contrary opinion. [We do not see how by any mode of placing the eylinder or of directing the thrust of your piston rod you can avoid the result to which we alluded.] One of our traction engines now at Hounslow, near Hatlow, by which we have satisfactorily demonstrated that independently of the propulsion of itself, it will do more in drawing ploughs than as many horses as represent its power, and think you will be much pleased to see the work don with a trenching plough, which the gardeners of the oeighbourhood say is much better done than if it had been trenched in the ordinary way by manual labour. James Boydell, Camden Works, Camden Toron.

## Eocieties.

Highland and Agricultural: Shorthom Breading. - A discussion on this subject took place at Inverness the other day, at which the question of purity of breeds was spoken on by Mr. Harvey, of Lillygreig, Aberdeenshire, and others.
It was asked-What are your shorthorns?-where did they improved shorthorn, there was a mixture of not one or for, in the

$\qquad$ the present breed sprung. They had now attained great celebrity a possessed characteristics well entitling them to the designation of a pure breed. For himself, he had cultivated the shorthor breed for about eighteen years, and he would inculcate on all
parties" that all who wished to rear this valuable breed of cattie hould hold by the principles of purity. As an argument in fatour of purity, he would mention, that while other valuable breeds arose from crowsing, the shorthorn improved with every successive gene-
ration, and that, consequently, it was a great matter to keep them ration, and that, consequently, it was a great matter to keep them
pure. The question had been started, how were they to keep them pure? The breeds of pure shorthorns were in the hands of a
lew, and were becoming less and less in the number of their changes; and in the very considerable district to which lie
belonged, it had become a question whether or not to introduce a cross among the pure breed; and if introduced, it would bo regarded as pure- whether at the fourth, the fifth, the sixth, or the seventh cross they should be regarded as reverting to the
pura shorthorn. He desired that question to be definitively
settled. A difficulty would thws be removed settled. A difficulty would thus be removed, and parti
bad taken a great deal of pains to rear another class of
through which, it must be admitted, the rents of the fa some parts of Scotland were in many instances paid, would be satisfied. He had seen, in his own experience, afier breeding
down to a sixth, seventh, and eighth cross, a bull appear which black and white marks. It mattered not what was the sym-
metry or what the pedigree of such an animal, the colonr was Wrong, and it ought not to be admitted into a shorthorn stock only, but for Europe, if they were rifid before in adhering to the principle of purity, they must be still more so now. There was bulls but Highland cattle at Paris, and he bappened to point on a very nice west Highland cow to a friend, when he remarked,
"3he is a very good one, but she is to like the shorthorn." He
liked the remark, for there stood an exhibitor sticking up for purity of breed, Every breed had its weight at this show, as it
had at Paris; let us therefore keep each of them pure. Each has its own points, which will in time develope themselves pro horn. It was not merely selection in the breeding stock, no the same attention to preserving the purity of the blood. If
they leaned on pure stock, let them stick to pure atock; if they arise, in addition to those already existing, let the same proattention at the hands of breeders, the same premiums from ou societies, as the three distinctive breeds we aiready possess.
Mr. Hall Maxwell (secretary) did not desire to take any part
in this discussion, but he wished to observe that the revolution submitted by Mr. Harvey embraced two questions. The first ously crossed? This was not a question on which he would
ventare to give an opinion before so many practical men; but
the second part of the resolntion afficted him considerably secretary of the Mighland Societr, and also his friend Mr. Harvey,
as secretary to the. Rnyal Northern Society, and the answer to
which wonld greatly assist them in the discharge of their duties, and was When may an animal with a cross in his pedigree be and at the same tume his points might be mo perfectly pure tha
t would puzzle the eye of a judge to tell in what respect the animal was different from a pure shorthorn, or to say why i
should not be exhibited as a shorthorn, as it had all the good points and economical advantages of that breed. There was no uch animals in the class for which they were entered, and
eave it to the judges to say whether they should be allowed to cornpete. An objection might be taken by some competitor, and
hus a stoppoge of a show noight oceur. Snch an animal migh gain a prize, and a challenge might be given by some disap-
pointed competitor, on the ground that the animal which had

nothing.
Mr. MCombie (Tillyfour) said that he quite agreed with Mr.
Harvey, and as completely disagreed with his friend harvey, long known as an enterprising farmer, Mr. Cruickshank Cloves, Any mark whatever of impure breeding Was mose dia-
tasteful to the pure breeder-there was nothing he detested 80 much. A breeder of polled stnck hated nothing so much as to
see shorthorn marks in his calves. It would be impossibie for
any one to pass off bulls and heifers as besng pure when in fact
they were crossed. He wished to say something in favour of the polled breed, and it was, that a good thick polied stot paid better
than a large cross one-me got as much for it. He was one of a livelihood, and if he found that the Baker Street butchers began to prefer another kind of animal than that which he supplied, he
would begin to think what he was about. Put at present he found that he got as much for his small polled beast as was given for the large cross-bred beast, even though a fourth part of the
weight more. He had sometimes been at Smithtield, and was lately there in company with a practical dealer, who took him to
a place where there passed by three sinall Galloways, a large a place where there passed by three suall Gallowaya, a arge
shorthorn bullock, and a number of Hereford butlocks as at as
mnd
"N Now mod. "Now," said thls dealer, pointing to these lots, "I will
tell you something that may be of use to you in making up your mind upon breeding. You see these different beasts; well, I cas great mountains of flesh-as much by your small, firm, broad-
backed Scotch ones as by any crosses, however big they may be." backed Scotch ones as by any crosses, however big they may be."
To return to the question of purity of breed. he believed that in To return to the question of purity of breed. he believed that in
ninety-nine cases out of one hundred, cross blood could be detected. They might pass muster with some parties, but not with tbose Mr. Brown (Linkwood) approved highly of keeping the breed pure; hut at the same time he must say that nothing could be
more valuable than the cross between the shorthorn and the polled, and he should be sorry to think that it would be considered
an uoprofitable thing to cross, for few eould afford to keep upa
pure stock. The country was much indebted to those who kept up the pure breeds-for purity of breed was a great matter in
crossing; and for his part he would alweys endeavour to go to the
best and purest bull, and would always try to get him a good cow. He could not speak as to the subject of when crosses became pure,
but was inclined to believe that that never tonk place. He Was
oorry that the Society had not continued to give prizes for sure that it was improved by the omission.
Mr. Horne (Langwell) said that if he thought the quention but as to the utility of crassing, which was the first question in Mr. Harvey's proposition, he thought no gentleman connected fortunate event that crossing in cattle and sheep in Scotland had paid uo rent had there been no cross. He was sure that no gentleman could doubt for a moment that, in breeding crosges, opened the question of mantaining the perity of breeds. He
did not think that any number of crosses would produce a pure animal-that was the safe doctrine for Scotland to hold by. Mr. Forbes Mackenzie (late M.P. for Peebles) said that, neve
having bred a pure animal in his life, he was ill-qualified to address such a meeting on this subject. He quite agreed pura nimals to breed from; and, as crossing was so generally wo questions which they ought to dispose of-one, wher, what
best for the Highland Society to eucourage? and the other
it was best for the country to do? Now it would beem to be it was best for the country to do? Now it would seem to who
better for those gentlemen who lived in ligh districts, nd whe had not the means or fitting opportunities for cultivating preed
atock-it was better and more profitable for them to bred
crosses. But how were they to get good animals unless they hid pure sires? and, therefore, it seemed to him again only to pure
that the Highland Society should give premiums onla
stock, which, when obtained pure, others sbould tase snd do

## Calendar of Operations.

 SEPTEMBER.
#### Abstract

nearly completed, and with the exception of the extraordinary insition of five dasg' continued rain the weather may besaid to have been very favourable; but that rain will by many be long to have been very favourable; but that rain will by many be long remembered. A great deal of corn was aiready cut and and sunday morning down it came! Some congratulated themselves upon it, and in many respects it produced most bene- ficisl results, as it renewed the pastures, filled the ponds, and give life and vigour to Turnips and Coleseed; but when on Tnesday and Wednesday from all quarters it still kept dripping Tuesday and Wednesday from all quarters it still kept driving with scarcely any intermission, and Thursday also Fas showery, how severely was the fortitude and resignation of the farmers taxed at such a critical time, without being able oo stir otherwise than patiently to put the sheaves of corn in their places that had been thrown down by the united forces of wind tered their men and shifted the stooks before the rain had ceased, the only consequence of which was that the sheaves got more thoroughly wet through; others were, we fancy, too hasty in carrying on the Saturday. It rain hyd again set in they would probably on the Saturday. It rain had again set in they would probably have been pleased at having got some of their corn in bad order to escape getting it in worse. Still those who could endure to be quit were rewarded afterwards by plenty of fine weather, and being spurred to exertion by the damage they had sustained they literally laboured night and day to secure the grain in stacks. This heavy rain ripened the late Wheats in the fens rapidy, and there ensued a great outcry for hands, as much as 25 s . an acre being given by several persons in remote parts where the labourers were scarce; high prices were generally given, and one bad consequence was that the work was not done so well se nual, it was not prudant to be too particular, therefore sheaves slovenly, dragging hall done or not done at all, and farmers glad to hire anybody as a makeshift to help to get the corn together. Matters are, however, now proceeding in a more regular course, the trim thatch and a little paring puts all to rights, and the hum of the steamer resounds in all parts to test the produce and supply the markets. The yield of Wheat will be collectively large, but by the acre less than an average; the weight is not so heary as was expected, there being more Wheat below 18 stone net than above that weight; yet for 61 or 62 lbs per bushel the Wheat will be of good quality where not sprouted, $i$. e. With less less bran or offal. Barley has been more injured than Wheat, particularly where it was not tied; all Barley not carted before the 17 th is more or less grown. Very few reaping nachines have found their way to this locality at present; it is supposed that farmers have been deterred buying them from the imperfect then then specimens procured by the few enterprising men who first ventured to purchase them; there is little doubt that as soon as anything like certainty of a reaping machine being obtainable that will work without much trouble or keeping in repair, scores of customers will avail themselves of such a welcome and necessary implement. Mowing is much practised here, but compared with the operation of a nounced a clumsy and defective method of gathering grain; reaping by hand is slow and expensive, and therefore the sooner We grow crops fit for the machine and have a machine fit for reaping tolerably heavy crops the better. J. $W$, Peterborough.

[^3]VALUABLE IMPROVEMENTS IN MOWING MACHINES.
BY ROYAL
LETTERS PATENT.

Under the Patronage of Her Majesty Queen Victoria, and His Majesty the Emperor of the French.

## ALEXANDER SHANKS AND SON, ARBROATH, FORFARSHIRE.-PATENTEES.

A. SHANKS AND SON, while soliciting the attention of the Nobility, Gentry, and Gardeners to their A. Horse and Pony MOWING and ROLLING MACHINES, the completeness and superiority of which are now well known, at the samme time respectiflly solicit notice to their new HAND MACHINE, specially adapted for mowing small lawns, vergeas around flower beds, \&c., and which has now undergone a trial amply sufficient to enable the Patentes with all condience to orier rle
as the cheapest as well as the most efficient and complete machine extant. The improvements effected by the Patentees enable the machine to be worked with perfect ease by one person. It requires no change of wheels or rollers in mowing verges; will ens close to the edge of fower-beds; has great facilities for quick turning, cutting and rolling at the same tims; the length of the cut can be effectululy regnilated in a few seconds by merely turning a serew, and being simple as well as complete in its construetion durability, and consequently not at all liable to get out of order. The work is executed with great rapidity, and in a manner vastly superior to mowing with the scythe, while the simultaneous operations of rolling and close cutting greaty improve and beautify the turf. The Rolling and Mowing Machine is now in common use at all the Royal Gardens, Windsor, Kew, Buckingham Palace and Osborne. Illustrated Price Lists forwarded on application.
N.B. A. Shanks \& Son finding that their Patented Improvements are pirated, beg to caution the public against purchasing Machines with their improvempnts without their name and address marked om the Machines.
A. Shanks \& Sow also supply Fleming's SALTING MACHINES, for destroying Weeds, \&c, on Gravel Walks, Court Yards,

## NEW PATENT INVENTIONS FOR STABLE REQUISITES.

Awarded a Prize at the Paris Exhibition, and Patronised by the English and
French Governments.

## cottam and hallen,

THE Original Inventors of the Patent enamelled manger rack and Water trough AS ONE FIXTURE,
A represents the Patent Halter Guide and Collar Rein, the ball of which is taken to the back of the manger, works with ease and
freedom up or $d$ own the tion, as also a sure preventative against the most restive horse being cast in the stall.
from the Patent Portable Seed Box can be instantly detached seed in a clean and useful state either for. The saving of the
or mixing with the food in the manger, is alone suffecent to claim general notice.
C The Seed Boz detached, made of Galvanised Sheet Iron, 0 The durable. used with Pateut sadute and harvess Bracks, where space is a object, as the long portion of the bracket can be turned up out of

COTTAM'S MANGERS are constructed in the best possible manner, both as to form and utility, are cleanly in appearance, durable, and impervious to infection; manufactured Plain, Galvanised, or Enamelled.
Improved Slable Guttering, with moveable safety cover's, Sanitary Traps, Stable Pumps, Double Corner Mangers, Harness-room Appendages, and every article in Stable Furniture. Chaf' Cutters and Oat Bruisers, kept on show at COTTAM \& HALLEN'S WORKS, 2, Winsley Street, Oxford Street, London. WARMING AND VENTILATING.-The New Illustrated Catalogue for 1856, and Estimates gratis

## T. GREEN'S NEW INVENTION IN LAWN MOWING AND ROLLING MACHINES,

SOLE MANUFACTURER, IRON AND WIRE WORES, NORTH STREET, LEEDS.

## REGISTERED JULY 24, 1855.-No. 3739.

THE ADVANTAGES OF THESE MACHINES supersede all others by having - a small Wheel in front of the Grass Box, consequently will mow verges and round flower beds, wet or ary the Grass any length required; and having two Rollers behiud, and a small one in front, they roll the width they cut; they will turn in very little room, and cut at the same time. All the working parts made much stronger than the old machines. The bottom Blades are so constructed that they cannot consequently ground; they are only drawn, and not pushed and drawn as in other machines, one person with ease; the two latter with a pony or donkey.

13 inches 16 inches 20 inches 24 (NET CASH):-

Testimonial from Joshua Majur, Esq., Landscape Gardener, Knostrop.
To Mr. Green, Lreds.-Sir, Ah your highly irpproved Mowing and Roling Machine. drawn on flat ground with ease by oue person, and
nicety. So complete and simple is the invention, that amateur gentlemen, and even ladies, may work either the 16 or 20 -inch size with ease nd pleasure. providing the Grass is not too long. For extensive places I should say the 24 inches would be most suitable; for even in undulating ground two persons may wour very valuable invention, which in my opinjon, entirely
 surpasses, anits operations, and consequently must prove a great saving in the mamgement of Grass lawns, and a great boon to

Theatre.

CIFFANY," a light, cheap, and dursble material for Shading Conservatories and other Hot-honses, effecout nbscuring ihe light; alen one of the best protectors of Frutits
from Birds and $W$ asps, and the Bloom of Wall Trees from Spring Frosts. Sold in pieces 20 yards long by 38 inches wide, at 3d. per yard or 5 s. per piece. A liberal allowance to the Trade when
not less than 10 pieces are taken. No orders will be attended to frnm unknown correspondents noless accompanied by a remittance.
Manufactured for and sold, Whelesale and retail, by John SHAw
B ENTALL's BOTANICAL DRYING PAPER. The above PAPER is prepared expressly for drying speci-
mens for the Herbarinn, for which purpose it has been exten-
sively used for several years past by the most eminen betanist of the day. It possesses all the requisite qualities, preserving form and enlour in the best posibiblemanner, and having the peculiar advantage of seldom, if ever, requiring a chunge of sheets whilst the plants are being dried, thereby saving much
tmpe and trouble. Ins stoutness and durability also combine to ordinary papers sold at a lower pricic. The proprietor has
zeceived the most flattering testimonials from Sir W. J. Hooker, Professor Lindiey, and rany other erainent botanists.
E. r the convenience of collectors of Foreign as well as British plants the paper is prepared in four sizes, viz. 66 by 10 tinche
(foided); 18 by 11 inches (ditto); 20 by 12 inches (ditto); and 16 by 20 inches (ditto, Price 15s., 18 s., 21s., aud 28 s . per ream. Agent for Loudon: Mr. E. Nuwman, 9, Devonshire Street,
BLAIR'S GOUT AND RHEUMATIC PILLS. of modern chemisery has conferred upon mankind; for during the Gout was considered the present century to speak of a cure for the of this medicine is so fully demonstrated, by unsolicited testimonials from persons in every rank of life, that public opinion prochime this as ons of the most important discoveries of the
 Medicine Vendors. Price 1s. $1 \frac{1}{2} \mathrm{~d}_{\text {a }}$ and 2s.9d. per box.

## Exposed to the scoristhing rays op tile Sux,  1 paration for the Complexion, dispelling the clond of langulor and relaxation, allaying all heat and rritability, and im mediately affording the pleasing sensation attendion rel mediately affirding the pleasing sensation attending, restored elasticity and healthful state of the skin. CONCRETE FOR WALKS AND FLOORS. PORTLAND ROMAN AND BATH CEMENT AND or Cansl. Reduction in price if Six Tons are taken by Railway, or a full cargo by Canal. $\begin{gathered}\text { Gresave \& Kbseaw, Warwick.-Sept. } 20 .\end{gathered}$

WATENPROOF PATHS OLOORS.
THOSE who would enjoy their Gardens during the Winter months should construet their walks of PORTLAND CEMENT CONCRETE, Which are formed thus:-Screen the is mixed with it and to every part of clazan graveladd une of sharp river sand. To five parrs of such equal mixture add one of Port land Cement, and incorporate the whole well in the dry state before applying the water. It may then be laid on 2 inches thick. An
 cannot grow through or upon it , and it resists the action of the severest frost. It it necessary, as wa ter does not soak through it,
to pive a fall from the middle of the path towards the sides. The same preparation makes first-rate paring for BARNS CATTLE-8HEDS, FARM-YARDS, and all other bituations Where a elean, hard bottom in a desideratum. May bo laid
winter equally well as in summer.
