for 1865:

## A.

## 

 Abortion, 1169Abronia fragrans, 1182
Acacia armata, hardiness of, 580
Acacia fibre, 1088
Accidents, First Heip in, rê., 81
Acclimatisistion, 31
Achillea ægyptiaca, 891 ; iưred, 891
Achimenes, new, 438
Achyranthes Verschaffeltif(see Iresine Herbitil) Aconite root mistaken for Jatap, 824
Aore, dimensions of an, 16
Acropera armeniaca 367
Adams' (Mr.) market garden, 33 Adiantum colpodes, 53
Aerides difforme, 698
Afriea, South, cultural defeete of 8 , 893 Apave Saundersii, 3 ,
Aglaonema marantwofllum fáactlatūn, 367 agriculture. Ancient and Moderi, rev., 14, Chamber of, 156: Egytian, 201, 203. Indian 229 ; progress of English, 420 ; of S. Wales,
83 ; Old Norfolk Firmer ont 543 ; ©iarterly Journal of, 711 ; Highland, 783 ; Northumberland, 783; Scottish, 784 , 中theory and Of, 999; Scotek; 999 , Scons 471 ; progress, causes of. 64,998 ; hindrances
 Allantus Bilkwerne
limanacs, agricultural, 1095; Brtisk, 1158 . Glenny"s, 1158 ; Hoge's, 1155
timonds, price of French,
Alocasia Lowii picta, 367
Aloes, growth of, 366 ; American, 792
Aloo flowers, preservation of, 728
Alpines, Scotch, 102; Backhouse on, 534; at colliege Garden,
Alstrōmeria (Bomarea) densiflora, 989
Alströmeria (Bomarea) densiflora, 98
Altheos officinalis, Puccinia on, 817
Amaranthus melancholicus ruber, 728; bybird, 890
Amber
Amberley Working Class Industrial Exhiti-
tion 394 Amen, 394
American Aloe, 792 : Heather, 1135
Amherstia nobilis, 868
Amminbroma, Torrey on, 558
Ammonia and tillage, 615,637
Amorphophallus, offonsite odour of, 509
Amsiterdam "Exposition Universelle?" 341 ,
364 ; Botanical Congress, 385 ; Botanic Garden, 727
Amyion,
367
and
Anæctochill, culture of, 76
Andrecium of Mentzellia, inorpliologlcal constitution of,
Androsace, 675
themione angulosd, 608 , 698 ; bordet, 675 fulgens, 797 ; Honorine Jub
Angling, Seerets of, rev., 654
Angola, plants of, 9
Angræcum Grantii, 509
Animals,
English,$~$,
780
English, 780
Anisoplia horticola, 603
Annatto, 40
Ansted on Geology, rev., 462
Anthurium Scherzeriahum, 990 Antirrhinums, double, 1088
Ants, ravages of white in st. Herohá, 195 .
cure for, 532 556, $651,{ }^{656 ;}$; 770; minute
house, 919,943 ; how to destroy ditto, 986 ;
and cocci, 1018
Aphis Wash, City Soap Works, 770 Apiary, Neighbour on the, rev.; 318 (see Bees)
Apples, Reinette Carrée
55 aples 128 Reinette Carree, 55 ; not free from
towtown Pippin, 488 ; Le Deut Jumelles, s46; of Sodom (Solanum), 944
Apple blossom, doable, 55
Apple crop in Devon, 554
Apple trees, Moss on, 22
Apricot blight, 895, 914
Aquilegias, 675 ; vulgarie, seedis of, beteteriotios
Arachnoidilisaud japonicus, 653
Araliaceex, Soerrann's revision of, 817 Araucaria imbricata, conies on, 880 ; Ruller,
991; Ridolfana, 1112 ; Saviana, 1110 , Arauja albens, 1178
Araug aibens, 11 is
Arbutuas, economic uses of the 797
Arisema papillosum, 667 , Wh Aristolochis Godijeana, 8
Arnott's Physics, rev., 1110
Arrowroot, Portland,
Artemisig
Artemisia annua, 627
Artichoke, Jerusalem
Artichoke, Jerusalem, 1034

- Artocarpus incisa, 1181 ; integrifolia, 1181
canariense, habitat of, 842
Arundel Castle gardens, 679
;

Arundo Donax variegata (versicolor), 891 ; conspicuaz, 1084, 1109, 1182
Ashton Court gardens, 499
Asparagua, Eigantic French, 554 ; I'Herault' mode of growing, 723, 770, 842; unseason able, 917
Asphalte, 51
Asplenium Hemionitis criststum, 6
Association, Southern Counties, 62 Assyrian Botany, 872
Astra Castra, by H. Turnor, Yev., 630 Athletic club. 1144

Notice to Purchasers of Seeds.
CUTTON AND SONS having received several Orders for GARDEN SEEDS without the SIGNATURE or ADDRFSS of She Sender, they fear inconvenience will be caused thereby, as they
cannot possibly ascertain to whom the goods should be sent. As these omissions occur more or less cvery year, Messrs. Surros request their friends who do not receive their goods promptly to wh
delay. Rogal Berizshire Seed Establishment, Reading.

## The (Gavieners' Chromitr.

SATURDAY, JANUARY 7, 1865.

## meeting for the ensuing week. <br> Sarvanax, Junuary is Royal Horticulturul (Show of Cyclamens),

The present is a seasonable opportunity to invite attention to the question of the Shortening of the Roots of Trees in Trangifanting. Roots in pots can be preserved entire when the plants to which they belong are shifted or transplanted; but where out-door trees have to bo removed that have grown at freedom for some time, especially in stiff soil, it is almost impossible to perform the operation without mutilating and bruising many of the fibres, All agree that bruised roots are worse than useless, nay more, that they are positively injurious, and that they should therefore be removed before replanting. The sound roots should be separated from the unsound ones by means of clean cuts with a sharp knife. If, however, the plant is in light friable soil, and can be taken up with scarcely any injury to the smallest fibres, would it still be advisable or advantageous to use the knife? It must be borne in mind that the extremities of the roots, like those of the shoots, are in many cases not fully ripened. In pruning, immature portions of shoots are properly removed, except perhaps in the case of the extremities of leading shoots. The sap when in action will flow more or less into every bud, strong or weak; but more, of course, into the former than into the latter; and if a shoot has, say 30 buds, and 10 of them next the extremity are comparatively weak, these will doubtless attract a portion of sap, though not a third, perhaps not more than a sixth, of what the best buds will get. The result therefore of pruning off the weak end of the shoot containing these 10 buds would be a stronger development of the remaining 20 buds. The growth of roots, although in an opposite direction to that of the shoots, is nevertheless somewhat similar. It depends on the quantity of elaborate 1 sap returned from the leaders; and if the quantity of roots is to a certain extent reduced, the remaining portions receive a greater amount of sap, which enables them to grow with proportionally greater vigour than they otherwise would do; and hence a small number of vigorous roots is better than a greater number of weak ones. In faet, a crowd of weak rootlets is often not equal to a. few vigorous ones that oan advance, and roam to a distance in quest of fresh food.
From what has been stated it will be evident that roots, in certain cases, may be advantageously shortened. But common and important as the operation of transplanting is, the pruning of the
roots previously to re-planting is not generally well understood. It would, therefore, be desirable to institute a series of experiments on the subjeot in order to determine when, to what extent, an under what cireumstances, the shortening in question should be made. In the meantime the解 by F. MABC fils, gardener at Notre Dame du
Vandreuil (Eure) may not be without interest:-
"I received towards the end of November, 1853," says M. Marc, "a package of fruit trees for the planting of some gardens of which I had the direction. During the transit, which required two days, the weather suddenly changed from rain and damp to intense frost, which penetrated throughout the bale and injured the greater part of the roots of the packages it contained As soon as I received the trees I cut to the quick the roots of all those which appeared to me to have suffered the most, and these were Apples and Cherries The roots of these were cut so that scarcely 2 inches were left, which was all the frost had spared. Some pyramids grafted on the Quinee, as well as Apples on other part of the roots had to be eit ns short as those hove mentioned peeolving to do the best I could with them, I planted them at home, not however ex pecting that many would succeed. They were well mulched with rotten manure to protect them from the effeets of dryness. In spring, these trees vegetated with as much vigour as if nothing had happened to them, and continued throughout the season to exhibit a vegetation truly luxuriant.
"In the autumn of the same year I wished to ascertain what had taken place underground, and I was much astonished at the fine long roots which the trees had made ; one or more tiers of these roots had pushed from the neek of each tree. The surface of the section of the largest which I had cut so short was sicatrized, and presented eight or nine roots from 15 to 20 inches long.
"This circumstance furnished me with a hint in refer once to transplanting wall Pear trees, four or five years old; for instead of saving, according to custom, the mallest rootlet, so that the tree might not feel its removal, I cut the roots well in. The tree, however, did not take badly, but the contrary. Only two trees were removed with the greatest oare in saving the smallest fibres, and I can affirm that they were the only ones of this plantation which did not succeed perfectly, as may "Sue observed after having been planted eight yearg. "Such was the commencement of the method which I now generally practise, and that on many hundreds trees every year. I ought, however, to observe that do not proceed to dress the roots as those under the conditions I have just mentioned. When the trees are in a perfect state, and not suffering from injury, I cut age and vigour of the plants; the small fibres I cut back to an inch or an inch and a half ; and I prune the
ree into the form I wish to give it at the same time."
M. Mabc says the best time for plant:ing the Peach worked on the Almond is from the 10th to the 20th of February; and the Vine from layers towards the end of March.
If roots are shortened it should be with the view of removing portions that are weak and inefficient, oo that stronger roots may push from the portions which are left. ||

A COrrespondent has sent us a portentous looking production, which appeared at the mouth of a wine bottle, on cork, and resembles a large oliveblaek powder puff. Though 3 inches or more in diameter, it weighs, even with a portion of the cork attached, only a few grains, and is so light as to be absolutely impalpable. It might well surprise any one who had never witnessed the stalactitic masses which often hang down from the ceilings of old wine vaults, where they are frequently the pride of the owners, and are religiously allowed to grow and perish at their own wild will. These masses are undoubtedly fungoid, and the production has been described under various names, the most recent being the rather strange one of Zas midium cellare, but no change of name or of system has ever thrown any clear lightupon its real affinity, and all that can with safety be asserted is that the Zasmidium is only some abnormal state of probably some common Fungus, which has been nursed into its present highly developed condiby the tiongh the favourable circumstances presented degree of moisture temperature and attendant sligh gree of moisture characteristic of a good cellar.
It is, indeed, quite astonishing how enormously tions. Instances have occurred in which a small cellar has been completely blocked up so as almos to forbid entrance, and a cask lifted up by the fungous mass, while every particle of surrounding wood was completely decomposed.
The Zasmidium appears to be comparatively harmless. For the most part it is quite superficial, and grows as readily upon the stone roof as upon
instances of its penetrating the tissues of the wine corks, and in these cases probably there [has been some pre-existent mischief from other sources. But so favourable \& report cannot be given of other Fungi, which are the pests of the cellar. not only attacking the woodwork and packing laths, but spreading from these and the sawdust to the corks, whose tissue is in consequence more or less completely replaced by fungous cells, which unlike the proper cork cells suffer the wine to dribble slowly through them, so that after a few years the bottles are found more or less empty, and the contents frequently tainted by some disagreeable flavour communieated by the Fungus.
In some cases the evil goes a step farther, and we have seen long branched processes sent off from the cork into the wine, destroying its distinguishing properties, and rendering it perfectly useless. It is not indeed surprising that fermented liquors should prove so highly nutritive to Fungi, if we reflect how active a part some of the tribe take in the process of fermentation. A slow ohange is constantly going on in all fermented liquors, however long they may be kept, and though fungous matter does not appear to be developed where the vinous fermentation has been tolerably complete, except in those cases where wine becomes what is called mothery (a condition which is probably always attended by a more or less decided acetic fermentation), there are instances in which such productions have been developed in strong bodied wines, as for instance in Madeira, one of which has been deseribed under the name of Conferva Vini. The way in which the spawn of certain Fungi flourishes in poisonous metallic solutions, by appropriating the oxygen and rejecting the metal, may illustrate possibly the growth of these productions in wine containing a considerable percentage of alcohol.

It is clear then that the cellarman has quite as much need to guard against Fungi as the oultivator, and with both, perfect cleanliness and care are equally desirable. As far as possible all vegetable matter, as laths, sawdust, exposed beams, and above all, wooden shelves should be avoided. Felt may be substituted in packing for laths, and if after all the exposed corks should be covered with a white floceose mould, which will sometimes be the case where neither wooden laths nor sawdust are employed, it is ad visable at once to wipe it off Sealing wax is not always a preservative, for we have seen corks highly decomposed by Fungi beneath the wax if cracked or chipped, which is often the case if the mixture in which they are
dipped is not sufficiently tough as regards its consistence. Metal capsules afford doubtles the greatest security, but these are used only for certain wines. The projecting portion of the cork might be painted with an aqueous solution of corrosive sublimate, which would prove a complete preventive, were not the metallic sal so dangerous as to make its use inexpedient except in very careful and judicious hands Where there is reason to think that the substance of the corks has been materially impaired, which may be easily seen by simply cutting off the projecting part, and observing whether the substance
is marbled with white veins or patches, it is requisite at once to recork the wine, putting aside those bottles where the spawn has penetrated so deeply as to impair the distinctive aroma. This has been practised within our experience with great advantage, and a valuable cellar has thus been saved, where mischief was not only threatened but absolutely begun. It is, however, the white mycelia which are most to be feared, and our Zasmidium may be left undisturbed wh
is still an affection for such monstrosities.
In conclusion we may remark that a substance similar to the outward eye, is sometimes found in coal mines. This however consists merely of the threads spun by some subterranean spider, blackened by coal dust. Simply burning a portion will at once show its animal nature, i there is no opportunity of examining it with the mieroscope. M. J. B.

The history of Mr. R. J. Grat's Asplinitum Hemionitis cristatum, for which a First-class Certifi cate was awarded at a recent meeting of the Flora Committee, is of sufficient interest to be worth record may be assumed, the curious varieties of Ferns gene rally originate. Some half dozen years ago, a plant in Mr. Gray's possession of Asplenium Hemionitis pro-
duced fronds which were divided or suberistate. plant had a stem of about an inch in length, elerating the terminal crown, and the fronds were of the subhastate general figure, familiar in the less developed forms of the species ; it however produced a lateral froms
about half-way up the stem, the fronds of which wer of the most highly developed palmatifid character ; and this lateral crown gradually robbed the terminal one,
so that frond after frond of the latter died off, till so that frond after frond of the latter died off, till the whole had perished. The spores of the crested fronds were in due time sown, and yielded a crop of plants, amongst which, as they became large enough to shom their peculiarities, could be detected representative both of the crested and palmatifid forms of frond. Thus brom seedlings of the original scarcely divided A. from seedlings of the original scarcely divided A.
Hemionitis, but with slightly crested points, we Hemionitis, but with slightly crested points, were
obtained, some plants with well develojed crests, and others with fronds deeply divided in a palmatio manner. It is the most highly developed of these crested seedlings which was shown the other day under the name of cristatum, and gained the firot class a ward This will, we have no doubt, become a handsome ever green greenhouse Fern, the primary lobes of its fronds being multifid at the apex, and sometimes even branched below, while the apices of each lobe become developed into fair-sized crested tufts, and their margins aro more or less crenately-lobed. The kind of variation which has thus been accidentally developed, aud which now appears to be fixed, is precisely what oceurs in some of the well-known varieties of the Hart'g-tongqs Fern.

New Plants.
283. Macleania speciostissima, Hooker, Botanical Magazine, t. 5453.
This very floriferous South American Vacciniaceous shrub appears to have been distributed by Mr. Linden as a species of Thibaudia-T. elliptica, under which name
it was received from Brussels by J. Bateman, Esa it was received from Brussels by J. Bateman, Esq., in whose garden at Biddulph Grange it produced it has examined fresh specimens from, however, who

carden, it is a species of the seldom seen genus Macleania, "for which, on account of its great beauty, has proposed the name speciosissima. "Rarely," it The specimens attracted much attention at one of the Exhibitions which took place at South Kensingto in April last. In a note accompanying tho specimens Mr. Bateman observed:-"I received the plant in 1859 from Mr. Linden, of Brussels. equires the heat of a warm greenhouse, and shoul be placed in a large pot, which ought to stand on bracket or shelf near the glass, In this way th dantly." The beauty of a plant such as this, with its long branches laden, as in our figure, with orange scarlet tubes, may be well imagined, and one can hardl restrain a longing to see some such specimens lending both novelty and grace to our somewhat tame exhibi ions of flowers.
Macleania speciosissima is described as a straggling shrub, of some few feet in the spread of its branches which are much elongated and pendent, well clothed oblong-ovate in form, entire, with three principal nerves, the young leaves being of a particularly delicat emipellucid purplish-red colour. The flowers are all drooping, most copious, in fascicles from beneath th leaves of the pendent branches, and have clavate pedi cels, an articulated five-winged purplish-red calyx, and a tubular corolla nearly an inch and a quarter long, contracted below the small lintb so as to be tubuloso ventricose, longitudinally five-angled, and bright scarlet
with a yellow mouth.

## FRUIT GROWING IN KENT.

I Have been much amused in reading the artiole, at $p$. 1203, 1864, by a Kentish commences with such a stretch of imagination as to assume that he must buy Apple trees at 1s. 6d. each. No fruit grower in his senses would think of doing such a
thing. A sane man would buy his stocks at some 50 s , or 60 s. per 1000 , and have them grafted where it wa intended they should be cultivated. This will at once dispose of his imaginary charge of 36l. per annum for
interest. Again, no prudent man would plant a fruit garden unless the land were his own freehold, or on binding agreement for the landlord to take the trees abundant crop of Apples this most exceptional season, all that your correspondent says about I know that in ome orchards they have not been considered wort the trouble of gathering. Still fine fruit, such as I properly selected and packed, and sent to Coven Garden Market, where really good fruit is appre ciated, makes a remunerating price, as inave proved Nonpareil, 8s. 6d. ditto. ; but to make such prices the fruit must be fine and carefully selected. Mine were owing to their growing near the surface of "Mother Earth,"-thus benefiting much by radiation-they were very beautiful. This is the effect of good cultivation. with respect to its being sent to market, for the most part I believe the Kentish fruit goes to the Borough market, which is only a little less dirty and disordery world-Spitalields, and for the most part it is sent in bushel measures, the Apples but seldom carefully selected as to size and quality.

To support my assertion that fruit is not cultivated have, Thave only the testimony of my own eyes, without exception, there may be many spots where county in England is so highly favoured by climate, soil, and site. I have seen standard fruit trees planted in rows among Gooseberry and Currant'trees, the ground carofully dug a spit deep every year, and all the surface roots driven from the beneficial effects of sun the trees crowded with wood, in favourable seasons bearing too many fruit, in seasons unfavourable none at all. I have seen many, very many, orehards planted irregularly with fruit trees of ail sorts unhappily commingled, some 10 and some 40 feet from each
other. Now, in all this there is no cultivation; it is a sort of hap-hazard barbarous method of "growing fruit words of your correspondent, who is most undoubtedly "Kentish Fruit-grower," and not a cultivator. The him; and I also observe that he fixes the"maximum produce of each bush tree at half a bushel, but this is equally imaginary, for from some years' careful observation I see no such limit to the produce of a
although I made it the basis of a calculation.

Adverting to the conclusion of the letter of your correspondent, no way can be pointed out by which he can make more of his orchards in their present state than he now does; his varieties are doubtless too day; and he cannot thin his fruit so as to have them extra fine, and have the chance of a decent crop every season. The poor trees are 'so exbaasted by the enormous crop they have borne this season, that it
may require years before they recover. If half, or even more than half, the Apples had been taken off his trees about midsummer, the remaining fruit would have been worth double, and the trees would not have tion, and not fruit that would have been fruit cul
As far as I have seen, the Kentish farmera in many instances sublet their orchards, thinking them infra dig. to attend to; well, perhaps they are so, under present circumstances. What is required in Kent is a lace of clever cultivators, who will be able to give a liberal rent for some of those numerous favourable sites to be found on almost every farm in Kent, i. e. if the freehold is not to be bought. A far-seeing landlord would grant a lease of not less than 30 years, and the end of the a certain prico for the trees at state. If the country progresses in wealth as it has done for some years past, there is a great fature for the clever fruit cultivator. As to the fruit grower he will be like an old stage coach-a thing of the past, and people will wonder that such things as Kentish orchards ever existed. As we increase in "population, so it is probable the difficulties of "getting a living" may increase, and we shall decrease in physical procultivators may one dere probable that our ruit present Kentish fruit growers are for the most' part portly gentlemen, it would seem advisable to preserve future (they would make capital mummies), so that future generations may see the difference physically botween a fruit grower of 1864 and a fruit cultivator
of 2064. Seriously, this matter of fruit cultivation is
quite worthy of earnest attention. quite worthy of earnest attention. Oar opposite neighinferior to that of Kent, are taking active measures to supply the London markets with fruit, and the "blunt John Bul" of your correspondent must inly thimself distanced. It was only the summer that a French fruit cultivator visited this place, and he was much taken with the calcareous nature of most of the soils here, and said that he had found some difficulty in finding in France soils like them, and so highly favourable for the culture of stone fruit, but that he had recently purchased a piece, 40 acres, near Rouen, which he intended to devote to the fruit growers as a class are very superior men, well acquainted with the nature of soils and their adaptation to the different kinds of fruit, and also with fruit tree stocks and their effects upon the graft. I do not wish to make invidious comparisons, but i have
not found much of this kind of information in Kent. I can 'realise perfectly the present position of the Kentish orchardists, for when a young man I inherited an orchard of very fine Apple trees, which had grand old trees used to bear from 20 to 30 bushels per tree. Among them were numerous sorts, so that when the winter kinds were stored in the fruit room, there were "cotchels (the term used by I soon] tound that I had too many varieties, giving extra trouble both in gathering and storing, and there were always some ready for market before their proper time, thus requiring much care in watching them. in dying, and re-grafting the trees not too old, I succeeded in reducing my market varieties to two-both good keepers. I have since then never had any
trouble with my crop, or reason to complain of the low price of Apples. If then, the " Kentish Fruit Grower would examine his trees, find out those that do well in his soil, but taking great care that the sorts he seleots for extensive growing will be marketable at a season when there is least fear of a glut, he may re-graft all his trees that are not too old and ciecrepid, and by reducing the sorts to say four or five, he will have much less trouble with his orchards and more satisfac tion and profit, at least for a time; but I warn all rough fruit growers of what must come Apples and Pears of the choicest kinds may and will be cultivated in Kent, but not in the way that has been 30 long the only way, viz., by buying sวme 200, 300 , or 500 standard Apple trees from the Surrey trees all good enough, but not selected wisely. Well these trees are stuck in among Gooseberry bushes and in Grass orchards, and in spite-of this treatment they fruit in favourable seasons, and few or none in season the converse. All this must be changed if the "Kentish Fruit Grower" wishes to keep his presen position, and as he is doubtless a wise man, he will I rust think about it. Perhaps after Jean Crapaud has made his way in the London markets, and is grinning good naturedly, (because his pockets are full) at the "Kentish Man," we shall see Kent really and truly a fruit garden. To bring this about, sites must be selected, soils examined, the stocks necessary for the apprenty refuse to grow if grafted on certain kinds of stocks and then again there must be but few wild but grandlooking standards (an old orchard near a farm house is the most charming picture of English rural life that can be seen), but trees all under the command of the cultivator, who must be able to see every bud and branch of his tree, so that the fruit may be thinned in du senson, and the shoots pinched in secundum artom no deep digging must be allowed, no Potatos, or Gooseberry or Carrant trees, but careful good culture, so that from one acre of fruit trees a greater income may bin This will surely come to pass, for every passing season tells me that wo have yet much to learn in open ai fruit-tree culture. Yet the task to those whose mind are active, is easy. Let us not be discouraged by the wail of a "Kentish Fruit Grower," but try and meet the competition that must come, by skill and capital. T. R.

## THE TRITOMA.

THe two finest plants of this genus-sometimes called Kniphofia-are those known as T. Uvaria glaucescens, and T. grandis, As I have grown these rather extensively, I may perhaps be able to offer a few hints on their cutivation, which may be useful to those who have been so unfortunate as to lose them during winter, or to have them so much punished by frost, that they have broken weakly and flowered indifferently the following season.
T. Uvaria glaucescens has long, rather narrow, glaucous leaves. It is a very abundant flowerer, throwing up the spikes from 4 to 5 ft . in height, and these bearing flowers of the richest orange scarlet. In a small bed planted last May I have had above 200 spikes. This sort commenoes to flower about the middle of August, and
continues until October; and before it has done T. grandis is allowing commences.
T. grandis is a magnificent species, well deserving its name, for it is the king of all the Tritomas. It is very different from the former, being much stronger in growth, with the leaves shorter and broader at the flower-spikes are from 5 to 7 feet in height, and the flower-spikes are from 5 to 7 feet in height, and the
blossoms of a bright scarlet and yellow, hang on the spike for a much longer period, and come in greater profusion than in the other. It commences flowering about the end of September, and continues throwing up until winter. A boxful of flowers was sent from the country to London for esamination, on New Year's Day, 1864.

I feel convinced that these two fine decorative plants, when seen and properly understood, will be much more extensively grown than they hitherto have been. There is scarcely any plant in cultivation as a hardy erbaceous plant that ean rank with them, flowering is they do for at least five months of the later portion of the year.
As plants for garden decoration, either planted
alternately in long rows, or tr clumps, a large-mass on floral beauty. I may also add that T. grandis makes valuable plant for the decoration of the conservatory, by potting it in May, and plunging the pots in the open ground until October, when they should be taken up and placed in the conservatory. Just at that time of the year the conservatory requires something to nliven it. As to soil, if it be rather light, I would dvise that it should be trenched as deeply as possible, putting in plenty of cowdung at the bottom, and also ther hand, if cowdung freely with the soil is heavy and close, it should be trenched, and plenty of dung put in at the bottom, bat it should be mixed with a quantity of grit or coarse sand and vegetable mould. The plants will grow almost anywhere-by lakes or ponds, in the flower garden, or
 large quantity of moisture. If the soil is not suitable for them, it can, by a little assistance, be made so.
They are best planted out in May. They may readily be increased by division. If the summer proves hot and dry, like that through which we have recently passed, they should be mulched and watered freely from time time. In winter the groand close around them hould be covered with rotten tan or leaf mould; and should the weather set in very severe, the tops ought to be protected with a little litter or dry Fern. Nothing more will be required until May, when some rotten fiery-looking flower spikes have gained for them the vulgar name of Red-hot Poker plants. T. Brown.

## TRADE MEMORANDA.

We are unacquainted with the firm of May \& Isaacs, of Edmonton.

## Home Correspondence.

Gardeners and Under Gardeners.-Every one having a knowledge of gardening must be impressed with the fact, that whatever the amount of information gardener may possess, either theoretical or practical, he will still be found wanting in some things; and it is a matter of regret to think how ill-informed many of our gardeners are even of the plain rudiments of education. This arises in some measure from the way wich young men are trained. A boy is taken to work in the garden, not with the intention of becoming a gardener, blished so firmly, that it would be difficult to suggest an alternative, for it is seldom that people think of apprenticing their children to gardening. If they can afford premiums, they endeavour to place them in what they imagine may become a more lucrative position and when such apprenticeship does take place in a
garden, the result practically is not much better than when the youth has to struggle onwards by means o his own exertions. There are certain individuals who never make any progress ; a sense of the real value of therefore, to impress upon garden superintendents is this: that every gardener in employing boys should make inquiries respecting their education, and, if he can manage it, should not employ any except such as have a tolerably good one. A contrary practice is, however, the rule; and young men who cannot even spell correctly, often obtain good situations. The proposed examinations, therefore, at South Ken sington will be one of the best things that can occur at any rate they will serve as a stimulant to persevering youths to push forward, provided the nobility and gentry will engage none but certificated gardeners. As the education of young men is generally effected by means of self application, it may not be out of place to offer few suggestions as to the best mode of carrying ont its improvement. Nothing is better perhaps than for them to unite into a class, and to take some branch of education for study. I would propose that the chie gardener be at the head of them-not to be always with them, but to pay them a risit once a week, in order to lend them all the assistance in his power. A society for the improvement of young gardeners has been esta-
blisted here, and is working well. Two are appointed to act as treanner and secretary; subscriptions being reqnired to purcbase weekly papera, eight in number Pomologist and the Journal of Horticulture are presented by Sir G. B. Middleton; he has also presented the Society with the following books:-" "Theory an" Book of the Garden," "Cottage Gardener's Dictionary," and other minor works, which are given out to be
read fortnightiy. Once a week each member has to be present, when one is appointed to give an essay on some subject connected with gardening; ten of these have already been delivered. The first was given by the head gardener (Mr. Blair), and was chiefly connined matters of education. After allowed to express his opinion on the subject, when sometimes animated discassions take place, perfoct decorum being maintained, as a chairman is appointed to have full power over the meeting. In adilition to this, the members meet twice a week for the study of English grammar, and as the Society advances, kind may be established in every garden in which a few young men are kept. I can assure thein that they will not regret it. An old adage says that "unity is strength," ard unity in stady will be found strongly antagonisl ic

Coal Ashes a Disinfectant.-As the subject of the utilisation of sewage and other manurial matters that our dwellings furnish appears increasingly, and not without reason, to occupy attention, it is I think the duty of every one to endeavour to throw light upon the may be ensured, and at the same time its offensive character removed It is evident that in its diluted form, it is deprived of much of its valuable properties ; I have, however, read with astonishment in your pages some suggestions respecting using earth to disinfect it, drying the same, and using it a second time. Now,
surely there is at hand in every house an agent better calculated than earth for the absorption and neutralisation of all offensive matters, viz., coal ashes. Who las not heard of the excellent results obtained a few sears ago from using peat charconl as a disinfectant, in a vile pit-the accumulation of years. After its applipation the contents of this were carted away through public thoroughfares at noonday without offence; and more than this, an indrpendent gentleman had some of
the material put in a vessel on his drawing-room table, to show that its offensive qualities were wholly negatived. I cannot say that I would be prepared to go $s 0$ far as that. But to proceed to my own experience: may state that during the last 26 years I have with the best effect. Our closet has 5 or 6 steps up to level, the walls of which are cemented inside; in this is a small doorway $i_{1}$ which a flagstone is fitted, leaving
at top a space of 8 or 9 inches to allow room for the introduction of coal ashes; over this opening, to
prevent draughts when closed, a trap door is placed on book hinges, so that it may be easily removed when the pit requires cleansing, which probably would not be othrowing in the ashes daily, the place may to paid more free from effluvia than many water-closets, and also cleaned out without offending the olfactory nerves Orchids in Plom. J. M. .
Orchids in Plower in December. -The following short list may prove interesting to lovers of Orchids
who may like to know what plants are in the habit of flowering at this dult season. I am of opinion that winter flowering Orchids are worthy of more notice than is usually bestowed upon them, as they enliven in other departinents. We have now in great beauty Angracum sesquipedale, with ivory-white flowers, A. eburneum superbirm, Ansellia africana, Barkeria Skinneri, Burlingtonia amœua, Cittleya amethysto-
glossa, one of the most beautiful Cattleyas in cultivation; Calanthe Veitclii, a beantiful winter-flowering
plant, bearing a spike 4 feet high, thickly set with beautiful rose-coloured flowers; C. vestita rubra nculata C. vestita lutea, C'elogyne tuscescens, Cypripedium hir
sutissimum, very fine, two flowers being on ench spike Fairrieanum, C. barbatum nigram, $C$ insigne C. venustum, Epidendrum vitellinum majus, E. amabile a magnificent variety, one that will become a general favourite when better known; Galeandra Stangeriana L. anceps, IL autumnalis, a charming plant; Lo. prestans, Lycaste Skinneri, Maxillaria venusta, six months in flower; .M. picta, and its larger vuriety; Miltonia
Moreliana atro-rubens, Odontoglossum Insleayii, true; Oncidium Cavendishianum, O. Suttonii, O. pulvinatum majus, O. sphacela um, Plajus maculatas, Phalænopsis laceum, Sophronitis grandiflora, S. cernua and violacea, Trichocentrum Pinelif, and Zygopetalum crinitum E. Mitchell, gardener to R. F. Ainsuoorth, Esq, M.D. Painless Ertinetionchester.
Human Food (see p. 1255, 1864) - On designed for Human Food (see p. 1255, 1864). -On visiting the
butcheries at Islington, which, moved by a deep sense butcheries at Islington, which, moved by a deep sense
of obligation I did, the intelligent head butcher, Mr.

Grimaldi, informed me that his men might fail once in about 50 times to inflict death at a blow. But in the
country I have seen, to my great horror, butchers hammer, so to speak, the heads of the poor brutes with many blows, ere, lowing and trembling, they sank on their knees and died. Striking on the head with the pole-axe, however well done, still inflicts a mighy pang ind the ox is dragged over the gory foor ere the deed detest blood, and do not come in contact with it without suffering. But the pole-axe, had it even nothing objectionable, yields no relief to the countless sheep
and other such animals which now are done to death with infinitely cruel accompaniments. I therefore earnestly, most carnestly, press the attention of the meud. Hewry Mac Cormac, M.D., Belfast, Jan. 3.

## Soctetirg.

Lnviean: November 17.-G. Bentham, Esq., President, lected F Fellow. Dr. Hooker laid before the Society lithographed plate of a gigantic species of Aris tolochia from the forests of Old Calabar, where it had been discovered by the Rev. W. Thomson, of the United Presbyterian Church Mission, who had transmitted a flower in spirit to Kew. At Mr. Thomson's request it had been named A. Goldieana after the Rev. H. Goldie of the same Mission. Dr. Hooker also exhibited some Hazel nuts, said to have been taken from a closed cavity of a large Oak tree at Llanelly in South Wales, where it was supposed they had lain for many years. The nuts presented a curious striped appearance, and the kernels were quite sound and fleshy, though discoloured. They had been sent to Dr. Hooker by Mr. J. Douglas, the proprietor of the saw mills in which the tree was cut up. The following papers were read:-1. Facts relative to the Move, ments of Insects, on dry polished vertical Surfaces. By J. Blackwall, Esq.-2. Note on a Skeleton of Dinor nis robustus in the York Museum. By T. Allis, Esq. Chingleput district, Madras. By Dr. Shortt in the enormous tree, it would appear, grows on the outskirts of the village of Pussumboor. The extent of ground which it covers is estimated at 4800 square yards. Some of the aërial roots have struck down close to the original stem, and by their rapid increase in girth have become united with it; others have united together, forming new trunks almost as large as the main tree, The number of aërial roots which form the support of the branches, as far as can be made out, is 2000, and the greatest height from which they descend to the soil is 60 feet. The extreme height of the tree is $83 \frac{1}{2}$ feet. The size of the tree and the regularity of its head wooded hill. From the minuteness of the seeds of the Banyan tree, they readily establish themselves in the smallest crevices either of trees or buildings, where they frequently grow to the eventual destruction of the support. The tree often fixes itself in the Palmyra, being arrested in the axils of the leafstaliks; and when in this position the roots gradually encircle the stem of the Palm and eventually destroy it. The natives term this union "the marriage of the Palm and banyan." The wood is light and useless except for fuel, but the aërial roots, when of sufficient size, are
used for tent poles, their strength and lightness rendering them well suited for this purpose. The leaves are sewn together to form plates, off which The milky sap is in great request for sponginess of the gums and aphthre, and the concrete sap supplies ird-lime. Several other kinds of same psoudo-parasitical habit.-4. On Pceciloneuron, dome; communicated by Dr. Thocason. This forms a arge tree on the western slopes of the Neilgherries, and is gaid to yield a valuable timber. The species was called P. indicum.- 5. On the naturalised Weeds Dy Dr. Hooker. After arriving at King Wiliam's Town the anthor had occupied himself a good deal with gardening ; but as the summer came on, it seemaed choked the cultivated plants, that the attempt was abandoned in despair. Most of the weeds referred to in the paper were stated to be thoroughly established and to be spreading with great rapidity, all of them increasing freely by seeds. Indeed, the luxuriance and prolificacy of the garden weeds were such as to force as Eschas on the attention. Certain garden flowers, as Eschrcholtzia californica, Cenothera biennis, Zinnia olegans, Mirabilis Jalapen Ipomcea purpurea, and Canna indica, were said to spread rapidly over gardens where they have been grown, till they become weods. Of the ipomea at least four crops come up in the season. Of the 32 kinds of weens mentioned by Mr. D'Urban, nearly all ralised, and it was suggented that they might, therefore, have been introduced with the American garden seeds, which are so largely imported into S. Africa. Among the more obtrusive was Purslane, which spreads manner. Mr. D'Urban suggested that as the

South African antelopes eat only succulent herbs and not Crass, and account by the Zoological Society, which had not been account by the Zoological society, whe in managing the animals of this class which from time to time it had acquired. Xanthium Stru marium was another plant that had spread with grea rapidity, so much so as to occasion alarm among sheep farmers and others interested in the wool trade, on sccount of the burs adhering to the fleeces. The Bur-Marigold, Bidens bipinnata, was also found most roublesome as a garden weed, hardly anything bein able to compete with it, except the equally vile Bristly Fox-tail Grass, Panicum verticillatum. These two wer noted as being enough to break the heart of a gardener Nicandra physaloides and Solanum nigrum were said to be abundant, the soldiers often eating the berries of the latter, which seem quite innocuous. Physalis pubes cens, the Cape Gooseberry, had spread in a wonderful manner, both in wild and cultivated ground. The Fingoe women collect the berries, which make a
delicious preserve, and bring them to market. The Thorn Apple was said to be a very disagreeably intrusive plant, the purple variety of it, known as Datura Tatula, growing 6 feet high. Various other weeds, as Shepherd's Purse, Chenopods; \&c., were stated to occur in great profusion.

## 

Bericht über einige der viohtigsten botanischen Ergebnisse der Bereisung der portugiesischen Colonie von Angola in West Afrika in den Jahren 1850-1860 durch Herrn Dr. Priedrich Welwitsch. Von Dr. E. Fenzl. Wien 1864, $8 v o, p p .10$. (An extract from
the 48 th volume of the Transactiors of the Imperial Academy.)
Professor Fenzl, who is so well known for his researches in botany, has lately sent us the small pamphlet of which the German title is given above. It is a report of some of the most important botanical results of Dr. Welwitsch's visit to the Portuguese Colony of Angola in West Africa from 1850 to $\mathbf{1 8 6 0}$, some extracts from which will in all probability be acceptable to many of our readers, and more especially as Dr. Welwitsel is now in England arranging his valuable collections, which have already afforded matter for some most interesting papers, and are destined still further to enrich our journals.
Dr. Frederic Welwitseh was born at Mariansaal, in Carinthia, and from the very commencement of his academical course he acquired a great taste for botany. He was soon well known for his passionate love of collecting, his scientific knowledge of his native flora, and his indisputable merit as a contributor to the accurate knowledge of the Flora of the Vienna basin and of Lower Austria, He soon however extended his researches beyond thene narrow limits, and included the Floras of the rest of Europe and other continent in the compass of his investigations. Desirous, however to observe for himself, he accepted, a slort time after he had taken his doctor's degree, the invitation of the Wirtemburgh Botanical Travelling Union to explore the treasures of the Portuguese Flora, a task which had been so happily commenced by Link and Hoffmansegg. Haviog accomplished what he under took to the satisfaction of his employers, he wa induced to remain at Lisbon as a teacher of botany
These brief details will serve to show how he becam connected, and eventually to his distinguished credit with the scientific expedition to Angola fitted out by the Portugnese Government. Furnished with all the informntion necessary for such a journey, hardened in body against the evil influence of a changeable tompe impunity all sorts of privations and difficulties, extremel enterprising and cool in the midst of danger, gifted moreover with an eminent degree of tact and diser mination, Welwitsch was exactly the man to b implicitly trusted with so hazardous an expedition.
More fortunate than Smith, who, together with mos of his companions in Captain Tuckey's expedition to
the river Congo, which at first appeared so hopeful, at last fell a sacrifice to the dreadful fever of the country Welwitsch examined the greater part of the coast between the Congo and Cabo Negro, as also that lying between $6^{\circ}$ and $16^{\circ}$ south latitude, $H_{e}$ penetrated moreover through indescribable difficulties from the mouth of the Cuanza 250 miles into the interior as fa as Banza di Quisonde towards the east.
In the first year of his abode in Angola he examined the coast between the Congo and Cuanza for more than three degrees of latitude, oppressed by the heat of the desert, added to hunger and thirst. In October, 1854 he passed through the hilly and mountainous districts to the east, in order to penetrate the wonderfol and richly-wooded districts of Cazenoja and Golungooalto Welwitsch remained nearly two years, wandering through these regions in every direction, mostly on
foot, oppressed by fever, and with legs swollen and covered with sores. From September to Decembe 1858 (the spring-time in Angola), when scarcely re covered from illness, he visited the shores of Dande to the north of S . Paolo de Loando, and in the followim year (1859) from June far into October the coant o Mossamedes as far as Cabo Negro extending southwar
and heallihy table land of Huilla, 5000 to 6000 feet
above the level of the sea, in order to return in good above the level of
heallh to Eurone.
A few only of his more important discoveries, whether A few only of hic more impartant discoveries, whether
as regrids $\mathbf{V}$ egetable Geography or Morphology, can be mentioned here.
montionet heore
In a
Inthical point of view, beyond 'all other
prticulars, the local but plentiful occurrence in the partienlars, the local but plentiful occurrence in thie
interior of Africa of a Cactus, a epecies of Rhipsalis, 6 to 8 fept lone, growing parasitically on Adansonix and Sterenlix more especially, excites our extreme
Were it not on the authority o nstonishment. Were it not on the authority of
Welwitsch thant this assertion rests, it might beregardel as scarcely more than an error resting on some
mistaken affinity, as all the many hundreds of Cactic belonging to various genera are exclusively confined to America, further important discovery, confirming the antici pation of Robert Brown, is that of Monodora Myristica, as well as a second speciess belonging to the same genus, This is the American Nutmee cultivated in the Wes Indies, respecting whose native country dobets have
existed, and which, as R . Brown properly remarked was introduced with Blighia and many other unefu plants by the Negroes.
species of the genus Vellozin species on we genus considered to te conflined to the Brazils ; as alko that of species of Begonia, Hypoxis and Cedrela a Raflesiad growing parasitically on the branclues of
Cæasluinixe, and a blue flowered Ouvirandra, in marshy but, not submergell places-species belonging to genera which were believed either not to oceur at all in Central Africa, or only sparingly.
In a journey through the wretched parched districts betwren the rivers Dande and Z nzza, while he was wandering thrnuzh the broad sandy plains stretcling
southwards to the left bank of the Zenzi, he came uponn sout thwards to the left bank of the Zenz 1 , he came upph1
a Palm forest five leagues in length, which consisted exclasively of the crowded stems of a branched Palm belonging probably to the genus Hyphæne, Like most African Palms it yields excellent wine. Should it prove on examination to be identical with Hyphæne thebaics or guineensis, it will prove the enormous extension in As regards the great quantity of new morphologically interesting plants, mentioned by Welwitach in his
different communicatione, we shall advert to one or two different communications, we shall advert to one or two
only in partienlar, to show that the well kuown saying semper aliquid novi ex Africa (always some novelty from (perhaps a true Banana) with a barrel-shaped stem the fops of the morntains of Pango Andongo, bove than 2000 feet above the sea. In the region of Golungo Alto, which abounds pernliarly in gigantic plants, he found an arboreous Uinbellifer, with a stem $1.1 \frac{1}{2}$ foot thick, which is prized highly by the natives for its as far as is at present known, the most gigantic plant of the order.

The most curiors, and in every respect far the most remarkab'e, of all the plants found in Angola, is the peculiar structure, that Dr. J. D. Hooker rightly remarks in his memoir in the Transactions of the Linnean Society of London, that since the discovery of Rafflesia
Arnoldi in Sumatra, no plant has excited so great an interest as the Welwitschia mirabilis, dedicated to the honour of its discoverer.

This prodigy amongst trees belongs to the order 100 Getaces, and certainly attains an age of at least 100 years. The unbranched stem, raised only a few inches from the ground, measures in very old in-
viduals about 2 feet in length, and 4 (aceording to Welwitseb), or even 6 (according to Mouteiro) in breadth at the crown. Ruised, as it is, 00 alightly
above the dry gravelly soil, it resembles a gigantic loaf split in the centre into two wide gaping halvea, or a massive round plate depressed in the centre, with entire never changed nor renewed foliage consists of two opposite evergreen coriaceous leaves sp:ead over from ground, variously curled and waved, which are from 1 to 2 , or even 3 fathoms long, and 2 to $2 \frac{1}{8}$ feet
broar, and what is most remarkable, they are the pair of cotyledons of the germinating plant, which continue to exist through its while life, a phenomenon of which the lisher orders of plants. The furked inflorescence the rrown, bears smaller bar"en hermaphrodite catkins, and larger carmine red female ones 2 inches long, and IV elsvitol cones. sunk in the soil with these mis-shapen monsters deeply sidurable quantities at Cabo Negro $\left(15^{\circ} 40^{\prime}\right.$ sonth lat. on the dry plateau of the cosst of lBenguela, which is 400 feet ahove the level of rubble, and from 300 ti this place at Mossamedes, in the neighbourhood of the Nicolas River, on the little Fishbay at $14^{\circ} 20^{\prime}$ south
lat., Mer Monteiro found it at a later period in a
*he crown, when divested of its leaves, resembles so
elosely the cracked surface of an old Polyporus iguiarius that
it might on a
perrectly similar situation on quartzoee sochistose soil
and Mr. Baines, as also the well-known Cape traveller, Mr. Anderson, in Damaraland, between the 22d and 231 desrees of $\operatorname{son}$ 'a latitu le in the neighis)urlhond of ever falls. Thie distribution of this remark
enthe plant ever fath. The distribution of this remarkable plant,
as at present known, which calls to mind some Pegetable of a creation long since past, falls within the 144 ch and 23 rd degrees of south latitude, and may therefore be considered as tolerably characteristic. It
is well known to the natives. We must mention as of peculiar 1 interest to the man of science, as also for the Pharmacist, or even the Ethnologitst, the notice in the Portuguese languaqe of the samples of wood, materia medica, and manutactures from Angola, sent to the
Industrial Exhibition of London !in 1862, of which Dr. Welwitsch is the author. It is greatly to be desired that this pamphlet of scarcely four sheets should find an intelligent translator, through which the obtain a wider circulation and eatimation.
 Longman \& Co.
In reference to a notice of this worl which apperred in the Gardeners' Chronicle of Deo. 24, which has been considered in some quarters hypercritical, we must remark how extremely difficult it is to notice a work of this charactor without drawing attention to omission and inaccuracies, while the undoubted merits of the book are passed over in silonce.
Such a course must tend to produce an unfavourable mpression; but it was very far from our intention to speak in a disparaging way of a work which our con.
cluding paragraph says "must prove extensively usefu, clading paragraph says must prove ex

## Garden Memoranda.

Seaforth Hail, Seafibid. Litrbbpool (Conoluded from $p .1136,1861$ ).-In enntimation of our description servatory areade, on the one nide, is a gymnasium, a very large play-room, fitted up with a variety of articles which, while affording innocent recreation and amusement to the children, will aleo call into exercise and play, the thew and sinew of the physical system. furnishe other sile is a billiard-room sumptuousiy dividing pauels of the compartment being portable can be thrown aside, thus forming a spacious ball-room.
Descending a few steps we are in the conservatory
proper, a useful buildag of octagonal outline, well suited for the cultivation of plantan It forms $n$ piensing terminus to the arcade already described. As usual in set in a handsome stone basin neatly carved. From this, which is also of octagonal outline, wired on the top in form of a basket, proceeds four wire trellisea perpendicularly to the rarters, which vere covered with
the plain and variegated Kennedya, Passifloras, Lapageria, and the handsome serrated-leaved Celastrus scandens. The specimen plants stand on Welsh slate stages towards the front, and the larger ones,
such as Oranges, Araucaria excelsa, of which there are two plants, faultless in symmetry, each about 10 feet high, stand on gravel level with the paths Lomaria chilonsis, and Hypolepis tenuifolia, hug notice, We have learned since writing our former notice, that the bulk of the large Camellias referred to are plants originally imported about 40 years ago from China by the late Lord Strathallan, then the Fon. the Chinese, and among the first Europeans who were allowed to go far inland unmolested. Mr. Drummond presented the identicul plants to the late Sir llobert Preston, Valleyfield, noar Uuyformline, in whose posReverting again to the plants that furnish this actagonal conservatory, we saw several specimens o Aphelexis and Chorozema; Sollya heterophyila; bandsome plant of the free blooming, small-leaved, white-flowered Leptospermum bullatum-a plant seldom seen in collections, and one deserving general uttention as a late autumn decorative plant; several Acacias, of which the fite yeliow elegant-foliaged oleifulia eiegans, the most interesting, and are generally the most neglected sorts. Brachysema too, alihongh a climber, and in this torm meriting more popularity, was in excellent andition grown as a bush plant, clothed with dense sweet-scented Cytisus tilipes, than which nothing of its kind is so well adnpted for pot culture, being more easily kept within bounds than other members of its ill large plants, involving the outlay of no inconsiderthle sum of money-in fact, no place that has yet come within our cognisance has been furnished on such a
seale. It seems as if the country had been rangrked seale. It seens as if the country had been ransacked
or specimens, regardless of cost, for there they are in abundance, and presenting a variety, especially among miscellaneous greenhouse plants, that we may look for in vain in a
lew and puny in size, unless we except Orclide and
Ferns, which are only no yet frebly peorenented reens, which are only as yet frebly represented. Of
course, to provile specinen Orehids to fill one of the stove honses would be no small matler ; but in a place such as this, where incioor gardening must ever form the most interesting feature, and whiere honses to such an extent prevail, it carnot be considered complete without the addition of some Ferns and Orelids, the more especially as other departments are so well repre sented. Among Orchids the only things notewo:thy were Cattleva Skinneri and Mospiss, Oncidium Lancea num, Inridum guttatum and Cavendishĭanum, and nne or wo Cypripediums, alonr with everal plants of $\mathbf{Z g g o}_{\mathrm{g}}$ petalum, of which maxillare was most worth notice Among flowering stove plants a Pittosporum (usually a greenhouse family) called enrenioides, with sweet-
scented flowers, rather thinly spreal, looked well, and was of course useful for its fragrance alone a rers fine trained plant of Clerodendron Thomgonæ, which if one of our beat recent stove flowering introductions aod there, always in agreeable plant to look nipon; In another stove, which was well filled with srecimen plants, stood that grand Melastomad, Medinills magnifica, with its long pendent thyrses of flowers hanging like huge bunches of Grapes; this when well managed is really the finest flowering stuve plant yet Allamandas two invaluable geners for deoorative purposes and for exbibition. Among ornamental foliaged plants there were unique apecimens of Croton ariegatum, Pandanus graminifolius, Dracemn mexí cana, ferrea and its varieties, Cyperus alternifulius, and numerous others not less interenting, but of much smaller dimensions. The houses are well suited for the growth of these plants, not being too high; and yot sufficiently accommodating in every other way. The system of heating admits of come improvement, the pipes generally being too far from the front wall, and ather low upon the ground while the valves, and the mode of conducting the branches from one division to another, are not of so masterly a charncter as the other
general detaile of this great plant and fruit place. The wonder however, in so gigantic an establishment, is that so little deficiency is apparent.
Turning our attention to the fruit ranges, we find span-roofed house accommodation of 100 feet lengtin, and about 18 feet width, for Pines alone. The plant: in these bousew are as bealtlyy as they are numerous, and will in another year outgrow the eoace allotted to them. We observed fruiting plants of Queens; Smnoth Cayennes, of which there were an excellent stock; Black Jainaicas und Montserrats, all good sorts, and in excellent health. They vere haated, both top and bottom, by there were numerous ovaporating troughs for keeping In Vineri pthere a keeping up a supply of fruit at all seasons. The young
Vines had made good canes, and the borders seensed to be made up of that stiff plastic-like fibry loam incorporated with crushed bones, in which the roots of Vines delight so much to revel. Hamburghs: common Black, and Muscat, Along with the Alexanirian Miscat, Lady Downes, and Black Alicante, form the chief sorts planted here. Peaches and Nectarines have several houses to themselves, and are grown both on the old and the present orchard house systems. Plums are served in the anme way. The roots of all these are restricted within doors to a bed, with a curb-stone forming the boundary, both at the paths and in front.
Then there are Cucumber and Melen houses, spanroofed in form, with a bed on either site the centre path, which had been of great service for furnishing a supply during the season.
our visit were plentiful, and plants for winter growing vigorons. Besides all these there is a detuched range, which Mr. Huglies must find very uselul fur many purposes. In fact these would make admirable Vineries, and the broad shelving at top would come in well for orcing Strawberries.
The gardening offices are plain and commortious, and embrace everything that a gardener requires. Tuey are 80 planned as to chime in with the obleer general affices, and have a good effect as a whole. The Musho room house has the usual double or triple tier of beds,
some in a state for gatherins, and snccessional lots coming forward. Probably the most surcesstul crops
droppings, as they came out of the stable, laid on the floor to ferment, thus giving off a surface heat far more nitural than either flue heat or that of hot-water. What seemed to fucilitate the propagation of the spawn was a blanket suspended from the ciling, which hat a whole seems a sensible plan, and is wontly of the attention of ail interested in Miviroom culture. Certainly we can vouch that the crop grown under such conditions was immense the week preceding Chiristmas.

As for vegetables out of doors there seems nothing to do so well-expised as this place is to the influmee us order Atlantic Ocean-as Asparagus and Seakaie. In order to check the violpnce of the wind, and shelter common vegetables, spars about 15 feet long are naile together in a diagonal form, presenting a wooden wal
windows of Elizabethnn buildings. These walls are 12 fe , high , and surround each quarter of ground Fruit trees are trained thereupon, but will have little chance to succeed. Ont-coor for there is scarce an must em be a the various shruls and trees planted for trial that we observed. The Green Tamarisk, Thorns of sorts, and the common Chestuat, are the only things that make a respectable appearance. Grass and gravel with a fees bedding plants, in sheltered places, are the ouiy things worth paying attention to. Chrysan themums, hovever, were in first-rate condition in one of these wnoden pens, promising an abundant yield of hoom. Ground limestone makes capital walks, having a good appearance, and being as firm as concrete. The responsibilities placed upon Mr. Hughes in the last two years, during which these operations have been begun, carried on, and completed, must have been of a very onerous natare ; and while, as in most places, the critic sees always something not quite to his liking, upon the Whole there bas been much done in Mr. Hughes's
department to sustain a welt-merited complisent.

## Miscellaneous.

Avouba himalaica.-This plant was discovered by Dr. Hooker in the Sikkim Himalaya; and notwith standing the general similarity of features between it and the Japanese Aucuba, that distinguished botanist regards it as a distinct species. Aucuba himalaich proves to be a very handsome freply-branched hardy evergreen shrul, growing from 3 to 5 or 6 feet in heipht, and having fall green stems, and large flat or expanded oblong-ovate leaves, very glossy whalst young. and maturing to a rich dark green hie. The flowers are produced in short dense terminal thyrsoid panicles, and have four small starry pink petals. The blossoms are succeeded by clnsters of bright orange coloured oblong one-seeded berries. Being found in its native habitat, at an elevation of nearly 10,000 feet on the most humid monntains of the Sikkim territory, it is considored sufficiently hardy to resist the cold of English winters, and may be regarded as a most valu able addition to the evergreen materials available for
planting flower garden shrubberies and belts. In the alinost total absence of flowers available for such situntions during the winter and early spring months, fruit-bearing plauts like the Aucuba are eapecially welcome, and its brilliant rich orange-coloured or coral red fruit, contrasoing with the dark green foliage, will be found very strikingly ornamental. The plants wil also form noble bushes with which to fill vacant niches, and wider spaces beneath the partial shelter of other planta of tree-like habit, in larger shrubberies and arboretums. As an evergreen alone the Aucuba himalaica is a valuable introduction, its luxuriant und other shrubs. From the allied species it will be readily recognised by its loftier and bolder habit, combining the proportions of a Magnolia, with the verdure of a Lasurel, by its considerably larger, longer, and more uniformly attenuated leaves; and by the gland-tipped teeth being much more prominent, as well as extended down two-thirds or more of the margins, while in A. japonica they scarcely extend to half the length of the leaf. Though adapted for all ordinary garden soils, the plant loves a deep cool border, and prefers partial shade to excessive sunlight. Illustrated Bonquet.

## Calendar of Operations

## (For the ensuing week.)

Now that the new year has fairly commonced, thorough examination of ornamental grounds should be made, with the view of seoing that all is neat and clean. Where evergreens are encroaching too much upon Grass they should be pruned in; wallss should be done that frequently rolled, and everything should be done that will serve to improve the appearance of the garden. If any portion of the kitchen garden or pleasure ground indicates a want of better drainage, this is an excellent time for remedying the evil, as there is greater leisure for improvements at this season than at any other; and as the surface is not so fly occupied, any disturbance of it is not to excavate it, now that it is thoroughly moistened The depth of the drains and the distance apart must depend entirely upon the nature of the soil ; but what ever the latter may be, the draining should be very liberally done, as it is of paramount importance tha the water should percolate through the soil freely an quickly, for the sake of the crops in the kitche garden, and to render the pleasure ground more enjoyn bie

FLOWER GARDEN AND PLANT HOUSES.
Euphorbias, Poinsettias, and plants of that descrip tion which have doye flowering, will now require le ae heat and moisture than they have been receiving in order that they may be ripened gradually off, and have about three months' rest before they are again more of the old planta than will be required for large pecimens, as young plants are easily propagated, and, f well grown, make nicer plants than the old onep, and, by discarding the latter, room is obtained for other things. Attend well to Tulips aud other forced bulbs now in flower, in order that their beauly may be preserved as long as possible.

Aurtculas.-Remove decayed foliage, but in doing this care must be taken not to injure the plants. Water sparingly, and do not excite growth before next month.

Carvatrons and Picotees.-Soil for these should be frequently turned and exposed to the weather Keep the plants dry, and dead foliage removed.
Dablias.-Carefully examine the tubers in order to see that they are not rotting at the crown; if that apporrs to be the case, set them at work at once in gentle heat in order that they may not be entirely lost especially in the case of valuable varieties. Pot roots keep sound longer than those from the open ground, and if not required for cuttiugs, make excellent early strong plants by starting them in gentle heat in the beginning of April.
Holly gardens in autumn, for cuttings, may be started in a little heat. When the shoots are about 3 inches in length cut them off, put them into thumb pots in light struck now will flower in September.

## FOROING GARDEN.

Asparagus.- If the bed made first has done bear Ag, it might be agsin planted with fresh loots, renew ing the heat by means of linings if necessary.
Cuoumbrrs.-These must have careful attention at this dull season. By a proper arrangement of the ventilators a constant circulation of air should be secured, and the portion of fresh air which is admitted from the outside should, if possible, be made to pass over the warm surface of the flues or pipes before it comes in contact with the plants. Upon a proper attention to this point the health of the foliage and the setting of the fruit very much depend. A high nigh temperature and a scalding evaporation are very njurious.
Peaches.-If not already done, outside roots of these should be protected by a straw thatch, which should throw wet off into the drain in front of the border If the buds are just swelling, maintain a temperature of about $50^{\circ}$ by night, and sprinkle the trees several times a day in clear sunny weather.
Pines.-Maintain a healthy root action, without exciting the top too much. A temperature of $60^{\circ}$ with a bottom of about $80^{\circ}$ will therefore be amply sufficient for the present. Let succession plants have all the light possible by uncovering them as early in the morning as the state of the weather will permit.
Vinks.-In the case of Vines started, keep up a moist atmosphere, and avoid sudden depressions o temperature by the injudicious admission of cold currents.
Strawberries.-Select some of the strongest best rooted plants, and after examining the drainage and ascertaining that it is in an efficient state, they should be top-dressed with a mixture of loam, well rotted dung, and fine charcoal, and plunged close to the glass
hardy fruit and kitchen garden.
Scions for grafting, of choice fruit trees, should be secured, and laid in under a north wall. In selecting these make choice only of those varieties which have been proved by experience to be well adapted to the locality. There are many varieties which do admirably in one county, but are worthless in another. In pur chasing new kinds, the above reason makes it advisable not to procure too many plants of any one variety til its applicability to the soil and situation has been tested. By procuring root-pruned plants on Quince stocks this may be easily managed in a couple o seasons. Planting of fruit trees should be proceeded with. It is well to be at some little pains in prepar ing the ground for the reception of Pears and other choice fruits. If the soil be deep and retentive, stratum of ashes, or some similar substance, should be laid within 9 inches of the surface, to check the down ward tendency of the roots. Loam from an old pasture, without manure, forms the best soil for the paalthy and fruitful development of the Pear tree Dig or trench and manure all vacant ground, and proceed as fast as possible with all pruning and ailing.
Peas and Beans. - A crop of some eariy variety of Pea and of Mazagan Bean should be sown as soon as the ground is dry; and if carefully attended to, by mulching when up, and by protecting with Fir boughs on the wind ward side, they will generally produce a better crop than if sown in November, and, unless in very favourable localities, they will be quite as early In sowing vegetable seeds, which are liable to be In sowing vegetable seeds, which are liable to be attacked by the mice, it wrenings in the drills.

Root House.-Take advantage of wet weather to examine and remove any decayed or decaying roots, and alopt efficient measures for keeping out frost

## The Agxicultural Gazette.

SATURDAY, JANUARY 7, 1865.

Another year has been gathered to the Great History of the Past: and nearly a week's sainple already taken of its successor. It is the fashion of journalism, and no unreasonable or useless fashion to assume that, in passing the landmarks of time, men's thoughts are poised for the moment between the future and the past, in the attitude of refleotion and of forecast; and that subjects may be addressed to them with some chance of profitable notice, which in the swift current of every-day life and business would be borne away and swal lowed up with little likelihood of a hearing.
${ }_{1}$ Nor is this assumption a vain one; for there are ferw men, even of the busiest olasses in the busiest marts of commerce, who do not in their inner souls carry, like a hidden iewel, the consciousness of some higher aim than that which shows itself in the daily drudgery of active life. And though it be but dim, and faintly developed, and coming but rarely to the surface, yet it does ussert itself and prevail at times; and those times are commonly such as this-the moment of turning from the old year to the new - the annual Death-and-Birth by which Time counts his, ages, and Man his losses and gains, his apprehensions and aspirations; and indulges-if ever he thinks at all-his Thoughts.
And lucky it is for us that it is so; for Thoughts are the parents of Things, and what we do is born of what we think, or what others think for us; as surely as the hurried labour of the swiftest wheels and noisiest machinery is due to the silent flame and the invisible steam that originate the action of the whole. At the corresponding period to this, a twelvemonth back, we used the opportunity t draw attention generally to the 'Wants of Ag'i culture,' referring amongst cther topics to that
clause in the Charter of the Royal Agricultaral Society whioh enjoins that it should "take measures for the improvement of the education of those who depend "upon the cultivation of the soil for their suppurt."

The appeal was not made in vain. The subject was shortly afterwards brought forward by Mr. Holland at a Council Meeting of that Suciety, and a Committee at once formed to discuss and report upon the steps which the Society should take, in order to remedy this apparent neglect of one of the objects of its original constitution. The immense strides made by Agriculture in material progress, admitted by nearly all observers as a fact cotemporary with the history of the Society itself; indeed its own success in most of its other objects, cuuld hardly fail to bring this topic eventually into prominent notice and discussion. It is in the natural order of things that it should be so.
When a man by a successful course of industry has raised himself in that scale of life that is measured by wealth, a want soon developes itself which increasing fortune far from satisfying only makes more prominent and exacting,-the want of origiual education better suited to his acquired position. He may be the last-thongh this is by no means alivays the case-to see it himself : the worse for him if it be so. Usually, however, the conscious deficiency reveals itself in the anxious care he displays in the education of those who are to come alter him, the child or children who are to inherit what he has won. Hardly can a higher tribute be offered than we often see thus vieariously paid to the advantage in question: but while it affords the best answer to those who ignorantly undervalue $i t$, the personally felt want trom which the action springs, suggests a ground for help that might hace come from without, a timely aid that would have saved much afterregret. "I might have been spared this mortification, which all I have gained by my industry cannot remove, had some kind hand been stretched out in early life in my favour; "such is the kind of reflection that occurs: and what is true of the individual may be similarly true of a whole class: and it is still more likely to be true if the class below them has been meanwhile receiving adventitious aid. The ground has been moving under thom. If this be true of the agricultural class it is chiefly traceable to that besetting disadvantage of farming life which may be comprised in the word 'isolation.'

The children of the poor are collected at the Parish School and there brought into daily contaot with social and educational influences far above what might seem to be their birthright: the children of the rich nurtured under evers possible home advantage from the first, are launched in early years amongst their eq:als amil superiors in our Public Schools and Colleges and thence into the thronged career of the various professions : the children of the trading and commercial classes forming the upper rank of Town population inherit the privileges their parents especially enjoy of constant communication, reciprocating knowledge and that kind of civilization, such as it is, which urban life and intercourse implies.
How is it with the children of the Agriculturist as compared with these? to what extent do they share the educational advantages of either? Even supposing those rural influences absent which render the boy only too willing a sharer in the out door occopations and amusements of the Farm, and his parent a too willing employer of work or superintendance that exacts no wages on Saturday night; what opportunities does the Farm House afford of home education, or do his parents enjoy of hearing of the best school, what inducement to send him soon enough, or keep him there long enough, for the real Work of Education?
Such is the general view of the case commonly taken. We are desirous not to overstate it-and we should be sorry to extenuate the aotual truth for either extreme becomes a fertile source of false or irrelevant arguments and merely wasteful discussion. To urge the question, for instance, as though the classes engaged in Agriculture were less shrewd, or less capable of availing themselves of opportunities than others, would be of very doubtful truth; but Shrewdness is not wisdom, nor even knowledge; on the contrary, it is ofteu evincident with extreme ignorance ; and Capability is even mure deplorable where it is s.en wasting itself through lack of opportunity. The case, fairly viewel, in fact resulves itself into one of specific disadvantage, arising out of the very nature of the calling, enhanced first by the unequal share of education
enjoyed by the middle olasses in this country as compared with those above and below them, an secondly by the consideration of the loss which the conmunity sustains; for the Classes of society are its Limbs, and the damage of one is an injurs to the whole.

But then come the difficulties which the detailed consideration of the question suggests. What is meant by agricultural education? Indeed, before we come to that, what is meant by the words "those who depend upon the cultivation of the soil for their support?" We are told by the highest authority that " the Kivg himself is served by the field;" and it was no uncommon boast, at the period when the Charter of the Sosiety, now nearly a generation old, was worded, that the class included in the above phrase numbered the greater portion of the whale ponulation of the kinchom This would be a heary charge to undertike! Ther are few probably among the 5000 members of that Society, and few even among its very Council who would not on this construction $b$ come the subiects of its educational care and operations

But assuming the phrase to point chiefly to the farming class-what, in fact, is that? A farmer may be the occupier of one or two thousand acres of his own land, or he may be the rack-renter of less than a hundred, or even fifty: but without pretending to inolude extremes, the class, if so it can be called, is one so wide and diversilied, that some sort o conventional understanding is requisite at the outset as to the very meaning of a term it would be so difficult strictly to define. And then, what is meant by agricultural education? - for this is the common term to which the question has been brought. To one person it may present the idea of the general education of the children of the Farmer: to another it may mean the specific training to the business of the Farm of any one intending to follow that pursuit: to a third it may signify the general information and mental culture requisite, irrespective of mere technica acquirement, to an individual destined for that position of Society which the status of the Farmer implies.

The first of these mould simply be a branch of What is called 'Middle-class Eduoation.' The apprenticeship to a trade. To learn a bisiness is one thing, to follow it as an educated man is another: and that this latter is the sense intended may we think be gathered from the fact that few persons in speaking of the want of agrioultural education allow their words to be taken as imply ing that farmers as a olass do not understand that the business itself though rich in soientitic bearings, is necessarily followed under certain social and educational disadvantages, arising from a monotonous daily field of intercourse, ohiefly with inferiors in mind ; and consequently, in that worst sense solitary, where a spurious seli-satisfaction slumbers at the post whish the spur of mental rivalry should be ever watching; a condition suffioiently unfavourable to adult life, but far more disadvantageous to the young who grow up to manhood in it, the subjects in this country of no recognised system of sohool education adapted to their condition, and bearing a just proportion with that already provided for those above, and those below them. They would be no worse farmers it is argued, and would ret more usefully fill their rank in the social scale, not by being made keener proficients in the technical details of their busiaess, but better informed in the topies of general education conmon to other men.

We have stated the question as it is popularly perhaps super:' cially, viewed. It would be too much to say that this is the view commonly taken br the agricultural class itself. People are seldom the best judges in their own case, especially on questions of relative deficiency: and it is of course much easier to prefer the vague claim of some 'educational' advantage that shall be beneficial to a farmer in his own special calling, than to grapple with the whole bearings of a subject so wide as that indicated by the very indetinite phras already quotel from the Suciety's Charter Seveu-and-twenty years have passed away since tho-e words were writen: and those years have seen vast changes in the agricultural world. During that p+riod the business of the Society has been condueted by a Council composed partly of Landowners, partly of 'Farmers,' aided by two or three professional mien, and the presence of one or two of the chief manufacturers of agricultural implements. That a governing body so consti tuted would be a very influential one-powerful
for good in its own
ceded; that it could possibly prove an educationa tribunal in any shape beyond that of its Journal, its weekiy transactions, its Lectures, and its stick, the first produced in its Journal, the two latter at its Annual Country Show, is more than the framers of its Charter ever probably contemplated. These have been its voice and utterance to its members, and to the agricul tural world at large: if by 'education' be meant special class information to farmers on the subjeot of their own ba=iness, we may venture without fear of contradiction to say that a more demonstrative and practical form for supolying it could hardly have existed, if the matter was equal to the mode. As to any thing beyond-as th Elucation in the true full meaning of the word or as to any direction or assistance to the farmin hild to kingdom and and eive up thel informed in the literature of their country, and versed in that kind of knowledge and thos habits of thought whioh free the mind from class prejudice and elevate the man individually and socially, apart from the mere profession or pursuit by which he obtains his livelihood-if this be the alluded to in the Charter, then indeed the case stands widely different.

This indeed would be a boon worth striving for, and one which if obtained or obtainable would be pregnant with results little short of a social revo ution throughout the whole organism of rura life in this country. But the position of the Tenant farmer' in England, where the aggrega tion of land into few hands, extinguishing as it ha done nearly the last vestige of a middle proprietary interest in the soil, likening its oultivators to nomade class tied by mere temporary interest-an annual or at best leasehold oocupaney-to the spo they inhabit, presents features far more anomalous than Educationists will readily deal with in the pages of a pamphlet or the Report of a C Jmmittee. The subjeot is one for a volume, and that too of matter more incisive and searching into the motives of aotion and latent springs of charaster, in classes and individuals, than agriouiturist are muoh given to refleot upon. Indeed, apropos tural literature offers a sort of crucial test o the whole question. If it be so probitless as shut the doors of publishers, and drive off the best writers into more fruitful channels, we have diffisulty of ugly significance at the very threshold, olosing the main avenue by which mind can speak to mind. "Tell me O learned Theban, how to make the Rent! Shers me 0 Sibyl, the one page in either of your proffered volumes tha gives the receipt for that; and you mar put the rest of it, and all the others with it, into the fire Preach how the educationist may, to this complexion it must come at last. Farming is a business, no a profession; and all that Science can furnish, or Colleges can give, will not save a man from misearriage if he have not mastered one seorethow to make a bargain: rather, how to make thousand bargains a year that shall shew a profit against the one great bargain to which he owes the aame of "tenant.
This is the under-thought that flaxes the whole question, making the ground like diaging in a quioksand. The ory is not shew us your soieare, shew us your knowledge, shew us your skill but-shew us your Balance-sheet! This is the true 'Diploma,' that all men are reedy to accept and countersign. Is there any apecitic form of education, it is asked, that can tesch this? Perhaps not: but it is said, Somewhere, that "the Life is more than meat, end th Budy than raiment;" and there may be mothing yet for Education to do, something left grievously undone, which lies beyond even the four corners of a balance-sheet. The matter is on its trial and the conclusion is not yet. $H$.

## NEW PORTABLE ENGINE.

Assumse that your subscribers include a large number of practical farmers and othere interested in the progress of agvicultural machinery, and also that they look to your columus with contidence fur notice of any novelties, with which many of the:a may have no other means' of becoming acquainted, I venture to remind you, that at the late Smithfield Club Show I exhibited au entirely new double expansive portable engine, designed for saving fuel and water, and which was generally acknowledged as the chief novelty, next to Messrs. Howard's engine, in the exhibition. As you were good enough at the beginning of the year
portable engines, I had hoped you would have included the first I have exhibited at Islington.
The very great importance to farmers of saving fuel and water, and at the same time saving wear and toar in stean machinery, induces me to ask you to give insertion to this letter, especially as I believe the arrangement I adopt is the only one by which an engine can be made at about the ordinary price, and yet capable of working to the same power as an ordi aary engine, and moreover, working economically

The engines at present in operatiou on my plan ar giving so much satisfaction from their great uniforonity and steadiness of working, and from their small consumption of fuel (about 3 cwt . par day for 8 -home engine, and 4 cwt for 10 horse), and working also without noise, or, except in cold and damp weather any appearance of discharging steam-it being expanded early or quite to the atmospheric pressure-that
drawn their attention to the subjoct.
During the past dry summer the importanco of saving water was very prominentiy brougat to thi brought many miles in sone esese for havis of the plongting or portable engine, especially the former workiug away from farm buildings.

As the principle upon which my engines are con structed was so ably described, I think in one of your February Numbers, I will only add here that the steam being used twice over ensures great regularity o to enable me to get rather more power from its second than from its first use. The steam from the boile also, acting upon a small area of piston, does not anduly strain the working parts of the engine, although the cylinders are considerably larger than those consequence also of the small: amount of steam required, the boilers are nearly twice as large in proportion to the work they have to do, as those of ordinary portable engines; and consequently produce steam at a much cheaper rate, and suoject the boiler to much less wear and tear, firing very easily and never requiring to be forced.
The alteration of ordinary engines by attaching to them new double expansion cylinders, I fully beliere can be practically carried out with great advantage to the farmer, either by giving him the same power, at great reduction of fuel and water, or a far greate or lastly, and which would probably better suit mos of those having portable engines, some additional power, and some (cot inconsiderable) saving of fuel.
So soon as farmers leirn that good serviceable engines aro made, capahie of doling a day's threshing or ploughing at less than half the cost for fuel and wate which they now incur, and inquire for such engines so soon, but probably not before, will the proprietor of threshing machines and engines and ploughing tackle, look about them for economical engines. Th farmer having to find the coal tends to make the owners of engines indifferent to economy, although when they understand that economy of fuel and water goes hand in hand with econouny of wear and tear, they will themselvas ree its importance. Edroar E. Allen, 5, Parliament Strest, Westminster, S.IW December 21 st.

WHEAT AS FOOD FOR SHEEP
Aclow me to make a few further recuarks upon the se of Wheat and cut Barley straw for feeding stock, particularly sheep, and at the sams time to answer one or two inquiries which have been privately addresesed o me on this subject
First, let mee say that 1 have not lost a sheep, old of young, since June last, although since I last addreased you I have added. 100 shearlings to my stock of 530 head; and I have also a first-rate prospeot of a large fall of lumbs. I last week killed a good average lamb in connection with an exporiment, to which I slayl further refer. The carcase weighed 72 lb , the skin 15 lb ; three-fourths of the lambs nearly reach this average, and most of the remainder are very young lamas. 30 it further remarked that the 50 best were reserved as ram lambs.
The allowance for the fatting sheep has just been increased to $1 \frac{1}{\frac{1}{2}} \mathrm{lb}$. of Wheat and Barley (mixed), wit $\frac{1}{3} \mathrm{~b}$. of Cotton-cake. An acre of very moderate Rap or Coleseed now lasts 188 sheep for eight days; and expect they will be quite ripe for the butcher as 800 as they can be shorn, if not sooner.
(2). My stock bsing now usel to the Wheat, fam indifferent about having it hoiled; and with the aid o an American grist mill, made by K ches \& wivel
find that griuding it is cheaper. The mill has give new impule to our agricultural energies; my
tive steam engines bein now much in reque occasionally make a half-day of overtine by griuding
from 6 p.s. till midnight, working at the rate of eight from 6 P.s. till
sacks per hour.
Thus a stack of 80 to 90 sacks is threshed on one day, the straw is cut into chaff next morning, and the corn is ground in the two evenings. But for this my pig account.
charge of $6 d$. per sack for grinding would give me
a trade profit on the use of the machinery, as the a trade profing account will show :-

Uso of mill and steam engine
( 48 sacks at 6 d., give 24s.)
Since the mill cost less than 302., 200 days ${ }^{\circ}$ work at 38, would clear its entire cost ; and the wearing parts, as I am told, may be replaced for $3 l$.
Next, let me say a word as to an experiment which I have just started to test cake and Wheat for feeding sheep.
I have selected four pens of sheep,' two from my wether hoggets, and two from my newly-bought shearling wethers--apparently out of Southdown ewes
by Westdown rams. There are five sheep in a pen. They all have per head, daily, 1 lb . of Clover chaff, and as much sliced Drumbead Cabbage as they will eat ; whilst one lot of hoggets and one of shearlings have 1 lb . of Linseed-cake apiece, and the other two lots have $1 \frac{1}{4} \mathrm{lbs}$. of corn with a $\frac{1}{4} \mathrm{lb}$. of Cotton-cake (undell as may be, to the standard suggested by Mr. Lawes in his recent valuable lecture on "The Chemistry of, the Feeding of Animals, \&c.," delivered before the Royal Society of Dublin. I am only at the end of the introductory fortnight of the trial, in which, as might be expected, all the lots have slightly lost weight on their removal from the field into a state of coninement. One feature in the case, however, has much surprised me, viz, that both the shearlings and about twice as much Cabbage as those fed on corn and Cotton-cake. I had reckoned that each lot of five sheep would eat about 5 stone of Cabbage per day, whereas, in fact, each of the two lots fed on Linseedcale eats 6 stone, the others only 3 stone. Thus far,
I have very little evidence that the lots fed on Linseed I have very little evidence that the lots fed on Linseed
are doing any faster than the others. The two pens of hoggets are still just equal in weight, as they were when first put up; but the five shearlings on Linseed have gained some pounds on their competitors, without giving any other sign of superiority.
I wish that, for the sake of comparison, I had two pens eating nothing but Cabbage in addition to the 1 lb . of cut Clover hay; but to make a fair trial, one
lot should be promoted to corn rather than another put back, as mine have bean, to the less concentrated diet.
I hope some other farmer may be induced to investigate this point in a proper manner-that is to sary animal; for, unless these be consulted, the rigid results which Science may obtain, with her scales and spectacles, will have but little value. As the experiment proceeds, I intend to have the manure of the
corn and Linseed-fed sheep respectively removed with care, and dug in at once in adjacent plots of equal size in a field close at hand. In these plots I propose to sow the greediest "vampire" of a plant lation, rather than on chemical analysis, to test the value of the manure.

With respect to agricultural experiments in general, allow me to add one or two observations which appear to me to be seasonable. The new year which is opening upon us is the first since the Royal Agricultural Society completed its first quarter of a century, and concluded the first series of its Journal. I hope that | our efforts to turn to the best account the lessons sug- |
| :--- |
| gested by the remarkable season of | this an epoch in our agricultural history. For the pro motion of this object it is almost indispensable that careful experiments should be made. Our Charter distinctly contemplates the encouragement of such exthese should bs suggested and modelled by men of science, and then carried out by men of practical ability and experience. The Highiand Society has just calied attention to this subject, by a paper iu its

"Transactions" from the able pen of Professor Anderson. We may, then, hope in time to procure from several quarters and under varying circumstances several series of experiments, as well designed and as perseveringly followed up as those of Mr. Lawes at to our want of Professor Anderson refers particularly intercourse with Professor Voelcker, as well as my requirements as a light-land farmer, have turned my choughts into the same direction. Well-farmed chalky loams exhibit a steady increase in their power of producing grain and straw ; but their crops of Clover much urnips (which require from six to eight times as still. It would may be' limited by the therefore, that their progress potash to macet some of our modern experiments. righe on light soils all the straw, hay, and Turnips are in the main a dirn the land, their stock of potash is vided once for all if protected by proper may be pro-

This consideration enhances the importance o securing a supply of potazh if required. Meanwhile, Barley or OAt straw, with a sood supply of cut chaff although in their exaggerated valuations of manures up along with it, will maintain the quantity of hay cut chemists have put a fancy price on potash, we farmers never intentionally purchase it. The fact is, we will not pay the cost of the refined salts of commerce ; and, for want of experience, we are not prepared to say what price कe would give for a rougher sample suited to our coarser uses, if modern enterprise brought such
within our reach. This defect slould certainly be within ou
remedied.

To return from this apparent digression to my subject
feeding stock on corn and cut straw. If I be my straw be eaten by sheep on the land or trodden into manure, I answer that for the butrition of plants little diminished in passing through the animal. By feeding sheep on Barley straw, on land intended for a Barley crop, the deposits are left very handy for the
young roots of the Barley, and a brisker circulation of my potash currency is secured, which is equivalent to an increase of capital.
The reader should bear in mind that the straw of Barley crop contains about three times as much potash as the grain, and 50 per cent. more than a crop of
Wheat straw. Straw has other merits, which should not be lost sight of; its gradual decomposition in farm- jard manure generates a series of acids, which
combine with and fix the ammonia as it is formed, so as almost to supersede the use of artificial so-called deodorisers.
But this is beside my present purpose; let me, therefore, conclude by proposing this "sentiment for the new year" to my brother farmers: "Success to Frere, Dungate, Cambriilge, Dec. 30 .

## Home Correspondence

The Water Supply.-Again I beg to call attention to that very important matter, the water supply of the country. We have aiready arrived at the middle of winter and are commencing a new year, and I venture to state that never in the memory of man were the subterranean springs so low, nor the outflowings of under-drains so scanty at this season of replenishment, as at the present moment. All observers of the laws of Nature which govern our perennial sources will admit that with the present low condition of the springs and subterranean supply occurring after two unnsually dry years, the supply of water from wells and streams during
the next summer muat be less than ever. I have the next summer muast be less than ever. I have
presumed to call the attention of the Home Secretary to the advantage of an inquiry into the general question of our water supply. and 1 now earnestly repeat the appeal, on the grounds- 1 st, That let the cause of the demands for the supply of water increasing in towns, villages, and farms, to provide if possible against such deficiency. 2d, That the indiscriminate uniform mode of draining various soils now prevalent leads to a derangement of our river systems. 3d, That the water we eject in winter and spring by drainage may be
applied or stored for use in summer and autumn ; and 4th, that while we are suffering from a ecarcity of water in a way which may frequently occur again as drainage increases, the rivers and watercourses are being polluted by the discharge into them of sewage from towns, to the injury of those who depend upon such streams for their supply. I submit that the question of water supply is one of equal importance with that of the utilisation of town sewage, and is closely allied to it, and that therefore any Commission or Committee dealing with the one should also deal with the other. J. Bailey Denton, 52, Parliament Street, Westninster.

The Breeding Flock.-At this season the breeding ewes demand the farmer's particular attention; this year, circumstances render them more than usuaily dependent on his liberality, from the sedrcity of roots throughout the greater portion of England, as also the absence of any quantity of fog or old Grass on the pastures, a few frosty thus reducing the keep to the cut chaff and artificial food suppiied in the troughs. Some farmers do not approve of giving their inlamb ewes much corn or other fatting or stimulating food until a short time before the period of gestation expires, as they say the ewe is liable to become too fat, if kept well for a length of time previous to lambing, which is consequently attended with greater danger to the ewe, rendering her, more liable to inflammatory disease or parturient fever. Our experi-
ence leads us to a different conclusion. Ewes in ence frads the middle of February to the middle of March should now be well kept; they will then be strong and healthy, and be much
better able to withstand the fatigue and pain of yeaning. By a niggardly system of pinching during pregnancy, the ewe greatly suffers both in health and condition, becomes emaciated, the wool gets dead, great quantities of it peel off, and are lost. When a breeding animal of any kind has gone half its time with young,
it is difficult then to greatly improve the condition of the parent; the greater portion of the nutriment of the food then goes to increase the fatus in the womb, in which case we have a large offspring and a weaker mother, consequently increasing the danger and difficulty of a safe delivery. One lb, per head per day of
healthy wor $t$, will maintain the ewes in a state of with their freedcm of puren have plenty of exercise of the results.

## Eocicticg.

Romsey: Jan. 4: Labowrers' Encouragement Asso ciation.-Lord Palmerston presided this afternoon at the 11th annual distribution of prizes given by the Labourers' Encouragement Association to the labourer in the district for proficiency in agriculture, length of service, \&c.:-

## Lord Palmerston said,-My friends and neighbours, -I have had great pleasure in distributing among you those rewards had great pleasure in distributing among you those rewards which your gencral good conduct and your skill and aptiturde in the several departments of agriculture to which you have devoted yourslves in the several departments of agriculture to which you have devoted yourselves have, in the opinion of the committee justly entitled you; and I trust that those rewards although they may not be of and I trust that those rewards, although be bighly appreciated by you as an ackno be highly appreciated by you as an acknowleigment of your good conduct-that they will arve as an incitement to jou to continue in that course by which poin heve attained them, snd will be an zacitement to the emulation of othera to follow the same course, with the hope of obtaining the like diatinc tion. I say distinction, for it is no litule matker for a man, Whatever may be his station in life, to be esteomed and respected by those among whom be mixes. It is a atit- faction to him, and it is an honour to faction to him, and it is an honour to the district to whick he belongs, and it is also, let me tell you an adme tage to the country and to the nation of Which he is a memaber; for the character of a nation, both in its own esteem and in the conalderation win nations, is built up by the aggregate good conduct of all the class, employed as it is in the production of those means by Which a nation subsigts, is the most important element in the has an important intuence upon the general cbaracter of the nation and upon the esteem which that nation receives in other countries, unon its power, upon the respect which it other countries, upon its power, upon the respect which is paid to lts independence; and therefore I would have all of you and all others belonging to your class to remember that in

 pursuing that good conduct which entitles them to thee tokens of approval- can scarcely call them rewards-and inpursuing that conduct which secures for them the esteem and
respect of their immediate neighbourhood, they are conforring respect of their immediate neighbourhood, they are conferring its wealth, its prosperity, and its respectability. But it would be taking a narrow and a limited view of what I must be
allowed to say are your duties-for it is your duty to con
tribute by your cood conduct to the welfare, and resper tribute by your good conduct to the welfare, and respectability view of these duties if you were to condine them to your own personal conduct, though that personal conduct is the ouly element by which the committee bave arrived at the conclusio
of granting you the prizes and awards which you have received of granting you the prizes and awards which you have received
But it is your duty not only to secure for the present genera-
tion by your conduct that respect of which are the foundation, but you havect children who are to succeod
you, and it is your duty to provide for the future ss rrell ast
ok to the present, you, and it is your duty to provide for the future as well as to
look to the present, and you are, therefore, bound to take care
that those children who flock around yoll shall be
 the first place to give your children the best education you can
obtain for them. In this town there are, I may say without
exaggeration, as mauy sources of instruction exaggeration, as mauy sources of instruction as in any osiner at an early age, to engage in industrial pursuits. The period tion must, therefore, necessarily be short, and the shorter it is the more care you ought to take that that period is wel
employedren ; they do not often thoughtless; the canno have in after life of a culti
experien experience; they do not know the value in after life of a cultihood of amusement and id'eness. It is jour business to
induce them to forego those childish amusements, and to
derote the short years applicable to instruction to the attain devote the short years applicable to instruction to the attain-
ment of that knowledge which may bo useful to them in after
life. You must not expect them to be scientific ; Fnt murst
not expect them to acquire those attainments which are open not expect them to acquire those attainements which are open laborious nccupations; but there arre three things which they
can acquire, which they ought to aequire, and which are mot can acquire, which they ought to aequire, and which are
important to them in their future ocupations-I mean re
iug, writing. and arithmetic. The power of reading with iug, writing. and arithmetic. The power of rending with ease
gives a man the neans, in thoso leisure hours which even the
most laborious and most constantly employed occasionally
have, of obtaining instruction from those parious means which have, of obtaining instruction from those various means which
the diffusion of printing and the greater improvements of the age now place within the reach of almost every man who is
able to read and take advan:ago of them. Writing is almost
as important as speaking, because evry man, whatever bis able to read and take advan:ago of them. Writing is almost
as important as speaking, beceanse evryy man, whatever bis
station in life may be, must have constant occasion to convey
bis thoughts, his wishes, his coroplaints, his desires 13 writing, his thoughts, his wishes, his complaints, his desires 13 writing,
and unless that writing be legible and easily read, with the
letters well formed, so that a person can read that writing
without trouble and delay, it fails by disgusting the person to without trouble and delay, it fails by disgusting the person to
whom it is addressed. I must say that in the present day
I do not think that instruction in writing is given in that

## Farm Memoranda.

Ter Home Fabm of H. S. Thompson, Esq, M.P., Ktrby Halle, Yorkshire.-On the Kirby Hall farm, as on others in this district under good and liberal \& five-course one, viz, Clorer, Oate, Barliey, Tarnipe, Wheat.

The farm is remarkably clean and free from Conch and weeds of all kinde, and we may safely say that in our journeys throngg the county we lave met with few
farms that in this respect equal it, and certainly none that surpases it.
*The corn crops are drilled and horse-hoed with a Garrett's hoe, and in some fieldis through which we went we could find no Couch and few weeds of any thoronghly clean.
To show how systematically this cleaning is gone about, and how thoroughly and inexpensively the weeds are kept under, we may mention that the stabbles are
gone over in autumn, and all the Couch and other gone over in autumn, and all the Couch and other
weeds "forked out," and so effectually is this done that rarely indeed is there any hand picking required in the spring.
We walked over a field of Swedes and Mangels which had been cleaned in this way, and in the whole field were unable to detect a single blade of Couch.
=The forking costs from 5s. to 10 s ., and in extreme cases 15s. per acre, and if we contrast this with the common management usual on the neighbouring
farms, it will be seen how greatly even on the score farms, it will be seen how greaty even onemy the practice is to be recommended. We auppose it is by $u 0$ means uncommon on those light sandstone soils for a farmer who aspires even to moderately clean farming, to spend from 15 s. to 30 s. cleaning bis laud for a root crop, but falling a little short of effecting a thorough cleaning, by the time the land is again in course for a fallow crop, the Couch is as
abundant as ever, and the same expensive process has to be repeated.
By forking we may assume the average coas of cleaning as 100 , per acre, by the other mode 20so per

And besides the heavier labour bill which the Couchgrowing farmer has to pay, he is also sabjected to much loss from short crops, especially in that of the last grain crop in the rotation when the Couch has
attained its climax, and being a Triticum, a member of attained its climax, and being a Triticum, a member of
the same :family as the Wheat, robs the soil of much

## nutriment, which bat for its pre

The farm-yard manure for root crops is usually pead on the land in nutumn direst from the covered ypread or boxes, and ploughed deeply in. On the light soils a reploughing is given in spring-artificials sown
broadcast, harrowed in, and the seed drilled on the flat: the common form of corn drill being fitted with proper gearing for this purposs, and with its extra width a great many acres are sown in a day.
On the clay soils most excellent crops of roots are frequently grown by being sown on the stale furrow after one ploughing given in autumn, and manure
The sheep kept are the Leicester breed, and for the last two years a cross with the Shropehire Down has
been tried on a limited scale, but with satisfactory results.
A breeding flock is kept, and the produce fattened out as hogs from 12 to 14 months old.
The Cattle are of the Shorthorn variety, and the early age at which some of those bred on the farm are sold off fat is ontures of it. The practice has been to buy incalving Shorthorn heifers, which calve about the end of March, and during April and May. During summer the calves run with and suck their dams, and
when weaned in Autumn are taken into a covered shed, where on roots, \&cc., they are carried on and come out prime fat at 1 year old, averaging from 36 to 40 imperial stones; and the bailiff assured the writer that under 12 montlis old, at the average price of $16 l$. a head. These are facts, and worthy the consideration of all interested in the breeding and fattening of cattle. The heifers usually get very fresh on the Grass, and after the calves are weaned are topped out on roots in the stall.
The Grass management is so fully described by Mr. Thompson in the Journal of the Royal Agricultural Society, that any details here would be superfluous. Suffice to say, we saw the old man busily engaged in the pasture collecting the droppings of the cattle, which, along with other vegetable refuse, is mado into a
compost, and in autumn respread, thus ensuring a compost, and in autumn respread, thus ensuring a utmost the whole estent of the field, as where the cattle droppings are no Grass caa grow for one season at least, and cousequently a certain per centage of the land is waste, and even in the follo ving season the Grass there comes so rank and strong as to be greatly disrelished by the cattle.
Some land sown to Grass a few years ago, and managed as described in the aforesaid easay, we went very good and in great variety, and showing unmis. takeable signs of the sounduess and success of the mode of treatment adopted.
But what appeared to as as the keystone of much of the success and economy evident in the management of this farm was the simple rnd inexpeennot no int most excellent covered yards. We need not go into con-

structive details, but would recominend all contemplating such an erection to pay a visit of inspection here before settling their plans. The great essentials of a covered yard, viz. shelter, warmath, thorough ventilation withont draughts, are obtained most fally, and judging from appearances we should say at a minimum | cost |
| :---: |
| In |

In practice the advantages arising from the use of this yard are found to be first, a saving of straw, and
that so appreciable that, the bailiff stated he had been able to keep several head of cattle more on the same quantity of straw than when the yard was uncovered. Secondiy, labour is economised, the manure being in a condition for application to the land direct from the yard, so that the extra filling, turning, \&cc., deemed necessary in ordinary management, is saved.

Thirdly, the manure is richer and better in quality, so much so that in its first application, being unaware of its strength, the usual dose was applied for roots,
and Burley following, the crop was spoiled by over luxariance. Since then little more than half the usual quantity has been used, and found to bo amply sufficient.

Besides the large cattle yard there is another on the same principle of construction, fitted up and used wholly as a piggery, in which are kent in considerable number the Berkshire breed of pigg. This also is well contrived for the purpose, and the pig manure, unwashed and undilated, is of the richest description.
The cart-horses have each a separate box in which the manare accamulates until on a level with the floor of the stable, and is then taken direct to the land; and contrary to what might be expected, the effluvium so common in ordinary farm stables is not in the least
perceptible in these boxes, the horses are much more comfortable than in stalls, and the manuse made is first-rato.
In short, we found here a meat manufactory and a maure manufactory in great perfection, and as a conproduction of arable, bat considerable quantities are also spared for the improvement of the Grass land.
Did space permit we could detail many more in teresting matters in connection with the management of this farm, but for the present we must be content
ambitious of excelling as a model farmer bumateup who makes it the practical business of his life, assuring them severally that a day spent in its inspection and in the inquiry into the various processes and practices which from time to time have been tried and received reliable answers, will be a day fraught with much inte. est, and, rightly used, not wholly unconnected with profit. From an Essay on Torkshire Farming, by W. . Moscrop, Kirkleatham.

## 

Agriculture, Ancient and Modern: an Historiaal Account of its Principles and Practioe, exemplified
in their Progress and Development. By "The 0 Id in their Progress and Farmer." Part 8. J. S. Virtue, Ivy Lana, We have referred to this book as the successive its references to the principles or the Art, have been the subject of praise in alnost every notice that it has received in these columns. One hardly understanda the plan of the worls, and it may, therefore, be premature instructions which it contains; for those defects which are apparent in any section may be supplemented farther on. There is, however, in the character of the engravings which have accompanied the succes. sive issues of the work, and in the general style of the author's references to details, sufficient indication that his volumes will not prove so good a guide to farm practice as they will to that general acquaintance with the history and principles of the Art in which agricul. turists are by the way generally much more deticient.
Even these however may be offended by the extrava. gances into which an unpractical writer is apt to fall; and it is well, therefore, in the interests of the work itself, as well as those of its readers, to point ont any such extravagances numbers be corrected.

In our last notice we called attention to the terms of anqualified belief in which the anthor spoke of the transmutation of grain, and in particular of the
certainty that Mr. Edkin's Barley lrad been raisod from Oats : and this we spoke of as a foolish story The author, however, asserts that, foolish or not, it is true.

With respect to the transmutation of seens," be says, "s and the case of Mr. Edkin's Barley raised from
Oats, I received the account from Mr. E. himself, and it is now in the hands of Mr. Wilson, of Ediuburgh (the brother of the late 'Christopher North') so that cannot send it to you; but it was confirmed by Mr. Fryer, of Chatteris, who sent me a sample of the different from any other type of the grain, and is in great estimatio with the maltsters. The transmutation of Oats into Rye is no new thing, and cases of it atio continually occurring. There was a remarkable case
Norfolk last year on the farm of T. Moore, Esq., Wareham, one of the Eirl of Leicesters tenants ; an account of it was sent to (and inserted in) the Mark Lane Express by Mr. John Hudson, of Castleacre, on his own authority, and he is a man too well known in an affair of the kind.
Now, in disbelieving stories of this kind, no one cate any doubt upon the "truthfulness" of any man; bat elements besides his honour. He must be a carefu and accurate observer, as well as an honest man, before his testimony can be pronounced unquestioriaule; a th we do not hesitate to say that the difficulties Mn , Way of believing the transmutatiou of Mr. Mr . Moore's Rye from the Oat plant, are infinitely greater than those in the way of acoepting these accounts as true.
The same tendency in the author to extravagant arge ment and assertion, misled in both cases by a tendency depart from common-sense views-perhaps dazzed dy the recent grand achievements of English agricultura so that nothing appears now to be impossible incredible-is seen in the elaborate chapter stam cultivatorn.

Of the four classes of apparatus for steam cultivatio -namely, those which travel over the land, polive on railways, drawing cultivators after them; those with on railways, drawing. calcivators ald engine moving alow he hary engine, an those with engle diemissed. the second, including Halkett's and Grafton's gnidem apparatus, occupies nearly three-ifths of the wecess of otory. Now it is plain that at present the succostber team cultivation has been, and bids fair to be, are enum dependent on that of the 3 d and 4th plans here esrvin ated. Tha 2 d is as yet a mare speculation, deser it a record indeed, and perhaps encomium; plan, which has been so largely successful, with a sind page, and devote 9 or 10 to the discasmion of a speculation.
In the chapter en the plough there is a good deal in disproof of certain passages quoted from the writiog of Mr. 1 Morton on the subject. But, unfortunater Mr. Morton has been an agricultural writer for nea
a quarter of a century. And though we are not prepar
to admit that the passages here quoted from him are
not defensible against the attack of the Old Norfolis not defensible against the attack or the onppose that Farmer, former has learned nothing during all that time. In fact there are fer of our writers on cultivation who
have of late years more confidently urged that its true olject is simply to prepare a certain quantity of internal superficies within that quantity which is available for that purpose, and not any particular conformation of the surface presented to the sky, is the real measure of efficient cultivation. culture," which is here quoted; but indeed th "Cyclopædia of Agriculture" was written 10 to 15 ygricultural progress, both in intelligence and achievement, which enis pertimer ought immediately to set about the preparation of another edition of it.
Of the present number of the work before us we have to declare that with the same pleasant style and eapecially in connection with the history and princinles details which the continues deficient in the pretica is a lack as yet of information about definite particulars, quantities, and prices; and if not supplied otherwise before, we recommend the author to collect and publish in an Appendix whatever information of this kind the its contents, to require.

## Miscellaneous.

Short-horned Cattle in New Zealand.-We learn from the Wellington Independent of Oct. 13, which bas just reached us, that the beautiful Short-horned Worton, and embarked for New Z alaind on board the good ship Asterope, have arrived sately at their destina of stock will experience a rich treat by paying a visit to the Asterope, now lying in this harbour, where we (a bull and a cow) yet imported, of the finest animal ascertain, this opinion is endorsed by all competent judges. The bull 'Knight Templa quality; it will be seen by his pedigree, that he fashionable both at home and abroad, and frou the high prices realisel? by this blood generally, we have every reason to belicve that his stook will be duly
appreciated in the colony. The cow 'Syria' is a deep appreciated in the colony. The cow 'Syria' is a deep formo. The condition of these animals reflects the greatest credit on Captain Stuart, to whose considera
tion the owners are greatly indolutert for the care and attention bestowed on them during the voyage. These catte are imported by some of our oidest settlers, Messrs. orming at Pound are the commencement The benefits derivel from the use of pure bloxil are to well known to require any comment. The animals in question were selected by James Glass, Esq., of Worton,
near Devizes, Wiltshire, for many years a Short-horn breeder, and their appearance certainly reflects great credit on his judgunent. They are from the herd of bull. 'Knight Templar' gained two prizes as a year ling, and it was only on the condition that he left England that Mr. Rich consented to part with him, herd. Both animals have been selected regardless of expense, and we cordially wish the spirited importers uccess, and trust their enterprise will prove remuneracalf to the 7 th Duld add that 'Syria' is believed to be in Rich for 500 grineas, after being hired and used for three years in Mr. Rich's herd; his dam, Dachess 69th, Was purchased by Captain Gunter for 500 guineas when nine montlos old." We understand that John Eurgess, 8) of Henry Burgess, of Allington, near Devizes, took charge of the animals on their voyage, and great credit upon them. Burgess was engaged here on behalf of Messrs. Nairn at 50 guineas per annum, with rations and lodgings; and to any enterprising and industrious young men New Zealand at the present time presents a fine opening, as there is no lack there of employment at high wages. Devizes Gazette. [Mr. Stiles Rich has, during the past 4 months, had 11 cow calves and 2 bull calves, chielly roans-all to 7 th DUKE of York (17,751).]
Nature an Economist. - What an economist is
Nature, 80 made by Nature, so made by God! She economises even the moon as a candle, after the sun has gone down, as we say, when he is but rising on other lands, and sends it meat, eivably far to us from the stars. She economises hearl, equalising it for the life and health of the whole World, by currents in the air and ocean and of the electric thuid. She economises water, to answer a different successive important purposes, in a thousand carefully she sifts out its minutes. How nicely and briny sea, to cleanse the air and revire the plants in
due season, to fill the springs, and paint the sky an
support all haman life! How, with her mighty eleinental argencies, slie crumbles and bears down the barreu rock from the mountains and the hills, to fertilise, for bouudless and endless crops, the valley and the plain! How she makes the ashes even of the dead
spring into Grass, and blossom into flowers ! How, applying the same economy to crude minerals, from the very gravel in the ground she distil the growing grain, though yon may not think what perhaps cuts your hand to bleeding is this varnish of flint. How she saves every hair, particle, nailpairing, and exhalation, to turn it to some account! How she man's ground, into harvests of corn and Wheat! How she nourishes her vegetable offspring, so that he animal may not die of hunger! 'the roots of a shrub artificial channel, have been known, in her regolution not to be defrauded, to find their way to the aqueduct under ground, and bore a hole through its soft wooden plug, that every fibre might drink its fill, as was view on Nature, it seems as if ererything with her were
extravagan't excess, We quote the line about "many a flower born to blush unseen," and we talk of closer inspection corrects thay to no purpose. But frugal her utility and perfect her order, enourh, but "no room to insert a particle," however Art may re-arrange her forms to educate and give scope to

human power,-Rev. C. A. Bartol.

## Calendar of Operations.

Jantary. -The ordinary work of the farm in this onth includes Trllago operations, Carriage of mamur ive stock in stable, byre, feeding house Management of and fuld, and Attention to Irrigation. The exceptiona work of the season is Land Drainage, Road-making Marling and Olaying, de. Reference to some or al of these will be made during the successive weeks.

1. Land Drainage.-The means are provided by various companien who accept a rent-charge of $5 l$. to $7 l .10$ s. for every 100 l . advanced, for terms of 20 to 50 years, according to the state of the Money Market. - (a) See that you have ample outfall with a clear run from it to the stream, and a depth to it of at least 4 feet from the lowest surfice of the land.-(b) Take your mains from the outfall along the lowest lin: of aight down the hill to it, 4 feet deep, and 7 to 10 or 15 jards apart, according to the texture of the subsoil.-(c) Let spring mains; and depend upon the general drainage of the lamd sololy for deating with the rainfall. -(d) Use pipe he smallest you should employ. Avoid the use of open ditches, if possible. Sheep drains, however, for taking off swamp water, are serviceable in mountain pastures. The use of faggots and straw rope, or of wedge drains, practised in soine clay districts, is not to e recommended. Plug and mole draining are cheap expedients available in pasture lands, and lasting some years, bat not to be generally recommended Deepening the drains in order to increase the inberval between them is not good practice. Adopt that depth which is best in order to the laying useful a sufficient depth of soil above them, and that interval which the use of test holes will tell you that the depth in question will command. - (e) Drains becomes clogred sometimes where there are undulations in the fall by the deposit of particles of the peroxide of iron. The remedy in very ferruginous soils is to open the land up with ditches before its under-drainage is commenced, so that the mischievous soluble iron-salt may be either washed out or oxidised will also soi. The application of lime to the land so tend to facilitate the oridation which is desired. In any case, defect in the uniformity of fall within the drain will give occasion to stoppige arising from solid particles carried by the stream; and hence the smallest pipe consistent with the largest probable flow of water is best to use, because in these when the flow is little it will be confined in a narrower rill, and so be better able to transport whatever particles it holds in suspension. As to stoppages by roots of plants, there is no remedy which does not involve the uselessness of the drain itself at the place where that remedy is applied. If the junction of the pipes be so perfect as to exclude the fine fibre of a root, it will also exclude water, and so be useless as a drain for that particular spot. It will however, be best to make it thus useless, except as a main carrier for water whenever it crosses hedgerows or passes near to hedgerow trees. And this is effected by using long and tight collars for the pipes; or even, if necessary, by throwing morter in above the tile when pliced ready for the re-filling of the earth above them. For stoppage by the roots of Mangel Wurzels and ther green crons, which have sometimes been observed there is no help; except it be in placing the drain at least 4 feet leep, and in such thorough and deep tillag of the land as shall distribute the shower evenly throughout it, and so hinder the formation of any
special stream of water within the soil, which would
guide the roots of plants into the drains, where they channel. Deep stirring tends not only to the uniform channal. Deep stirring tends not only to the uniform
distribution of rain-water and of roots throughout the subsoil, but also to the efficiency of land-drainage whatever system be adopted. And the deep-stirriug of the land by some other means, should always follow drainage. Shallow caltivation tende to the formation of a crust or 'pan' beneath the surfece. The hardened floor on which the horses have trod while ploughing for a centary or more, has become nearly impervious to water, and must be broken up before the drains can ct efficiently.
Let mee urge the need of thoroagh work. It is an true in agricnlture as in every other thing, that nothing is stronger than its weakest part; and a patch in a field left undrained, though all the rest be dry, will often stop the whole tillage of the field, and even hinder the application to it of means which, had it not been for this partial failure in one spot, would have influenced for good the whole produce of the farm. (f) Among the resalts of land drainage may be enumerated greater facifity and sconomy of cultivation, which, if not changed to the feeling of andmals is wonderfully changed as to its influence on plants. They are thas started earlier in spring, and kept more continuously growing, being less dependent on changes in the temperature of the air. And they are thas brought earlier to maturitr. Harvest has been made a fortnight earlier on individual farms by the mere influence of land drainage, Manures which were formerly washed to waste exert their full influence on plant grow th in well-drained land. And tillage, which on wet lands is often mischievous, exerts after thorough drainage, and on land in proper state for it, the wonderful influence for fertility which it possesses.
2. Threshing and Cutting Chaff.-The threshing of grain by machine may be put at $2 \frac{1}{2} d$. to $3 d$. per bushel for Wheat; and less in the case of those crops which yield more grain to a given bulk of straw. The superiority of steam-power threshing over hand labour con asista chiefly in the greater quickness of the process; and the ability thus at once to supply the market without materially interfering with the ordinary labour of the farm, and without exposing the labourers to a constant temptation to dishonesty. It is now the custom in ome districts to store away several months' supply of cut chaff at a time, and however stale it thus might be aupposed to be, the cattle relish it when mixed with pulped roots or scalded with some hot water in which a little salt has been put. The following is the account given by Mr. Samuel Jonas, of Ickleton, Cambridgeshire, of his experience. He says," writing in July :-

 When delivered from the threshing machino, is carried up an
itclined plane by spiked rollers to a height of about 9 feet; it
then comes down an in inclined rack, nearly yelcoed and ready then comes down an incliced rack, nearly yelced and ready
for cutting into chanf. I can work off the produce of abut
8 acres of good strong Wheat ner day, thus cutting about soj fans
wo meee men yelm the straw and feed the chaff cntter, and three boys should tread it down close, so as to culuse it; to hoat The only extra expense is for from 4 to 5 cwt . of co afterwards, the straw is stacked as
man-cattor woeld be as follows:-
men to yolm stran
men to carry away ohaff
Hire of angine and ohaff-ontter (this inaludes
Coals, 5 cwt.
$\begin{array}{rrr}110 & 0 \\ 0 & 4 & 6 \\ 0 & 2 & 0\end{array}$
"This will out from 600 tana to 900 fans per day 82.12 to 11 tons), according to the lengthe of cut: the first out being about
$3-16 \mathrm{ths}$ of an inch in length, the lattor about $3-8 t h$ The cout
would be, the very short cut $1 d$.per fan ; the latter cost $1-3 d$ of a panny par fan; but, by cutting the ohaff at the same tiene
you thresh, you save 478 . per day, or, in fact, cut 800 fans
3. The Dung Heap. - There in a considerable store of dung accumulated by January, and during the frosts of winter a good deal is generally carried to the fields.
"When cattle are fed in open yards, the dung may be either carried out now, or left till spring, and then turned over and made fit for application to the land at once. This, however, is a most wastefnl practice; for the manure thus suffers the greatest possible exposure both to air and rain-water. When cattle are fed in covered yards, such a method is economical and efficient enough, as the dung so made is not then exposed to the washing
of rain-water. When stall feeding is adopted, the soiled litter is thrown daily into the rard, either covered or open; or it is carried deily to the heap, and there covered with earth. Wheu box feeding is adopted, the litter accumulates under the cattle, and adopted, the litter accumulates under the cleaped out only at intervals of month It is then cut out and carted to the field, and either spread at once and ploaghed in, or, if this camnot be done, carted to heaps in the flelds where it is to bo used. When carted together in January, the cart should be driven over the heap, which should be about 4 feet high. This treading down excludes air, and so checks the rotting process. Later in the ceaton the
carts are backed against the heap, which, lying more loosely together, ferments more rapidly, and so the soner acquires that rotten texture which enables it to Le easily buried under the surface, or perfectly mixed with the soil. In any case, in order to the retention noth of the volatile and the soluble prodacts of this fermentation, the heap should be laid upon a bed of loamy soil, about 6 inches deep, and covered with a layer of such soil 3 or 4 inches thick; and when the ueap is finally mixed together, before being carted out, lost, should be mingled with the mass."

*     * We shall be glad if our Correspondents under this division of our Paper will endeavour to state the probable proceedings of the ensuing week or two as well as describe the past.

Deticotion of Adulteration in Manure: Correspondent.
Earth adds to the weight of guano, which ought not to weigh Larth adde to the weight of guano, which ought not to weigh
more than 70 to 72 lbe. per bushel. Water is a common more than 70 to 72 lbo. per bushel. Water is a common
adulteration. Guano ought not to lose more than 10 to 16 per cent. by drying. Gypsum is often added to guano, and water which has been standing over some of the manure in a glass some chloride of barium to one portion, and some oxalate of ammonia tn another; if both are rendered turbid, gypsume is present. But gypaum is rightly present in some manures; then weigh a portion of the manure, treat it with a solution of carbonate of ammonia, a nd wash with dillthe sulphate of bargtes is thrown down; collect it, and weigh; for every 116 grains of it thius obtained, 68 grains of gypsum bave been present; compare this with the published analysis of the manure. Chalk is detected by effervescence with an acid; the acid solution is afterwards ammonis added; if lime be present, oxalate of ammonia will be precipitated. Common salt is added often to nitre, sulphate of ammonia, de. Sulphate of ammonia, if pure,
will be wholly dissipated by a red heat ; any remaing will be impurities. Common salt is detected in solution by adding a drop or two of nitrate of silver dissolved in water, when, Common salt makes a sparkling crepitating sound when thrown on hot coals ; pure nitre causes brilliant burning of the coal without any noise.
Dissolving Bones: $J$. The following is a prescription:Plaster and puddle a floor of clay and let it dry. Lay thereon a ton of bone-dust-say 7 or 8 quarters; it should not be coarse, but need not be literally dust; if boiled or the after nperations Pour water on the heap fur a day or two as long as any is absorbed - then flatten it down and lay a lot of ashes round the edges-trample them firm. Pour on gradually 6 or 7 cwt , of sulphuric acid-four or five of the oroinary carboys. It should be poured into jugs, and thrown from the jugs on to the bones. The slowneas of this
plan, as well as its safety, is a recomnendation. It will boil and fume, and effervesce, and you bad better stand to windward of it. Before night it will be quiet, and, if still very
wet, it should have the ashes closely packed around it. They may be mixed with the heap in a day or two, and it will be fit for the drill in a fortnight. If a emaller quantity is required, it may be made of the same proportions in a cask
or in a slate tank.
 6 oz . ; sweet oil, half a pint. Put the honey into a jar by the fire, then melt the other ingrediente, and mix them together; to be apread very thin on linen, and changed twice a day
Sweet Casks : $N$. In order to preserve these sweet, they must be kept tightly corked at all times, and the sooner after emptying that they are filled again the bettor. The longe liability to becoming foul; and when once foul there is no cure. If, however, they are empty, and are to remain so, their heads should be taken out, and they should be thornughly scourred and scalded, and thereafter left with the heads out in a dry and airy shed. We bave a cask which is in use for at least 35 years, yind good beer, It has been nearly rotten, still remains sound enough for use, and is as sweet as the day fit was made, having received no other management than careful attention to the particulars named Weove.
Weight of Catrle: J Smith. It is estimated from measurement as follnws:-The girth is to be taken where it is shoulder; the length from the front of the shoulder to the insertion of the tail. Multiply the square of the girth in feet and inches with the length in feet and finches, and the product by . $24,26, .28, .30$, according to the fatness of the animal, the result will be the weight of the carcase in
imperial stones. The weight of the cor imperial stones. The weight of the carcase is to the live in cattle -as 8 to 14, or thereabouta, in fat sheep; as 2 to 8 in the case of well fattened pigs. These proportions to 8 according to the condition and breed of the animal.
Winter Food for Stock : J.M. The following are a number of different plans :-(1). 4 lb . of Bean straw, 12 lb . of Oat (Mr. Horsfall); ( 9 ), 2 lb . of crushed Linseed bniled in 301 lwedes of water, 5 lb . of ground corn, 10 lb of straw chaff 3 gallons yellow bullock Turnips, with a little Whaw chaff, 80 lb . of (4), 8 d . worth of Stone of Linseed-cake, 140 lb . of Turnips; (Mr. Hutton); (5), 1 llb . of Linseed, 5 lb . of Besn meal, with Turnips; ( 40 b . more Turnips than in No, and 3 lb . of Bean meal,
 (9), 4 lb . of oil-cake, 2 lb . of Barley meal, and 100 ib . Turnips (Harkness); (10), 4 lb . of Linseed and Bean or Barley meal coored adith. (11) each, and water (Lincolnshire)

PORTABLE HOT-WATER APPARATUS,
WITH TRUSS'S PATENT JOINTS FOR HEATING CONSERVATORIES, HOTHOUSES, \&e.

## T. S. TRUSS

Begs to offer complete HOT-WATER APPARATUS for GREENHOUSES (consisting of 4 -inch Pipes and Joints, Saddle Boiler, Fire Doors, Bars, Soot Doors, Damper, Supply, Cistern, Feed and Air Pipes, in England, and to erect the rame within 25 miles of London, at the following prices:-

4-inch pipes along one side and one end of house.

We may congratulate the Fellows of the Royal Horticultural Society on the preservation of the two most important and useful praotical elements of the Society-the Floral and Fruit Commit. TEES, the dissolution of which seemed imminent a fow days ago, in consequence of the utter impracticability of their meeting being holden on the days which had been set down for that parpose. It was not to be expected that some 60 or 70 men, including the best practical horticulturists within easy distance of London-men who are for the most part daily engaged in the keen pursuit of horticulture, either as gardeners or nurserymen, and who had cheerfully made the offering of their gratuitous services, could add thereto the utter disarrangement of their home affairs merely in order to accommodate the unfortunate Saturday meetings. We think therefore that the Council has done well to accept the offer of the Committees to continue their meetings on Taesdays as heretofore. Had it been otherwise, we happen to know they would have met elsewhere.

This arrangement seems to be the best thet could have been adopted under the circumstances, though we believe the best of all would have been to bave augmented the Tuesday instead of holding the Saturday meeting. At least, it will give those cuuntry horiculturists who have pointed out that Saturday meetings virtually exclude them from exhibiting at all, an opportunity of staging their flowers and fruits before a London tribunal ; it will enable the Committees to continue their good work of eliminating the bad from the good, to the great advantage of purchasers ; and we trust it may be taken as an tarnest that the horticultural body will henveforth be allowed to have its legitimate influence in the affairs of the Hortioultaral Society. If this be so, then the

simultaneous fecundation by neighbouring Wheatflowers. I allude to these facts only as showing with so as not, on the one hand, too hastily to oppose the evidence of our senses to reason from analogy, nor, on the other, to
experience.
Almost all experiments and observations upon hybridism have leen apon plants in a state of cultithere is this difference, that exceptionally fertile hybrids must be still more rare; for to the obstacles opposed by sterility. or return to parent forms (or, say,
disjunction of parent essences), to the establishment of disjunction of parent essences), to the establishment of ensuing from the want of the protection and assistance ufforded by haman care. Of this a curious instance
is mentioned by M. Godron, in accounting for the rarity in a wild state of the Egilops speltæformis, which seeds so readily under cultivation: the structure of the spike is such as to render the germination of the seed exceedingly difficult without extraneous aid in forcing generally received opinion, that although hybridism in a wild state between races sufficiently distinct to be
fairly called species is not unfrequent, the individuals fairly called species is not unfrequent, the individuals
are few, and generally differ from each other as much as they do from either parent. The modern practice, therefore, of giving rames and descriptions of these hybrids as of distinct races cannot be too much depre-
cated: it is an attempt to give fixity to that which has none, confounding individuals with races, and overloading with practically useless matter our floras and faunas.

As to the direction in which future researches on hybridism are likely to be the most useful, it does not appear that any further evidence is required in support by Naudin. No number of cases of sterility in hybrids will disprove the well-established ones of exceptional fertility. Bat Naudin's hypothesis of the intermixture and subsequent disjunction of parental essences opens out a new field of research, requiring for its confirmation or refutation numerous varied and careful experiments which may altimately give us some further
insight into the hitherto concealed mysteries of fecundinsight into the hitherto concealed mysteries of fecund-
ation. Practically also, much is to be done in the observation of plants in a wild state. Hybrids in our cold damp northern climates always appear to me much less frequent than in the south, for the same reasons, perhaps, that the proportion of perennials to annuals, greater in the north than in the south. Is that the Willows, for instance, mainly owing, as sone pretend, to the frequeucy of hybrids, or to our having attempted
to define as species races as yet too closely allied to to define as species races as yet too closely alliod to
have become fixed? These and similar questions may be well worth the attention of botanists resident in the experiment. From the President's Address at Anniversary of Linnean Society.

## RARLY FLOWERING BULBS.

 The Hyacimth.Wiri the following few remarks on the Hyacinth, I beg to conclude my short series of papers on this up" is evarything connected with Hyacinth culture, that I will confine myself to a hint or two relative to the management of this usefal flower in glasses. Two or three lumps of charcoal should always be placed in the glass; when this is done it is seldom necessary to
change the water. Stale rain.water should not be used change the water. Stale rain. water should not be used
for Hyacinths on any consideration; unless it be well tiltered it contaios a great deal of putrid matter, which in a few days becomes highly offerisive. Clear drinking. warm when the bulbs are placed in the glasses. Let the water just touch the base of the bulb, aud place the damp one, which is quite nusuitable for them. A cupboard in a sitting-room where there is a fire is the best place for them. When brought to the light avoid violent variations of temperatare. Keep them in a
window, but not in a draught, and no frost must be permitted to assail them. The coolest, lightest, and mnost airy part of the room, which is geuerally the
window, is the place for them. As soon as the buds show colour, fill the glasses up to the brim with water and leep them in that condition. Avoid grano and other manures; a splendid head of bloom can be applications invariably, produce harm. With a very fer exceptions, grow single flowers only in water.
The revolution of opinion that has taken place during the past few years as to the comparative value
of double and single Hyacinths is worthy of remark. In 1857 this dictum was given in a contemporary:"I give my full assent to the statement, that single footing with their formidable rivals of the double class, and that, depite the enormons trusses of the singles, the contest would be unequal." The writer assumed the double varieties to be much superior to single
Howers, inasmuch as the latter had "a poverty of
left them immeasurably behind the double varieties." Now the double flowers are rarely to be seen at our Hyacinth shows in the groups of 24,18 , or 12 , with varieties of the past two years, scarcely a double flower has appeared. The Dutch growers generally still thiuk double flowers the best, but as the tendency in England is towards single flowers, they are
devote themselves to their production.
A liking for the larger and more substantial bells of double flowers is again taking root; but perfection is sought for chiefly among the single flowers. We are thus on the eve of another change. The largebelled kinds, of which we have conspicuous examples in Snowball and Madame Van der Hoop in the whitee, and La Grande Vidette and Thorwaldsen in the blues, are certainly rising in favour. Many of the single
varieties in each of the three classes of colours, with varieties in each of the three classes of colours, with
spites thickly enough studded with bells, are howpver wanting in that shape and substance which is required to bring them up to the level of progress attained by to be types of the "coming "flowers. Some of the bells, as for instance in Madame Van der Hoop, are already beautiful in shape, and have that peculiar waxy appearnee which makes them so attractive, and when fully reflexed, display as much beauty of symmetry as can be seen in a finely-formed and fully developed Fuchsia. The greatdesideratum is, more bells on the spike; but to effect
this must be the patient work of time. The blue and white classes already furnish flowers of this character, but among the reds the development is only just discernible. I was conversing during the past summer with a cele. brated Dutch grower, and in reply to my remark that English taste was taking the direction I have just indicated, he suid that the preference was already anticipated in Holland, and that they were hybridising with a view to procure such flowers as I have named. istics accomplished, that it will be years before a stand of 12 large-belled Hyacinths shall be staged; it is surely, however, in the future of our Hyacinth exhibitions. This will necessitate the recognition of the idea of "shape" for the individual bells by our Hyacinth esymmetry of the spike hides defecta of shape in the bells; then, there must te the presen
of this desired feature in both bells and spike. Quo.

## Home Correspondence.

Castle Kennedy Fig.-If "S. B." in his former communication whs at fault in supposing this Fig to be synonymous with the Brown Turkey or the Brunswick, munication I think he is nearer the truth in supposing it to be the sane as the Large Brown or Chestnat Ischia of Miller, a valuable variety supposed to be lost. "S. B." says-" It seems probable that the old and representative in this kingdom of a Fig cultivated by Miller, and which stands first on his list. Of Figs now cultivated here (except the recently imported Adam) the largest is the Brunswick; this was known to Miller, who describes it. Yet le states that his
No. 1 is decidedly the largest Fig he knows, and therefore larger than the Brunswick. He speaks highly of its earliness, hardiness, and quality, nor does he say anything disparaging of it except its
liability to crack in wet seasons, like many other thinskinned fruit." This description agrees very closely with the character of the Fig grown here, as any one can see by referring to Messrs. Lawson's descriptive circular respecting it. When allowed to hang after being ripe, if water is freely administered to the roots, I have occasionally observed a tendency to crack, but this can easily be prevented by withholding water when
the fruit is approaching maturity. It is a very early variety, being always first ripe in the Fig bouse; in fact it is nearly three weeks earlier than the Brunswick, and out of doors it is a fortnight earlier than any of the larger varieties grown here. Figa and other fruits were extensively cultivated here His duties compelled him to frequently reside on the Continent for longthened periods, and his well-known taste for gardening would doubtless induce him to
embrace these opportunities for collecting some of the finer sorts of fruits. In this way it is probable the Fig in question may have been introduced here, or, what is equally probable, it may have been brought from England, and planted in this rather out-of-the-way place. It has been growing for an indefinite periodin this noglected in this neglected state in favourable seasons it has pro-
duced abundant crops of fine fruit. Archibald Fowler, Casito Konnedy, Stranraen
Paxton Homses.-In reply to the inquiry of your correspondent "A.", in your Paper of Dec. 24, as to whether Sir Joseph Paxton's Patent Span-roofed Hothouses answer equally well whether set from east either aspect they equally fouth, I beg to say that in erection. If placed with the ends east and west, one lean-to side, by facing the south, will receive the direct rays of the sun, and the fruit will in consequence sipen earlier than if the house stood in another aspect; the
less direct sunlight, the fruit will ripen later and will form a succession crop. If the house is pluced with the ends north and south the crop will ripen equally on both sides. It is somewhat wonderful what may be effected even with the smallest houses on this principle of perfect ventilation. A little model in my possession of only 8 feet equare, and standing in the cold climate of the Peak of Derbyshire, had Vines planted in it three years ago, and this last summer, owing to their
Figorous growth, they were allowed to carry 30 vigorous growth, they were allowed to carry 80
banches of very fine Grapes, besides which the house contained an excellent crop of Figs, Cape Gooseberries, and other fruit, all of which ripened exceedingly well In winter the little place is used for sheltering bedding. out plants, and with a very smail flue and a handful of fire all frost and damp are excluded. Sumuel Hereman, Jan. 10.
Glass Houses at Seaforth Hall.-In a long descrip. tion of the garden doings at this place, which you havo it to be inferred that everything has been done by the gardener there. So far, however, is this from being the case, that I have the best authority for stating that the garden structures were designed entirely by Mr, Kemp, of Birkenhead Park, and that they were erected from his plans (the heating apparatus excepted), under the direction of Mr. Horne, a very superior and intelligent clerk of the works, who supplied some of the details. In the new edition of Mr. Kemp's book on
Landscape Gardening, indeed, a plan and description of the whole arrangement are inserted, and this plan includes some portions that have not yet been carried out. Vindex.

Prize-taking at Exhibitions.-As an exhibitor of flowers at some of our principal national exlibitionsand not an unsuccessful one-perhaps you will allow me to say what I think of the question lately raised by "Florist:" premising that I think your own remarks generally very just and sensible, though I am not quite of your opinion when you say that the practice which has become prevalent of late of entering flowers, \&c., in the gardener's name instead of the employer's, is "probably not the result of design," for one of your correspondents says that it is a matter of $£ . s_{0} d_{0}$, and that a spirit of emalation is no motive at all in getting up flowers for exhibition. I quite agree with "Florist" that the employer is the person to whom both "praise" and prizes" to use one of your correspondent's expres-
sions, of right properly belong, as in the case of other entlemen's properly belong, as in the case of other I think perfectly analogous : he is the exhibitor properly speaking, though he may think fit (and probably usually does) after deducting travelling expenses and entries to give the rest of the amount of the prizes to his gardener as an encoaragement. trip free of expense to content with this; he enjoys the trip free of expense to
the exhibition, with his day or two's boliday, and the opportunity of seeing the specimens exhibited by the competitors, and learning something only (as your correspondent seems to suppose) of the amount he shall clutch by the awarded prizes. If it were not so, as you very properly say, "the remedy is in my own hands,", and I should either cease from exhibiting, or provide myself with another gardener.
One of your correspondents asks, "Does 'Florist' mean that gentlemen are to become practical gardeners?" and he instances the extreme cases of Lord A. and the Duke of B. not superintending the growth of their Cucumbers. Does he mean to say that the employers generally leave the matter entirely to their gardeners to do as they like-cultivate what flowers or truits they choose, and leave the mode of cultivation entirely to their skill and judgment? This is to misrepresent the case, I am satisfied, of the generality of employers. And if they were not "practical gardeners," what
would become of our exhibitions? Heads as well as hands come into my view of practical gardeners, and there are intelligent employers as well as intelligent gardeners. Take the amateur class (I speak of flowers particularly) and see who are the persons who usually exhbit; they are amateurs in the real sense of the have, it may be, one or more pet flowers which they are desirous to see brought to the highest pitch of perfection, and would themselves, if possible, have the honour of leading the van amongst the competitors towards that attainment. Amateurs must be practical I am proud to claim the appellation, bringing both head and hands too to the work; and if I were not, my gardener's name would probably never have been known beyond the narrow limits of his own birthplace. I say not this from any conceit, but simply claiming the position we do as the real exhibitors, and
don claining also the "prizes" as well as the "praises accruing to the awarde. I said I bring head and hands too to the work-I take great pains with my seeds for rearing good seedlings, and see them sown; usd
my own judgment in selecting the old flowers I intend growing; am very busy in my forcing house in the season taking cuttings, potting off, and watching their growth when planted out; superintend the staking and trimming out ; select the flowers for exhibition ; and last, not least, "pay the piper too" who carries out my "praiser and prizes" toa, howeyer I may share them

| afterwards with my gardener. I do not at all object to | should be arrived at; but the question does not seem |
| :--- | :--- | :--- |
| the gardener's name being mentioned in the award, this | to be disputed, and it is pleasant to know that most | is only his due; but I don't like, as a friend of mine ladicrously puts it, to bave the firm called A. \& Co., A. long resisted this new practice of which "Florist" justly complains; but latterly, finding myself almost alone, have unwillingly fallen in with the prevalent

custom, and shall be glad if "exhibitors" in future make up their minds to return to the good often better than the innovation. Vindex. [As far as our memory serves, the present has been the practice at the great London shows from the first.]feelings of but a very small portion of the gardening feelings of but a verist" takes "racing to begin with," and asks, Ought not great race prizes to be given to the trainers on the principle in question? gardeners is unjust. Blood is of first importance in horse-racing, the owners generally select their own stock, and a gentleman with a fine stud has no difficulty in getting a trainer to keep it in the best state; but where is the trainer who does for his master as much proportionately as many a gardener has done-sub sticute in a few years a first-rate and winning colection of plants for one of the jockey who rides a horse is often quite as important a person as the trainer. Then, again, is it fair to class together competition for the Derby or the St. Leger, with 60002 . for the winner, and perhaps $20,000 l$. in bets, with that for the prizes at a flower show, where they are often worth as little as 28.6 d . I will just remind "Florist" that it was Mr. Anson, a trainer, who won the last Derby and st. Leger, and that in these fashionable and most highest in the land. Yet we do not hear of any narrow-minded nobleman complaining to the press that he was obliged to compete with a person who at that very time might have been acting as his servant, and sug gesting the formation of a separate race for all "infeto any gentlemon supper present "A cain as to yach ing," I submit that "Captain Blowhard" should not be compared to a plantsman who inserts a cutting, and in the course of time stages it a winning plant; for the build of a yacht has generally much more to do with her sailing powers than the skill of her captain. Again, most noblemen and gentlemen pride themselves on their knowledge of stock and breeding, and for a very good reason never meddle with the minutiw of gardening; yet "F." says, "it may be easily guessed how many at the expense and trouble of rearing," if the prizes animals-which they should not be Surely " $E$, must know that even far greater be. Surely inentions have for years sent their fruit and plants to the London shows, and it may not be easily guessed when they shall discontinue the practice. During the past autumn I have seen the practice which "F." is so hows, withtroduce, carried out at several provincia it appeared to me, a great loss of dignity to the noblemented to know what gardener had produced the best brace of Cucumbers, it was found to be the Right Hon. Lord So-and-So, who had thereby added 2s. 6d. or 5s. to his princely revenue. And so with the Squire's fat Lettuces and Onions, which gained the blue-blooded owner the 1st prize, value one shilling. Now if the whole or any respectable portion of the gardens, forests, and competition a charms of properties could be tested in a prizes which tend to improve the whole, must of neces sity be given to very petty items, I am sure such unfair merit-recording is lurtful in its effects on gardening, inasmuch as it may prevent many of our most influen-
tial proprietors, who would not like to see their names bandied about as victors amongst Hollyhocks and Cabbages, from having anything to do with flower shows. On the other hand I have observed many gentlemen Whated and loquacious about " my gardeuer's" success, display of costly plants? An exhibition of garden pro duce can in no sense be likened to one of articles of virtu, nor gardeners to those who merely "take care" of things. The prizes are given for excellence of culture; and as in nineteen cases out of twenty that excellence is the result of the gardener's skill and brains, it is not just, of the honourable, it is hardly honest to deprive him anotl merit which attaches to victory. The prize money between matter, and one which must always be arange merely picks and sends them for exhibition, his say peaches scarcely be said to incur any additional expense his gardener the prizes wo contrary, the master won in this way; but if, ou tho exhibitions, then the case is totally different, and a share of the money returns must often satisfy the gardener, as the expense for vans, carriage, \&c., some of cises between amount won. As there are all sorts little or no expense extremes of those who exhibit at outlay, it is not in the nature of things do at a heavy
entlemen allow their gardeners the money so well earned. With respect to "Faunus,
about the case which he says "'Florist' so Horticultural Society has lost a fire-eating member he horticultural press, moreover, must be specially benefited by the appearance of so uncompromising censor, who has given his "first warning," as they do
over the water. But the press is of all other powers east likely to award merit where it is not due. I would advise both "Florist" and his admirer to read a paragraph concerning the death of Mr. J. Lawrence, letter (p. 1207, 1864.) Men whose memory their letter (p. 1207, 1864.) Men whose memory their
country has not yet "lej die" have said that gardeners as a class were more worthy and intelligent than any ther men of the same social rank, and that that is true will not be doubted by those who have even the slightest knowledge of them. What has made them so? Is it money? They are the worst paid class of men in existence, taking into consideration the skill and knowledge they require, for many gardeners, in addition to professional knowledge, possess and must possess the knowledge of an office clerk, and yet are frequently paid less for all their duties than is often paid for that. No class of merı work harder than prize-taking gardeners. believe that the fact of the acknowledgment of merit by the press has not a little to do with the ability, the character, and the intelligence of our
gardeners. Therefore I think that the system which gardeners. Therefore I think that the system which shows, should be adopted at all others where it is not followed; that where an individual, be he what he may, wins a prize with his own hands and with deprive him even of the nominal merit of having done o; and that where an employer has time enough, skill enough, and love for gardening enough to become his own cultivator (a case which cannot often happen as society is at present constituted), he should,
exhibitor, enter his plants in his own name, for surely if be is not above potting and watering, and tying and pruning, and gathering, and staging, and all the other abours of a gardener, he should not think it beneath him to contend with some of the best and most skilful nembers of a class which has done wonders towards beantifying the British Isles. Wm. Robinson.I have no desire to revive the little controversy you were so obliging as to permit me to initiate in your motives sadly misinterpreted favour me with the insertion of a few parting words, You put it to me-whether I consider it beneath me to meet a respectable gardener in floral competition? I mphatically answer, no. I have now been an exhibitor During that time I have met with amateur florists, nurserymen and gentlemen's gardeners, and with some lew exceptions have derived gratification and pleasure rom their acquaintance, and although there have been masters had been the exhibitors, I have not on the whole had reason to regret having entered into competition with gentlemen's gardeners as a class. It was militate against the increase of gentlemen as exhibitors, is the non ascription of prizes to them for their own fowers and fruit, that I was induced to moot the subject, and that such increase is much needed must be apparent to all who know anything of the metropolitan hows. Were it not for the coatributions of the leading nurserymen, who thus in a manner advertise themselves, and of a few enthusiastic amateurs, the floral part of these exhibitions would be meagre in the xtreme. Year after year among the few gardeners, exhibitors of plants, we meet with certain stereotyped names-and why is this? Are they who bear them the only gardeners in Eagland or even in the environs of London who can grow Orchids, Ericas, \&c.? The same obtains with respect to cat fowers, very few of the class being exhibitors of Roses, Dahlias, Gladiol, ec. here also the nurserymen and amateurs carry all before them. Now there are, I may say, thousands of gentle men the land who beep capacity and intelligence; I quite believe that among them are hundreds who could if so required exhibit plants and flowers quite equal if not superior to those of the leading nurserymen, and yet how very few of these are ever heard of in connection with the London shows? I grant that as regards fruit the case is somewhat different, for here they turn the tables on the nurserymen ; but this only renders their shortcomings in the floral department the more conspicuous. The reason is obvious.

The gardeners excel in fruit grow ing, because their employers have a direct interest in the matter-for where is the master who is not partial to fine fruit? But the case is different as regards florical ture for exhibition. The masters are ignored, and therefore have no incentive to allow or to require their men to grow for competition: and that they are altogether ignored, the reports of the metropolitan exhibitions in the floral publications abundantly testify -the gardeners' names alone being asually given. Thus in your own report of the autumn Crystal Palace Show
may be found as Melon prize takers, Mr. Young, Leigh mark; Mr. Blair, Nhrubland Park; Mr. Godfrey, Ware

Park. Was there ever such a case of borrowed plames priated? No, no. they are so printed merely for brevity; the full address, unless by oversight, being given once in the report.] Much as I have been found fault with for advocating the placing the master's name first, and the gardener's second on the prize cardinstead of vice versâ, as at present, the great outcry raised against the proposed alteration confirms me in the view I have formed of the advisability of the change. For surely, if the gardeners lay such stress upon the prizes being awarded to themselves, asserting that the contrary would still further diminish their numbers as exhibitors-the converse should hold equally cood, and we may fairly presume that the same equally good, and against gentlemen taking grenter interest ings militate petition. The argument that the masters have the remedy in their own hands is mo doubt correct, but only to a certain extent. Some few gentleown hands and Rosarians, do take the law in their majority do not wish to enter in oullor, gardeners on the point, and so keep back. I suggested exhibiteration with the vielv of attracting to the may add more especially, ladies, who, though very fond of flowers and floriculture, are not sufficiently enthnsiastic in the canse to come formard as erhibitors under the present arrangement, but yet would become, under different system, so interested on seeing their names in the prize-lists, as to cause them year by year to take competitiou. Of this, besides several instances I might mention, I may adduce my own experience as a case in point. Years ago I took but slight interest in floriculture, and it was the spirit of emulation, and the excitement engendered at seeing my name as prize-taker at a local show, that first led me to tak pleasure in growing for exhibition, and has at length brought me to the pass of being considered by my
friends "a wee bit crackit" on the subject. My opponents keep beating the air about the money awards. Irepeat consider it reasonable and right the masters should give the prize money to their men, and I beliave it would be difficult to find a case where it is or could be country do not exhibit for fear they should be thought mean enough to keep back from their gardeners the few prize shillings, or may be pounds, it is so supremely absurd as to be beyond cavil. That there must be something which keeps gentlemen and ladics from floral competition must be manifest to all who consider with what keenness and avidity so very many many hornets into whose nests I so unwittingly placedimy hand, must agree with me in thinking that a pen of "great gawky fowls withont a tail" will not bear comparison with a stand of 24 beautiful Roses. And yet, will any one tell me the reason why ladies exhibit Cochins and not Roses, all the time profes sing the deepest admiration for the latter? I could add much more to the point, but I refrain; and in bidding adieu to the subject, and thanking you much for your courtesy, I will only say, that if I have given offence, I meant it not. My devotion to floriculture alone induced me to come forward, and I trust that my passion for flowers will be sufficient excuse for having adopted the siguature, of Plorist. [We cannot afford space to continue this discassion further.]

## Societits.

Roxal Hortroultural: Jan. 7 to 11 (First Weekly Show). -The flowers selected for exhibition on this occasion were Primulas, which, together with some interesting plants of other descriptions, and a little fruit, were arranged round a fine specimen of Encephalartos Altensteinii, in a warm compartment at the eni of the Eastern Arcade. From Mr. Smythe, gr. to Lord
Sondes, Elmham, Norfolk, came Corras magnifica, wellgrown, and finely-bloomed. Mr. Hally, of Blackheath furnished various handsome zonate-ieared Pelargoniums Messrs. A. Henderson \& Co., of Pine-apple Place, sent miscellaneous collection of plants, consisting chiefly of sorts remarkable for the beanty of their leaves, associated with Early Tulips, and the pretty mixed with flowers of the charming Lapageria rosea, came from Mr. Coysh, gr. to Mrs. E. Wnod, of Eugby, together with a small group of Stove and Greenkoule Plants, in which were Begonias, Oncidium divaricatum, and the showy winter-bloomiug Sericographis Ghies breghtiana, well furnished with crimson-scarlet Justicialike blossoms. The same exhibitor also had a collection of nicely-flowered Primulas. Mr. J. K. Hedges, The Castle, Wallingford, sent examples of Rougainvillea speciosa, covered with gay mauve-coloured bracts.
Messrs. E. G. Henderson contributed an interesting collection of Primulas, including examples of their pretty Fern-leaved varieties; and from the same firm also came an example of Schizostylis coccinea, a Caffrarianf Iridaceous plant, bearing crimson blossoms of great beauty. From Mr. Short, Clewer, near Windsor, came Libonia floribunda, a neathabited sab-shrubby plant with bright-coloured tubular blossoms, not unlike those of Manettia bicolor. From the Garden of the Society came various contribations of Primulas and other plants
which, being neatly arranged on tables of different
shapes and sizes in varions parts of the exhibitionoom, had a good effect.
The fruit consisted of a magnificent Cayenne Pine Apple from Mr. Ingram, of the Royal Gardens, Frog. more, Whence also came a basket of excellent
Muslirooms. From Mr. Smythe came a bunch of Musiroomso From Mr. Smythe came a bunch of
Barbarossan Grapes cut from a Vine grafted on the
On Muscat of Alexandria, a stock on which the Barba-
rossa is sail to bear and keep well, the bunch in rossa is said to bear and keep well, the bunch in
question laving been ripe in August last. Finally, question having been ripe in August laat. Finaly,
capitally
ripened handsone Black Hamburgh Grapes were shown from one of Sir J. Paxton's patent houses very little, if any, fire heat, and where the crop has, we believe, been excellent.
Linwean : December 1.-G. Bentham, Esq., President, in the chair. H. G. Dalton, M.D., was elected a Fellow. The following papers were read:-1. On new
tubicolous Annelids in the collection of the British Museum $\rho$ part 2, by Dr. Baird.-2. On the structure of Bonatea speciosa, vith reference to its fertilisation, by The author's object was, he observed, limited to the illustration of the manner in which the structure of the flowers of this plant ensures the removal of the pollinia by insects resorting to the flower, and how
fertilisation ensues through the same agency. The fertilisation ensues through the same agency. The was said to be the cohesion of so many of its organs with the lip: the long stigmatic processes cohere on
either side for more than half their length with its upper surface, the anterior portions of the upper petals cohere for nearly a fourth of their length with its
outer edges, and the inner edges of the lower sepals cohere with its under surface for about a third of their length. Thus a section through the base
of the lip would divide these parts also, passing of the lip would divide these parts also, passing limbs of the lip as petaloid anthers, of nine distinct organs. The rostellum forms a conspicuous green
hood with its sicles produced anteriorly into two long arms projecting upwards, and its apex similarly produced, but shorter and recurved. The membrane at the anterior edge of the lateral horns is folded back so pollinia lie, and the two discs are situated on "the polinia lie, and the two discs are situated on the ture to insect fertilisation was pointed out as remarkable: an insect forcing its way into the rostellum cup,
attaches one or both of the viscid discs to the under side of its head, and thus carries thom away to another flower.-B. Brief notice of results obtained by experifree Nematoids, marime and freshroater, with deserip. tions of 100 species: by H. C. Bastian, M.B.
December 15.-G. Bentham, Esq., President, in the
chair. Dr. St. Brody, exhibited specimens of Ammi glaucifolium, Lin. (A. majus $\gamma$ glaucifolium, Gren. et Godr.) gathered by him on the banks of the Severn,
near Gloucester, in September last. Dr. Shortt exhibited four samaples of tea manufactured from the leaves of Coffee, three prepared in the Chinese method, and the fourth in the mode employed by the natives 1. On the Tsetse Fly of Tropical Africa (Glossina morsitans, Westroood). By Dr. Kirk. The author gave a
brief resumé of what had been already recorded regarding this venomous fly, and added thereto such observations as his own experience suggested. In
$183 \%$ Captaio Harris had marked on "country abonnding in flies destructive to cattle." In 1850 Gordon Cumming, heedless of this, and of information received from the natives, advanced into
the fatal region, and the next day one of his horses died from the bite of the 'Tsetse. The head and body of the poor animal swelled up in a most distressing
manner, his cyes wore so swollen that he could not see, ant in darkness he neighed for his comracles who stood; feeding before him. Major Varden, who was the first to bring specimens to Aware of the existence in certain districts of the
Bechuana country, of plants poisonous to cattle (such as the Koiwhane, a species of Lasiosiphon) and suspecting that some such herb might be the cause of the
mischief ascribed by the natives to the fly, he put the matter to the test by riding his horse into a Tretse infested part, without dismounting or allowing the animal to feed. The result was the death of the horse. being free from it. He had ridden up a hill and tound the Tsetse increasing at every step, till at least 40 or 50 brought to England cost him one of the best of his stud; the animal was stung by ten or a dozen of the fies, and died in 20 days. Mr. Oswell, one of the disthe marahy regions of Central Africa on the Upper Zamabesi, states that the fly is strictly localised, and day it is active, but it does not bite by night, and the Watives then pass their cattle thruugh without loss. Whime man, the goat, and wild animals are bitten with animals perish. Dr. Livingstone mentions that the
ass is not affected by the bite, ass is not affected by the bite, and although the
suoking cal. lives, the dog fed on milk dies; but

Livingstone's most important observation is the connection between the fly and large game, especially the
buffalo and elephant, and its absence from parts where they do not exist, pointing to a possible means o ridding a country from this curse. During the
Zambesi expedition, Dr. Kirl met with the Tsetse on many occasions and at distant parts. It was found to frequent open forest and well-wooded country, but to be absent from extensive Grass plains. In the morning while dew hangs on the Grass, and before the snn ha
warmed the air, they are sluggish, but with the heat o warmed the air, they are sluggish, but with the heat o
the day they become a real annoyance to the traveller constantly biting him on the hands, face, and neck dexterously avoiding a blow, and again alighting on the very spot from which they had been driven. If permitted unable to fly to a distance. On man the effects of the bite are not more than follow an ordinary mosquito bite. Dr. Kirk also remarked, that wherever he had
found the fly it had been accompanied by the buffalo or elephant, but that it did not follow them every where, circumstances still unknown seeming to check its universal distribution. It was added that a dilation found at the base of the proboscis had been suggested found nothing of the kind on dissection. The effects which in man foliow the bite, show, however, that some irritant matter is injected. The
object of this, it was observed, is no doubt to cause local congestion, and thus facilitate the
sacking of blood. The accidental effects o this produces no after result in animals among whom the Tsetse naturally lives, but in certain domestic animals proves fatal.-2. Description of a new variety of Lepidonotus cirratus, parasitic Baird.-3. List of Diurnal Lepidoptera collected by Mr. Wallace in the Eastern Archipelago. By W. C Hewitson, Esq.-4. IOn the Lentibulariece collected in African species. By Professor Oliver. This paper includes the results of Dr. Welwitch's explorations, together with notes on the other African Utricularim found in the Kew, Dublin, and Limnean Nocieties Cerbaria. Ten new species of Utriculaxia, and one of Plants collected in Japan, and in the Islands of the
Korean Archipelago in 1862-3, by Mr. R. Oldham. ate Gardens, Kew. By Professor Oliver. This paper was chiefly of botanical interest. It was, however, mentioned that fruiting specimens of the plant called Rhynchospermum jasminoides show it to be no
Rhynchospermum, and that it must for the present be retained in Panechites, being probably identical with P. Thunbergii. As, however, the fruit of Panechites itself is undescribed, the Japanese plant may some day require another transfer. The Ichnocarpus fragrans of Wallich was said to be very closely similar to $P$. Thunbergii, apparently congeneric, perhaps even con Professor Oliver remarked, that Mr. Oldham had sent several specimens under this name obtained at Yokohama, and said to have been brought from Fusiyama They consisted of the branches of an Abies bearing pseudo-cones of various size, precisely similar in form and structure (though mostly much larger) to those which, owing to insect punctures, infest Abies alba and oxcelsa in our plantations. "I cannot doubt," h observed, "that it was from fragmentary specimens o these malformations that the genus Veitchia was pro-
posed in the Gardeners' Chronicle (1861, p. $\mathbf{z} 65)$, though Dr. Lindley was no doubt misled by some seeds supplied to him which he understood were produced by the cones in question. I cannot be sure of the species of Abies, as none of the normal cones accompany the Africa belonging to the Natural Orders Bixinere and Tiliacea, with a note upon the genera Oncoba and Mayna. Pyramidocarpus, belonging to the Bixiniex ; and Ancistrocarpus, belonging to the Tiliaceæ. Prof. Oliver believes it will be necessary to unite Oncoba and Mayna. By Dr. R. Caspary ; communicated by Dr. Hooker. In the author's herbarium are specimens of this species collected in 1850 by the Rev. Mr. Trimmer, in a pond near Framingham Earl, Norfolk. The English form is said to be intermediate between the varieties named Eriophorum angustifolium.-8. Notice of two forms of Eriophorum angustifolium, by Dr. Dickie. In a moor
near Aberdeen, visited last May, Dr. Dickie found two evidentlya different forms of this plant one with slender spikes having only stigmas visible, the other with shorter blunter spikes, very prominent anthers and short stigmas. On dissection the former showed three stamens in a rudimentary condition; and a fort night later they were in the same condition-quite
rudimentary, and without a trace of pollen. In the other form the anthers were large, with copious pollen, and the stigmas short but apparently well are only at one get interuived both the seeds apparently reached full maturity, and each under precisely situilar couditions, almost every seed of the plants cvith large anthers and short stigmas sprang up and continued to grow, while of the others
not more than five or six showed any signs of lif

Manuel de l'Amateur des Jardins, Traité générel
d'Horticulture. Première Partie. Par MM. J. d'Horticulture. Premiere Partie. Par MM,
Decaisne et Ch. Naudin. Paris, 8vo., pp. viii. and 703, This is but a first instalment
intended to comprise a complete system of $\bar{H}$ rticul The names of its authors are quite sufficient to insure a careful exposition of principles and a useful practical application, for not only do they stand in the firs ranks of science, but they are no less remarkable for their thorough knowledge of everything relative to
cultivation. It must however be premised that as for as it goes, it is rather adapted for persons of educatio than for the self-taught, though we are happy to say that every day there is an increasing number of avail themselves of every opportunity of acquiring not merely a knowledge of the general system of cultivation but of the principles on which it rests, and ol' the rature and intimate structure of the objects which at placed under their care. The work before ns, should it be thought requisite to publish a
translation, will not indeed supersede such a the well-known Theory of Horticulture, which is in th opinion of the writer of this notice and of many athers botanists the one on which, notwithstanding the valo of his systematic works, the fame of the author will more especially rest; nor will it stand in the way of th admarable though simple Introduction of Professo Oliver, but it will give in a compact form a mass of information, on which the most inplicit reliance may in general bo placed, which would in vain be sought for in either of the works just mentioned or in any other we could name.
That more accurate information and of wider exten is a great desideratum amongst our cultivators is clear to every one who has deeply considered the subject As regards the farm almost every one who has a littl capital is anzious for land, and fancies that he can carry on its business, though he scarcely linows so much as the requisite rotation of crops; and it is oftea mach the same with the garden, apart from those processes which require manual dexterity combined with judg ment. The nature of the objects of cultivation, and ome knowledge of their natural affinities and habi of their mode of nutriment and growth, of the differen
conditions of temperature requisite at different seasons, conditions of temperature requisite at different seasons,
of the comparative importance of top and bottom-leat of the effect of evaporation and the circumstance under which it requires to be checked or promoted, together with a thousaud little matters for which no rule of thumb, however good, can compensate, are all matters without which no one has a right to consider himself even a second-rate cultivator. And then, order to meet the various difficulties which attend artificial growth, he ought to have some knowledge o
the nature of the diseases to which his plants are sub ject, which he cannot possess without some accara views as to the functions of the different organs, and the various vegetable parasites to which they are exposed Without such knowledge he will try experiment after ex periment without advancing a step towards the desir end, if he does not do permanent injury to valuab
plants which may be under his care. He may do we enough for ordinary emergencies, but in cases of dit culty he will be at a complete standstill. A little kno edge in such a case will often be worse than none. For these and for similar reasons we cannot sufficiently praise those directors of public instititions nore wealthy employers, who either take measures imparting correct views by actual instruction, or by pro
viding their men with books and journals of a real scientific character which may enable them to ghin such general views of the subjects which form ought we to be less thankful when such men as Decaisu and Naudin descend from their higher studies to cater or those who are in comparison "hewers of wood and drawers of water," the practical man, that
It is time original investigator.
It is time, however, to give some notice of the con terits of the important work so happily commenced.
The Part now published contains the principles Botany and Vegetable Physiology so far as they ar necessary to the cultivator, together with a theorel and practical exposition of the requisite operations
the cultivation as well of usetul $2 ;$ of ornamenta plants. Two volumes are to succeed, comprising pat ticulars as to the cuiture, first, of ornamental plan and secondly, of vegetables and fruit trees.
The first 164 pages contain the particulars unall found in what are called introductions to Botany aparh from details of classifcation. As in most treatises of the kind, in opposition to the principle which was so lum nously held forth by Prof. Henslow, and which has 80 m terially modifed botanical examinations in this col the work commences with a description of the eleme
targans of vegetables. We are ourselves strong We are ourselves strongl
better to descend from th of the opinion that it is better to descend from the
elements, and then for 200 pages we have not only a and injure their scythes. In every conntry they are Eletch of the principal systems of classification of actively hunted, and there are even professed molerccetables, but a notice of the characters of each natural order into which they are divisible with the names of the principal genera. Then follows a chapter first grand divisiou of the volume.
first grand divecond division contains the general principles of gardening, and the operations employed in practice.
Here we have first the conditions dependent on climate, together with the modes of supplying artificial heat to the soil and air. Then follows an account of the varieties of soil and necessary manures, together with the means of suid with advantage about radiation, m matter which is little understood by cultivators in general, but which is perhaps one of the most important matters in cultivation, a thorough knowledge of the hygrometer being quite as desirable as that 70 pages. The remainder of the volume is occupied by details as to the different implements and practices employed in thej cultivation and propagation of plants, together with notes and rotation of crops, and lastly a treatise"giving a slight sketch whin plants are exposed, a subject which for practical purposes would require a whole volume.
Such are the contents of the work before us, which from its nature is rather calculated for reference than extraction. We shall however briefly advert to a few
of the matters it contains, which will serve as examples of the sort of information to be found. As a first extract we may give that which relates to cblorophyll.
"Of all the matters, solid or semi-fluid, contained in the cells of vegetables, those which perform the principal part in the phenomena of vegetation are the substances known under the vague name of chlorophyil. It is to these that plants are indebted for their colour.
Chlorophyll appears generally under the form of globules or irregular masses of a green or greenish, or the cells. Its physiological action is still imperfectly knows, but its presence in almost all the aërial vegetables, its abundance, and the place which it occupies in the yourgest organs and those which are most directly exposed to atmospheric influences, leave no doubt that it is of the highest importance. It is consequence plants are more highly coloured in proportion as they are more directly exposed to the rays of the sun. We may indeed remark, in general, that they are so much the more vigorous as their verdure is deeper, and their flowers more vividly coloured, as egards the peculiar tint inherent in each species, and that their vigour is so mucin the
Such observations are of course not without exceptions, but they are illustrated by the fact that many plants which were highly ornamental when first introduced, after a year or two's cultivation in our less
genial clime lose much of their beauty. Phygelius capensis is a case in point, and others are well known to cultivators.
Our secoud extract shall be made from the chapter on the conditions dependent on climate.

Each species in the vegetable kingdom is, so to speak, a living therinometer, whose point from which the degrees are reckoned (or zero) coincides with the sum of temperature necessary to put its sap in motion.
This motion, reckoning from the instant when it comThis motion, reckoning from the instant when it comncreases or diminishes.

The heat strictly requisite to make a plant or seed vegetate, and produce the organs of nutrition, such as the leaves and roots, is in general insufficient to make most cases it requires a greater degree of heat to determine the formation of flowers and the ripening of the
fruit. There is no horticulturist, however small his experience may be, who does not know that many vegetables brought into a colder climate than that from which they originated, and cultivated in the open air may be clothed with a luxuriant foliage, and still never bear fruit. Thus, for example, the Olive scarcely ever shows its flowers, even in the mild climates of Bretagne and Ireland, while the Jujube, though flourishing at Paris, never fructifies."
Acclimatisation is only posible within certain remark is scarcely true that in Ireland and the West of England, Potatos, Turnips, Beet, and Carrots almost universally take the place of corn. The extensive cultivation of Potatos in Ireland arose probably quite certainly from social as from climatic regions, and western counties, including Wales.
wology for room only for another extract, which is an apology for moles, which, whatever their worth may shall, however, speak for themselves.

Moles, though belonging to the tribe of insect injurious to agricultare. They cause, indeed, some plants and gardens by loosening the earth uthder the plants and unrooting them; they are more injurious in which projecting from the ourface impede the mowers

## catchers who go from farm to farm, and destroy multi-

 tudes. However, notwithstanding his evil deeds, itmay be doubted whether the mole is not more useful than injurious. It is certain that he never touches plants, but lives exclusively on subterranean insects, especially worms, maggots, and larve of insects, which are very injurious to agriculture. It is believed that in places much frequented by mole-catchers, as for quence moles have become comparatively in conse quence moles have become comparatively rare, a
greater number of trees and other plants perish from the attacks of maggots, than formerly. It appears even that the trees rendered weak from this canse are much more attacked by Scolyti and other wood-feeding insects than healthy trees, and that they thus become so many foci of multiplication. If this conneconly probable should ultimetely be demonesent it would be a new proof that in nature nothing has been created without some useful end, and it would
resuit, as a practical consequence, that it wour he
ecessany heaceforth to abstanu from the dernedion an animal whose misdeeds would be more than compensated by its services.
We may perhaps give further extracts hercafter, but these must suffice for the present.
In a book of such extent it is almost impossible that sone errors or hasty statements should not occasio.ally slip in. Cellulose, for example, is called at page 11 a quaternary substance instead of ternary; and at page 24 while the property of the spongelets in absorbing moisture is pointed out, in contrast to the surface
which, if absorbent at all, is only so in a slight degree, which, if absorbent at all, is only so in a slight degree, them, especially in an early stage of growth, and aid materially in the work.
We are rejoiced to find that in the description of the cells the old fancies of primary and secondary utricles are exploded, and the whole cell wall, however modified and thickened by after growth, is considered as essen. tially one.
First Help in Accidents, a Surgical Guide. 2s. 6d. By Charles H. Schaible, M.D., Ph.D., Koyal Military Academy, Woolwich. Pp. 225. 12mo. Robert Hardwicke, Piccadilly
If one is to believe a tenth part of the statements put forth by certain insurance offices, there are hosts of accidents to which men especially are liable, in riding and driving, in shooting or bathing, in the pursuit of their favourite amusements, and in the following their ordinary occupations; ladies too come in occasionally for burus and scalds, "and sometimes take poison in mistake for physic. Indeed the chance is not inconsiderable that any particular young man may figure in some accident or other, either as a sufferer or spectator.
Now it very generally happens that no professional aid is at hand, while in many cases the life of the patient depends upon prompt assistance, and in every case the amount of suffering and the hopes of speedy recovery are closely connected with the promptitude and nature of the first help which the sufferer obtains. As a physician Dr. Schaible is perfectly aware of all hese matters, and in frequent interc young men at the Woolwich Academy, the importance of his subject, as it bears upon military men, has been forcibly brought under his notice. He has heard of saved had a comrade possessed the most slementary knowledge as to the direction of veins and arteries. He has heard of excruciating sufferings inflicted with the kindest intentions, and misdirected help proving absolutely fatal.
To remedy such errors, and to direct people aright, Dr. Schaible has written a very useful little book, intended originally chiefly for the direction of soldiers, but calarged for general use; and surely every educated man ought to know as much of the treatment to be adopted on the occurrence of common accidents as shall enable him to maintain his presence of mind, and shall give him sufficient confidence aither to render prompt and efficient assistance himself, or with a well grounded air of authority to direct the efforts of others.
We have carefully looked through this little work, and cordially approve alike of its object, and the way in which that object has been carried out. The directions appear to be very simple aud intelligible, and the importance of getting regular medical assistance as soon as possible, is duly insisted upon.
We are compelled, however, to notice a mistake upon page 170, where, in speaking of the ill effects of breathing foul air, and the proper size of apartmente, it is stated that-" The smallest cubic space for each adult should be-in bodroom, 300 cubic inches; in sitting room, 400 ." This is about the quantity of air required for a single minute's respiration. Probably the word inches is simply a misprint, and for cubic inches we should read cubic feet.

Hardioicke's Science Gossip, No. 1, Jan. 1865. (To bo published monthly.)
This is a very cueap, amusing, and useful publication, which we may safely, recommend, especially to young which we may containing some very good reading, and
much correct information. We shonld recommend
W. M. B. to parsue his atodies of the W. M. B. to parsue his studies of the fly-mould. If he places these mouldy flies in water, he will probably have quite a new world burst upon him, full of interesting
marvels. The extracts from varions quarters are admirably chosen, extracts from varions quarters are lovers of science who hare not the opportanit of seeing the numberless joumals which load the tables of public ine numberless journals which ioad the tables of public obligation for information on matters which had escaped our notice.

As regaris the error in the first volume of Iomdon's Magazine of Natural History, that "the common rosewood of cabinet makers is the root of Couvolvulus
scoparius, common in the Canary Islands, in Rhodes and Cyprus," which we have no opportunity of col lating, we may remark that if the statement really occurs as reported, it probably arose from the fact that the root of Convolvalus scopariua land the reparation of possessing a fragrance rendering it an eijject of supposed commercial interest. The root bore the name of Leãa noel being an evident corruption. of the Lignum Aloes or "lign aloes" of Scripture. A very intespecies of Convolvulus, known under the name of Chiparro, which has the same reputation, will be tound in the Annals of Natural History for September, 1860.

An Aocount of the Progrets of his Grace Henry the first Duke of Beayfort, through Wales, 1861, and Nom Cambro- Britannica. By T. Mneley. IE itec from the original MSS. in the possession of his Grace
the eighth Duke of Beaufort, by Charles Baker, his the eighth Duke of Beaufort, by Charles Baker, his
Grace's.Steward of the Seignories of Gower Kilvey, Printed for Private Circulation. 1864, 4to, ppo vio 284 and 16.
A little before the Great Rebellion, Dagdale went through several of the Midland counties, and made copies of all the inscriptions he conld fint in the churches. The manuseript, consisting of several volumes, still exists at Elastwell, in the possession of the Earl of Winchiisea, and has, we believe, never been published. Dugdnle foresaw the ravages which would struggles. A curious intimation of it occurs in the church at Marholm, the burial place of the Fitzwillian family, where the following inscription occurs on the tablet erected to the memory of Sir William Fitzwilliam
tir Cotrteote goiditre. Belzo ctithi thetante.
No crucinix you see, no fiery brand
The Duke of Beaufort's progress as Lord President of Wales and the Marches thereot, unhappily did not tak place till after the Restoration, when much'damage hat been done, but still in the work before us there are many copies of incriptious which have lung since vanished, and which are of much interest to the archeolo_ist. It, moreover, contains many instructive illustrations of the existing state of society, and many excelient sketches of the mansions where he was received, and of the churches of the country, which are extremely valuable. The book is very nicely printed on cream-coloured paper, and the woodcuts are admir able reproductions of the neat pen and ink sketches with which the MS. abounds, and which we have had the pleasure of inspecting.
One or two inscriptions are given from monuments in France, with a reference to the Duke's Freach Journall, under the title Normandy, but we are afraid that this is no longer in existence, or it would be well worth publication.

## Garden Memoranda

Calcutta Botanic Gardens.-Among the severest losses to Calcutta sustained on shore by the late Cyclone
is stated to be the total destruction of the Botanic Gardens. The valuable collection of plants from al parts of the globe. says a Calcutta paper, which was all the fruit trees and rare plants lately prepared for distributiou, have been thoronghly destroyed. This, it need not be said, is a loss not only to the botanist but to every lover of nature, and every one interested in introlucing foreign plants and trees into India. A long course of years alone can repair the damage done there in a day. Dr. Anderson's energies will he taxed to the uttermost for some time to come, and Government assistance will doubtless be necessary to restore the gardens to auything like their former bearty. Many of the plants that have been destroyed cunnot be pasily replaced in India. Dr. Anderson's house suffered up literally into the gardens. Stately trees whicb lined a also, it is said, been thrown down o atripped of their branches.

## Miscellaneous.

The late Mr. William Cola-In our last week's Obituary the death of Mr. William Cole, of Fog Lane Nursery, Manchester, was annonnced, but the high pusition as a plant grower which Mr. Cole reached
during a period of 2.3 vears, is in itself a sufficient reason why his death should be more prominently noticed. Those who had watched him for the last three or four years, saw that hard work and mental anxieties were telling upon him. The up-hill work of
a world-wide reputation as a most successful plant grower and exhibitor, was no ordinary task, and, as with
thousands of others, Nature gave way, but the name will long remain in the memory of plant growers. Erysipelas and fever laid hold of him, and after a briet illness a peaceful death awaited him. He died Dec. 28, aged 52. Orisinally following another pursuit, cir he at once placed bimelf unde. Mr. Robinson, cardene to - Delafield, Esq., Tunbridge Wells, with whom he remained three years. He then went into Messrs. Cormacks Nursery at New Cross, and we believo ment at the same time. Moth have become eminent, each taking a lead in the two sections of plant growing, and continaing fast friends. In 1841, he went as gardener to - Lewis, Esq., of Blackheath, with Fuchsias, and being encouraged by Mr. Lewis, he followed with Heaths, \&c. In 1845 he became gardener to H. Collyer, Esq., of Dartford, and remained with him until Curistmas, 1853. During that period he fought many a hard battie at Chiswick and the Regent's Park with the late Mrs. Lawrence, and being well matched, Mrs. Lawrence, who at that time stood
high for plant culture, found in Mr. Cole sometimes a defeating opponent. As a sound, practical plant grower, William Cole stood in the foremost rank. He was the friend of such men as Barnes, Stanley, Green, Fraser, May, and others, whose names are well known. Few men have brought into the exhibition tent more specimen new plants than he did. He sought eagerly for new things when at Dartford, and then did his best to
bring them nut as extubition plants. We believe we are correct in saying that he was the first to bring out in this way Rullisson's variety of Ixora javanica, Genetyllis tulipifera, Franciscea eximia and confertifora; Ixora alba and salicifolia, Rogiera amœena and two other kinds, Allamanda neriifolia, Hebeclinium ianthinum and nther plants. We well recollect how he experimented with Stiflia chrysantha, a promising looking subject as it appeared in the illustrations of a Belgian periodical, but which fairly baftled him. In 1853 be was strongly recommended by Mr. Turner as the manager of the Fog Lane Nursery, Manchester, then just started; soon after he became the proprietor, and year after year he fought his way as the most successful exhibitor at the Floral Exhibitions in the Midland and Northern Courties of England. Manchester, York, Hishop Auckland, Ripon, Lueds, Bradford, and many other towns owe much to him, for Cole's plants not only helped their Shows, but spurred gardeners on to similar successes. He was occasionally blunt in his manner, but we are certain that regret for his death will be univereally felt. The expression used in a letter to the writer of these remarks by a well known exhibitor in Scotland, who defeated Mr. Cole at Glasgow last August, will be shared by many, especially by those who knew him best, "We have lost a truly clever man." He has left sons, three of whom will carry on the business as usual, for the benefit of the widow and family.

## Calendar of Operations. <br> (For the ensuing voeek.)

Few spectacles are more attractive than a well grown bed of Ranunculuses, and it is to be regretted that the sight is so rare. A few solitary patches are occasionally met with, but a large bed, containing 150 or 200 distinct sorts, is so seldom seen, that those who have had the privilege of leisurely contemplating such a sight will not readily forget the pleasing impressions it produced. The bed, if properly planted, will be covered with a carpet of soft green leaves, from among which, at intervals of 3 or 4 inches, will rise the slender flower stems, surmounted by beautiful variously coloured blossom3. As the roots will not require to be planted for a month to come, let us hope to induce some of our readers to attempt the production of such a bed. In its formation choose a spot in the lowest part of the grounds, where the rays of the sun will only fall for about three or four hours a day, either in the morning or evening, although the former is much to be preferred. The soil of the garden may be taken as it is, without any admixture, unless it is very poor, may be added. Dig up the bed thoroughly to the depth of 12 inches, and leave it rough until frost has pulverised it. Then level, and after some heavy rains have settled the soil, any time in February the planting may take place. In the meantime, however, carefully survey the domain, and cantiously choose the site, which should be such as will best secure fresh air, moisture, and shelter in the heat of midsummer. That done, boldly commence operations, and in an hour or two you will have done all that can at present be accomplished.
flower garden and plant houses,
The plensure to be derived from a garden at this season depends much upon neatness and cleanliness in every department. Lawns should be carefully looked over and cleared of dead spray from trees, worm-casts, drc. Walks should be freed from weeds, and neatly rolled-operations which in the majority of cases require attention rather than much additional labour. In
plant houses the principal work will consist in keeping them and their inmates scrupulously clean.

Moderate fires, and frequent washing will be necessary. heads to blanch on dry days; protect also from hard Conservatories, and indeed all show houses, should frosts.
now bo gay with forced plants, of which a supply must heat as often as may be necessary.
Azaleas.--If an early display is required, a few of the most forward plants should be placed where they can have a temperature of from $50^{\circ}$ to $55^{\circ}$. Water
carefully when necessary, and in mild weather ventilate freely.
Camelijas.-Some of these will now be in flower Water must therefore be liberally supplied, and air given tolerably freely during fine weather.
Cinerarias.-These require careful attention in the way of watering. Do not place them so close together as to touch ons another, and be sure to keep them secure from frost.
Chinese Primrosks.-Plants in bloom should be introduced to the greenhouse or conservatory, and others brought on to succeed them as their beauty fades. Do not let them suffer from want of water.
ike blossoms of this hardy Jasmine have such a cheerful look at this time of the year, when flowers are comparatively scarce, that a few plants of it should intermixed with green-leaved plants, they have a fine effect.
Pel.argoniums.-These must be kept free from dead eaves and insects. Specimens intended for flowering in May should be placed as near the glass as possible; let the temperature at night be about $50^{\circ}$. That for
the later blooming plants should not be above $40^{\circ}$.
Solanuar Capsicastrom. - This, together with S. Pseudo-Capsicum and other sorts bearing small round bright-coluured fruit, are very useful at this season for purposes of decoration. See therefore that those in conspicuous situations do not suffer from want of water, especially if unavoidably placed in the neighbourhood of hot pipes.
Violers.-Both Neapolitan and Russian varieties will now be in flower, the latter out of doors. Let the pits in which the Neapolitan is grown, have plenty of air while the weather is mild.
Forced Flowers.-These will at present consist chiefly of Tulips, Hyacinths, and other early blooming bulbs, of which successions, equal to the requirements of the establishment, must be at short intervals continually introduced into the forcing pit; as must also be Azaleas, Roses, Lilacs, Rhododendrons, and plants of that description. See that they have a healthy moist atmosphere, which must not, however, be over warm. A temperature of from $70^{\circ}$ to $80^{\circ}$ will be ampiy sufficient for the present.

## Forcing garden

During open weather like the present, fire heat should be used with as much moderation as possible. Keep an eye to the maintenance of constant successions of crops.
ads.-Make a bed to succeed that in use last month. On fine days draw off the lights to allow the heads to acquire their natural flavour and colour
Cucumbers.-Keep down thrips and red spider on these by maintaining a moist healthy atmosphere.
Figs.-Trees in pots may now be started, beginning gradually at first and increasing both heat and moisture by slow degrees as the plants progress in growth.

Mushrooms.-Prepare horsedroppings for beds to succeed such as may soon become exhausted.
Peaches. - Give abundance of air during the day, keeping gentle fires at the same time, so that during the present mild weather little fire-heat may be required at night.
Pines.-Plants intended for fruiting during the summer must now have careful attention. Let them bave a steady earth temperature, and a top heat of about $65^{\circ}$ at night. It is not too early to excite the general stock, which, however, must not be allowed to become drawn.
Vines.-See that there is always a steady warmth in the covering on the outside borders of early houses. Attend to the stopping and tying in of young shoots as they advance in growth. Let Hamaburghs have a night temperature of about $65^{\circ}$. Muscats should be kept $5^{\circ}$ or $6^{\circ}$ higher.
hardy fruit and kitceen garden
While the weather keeps mild new fruit trees may be planted. Where old trees too are not growing well, a portion of the soil might be carefully removed from their roots and replaced by better material. All unoccupied ground should be rough dug, trenched, or ridged, regulating these operations according to the nature of the soil and the character of preceding and contemplated future crops. Keep frost, should it occur, out of fruit rooms, and remove all decayed fruit. Diligently proceed also with pruning, nailing, and training.

Apples. - Let all trees infested with insecta have a thorough cleaning and washing with Gishurst Com pound, used according to Mr. Wilson's directions.
Beans.-If not already done, plant Egrly Mazagan in arm situation.
Cauliflowers.- Keep slugs from these, and should severe weather set in, see that the plants are properly protected.
Exdive-Continue to tie up some of the finest

LetTUCE.-Protect in very bad weather, but expose reely on all other occasions. Sow for an early crop. PEAS-Sow some early kind in a warm situation and protect with Fir branches or dry Fern in severe weather.
Rhubarb and Seakale. - Continue to introduce into warmth successions of these, as plauts in use become worn out.
Strawberries.-A few may now bo pushed forward; but do not drive them too fast, or the blossoms are apt to become "blind." During mild weather those in
frames for succession should have pleuty of air in the day time, but at night the lights should bo put on in order to secure them against frost.

STATE OF The WEATHER AT CHISWick, NeAR LOMDON

## The (axtitultural Gazette.

Where manure is plentiful, and produce commands a ready sale, the soil in the hands of the energetio cultivator becomes a mere machine for converting the one into the other. So far from itsolf contributing one may almost say anything whatever to the result, it becomes euriched by the process. Thirtr, fifty, even seventy tons of Cabbages and Greens in two or three successive crops within the year, 12 to 20 tons of Carrots, eight to a dozen tons of Potatos, followed by ten to fourteen tons of Onions, and these again succeeded by Greens and Cabbages, are rielded per acre. As soon as one crop is off another is put in ; the only respite is in the winter time, before the Onion crop, when it is left bare for a season's frost. The land is being, perpetually robbed. As much as 40 s . an acre every year is paid for the mere commission of the salesman of its produce. The only rest it ever gets is an nceasional crop of Wheat or Peas. Otherwise if that be otherwise, it is perpetual robbery which is suffered by the land. This is the history of most of the market gardens around London.
But this is only one side of the picture. Notwithstanding a robbery so constant and so heavy, the land inoreases annually in fertility; for the supplies of dung are as abundant as the sales of produce. Eighty tons of dung per acre are not an infrequent dressing in the year. When three crops of Cabbages are takeu, as they sometimes are, between the last crop of one year and the first of the second year thereafter, at least two of these are dunged at the rate of 40 tons an acre; and the land is worked so as to enable it to feed all this enormous quantity into the roots of plants. It is drained, it not naturally, artificially; and it is ploughed to the full depth of the staple, i.e. 10 to 12 inohes deep. We saw the process going on the other day: there were a number of three-horse teams in a 60 -acre field turning over the Potato land deep for the Onion seed time of the coming spring. A heavy aressing of manure had been applied the previous March, and a heavy crop of Potatos had been removed. The land had been well tilled during the growth and in the removal of the crop, and now it was being turned, still full of fertilizing matter, nearly 12 inches deep; and it will lie aud gather titness as an Onion seed bed during the ensuing winter.
A sufficient depth of soil, better a free than an
natural drainage, which must be afforded artificially if Nature does not furnish it; deep and thorough tillage; the nuighbourhood of abundant supplies of dung upon the one hand, and of an insatiable market for produce on the other: these, together with an energetic activity which will takc advantage of them to the utmost, are what create the most intensive and successful agricultare known to English farmers.

All this we saw the other day between Plaistow and East Ham on the east side of London. Mr. W. Adams, of Phashet Hall, East Ham, succeeding lris father and grandfather before him in the same ocoupation, has now for many years been the tenant of 800 acres in that neighbourhood. The magnitude of the business will be gathered from some of his annual items of expenditure. His annual lakour bill exceeds 6000l. 70 horses are employed upon his farm; his rent, rates, tithes, and tares amount to upwards of $5000 l_{0}$; his payments to Covent Garden and other salesmen for commission on the disposal of his produce amount to 1500 l. \& year; his contracts for manure extend over many of the largest stables, breweries, and cow-houses in London; his total payments amount to close on 20,000 l. a year. We do not suppose that there is a larger manufactory of food for London any where.
Perhaps the most striking illustration that his experience furnishes of the unusual stgle of agriculture which is here pursued, occurs in the adoption of an occasional crop of Wheat or Oats (of which about 100 acres are annually grown) as a "rest." That which is the "soourging" crop in ordinary agriculture is here adopted as a relief from the severity of the general cropping.

Cabbages taken year after year from the same land are found to be attacked by the root disease called clubbing, which shows itself very shortly after transplanting from the seed bed; and in order to escape this risk and "sweeten" the land generally for the other greeu crops, it is necessary both to retain some portion of land for the seedbeds which shall be always altogether new to the Cabbage plant, and also occasionally to take a grain crop, during which the land shall have a chance of hardening and acquiriag that condition of both texture and composition which perpetual yield of abundant fallow crop destroys.
The principal crop grown apon the farm is Cabbages. The East Ham Cabbage is planted at all seasons of the year. Planted at intervals of 12 inohes by 20 or 24 in autumn, it yields a crop of greens all through the winter and early spring months. Ploughed up as soon as possible in spring, the land is again covered with plants dibbled in at once about 16 inches by 24 , and in 10 weeks another crop is ready; and a third is generally taken in autuma, the plants being dibbled in, and if necessary, watered individually from a water pot, as they are planted in August, and they yield an autumn crop. The first crop of Greens, perhaps after Peas or other grain crop, may have been heavily manured; in that case the second probably was not manured at all, but ithe third would again be heavily dressed. The land on the removal of this crop is deeply ploughed and left till March or April, when Carrots perhaps are sown without manure. These are pulled in summer, washed and bunched for market-the work being undertaken by a man digging, women and boys and a man washing and tying, at the rate of 7 s . per 20 dozen bunches; and as 50 dozen bunches a day may be accomplished by a party thus constituted, large wages are earned. After Carrots possibly there may be time for a crop of Greens before the next spring's Potato planting. Here, again, a heavy manuring is applied; and after the Potato harrest the land is deeply cultivated for Onions.
But the rule which is thus desoribed is not invariable. Whenever occasion offers a crop of Cabbages is taken, and to this end seed-beds are continually being provided for use at any time of the year. On the occasion of the first Potato failure, which ruined many growers around London, Mr. Adams promptly sold off his orop, being early convinced chat it was to be a general luss, and he got but 10l. an acre for it; but his land was no sooner bare than he had it manured and ploughed, and in 10 weeks' time a Cabbage crop for sale was ready, worth $30 \%$. an acre. This crop is sent into marizet almost daily throughout the year in waggon loads of 260 to 300 dozen, and these are disposed of by salesmen, who charge 8s, a load for their commission. Potatos in like manner are sold on a commission of 58, a ton. The waggons bring baok loads of dung of about 4 tons apiece, which the waggoners take to the field, and it is
thrown ap for 4d: : a load, and this is afterwards turned before use for $\$$ To a y yard. The digging of Potatos, dibling of Cabbages- - s. to ot 103. . per aore for 2 feet and 1 foot intervals respeetively; the cleaning of the Onion crop, about the pulling and washing of Carrots and Parsiips, are all piece-work. The labour bill, varying from zol. a week in winter to nearly paid over in detail to a number of foremen of the sereral contracts which have been entered into. These are either 3odies of men, on terms of share and share alike ; or where man, women and children are employed, they are, as far as posibibe, family parties, having a common interest on the result.
Beides the principal orops whioh we have named, Mangel Warzels are oceasionally grown for sale to the extent of 30 or 40 a⿱omeres annally, some 10 acres of Rhubarb are cultivated, an ocea.
sional orop of Peas is taken, and as already said, sional orop of Peas is taken, and as already said,
about 100 aores of corn are grown. The ohief crops, howeerer, are Cabbages and Carrots, Potatos, and Onions, and of thees, taken in sucoeession, six to eight crops may be grown in the four years, and at least three of them are heavily dressed with manure from stalls and stables; probably 120 tons of dung per acre may be thus applied, or 30 tons per acre per annum, and the land will have had at least eight deep thorough ploughings.
Rent, and labour, and manure during these four years have annually cost from 20l. to 300 , an acre, and the produce of course has been proportionately large. Over some portion of the farm there will follow, after, perhaps, a erop of Peas, another four years of pretty mueh the same style of management. Over a considerable remainder the seoond four years will include Wheat and Vetches, and other crops less intensely cultivated, and more in acoordance with the rules of ordinary farming. And over some portions Cabbages are never taken, in order that seed beds may be provided perfeetly fresh to the erop, yielding plants, therefore, with the least possible liability to disease.
The land abont Enast Ham lies in large and open fields, and is admirably adapted for steam enltivation; and Mr. ADAMrs is on the point of introducing the steam plough. It will be almost the firse introduction of it into the business of growing vegetables for the London market, to which it is nevertheless so perfeetly adapted. For although Mr. Sireprakd, of Lewisham, who employs it, doess oultivate for the London market, Yet his is muoh more of an ordinary farm, obeying
the common rules of arable cultivation, than that the common rules of arable on
which we have just deseribed.
Perhaps one of the best lessons which the eultivation here affords is one which may be uefully read by Mr. Eluis, Mr. Mrciil, and other enthusiasts on the value of London
semage, who think that by an fow hundred tons per aere, containing abont 1 ton of solid matter in 700 to 1000 tons of the liquid, the demands of a rapid and abundant regetable produce may be met. Do they think that this is to satisfy the wants of a large suceulent growth? Let them ask Mr. ADass, who applies 40 to 80 tons of solid dung per acre, when he wants excessive growth of that kind - who indeed applies 25 to 30 tons per aere over the whole of his green crops annually. This, even admitting that it contains a large proportion of water, is the quantity corresponding to 20,000 or 25,000 tons of the sewage, which when used at a much smaller rate than that per aore, is deelared by them to be applied with such outrageous wastefulness.

The West Riding Justioes are interposing to forbid locomotives on turnike roads. In at least one district of Yorkshire Sir Grozae Grey, obedient to the remonstrance of the magistrates, has probibited owners of threshing machines and cultivators drawn by steam, from driving them atong public roads between down and midnight. On the 30th of Deeember, Mr. Joris Rowbortour, part owner of \& ateam threshing machine, was
 village near Donaaster, to Arnthorpe, at 3 ,'clock
in the afternoon, and was aceordingly summoned before Messrs. Aldam, Walier, Coore, and Frask and sir Isach Mobley for negleoting to comply with the Home Secretary's order. He admitted being on the highway at the time named, but denied that he was passing from one place to another, declaring that he was merely moving his engine to and fro to try it after it had undergone oertain repairs. It was quite impossible to make oureh
a trial at atight, and he was sabjeoting it to this test
in the day time in order to see if the alterations made were effeetual. The Bench made farther inquiry, and on aseertaining that the engine had actually passed from Cantley to Arnthorpe, they fined the defendant in the mitigated penalty of 18 . and costs, and the police were directed to give notiee to toll keepers that they must warn all persons pasing through with steam engines that proeedings would be taken against them, and that they are liable to the penalty of 10 l , for each offenoe.
We do not wonder that the Wakefield West Riding Steam Plough Company have memorialised Sir George Grey to refuse any farther prohibition that may be desired until he has heard the other parties interested in this matter. But who are they that are interested in this matter? We have no hesitation in saying that the mere owners who are being attaoked and fined, and who, as first smarting under the infliction, are protesting, have less interest in this question than the general body of tenant farmers of the country. the Sarsden Estate steam plouygh has, during the past year ploughed and grubbed 726 aeres, and earned 2581 , at an expenditure in all of $75 l$, being 183l. profit, or deducting 15 per cent. for interest and tear and wear on 1000\% the value of the apparatus, leaving a olear proit of 331 . Who suffers by obstructions in the way of sending this maclinery from farm to farm-the Earl of Ducre, who is the owner of it, or his tenants who seek the use of it? They have all their arrangements wasted and upset br these interferenoes. The work may be completed on one farm by mid-
day, and another is ready to reeeive it. machinery could be shifted and placed ready for its work in the afternoon of the same day; but the Home Secretary, at the bidding of the neighbouring "quality"," whose carriage horses do not approve of steam, prohibits its removal, and the whole business of these farms is hindered and upset. Of course the time is coming when looomotive steam threshing maohines and steam cultivators will be commoner on common roads than even the carriages of coanty magistrates, and when the latter will hardly be able to oclaim preeedence on a fair consideration of the interests at stake. But it is to be hoped that long before that time we shall find both the magistrates end the Secretary of State anxious rather to facilitate than hinder the greatest improvement in modern agriealture.

## rational sezding.

1 zxocose for publication in the Agricultural Gazette correspondence respecting
in behalf of ohllienge
Rational in beaalf of Rational Seeding. If my proposed
conditions are in any way unfar, probably gome of your readers may take the trouble to suggest their amendment. My only object is to show practically that a crop may now be confidently relied upou from a seeding less than one peck. per acre, and I wish the trial to be as fair a one as is possible upon two soils so different in value. Preed. P. Hallett.

1. To Mr. Hallett.- I see in the Gardeners' Chronicle you challenge the United Kingdom to produce a seven acre field of Wheat equal to the one you have sown 7 gallons of sead upon, quantitiy and quality to be taken into consideration, and straw also, I presume. Will you allow me to ocecept your challenge, although $i$ know I stand bnt a poor chance, as none of my Wheat is out of ground yet, having gown so very lately. Chas.
Bates, $D$ agenhlam, Essex, $D e c$. Bates, Dagenhiam, Essex, Dec, 24, 1864.
The following is the challenge at p. '1236 (1864), referrei to :
"Rational Seeding,-In a recent Number ' Experimenter', stated he band a small piece of Whent planted at lese than a peck per acre. In support of the causo of
 that 1 have a field of 7 acres drilled (in one day, witit
only the ordinary expense) with 12 ( 2 gallons of wite only the ordinary expense) with 12 2t gallons of, ol white
Wheat on the whole 7 acres, which is and will be open to thelingpection of any one who will give me an intimation oi his intendel visit. The wirevorn a thacked it seererely, but I will venture to challenge its produco per aere anid its millers' value per quarter against any other 7 -acre feid in the United Kingdom to be now named. The soil op my field in a poor one, and no manure was or will
be applied to the crop. Pred. $F$. Hallett, The Manor Howese Bighton.
 seediug, $I$ beg to no in the canse of "Rational conditions. I an glad youn have accen thed foll beeng you Lave told me your land is worth $3 l$, an acre, and some of the finest Wheat land in the kingdom, while mine ie as an yon know from inspection, of a very different
character character, and was callied by thic late Mr. Sumuel Druce,
of Eynuhum, worth soim Of Eynahum, worth some 12. ant acre; the advantage
will therefore will therefore be greatly on your side.
In the firist plice I shall aakk you to be so good as to farriah me with a map showing exactly your 7 -acre And next that the in compes.

Morton (iflie will be kind enough to act), and troo Four other impartial gentlemen of standing, have of them to te practical farmers and half practicial milen who are to decide the following points:-

1. Quantity of produce per acre.
2. Millers' value per quarter of produce.
3. Millers' value per acre of produce points to be the winner, and the owner of these threy pay 10 guineas to cover the expenses of the othert will inspect the growing crops just before harvert mber appoint some one to see them thresbed and dresesed take for their adjudieation one sealed sack of eachecrero and to furnish to each of us a certifificate of the quamit produced.
My soil, from deficiency of staple does not prodmen
Wheat weighing more than 62 lbs , the imperither Wheat weighing more than 62 lbs , the imperial buake which is to be duly considered by the jury in their decision, otherwise the advantages would ive too mach on your side.
I have made no mention of the straw, as I know no means of making it practically assume its just valne (and that only) in the decision, but I feel even more confidence upon this point than upon the others.
If either crop become destroyed by accident or other wise, so as to render the comparison uniastructive and useless, notice to be given by the owner to the othe party by the 1 s $t$ July, and the affair to be at an end If your approve these proposed conditions, I will be their insertion in the Agricultural Gazette.
I assume that your Wheat is "thick-seeded," and the difference will be added to my produce by the jury
Whatever the result, I hope some deductions valuable to agriculture may be practicable, and my object will be attained. Frederic F. Hallett, The Manor Howse, Brighton, Dec. 27, 1864.
inst., I sent your letter In reply to yours of the 27 c inst., 1 sent your letter to a friend asking him to make
terms with you; he states his inability to do so, hence the delay; I therefore propose that you ask Mr. Morto a to make such terms as can be carried out, and that shall not be to the prejudice of either party. For myself, I do not care so much about bhe terms, but as I an in this instance the representative of the views of the majority of British farmers, I must be careful how the trial is conducted. You may consider that I have accepted your challenge to produce 7 acres of Wheat as good as yours. Charles Bates, Dagenham, Dec. 31.
4. To Mr. Bates.-I have sent our correspondencs to the Editor of the Agricultural Gazette for publication, with a proposal that any of the readers of that Journal should suggest an amendment of my condition if they are thought unfair in any way. Of course you must at once name your field, as I do not challenge any F. Hallett, Manor House, Brighton, Jan. 2, 1865.

## WOOD PIGEONS.

[The following letters have appeared in the Times newspapa (1) In your paper of the 13 th inst., "Philornis" wood pian as resolved on by many this and neighbouring counties. Allow me through your pages to attract the attention of those interested in this and other supposed pests.
The wood pigeon decidedly prefers the seeds of plants not useful to man; wanting those, lee, of course, due damage to the farmer's crop. But is the labourer not worthy of his hire? If they take the seeds, are they not taking "away the noisome weeds that withonts profit suck the soil's fertility from wholesome flowers?" In a dozen of crops of the wood pigeon cut up lact year, nothing was found but noxious weeds The sparrow prefers, as I have olten seen, au insect to 8
seed. I have observed flocks of them in my carden busily employed in Pear, Plum, and Peach frees, while only a fir degraded tastes were basy at my Peas.
It is amusing to see how complacently the farmer looks on the rooks as they follow his plough in late
autumn or early spring, when the birds are perfurnis atutum or early spring, when the birds are perfon
for him gratuitously the function of scavpiners on land; but when they attacis his Twruips ther services are forgotten, and death is the sentence passed upon them. Let the farmer extirpate the crows, and the worms will soon do the same to his Turnips.
The evil done by these birds is often seen: the eril avoided very rarely is apparent. Let me give your farmer-readers a fact which came under my own obser-
vation. The late distinguished President of the Roye Society of Edinburgb, Sir Thomas Brisbare, wal desirous to extirpate all the wasps on his property, per 100 dead wasps he paid to the boys, and $2 s$. $6 \mathrm{ch}_{0}$ every wasp s nest brought in. What was the con
sequence? In two years the place was infested lito sequence? In two years the place was infeated
Egypt with a planue of flies. The cause was clear, for Egypt with a placue of flee. The cause was clear, the wings of insects.

The wasps were, therefore, doing their duty as conver. vators of the "balance of power," much better observed in nature than in Europe. Let not the farmer seek to destroy this balance; reduce by all means what pests, but extermination is folly. Let the farmers
rid of weeds, they prill stop the food of the wood pis at a time when it cannot roh them of their crops; to set forth on a mission of axtermination will infl
us a plethora of pigeon-pies, and shortly reduce th

## 

(2.) In support of Mr. Bryson's plea for the maligned and persecuted wood pigeon, allow me to refer to a paspace in the Highlands" (Colonial and Home Library, vol. xviii. page 119). The author, a true sportsman, and m.) menh maturalist, and in pronf of his own favourite axiom ot at every wild animal is of some use to man, he derermined to shont some out of an immense flock of wood pigeons busily at work (March 8 ) on a field of
Clover, beionging to the farmer, which hal been under Clover, beionging to the farmer, which har been under
Barley the previous season. He accordingly killed Barley the previous season. He accordingly killed
eight of the birds, and immediately opened their crops is the farmer's presence. Every pigeon's crop was as full as it could possibly be of the seeds of two of the worst weeds in the country, had found on the surface of the ground, these plants ripening and dropping thei seeds before the corn is cut.
Mr. St. John truly remarks, "No amount of human labour and search could have collected on the same ground at that time of the year as much of these seeds
as was consumed by each of these 500 or 600 wood pigeons daily for two or three weeks together. Indeed, during the whole of the summer and spring, and a con. siderable entirely on the seeds of different wild plants."
Mr. Bryson says as to the utility of the sparrow and other small birds. I kept a young chaffinch, which had quitted the nest but was unable to fly, for a considerable time in a cage outside my bedroom window, and all the time one of the parent birds (the cock) came constantly throughout the day and fed the young prisoner through the bars of the cage with caterpillars and other insects. A great many of these destructive pests were thus destroyed for the food of one young bird daily. Would it be possible for human hands to do the
cleverly and well? J. W., Edinburgh, Dec. 22 .
(3). Farmers are taunted with making grumbling a part of their profession, but surely they have a reason for complaint in the fact that they are constantly being
instructed in their business by persons who know nothing about it, and advised, rebuked, snubbed, or what is worse, patted on the liead and called "intelligent" by people whose special fitness for the office of Phil
Philornis," dating from Oxford, has raised a dis. cassion in your column3 on wood pigeons, and thinks Scotland to reduce the being made in some parts of shortsighted."
In support of his opinion he quotes Morris's British Birds, where, after giving a list of the plants and seeds apon which the wood pigeon feeds, the author expresses Mr. Sto John, in his "Wild Sports in the Highlands reads the farmers a similar lecture upon exactly the Moray Firth, or "Philornis" at Oxford, ever' saw a flock of wood pigeons as they are to be seen in the grain districts of Scotland. The word "pest" has plague. The vast congregation darkens the air, and far as the eye can reach into misty distance the endless
train extends. When they alight in a field, it seems as if a blue cloud had bodily descended upon it. Mr. Alexander Bryson, who follows "Philornis" (and who is an admirer of wasps as well as wood pigeons), speaks truly of the "balance of power" in the " bird creation; been destroyed as regards these pigeons. In the first place, it is only since improved cultivation introduced has been attracted in such clanmmbers from more northeon districts; and, in the second place, the "balance of power" was destroyed when game preservators alinost magpie. Those writers who think that because the therefore innoxious are entirely in error. The bird is an epicure as well as a glutton, and its weeds bear the same proportion to its corn that Falstaff's balf-penny worth of bread did to his intolerable amount of sack. As illustrating the wood pigeon's powers of destruction in winter, I may mention that some years ago I had 20 acres of Rape-seed which was attacked by such mulin one week, , et the picons sent to watch it killed 1200 up every particle of the crop. Then in summer, though each bird has his crop crammed with corn till it resembles a cricket ball, the food consuned bears no proWhertion to the food destroyed. They fix on a part of a Wheat field where the grain inclines to one side. They trample it flat and beat out the corn with their strong straw.
Mr. St. John lets slip a sentence which gives us a hint as to his affection for the wood pigeon. He says truly it is an admirable gamekeeper's assistant. Let a poacher set his foot in a wood at night, and instantly man can be traced by the loud clapping noise of the watchful birds as they atart from the trees.
Mr. Bryson seoms more cruel than the
Marquis of
"Weeddale or the East Lothian Society. He says:food of the wood pigeon at a time when it cannot rob them of their crops." This includes nearly their whole food. Then, were it a rook (an agricultural saint, by the way, compared to the wood pigeon), I would decline aring Mr. Bryson for an adrocate. He says:-
amusing to see how complacently the farmer looks on the rooks as they follow his plough in late autumn or early spring, when the birds are performing for him gratuitously the functions of scavengers on his
land; but when they attack his Turnips their services are forgotten, and death is the sentence passed upon "s It
y amusing to see" how completely Mr. Brysun misapprehends the two raral acenes here described The rooks while following the plough may, indeed, by some rare chance pick up a stray grub, but they are
there for the purpose of feeding upon the earthworm, one of the best, if humblest, auxiliary cultivators w have; while the presence of crows among the Turnip fielis in early summer indicate3 the existence of grab. They are then never disturbed, as their operations ar "Philornis" that there are birds more aleserving of sympathy than the wood pigeou, and persons more worthy of censure than farmprs. I see in the Field with horror and disgust, that there is a club of fishera at Stockbridge wlio have declared war against king
fishers, and have during last summer murdered 34 of those rare and beautiful birds.-Yours, \&c, Rober Skirving, Camptoun, East Lothian.

## Home Correspondence.

Poisoning by the Meadow Saffron and the Yew.-The sudden death of a horse employed in one of the Madeley coal-pits has been attributed to the hay which it
received cut up into chaff, containing the Meadow Saffron (Colchicum autumnale). The plant abounds in this neighbourhood, but as the cattle appear to avoid no ill-effects seem to result to the animals from grazing where the plant grows. From the Colchicum being cut up into chaff with the hay, it is supposed that the horse in question had no power to reject the noxious herb. Would you, or any of your correspondents, be so kind as to inform me whether any ill-effects have before been noticed from the presence of the Colchicum in hay or in pasture? It is generally believed about here that browsing the Yew in the green or living state innoxious to cattle, but that when either dry or only partly withered it becomes a violent poison. May also ask for information on this point? Geo. Maro Benthall Hall, near Broseley, Jan. 4. [Browsiug green Xe is generally believed to be harm
haps our readers will state their experience,

## Foreign Correspondence.

Awamos, Bumpos Arbes.-As a very large numbe of emigrants from the three kingdoms have found their way to Buenos Ayres, and many are almost weekly arriving there, for the most part dedicating themselves lands and sericulueal and asion live of the country, with other incidental matters, may not be out of place in the Agricultural Gazette, or uninteresting to its readers. I will, therefore, endeavour to give a compatible with the space you can appropriate to toreign matters.
It will not be an unprofitable digression to point ont here the class of emigrants who are calculated to thrive in this country, viz., practical shepherds and breeders with a moderate capital, who can at once purchase land and stock. Shepberds hardy and thrifty, men who while young have intelligence and energy sufficient to win their way to competence, and the moral courage to resist the "bottle" under the temptations thereto presented in a solitary sort of life in the "plain." Sober and intelligent farm labourers, sufficiently young to nould themselves to modes of living and custom entirely new; handy fellows who can work with any
team or any yoke. Also good journeymen, tradesmen, team or any yore.
and female servants.
The province of Buenos Ayres is, par excellence, 30 or 40 feet of level. A rich alluvial plain, without wood, watered by sluggish streams and dotted with shallow lakes and pouls, some of which are mere deposits of the rainfall, aud others formed by the opening out of the rivulets as their cousse debouches
on to the lower lands. Myriads of wild duck of endless variety, shipe, plover, swans, geesp, curlew spoon-bills, flamingo, herons, turkeys, et multis aliis, and other ground-buitding birds do on the lesa low lands.
Except near to the towns and a few particular districts, in which considerable quantities of Wheat and Maize are grown, there is no cultivation; grazing in the plain, sheep, cattle, and horses, is the busmess of the country at large.

The plain, or campo, as it is called, is clothed with herbige, or parched and brown, according to the season, and greater or less rainfall. Nothing could be more varied, and in its way nothing more beautiful more varied, and this alar-st boundless plain, cargeted
racts of the Spotted Medicle Clover, with its broad leaves of rich green (with a black spot whore our own Clover has a white one), (rom among which peep the fine points of Grasses, which witl take its place ns the Trifolium dies down (this, as well as nearly all (ur Grasses, is anuual), vast trac's again of Ryegrass (annual) mised with many spreading panicled Grasses, and interspersed with wild flowers of varinus colours; here and there come broal pitches, of scores of acres,
of Scarlet Verbena, brilliant to look upon, others of purple, white, or pate pink; then perlaps a carpet of purple filwer, the "Flor Morma." stretching miles-a sheet of water, or a mirago which looks like orie, reflecting with magnified and elongatel reflection groups of cattle, or it may be the few trees which are planted about the houses of the "Estancieros," or landowners; or one or more of those grand looking
"Ombre" trees, which are dotted here and there, may be a league, or may be two or three leagues distant.
At other seasons we have leagues of the wild Chamomile, apreading its clustored flowers and híding tre crasses helow. But pronably the mont remarkablo aunual 'Thisthe, variegatel leavel, growing \& or 10 feet high, so thick as to be utlerly impenetrable except where cattle have-single file-worked tracks through
it, and among which thousands of cattle hrowse hidden

## entirely from the eye

These Thistle beds cover the country far and wide at a certain aeason of the year (spring). It is when in flower that it presents so remarkable an appearance; as far as the eye can reach, standing high in one's stirrups to bok oper them or from a little higher around that usual, on all sides the flower of the Thistle presents an all but unbroken sheet of beautiful rose purple colour. In districts a ride of a dozen leagues leaves the traveller still with the Thistle bed stretching to the horizon. This after seeding dies away, the whole plant stems, us thick as a man's wrist, virtually dissolve iu a brief time ander the action of sun and rain, leaving scarce a trace on the ground. In its place an autumn Grass covers the ground, in its turn giving place to the young Thistle plant, springing in dense inasses from the fallen seed, and presenting a vast carpet of green and white, the colours of the leaves.
It is not always that tho manifestations of rich but ere are presented to view. There being scarce any spring and the auturn, when all is brown and parched In an unusually dry season there is scarcely a vestige of vegetation, the mamals subsisting on the dried roo sof the faded herbage, and in extreme cases dying by thousands for want of food and water. From the nature of the country, thiniy populated as it in, it is
natural that pastoral pursuits should prevail, and as I have said, such is the case.
The great pastoral farms are of two descriptions, or a combination of the two. The larger and more distant from the capital are almost exclusively devoted to cattle breeding. Large herds of semi-wild cattle and horses are reared und pasturel on these "estancias," as they are called, many of which are of great extent compressing 8, 10,15 , or 20 square leagues, some of the estancieros counting 20,50 , or 100,000 head on "heir pnssessions, all of which bear the owner? "brand." The cattle are divided into convenient "herds," which are under the charge of "Puesteros," who have their huts or houses on different points of the land, each having a given tract for the grazing of the als. These men have their tropilla of tave horses and generally the charge of a "Yeguada," or troop of wild mares, many hundreds in number, with which run their progeny of unbroken horses.
Each of these "puestos," or stations, has its "corral," a staked enclosure for driving in the animals for whatever purpose may be required; and there is also a piece of ground near to each station called a "rodeo," 0 which the cattle are brought upand settled to rest at night by the men in charge riding round them, from process it talee ite name, and through which the animals are prevented from becoming absolutely wild This is the means also used to tame them when they have become wild.

The great anuual events on a cattle 'estancia' are the marking (branding), and "cutting" of the young cattle and bulls. On these occasions the neighbours are invited to attend, and have thas an opportunity of parting out cattle of their own respective "brands" which may have strayed into the neighbouring herds The scone presented at a "branding " and "cutting " is very animated'; the animals are driven into a "corral, where they are lassoed and drawn out, thrown down and the operation performed; when the lassoe are loosened the enraged animal frequently gives chase to the horsemen, and he who is not on the alert run the chance of his horse being gored, and himself hurt or killed.

Loud shouts, laughter and jokes, express the excitement of the picturesquely accoutred "Gaucho," the most expert of horseinen, on the occasion of these "Chevies;" a dance and other merry making which have been sold tor slaughter is anothe event in the Estanciero's life; some hundreds, or thotsands, are sold of a certain age and condition, and these hare to be picked out from the herd; for this pur-
pose trained bullocks called "señaleros" (or decoys) are off the animals parted out. The "tropas" being thus formed they are driven off to the killing establishments, a distance in some cases of 80 or 90 leagues. To drive in a herd thas formed it is generally considered that the staff of "peons" Bufficient for the purpose is one man for every 100 adimals. The advance guard or detachment consist of a "tropilla" of horses for the use of the peons or drivers, and these follow the lead of a follow these in advance of the cattle to keep them. from rushing forward, the other horsemen disperse themselves conveniently for keeping the animals together, and pushing them on at a slow pace. In the evening the cattle are rounded and settled to rest, the men slauglter an animal, picket their saddled horses, light a fire of Thistle stalks, bones, or anything they can find, and roast their supper.

The cattle are a long-horned hardy breed. Isolated attempts have been made to improve the breed by crossing with the Short-horned and other British bred
cattle; the result of these attempts las been as a rule cattle; the result of these attempts has been as a rule
a financial failure, which I conceive was only to be expectea, inasmuch as the cross of a highly and artificially made animal was sure to degenerate when subjected to rough treatment and acquiring wild habits of the native eattle; moreover, when the hide is the chief value of the animal there is no field for compensation for the expense.
I conceive that the improvement of the breed should commence in establishments of lesser magnitude, and near to the town, where greater care could be taken of them, and their qualities as beef and milk yielders would have a better prospect of telling. A few parties had foreseen this, and there are a few establishments at convenient distances from the capital where the breeding of oxen and dairy cows promises to take root and prosper, and from a nucleus thus formed an improvement will be gradually effected to the great advantage of the country; and at no distant period I conceive it will be practicable and profitable to feed the crosses of the Short-horn and Hereford to an extent which will render the beef sufficiently firm to take salt pickle and become an important item of export.
The other pastoral pursuit is sheep farming, and ivals in importance that of the cattle
During the past 25 years this branch has had a wonderful development, and has gradually spread itself, driving back the cattle establishments year by year to radius of about five leagues from the city are chiefly occupied by villas and agricultural farms, and from that distance to about 30 leagues the chief "occapations" are those' of sheep farmers ; at the same time the sheep farms are by no means confined within that distance and in many of their more distant establishments the Bro pastoral branches are united.
British residents in the country ("campo") have mainly dedicated themselves to this occupation, and there are a great number of our countrymen"well to do" to "wealthy" sheep farmers, some renters of land or owners of land, of half a league 1000 to 50,000 squeep; and others are part owners of flocks, or have a proportion of the increase of flocks in lien of payment for taking care of them. No business in the country has increased to such an extent, and no "stock" improved so much in class or value. Twenty years ago the average value of a flock of sheep was from 4 f. to 6 f. per head currency, equivalent to, say an average of $10 d$. to $1 s$. sterling per head. At the present day an average flock is worth 40 . to
45 . currency per head, and the fine flocks of superior 45 f. currency per head, and the fine flocks of superior
crosses 300 f. to 400 f . per head. Young rains bred in the country from imported sheep have been sold as high as 5000 f . currency per head, and third to fourth cross rams 500 f , 1000 f , to 2000 f . each. A square lengue of land is assumed to suffice for the grazing of 10,000 to 15,000 sheep.
Sheep farms are conducted in a similar manner to the cattle "estancins ;" "puestos" (or (stations) are put
up at convenient distances, and are provided with "corrales" formed of hardles for use when required bat in fine weather the sheep are frequently left in "rodeo." Each flock is under charge of a shepherd, who interest in the wool and increase of the for one-third usually comprises about 900 to 1000 sheep in the first instance, and is allowed to increase according to the pastare room to 1300,2000 , or 2600 , and sometinies to Whioh is cnt on the ear.
The wethers are sold for the market when opportunity offers. In most instances the "rams" are allowed
to run with the flock, but in the better regulated esta blishments they are taken away and formed into a flock by themselves, and are distributed at the proper season. A shepherd having one-third interest in a share of the wool ans sheep will not carn from his arricultural labourer, bat at the end of the "contract," it he has been careful he will have a third of increase, which will more or less make up the difference.
The wages of a shepherd are not quite so high as those of an agricultural labourer, which are about, in
(say 50 s. to 66s.), according to the skill of men; this, equal to a wage of 17 . to 24 s. per week.
The shearing commences towards the close of the month of October. The breed of sheep originally in the country was a coarse-woolled long-legged animal, fleet of foot, lean of flesh, and scarcely eatable; this was crossed by the "merino," and by continuous crosses, classes oi sheep were produced yielding wool of various grades of fineness, the finest closely approximating to the "merino," having a plump carcase of delicate-flavoured mutton.
Of late years it has been found that the wool had deteriorated in quality and staple, probably owing to feeding, as they were wholly dependent on "pasture," which, owing to the excessive stocking of land, was too irequently scant in the extreme. Several year y influenced this
Moreover, the fleeces were found to have become
very light, not yielding in many cases $2 \frac{1}{2}$ lbs. per fleece. A remedy was songht in new blood, and several of our English breeds were introduced, such as the
Leicester and Southdown, but these crosses have not "nicked," probably from the wide disparity between the breeds and the inferior quality of the wool; pltimately the Negretti and Ramboulette breeds have been introdnced for the purpose of crossing, and with highly satisfactory results when extra care has been The cross the flocks, and the land not overstocked.
The cross with the Negretti has augmented the whole, the cross has been a decided "nick." The Ramboulette cross has been equally, if not more, successful; iarger carcase, much heavier fleeces, and longer and stronger staple $\rightarrow$ matter of great importance, inas nuch as exceedingly fine and delicate stapled wool are
relatively much more prejudiced by the relatively much more prejudiced by the presence of
burr than longer and firmer stapled ones.
The sheep farmers have hitherto made no provision for the sheep, while at the same time they have overstocked the lands, an evil the greater where almost all the Grasses are annuals; the consequences have been very serious losses, for neither food nor water have they had in many districts where drought prevailed. In some instances whole flocks have disappeared, and
others have only been saved wholly or in part, by others have only been saved wholly or in part, by
being removed in time, and dxiven 20,30 , or more being removed in time, and driven 20,30 , or more
leagues to lands more favoured, or which had had but little stock on them. The past year was a calamitous one from this cause, and it is only to be hoped that sad experience will have taught them to be more provident.

The value of lands has increased rapidly during the past 12 years; 10 -fold is under the mark; a dozen year ago, $80,000 \mathrm{f}$. would have purchased a square league
of land in the most favoured districts for sheep farming recently $800,000 \mathrm{f}, 1,000,000$ currency, has been paid for a square league of land for sheep farming parposes. Such prices are however excessive Lands within the agricultural radius have increased in value at much the same ratio, 250 to 300 f per square $=15 s$. per acre, was the price of agri-
cultural farm lands at a distance of 4 to 5 leagues cultural farm lands at a distance of 4 to 5 leagues
from the city; to-day it is worth ten times that, and more in some districts. We have now four main lines of railway working in the country; two are already open to traffic in part of their extent, and their influence on the value of property is very great; these iron arteries virtually radiate life through the country they raverse.
(To be concluded next week.)

## Eocietios.

Midland.-A long discussion on "The tenure of land" has just taken place between the members of his Club, at Birmingham. It has extended to three of their weekly meetings, and it terminated in the adoption of the following resolutious:-

1. A stamped agreement, bearing the signatures of the contracting parties, shall be entered into, and any concession from the stipulations therein contained shall appear at the foot of the same before the signatures are attached.
2. A twelvemonth's notice is most desirable.
3. Landlord in all cases to represent the in-coming nant.
4. To pay for all compost and all the manure in the yards, and all the unconsumed hay and straw, at the market price, less the expense of carting the manurs from the nearest depôt. That under the altered circumstances of the times, when the great demand is for meat, it is necessary to give encouragement to its production by giving to the out-going tenaut some share of the money value of the cake and corn used during the last year of his tenancy, and that it is an especial necessary to improve the Grass lands, and therefore some remuneration should also be allowed for food onsumed on either old pasture or seeds.
5. That at the commencement of a tenancy the farm shall be inspected by qualified persons, who shall fill up a properly prepared schedule, showing the general state of the cropping and the state of fertility of the
various fields, and at the end of the tenancy there various fields, and at the end of the tenancy there
shall be a similar inspection to decide what permanent
improvements have been made, which shall be paid fo the outgoing tenant shall pay to his landlord such sum as the arbitrators shall a ward.
6. In the opinion of this meeting no restriction
should be placed upon the tenant selling anything the produce of the farm cropping of the laud

That as it has become necessary, in order to render amount of canital in the cultivation of the soil a largo exercise great skill and industry, and use the athon to care and economy in every branch of farm management it is the opinion of the Club that permission should be given to tenant farmers to destroy the whole of the rabbits upon their farms, and that where there are woods and plantations, the landed proprietors should undertake the destruction of those pests of the farm an the only means of preventing the serious losses which are now experienced in so many localities from injury done by rabbits to ordinary fences, and especially upon is of opinion that the breeding generaily this Club confined to warrens and waste lands, and that they should never be permitted to remain after land has been brought into regular cultivation
8. Cottages: That the landlord shall provide sufficient cottage accommodation, and if the tenant requires any new cottages beyond those stipulated for upon taking the farm, the landlord shall be paid five per cent. upon any outlay not exceeding 100l. each.
The only opposition was to the seventh resolation upon which Mr. R. Fowler moved the following amend

That no reservation of rabbits by landlords be made, such being prejudicial to good husbandry and public policy, and contrary to the spirit and letter of quantily of game be preserped by lundlords compena ion for injury to crops be from time to time ascertained by arbitration, and paid for to the tenant."
A further amendment was moved by the Chairman is
"In place of valuations and compensations, the who question to merge in one of rent. Then will be established a game rent in contradistinction to a farm rent and the landlord, being a game preserver, will know what he is paying for his share on the stock on the farm.
On a show of hands being taken, there appeared for Mr. Fowler's amendment, 9; for the Chairman's amendment, 6 ; for the original motion, 14. It was then resolved:-
That the following gentlemen be appointed a Committoo expressed in the ofbove resolutions, and that they report to

The meeting was then adjourned to the 26th of Januany.
[Since the publication of these resolutions the following letter has been addressed by Mr. Randall, of Ever sham, to Mr. Masfen, by whom the discussion wal opened :-]
I am sorry that you did not say, when asking me to bea
member of a committee appointed to prepare $a$ form of agreement to be submitted to the Earl of Lichffeld, that the Midiand Counties Farmers' ${ }^{\prime}$ Club had adopted certain resolutions which
were to form the basis of that agreement. I was not aware of were until I saw the report of the proceedings in the Midland
Counties Herald; and as I am entirely Counties Herald; and as I am entirely opposed to the more
important of the resolutions which your committee have no
choice but to act upon, I have no alternstive but to ask you to let my name be withdrawn from the list of that committee. ings, and if I stayed away I might be supposed to concur in
the resolutions which had been adopted. I will state, as briefl as I can, why I do not coincide with you, and consider the resolutions seviatim.
course; but if the terma of that agreement have been well considered, why need you provide
2. Twolve months notice.-Undoubtedly desirable; but it
questionable whether the possessor of an entailed estate hat
power to agree to this.
3. The landlord to
3. The lardlord to represent the in-coming tenant. - He does 50
of necessity, where the farm is not re-let. When it is, this

London : Subjects for Discussion in 1865.-
February 6.-Middle Class Education.-Proposed by Mr. Edmunds, Rugby.
March 6.-The Breeding and Management of Pigs. Market
April 3. -The Management of Grase Land.-Profeasor Coleman, 150, Leadenhall Street, E.C.
May 1.-The importance of Shelter and Covering to the Farm and the Homestead.-Mr. J. Bailey Denton, Woodfield, Stevenage.
November 6. - The Management of Benefit Societies in the Rural Distric
December 4.-The Breeding and Management.of Cattle.-Mr. T. Duckham, Baysham Court, Ross, Herefordshire.
A Silver Cup, of the value of not less than 10 guineas, rend during the year. Members unable to attend these meetings are invited to forward practical information upon them. Their letters will be handed to the introducer of the subject to which reference is nade.
The discussions will commence at half-past $50^{\circ}$ clock P.M. There fare no meetings in January, June, July, August, September, or October

Cazbmarthensirire : Entry to a IFarm in Wales -The following capital illustration of this from actua experience was given by Mr. Buckley at a late meeting years ago I tools to and entered upon a farm, say here years ago I took to and entered upon a farm, say here,
in the vale of Towy, if you please, upon the Silurian formation. It was a farm of the average quality, and of about 230 acres extent, reaching from near the river to the top of the hill. About 60 acres of it in the bottom were mostly very wet, and some 20 acres was ; about 140 acres lay on the side of the hill, and was tolerably clean land, but most of it wanted
draining; and the remaining 30 acres were still higher up, very precipitous, and nearly covered with furze and only parts that and the 60 acres of meadow were the only parts that the former tenant had not had under and exhausted, and been all periodically broken up worn out." The rent at which I took this farm for more than year. It had never before been let landlord granting me a lease for 14 years, and ex. of ming the outbuildings a little for the accommodatio course, well lock, I paid the additional rent. I had, of exarse, well looked over the farm before I agreed for it, oxamined its soils and the capabilities for drainage and experience imemente, and felt quite satisfied from capital of $1600 l$., which answer my purpose. I had a management and economy, help me through. I ought to have had 2000 l . for the undertaking, so that my
progress at first was somewhat more slow. I entered upon my farm at Michaelmas, found upon it a rick of rough hay and a moderate-sized heap of dung in the land, and for these I paid him. My first business, after having got my drainers fairly to work, was to select several fields of the driest and most suitable land to following spring were appropriated as follows :12 acres to Mangels and Swedes, on which I
expended the whole heap of dang, besides a good quantity of superphosphate, 12 acrea to Barley, and 12 to Oate and a little field of 3 acres to Wheat (that 1 might not have to buy bread), all of which I dressed with artificial manures, chiefly gaano; my great object being to procure as good a supply of roots and straw as I possibly upon which I was just entering, I had very little stock indeed, and did not commence buying any until the new Grass afforded a bite in the spring. I also shut up
my meadows, and a couple of fields my predecessor my meadows, and a couple of fields my predecessor
called Clover, with the like object of a good supply of food for the following winter. Through the spring and and heifers, and some cows to set my dairy going. These I selected with great care, preferring to pay a good price for what was low-priced and inferior. They were all of the native black breed, which I considered would answer my purpose better than any other. Not but that I am a great admirer of the improved fargurite breeds of Short-horns, Herefords, and Devons, and have no doubt that upon our best and most sheltered farms, under such culture as I have intimated, they may be sept profitably ; but they must have all that such farms can afford, and an allowance of oilcake aud something else as good besides, to keep them even at par; whereas the native blacks (if well selected) will, with a little better keep and extra protection and care, soon show
striking improvement, and tell you that it is time to take them to market, and a few pair of handsome three years old black steers or in calf heifers are always a ready sale at a good price. I had besides, I must confess, a considerable predilection for the blacks, since seeing some noble specisens from North Walesexhibited at the Smithfield Club and felt convinced that by selection and careful breeding they might be brought to rival the noted Scotch breeds, such as the Galloway, that fetch the highest price in the London market. Of course judgment, perseverance,
and time are required to bring them to so high a point. and time are required to bring them to so high a point. nto detail, and it must suffice to say that by the end of the fourth year I had brought the farm into a fair course of cultivation, and on the highway to a much better state of thing. Kaving ploug oep, brose had not oxhausted, as I had thought, the crops being much better than I bad calculated upon. My means of sup porting and adding to my stock increased year by year and with it my power of extended manuring, maixing me gradually to discontinue the large use or art. M dairy produce and sales of stock had also increased in like proportion. Fifty acres I had broken up to be continued as arable land under a regular course of alternate cropping, as stated. The remainder of the 140 acres was in Grass, and had become far more luxuriant and fine in quality under the treatmenc named.
I must now run over a little more in detali my mode of cultivation. The whole of my ploughing is done in the autumn during the winter and do not again touch it until seed time When by the use of Coleman's cultivator, $\boldsymbol{R}^{2}$ roller and harrow,
s fine deep tilth is produced. With roots (crop No. 1), I manure beavily-say with 15 good cartloads of dung. $4 \mathrm{cwt}$. . of super
whosphate, and 1 ewt. of common salt; and this crop, which
s usually a heavy onc, is carted off the land early in November is usually, havy one, is carted off the land early in Novomber, and ploughed in, the land renains as before through the
\#inter. In the month of March, by the use again of the
cultivator, roller, and harrow, the Barley seed (crop No. 2) finds a congenial bed in a deep and rich soil, ints which it is

a light dressing of three or four loads per acre, and immen
diately plough for the Wheat or Oats (crop N. 4). If for
autumn sown Wheat, I turn the furrow slice over and drill or

more certain cropand larger produce, in which case I work th

Wheat. Thus, by the circulation of the course, every Gel

that has been going the rourops of Clover off, valued at, near
2 tons per acre eaht crop, and followed this year by about the
largest crop of Wheat I ever reaped.
y. Drainage.-My draining was carriod on siusal. taneously with my other work from the beginning. I at first got on swimmingly by having fortunately hit apon the source of the water or springs in several instances, which I tapped, and led off the water, some times hy a single drain, and by that means, laid dry a onsiderable area of land at little expense; but other parts of the 140 acres I could not thoroughly dry without cutting parallel drains throughout; and the work became laborious and expensive, and, at length not a little discouraging, for it was draining away my money almost faster than I could find it.
During the cold dull days of winter it whin indeed a mont nncomfortable and choerless occupation. I beomene foarful as ony health; and, as to the poor men, their condition was
often piliable-seeing them in the wet clothos in the
morning damp, master". said one of them, half up to his knees
a water. "Why, yes, it is, John," I repliod. And I felt
it so too, not abnut my foot only, but my pirita were
damped that morning. My purae Was draining. I fand
faster than the land, and a great deal had yet to be done aster than the land, and a great deal had yet to be done.
A little reflection, bowever, set all right. Former oxperionco
assured me of the reault. Golden harvesta and green meadows
 ducks, but the quantity of wator was such, during the winter
months, that the overflow pipe not only merred to turn my
daily-at-work ohafi-cutter and root-mincer, but would work apy three-horse power machine, when required, until about the close of my sixth year aha my farm was fairly drained,
excepting about 40 acres of the boggy moadows; and, to attempt that, was quite too formidable and expensive an suade him to take it in hand, offering him 6 per cent. on the outnot but see how admirably the draining I had doue answered and what an ?mprovement it would be to his estate to accomplish let wholo. He replied that he had not the least idea, when he valuable stook and crop and productive dairy. I must be out to him some of the neighbouring farms in I protehed poverty-stricken condition, and assured him that they ware improvement. He thought me rather and equally capable of dide to effect the drainage of the boggy meadows, and said he It was at length arranged bosween us that I must drain the years to my lease, and extead the accommodation for m stock in the way of additional sbeds, for I had been put to al Kinds of temporary contrivances for their winter protection. expect a considerably increased rent at the expiration of my that I or my son might probably offer him 501. a year more, addod " no one shall have the farm at anything near what yon
or your family shall have the offer of it at; ant an applicant
without ample meana, should nut havo it at any amount of ront deteriorate the farin to make capital and pay me ; and the end would probably be that it would be thrown on my hands we partod, with a good understanding as to the futvore.
Nothing, then, it appears to me, can be more plain than two conclasions. The first is, that it would have been very unwise in me had I done all that I have without the security of a lease; and the second is, that it would have been equally unwise in my landlord had be granted a lease to a tenant without adequate capital and knowledge of his business, as it would have been bar to the improvement of his property, and the advan tage, if any, would have been all on one side. The egitimate deductions to be drawn are-that men of capital and requisite agricultaral information are the great desideratia for Welsh farms, as they are indeed the great panacea for poor farming every where; and that such men should be attracted to the soll by proper securits and tenure, for, without that, they cannot be expected to invest their money, and will not do it.

## xicbictus.

An Address on the Condition of the Agriculturat Labowrer and his Cottage Howe. By E.W. Moore, Coleshill. Simpkin, Marshall, \& Co
This address, delivered at a meeting of the Oxford Farmers' Club, was referred to at the time in these columns. Mr. Moore, who spoke at the recent general meeting of the English Agricultural Society on the education of the children of agricultural labourers, and was then answered with such warinth by Mr Acland, has done well to publish his lecture delivered ong before, in order that his sentimenta on the condi tion of the labourer may be fully known. His assertion at the discussion before the English Agricultara Society was that children are educated at our parish schools both beyond and below their future life-beyond in matters which it can never be of service to thom to have acquired no fitness for the work on which they ave immediately to enter. Mr. Acland's rejoinder pade with great rehemence, was that he had hoped that it was understood education was not for the pur pose of making better tools of the poor children-better hedgers and ditchers, but better men and women-the soul rather than the body needed education, and it was to awaken the soul not to drill the body that chools were wanted. It is plain that truth was uttered both by Mr. Moore and by Mr. Acland; but in one opinion Mr. Moore's was the wiser speech of the twa They were, of course, mere. words in both cases-
bat in one only were they words attered for a purpose Which words are able to accomplish.
It was fair to assume, as Mr. Moore was right in doing, that the members of the Society addressed were interested in the welfare of the labourer ; and, admitting that we all desired the real advancement of these which in the spirit of it was to actuate them rightly all through their life, should have some special fitness to the station and the occupation in which their future livelihood was to be obtained. Given, common understanding as to the ultimate object of the whole training given at these schools, wise words temperately attered by a man of known experience could exert a useful influence on the mere details of management, and we believe that those of Mr. Moore on the occasion referred to will not be lost.
On the other hand it was unfair and ill-judged to asanme, as Mr. Acland was wrong in doing, that the members of the Society wished only to make the children of the agricultural labourer better drilled that the real advancement of these children is not in every case so heartily desired, it was unwise to raise a prejudice by speaking of them as half starved creatures, and of the general body of farm tenantry as desiring to keep them down.
And even admitting that their employers are not always fully alive to the real interests of these children, angry words on sucb a subject, intemperately uttered, are incapable of bringing about that right mind which is desired. It appeared to us that Mr. Moore used words just for a purpose which words can serve, and was silent where sience too is best, leaving example and home labour to do their work towaras the spreading a right influence, without any talk to help, or more probably, to hinder them. And it scemed to us that Mr. Acland used words for a purpose which mere words will never serve; and was silent on a subject on which his experience no doubt would enable him to speak with great authority and usefulness.

Te happen to know very well how long and earnestly and quietly the author of this pamphlet has laboured for the good of all around him; and his pages here, just as his words at Hanover Square, have all the force of character and experience to back them. Both have the same good end in their purpose in either instance. And whether it be the useful instruction of the child, or the diacent object, it is as they shall severally serve to educate in every respect a better population that they are desired. The pamphlet before us is chiefly directed
to the discuation of the cottare question ; and both descriptions of the state of things as in too many nected with things as they ought to be, are supplied, The subject of wages is also discussed, and a great deal lected and publisbed.
The mischievous effect of the law of settlement is illustrated; the evila due to beer-houses and to drunkenness are alluded to; and finally, education is defined and illustrated and urged with a large heartedness and fullness and force which will satisfy, we hope, even Mr. Acland himself.

Instruct children in the two great commandments on which hang all tho law and the prophets, and if you have done responsibilities of life than, though neglecting this you had
taught then all knowledge beside. Education commences in
earliest infancy-before the child can understand a single
expression - and it continues till the end of our earthly
course, girls should have a similar training, to fit them for
domestic service, whick would prove not only useful to tho whilst so occupied, but especially so after thes have entered pue resposibe bre
These are the word of a man of long experience in country life, and long acquainted with the relations of the owners, occupiers, and cottagers of country parishes. We hope that his excellent address here published, may have a wide circulation.

## Farm Memoranda.

Wheathampstead, Herts.-At Wheathampstead ny attention was directed to a farm, the management of which is the very converse of the mode of farming too common in Hertfordshire.
The farm consists of 317 acres, of which 26 are in not very productive Grass land ; 56 acres of the arable are upon the strong loam of the higher levels, and the remainder is of a lighter character, rather a sharp flint gravel, somewhat under the average quality of chalked from below, according to the custom of this county. The fertility of the farm is maintained, not by selling off the produce and trusting to London and other extraneous sources for an equivalent, but by developing and trusting to its own internal resources
The following list of animals fatted and sold from the farm has been vindly furnished in illustration of
the system pursued :-
Lambs
Sheop
Beasts
Calves
Pigs
$\begin{array}{r}1863 . \\ 392 \\ 356 \\ 5 \\ 50 \\ 198 \\ \hline 1001\end{array}$

The system of cropping is four-course, managed with especial reference to sheep stock. Much reliance is placed on the deep cultivation of the soil, which is principally effected by the use of a 2. Wheeled plough
divested of its mould-board, which follows the twistplough, armed with a share copied from that of the unvieldy and disused old Hertfordshire plough. Besides the usual succession crops of Swedes, Mangel, mixed layers, Tares (to be followed by white Turnips), it is the practice here to sow Rape between the row of Beans on the heavier portion of the farm. certain portion of the ewe flock, which averages 330 head, consists of Dorsets, which are put to a Sussex or half-bred ram; both ewe and lamb are generally fatted for sale, and the stock replenished from farms.
The farm has been brought into a good condition after a somowhat lengthened occupation, by the system of which the following is a slight description. As rearing and maintaining the sheep stock is the leading
feature of the farm management, the cropping the land is ruled by, and has special reference to, carrying out this object. Or the average 330 ewes are put to
the tup; these consist of a certain number of Dorsets, of half-bred and West-country Downs. The first are put to a Sussex or half-bred tup, and bring the earliest with a view to their early maturity and fatting qualities. The lambs begin to fall early in December and the lambing closes with January or early in lambs as they fall are protected by a standing fold placed in a field of Swedes. As the season advances and the weather permits, and as the lambs gather strength they are, with the ewes, transferred to an open fold, where the lambs are allowed a forward run by means of hurdles constructed for the purpose of allowing them to pass to the standing Swedes, which are, as is usual in this part of the county, drilled on the flat, partly because that system is found to answer, and also to guard against the very common danger of the sheen being cast between the ridges.
In addition to Swedes, and Mangel when the Swedes fall off, the lambs receive hay, chaff, cake, and Poas, and go off at weights of from 4 to 6 stone to the London market, bringing at that early period highly generally bought in at a full age, receive oil cake to maintain their condition, and are generally made off as fat; the remuinder of their food is the produce of the farm. The Swede crop, with hay and straw chaff, is the staple of their food in winter. Tares on the fallow generally succeeded by White Turnips the same season; a mixture of Trefoil and Dutch Clover which is sown with the Barley crop in lieu of Clover when it is deemed expedient to make the change, is grazed; Rape sown between the rows of Beans on the heavier portion of the farm fitted for that crop; -these together with the run of the pastures, sustain the flock till they are in due time either made off fat, or again put to the tup. As all the produce of the ewes is made off, the stock of ewes is replenished from fairs, not so much with reference to their high blood as their useful haracter.
It is unnecessary to enter on the details of the husbandry, because it must be seen that so much food could not be raised on a farm without due attention to every operation. Other sorts of atock are also fed upon this farm. A certain number of cows are kept, usually
Weish, as these are better fitted to thrive on the
pastures, which here, as in Hertfordshire generally, 40 calves. Added to this a large number of pies a
various ages are fatted. J. C. C. various ages are fatted. J. C. C.
It needs no further comment to prove that the fertility of this farm is fully maintained by the manum made under this system, which produces so much fa stock ; and it contrasts favourably with the practice which depends on the importation of manure, and by which farms contribute very little in proportion to their acreage under cultivation to wards meeting the increasing demand for animal food, by a daily
increasing population. It is manifest, also, that the mode of cultivation carried out on this farm requires security for the capital invested, and encouragemen to the industry and skill by due fixity of tenure. J. O. O

## Miscellaneous.

Farm Bailiff.-He should be industrions, stim intelligent. He should be first in the morning, and last at night. He should not only order men to their
work, but lead the way; and should on all occasion move from one department to another without deler assisting and directing where requisite, but alway keeping the adage in view, the eyes of a master do more than the hands." He should be as the first porme to the machine, and the best implement on the farm
and should assist his master "to manage the men, not the men to manage the master." He should be punctual and correct in his accounts, honest in hir dealings, and regular in bis business. He should every night note down in a book the operations of the day the labour of the men, the corn and food consumed by the cattle and horses, the corn bought and sold ; and having done this, write down what is required to be performed on the following day, on the opposite side, which the next night's account will confirm; he should then inspect the premises-see that all the locks are secure, the cattle safely housed, and retire early to ber as the only certain step to rising early in the morning He will take care at all times to be prompt and
decisive with the workmen, and if they are found ide decisive with the workmen, and if they are found ifle,
dissolute, or disorderly, admonish them ; if no reform takes place, discharge them. He should on the other hnnd always treat them with kindness and civility, and will not fail to obtain the same kindness in return; h will never allow them to indulge in abusive or bla phemous language or in drunkenness, much less wil he by precept give them encouragement to follow hid
example, or allow them to suppose he can be guilty of such practices himself; and he will do well to discharg all that are in the continual practice of either. H will endeavour to pay them fair wages as the only sur mode to have the work well performed, encourage his labsurers to for labour by the piece, an give it ; and so long as the workmen do the wort properly, continue to give it. By lowering the price by so doing check their exertions and earnings, he wil ins, and induce them work should not be allowed to exceed certain waga weekly, they will always require a great price for the believe is due fur their exertions when tha labour ouly half bestowed. The late R. Baker, of Writtle.

Adulteration of Guano. - (1). Weigh 50 grains of the sample, and dry it completely before the fire. The tom of weight, multiplied by two, will represent the amoue of water present in 100 grains. (2). Weigh 20 graing of the dried sample, and burn it (either on a pioceo exposed to the heat of a clear fire), until the blackness which is at first produced by the charred orgai. matter, las entirely disappeared. If the residue greyish white, the guano is probably genuine assumes a reddish colour, it has been mixed with earbil matters. The loss of weigist, multiplied by five, wily g the am water found by opera tion No. 1, represent the percentage of organic and
ammoniacal matters. (3). Place a tea-sponful of the guano in a bottle; add to is about a table-spoonful quick lime, made into a cream with water. Suare alts produce. the stronger the smell of Introduce the natter which is left on burning the sample of $g$ (operation 2) into a tumbler, and add to it a teaspo of spirit of saits, and about half a glass of water.
a brisk escape of gas, shown by the bubbling up of th a brisk escape of gas, shown by the bubbling up of time
liquor, is observed, the guano is adulterated (by lime liquor, is observed, the guano is aduler mixture a filter formed from a piece of blotting paper, and it from the acid by pouring water over it two or times. Dry the solid residue thoroughly before fire, and ascertain its weight, which, multiplied by fiv will represent the sand and earthy matters contained the sample. Dr. Hodges, of Belfast.

Immediate Running of Deep Drains.-Mr, H. Thompson gave a very lucid and ingenious illastration of the greater quickness of the deeper drain. He hille had glass tubes made, of different lengths, and fille to drip when water was poured on them all at the same moment. If the soil was dry, the short tubes, whic represented shallow drains, began to run first, water was again poured on the tubee, bethey begal
previously poured on had all passed through, they
to drip again immediately that the second quantity o Water was poured on, sand without waiting for the vidently due to the elasticity of the air confined evidenty the free water at the bottom, and that at the between the free water at the bottom, and that at the tubes, of whatever length, began to drip at the same moment. If, however, the tubes, after the first applization of water, were allowed to remain some weeks, the short tubes discharged the whole of the free water, bnt the long ones, representing deep drained land, still retained a fittle free water at top, this free water was immediately discharged, o the deep drain began to run; whereas the short tube or shallow drain, having discharged all its free water, did not begin to drip for some time, in fact, not till the water had percolated through the column of soil.

## Calendar of Operations.

Jasuary. - We continue our reference to the subjectary named in our last Namber as coming under the notice of the farmer during the current month.
4. Tillage Operations.-January is the worst month in the year for these, but we cannot travel far even out of the chalky, rocky, and sandy districte, with good natural drainage, where, if anywhere, land may be moved in a wet season without harm, but we see long teams of horses in the fields even now; they are doing nore harm than good; stubbles and Grassland ought to have been all turned over before this. A thorough shattering of the lind in October by steam power is as good as a summer fallow, and any subsequent move
ment of the land till just before the seed time is not only useless but injurious. Where ploughing must be completed leave the land in ridges, and clear out the waterfurrows well behind it, so that good surface
drainage, needed where the land has been trodden drainage, needed where the la
5. Sundries.-Horse labour is almost entirely confined to work with carts and waggons on roads in soft weather when tiles, stones, lime, and grain may be carried, and during frest on flelds to which manure will continue to be taken. All corn stubbles and Clover lea ought to have been ploughed by this tima: if any remain they hauling, and wheeling of marl, clay, or chalk on the lands appropriate for it may be done any time during winter; of course the earlier in the season the better, as the frost will have the longer to act on them. sheep requiring an abundant supply of litter. During wet weather the men may be employed in preparing compost manures for use in spring. Mixtures
of bones and ashes may be made, and well soaked at intervals with liquid manure. Superphosphate of lime
may be made by the action of sulphurie acid on bones, Salt and lime may be mised- 1 cwt . to 1 ton-and spread on any dry sheltered floor. The contents of shelter, of turf ashes, hurned clay, charcoal dust, charred peat, sawdust, spent bark from the tan-yard, or why the liquid or its volatile parts, or of rotting the more rapidly for its saturation by a substance in the act of
fermentation. Where the system of box feeding is fermentation. Where the system of box feeding is absorbed by their litter, but even here the stable tank remains as a supply for all these purposes. In wet weather also, men may 'lease' straw for use as thatch and then for cleaning the harness. 6. The Sheopfold.-Pal harness
chaff are good feeding for ewest Mr. MacLagan, of Pumpherstone, Midlothian, thus Mr. MacLagan, of

Agricultural Gavetle orthampton, in a late volume of the For shel
and manger for a large covered shed, fitted with rack with the exception of hurdles, open on the other, will be the most convenient building; and close adjoining purpose of receiving ewes with weally sides, for the gevere weather, to accommodate the lambs as fast as gevere weather, to accommodate the lambs as fast as
they fall, until they get a little strength. The sheds rill, of course, open into the lambing-yard, which should The yard should face to so the to the shepherd's cottags. bedded with earth and the south, and should be well insure cleanliness and afford warmed up and comfort to ewes.

Of course, if the flocks are kept in the field, either shepherd, so that he may not only have shelter for himself, buta fire likewise, with the aid of which he can warm gruel for an exhausted ewe, or prepare any onvenient remedy that may be required. The ewes should be visited from time to time daring the night, so as to afford assistance when really required, but not to do so officiously; for although in many cases lambs are lost for the want of assistance, yet in others the ewes are sometimes destroyed by unnecessary interference. One rule of importance should be borne in mind, which is, that manual assistance should be rendered to assist and not to control or oppose the efforts of nature The cases most frequently requiring assistance are those where the presentation of the lamb is unfavourable, and where the lamb is dead. The ordinary presentation, it is well known, is with the fore-feet parts thus presenting themselves in the form-the wedge. Sometimes the head and at others the legs are bent back, or the fore-feet may be coming together, or the lamb may lie on its back. These are false presmall hand and skilful manipulation to turn the lamb, or push back or bring forward the parts that are mis placed. In some cases this cannot be done without the lamb than the ewe. Sometimes the hiud parts present first, and then the labour is difficult. With egard to medicine, the following may- be given in difficult cases, more particularly when there is much exhaustion:-

## Opium powdered, 4 drachms; spirit of nitrous ethe be

The free use of Turnips for heavy ewes is to be avoided before lambing. The result of many fact enables us to assign as the cause of warping and water. food.
House Lamb and Warly Lamb are already recoiving in our southern counties the attention of the shepherd flock is abridged from the Agricultural Gazette flock is

Even when the lambing takes place in the months of December or January, it is generally unnecessary to On the other hand, it is not advisable to allow the ewes to roam at large during the night time, as those about to yean are too apt to stray away from the main found dead. A shifting fold should be used, being placed ou the driest and most sheltered part of the pasture field, and removed on to fresh ground every day; and in heary rain it is necessary to take them to a hovel or covered shed. Bat in general, when the net be necessary to put them under cover

If Italfan ryyegrass han heen sown over a certain extent of Wheat, then the ewes with tueir lamhes should now be placed on the best of this in the Wheat stubbtes and on the young Clovers, taking care to foed the Clovers at the day time and the Wheat stubbles during the night. In this manner the owes will give the greatest quantity of milk, and they may be kept upon these Grasses until the lamb is a month or five weeks oid with immense advantage; for the lambs will be found at the end of that time in the best possible condition. At a month old the ram lambs should be castrated, and then the lambs, as well as the ewes should be taken from the Grass and placed upon rootfeeding. It is customary to fat the ewe and the lamb The lambs should feed in advance, and separate from the ewes ; aud, therefore, a lamb-gate should be provided, with space between the rounds to allow the lambs to pass through freely, without being sufficiently wide
Feeding should commence as soon as the shepherd can see in the morning, giving hay first, both to lambs and ewes; after which, the troughs should be filled with cut roots, taking care to have them cut finest for the lambs, which is done by passing them twice through the cutter, which plan reduces the food into a state resembling dice, in which state the lambs can readily consume it, and are induced to feed at the earliest period, without loss of time and without waste. As soon as the tronghs have been supplied with cut roots, then proceed to give oil-cake and Peas, the quantity to allow them as much as they will eat. To prevent waste, let the oil-cake be broken fine-about the size of a Horse Bean is the best size-otherwise great waste will occur; for the lambs, whilst young, will take large pieces up and drop them outside the troughs, where it
is trodden under foot and wasted. To induce them to eat cake or Peas at first, it is sometimes necessary to mix a small portion of common salt with it. The ewes should next receive their allowance of cake, but without ny Peas, commencing with a quarter of a pound per ay, the half of which shou,d be given at this time, the evening. After receiving cale for two or three weeks
the quantity may be gradually incrensed up to a pound per day each, taking care to feed with only half the full allowance morning and evening; and towards the end of the fattening process half a pint of Beans should be given them daily. This renders their flesh more firm, the great objection to ewes fattened while suckling their lambs being, that they are mostly deficient in firmness and quality of meat. Cut roots should be given at times during the day, and the trough quite filled at night.
The lambs whilst young should have hay or hay-chaff twice a day; bat after they arrive at the age of eight or nine weeks, they should receive hay three times per day; the first bait, as has been stated, the first thing in the morming, the second at noon, and the third about 3 o'clock in the afternoon.

The following are actual reports by a Hampshire farmer on this subject:-

Merse of Berviokshire, Jan. 7.-A month ago we reported that, excepting on bare fallows-and that of small extent-no Wheat had been sown. Just then the weather was improving, and some patches of drier land were finished in fair order ; but the resumption of accustomed wet prevented anything being done in the clay country, and many farmers there have not sown a single handful. These men, whose mainstay was fallow Wheat, are largely extending the cultivation of root crops; for a dry spring is favourable to the preparation of their land, and the drought was not materially injurious to Turnips sown in May or early June. Soft weather continued, with a little snow on the 18 th , until the 231, when the air got decidedly clearer. We were thas, during the Christmas week, enabled to secure a large portion of the swede crop in
good order; and on frosty days we got the crop nicely off the wettest land, where it had been stored in small heaps under shaws and earth. This crop has turned out a good one, on good land sown in good season; yet throughout the district you may see plenty of roots no bigger than Apples. The sharp dry frosts of the new year, though not injuring Swedes, had the effect of turning attention to muck-carting, which was rather in arrear. The wind blows strong and fresh to day, and the ploughs are again moving. The rainfall during five weeks is $3 \frac{1}{2}$ inches. Pastures have been unusually bare, and the ewe flock requires a faw Curnips, and hay and straw in hard weathor. Togg affered much from anseasonable so and, in specia instances, heavy loeees were incurred by the use of inperfectly decorticatod Cotton-cake. As a cure fo scouring, as well as a saving of Turnips in dirty weather, we began cutting a month earlier than
usual, besides exhibiting daily a small portion of mixture of Oats and Barley ; and now that the ground is firm, the flock is flourishing. Cattle are thriving on full Swedes, and an allowance Barley meal and Rape-cake, with the immediate prospect of Bean meal in addition. Corn is getting into condition now, and this will be the only thing to harden prices. Barley was extensively grown, and yields fairly; but the finest only is in demand, and good grinding quality can be had for $8 d$. a stone. Oats are a small crop, and bring a shade more money. Wheat we have just tried, and it would seam the best has gone with the wind that shook latter Barley and Oats too. With good foeding corn at just half the price, we are not inclined to use much Linseedcake, except it be for a finishing bite. Potato are a small crop of sound tubers, but of limited acreage; and the county is nearly back to its normal condition of a Turnip-growing district. J. T.

West sussex, Jan.! 10.-We are passing through a mild and very dry winter; the land ploughs up drier than perhaps any one has ever seen it do at this tiune sowing might be goisg on at the same time. A3 it is we shali soon put in the Peas, as they perhape are not so likely to blight if put in early and grown slowly, as they will do if put in about this time. Last year the crop failed so much with us tkat we feared good seed would hardly be got, but such is not the case, as there is a good supply brought from some other places, and the price froun 40s. to 42s. The land being so dry, ploushed up early, so that it may lay and got a littlos firmer, especially for Barley and Oats.
The winter being so mild, has saved the bay very mucts and every week it becomes more diff.
cult to diapose of. But we think a great
mighate ig often made in being too sparing with it, though perhaps this year that will not be so much the case, roots being so scarce.
The lambing season for early Southdown is now on, and as may be expected, goes on well; the lambs are strong, and losses are fow. But roots will be short, and corn or cale must be used largely. We prefer Oats given to the ewes, which we think tends to keep them in fuller mill and healthy : and cake given to the lambs ground fine and mixed with a little chaff, and no more given than will be eaten up clean every day, as sain tends to make it unpalatable. As a matter of course work is well forward. We never cart out dung to pat in heaps in the field, as our land being heavy and rather wet, we do more harm round the heap than is rectified for a year to come. And as we like to apply the dung fresh and long, we never care to turn it up to rot, preferring to let it do so in the iand. On light land this may not be so well, though I should be disposed to try it even there. There are not many cattle being fatted in the usual way, the common plan this year is to have rather more than the usual number of store beasts in the straw yards, getting a few pounds of cake or corn to keep them just fresh, and trust to be able to make them out a little on the Grass. G. S.

## Notices to Correspondents.

Arratto: Anon. The following is Mr. White's eatimate:Supposing the matter used to be geuuine annatto, which is a Weat Indian dye ( $w$ hereas the great bulk of the colouring
matter that is used is an imitation of this annatto, containing matter that is used is an imitation of this annatto, containing
turmeric, soft soap, and train oil). yet it is expensive, and, at bent, useless. It coste 78.6 d . per lb . ; and if 6000 tons of dye costs 2250 L -s tax which consumers impose absurdly on thomselves.
Asphalte for Baris: Young Farner. The following are reasons for proferring it to wood:-(1) the imperviousness of asphalte to moisture; (2) the exclusion it occasions to
vermin ; and (3) the preservation of the grain in a sweet state vermin; and (3) the preservation of the grain in a sweet state
from the dryness in which it is kept. Get the asphalte in from the drypess in which it is kept. Get the asphalte in
blocks; and having set up an old boiler near the place, mix gravel with it while hot, and run out the mixture on the surface required to the rhickness of about 2 inches. In a fow hours the asphalte-floor will bear any weight, and it will be found not only better but cheaper than wood., its cost only 7l. for an area which, of Oals, would be 40 L
ahaws, Dunse, N.B., or possibly to Mr. To Wi. Bertram, CranMaws, Dunse, N.B., or possibly to Mr. J. Wilson, Woodhorn you resire.
Concrete Floor: $X$, The following is a recipe by Mr. Lawthe blacksmiths' forges to three parts coal ashes (those from lime from gas-works, to be thoroughly mixed, and then made into a mortar with gas-tar. If the g's tar come from will be sufficiently mixed for the purpose ; but if the lation be soparated, and the tar bs thick, it will set quicker if about when used. Fart of wator be mixed thorougbly with the tar about 3 inches thick in one layer, on an even surface of gravel. or stone broken very small with a sprinkling of gravel over, and rolled down. The mortar may be laid on dry warm weather, if the mortar has been carefully in the floor will set firm in a fow days. For any ordinary outhouse, half the thickness will make a permanent flour.

When Wheat is sown very early in the autumn, a leas than usual amount of guano must at that time be applied, and the rest in the spring. The Wheat otherwise frosts. Artificial manuriant, aud be injured by subsequent and only in quantitiss sufficient for the particular on the tended to be grown, and not with the intention of assieting the succeeding one. Each crop should be separately manured. Guano, before application should be mixed with at least fine soil. It should on no account be allowed to come in direct contact with seed.
Leaves or Graes: 8 P. You had botter rake the laves of fall yuite a covering of the troea aro to thick as to make th
Mowasses: Correspondent. Mr. Keary, late of Holkhmm, has uned it largely. He gives young stock ronts, or Turnips cut good sweet Wheat-straw chaff, moistened with a mixture o molasses and water, about 1 lb . of coarae molasses to $1 \frac{1}{2}$ gall.
of wator, and thrown over $1 \frac{1}{2}$ brashel of straw. He adds-
according to the age of the animal-bran for young calves, Rape-cake for young steers, sbout 2 lbs. per head, and Linseed, aboul 3 lbe. or 4 libs. per head for older steers just about to be fattened. The straw and treacle save the roots, of which about 1 bushel a-d
Soab: $X$. Professor Simonds thus alluded to it :-It is to be cured only by the destruction of the egg of the insect which produces it, in addition to that of the insect itself. The cations were more potent, but they required great care, The best mode was that of sprinkling a solution of arsenic, again and again, over the diseased parts. The preferable form of such solution was that of arseniate of potash, blended with vegetable infusions, such as those of Foxglove, Stavesacre, Henbane, Dock-roots, sce. He recommended 2 oz of common arsenic, and 2 vz of carbonate of potash to be boiled
together in a quart of water until they were diasolved, when a further quantity of water was to be added to make up a gallon of solution. To this gallon of solution, a gallon of vegetable infusion was to be added, made by pouring a gallon of boiling Water over 40 Oz of Foxglove leaves, and allowing the infision to remain till cold, when it was poured off. These 2 gallons of liquid constituted a safe agent and
one of the most potent remedies for scab. Half a pint of it at intervals of a few days, was to be sprinkled (from a bottle, through a quill in the cork) on the skin at the back and sides of the shoep. Two or three dressingg would be found sufficient.
Seede of Wenids: $R$. The following are Professor Buckman's figures showing the way in which a single plant may multiply by seed; the d

SECOND-CLASS

SATURDAY, JANUARY 21, 1865.
mestive for the ensuina webk.

In his celebrated Essay on Gardens, to which we formerly alluded, Lord Bacon enumerates flowere and fruits under eight seotions, suitable as ho suggests for furnishing and decorating so many successive gardens. Perhaps this specification of seasons was intended merely to illustrate his ideas on the subject, for he proceeds to say:-" These particulars are for the climate of London, but my meaning is perceived, that you may have rer per-, petuum (perpetual spring) as the place affords." There are now a vastly greater assemblage of ornamental plants in England than existed in Bacon's time, and therefore more abundant meaus of fittiny out such gardens, yet eight separate departments in the flower garden are not to be thought of in actual practice. In places of ordinary extent, they would very much resemble children's gardens; and it would be intolerable to suppose that only one eighth part of the kept grounds was in perfection at one time.
Subdivision is obviously carried far enough when we have a garden, or rather a seotion of a garden, for each of the four seasuns. Indeed Spring and Summer Fiower Gardens do not offer any very natural point of separation; they ran into each other ; and it is expedient to distinguish them only to prevent dilution and diffusion, by intensifying the respective beauties of the two seasous around special centres. The begianiug of june may be assumed as a convenient transition in poiut of time. The improven modern Mhododendron may be concoived as the Priace of the spring garden,
while the equally improved Rose may be acknowledged as the Queen of the floral tribes summer.
Every one loves Spring Flowers. There is something peouliarly charming in the opening year, in the resurrection of vegetable life, in the gradual influx, and at length the full spring-tide of the multitudes that swell the train of Flora. How attractive is the simple elegance of the Snowdrop and vernal Snowflake, the lavish beauty of the Croous, and the constantly increasing throng of spring-flowering bulbs whose name is legion. Then there are the hosts of Primroses, and Polyanthus of various hues; the self-coloured, or Alpine
Auriculas, as they are now called, and other Auriculas, as they are now called, and other species of Primula, too frequently overlooked or
unappreciated. There is Khododendron dauricum atrovirens from the steppes of the Amoor, which sometimes blooms at Christmas, but which is sure to find a fresh and lucid interval before it is overtaken by its congeners. How miserable to find only a plant or two of this species in otherwise well appointed gardens. Then, too, there are the other Rhododendrons and Azaleas, Lilacs of
many sorta, Daphnes, such as D. Mezereum, D. pontica-Dr. ArNold's favourite shrub, D. Cneurum, and cullina, and many others. In respect to shrubs, we must " mark our cardeas deficient" to borrow Bacon's phrase-deficient both in selection and treatment. In shrubs, there are many nurseries that put our best gardens to shame.

But to return to Spring: it is a beautiful season, but an uncertain one. The sky is uften brilliant overhead; but it is not less frequently dark and scowling. In many places about the end of Mareh, one is reminded of the quaint lines in Christabel :

## 'Tis a month before the month of May,

And the spring comes slowly up this way.
Eren in localities with an average climate, apring is rather a bleak season in Britain. It is
late before the east wind exhausts its chilling breath; and the rell moon of April-the Lune rousse of our neighbours across the Channelseems to shed down a nipping and malignant intluence. These circumstances plainly indicate that the Spring Flower Garden should be in a sunny and sheltared situation. Perhaps the
position most desirable for it may ba found in the position most desirable for it may $b=$ found in the stand apart, as they always ought in do, from the Itheral foroing and more atilitarian glass ranges. house or conservatory, already respleadent with early blooming plants, into the scarcely less attraotive parterres tenanted by spring flowers in in regard to situation; but it is freely admiitod that in the inmense diversity of local circumstances, it cancot always be attained. And it are shelter and sunshine, and a moderately light, rich soil, or the means of improving it, the Spring Garden is sure to prosper.
The peculiar style best fitted for this sort of garden is a matter somewhat difticult to deterinine. will be admitted by all; it is this, that the bloom of spring and summer flowers is individually of much shorter duration than that of the inmates of the autumnal garden. A week's bright sunshine will efface the splendour of a bed of Crocuses.
Even in cloudy weather the seldom retain their beauty for more than two or three weeks. It is much the same with masses of Tulips. It is true order of their blooming, from the earliest $V$ in Thols to the latest Bybloenens, three or four the Tulip seazon for five or six weeks; but of course the earlier and the later sections cannot be shown together. So, the early Rhododendrons come dropping in, from the beginning of April to the middle of June; but it is only after the middle able masses. With suoh materials it is evident we cannot produce that gentral pictoriul effect and which its detractors seornfully call the shawl or carpet pattern. The effects in the their general expression, and more sucoessional. From these emsiderations it seems to resurit
that the spring garden must be in what is called the mixed sarden must be in what is ceons plants, and shribs must be skilfully character of intricacy, and at the asme time a
series of gradational effeets. In this way the tout ensemble may never be so striking, at any one time, as in the autumnal flower garden; but it may be relieved from the disagreeable element of sameness sometimes complained of, the particular effects may be exquisite in their kind, and by hapoy contrivance and foresight on the part of season may be introduced and prolonged.

It will be understood, that when we say the spring flower garden should be construoted in the mixed style, we are not recommending the adoption, or the retention, of the old mixed Hower border. In the present state of the art, that antiquated affair may be abandoned to the botanical amateur, who otherwise may not be able flowers should be massed: only as they are not intended to produce one general effect which is to be broken and varied by single plants, or clumps, or curtains of flowering shrubs interspersed among them. Ribbons may be admissible, but there is
little rocm for panelling, and still less for the old rectangular beds, some four or five feet broad, which used to be the normal arrangement in bulbgardens 40 years ago. The masses themselves need not be very massive, but they should be so intertwined and relieved that flowerless spaces of a few feet in breadth should hardly occur during the whole season.
Supposing it admitted, then, that the Spring Garden is to be laid out in what is called the mixed style, the question remains-what ought to be the ground or platform on which its parterres are to be projected. Uught it to be on lawn or gravel? Should the figures be separated by opinions will naturally vary with the tastes of individuals. With all deference, our preference is in favour of gravel walles. Grass sward, which is so cool and pleasant in summer, does not yield a firm dry footing in early spring; it is hardly ever in tine condition before the first mowing in April or in the beginning of May; but well made gravel walks are serviceable at all times. Besides, they tation which is necessary to secure the successive effects of which we have spoken. For these reasons, we would reserve the well shaven lawn -the glory of Britain-to the warmer and drier seasons of summer and autumn.
The means and applianees for decorating the spring flower garden demand a fuller discussion than our ppase will now permit to us. They Materials exist in abundance, yet in most cases they are not wielded and applied with sufficient skill and foresight. We believe that in this respect the spring flower garden does not receive the tithe of the attention that is lavished on the autumal garden. This undeniable neglect is perhaps not unaccountable, hut it is much to be regretted, and should be amonded if possible. Here we may point to one mistake which might so called, everything that needs awnings and nursing frames, should be exoluded from the flower garden, and relegated to some reserved department attached to the forcing or kitchen garden. The Tulips, for example, in the Spring Garden, should not be florists' flowers, or at least, should not be treated as suoh; they should rather be eelectiuns from the richly-coloured Early Blooming, Parrot, and Double-flowering varieties, of
which the Bulb Catalogues of the metropolitan nurserymen afford such an abundant supply.
We observe with pleasure that the enterprising planted no fewer than 50,000 bulbs of these have sorts in the Garden of the Royal Horticultural Society at South Kensington. It will be a fine sight. We trust every admirer of fine flowers near London, who keeps a note-book in which to onter a promising Verbena or showy Pelargonium, will visit these Tulips when in bloom, and record the names cf those possessed of marked ornamental properties. The same remarks apply to Anemones. There is hardly anything better in the spring arden than the common Poppy Anemone, particnlarly the scarlet sorts. There are various other
species, such as A. apannina, Pulsatilla \&c., that are very useful. Many admirable bulbs are sadly forgotton or neglected in the present day. In old places one used to see doublo Narcissus poeticus, beautiful and fragrant as it has been called. Its many single varieties, such as angustifolius, majalis, serotinus, are
soarcely less ornamental, And on what beds of
Jonquils were we wont to Jonquils were we wont to gaze with admiration many-flowered N. Jonquilla, resplendent in cologle and rich in fragrance-not $N_{0}$ odorus, single or double, though that also is a fine plant. We are sometimes tempted to ask: can gardeners grom Jonquils now? Not many we fear; they keep pottering at them, lifting them, dividing them, drying their roots; whereas soil and situation, being favourable, they bloom in greatest profusion when they have stood three or four years in the same place ; but this by the way. And fine beds, too, we have seen of the Polyanthus Nar-oissus-exquisite at least in their delightful Wour, if not distinguished by brilliancy of colonr N. (Ajax) maximus, and many others, for even a botanioal collection of Narcissi is a sight worth seeing in a flower garden.

We have already pointed to the magnifioent hybrid Rhododendrons, Azaleas, and their con geners; these form an admirable framework or setting for the bulbs and other plants indicated above; and indeed they might furnish out a very noble garden by themselves. As May advances, the various species and varieties of Pæonia come into bloom. Where the olimate admits of them, the varieties of P. Moutan, now almost too numerous, are exquisite additions to the Hower garden. Still finer perhaps, if that be possible, are many of the varieties of the herbaceous species, such as . albiflora, edulis, tenuifolia, \&c. These most beautiful plants have been most unaccountably neglected, from prejudice we suppose, or because people have not taken the trouble to inspect them, To be convinced of their decorative value, the gardener or amateur need only visit, at the propar time, the collection of Mr. Salter at Hammersmith, or that of any other nurseryman who has paid sufficient attention to the family. But these, with the hybrid varieties of Iris germanica, in most climates of the island form the transition to the summer flower garden; and as such we leare them for the present.

We referred last week ( $\mathrm{p}, 26$ ) to some special cases of Grafting Vines, in which results of a decided oharacter seemed traceable to some peculiar influence exeroised over the graft by the stook on which it was worked. The subject, as we have already said, is one of some importance, and we invite especial attention to some remarks thereupon by Mr. Thomson, of Dalkeith, whioh har lately appeared in the Florist. Mr. Thomson, it
will be rumembered, was one of the first to dram will be rumembered, was one of the first to draw sucoess in grafting the Muscat Hamburgh. H9 now writes
"I consider it of great importance that, by the evidence of facts, some just conclusion should be come to us to the stocks on which our high-class but delicato Grapes will succeed best. I have inarched Vines on the Black Barbarossa, and found the Grapes deterioratedWest's St. Peter's, and White Muscat, without any improvement, though with no deterioration. On the Black Hamburgh I have only tried Snow's Muscat Hamaburgh; but so satisfied am I with the extraordinary improvement in this best of all Black Grapes, that have this season inarched a number of young Black Hamburgh Vines with it. On its own roots this Grape orms ragged unshapely bunches, the berries swell unequally, aud many of them shank and never ripen at all; whereas on the Black IIamburgh stock I have had bunches 5 lb . weight, with berries equally swollen, and
well coloured and finished in every respect. I would strongly advise some enterprising nurseryman to work a stock of plants of this Grape on the Black Hamburgh, for one day it must become a most popular Grape grows and ripens in the same house as the Hamburgh,
and rivals the White Muscat for flavour. I have inarched the White and Grizzly Frontignans on Hamburghs this season, inflienced by the effect of this stock on the
the result.
"One caution is necessary for those who may try experiments of this sort-they should take care that they inarch on stocks in good bealth and vigour. sometimes happens that a particular Vine becomes,
from some cause, unfruitful. To cut this Vine down, and graft it with another sort, and if success did not attend the operation to conclude that the Vine in question was an unsuitable stock, would not be a fair inference, when it is considered that the Vine was unfruitful when the experiment was begun, and might be expected to contiuue so, no matter what sort might be
grafted on it, unless some radical grafted on it, unless some radical change was wrought

Thegrd to its general circumstances.
The splendid bunches that Mr. Hiri, of Keele Hall, showed at the London exhibitions last summe were from the Black Prince on a Hamburgh stock, as
under my observation point unmistakeably to the Black Hamburgh as the best stock for that the Raisin At first sight I would have concluded that the Raisin de Calabre would be an excellent stock. The Vine is hardy, grows and ripens its fruit well in a cool Vinery, and is a most vigorons grower; but it seems that it failed with in as far as it sent up more sap than was of vigour, in as far as and burst them. Probably this could be avoided by leaving a more than ordinarily heavy crop on the Vine-a very pleasant way of effecting a cure, if it answerei. trial as a stock; it has many sbould have a fair trial as a stock: it has many
qualities to recommend it. If all who try such experiments would give the results through the press, the matter could soon be settled, and a great boon conferred on Grape-growers.
We quite coincide in Mr. Thomson's last recommendation, and shall be happy to learn what has been the general experience of our readers on this point.

The tribe of One-seeded Cucurbits forms a small but very curious division in that important natural order. Amongst these the Chuchu or Chooho (Sechium edule, $S$ w.) is largely cultivated in warm oountries, as for example in Madeira, where it bears the name of Pepinella or Cahiota, and from whence exeellent specimens have just

been received through the kindness of the Hon. Mrs. Rowley, from one of which the accompanying figures have been prepared, which will be acceptable to many of our readers from the singular mode of germination, though the oultivation of the plant can never be more than one of curiosity in this oountry.
An admirable and full description will be found in Mr. Lows's Manual Elora of Madeira, to whioh we are indebted for the following particulars.
Two varieties are extensively grown in Madeira in gardens aud about houses, one of which bears

pale green flowers and fruit; the other, though better looking, and bearing larger fruit, whioh with the flowers is cream-coloured or white, is inferior in quality.
The habit of the plant is that of a Cuoumber but the annual stems, which are succulent and shining, spring from a large shapeless massive rhisome or root-stook, whioh is corky rather than fleshy or woody. The male flowers grow in short Whorled axillary racemes, and have a delightful Peach-like fragrance. The female flowers are mostly solitary. The stigmas are combined into an umbrella-shaped mass. The ovary like its s top-shaped or clavate above, more or less indisinctly or irregularly five-lobed, one-selled, with
single erect ovule attached by the midale of one edge to the cell wall. The fruit is from 3 to 6 inohes long, and about 3 inches broad above, where there is a large deep narrow transverse umbilicus, the edges of which are more or less puckered. At the base there are four or five irregular lobes or grooves, as in the upper figure In germination, as in our lower figure, the radicle and a portion of the broad flat leafy cotyledons, whioh extend through nearly the whole length of the fruit filling the cavity, protrude from the fissure, the plumule making its appearance at one side. The coarsely ragged and uneven shining surface of the extremely solid and heavy fruit, which is described as setoso-echinulate, though perfectly smooth in the example before us, is very remarkable. The flesh is about an inch thick hard, firm, and solid, fibrous inwards, and gradually compacted and blending with the large compressed softish fibrous shell. When boiled it is a favourite vegetable in Madeira during the autumn and winter months, resembling young Pumpkins when immature, but when ripe somewhat firmer, drier, or more mealy in consistence, with a peculiar nutty flavour. The specimen from whence our drawings were made proved excellent when boiled for nearly two hours. After germination the fruit enlarges into a persistent subaërial rhizome, one of the most singular peculiarities in the plant, which is of American origin. We believe that there are living plants at Kew. M. J. B.

ONE of the popular flowers of our time is unquestionably to be found in a race of Pelargonic ms, which is wanting a name-a name that is, that shall be definitive, and not contradictory. The varieties of this race have been designated, for the most part, Scarlet Pelargoniums, but this title has long since become inappropriate, from the number of varieties having white or salmon-coloured, or pink, or rosecoloured, or parti-coloured flowers. They have been called Horseshoe or Zonate or Zonal Pelargoniams, but these several terms, as implying what is true only of a part and not the whole, are as inappropriate when applied to the entire race as that which describes their original colour. They have been called Bedding Pelargoniums, but this is not discriminative enough, inasmuch as Pelargoniums of other races are more or less freely employed for bedding purposes, and besides, these are not exclusively bedding plants, for some of the varieties are amongst the most desirable acquisitions of modern times for conservatory decoration and for exhibition purposes. As we have, however, amongst them a group
called Nosegays, might we not, from the profusion in called Nosegays, might we not, from the profusion in
which they produce their blossoms, and failing a better name, extend this idea with advantage, and by calling them all Garland Pelargonivms, avoid any further contradictions?

We have said that these Garland Pelargoniums, as we venture to call them, are desirable acquisitions for exhibition tables. Some perhaps who may have watched
their fitful presence at our flower shows, and their too their fitful presence at our flower shows, and their too
common appearance when present, may be inclined to question this, but we repeat advisedly that they are acquisitions for exhibition purposes. The reason they do not generally present the appearance they ought to do, is found partly in the inconstancy or insufficiency of the encouragement held out, and partly in the recent origin of the finer and more varied binds. Prizes are offered sometimes and sometimes not, and consequently the growers are not prepared to show. The subjects are treated as common bedding "stuff," and insufficient prizes fixed, and the growers, few of whom are so much as atimulated to try, take just as little trouble as will suffice to win. Let it be known however, that f:ir remunerative prizes will be always forthcoming, and the growers will do the rest, though they may not just at first hit the same degree of perfection in growth as has been realised with the show Pelargoniums, after their treatment as show plants. No doubt the fact of calling these things "Scarlet Pelargoniums," or "Scarlet Geraniums" as many say, has militated agairst them at exhibitions, the very nan e being so intimately associated with the idea of parterres and bedding out that they have been looked on as common and vulgar; but we propose to show that the materials are so much varied in tint, and so refined in character, that such an estimate of them is altogether false.
So much by the way. We will now run rapidly through the lists of these Pelargoniums, noting as we proceed the choicest of them, so far as they have come under onr observation. For our purpose we may bring them all under the following colour groups :-Oculate,
White, Rosy-pink, Salmou-colour, Cerise, and Scarlet White, Rosy-pink, Salmon-colour, Cerise, and Scarlet. For the present we
Of the Oculate series, that is to say those with white blossoms having a coloured eye, a group which is under going rapid improvement, the varieties named Amelina Grisseau, Eugène Mezard, Beauty, and Leonie Nivelet may be selected as especially good, differing among themselves in the amount and depth and arrangement
of the salmon colour of the centre. These are all most refined and charming grown as pot plants.

Amongst Whites perhaps none beat our old friend Madame Vaucher on all points, more especially as a fection and Vierge Marie in great beauty. These are certainly all good.
Of Rosy-pinks we look upon Bearté de Suresne as the best we have met with as to size and shape amongst the deeper-culoured varieties, whilst Flora, Mrs, Wilham Paul, and Eve, are all exceedingly fine large-flowered sorts of a pale peach-blossom. Rose Queen, Christine, and Rose Rendatler are thoroughly good older varieties of this group, fine both indoors and out.

The best of those with Salmon-coloured flowers is we think, a Chiswick seedling called Princess Mary, the flowers of which are large, finely formed, and of a shaded salmon pink. St. Fiacre, salmon, deeper at the centre, is thoroughly good, a most prolific bloomer, and moderately dwarf; while Fanty and Auricula are two serviceable free-flowering varieties in this particular shade of colour. These are all admirable indoor plants.
Amongst Cerise or Rosy tcarlet flowers the choice is greater, and some of the finest of our Gtarland Pelar goainms will be fousd here, the chedes of colour varying so much as they verge towards scarlet on the one hand and salmon colour on the other, that it is vam to attempt to describe their peculiar tints. Heotor,
Roi d'Italie, and Monsieur Martin are gems amongst them, and perfectly distinct, the first of a brigh and light cerise-rose, the second a saluony sarlet, and the third a cerise-scarlet, all of them buth as to pips, truss, and habit being everything that could be wished. But scarcely, if at all, inferior to these stand Umpire, Nora, Lord of the Isles, and Herald of Spring, all of them five rosy scarlets, merit ing a prominent position, and, like most of the varieties of this group of colour, exceedingly effective as pot plauts.
Finally, of Scarlets, the name is legion. The zonate rarieties are the most abundant, and of these Victor Emmanuel, Attraction, Amiral Protet, Martin Gireau, Clipper, and Adonis, which vary as much in their leaves as in their flowers, are amongst the best. Punct is not heaten amongst che large-flowered green-leuvel sorts, but Faust is probably as good and different, while in Waltham Pet we have a green-leaved miniature scarlct of great beauty.

We look forward to the coming reason as likely to yield a considerable advance upon the materials we have here indicated, but even with these who shall say the Garland Pelargoniums are mere " common bedding stuff," and uuworthy a prominent place at our flower shows in the month of July, when the glory of their congeners-the more petted Show and Fancy Pelar goniums, has departed

## FILLING FLOWER BEDS IN WINTER

This is a subject to which attention has been occasionally directed. Evergreens, variegated Hollies, and other dwarf shrubs, have been recommended for the decoration of the flower garden during the season of the jear when flowers are not avalable, and there can be no doubt that by such means the beds are made to look furnished and neat, but certainly not like what they are in summer. As far as is known to me it has been left to Miss Hope, of Wardie Lodye, near Edin burgh, to introduce an entirely new and unique system of filling flower beds during winter; and it not with flowers, with that which is so like them that it re quires close inspection to discover that flowers are not employed. Miss Hope is distinguished for her love of plants, and for the extensive knowledge which sbe possesses of their nature and colture, as well as for her devotion to her garden; and for years she bas furnished her geometrical flower gardens with dwarf shrubs at an annual cost of some $50 \%$. or $60 \%$. She however longe for something that would produce an appearanc more like a flower garden than slrubs, and having observed the fine tints of some varieties of what is called "Posey Kail," she made a selectiou of a few of the finest, and saved seed from them. She again selected the best varieties, and seeded them until she has arrived at what is all but perfection, as far as regards the various tints of parple, white, mauve, pink, and other intermediate shades. These she now grows i an open exposed field till the flowers that have occupied the beds in the garden during the sumnner and autumn months are cleared away; the beds are then well dug up, and filled in some instances entirely with the various shades of the Kail, with the exception of a single dwarf Cypress or other shrub, which is placed in the centre. Circular beds have a row of white Kail round the dark green slirub, then a row of purple, outside of which is a row of a very dwarf pink Kail. In other instances large oval beds have a taller shrub in the centre, and the ground run off into panels by means of dwarf plants of variegated Aucuba These panels are planted with the various hiegated Ivy.
Other beds are formed into panels by means of dwarf specimens of common Green Kail, and are edged with Cerastium tomentosum, the panels being filled with variegated Kails. Long beds are planted in the ribbon style, and such phants as the variegated varieties of Veronica Andersonii, Arabis lucila, some of the dense-growing green foliaged and variegated rarieties of Saxifrage, are used in connection/with them and certainly with remarkably good effect.

The geometrical garden which I have so impertectly end of this grand drive, is a specimen which has given described, occupies a sunken panel of Grass, and consists of some 20 beds, that would require about 5000 bedding plauts in them for summer decoration. This garden seen now, with the setting sun upon it shining through is more like a scene looked at through a kaleidoscope is more lise a sceene looked at through a kaleidosc
than anything else with which I can compare Viewed from the windows of the mansion it has quite the appearance of a well-furnished flower-garden in the month of September, with this difference, that on is quite at a loss to conceive what Pelargoniums, Ver-
benas, or other flowers, yield such charmingly soft tints of colour as are afforded by the pink, mauve and almost magenta-coloured Kail.
Miss Hope's very intelligent gardener informed me that these several coloured varieties of Kail are perfectly bardy, and stand in the beds, not in full
flower certainly, bat in full foliage till May, few flower certainly, but in full foliage till May, few
of them running much to seed before that time. Some varieties stand for two or more years without seeding, and he pointed out one very remarkable variety that could not be gotrefeed at all. This sort he however propagates from short side sprouts, which dwarf, being not more than 4 inches in height, though they spread thoir foliage to some 8 or 9 inches in diameter

Plants are obtained by sowing seed in March, and afterwards transplanting on poor light soil in an open exposed field, which no doubt has something to do with keeping them dwarf and stocky. When required for
filling the beds, the proper tints and sizes are selected filling the beds, the proper tints and sizes are selected
for the various panels and circles. They are removed with a small ball of earth at their roots, planted to the depth required, and watered to wash any earth off their leaves, and to settle the soil round their roots; they then require no farther attention except the removal of any decaying leaves which may appear on them during the winter.
Some may be disposed to smile at this style of flower gardening, and I confess that I had a strong tendeney in this direction while on my way to Wardie Lodge, but as soon as I got a sight of the object of my visit, I made a mental apology to Miss Hope, her gardene
and her Kail. W. Thomson, Dalkeith Park, Jan. 18.

## NOTES ON GARDENS.-No. XXVI.

The Dublin Phegix Park and its Gardens.
The main entrance to the Phenix Park, or the
Dublin Gate as it is called, is a little beyond the Dublin Gate as it is called, is a little beyond the
King's Bridge-the most western of the city bridges, "on. proceeding a little further than "which," says the finest national playground in Europe, and I believe in the world. Indeed, it contains no less than 1700 acres shrubs, growing as wild as in any uncultivated region of the globe, all open to the public." This might be but Sir E. B. Head is quite right, barring a slight mistake about the size of the Park, which is 1752 acres and odd in extent, and 7 miles in circumference, its size, pure air, and magnificent mountain views all combining to make it decidedly the "finest national playd thus escaping city vapours; bounded along its whole southern length by the Liffey; fanned by the purest mountain breezes; unpolluted by houses, even western limit of the city, in an obtusely acuminate manner, like the upper half of a leaf of Ficus religiosa with the apex bitten off-as if it had been designed to give the most convenient Park landing-stage to the city, and at the same time to keep the "groves of possible); traversed by the finest roads, with immense lawns, water, wood without end, wild hollows, herds of deer, and frequent military displays, this Park, as may be readily supposed, offers an inexhaustible meet this individual in the Park on a Sunday or holiday pugnacious looking dog, just as the real Simon Pure takes himself to road, or marsh, or heath, in preference For there is one broad and excellent road, nearly three miles long, running straight as a gun-barrel from the Dublin end of the Park to its north-western extremity, and then, if the pedestrian takes the boundary roads, he may walk till exhausted, without the slightest chance strangers in the Regent's Park-going round the sarcae circle till the trees begin to be familiar objects.
Along this great central road
here are opposite clumps of trees, each surrounded by iron fencing. Mr. Wilkie, the chief bailiff and superintendent, reeditates a grand improvement hereplanting a Wellingtonia in the centre of each clump; Californian giants, and being at about the right distance apart to allow for their colossal developmento All that is wanted to effect this is of course a grant of
money, though not a very large one. But would they money, though not a very large one. But would they
grow and thrive? Yes, most assuredly, for in Mr.
Wilkie's garden, a little to the grow and thrive? Yes, most assurediy, for in Mr.
Wilkie's garden, a littie to the north of the oountry
end of this grand drive, is a specimen which bas given
me the best idea I have vet had of the beauty and glorious dignity of the Wellingtonia. It is about 17 feet" high, feathered to the ground, with the branches
beginning to swing downwards a little from weight, but with such a strongly and beautifully built stem! Look with such a strongly and beautifully buits stern mathe
at the pencil-like apex, pointing skyward with mathe matical precision, and then trace it down, getting larger by degrees and beautifully great, till the basesufficient for a tree of twice the height and size-is
seen half hidden among the Grass. What excellent preparation to send a vegetable tower into the skiesa tower too, which, if it fulfils the promises of the foundation, and is always preserved as now by loving hands from injury, may survive strong 19th century buildings of man; see nations buried; and perhaps afford
interest to the New Zealander (who will certainly not be a Maori), should he cross the Channel, and when walking up through the noble but smaller trees, see at last Mr. Wilkie's monument, the king of the grove!
To the right and north-east of this central artery, the first establishment within the Park, and then some picturesque ponds in hollows are met with, but on the whole there is barely sufficient expanse of water in the Park for its extent. Then comes the head-quarters of that peculiar but excellent force the
Irish Constabulary. From this finely situated barrack, the recruits are distributed over the country after being drilled and trained, and it also contains a reserve of picked mon, and a troop "of cavalry, ready to act or atart for any part of the country upon emergency. Just beyond the police depôt is the Zoological Garden, very picturesquely situated, and with a handsome aheet of water dividing it from the Park on one side
The garden is a favourite resort of the people on Sundays, being opened after divine service at a penny charge.
Next comes the Viceregal demesne, containing 209 acres, well wooded, and cut off from the Park by a sunk fence, thus not interfering with the general expanse and beauty of the scene, but, on the contrary, improving
it by presenting such a large oasis-like sweep of rich wood to the view. Nearly opposite the Viceregal entrance in the centre of the long road, stands the Phoenix, a pillar erected by Chesterfield when Governor of Ireland, and surrounded by a representation of the ornithological emblem of Immortality rising from its ashes. The Under-Secretary's (containing 52 acres) and Mr. Wilkie's places are the remaining ones to the
right of the main drive, both finely situated, beautifying the Park, and of course adding immensely to its horticultural interest. Wellington's monument, a huge pile of granite, with the victories of the Duke rises 289 feet, and if not a very classic monument (it is sometimes alluded to by the "pisanthry" and others as "the big milestone") it is at all events a very simple, permanent, and imposing one.
The demesne of the Chief Secretary contains 71 acres, and is situated to the left of the central road, nearly pposite that of the Lord-Lieutenant, and there are several other extensive establishments on this side though far removed from it. Among them there are Ene Mountjoy Barracks, the head-quarters of the Royal Engineers, occupying $9 \frac{1}{2}$ acres; the Hibernian School,
surrounded by grounds 40 acres in extent, where great numbers of soldiers' boys are brought up; cricket grounds, plantations, \&c.; but all these merely skirt the woods on the margin of a verdant prairie-like expanse, called, or miscalled, the "Fifteen Acres," where the reviews of troops take place. "Bosides being the only spot in the United Kingdom in which a large army could be manceuvered, it is perhaps the most picturesque ground for the purpose that could possibly
be conceived, for not only is it surrounded by Fir and Larch plantations of various shape, but on the south the horizon is bounded by a chain of mountains of extraordinary beauty," says Sir E. B. Head. Here in 1849 before Her Majesty, and on numerous other ccasions, many thousand men have been reviewed not in the Hyde Park style, but with the swiftest and most dashing movements of every branch of the "Fifteen Acres" are flitted and swept over by the the Artillery and the united charges of three or four regiments of cavalry-when the whole force falls into line, extending, perhaps, a mile or more, and when the moke and parade of "battle's magnificently stern array" are so fully represented, the view over the plain from its rising woody margins and mounds is a
most attractive one to the The restractive one to the citizens.
The road along the sonthern side of the Park commands beautiful and striking views of the Dublin mountains; winds in and out amongst well wooded and picturesque glades, mounds, and banks; looks down upon the Liffey, just outside the falling margin of richly verdant and winding valley; passes by numerous "hias of Furze, \&ca, quite sufficient to suggest "hiding in the bush," if not'being "lost" in it ; and finally runs out beyond the Park towards the "Strawberry beds." These last are the very steep banks of the but planted for a great length with Strawborries whiskey shops along the road at the base of thents and berry ridge. To these united attractions the number
of Dublin "boys" and girls that are attracted on a ime ing. In fact nothing would give any idea of it but the clouds of dust kicked up by the tightly packed jaunting cars dashing out in close file through the Park with very merry passengers, all bound for "the beds" There are lines of fine old Elms in the Park, and some old wood in various places, but by far the largest portion is comparatively young, Mr. Wilkie having planted many score thousands of very varied trees many of the best deciduous trees being seen in
abundance, and also the commoner Pines abundance, and also the commoner Pines. But
beautiful as the'woods are in many parts already, the beauty and the interest which might be added the charms of this noble Park by liberal and judicione planting of the rarer and more recent Pines, deciduous trees, and evergreens, may be easily imagined. No scene in the British Isles is more susceptible of
improvement in this way, and no man living is better fitted to effect it than the much respected, or more correctly much-loved Superintendent, who in his ore garden exhibits the finest, rarest, and noblest of our Pines, shrubs, and deciduous trees planted at his own expense, and now in the rarest health and beauty

Spent in the planting of the finer trees and shrubs, what a different result does money produce compared with its outlay on endless floral decorations, perishing with the first frost of autumn, as may be seen in some of the London Parks, with a perennial roundeiay of expense for housing, propagating, \&c. I am not justified, nor do I wish to object to this system if carried out in moderation, but when one stands amidst some of those scenes and looks about for that most eesential of all beauties in park or garden-trees, and no end of pudding-headed Limes, Elms, \&c., are all that offer themselves for the eye to rest upon, it is not too much to wish that more skill and expense were devoted to the shrub and tree interest. "But they won't grom" may of course be said. Very few evergreens will grow in London, and with the exception of Aucuba, Box, and Holly, and perhaps a fow others, it is a mistake to plant them ; but if the soil were properly prepared-made if necessary (it is so on the north side of London, and
the expense incurred during a few years by a garcon decorated in the common manner, would probably furnish the same space with a sufficient depth of any desired soil), there can be no doubt that better things could be done with deciduous plants in the parks thas we have yet witnessed. And after all, these evergreens are not so very desirable for the parke, for during the season when they are most enjoyed and enjoyable, deciduens possess no advantages whateve do we see in the parks during the winter season, except those who pass through on business? Very few indeed.
Hawthorn would have been a much more fitting name than Phoenix for the Dublin Park, for of all the subjects that at present embellish it, it owes most to the normal form of Cratregus Oxyacantha, There an thousands and thousands of fine old gnarled speci of it in various parts of the Park, covering hill hollow, of great size, standing singly on the turf, and They are all old indigenous plants, annually of courso "mass of flower ; and at that season, of all " fragrant shades" that I am acquainted with, this is the chiel The effect of these trees when in flower to one
wandering towards dusk in parts of the Park como manding a good view of a sheet of their tops, is at first sight, as if they were covered with gnow. This plant and its varieties, and the host of beautiful Europesan and American species of Hawthorn, do almost as well in the London Parks as in other places, and as in fruit or flower nothing can be more beautiful, we cannot have too many of them. For the fruit alone some
species would be well worth planting in quantity; bat apecies would be well worth planting in quanmon one and give us the finest "May" for three weeks atter that month is past, more need scarcely he said in favour of the genus Cratægus. Some fine Elms that bordor the main drives were planted about 120 yeard ago. Among other improvements which were being
carried out at the time of my visit, was the formation of carried out at the time of my visit, was the formationt with Austrian and other Pines on the mounds-a sijg instalment of Mr. Wilkie's grand scheme of improve ment, the sooner he is permitted

Park.
There is at present no flower garden proper in the Park, but it is contemplated to make one, and no doubt the sprinkling of flower bods over one of would be a boon to many, though such is by no me necessary, nor perhaps desirable, as the sort of impro ment contemplated by Mr. Wilkie-great variet separated, with here and there nearly distinct grou to give decided features and peculiar charm3 separated spots-is that which above all others wou oxercise the people in the Park as it were; make travel and traverse miles from charm to charn, a thus effect for their bodily health, what no concia elaborate, expensive garden in which the people cram
about ever could. It seems to me that there is an mpression abroad that it is impossible to embollish a park with trees and shrubs, and that Tom Thumbs must be resorted to. This would be right eno pivet
or Plane and Willow, were the chief things we could boast of in that class ; otherwise certainly wrong. Sir J. Paxton was quite right in his opinion on "gardening in the Parks at least have been finished as parks before theing garnished with gardening; should have been made the most of with hardy subjects, before heavy erpense was incurred with fugacious tenderlings.
The Phcenis Park was first "laid out" and opened to the public by the elegant Chesterfield, when LordLieutenant of Ireland. The name "Phonix" is supposed to be derived from a spring of limpid water, in Irish fionnuisge, which antiquariaus suppose to be gradually corrupted into Phenix. This spring is a strong chalybeate, now covered over, and near it, for the accommodatiou of those who frequent the spa, is a rustic dome with seats around, given, as an inscription tells, by the Duchess of Richmond in 1813. The
Park, or a great portion of it, belonged, in very old Park, or a great portion of it, belonged, in very old
times, to the Knights Templars, and afterwards to the Knights of St. John of Jerusalem. On the suppression of the monasteries it was surrendered to Henry VIII., and enclosed for a deer park by the Duke of Ormonde in the reign of Charles II. To Queen Elizabeth is attributed the idea of making it a Royal park. William Robinson.

## (To be continued.)

## THE WEATHER OF 1864.

January.-It may be remarked that at the end of 1863 the amount of rain was nearly $3 \frac{1}{2}$ inches short of the usual depth, so that the ground was in a comparatively dry state at the commencement of 1864. In January there fell little more than one-third of the usual quantity. The mean temperature was lower than usual ; but, with the exception of the 6th, when the thermometer fell to $7^{\circ}$, there was no severe frost. East and N.E. winds were most prevalent. The barometer stood very high on the 3d, and its average for the month was higher than usual.
Pebruary.-This was another dry month. The depth of rain was only about $\frac{3}{4}$ inch. The mean temperature was nearly $4^{\circ}$ below the average. Though generally cold the weather was not occurred on the night of the 9 th, therm. $11^{\circ}$. The barometer averaged somewhat lower than, usual. North and easterly winds were most prevalent.
March.-For five previons months the rain which fell in each was respectively below the average ; but in this the quantity was nearly double the usual quantity for March ; and it mostly fell on the 3d, 5th, and 9th. The barometer was generally low, aud on the 7 th it was remarkably low. The prevalent winds were from east and north-east. The highest indication of the thermo. meter was $60^{\circ}$, which occurred on the 20 tin ; the lowest,
$19^{\circ}$, on the 23 .
April.-The mean maximum temperature was $\mathbf{g x}^{\circ}$ above the average; mean minimum $1^{\circ}$ below, and the
mean of the month was $1 \frac{1}{3}^{\circ}$ above the average. The highest temperature in the shade was $75^{\circ}$, on the 20 th. There were 12 frosty nights, the coldest of which was that of the 12 th , therm. $25^{\circ}$; and ous the 22 d it was $26^{\circ}$; the latter affected vegetation more injuriously, in consequence of the previous very warm days, the thermometer in the shade being as high as $75^{\circ}$. The highest temperature of the days was $3.76^{\circ}$ above, but that of the nights was somewhat below, the average The barometer was generally higher than the average
mean. The amount of rain was scarcely half the usual quantity. The prevalent winds were from north-eas and east.
May.-Fully an average temperature was maintained in this month, owing to the heat of the days, for the nights were on the whole colder than usual, and six of them were frosty. Even as late as the night of the 29th the thermometer indicated $7^{\circ}$ below freezing. The amount of rain was fully equal to the average quantity for the month; the greatest portion of it fell on the 6th, 9 th, and 31 st . From the 15th to the 20 th inclusive, the maximum in the shade averaged $82^{\circ}$, that of the 15th being $83^{\circ}$; this exciting influence as regards vegetation was followed by frosts on the 23d 29th, and 30th; the thermometer on tirese night indicated respectively $6^{\circ}, 7^{\circ}$, and $4^{\circ}$ below freezing these degrees of frost were very much against tender sorts of vegetation, bedding-out plants, \&c..
June.-The mean maximum temperature was not quite a degree below the average, but the mean minimum was more than $5 \frac{1}{2}^{\circ}$ coller than usual. On six nights the thermometer averaged only $3 \frac{1}{2}^{\circ}$ above freezing; on the 26 th it fell to within $2^{\circ}$ of that point. This was unfavourable to half-hardy kinds of vegetation. The days, however, were generally very fine, with abundance of sun; and with this the hardier kinds of vegetation made substantial growth. In previous years we have frequently had occasion to remark, that, with sunny days in June and July, even although the nights may be cold, the crops of grain give a better yield than when the mean temperature in these months is above the average, or higher than it was in this month, but derived from warm nights and warm but comparatively sunless days. The amount of rain was one-fourth of an irich below the average. The wind was from the west for half the day in the month. The barometer was gemerally steady.
July. - The days were very hot and dry, but the nights unusually cold. The mean maximum was $77.03^{\circ}$; the meau minimum $44.54^{\circ}$; the range between the night and day being $32 \frac{1}{2}^{\circ}$. The thermometer was frequently as low as $40^{\circ}$ or lower, on the 7th it was within $3^{\circ}$ of the freezing point. Only half an inch of rain fell, little more than one-fifth of the usual quantity for this month. The barometer was tolerably stoedy, its mean height being a little above the average South-west winds were less prevalent than usual, while those from east and north-west were more so.
August. - There was a still greater discrepancy
between the mean minimum temperature at night and hat of the average than was the case last month, fo the temperature at night averaged fully $9^{\circ}$ colder than usual ; the mean maximum was upwards of $1 \frac{1}{2}^{\circ}$ higher than the average. There was much hot sunshine, and fruits of trees that had sufficient moisture at the root increased to large size and acquired perfect maturity but in many instances the trees suffered from dryness, and the fruit was comparatively small. The harvest was brought forward early; and from the abundance of sun-heat and light in the previous months, whilst the foliage of the corn plants was yet green, and capable of elaborating the jnices tbrough the sgency of powerful solar rays, the grain proved very substantial, much more so than when growth is made in warm but sunless weather.

September.-Although a month later in the season, the nights were actually warmer than in the previous month, still they were below the mean $2 \frac{1}{2}^{\circ}$; whilst the mean maximum of the days was nearly a degree above the average. On three nights the temperature fell as low as the freezing point. The quantity of rain was in excess of that which usually falls in Sentember; but it was soon absorbed by the parched snil, and without reaching the lower roots of trees. The want of water had been severely felt in many parts of the country: but the rains in this month refresbed at least the surface of the ground.

October.-The mean maximum temperature of the days was fully maintained; that of the nights was, as in all the months of the year, below the average. The lowest temperature occurred as early in the month as the 5th, when the thermoneter indicated $25^{\circ}$; and on six other nights the temperature was at or below freezing.
November.-The nights were generally more or less frosty. The thermometer, as early as the 3 d , was as low as $20^{\circ}$, and on the 9 th it fell to $17^{\circ}$, which was the lowest point reached in the month. The average temperature of the nights was upwards of $6^{\circ}$ below the mean; that of the days was, however, fully maintained The quantity of rain was below the average ; little fell till the 23 d , when there was nearly an inch. The barometer on the 14th and 16th was remarkably low, and tha too with an easterly wind.
December. -This month was cold and dry. The mean temperature was $2^{\circ}$ below the average. The amount of rain was only 0.34 , or about one-third of an inch. The roads were often dry and dusty. The arrears of rain at the commencement of the year was 8.32 inches and if to this be added the deficiency in 1864, it appears that at the close of the year the arrear was $10_{1}$. inches. This is nearly equat to half a year's fall of rain. The deficiency may be spread over a number of years, and nay be made up by degrees. But if it should be made up in the course of 1865 , this would be the wettest year recorded, near London, for the last 24 at least. The springs have never been so low as they are at present for the last 40 years. $R$. T.
 of Thirtu of rix Years.

The Mean Pressure was .011 inch below the average.
The Mean Temperature about 1 it degree below the average.

## Home Correspondence

Eriophorum angustifolium.-I see in your last Paper that Dr. Dickie has brought two forms of this vefore the Linnean Society. In April 1863, I noticed the following forms: -1 , the sexes in different plants; 2 , sexes in in different spikes on the same plant; 3 , the sexes in different flowers of the same spike. These
forms were in Sunninghill Bog, Berkshire. I could not find any hermaphrodite flowers there. My note sys nothing as to any difference ia the size or form of the spikes, or as to any rudimentary organs. The first and second forms were in a great measure if not entirely separate; I cannot say how this was as to the third form. I have seen forms 1 and 2 in the same place in former years. If Dr. Dickie happens to see specimens with pleasure at the proper season. G. $\boldsymbol{H}$ awyer, Heywood Lodge, Maidenhead.
Erianthus Ravennce, -I beg to assure your Correspondent (see p. 1181, 1864,) that I have proved this Grass to be perfectly hardy for 20 years, and I wish of the late W Bormat it has flowered in the garden did not ripen seeds. I may. Henfield, Sussex, but it

The Mean Maximum Temperature neariy ${ }^{2}$ degree above the Amount of Rain upwards of 6 in inches below the average.
respondent's information, that it is by no means a new Grass. Charles Green, Hillfield, Reigate.
Grafting Tines.-In the spring of 1863 I grafted a Dutch Sweetwater on a Syrian, cutting away a long rod of the latter owing to the difficalty of ripening it with the heat at command for Black Hamburghs, of which the other Vines in the same house consisted. In 1864 the scion produced some 20 bunches of Sweetwater Grapes, which were quite ripe about the middle of August, having precisely the same flavour and appearance as those on the parent stock - yet the syrian appeared to have imparted a little additiona thickness to the skin and rather more firmness to the properties of the Grapes seemed to be considerably enhanced. Some of the bunches were quite fresh and good on the 6 th of this month (January, 1865), although the house had not been kept particularly dry-no fire having been used, except once, when the temperature the sea haur., an foliage on the scion had the same appearance as that on the parent Sweetwater, until rit faded in November, when it assumed the beautiful mottled yellow colour of the Syrian-at a time when

The Mean Minimum Temperature fully $3 \frac{1}{1}$ degrees below The Mean
the parent Vine was yet green. It seems probable that the advantages of grafting Vines may be found considerable, and every contribution of experience in this direction may prove useful in inducing some either to proceed in one direction or to pause in another. $C$. W., Calder Mount, near Garstang.
Trade Catalogwes. - Permit me to direct the attention of seedsmen to their Catalogues, and to ask whether or not the latter cannot be profitably condensed, inserting only the names of such flowers and vegetablew as deserve cultivation. I have now before me a flower seed list, enumerating not less thau 1500 sorte ; a column is left for quantities ordered, the prices per ounce or packet are quoted, and here ends everything like information. What a talk it is for us to wade through such an army of hard names in onder to select one's 30 sorts. We require them good, and we wish to have our little garden gay. We cannot all afford to purchase bedding plants, which all of us have not the convenience for growing curselves; neither can we at all times leave the selection of seeds to our seedsmen. therefore do think that seedsmen ought to give this much information, viz.:-Daration, Height, Colour Time of Flowering, and whether adapted for massing
or not, \&c. I am of opinion that if nine-tenths of the
names were altogether left out it would be a move in the right direction. Seedsmen should strive to excel in judicious selection, rather than in collections of mere botanical curiosities. Ignoramus.

Gardeners' Discussion Classes.-One of these was commenced at Shrubland undervery favourable circumstancee during the time Mr. Taylor was gardener there, and was conducted exactly on the same principles as those related by your Correspondent. I am glad to be able to say that the young men belonging to the place were fully aware of the advantages to be derived from such meetings, and that several of them are now holding very respousible situations. I may also add that the papers after being read by the members were sold, and that they often realised more than their original cost; the money thus obtained was appropriated to the buying o useful books, which became the Society's property. would strongly advise head gardeners where a sufficient number of young men are enployed, to assist in forming such societies, which in the end would prove beneficial both to masters and men. E. Welch, Gardener, Palace Gardens, Armagh, Ireland.
Elihu Burritt's Walk from London to John of Groats. - Under this title Mr. E. Burritt has pub. lished a most interesting little book, containing the remarks of a wortby and simple-minded man on suljects chiefly rural. Prefixed to it is his photographic portrait, which from its tall gaunt form, graphic portrait, which from its tall gaunt form,
with hard-lined features, might readily pass for

The Year 1864 at Weybridge Heath, Surrey:-

## W. F. Harrison, Bartropps, Weybridge Heath, Jan. 3.

## §ocicties.

Roxal Horticultural: Jan. 14 to 18 (Second Weekly Show.-Cyclan ens, which formed the principal leature of attraction at this meeting, were contrihuted by Messrs. E. G. Henderson, of the Wellington Nursery, St. John's of C. persicum. From Messrs. E. G. Henderson aliso came Senecio Ghiesbreghtii, a useful-looking subshrubby plant, with ample deep green leaves, and great corymbose panicles of golden-y ellow blossoms. The same establishment likewise furnished a well-grown specimen of Sonchus laciniatus, a plant with bandsome Feru-like foltage.
From the Rev. Geo. Cheere, Papworth Hall, Caxton, came a plant of Mignonette, well-Howered, and another of Mrs. Pollock Pelargonium, which still keeps a foremost place among three-coloured leaved kinds. Of other plants useful for purposes of decorasorts, Veronica Andersonii, Daphne indica rubra, the fragrance of which quite charmed all who came near it; Jasminum nudiflorum, Solanum Capsicastrum, laden with bright orange-scarlet berries; Dracæna heliconæfolia, and last, but not least, a pretty little specimen of
Dendrobium nobile Dendrobium nobile.
Of Fruit, Mr. Meredith, of Garston, near Liverpool, sent three beautiful bunches of the true Black Alicante Grape, in the culture of which he is so very successful; also a handsome bunch of Chuld of Hale, a promising seedling Grape, a cross between Muscat of Alexandria and Syrian. This, together with the Alicante, was in a state of excellent preservation.
Entomowarcal: Jan. 2.-F. P. Pascoe, Esq., F.L.S., President, in the Chair. Mr. F. Bond exhibited ppeeimens of Ephestia ficella, reared from cork; also of Depressaria olerella; and of some remarkable varieties of the common Hepialus Humuli, from Lerwick, Shetland, as many as 20 males of which had been received, and colour of that sex, exhibited the normal pure white colour of that sex, the remainder showing thore or lees

the picture of "honest Abe" himself. Among many acute and intelligent remarks, there are some rather questionable statements indicative rather of faith thau knowledge. Thus, at page 170, he gravely relates a fable of the conversion of Oats into Barley! "The Oats are sown about the last week in June, and before coming into ear are cut down within $1 \frac{1}{2}$ inch of the ground. This operation is repeated a second time, and after standing through the winter, the produce in the following season is Barley." The authority given for this transformation is Mr. John Ekins, of Bruntisham, near St. Ive's. Again, at p. 122, he states, as an established fact, that the Potato is originally from New England! "The men and women, whom Hooker led to the banks of the Connecticut, sought for it in the white woods of winter, scraping away the snow with their frosted fingers. The largest they found just equalled the Malaga Grape in size, and resembled it in complexion. They called it the Ground Nut." But surely not with E. B. the "Potato." In the grounds of Burghley Park, he notices with special gratification the (American) White Birch (Betula papyracea). "There was not one that spread such delicate and graceful tresses on the breeze as our White Birch. I was glad to see such justice done to a tree in the noblest park in England, which with us has been treated with such disdain and injustice; and thought how it was regarded as a nuisance, so that any man who owns or can borrow an axe, may cut it down without leave or licence wherever he finds it." $G$.
Weather,

Driset month, July.
Wettest ditto,
and the winter evenings are almost certain to han heavily on hand. There are of course a few amng ments suitable for the country, and a few more, bette calculated for a residence in town, but practicaily
nobody knows how to occupy the time of the nobody knows how to occupy the time of the soung
gentlemen in a satisfactory manner, and they are rent gentlemen in a satisfactory manner, and they are really
left to amuse themselves as they best can. left to amuse themselves as they best can. Much time
is spent in shapeless idleness; and ten to one the members of the family, including the young linpefor thenselves, are not sorry when the time comes for their return to school.
Half the secret of happiness to these young folks lies in a judicious plan of voluntary employment, and any.
body who can invent a scheme combining and body who can invent a scheme combining anucement
with instruction, is a benefactor to the rising With some such thoughts as these, we have peration charming book, with the above title, by Dr. Presed This gentleman, it seems, is so fortunate as to tee the father of four intelligent boys and a little girl, and has long considered it a duty as a good Paterfumilias, to cater for their amusement; and it is impossible for ang.
body to examine his book, without giving a decided opinion that he has succeeded admirably.
There used to be in bygone days, a well rememberel little volume entitled "Endless Amusement," and certainly the experiments aud ingenuities propounded in the book in question were numerous and varied, but they were in general far too difficult for young persons io manage without the assistance of older hands.
Then, there was a volume called the "Boys" Omn Book,", which enjoyed a certain amount of celebrity, at least that something too puerile in its concoction boys that was impression) to please sharp livel both these opposite faults, and in this third edition ham presented a book that is by far the best of the kind that it was ever our fortune to meet with. Who would not willingly be a schoolboy again to have such a field of endless amusement before him!
There are, first of all, a series of experiments depending entirely upon the ordinary laws of chemistry. These are indeed" "Nature's own magic." They are highly instructive, and are well calculated to create a taste, which may lead boys of an inquiring mind to the systematic study of chemistry-enchanted ground, stocked with inexbaustible delights-a science which is evidently destined for many years to come to hold an increasingly important position in the world.
In the second place, there are many puazles and ingenious tricks that depend upon the application of some well-known principles of arithmetic and geometry; and these again may induce a taste for stadies, which though termed severer, are not without an indeseribable charm to minds of a certain charecter.
Again, there are explanations of some of the most famous tricks of our conjurors Houdin, Frickell, H . showing how the feats are performed, and explaining sometimes the mystery of "clairvoyance," and sore times the "ineahaustible bottle trick."
There is a good sprinkling of woodcuts illustrating the construction of "the funny funnel," "the revolving syphon," "the magic coffee pot, \&c., and for a frontio. piece there is a representation of a picture frame withs portrait of the author, drawn with invisible ink, which appears when) warmed, and vanishes again on cooling.
Information is also given as to where clymical and Information is also given as to where chymical and
philosophical apparatus, \&co, may be purchased at a moderate cost.

Furnished with Dr. Piesse's book, boys must be dall indeed if they cannot find amusement for themselvers and make fun for their compunions.

Of De Candolle's Prodromus, the first fascicle of Section 2 of the 16th volume has just been issued. M. Alphonse De Candolle takes Cupulifere, containing the Oals, Chestnuts, and Beeches; Corylaceæ, containing the Hornbeams, Nuts, and a few other genera; and Platanacex, containing the Liquidambars and Planes; and his son, M. Cnsimir De Ciandolle, the Juglandacea, containing the Walnuts, Hickories, \&c.; and Myl cacex, containing Myrica and Leitneria. Fortuvea in referred to Platycarya of siebold and Zuccarinio of Onks 281 species are described. The common Oak, Quercus Robur, nccupies more toan seven pages, and comprises, as subspecies, pedunculata with 13 , and sessiliflora with 19 varieties.
The sixth fasciculus of the 6th volume of $\boldsymbol{W}^{\prime} u l p e r{ }^{\prime}$ Annales Botanices Systematicre, contains the concla. sion of Orchidact $¥$, by Prof. Reichenbach, and a portion of Graminaceæ.
Hogg's Gardeners' Year Book for 1865 is occupied by a variety of usual information, the most importand of which are the notes on new fruits, plauts, and flowers, and the comprehensive Horticultural Directory The portion of the latter devoted to the seats of the nobility and gentry has been very much amplified. het Directory however now occupies so much space that is perbaps a question whether it might not be advisath to issne it separately, so as to be able to afford in terers more directly relating to cultivation.
The Botanical Magazine for January contains fimitrs of the foliowing subjects:- Lissochitus Horsfallih, a fine stove terrestrial Orehid from the (),d Calaum to River. It has plaited and very acute leaves tiv to three feet long, and a tall scape twice the length the leaves, supporting a dense oblong spike of large sil and
reflexed, the petals broader, standing forward, white
suffused with rose, and the lip funnel-shaped at the bave, green streaked with purplish crimson, and with the promuent middle lobe deep pace colour, with three whitish elevated ridges on its disk. It has been intro
duced by T. B. Horsf.ll, Esq., M.P., of Bellamour Hall, Staffordshire.-Dombeya Burgessic, a subarboreous Staffordshire.-Dombey a burgessice, a subarboreous
Sou'lu Afric:u plant, with pubescent cordate fivelobed leaves, and cymose corymbs of five-petales white flowers marked with crimson lines radiating from the centre, and tragrant. It is no doubt a fine plant for a large greenhouse conservatory, and
has towered at Kew.-Dendrobium Parishii, a handsome Moulmein epiphyte, introduced by Messrs. Low \& Co. "At first sight it appears to bear a certain amount of re
 ly its thick clumsy leafless stems, which are bent downwards in a stiff ungainly manner." It blossoms, moreover, in summer. The leaves are leathery and oblong lanceolate, and the flowers geminate or ternate, the sepals and petals and lip of a deepish rose-colour, the Iatter being pubeccent and riculate-- Proustia pyrifolia, Vitch. It is a climber with sma!l ovate leaves, and a panicnlate inflorescence of white flower heads " unattractive in its flowers and foliage, yet as the fruit advances to maturity becoming a singular and beautiful olject, the long pendent branches and foliage being alcoost wholly concealed by the mass of rich rose-purple feathered pappus." As a greenhouse climber it cannot West Australian species introduced by Mr. W. Thompson, of Ipswich. It has pinnate leaves, and rather large purple flowers.
In the Floral Magasine are figures of Vallota eximia, a fine pale centred variety of V. purpurea;
Clematis Jackmanni, to which we have already frequently adverted; a yellow and red Calceolaria Bird of Paradise; and three varieties of Tree Carnations. The Florist and Pomologist has a very good figure of one of Beaton's Pelargoniums called Indian Fellow an orarge-scarlet with a strongly marked suffusion of
Indian yellow, and quite an acquisition for bedding purposes. It is in the hands of Mr. William Paul, who it appears has several others from the same source including Amy Hogg and Rebecea, which will also be great aequisitions for garden decoration.
Seemann's Journal of Botany contains a figure of the new Irish Orchid Neolinea intacta, found as Castle
Taylor, Galway. This is described by Prof. Reichenbach, who after enumerating many habitats in Europe and some in Asia and Africa, observes-"May those Who believe that every species was created in and originated from one centre, determine what that centre was in the present instance, provided man has vineyards. The new theory of transmutation be a great help to them. We may quite expect thas, by various favourable and unfavourable conditions and circumstances, developed or retrograded into other species, perbaps Orchis ustulata, or Polygonum
Bistorta." The January Numberalso contains papers on the sunken island of Atlantis, by Dr. Unger ; notes on British Roses, by M. Déséglise; and a notice of a new British Truffle, Tuber excavatum, by Mr. W. G. Smith who states chat the specimens examined for identification were from the Truffle districts of Somersetshire where it is not unconamon, and that it is probably
frequent in the Truffe grounds throughout the country. The Numbers of this work for November and December contain figures of Potamogeton vitens, recently found in Ireland, and of Lasiandra macrantha, a fine Brazilian Melastomad, introduced by Mr. Linden, which has ovate acuminate leaves, and bears violetpurple flowers, upwards of four inches across, larger than in the well-known and similarly-coloured Pleroma
elegans. The Editor points out that the Eranthemum Co peri, lately figured in the Botinnical Magazine, is the Justicia longitolia, of Forster, and the Justicia describes two species of Citriosma from Brazil, culti vated by Mr. Linden. These are called C. Thea, and C. Lindeni, both shrubs, the first with oblong acuminecond with elliptic acuminate leaves emitting a Citronlike smell.
The Reoue Eorticole, one of the leading horticultural periodicals published in Paris, has, during the past -Dahtia Decaisneana, a tail habited Mexicat plant, smail sized by M. Roezl, and producing flower-heads of disk, viulet with the fhitrets in a single series around the moiselle hiaria Joigneux and Mademoiselle Jeanne Barral, the first lilac with amaranth stripes, the second ayellow, laced with faint rosy-tinted white,- Hyacinth dmorphous Moss Rose, which single violetablue.-A duced a flower of the ordinary centifolia type.-Pcoony Carriòre, a magnificent herbaceous variety, with. fine Verilier, of paris and flowers, raised by M. Charles Pseudo,platanus erythrocarpum, a variety of Sycamore with the wingeit fruits of a deep dull red.- Pyrethrum rosenm M. Barral, a full double variety, with the

Nore pleno, a fine double rosy-purple flowered variety of great beanty amongst annal flowers.-Groups of other subjects. Among fruits there are the Pomme d' Api Noire, a carious-looking blackish purple Apple-
Pomme Reinette Carrée, described as an Apule of the first quality, ripening in January, when it is of a golden yellow, a little flushed with red, and marked with russet dots, the flesh fine, sweet, and perfumed, of a
salmony tint.- Poire Fortunee Boisselot, a large
 yellowing, and taking a tinge of red at, maturity.
is ripe in March and April, and is said to have a fine and a fine flavour. The variety was raised by M. Auguste Boisselot, of Nantes, from the Bergamotte Fortunée. - Poire Roux Carcus, an extraordinarily fertile variety, obtained by M. Roux, of Carcassoune. It
ripens in August, is roundish oblate, and of medium size, russety pale yellow in colour, and having a sweet mellow juicy and well-flavoured flesh. It is recommended as likely to be a useful suminer Pear--Poire Beure Storckimans, is winter varip y, now prety
weil known,-Poire Le Brun, a fine melting perfinmed musky Pear, raised by M. (inéniot of Troyes, and President of the Horticultural Society of LAube. It ripens in September and October, and is large oblug clavate obtuse smooth, of a citron yellow with russet patches, the flesh fine white buttery and melting, with abundant juice, and a musky flavour, "something li
Poire William, only more delicate and agreeable." is said to be without pips or cells. - Brugnon Jarais freestone Nectarine, raised by M. Jalais, of Nantes, and having the fruit elongated, pale yellow at maturity clouded with red, the flesh fine and melting, and the juice sugary, with a vinous flavour.-Gros de Candolle
Grape, and several varieties of Strawberries.

Catalogurs Recerved.-Carter \& Co.'s Gardener's and Farmer's Vade-Mecum for 1865 : Part 1. Flower Seeds and Plants; Part 2,Vegetable and Agricultural Seeds. These are perhaps the most elaborate seedpatalogues published; and we observe that the tivo parts above specified are now issued separately. There
are several promising novelties both amongst flowers and vegetables.-Louis Vam Houtte's Prix-Courant de Graines offers a good assortment of sorts, old and new,
and may be consulted with advantage. - William Paul's and may be consulted with advantage. - William Paul" ist of some of the best things in the different departments. The Waltham Brussels Sprout is particularly -Butler \& M'Culloch's Spring Catalogue of Seeds, 1865, is another of the amplified lists, with remurk and cultural instructions.-W. Cutbush ${ }^{\text {W }}$ Son's anongst them occurs Catbush's Divarf Brussels Sprout, which is said to be that sometimes known as Judu Flower Seeds for 1865, contains a selection of the best Flower of Vegetables and Flowers, the names of the former accompanied by useful remarks, and various parthulars concerning the latter being tabulated Amongst the new flowers we notice that seeds of Nolana lanceolata are offered.

## Garden Memoranda.

S. Ruckrr's, Eso., West Hill, Wandsworth. S. RUcker's, Esq., West Hill, Wandsworth.-
at this dull season, when flowers are everywhere At this dull season, when flowers are everywhere
scarce, the display made by the charming Culanthe Veitchii in one of Mr. Rucker's Orchid-houses is well worth travelling miles to see. This glorious plant, a Limatodis rosea and Calanthe vestita, greatly sur passes both parents in grandeur of appearance, having a constitution even more robust than that of the Calanthe, and a colour much brighter than that of the Limatodis. Had Mr. Dominy raised no other seedling Orchid than this, he would have been entitled to the best thanks of all lovers of flowers; but fortunately for us other equally valuable results have followed his exertions, some of which are in this collection; but none of them are at present in flower. Other varieties as are likervise several magnificent examples of Lycaste Skinneri and Barkeris Skinneri, the purplish violet Epidendrum dichromum, and one or two others. In the Orciaid house properly so called, several plants of Phalænopsis grandiflora now keep up a gay diaplay, as do also one or two species of Angreecum, the most conspictuons among which is A. sesquipedale ornamented With some 20 long-tailed ivory-White star-shaped conditiou, and Lalia auceps and others only want a few bright days to render them masses of floral beanty.
In a cool house Cypripedium insigne is blossoming freely; among comparatively hardy Orchids this is flower, and for the ease with which it may be managed satisfactorily. Along with it is Odontoglossum pulchellum, the beautiful spikes of white blossoms of which are as fragrant as Josmine. In the same house is likewise the rare Masdevallia candicane.
In a warm stove a fine variety of Epiphyllum truncatum, together with Linum flavum, the deep orange Rhododendron javanicum, the crimson Begonia fuchsioides, the bright blue Eranthemum pulchellum,
the orange Imantophyllum miriatum, and Monochætum ensiferum, a useful rosy-pink flowering plant, all contri-
bute to maintain a certain amount of gaiety, which is enhanced by a liheral introdnction of such things as Dracemas, Coleus Verschaffiltii (both in the shupe of standards and dwarf bushes), the green and red-leaved . marmoratus, and some of the best of the many variegated-leaved Begonias. Associater with these is also a pretty specimen of Gardenia citrindora, a whito foweret deep green-leaved shrub, not half so extensively Camell suould be
Camellias are now beginning to come profusely into flower; and on a comparatively cool greenhouse shelf in front of them are Epacrises ( 1 oth red and white), Chinese Primulas, Myrtle-leaved Oranges laden with ruit, Skimmia japonica ornamented with numberless ittle crimson berries, and Daphnes.
The tropical aquarium has just been put in order for the spring. Immediately over the water are hung baskets full of different sorts of plants suitable for such a purpose, and round the margin of the tank are placed
some fi:e Alocasins, consisting both of metallica and Unwi, intrymixed with Dendruhium of metalliea and other (Orehids in hossom, as well as with Mrant:a and other plants remakable tor the beanty of them leaves. In the glasec. vere. promenade one of the mont remarkable phats at present in flower is Enkianchus
reticulatus, a stately shrub) covered with mumernus dronping clusters of pink and whte boll-shaphed blossoms that heep in heanty for many weeks to reth. r at a
tume. On the conf Lapageria roses hat heen, and still is, blooming profusely. It is plantel in well drained and light porous soil, in which, with proper attention to watering, it grows most luxuriantly. Its princinal enemy is slugs, which eat off the young shonts cloze to the ground. To prevent this the stems are surrounded by narrow zinc troughs placed in the form of a square, and kept constantly full of water-a barrier over which slugs find it impossible to pass.
Of both Lycopods and Ferns this establishment are some enormous Gleichenias, Cyathen mednllaris, and others, among which we noticed wonderfully fine masses of Trichomanes reniforme, both covered with bellZealand Fern, of great beauty ; Hymenophyllum pulcherrimum, multifidum, and others, all in excellent health, and about to pash into fresh growth.
Among other plants is a shelf-full of Nerine Fothergiilii, in a cool house. This is one of the most useful of bulbs, flowering as it does every autumn, when its searlet blossoms produce an admirable display. Mr. Pilcher bonons it in the same sized pots year after year so satisfactorily that this season he is srying the Guernsey Lily in the same way. Of the result we hope to be able to speak in a fature $r$ port

## Miscellaneous.

Black Hollyhocks.-A rather extraordinary special culture is now carried on in the neighbourhood of common Hollyhock (Althea rosea), which is so deep in colour that the flowers appear almost black. These contain a great quantity of a colouring principle which
is employed in colouring wines and dyeing Cotton. This article is more especially exported to England, where they bave succeeded in fixing the colouring nutter upon the fabrics. This cnitnre Mr. Heerdegen, a manufacturer and agent at Nurembiry, exports couiderable quantities. La Belgique Morticole.
Wush your Watercresses. - In Croses prepared for the table I have noticed portions of Frng'shit (Hydrocharis morsus ranac) and other weers. These vegetables have often small mollusks and other aquatic animalcules adhering to them, and it the former are eaten in an imperfectly washed state, it will consequently happen that the latter are swallowed during the meal. Small mollusks are known to harbour larval parasites in prodigious quantities, and therefore it is not unreasonable to conclude-bearium in mind the extent of our knowlenge of the transformations which these
para-ites madergo-that they are at least the source of one or more of the fluke parasites which nceasionally invade our frames. The fullowing case will best illustrate my subject:-A young girl, the danghter of a ahepherd living at Kaplitz, in Bohemia, was in the habit of eating Watercresses, and drinking the stagnant water of ditches in the locality where she lived.
After a while her health falled and her body became After a white her health falled ani her body became
much cnlarged. A medical man, Dr. Kichner, saw her only three days before she died, and by a post mortem examination, be ascertained that no less than 47 specimens of a small Fluke (Distoma lanceolatum) had taken up their residence in this inappropriate "hoat." I say "inappropriate" because the parasite species in question has ouly three times heen detected
within the human "s host " its proper habitation being, apparently, the liver of the ox and sheep. Popular Science Review.
Double Orchids.-I observe that Dr. Moore is interested in the double-flomered Drchis Morio, flowers (Journ. Bot. ii. 176). Will you allow me to onwers that the list I sent you was in great measure compilation from various sources; and that I personall have not seen a double-flowered O. Morio, but cited it
Irom Jacob's "Catalugue of Favershan Plants" (1777)

| one of the earliest local Floras of this country. At |
| :--- |
| p. 75 of that work, it is mentioned that "in a meadow | pear Cades, in Ospringe," some of these plants were found with flowers "of a rose colour, some white, and a very few with doable flowers." No further description is given, nor does the accompanying engraving shed much light on the matter. According to the figure, the flower have a circular outline, seem very double, and apparently have no nectaries; all the flowers of the spike are alike affected. The Ophrys aranifera, included in your supple mental list (Journ. Bot., iii, 318), was only semi-double. thad three lips, one in the ordinary position and two ateral ones, representing the two lateral stamens of the outer series, which are usually suppreased; on one of these additional labella was an imperfect anther. In addition, the three inner stamens, which are generally wholly suppressed, were in this instance all present. A description and figure of this hishly interesting specimen will be published in a future part of the frofessor Asa Gray and Mr. Darwin, I am enabled to record another double Orchid, which presented almos precisely similar changes to those found by me in $O$ aranifera. The plant in question is Pogonia ophio glossoides, and was foand yy Dr. J. Paine in a sog near Utica, New York, This American Orchid, and especially my O. aranifera, go far to confirm Brown's view of the structure of the Orchideous flower, - a view aclopted andi confirmed by Darwin (Pertilization of Orchids,

p. 292.) For further remarks on this interesting p. 29bect I must refer to the forthcoming par sabject I must refer the the fornal of the Linnean Society. Dr. Moore has favoured me by forwarding some flowers of Orchis pyramidalis similar to those mentioned hy him (Journ. Bot. ii. 319), but even more curious. In usual ; within these a double, and, in some instances, triple whorl of petals,', most of the latter being lip. like in form and colour. I could find no trace what ever of ovary or column, of pollen or nectary; but standing up in the centre of the flower, in the place usually filled by the column, was a small raceme, con sisting of numerous bracts subtending a number of flower-buds. These latter were made up (so far as their structure and arrangement could be made out), of three sepals, enclosing some rudinentary petals, and these again encircling a prolonged axis with minute bracts and rudimentary flowers. The smallest of these tertiary flower-buds that I examined measured 1.100 inch in diameter, and consisted merely of a central dome or pimple of cellular tissue, encircled at the base by a shallow cup, whose edge was slightly three-lobed, the lobes indicating possibly the future sepals. In other minute buds the central dome was suriounded at the base by a four, five, or six-lobed cup; but as it was impossible to make sufficiently accurate examination of these rudimentary buds, I refrain from giving further details, but will merely rdd that these flowers present, so far as I am aware, the only recorded instance of median floral prolification in Orchids. Mr. Currey forwarded me some time since a flower of Oncidium sp., which I may term spuriously double; the sepals and two upper petal but separate pieces, confluent with the base of the column; each of the subdivisions had a callosity, in the centre of the "claw" in the case of the median segment, close to the upper and inuer edge in the outer two lateral stamens and one of the inner stamens? -their position justifies such an assumption. The flower in question had no ovary, although the column was present, bearing below a stigma, at the sides two triangular membranous wings,-representatives possibly abortive pollenless auther. In conclusion, I will take the liberty of soliciting those of your readers who may meet with any malformations in plants to allow me the opportanity of inspecting them. Dr. Masters in Journal of Botany. [Dr. Masters, whose address is Rye Lane, Peckham, would, we are sure, be glad to have sent to him any specimens of plant malformations. ]

The Silurus-An inportant highly useful addition has been lately made to our
lake tish by the importation of 14 young specimens of the Silurus glanis, from Wallachia. The Acclimatizu tion Society 18 indebted for this valuable acquisition to Sir Stephen Lakeman, who possesses an estate at , in Wallachia, where this fish is abund favourable conditions, thrives in lakes having peaty bottoms, and is remarkable for its delicious fiavour

Japanese Matches.-At a recent meeting of the Chemical Society, Dr. A. W. Hofmann exhibited some matches, or fuzez, which were brought from Japan by the Prussian expedition. Besutiful arborescent sein The natore throwa olf durg heir slow incerest and a criess had been hazarded that steel-flings were used among the ingredients to produce the sparks, but analysis had shown that there were no metallic particles, and that carbon, under the circumstances of the case, was capable of undergoing this remarizable kind of combustion. The composition was made of two parts of woid charcoal, three of sulphur, and $6 \frac{1}{2}$ parts of nitre. The paper covering was of the finest tissue, or that commonly known as
Chinese paper," and about 40 milligrammes of the

Telescopic Ladder. - A ladder has been invented and patented by Mr. Henry Druce, solicitor, of Oxford. It is constructed on the telescopic principle, and cona single and distinct ladder of itself. These ladders are made to slide one into another, so that the ladder can be extended to any length according to the convenience of the person using it, and the number of pieces of which it
feet long

## Calendar of Operations <br> (Fior the ensuing week)

We last week gave some directions for preparing beds for Ranunculuses. Let us now add a few words regarding choice of sorts. It need scarcely be stated and seedlings which have been raised during the last few years. The tubers of the former are generally less robust and plump; the foliage is often weaker, and the fowers are almost always inferior in size and substanc of petal to those of newly-raised seedlings. The art of
hybridising has been wonderfully successful with the Ranunculus, and some new and fine kinds are annually produced. Unless, therefore, the old varieties are very triking, and unlike the modern sorts, growers, especially if beginners, should make their beds of new sorts, Good kinds are, however, expensive, and a failure when it occurs is therefore the more provoking. A very fin show may, indeed, be secured by one or two huudre mixed roots, which may be purchased at very smal cost; or get a dozen of say first-rate roots, and placing them in different parts of the bed, which a health with comoon ones. The criterion by fortions root is known, is the plumpness of the forked portions and the fine velvety texture of the crown; especially
the latter. The tuver itself may be small and shrivelled the latter. The tuber itself may be small and shrivelied while, on the other hand, a plumpness of the tuber is of no service if the crown is dull, and instead of becoming bright when rubbed by the hand or on the coat, crumbles way. It should be remembered too that the silkines
(v) although always present in some degree increases as the growing season advances. The Turban Ranunculus makes a splendid show, and it is surprising that it is not more grown in large gardens than it is, as beds of it, each filled with flowers of one colour, have a most imposing effect. The various kinds of Turbans As an early flower it is well worthy of notice. The Ranunculus may be taken up without injury as soon as the flower is withered, if mould is allowed to adhere to it, and all the roots thus removed are put into the ground in a place secured from rain. They will then gradually become fully matured, and may be cleared away in July. This latter circumstance removes the objection of the beds being occupied too long to allow their being afterwards filled with flowering plants. Half-a-dozen beds on a Grassoplot would present gorgeous sight in May and June.
flower garden and plant houses.
If not already done, look over beds of Crocuses and other bulbs to see that they are uninjured by wether or mice; also inspect lalf-hardy plants. As severe weather may yet be expected, every precaution should be taken to ward off its 'ill effects.
Auriculas.-While the weather continues favour. able let these have as much air as possible; they dislike close confinement.
Bedding Plants.-These, if in pots, must also have air while the weather is mild; but means of protection at night must be at hand.

Camnations and Picoters.-Draw "the lights off these in the day time when dry, but let them be put on again at night.
Forced Flowrrs.-A second batch 'of Roses may now be placed in heat to succeed those in active growth. Keep down fly on the latter by frequent fumigations, and the Rose maggot by haud picking. Place in heat potsful of Tulips and Hyacinths to succeed those now in bloom, and see that the latter are not allowed to droop rom want of water
Pelargoniums.-These will now be growing slowly therefore in fine weather let them have as much air as possible, consistent with the proper temperature. Fancy varieties may be kept a little warmer than ordinary kinds.

## hardy fruit and kitchen garden.

Digging and trenching may now be carried on with activity, and, where necessary, drains may also be put in Wheeling should, if possible, be kept for hard weather. Apples.- Pruning and thinning of these must now be pushed forward with expedition. Where necessary root-pruning may also be performed; but this kind of work is best done in the autumn.
Pears. - The observations made in reference to Apples also apply to these.

## Forcing garden

During the present sunless weather high temperatures must be avoided, or uyhealthy growth will be the result. The proper temperature to maidtain is there fore a matter of the utmost importance, and will require during this and the next month or so great Aspara
Asparagts, - If not already done, make a bed to
succeed that now becoming exhausted. On fine days
give as much air as possit.
Cucumbrrs.-Worn out plants in houses may no e rooted up, the beds renewed, and their places fillal ith young plants.
Peacers, - Adinit air freely whenever the weather is mild, and keep the atmosphere moist, maintaining a houses ing temperature of abcut $50^{\circ}$. Very earl houses in which the fruit is set should be aforded nice growing temperature, syringing liberally to prevent red spider, and keeping the border in a healthy state a moisture, to secure a vigorous root action.
Pings.- Young plants growing in beds that have been some time planted will be benefited by having th soil lonsened up as deeply as can be done withoot injuring the roots, giving it a liberal soaking of tepid water if it be found to be too wich a rose on it, and not so fast as to flood the surface, for if this is done the soil will be rendered almost as close as before forking up; indeed, careless watering is the great cause of th up; indeed, careless watering ilose great cause of the be carefully avoided. Endeavour to afford a nice regular bottom-heat, with a thoroughly moist atmosphere, and keep the plants growing as freely as may be consistent with preserving them dwarf and bushy Have a constant eye to maintaining a succession o fruit, or securing a supply at the season when it may be most wanted, and let the treatment of the plants b regulated accordiug to circumstances; this is a matter which demands considerable forethought, and which can be successfully managed only by careful observation and attention.
Vines.-Take advantage of all favourable oppor. tunities to admit fresh air as freely as can be done with safety, and be satisfied with as low a temperature from fire-heat as may be considered safe under the state o the Vines, but shat up early, allowing the thermometer to rise considerably. This will to some extent econo-
mise fuel, and will he much more congenial than employing strong fire-heat.

## The Sgrícultuxal batette.

SATURDAY, JANUARY 21, 1865

Tire greater portion of our Paper is this day occupied with two disoussions, which may be both described according to the title of one of them, as on the present position of the Britise Farmer. They both deserve the careful study of agriculturists. It is instructive to notice, which we shall do more fully on another occasion, the different tones adopted in the North and in the South respectively by the speeches on this subject. We have abridged the report of the proceedings before the East Lothian Club, bat the paper read before the Hungerford (Wiltshire) Club is given unabridged aud in full. The latter is unquestionably a very able lecture on its subject. Mr. Williams is well known in the agricultural world as a man of great ability. It cannot, however, but be seen how the political partizanship of the speaker does in his case interfere with that business-like discussion of the present difficulties of the farm which they seem to have received at the hands of the East Lothian Society. The latter is suggestive, helpful, hopeful; the former is passionate and angry, almost desperate. To this we shall hereafter draw attention in detail. Our reference to both these reports at present is merely to express the hope that readers will not be deterred by their length from giving them their best attention.

That was a ourious bit of thoughtlessness or forgetfulness which was displayed the other day at the annual meeting of the Norfolk Agricultural

Sooiety, and is reported in the papers this week. Society's Journal, is not satisflied with the South down ewe as the mother of the cross-bred lamb. Plenty of wool, and a sufficient carcase of good quaity early ready for the butcher are what he wants; and to this end he would use the best long-woolled ram he could find, but for the dam he prefers the old black-faced Norfolk sheep improved. The original breed were "a wild and hardy race, well fitted for a country of seanty herbage. Both sexes were crowned with horns, which, as the rule, were thick and spiral. Tieir limbs were long and museular, their bodies long, and their seneral form betokened strength and activity. They have accordingly been regarded as well fitted for distant journeys and for bearing the rough treatment of the fold. They held their neeks erect, and in their carriage more resembled the Chamois adtelope than any other of our races of sheep.'
This is the description given of them by Professnr Low, and it is the ewve of this breed of which Mr. Frere asked, whether the old Norfolk sheep improved first with the Southdown and then with the rest rams out of the West, was not a better mother than the Southdown, giving them a large early lami, and an early sheep for the butcher.
His reasoning was this: The offspring of two parents partakes most of the character of that one which has held that character through the greatest number of previous generations. A well-bred male, one with a lengthened pedigree of equally well bred ancestors, is certain to hand down his valuable oharacteristics to his offspring when put to a female whose parentage bas been various and mongrel. It is the long wool and the larger frame of the Cotswold or the Leicester that we want to unite with the quality of mutton of the Blackfaced breed. Shall we not be more certain of a profitable sheep by taking the larger framed inproved Norfolk ewe, uncertainly bred, without the momentum of many previous generations of fixed oharaoter to contend with in her cross, putting her rather than the well bred smaller Southdown sheen, more likely to hold her own in the "contention," to the long-woolled ram on which we are all agreed.
This was the nature of the suggestion, and its policy was to be determined in the usual way by a "sporting match." Mr. Frere was to send 20 good uld ewes to some good breeders of Southdowns, and they were to be put to a good Southdown ram. He was to reeeive back ten of his ewes thus crossed and ten of the Soathdown ewes of the other's flock similarly served, and each party to the experiment was to fatten off the ewves and lambs, and exhibit and report the result, showing a score apiece, ten of the one cross and ten of the other cross, with their dams, at some future Nairer than the details of the proposed experiment fairer than the details of the proposed experiment, or, indeed, more amusing than the simplicity with
which these arrangements are proposed, as if no such trial had ever been made before.
But the proposal is made in apparent ignorance or furgetfulness of one essential point, on which, more than anything, esuceessful grazing for surely there was considerable pluck in this attempt to teach the agriculturists of Norfolk their interest and business-was accompanied by the protest that he had come there " "not to assert any opinion, still less to theorise;" but this was theorising of the most faulty sort. It was speculating in forgetfulness of some of the leading and most active facts conneoted with the subject. In necessarily a more profitable sheep. The larger frame is made possible by the pareutage of the acimal, but it is actually built up by a proportionate consumption of food. See what Mr. in another column:-" It has been pointed out to us," he says, "as a fault that we are content to sell sheep at $2 l$., when Liccolns or Cotswolds would fetch $4 l$, each. Now, I think a little sheep just eats in proportion, and I would not keep
Southdowns
one week longer if ansthen siouthdowns one week longer if anything
would pay better." The btaining as our anitual whose tendency is to grow more lasgely which a heavier carcase, and upon which a heavier fleere shall be found when it is ready for the butcher, is not necessarily a desirable thing at all in the intertst of either the grazier or the breeder. emory or of judgment displayed in Mr. Frere's memory or of judgment displayed in Mr. Frere's
proposal. The ewre is to be a cross bred "improved "
and therefore mongrel animal, in order that the superiority of the ram may be fally displayed in her produce. Her characteristics are to be held without tenacity, in order that those of the sire may be more certainly reproduced. But there are characteristics of the ewe which it is quite as desirable to retain and reproduce, as those of the larger framed and longer woolled ram to which she is put. We want her quality of flesh, her early malurity and aptitude to fatten, quite as much as his larger frame and heavier fleece; much more so indeed if Mr. Skirving, and the experience of graziers generally, be trustworthy. Put the long-woolled ram to a mongrel ewe, and you lose the advantage of that दixity of type which a well-bred Southdown would ensure you, and which would secure for you in their offspring her precocity and quality as certainly as his long wool and size. Your lamb may certainly enough grow into a large and long-woolled brute, but as to its proving a kindly feeder, and therefore a profitable sheep for the butcher, you have no certainty whatever.
All this is proper for discussion in this speculative way, because it has long since been realised and ascertained by experienoe almost every where. And accordingly it was at once pointed out by Mr. Woons, the agent of Lord Walsingeriam, and the proposal feil to the ground.
Mr. Woons was quite prepared to meet the clallenge between the Southdown and those long-legged blackfaced ewes which appeared to meet with favour in the mind of Mr. Frere. They had been acquainted with them for years, and their acquaintarice had more thoroughly satisfied them that the less they knew of them the more profit they got into their pockets. I he understood him righitly, he would try some ewes bred from the Suffolk downs and West Country downs, against the produce of Southowns. Now, if it should be tried, as Mr. Frrre wished, by some impartial man, he believed that the result would be that which had been proved by every successful grazier in the country that the more quality they got in the animals they had to feed the sooner they were fatted and the more profit the graziers would receive. He believed they would et very little quality in the stock bred froin those long-legged, long-neclied, ugly sheep, which would be the result of Mr. Frere's cross.
Mr. Woods added that Mr. Frere was starting at no new point, but running on an old and welltried path, because all he was advoeating there had been tried scores and scores of times, and if they wanted an example, they might go on Norwioh Hill that day, and go over the pens of sheep at Tombland fair, and they would see the very animals, the very breed of sheep, that he was endeavouring to make a great point of, and bringin $\%$ it forward as an important discovery, and one which practieal men had lost sight of.
The Editor of the Norwich Mercury, in his comments on this discussion, points out that so long ago as one of the Holkham sheep shearings the late Earl of Leicester, then Mr. Core, had spolen in precisely the sense of Mr. Woons' remarks, and against the proposal now so courageously ma"e by Mr. Frere. He had said: -
"Southdown sheep have been found pieferable to the Norfolks in every essential good quality-in wool, in carcase, and in early maturity. Mr. BLyTH, the father
of the present owner of of the present owner of Suseex Farm, was the first person who bought some, and he told ine he gained by them the first year more than the amount of his rent. It has recently become a very general practice in the county to cross the Downs with Leicesters for the purpose of providing a staple of wool suitable for the Norwich manufacturer. One eross is advisuble. It produces not only a good fleeece of wool, but a good carcase of mutton; but it would be very injurious to breed from those cross-bred animals, as their progeny would degenerate into a mongrel breed, deficient iu every quality requisite to form good and profitable stocks Norfolk sheep.-breeders cannot, therefore, be too strongly cautioned against the dauger of falling into an error in practice at once disgraceful to the county, and injurious to the community at large, as well as to individuals who may have been led to commit the error."
May we not add that the Editor of the Agriculcural society's Journal, or, indeed, of any other agricultural periodical, mistakes his vocation when he pretends to teach agriculturists their busir os s . His endeavonr should rather be directed to induce them to teach one another.
the pliesent posilion of the farmer.
The foilowing paper cas read by Mr. Williams, of Baydon,
The position of the British farmer at the present time Club to discuss, for ho it is a fit subject for a Farmers' learn from each other thewever profititable it may be to learn from each other the best mode of breeding stock
feeding and grazing cattle and she
themselves for further developjects which sugge occasionally, and especially at the present tim as mel to ourselves and see if we are in that heal he, regards our affairs, which the welfare of nyr state a equires of so great an interest as the agricultural ond It was wisely said (some 20 years agat by by $\mathrm{H}_{\mathrm{p}}$ Coawrence, the then American Min'ster at the Englis England!". If so, it is also the spine; and it beho of as to look into our condition, and see if there is any anger of its being injured.
The farmers of this country ever have been, and trust ever will be, noted for their industry and
perseverance: they have the assurane man that ever lived, "that in all labonr there is profit ;" but unfortunately of late years they have tro nuch reason to regret that of the labour bestoned by thenselves, and paid for to others-however true the words of Solomon may be-the profit goes to the pobiic at large, and not to those who produce it.

1. Let us first consider the liabilities the farmer is corn, there is any hope of meeting these liabilitios of making both ends meet; and also if there is and remedy that can be applied to meet his case, either by legislative enactments, or by his own means.
For example, then, I will take a farm of mediom quality, of 400 acres arable, farmed on the four-conne system.

Rent (about an average) would be
Tythes, about 7 s . per atere.
4s. $6 d$, in the pound on $360 l$. according to the New,
Labour, an average of $8 \%$. per week,"
and hall assessed taxes, and insurance from fire
Uorn for 13 horses, 125 qrs. of Oats, at 203 . per cr
Tradesmon's bills for repairs, hire of stearm engine
Wear and tear in horse for labourers
Wear and tear in horse flesh
I have worked those figures out in detail, and am se tisfied that the above sum of $1663 l$. is as near as can be the expenses and liabilities of the tenant who occupies it.
We will next see what the farm will produce, with sheep and wool at a very high price, and corn at a very low one.
Assuming that 32 acres are down to Sainfoin, it will acres peraunum; there would be consequent of s the 4 field system 92 acres of Wheat, at $S$ sacks
per acre, at i9s. per sack 60 acres
40 acres
40 acres of Oats, at 6 qrs. per per acte, at 20 s. per qra $q$ q...
8 acres of Peas, equivalent to the 8 :cres of sainfoin
acres of Peas, equivalent to the 8 acres of sainfoin
not planted with Wheat, 4 sacks per acre at $18 \mathrm{~s} . .$.

We will assume there are 300 breeding ewes, tingether
with 100 ewe lambs kept on the fir
with 100 ewe lambs kept ous the fing ew, ind allowing
for a loss of 5 per cent, per anuum, or tu iu number,
there would be 80 full mouth ewes for sale, at tos. there would
Allowing a lamb to an ervo for viso owes, and derincting
sale ewe lambs for stock, there will renatin for
60 mixed cull ewe and wether lambs, at 20 s . per

The next item is wool, and take 330 flecces, at an
average of $3 \ddagger 10$. per fleece, or $4 t$ tod, at $5+3$,
average of $3 \ddagger \mathrm{li}$. per fluece, or 44 tod, at $54 s$. per tod

Rape Cake, \&c. [The following letter has been forwarded to us by Mr. Alderman Mechi, to whom it was addressed.] - At the risk of having this my effusion it to you. My object is to point out one or two matters which I think are confirmatory of the views taken by you on the same subjects. Although my experience as
an agriculturist in England is nil, I have had considerable experience as an amatear agriculturist in the Rast, and there are few of the staple crops in India that I have not tried, and some to a considerable extent. The subjects on which I shall touch are straw as food: burnt clay, and what you call rape cake, but which I suppose is the refuse after the extraction of the oil from the mustard seed.-(1) First, with regard to straw, the working bullocks in India get little but the Rice straw cut up and mixed with the cake of the Mustard the bullocks in India reject the Linseed cake, but take greedily to the Mustard cake, if it be not too new. after it has been soaked in water about 12 hours, and it is then eaten with avidity by the bullock. 1 have often noticed that if given too fresh from the mill, or
in too large quantities, that it produced purging, but in too large quantities, that it produced purging, but
an exposure of two or thrce days to a tropical sun did away with all laxative tendency. So much for Mustard or Rape cake.-Straw as food: Throughout the East, at all events in the densely populated parts, months in the year Grass is not to be had. So far from bullocks not thriving on straw, nearly all the bullocks fattened for the supply of Calcutta are fed on chopped straw and Mustard cake. The manure is not used for the land, but is eagerly sought your valuable work on Farming, to see you write about using finely cut straw for litter; to quote your own Words, you might as well plough in Linseed-cake, Beans, or anything else for manure before it passed through the stomach of the animal. It you want bed-
ding, why not use burnt clay and eat all the straw. I have used it with adrantage in the East both for sheep and bullocks, not with a view for the manure bat on
better suited for a climate where fermentation was
rapid.-(?) Burnt clay, where it is kept covered and not spent by exposure to the afmosphere, is one of the best preventives of putrefaction, and from its absorbent powers retains for vegetation what it has absorbed, only giving it out when wanted. I tried it 16 years ago for Sugar-cane. I followed what General Beatson said in one of the volumes of the Society for the
Diffusion of Useful Knowledge. Its effect on Grasses in India is something wonderful; the ordinary Grass of the couatry is called Ooloo, stiff, raw, and harsh, with spikes at the end strong enough to run into the finger. Give a piece of this Grass land a stiff dressing of burnt clay, and the Ooloo Grass is supplanted by a beautiful succulent creeping Grass, caled the Doss, which vegeGrass that attracts the moisture or the burnt clay I cannot say. I am inclined to think it is the burnt clay, but independently of its value for litter and manure, burnt clay is invaluable for mixing with lime to make mortar and cement. Sand is never used in India, but in its place burnt clay powdered fine into dust called make that in many of the old forts built many hundred years before the English knew the country, it is easier 'to break the brick than the mortar. I
grind it up for mortar in a mill with two heavy rollers and a pan turned by a steam-engine, 11 -inch cylinder, and use it not only for building but for litter. If you can burn your clay at $6 d$. per cubic yard you can grind it for $9 d$. and have it every grain of ammonia, and in the place of the fermenting mass of straw litter, in which, as far as I can make out, nearly all escapes, either in the shape of ammoniacal or carbonic acid gas, you will have a manure that you could almost sow out of a drill. So convinced I With what I have seen of burat clay, and from what i have read in your booz, that I intend to try my will burn at least 200 yards to the acre if it can be done at a shilling a yard. When I was at home from India last year I paid Tiptree a visit, and I do not know whether I was more astonished at your pluck in taking to such a forbidding soil, or at the results you had obtained. When I do get fixed in a farm I shall take the liberty of calling on you and asking the favour of your opinion as a guide in many matters in which my experience would not be worth much. $\quad$ [What he alls Mustard I call F. India Rape. J. J. M.]
Potash for Manwre-I am very glad to see your Correspondent Mr. Frere has drawn attention to the want of potash as a manure; it has often struck me injreading the analyses of plants, that if potash could be beneficial manure, and I believe it has recently been used in East Lothian for Potatos with the beat result. The question is -how is it to be procured in its cheapes form ? If some chemist would tell us this, and some respectable manure dealer would sell the salt at a reasonable price, I think it would meet with a large sale; at all events the dealer would find a customer in on

On Laying Down Land to Grass.- I have long d at the conclusion that it would be impossible to grow Wheat profitably to any extent upon strong clay
lands; and my observation, in going over several thousand acres every year, has also shown me the great advantage to be derived both by landlord and tenant, in adopting the system of laying down this description of land to permanent pasture. It should, however, be borne in mind that it is only strong clay soils which it is desirable to take out of cultivation, as, whilst these soils are most difficult and unprofitable to work, under existing circumstances, they produce, when properly aid down, the best pasturage. On the other hand, " middling" and "poor" soils, with porous subsoils, opinion that, whilst a great portion of strong land should be laid down, there are "poor" and "middling" pastures on porous subsoils, which would produce much more, and be found of greater profit to the farmer, by being ploughed up; and I have, there-
fore, in various lettings, allowed such pastures to be converted into tillage, on condition that the In the system of yearly tenancies it can hardly be expected that a tenant farmer should, under ordinary circumstances, without assistarce, undertake the laying down any great extent of clay land, as it is a fact nown to all practical men, that after the first two or hree years the greater portion of the young Grasses disappear, when the land becomes for some time comparatively useless, and without good dressings of long period elapses before the pastures are established, Mr. Base, in his speech at Derby, suggested an allow. ance of three years rent by the landlord, and in the discussion at Uttoxeter this was considered liberal, bat by some unlikely to be allowed. I am glad to be able o state that I could name several landlords who have acted very liberally in this matter; and in a recent valuation and re-letting of an estate, upon which there is a good deal of old tilled clay land, I arranged for laying down a considerable portion, as the fields becone fallow, the landlord providing all proper Grass seeds, and in the second year allow. ing the coat of 15 tons of good manure, equal alto-
rental of the land being a little more than the annual I am happy to say the arrangement was considered satisfactory to both landlord and tenants, and I have ad doubt that, ultimately, the money so expended, whilst benefiting the tenants, will prove a profitable iavest ment to the landlord. Various opinions exist as to the best mode of seeding down for permanent pasture. Is many districts, where the land is naturally suitable for Clover and young Grasses, the practice of seeding dorn without a crop has been successfully adopted; but in my own experience, on strong clays, I have found it best to make a good dead fallow, well prepared before the year, when the land should be worked as fing of possible, and the Grass seeds sown in the ordinary way Of course, before seeding down, or indeed before any profitable system of culture can be adopted, the land should be made thoroughly sound by all requisite under-drainimg. John Shaw, Land Agent, Derby.

Tithe Commutation: Septennial Averages.-As many of your readers may feel anxious to know the result o 1864, published by authority in the London Gazette of the 30th ult., viz. : -

Per imperial Bushel.

I beg to state for their information that each 100\%. tithe rent-charge will, for the year 1865, amount to $98 l .15 s .10 \frac{1}{2} d_{\text {s, }}$ or abjut $4 l .8$ s. per cent. lower than Tithe Commutation Table," will show the worth of 100l. of tithe rent-charge for each year since the passing of the Tithe Commutation Act, vi\%.:-

Charles M. Willich, Actuary University Life A ssurance
Facrety, 25, Suffolk Street, Pall Mall East, Jan. 13.
Yew Poisowing. Two years ago last September
number of yearling cattle of both sexes grazing on mixed seeds strayed during the night into a youns plantation in whicb there were several plants of the Common or English Yew (Taxus baccata), of from 6 t the following morning, one had already died. Judging the cause, we had them at once removed to the farm Jard, a distance of less than a quarter of a mile; on their way there one dropped down and instantly expired; three others were also severely affected. They seemed paralysed, and in a state of stupefaction; they also fell down several times between the field and farmyard. After remaining on the ground for a short time they could be induced to get up and proceed for a little distance, when they would gain fall down. In each case the belly was distended to an unusual extent, sometimes the nervous
system seemed affected, producing a twitching and convulsive motion of the muscles of the body. We lost no time in administering a bottle of Linseed oil to each of those appearing to suffer, and at once sent for a veterinary surgeon, who recommended purgative medicines in order to free the system as quickly as possible of the offensive matter. Those who recovered ppeared dull and sluggish for several days, though we could not afterwards discover any ill effects either on their health or progress. .On post mortem examination the young succulent shoots of the Yew were found in the paunch, though only in small quantities. In cases of this kind, where timely discovered, we think Read's Pump might be used with advantage, as by liberating the gas the danger might be mitigated or avoided. Poisoning by
Poisoning by the Meadow Saffron (p. 35 b).-
answer to Mr. Maw, I would refer lim to your Journal tor 1862, p. $506 a$, and also extract the follow. ing from the Bath Chronicle, some time in December, 1857. "Benjamin Freeman, haulier of Eristol, fed his horses with purchased hay made into chatf; the horses shortly after eating it were taken very ill and appeared to have been poisoned. Three of them, valued at 73 .,
speedily died. The hay from which the chatf had been made was then submitted to Mr. Herepath, the analy tical cbemist, for examination, and found to contain a large portion of Colchicum autumnale. Diss.

## Foreign Correspondence.

AtAMOS, Burnos 'AYRRs (concluded from p. 36). -It remains to me yet to give your readers a sketch of our agriculture and its developinent. In the more immediate vicinity of the city of Buenos Ayres there
are a number of small farms devoted almost exclusively to the production of green fodder (Lucerne) for the
supply of the city in spring, summer, and autumn used for the feeding of horses
little farther out Wheat, Barley, Maize, Potatos and Pumplins are grown, and Lucerne extensively cut for hay, as well as tor soiling; also large plantations of
"Peach" wood, "Paraiso," and "Acacia" are made, rielding fuel and posts for fencing purposes; there ar also farms on which stock are kept for dairy purposes and sheep for sires, for the improvement of the native breed of horses, \&c.
breed of horses, ev. There are several outlying districts and colonies in
the heart of the province, on the coast, and on the banks of the rivers, where grain, Wheat, and Maize are extensively grown; and efforts are being made towards extensiverth to introduce the regular cultivation of Cotton with some prospect of success.
Agriculture has not been behind in the general advancement. A few years ago the true Roman plough, with hardwood share, and a rether with hide, were the with implements of tillage in use; the plough merely scratched up the surface, leaving the uprooted Grasses t be dried by the sun. On land so worked over a couple of times, the Wheat, Barley, \&c. was covered in with Grasses and weeds came up together in no very unequal proportions; the crop when ripe was cut with the of hard bare ground, encircled with stakes and hide rope, and into this circle a number of mares and horses were turned and driven round and round until the grain was threshed out and the straw broken up into fine chaff. The winnowing process consisted in the mass of grain and chaff being thrown up into the air with shovels, the wind separating the chaff from the grain; not unfrequently, rain coming on, much damage was done, and sometimes the whole crop lost.

The cultivation of the Maize consisted in the grain being dropped in the furrow of the plough (if furrow it could be called), and covered by the succeeding course, and so on every third furrow; the crop then took its chance till'ripe, when the ears were gatbered
from the stalk. Anything like a "fence" was rarely seen; Potatos there were none grown, and those that appeared on the tables of a few were imported. The "Pumpkin" was the chief vegctable; for these the land was ploug (somed) and furrows opened at about 5 yards apart ; others were then drawn at right angles with these at about the same distance at the inter-
secting points, a little soil was gathered in a mound, and three seeds placed in each. All crops were exceed ngly precarious by reason of the impertect and shallow
tillage. In a'season a little drierithan usual, as a matter of course when the ground was stirred to a depth of scarcely 2 inches the crop was burnt up. Such a thing as hay was almost unknown comparatively few years agn. Barley for horses. Subsequently Lucerne was introduced, and sown in smat plots in the outskirts of the tows
The first improvement in the country plough was to point it with iron, and this iron point gradually form of a share. Some British settlers introduced the old English swing plougb, and trained horses to draw it. At the present day all the farms within many leagues of the city are fenced in with wire fence and dited, and many are surrounded with an impenetrable
hedge formed of a prickly plant of the Mimosa kind, known as Napendy. The farms vary in size from 30 to 40 acres to several thousand acres, the larger ones coubining tillage, pasture, and plantations for fuel and posts for fencing purposes.
The Crops.-Lucerne is grown for feeding horses in the city and for hay. A relatively immense eurface is ccupied by this crop, yielding large quantities of fodder. For soiling, Lucerne can be cat six or seven
times in the year, and three tiraes for hay. On several farms no less than 250 to 300 acres are occupied by this permanent leguminous Grass. The various sorts of grain especially the Maize. Potatos are also a crop of importance; two crops of these of the same variety are taken off the same ground, one being sown in the spring, and these being gathered, seed of this spring
crop is sown in autumn. Wheat in some districts is grown extensively year after year ; in others it is rarely
The tillage for all crops is very much improved. The implements generally used are the common American plongh, drawn by oxev, and a henvy harrow of wood, with iron tines, with which a furrow of some 4 inches is turned and reduced to a good tilth with the harrow but there are a few farms in the possession of our
countrymen, where some of the best English imple. ments of tillnge are used.
The Scottish swing plough, iron-Howards' and Ransomes swing and two-wheeled ploughs, iron harrnws, chain larrows, Rollin's cultivators, ridging everal mowing and; and during the past two years bave been introduced and worked with complete ruccess. I myself cut over 250 acres of Lucerne with
Burgess \& Key's mowers, and raked the same with Experim horse-rake this past season.
Experiments are being made by two or three parties
sundry of our fallow crops, and the period of the
year at which they can most advantageously be sown. These trials extend to the Swede, Mancel, Carrots, and Rape. The only difficulty I foresee lies in the frequency of lengthy periods of dry weather, which will necess:rily render such crops precarious. Eftorts are about
be made to introduce some of the perennial (Arasses most esteemed in Eugland. Beans do well, aud will prove a aseful crop
The soil is a rich alluvial loam, without so much as a pebble, "resting ou a subsoil of silicious clay. On the
lower lands, called "Buñados," the coating of loam is very thin, having been but recently freed from permanent surface water by the natural decpening of after rains, and the soil appears to be scarcely formed, retaining much of the character of mud deposits. By opening a few ditches to drain more rapidly the surfac water these lands prove very rich under tillage, pro
vided it be efficient, and deep-rooted plants thrive i the severest droughts. In moist seasons the growth of everything sown on thom is excessively rauk; straw crops would be impossible, or rather, I may say, straw as to be almost unfit for hay, but producing enormously for soiling purposes when cut at half growth; if, how ever, the surface draining is not effectual, and tillage
deep and thorough, Lucerne rapidly dies out by reason of the existence or generation of hydrated silicic acid.
I conclude abruptly, as I find I have exceeded the limits I proposed. I fear you can ill afford space fo the matter. Alamos, Oct. 24, 1864. [Mauy thanks.]

## Socteties.

East Lothian: Is it expedient to Increase the Number of Sheep in the full und most inteligest insideration ht a recent meeting of this Society. The following is an abridged report of the discussion :-
The Chairman, Mr, R. S. Skirving, Eaid: This subject we are about to discuss appears to me to involve five points or propositions, each of which I shall notice very briefly. The propositions to which I have alluded are-1st, Are the present prices of grain likely oo be permanent? 2l, Are the pese pent prices wool likely to be permanent? 4th, Can our agriculture we so changed as to admit of a large increase of sleep? and 5th, What variety of sheep would it be prudent to cultivate?

don't
 he only had 98 acres in Turnipp, yet he had 1200 sheep, 90 catcle sheep in a great measure on artificial food. It is quite clear that
at least one East-Lutbian farmer at that time did oxactly at least one East-Lutbian thamer our farms manufactories of
what Mechi has told us to make
beef and muttou. Men like the late Mr. J. Brodie of Abbeymains, and Mr. Cuthbertson, we must all look upou with
pride. Now, it was all very we!l to say, "Go and do likewise." But you require three things. You require furms capable of
dring it. I deny it could be done on some farms-strong clay bred to cultivate grain, and it requires a great deal of special myself a fair farmar in producing Wheat, Barlog, and Onts; there is another difficulty iu the way of farmers buying some
2000 or 3000 sbeep-that of having insufficient capital. Mr.
Mechi, in his panaceas tor that, says, if we have not money,
why do we farm so much land. Instead of a man takivg

Mr. Douclas, Athelstaneford, said: In making the following remarks upon the subject under discassion, I shall treat it under two heads. First, "whether it would be expedient to endeavour to incrense the number of siseep in the county;" and, secondly, "what varieties it would be most profitable to cultivate."
We have two very important reasous to induce us to increase
the number of sheep on our farms at the preaent tine-viz. the number of sheep on our farms at the present time-viz.
the low and unremunerative price of corn crops, and the coma
paratively adequate paratively adequate price of beff, muthon, and wool-the
former being fully a thrd below the ralue it can be grown at
to pay, while the latter
valy to pay, while the latter may be paid to be at a pricg fllly its
value. Bexides, by throwing more land into arass, we shall
lessen lessen labour, curtaido ur guazo bill, and save at least a pair of
horses on the farm, and the tear and wear inseparably
nected cropping is pursued, that the proportion of a frotation of
grain cher grain crop is paysulug, at that the the proportion of a frices a much under less sum than duriug of the fast eight that have been let in the connty
money preceaing 19 years, or about 53 s , per quarter), the other
half being puid in grain accurding to the fiars prices.
Now this is in unsitive thess to the farmer of
no nn that pintions of his farm for which he pays muinery.
Of courne, Ido not adineate niggardly farming the taking all.
and
 a full arverge crap in ordinary beasons, as 1 , consider a Farmer
never lose if he gets bdek the expense of tio top) dreaning in

 be again for the simple reason that there are too niany in the
trade. It think it will of beof much mere easily than half-a-quarter of Wheat, and now it is up horn, down corn. Iustead, then, of purauing the Barley, Grass, Oats, Beans, or Potatns, Wheat, which consisi of ouly one crop of Grass during the six years, let us change it -being two-fifths of the farm in Grass, one-fifth in Turnups and the most suitable will be Turnips, Wheat ur Barley, Gras3, thereby save in labour, Grass seeds, guano, and horses; justified in making an alteration in our proportion of land growing graiv, and that it is desirable to sow down more to
Grass; for myself. I may say it is my conviction that we shall nover see the same prices for Wheat again, and do not helieve that it will average about 40 s. per quarter during the noxt
18 years b and I think it will be generally admitted, that it is
not pos-ible to grow Wheat at that price to pay present rent "What come to the second division of the subject, viz.
"Wate" In my op sheep it wonld be most profitable to culti-
of it; for it will bis by far the nost impor proper selection of stock. I think that as a rule, and considering present prices, a etock of part breeding and part
feeding sheep is the most profitable. and that half-bred or three-parts bred ewes are the must suitable for breeding eitber for lambs or aged sheep; at the save tiuse, a good deacriptinn They are good nurses, and kive little trouble, if it is so ning of April, when the young Crass is getting ready for
them. Their half-bred lambs get to more weight than the
three-parts bred, when kept until they are wedter ant fod three-parts bred, when kept until they are wedders and fed be employed with advantage in many cases to halfbreeds and three-parts bred ewes. A Innger ataple of
wool would be aot, and an extra weight of carcase, while early
waturity would not be a wanting; and I belleve this croes waturity would not be a wanting; and I belleve this croes
will feed as quickly as any other; but the largest class of ram should be avoided, one of a middle size should be preferredquality of mutton, a moderately short thick neck, and having a lambs being lengthy and ill-shaped or bad feeders.
Mr. Hope, Fentonbarns, said :-The long continued steady demand for butchers' meat at such bigh prices calls on us to consider whether we nay not with advantage modify the rotation of crops on our several farms to enable us to breed or feed more sheep, even though we should grow somewhat less grain. On every hand you hear farmers lamenting that the low price of corn swallows up the admitted large prolts from stock breeding aud feeding.
The natural remedy for this state of matters is to plough lens and pastmre more. In my neignbourbood land is seldom grazen for more than one year. At one time I considorend
this the most profitable practice. I have changed my mind
and my practice on this point. I fied by feeding sheep with

 best way of feeding. Thea, instoad of their going into firts orsecond years drass, he thought it would be better to adopt
Mr shirrefts suggestions in regard to permanent Grass, parMro shirreffs suggestions in regard to permanent Grass, par-
ticulaly on dry land. While he thought sheep might be in.
creased with a little difference in the management, he could throwing of land into Grass, as being more profitable in the
Tresent state of things. He did not see how that could
They wanted to make their stock fat, at least : with Turnips They wanted to make their stock fat, at least; with Turnips
they culd do that; and they could not grow Turnips except
by a ssstematic course of cropping. He would say let them
increase their number of stock-at least leaving one arable field near the mains laid down in perraanent Grass. The
might add another field whou the price of grain was so low
but let them continue a systematic course of cropping witl outher operations on the farm. This he might say: that while t. was desirable to have as few resitrictions as possible regarding
croping, he confeased he had never yet known auy grat
benefit benefit to result from departure from the mogt approved
methons of croppng. In regard to the gecond part of the
subject- the varieties most proftiobe to cultivate in this
county, he held that the most profitable way of farming was to coupt-the varieties most profitable to cultivate in this
count y, held that most proitable way of farming was to
deal with the well known and apporod stock suitale for this
climate, and in keeping with other circumstances. It was a alacy every where. He considered that for this part of the county it was the crosses and the Leic
them all in all, were the most profitable.
Mr. Paton, Slandingstanes, said: The question "Whether it would be expedient to endeavour to increase the number of sheep in the county?" will be easily answered in the affirmative. Any one going into the grain market of Haddington on a Friday, an again into the stock sales on the following day, will at once see the great contrast betwixt the biddings of the
buyers of grain and the buyers of sheep. In the grain market, after the bell rings to open the bags and com mence sales, one is sometimes inclined to think the merchants must have come only to see the market and lot of good or even indifferent sheep are not half-aminute in the ring before there are balf a score of bid showered upon the auctioneer from all directions, and he has often some difficulty in selecting one of them to run the lot up to a very high and paying price to the exposer, if they have been at all well managed. Now what is to be learned from the two markets? Cer tainly that there is too much grain grown, either in It is nower counties, but not too much stock.
It is now eight or nine years since I first went to Melrose will not now bring 40s. Int think worth 80 s. per qr. then
the figures answer pedient to endeavour to increase the number of sheep, and oreeding ones in particular, since lambs have gone to such
an extravagant figure ; more could be kept by changing the
 kept in Grass for two years-that the second year is not
nearly equal to the first, and the third is still worse if it will Tot grow pasture proftably, surely by manuring it will grow
Tares. No doubt, Tares often leave the land in a very dirty condition, and, if taken as a green crop, often leave their bad sown as cleaning or green crop? Taking the average price of good crop of Tares, partly cut and carried into conurts for cattle, and the remainder eaten on the ground by sheep, will pay as cleaner too. Many English as well as Scotch farmers are using wheat pretty freely in feeding this winter, and for all
secondary Borts perhaps it is as good a market to'diapose of it as they, can get; but I'm sure that dear as butcher meat is, it
won't pay to grow Wheat to feed stock with. Then, instead of a crop of Wheat after Tares, a crop of Turnips might be taken,
and is often taken in other counties and it is well that Turnips do very well after them, and can be rained with lese manure than in any other way. Still, where land will grow
good pasture, the expenses are very much less. Many more good pasture, the expenses are very much less. Many more
shhep could be kept were fewer Potatos grown; and, excert
those farms somewhat near to a railway station, and wherp those farms somewhat near to a rail way station, and where $\Omega$
supply of manure can be obtained without a long cartage, it is questionable (taking yeear after yeart if they thil learvage it it it
per aore as Turnipg will do. No doubt, on roal Potato soil no
cro
Cra
eve my experience of last pummer very little per acere; but, lambs gives as large a return per acre as Oats are giving this winter with present prices. And compare the expenses of the but was it not too dry for Grass alleo? Again, I understand
that this county suffers more or less every third or fourth year from high winds. Very little wind hurts a head of grain when alwarly ripe; but it is quite the opposite with shoep, for they
al of day to sell them to advantage. On the card the question is also asked, "What varieties of sheep are most profitable to
cultivate?" We will seek far and wide before we find a variety that will grow so much wool and mutton for the fond consumed,
combined with early maturity, as the combined with early maturity, as the Border Leicester. I
think the main point for us is to endeavour to grow as much fond as we possibly can for sheep, and let each ore choose for
himself the variety monst suitable for the kind of fond grown.
The motion of Mr. Hope. "Thet the mition of mr. Hope, "That the club is of opinion that
increased, and of stock in the county may be still further and crnsses from them, have proved most remunerativesters unanimously adopted.

Southerbn Countirs Assoclation for the Encouragemont of Agriculture, Arts, Science, Manufactures, and

Commerce.-An Association under this head is no being formed, the objects of which are to promote by
meetings in the counties of Hants, Berks, Orfoul Surrey, Sussex, and Kent* in succession,-1st, exhibition of atock and implements, or urticles connecter with the pursuits of any of the departments established by the Association; and 2djy, for the reading of papery and discussions on subjects embraced withio the scheme of the Association. The Association will be under the management of a Council empowered to make bye-laws, offer prizes, nominate local or sub. committees, fix meetings, and do anything necessary and the Council is to consist of a president, two vice-presidents for each county, an honorary secre tary for each department, and 36 members, of whom an equal portion shall be chosen from each county b the members belonging to that county, or in default thereof, by the members in general at the annual meeting. An annual meeting and exbibition will be held in the months of May and June. Portions of the mornings or evenings of each day shall be given to bre reading of papers and discussion. Each separate under the control of the Council, by a sub-committee of the cepartment to which it belongs. Other meetings and be fixed by the Council for the reading of papers subject embraced by the A department for each blished, and the societies promoting these objects, for the purposes of the exhibition and meeting, will be implements and machinery, will form the firsi department; natural history, local geology, botan and horticulture, the second; the arts, manufac
tures, and commerce, as developed in these sir counties, the third; local history and archao ogy, the fourth; and the improvement of the awellings and the general condition of the
abouring class, the fifth. Any other department may be added by the Counill. Every subscriber of 10 s . per annum shall be a member, and entitled to ofe for the election of the Conncil. Every subscriber
of shall, in addition, be encitled to receive the reports and papers of the Association. Every sule scriber of $2 l$. per annum shall, in addition, be eligible for the office of president and vice-president. No subject or question of a political tendency shall be introduced at any meeting of the Association. Coo munications may be addressed to the Hon, and Re Samuel Best, Abbott's Ann, Andover; or Thomas
Pain, Esq., Ugford Cottage, Salisbury. The first eneral meeting of the members, for the election of the officers and Council, and other general business, will be held at Guildford, Tuesday, January 17, at one o'clock A large number of noblemen and gentlemen influence, and residents in the several counties, har signified their adhesion to the Association.

Night Schools. By Charles Whitehead. Pp, 少。 Longmans.
We have read this pamphlet with great enjoyment and we think most readers of it will agree with us in praising it. They may, perhaps, be at first displease by what seems to be an affected mannerism of style but there is thorough good sense, evidently the result o both sound judgment and experience, in the matter of this publication; and this very soon reconciles us to any peculiarity of phraseology or of diction by which is characterised. Besides, it is by no means certain that the peculiarity will be disagreeable to all. Let ut quote the Preface as an example of it, and then refer in more detail to the substance of the pages which succeed it:-

He who writes to the Times, pulls, as it were, the string of impertinent appeals; he gets cold water poured over him in buckets-full ; maniacs spout over him their anouy,nous
gibberish; desponding Christians damp his ardour with warnings 'and prophecies of the 'grcat tribulation ;' philan-
thropic parsons send forth streamas of inquiries and advices and taps of modern advertising ; and kind-hearted ladia interest. In self-defence he sends forth this little pamphlet."

The pamphlet thus introduced is divided into five chapters, entitled respectively The Banes-The Anti-dotes-Practical Hints-Clubs and Associations-an Certificates of Merit. The first sentence declares that " labour interferes, and always mist interfere, with the education of the working classes." This, however, we are glad to say, is far from striking the keynote of the whole performance. It sounds as if the author loore upon education and its object as something other tha the assistance which good training will give to and man towards attaining the full purpose for which thi life has been granted him. Labour is the lot of all and it need not interfere with the "education
whether they be handicraft labourers," living by their fingers or their brains. the word be used to signify that cramming of the
memory with knowledge and with rules, to which often is confined, then no doubt those who are fatigued

## Farm Memoranda.

Middlisex Farming.-The term Middlesex Furmer is generally understood in Hertfordshire to mean a per son who farms Grass land and finds a market for its pro duce in the London hay markets. A very considerable portion of the district now under consideration is occupied by parks, paddocks, and lawns in the hands of their proprietors, though the soll, except from its proximity to Londou, has little attraction fur the residence of the gentry. Some farms consist almost exclusively of Grass land, others, especially those which abut on the chalk district, are of a mixed oharacter. requires, as compared with arable cultivatiod, but little capital, fow and simple farm buildings, and no great amount of agricultural skill. The great object is to secure the first hay crop in such a condition that it may retain its welght, be set off by the best colour and bouquet," and so obtain the best price in the London market. The other operations of the farm have refer ence to, and are made subservient to, this prime object. Very many of the fields are laid out in small and not very convenieut enclosures; frequently overgrown with
timber in the hedgerows, which are generally laid after a cortain number of years' growth, though on some farms the Quicks are kept always neat and trim. Hay farming from its very nature is a precarious and anxious occupation; ruled very much by the changes of the weather, and requiring the constant practical application of the proverb, to "make hay whilst the
sun shines." Many of the farms, and "especially those near London, are held by persons engaged in some other business, as the hay farmer has obviously much time on his hands. Where the land is exciusively Grass the number of permanent labourers employed is very limited; mowing and making the hay are often performed by strangers. The mowers come from the counties of Bucks, Berks, Uxford, and other places, in companies; the work, as is usual in such cases is done by the acre, the price varying very much with the demand for their labour, the state of the weather, the weight and condition of the crop, and such like incidents. The haymakers are often, like the Hop pickers in Kent, strangers brought from various quarters, seeking this casual and for a time fairly paid employ ment. They are sometimes even hired by the hour, so that if the employer be dissatisfied with their work, or the farms consist of arable as well as Grass land, the labeurers on the farms, with the assistance of the casual labour which the agreeable associations of the hay field seldom fail to call out, are found sufficient to secure the crop. Tedding machines, which are now brought to such a state of perfection, are much in use by the larger farmers, though much hay is still made without them; these as it is well known not only throw the hay from the swathe after the scythe, butare found most serviceable, especially under some conditions of weather, in securing that rapid accomplishment of the process, by which the colour and weight are both retained, and time and labour economised. The introduction of the use of rickeloths said to have been invented by Sir Joseph Banks for the protection of the rick in the course of its building, and portable scaffolds to facilitate the pitching the hay from the carts, is within the memory of man-and are now
amonget the most economical, if rather costly articles of the hay farmer's stock. The larger the rick generally the better it cuts out. It requires much practical experience, much patient discretion, to put all the water must be evaporated to prevent mould
and dust; to strike the balance betwoen the too great desiccation of the hay, and its consequent loss of those succulent properties on whioh its weight depends ; and the carrying too soon, and so endangering over heating and firing the mass, or the veratious alternative of cutting or turning the rick, a process which, as is well known, calls forth from the passer-by the jeering inquiry, "Farmer, have you lost your watch?" Large
ricks also require skilful builders, under whose guidance the work on the rick is carried on, special attention being paid to the probable setcling of the
whole equally aud in proper form; when the rick is finished in a rectangular form, the sides are pulled and the thatching performed with care and with especial regard to the eoonomy of straw in a district, where if not grown on the farm, it must bo bought at a high
The hay is
The hay is sent to market in loads of 36 trusses of 56 lb . each, and is usually consigned to a salosman in the London market, the trussing and placing the hay on the carts, the making the bands, and cutting out, all require skilful and experienced hands, who either truss by the load, as casual labourers, or belong to the farm. The carts used in the field and on the road are of rather an uuwieldy character, with large and broad Londoa market receives the entire produce of the furm, a load of London stable manure, which usually costs about $3 s .6 d$. at the mews or stables, is deemed an equivalent in return ; this is deposited in clamps, is which some in due time finds its way to the fields, bears the local are mown a second time. This crop sumed by cows; this is deemed a bad practice.

The after Grass is sometimes fed by neat cattle, but mostly by sheep, in addition to such artificial food as will make them off at the turn of the year, before the fields are shut up for the succeeding hay crop. The hay trade thus carried on involves the necessity of
much night work on the road for men and horses, and too often has a bad moral effect on the former, by constant temptations to drink, and sometimes to dispose dishouestly of the fodder of the horses and cceasionally of a portion of the load itself. These evils are so keenly folt by some persons that they prefer grazing their land to sending their hay to the London market. Long-woolled or half bred sheop are preferred for this purpose, as it is well known that they are less gregarious than Downs, and are content to lie singly on the pastures. J. C. C.

## Miscellaneous.

Steam Locomotion on the Righway.-In corroboration of the statement in the memorian from the Wakefield West lading Steam Compauy, that locomotives are less dangerous in the day than at night, Mr. J. IIoward, on the reading, at the weekly meeting of the town which the writer complained of "sundry infernal machines" passing through the streets, and endangering the lives of the public, said that "hundreds of been loconotives were now in use, and so far as he had occurred for ascertain not a siagle accident had where excluded from the streets in the day he could bring evidence of injurious results that had taken place in the night. It was the practice of his firm invariably to send a man a hundred yards in advance of the locomotive, in order that he might, if he met spirited animals-whether in a carriage or not-stop the machiue until they had passed, so that there should be no accident. One went to London and back the other day without the least trouble. He saw no more danger in it than in an express train passing a level crossing, nor yet so much, because they could see the road locomotive in time to get out of the way, but there probably would not be time to get out of the way of an express. He rode as spirited a horse as most people, and it took little notice of locomotives. Horses must be broken to it; for they might depend upon it that road locomotives would come into general use in the kingdoun ; it would be as little use to oppose them as it was to oppose railways."-BelC's Weekly Messenger

Wages in Lincolnshire.-The lodging and mainte. nance of agricultural labourers was the subject of a very
interesting paper some time ago, read by Mr. Marshall interesting paper some time ago, read by Mr. Marshall
before the London Farmers' Club. The following are the arrangements adopted in North Lincolnshire, on a farm of 500 acres of Turnip land, where five farm servants, under the superintendence of a married foreman, are em-ployed:-An ample house, and garden for vegetables, is provided rent free; 30l, a year in wages is given: to the foreman, who has also the produce of two cows for five or one cow for three men; 26 stones of bacon (i.e. a fat pig weighing 26 stones) for himself, and 25 stones for each of his men; be has further 40 stones of flour, 20 of best seconds for puddings and pies, and 20 best thirds for bread for each man, one quarter of malt for himself and the harvest men, and one sack for each man servant (equivalent to one pint per day and four in harvest). He brews himself, and has five tons of coals for the year's consumption; he finds candles for the day fos and chaff house when required; and has 1s. pe day for all casual boarders, such as additional harvest men, blacksmiths, carpenters, \&c., who work by the day, and have their board. The men have three meal per day. For brealflast, hot bread and milk, and cold
meat; for dinner, hot meat, pies and puddings, vegetables, and one pint of ale; for supper, hot meat, bread and milk, or pea soup. By this means they have always meat three times a day, milk twice, and beer once. They pay for their own washing, and are allowed an interlude of three or four days as a holiday at some fitting period during the year, which always expires on the 13th of May. The annual expenses of their board and wages may be set down as follows :-

Foreman's wages
26 stones of bacon
1 quarter of malt
2 cows, at $9 s .0 \mathrm{~d}$. each per week.
130 atones of bacon, for 5 mell a
5 sacks of malt, at 98. a bushel
5 tons of coals, at 128 .
2 wagko coers' wares, at $12 l$
2 middle men, at 102
2 middle men, at lú
1 boy, at $6 l$...
These items amount to 188l. 8s. for six men; the y early per week.

## Calendar of Operations.

Jandary.-The subjects to which we refer this week as among the topics requiring special attention this month are the following:-

Manure Management.-The following account of the advantages of a covered dung-heap is taken from the Agricultural Gazette of 1852. A correspondent then spoke of the three ways in which alone manure is perfectly saved, viz: -1 -1st. The plan now general over the better farmed counties, of ploughing in fresh manure on the autumn stubble, in preparation for the succeeding green crop. 2d. The plan of liquefying the whole exuvie for distribution by steam power and iron pipeage over the land. 3d. The plan of having the manure made in covered court-yards. The droppings and soiled litter of stall-ferd cattle, and the same from the work-horse stable, are daily thrown into a walled and covered pit, care being taken that they are intermixed. A dozen feeding pigs are kept in the pit; any loose litter there may be found lying about, together with road scrapings and odds and ends of animal and vegetable refuse, are thrown in ; the pigs mix and incorporate the whole well together. From time to time liquid from the manure tank is pumped in; and thus we have generally a deposit of a considerable quantity of well-made manure at hand, to supplement the dung heaps when they are exhausted. These (the dung heaps) are managed on a system which is simple and efficacious. The manure is carted out as the boxes become full, and thrown out of the carts into a heap of 5 feet in heirht by 12 feet broad. As we advance in this building we follow with a cover to the top and sides of clayey mould. This cover is at first about 6 inches thick. The still open side, to which we are adding, admits a small degree of atmospheric action, which induces a gentle heat. When this bas gone on for three or four days, we add 3 to
6 inches more clay or soil, over which we pour dilute urine. This keeps the fermentation going on in the heap, the gases from which have to permeate the clay ere they can reach the atmosphere, and the now wellknowu absorption of ammonia by. aluninal earth prevents any waete. Indeed, with manure taken from covered boxes, there will not be any escape of vapour from the clayey covering till the dilute urine is plentifully applied ; even with manure made in courts exposed to rain, there will be an escape of nothing
but of watery vapour; a loss which is a gain, as there is less weight afterwards to cart on the ground. In ten days after the heap has been made, it will, if it has been properly attended to as above, be fit for using in Bean or Potato drills, being soft and unctuous; it is cooked in its own steam. Should it not be required for a month or longer, all that is necessary is to give it a coat of 6 inches more clay or mould, and it stands ready to be cut up when wanted. I find this system to work exceedingly well. I am satisfied that trom 70 loads of manure, carted out and covered with 30 elements than' $I$ should have from 100 loads of similar manure carted out and trenched up in the old mode to ferment.
8. Seed Time.-Wheat may be sown when the land is fit in January. Autumn Wheats are still proper for use. If the land be in good order 6 pecks per acre wil on a staie furrow. In situations where there is greater risk 2 bushels may be sown. Oats may be sown in January, though the better seed time is Febriary, and the more usual seed time is March. Arthur Young, in his Farmer's Calendar, referred to an experiment by an Earl of Winchelsea, reported by ,himself. His lordship said :-
"The genoral time of sowing Oats here fis from the boginning of March to the end of April: and it fathe opinion Iiable to beodestroyed by sprine frosts. Laat winter was very favourable for the experiment, as the weather was onen at I dvided a deld of 8 acrese equally: one hall was sown the day
after Christmas Day; the other half the middle of March. Five bushels per acre were sown broadcast on each part, and smalls. The early sown were ripe and cut one week bofore the exponed to any bad weather. I had a rood of each set out very
carefully in the middle of the field, reaped and threshed
soon as carried. The produce and weight were as follows:Winchester Bushels.

Late sown

- per rood, $2.2 .$. or per acre

| Qrs. |
| :---: |
| 11 |

Weight per Winchester bushel as soon as threshed:-
 Potatos the preceding year, 450 buyshels per acre, and was not manured for that or the Ost crop; it had before that been in
Grass for six or seven years. The soil is a red loam. In am inclined to think that ths early sowing will answer here, as unnecesary busbels per acre are still a common, they are an cient, and when the land is in. good tilth and in good condition, Peand
Peas and Beans may both be sown in January, though they are generally sown later. Peas for the London market are, however, very commoniy sown in January on light dry soil, in drills 15 inches apart. They are sown by hand in these drills, and covered by pulling down a part of the ridgelets between the rows by the hand-hoe.

The Feeding House and Cow Byre,-The following particulars are gleaned from Morton's Farmers' Calendar (Routledge) :-
Fatting beasts continue to receive their misture of chaff, pulped roots, and meal-which is made richer as the fattening process is prolonged. One half the quantity of roots formerly commonly given (or, say $\frac{3}{3} \mathrm{cwt}$. daily), is thus used along with 20 lbs . or more Beans and Barley meal, or oil-cake crushed and moistened, or their equivalent in Carob pods or Cotton-seed cake.
Cattle in store condition may be kept in a healthy, and, if young, in a growing state, on a few Turnips or Mangel Wurzels daily in yards, and fresh straw in their cribs, and a meal twice a day, consisting of a bushel of straw chaff, over which a hot and somewhat salt, thin, Linseed mucilage has been thrown. One or two pounds of Linseed meal and a small handful of salt to every gallon of water may be thus boiled in a copper, and thrown over two bushels of chaff, and given at twice during the day.
Certainly the practice of feeding cows in calf up till calving on straw alone, cannot be too much reprobated: the food is very insufficient, and lets them down so much in flesh, that when they calve, and are expected to yield productively, they lose a considerable time, and that, perhaps, the most valuable, in getting again into flesli before they give their usual quatitity of milk; but if they have been well and sufficiently wintered, they yield at once adequately.

The proper food for cows in this month is cut chaff, one half hay and the other half straw, with a good
bait of Turnips or Cabbages. Or, if green food and hay be scarce, less of them, with straw chafl' soaked in thin Linseed mucilage, as already said, may be substituted. For young cattle, the same chaff, and as much Cabbage or Turnips or Mangel Wurzels as they

Cows may, some of them, calve this month. If they have been receiving fodder in the straw-yard, as just stated they will be in good condition for calving. They should atterwards receive more succulent food than formerly-as Turnips, Cabbages, Mangel Wurzels. After they calve, they should bekept quite from the other lean stock, either in the house or in another yard, and be fed upon those articles and hay, or cut claff, mixed with pulped roots and 2 or 3 lbs . of meal, darly. The great expense of winter-feeding cows with hay alone eats up the profits of the dairy, even if none be given till they calve; for supposing them to calve in January or February, there remain three or four months for that expensive food.
In estimating the cost, it is not necessary to consider whether it will answer to give hay to them when at certain high prices, as many farmers are, by their leases, deprived of the power of selling hay. Where this is the case, the hay must be valued at what it costs, and not at what it would sell for. This estiuate easily made: and it will be found on calculation, that it can hardly bo valued as less than $3 l$. a ton.
it is found that cows fed on pulped Turnips or Mangels, 1 ewt a-piece, mixed with 15 or 20 lbs . of
straw chaff, and 2 or 3 lbs. of Bean-meal, give butter without any disagreeablo taste. And this is a much more economical food thau hay
In the weaning of the calf there are many methods. One as good as any is to let it suck for a week or ten days, feeding afterwards from the bucket with new milk for "another week, till it can driok easily, giving it 3 quarts at morning, and as much at evening. After wards, for the new milk skim milk is gradually substituted, and half a pint of good Oatmeal for each meal per calf is mixed with hot water for some hours before it is added to the allowance of skim milk which each calf receives. When many calves are thus fed, the oatmeal and water are in quantity enough, if boiling in the morning, to keep warm till night, and 1 quart of of warm mucilage may then be mixed with 3 quarts similarly prepared, may be substituted for the oatmeal. It is proper to add, that when calvez are brought up by haud to be afterwards reared and fattened as boef they should receive new milk constantly; the quantity being gradually diminished by the substitution of dry food, with access to water.: Oil cake may be given to
them, a piece to suck being put in their mouths after driaking their milk, so that they are easily accustome to the taste of it ; and a netfull of sweet hay aboal The lat
The last year's calves should now be fed libenll with chaff of hay and straw, mized with pulped rook either Turnips or Mangels; and they should be thoroughly well fed, and kept perfectly clean by mame of litter. At this age it is a matter of great cone quence to keep such young cattle as well as possible tor the contrary practice will inevitably stop "the growth, which cannot be recovered by the best summe food. To steers and heifers two years old, the same food in proportionate quantity may be given, the chan being of hay, if it is abundant; or straw, with baits of Turnips, Cabbages, \&c. It is not right to keep year ling calves and two-year-olds together; they should if in yards, be sorted out in lots of equal size and strength, or the weak ones suffer. And if the practica of giving them out l'urnips along with a little hay or access to the straw, should be adopted, yearling should receive in addition 1 lb . or 2 lb . of oil-cake
daily apiece. The two-year-old steers should bg i fattening order on the best food of the feeding homem as already described-or, if heifers, on the less fatto ing diet to which reference has already been made.

## Notices to Correspondents.

Carob Pod: X. The following is an analysis by Mr. Kenim

## GRAY'S OVAL TUBULAR BOILER.

INTERNATIONAL EXHIBITION, Class IX., No. 2119.
Mr. Gray begs to call the attention of the Nobility, Gentry, Nurserymen, Gardeners, \&e., to his

## NEW OVAL TUBULAR BOILER,

acknowledred by practical judges to be a great improvement on every form of Tubular Boiler yet introduced. It has proved itself superior to all other Boilers for quickness of action and economy of Fuel, doing its work with one-third less the amount required by any other.

Extract from Report in Gardeners' Chronicle of International Exhibition, May 24, page 476.
"The upright form of Bniler is usually made on a circular phan, but the oral form given to Mr. Grar's variety of it is said to be prefer able in conssquence ot its bringing the tubes in closer contact with the fire. The usual form of a flurnace being a parallelogram rather than a square, it seemis fensible that the Boilers on the oral puan anouma ring the
this being so, the change, though \& slight one, is no doubt in improvenent."

They are made of all sizes, which, with prices, may be had on application.

## GREEN'S PATENT SILENS MESSOR,

## NOISELESS LAWN MOWING, ROLLING, and COLLECTING MACHINES,

by spectal appointment, sole manufacturer

TO HER MOST GRACIOUS MAJESTY the queen.

GREEN'S PATENT LAWN MOWERS have proved to be the best and carried off every Prize that has been given in all cases of Competition. The Judges at the Royal Horticultural Society's Show, held July 20, 1864, awarded them a First-class Certificate (No Prizes were given), and at the same time suggested a slight altentim which has been done. Mesgrs. T. Green \&\& Son consider their MACHINES now as near perfection as possible, and in consequence have continued making them as ustull they will have nearly 3000 ready for delivery at the commencement of the season, and they hope with their present facilities to be able to execute all orders on the ider they are received:

Buth the HORSE, PONY, DONKEY, and ILANI MACHINES possess over all other Makers the advantage of Self-sharpening; the Cutters being steel on each side, when they become dull or blunt by running one way round the cylinder, can be reversed, again and again bringing the opposite edge of the cutters against the bottom blade, when the Machine will cut equal to new. Arrangements are made so that the cylinder can be reversed by any inexperienced person in two or three minutes.

Illustrated Price Lists Free on application.

Delivered Carriage Free to all the principl Railway Stations and Shipping Ports in Englarid

The above ROLLERS possess many advantages over all others; they are made in two parts, and are free to revolve on the axis, affording greater facility for turning and the outer edges are rounded off, or turned inwards, thus avoiding the unsightly marks left by other Rollers. They are manufactured of the best materials, and are got up ins manner surpassing any ever yet brought out.

## The Garvenersi Chomide.

SATURDAY, JANUARY 28, 1865.
mbetings for the ensting wbek.

A translation has lately appeared in the Annals of Natural History of a very important memoir by Professor H. Karsten on the mode of Formation of Cells." Two theories, more especially, have hitherto prevailed on the subject: the one that of Monl, who considered that cell-formation took place by the intrusion of a fold from the mother cell wall dividing the included mass; the other that of Schleiden, who conceived that the nucleus whioh is so often present in young tissues where an active process of dcrelopment is going forward, was the builder of the simple cell-wall, by effectiog a transformation of the mucilaginous substance around it into a gelatinous envelope, which subsequently becomes the membranous wall.

The latter notion is now pretty generally exploded, as the formation of the nucleus does not always precede the formation of the new cell, at well as from other considerations, amongst which is the fact that the nucleus is often external to though combined with the new cell or cells ; while with the former is combined an opinion, that free cell formation sometimes takes place without any interference of the mother cell wall.

An examination of the process of the formation of sporidia in the ascigerous Fungi is quite sufficient to show that free cell formation does take place, and some phenomena in the produotion of cells in gum, seem to indicate that free cell formation may occur in vegetable fluid still in connection with the plant, as it does in the animal kingdom in orgauisable lymph.

Monl added a theory to his account of the formation of new cells by intrusion, which has not received much countenance, viz., that the new
\#Histologtoche Untersuchungen. Mit drei Tafeln in stelo.
caruck. 4to. Bellin. 1 Thlr. 20 Sgr.
cell is at first clothed by a delicate nitrogenous membrane, whioh he calls the primordial layer and that this remains unchanged antil cellalose membranes are deposited upon its outer and inner surfaces.
Karsten now comes forward with a statement that in every case the formation of oells is free, and that their septa, when in apposition with each other, arise from these confluent membranes, and not from any development of the wall of the mother cell.
After speaking of former observations he says,
I shall here endeavour again to prove that all cells of vegetable tissue, as far as observation has yet gone, originate as minute free vesioles within the fluid contents of previously existing oells, and attain their normal dimensions after undergoing many determinate ohemical ohanges; and moreover, that the involution of the parent cell to form sopta, as far as is yet made out, though it may secompany its maltiplication, does not originate or pause it."

In support of this, he brings forward a variety of facts tending to show that the annular thickening of the cell wall in several Algæ, on which so much stress has been laid, never proceeds so far as to form a real closed dissepiment, or to divide a previous cell completely in two, though it may occasionally aot as a ligature, cansing a marked constriction.
His theory is far more simple than that of his predecessors, and for that reason more likely to be true ; and we think that it is very elearly stated, and rests on very powerful arguments. He has not, however, depended entirely on Algæ, but has supported his views materially by the investigation of the corkcells formed on the cut surface of several plants, both endogenous and exogenous, as also in Zamia and Cyoas. He seems, moreover, to disbelieve entirely in the notion of the organs which are called vacuoles being mere oavitios in a common substance. According to our author they are really cells surrounded by a very delioate membrane.
It is impossible for us in this place to enter into any details as to arguments on which he supports his views, but they are so simple, and so consistent with what takes place in the embryo sac, that truch, though some of his observations may not endure rigid oriticism, any more than some of those which he has clearly overthrown.

One of the most ourious observations he has made, and one in which he could not be well deceived, is that as to the behaviour of the contents of the cells of the common Cladophora glomerata, to be found in almost every brook, where a perfect joint is left between two which have been out
aoross. Free cells are formed or already exist in the sonnd joint, two of which are privileged, and expand into perfect cells. The upper one of these gives rise to new joints and branches continuing the growth upwards, while the lower one bursts through the old septum and the remaining endochrome in the wounded joint, and projects ultimately from the original cell wall, forming the radioal end, and attaching itself to any objeot with which it may come in oontact-sometimee to neighbouring threads of Confervæ. It thus presents a striking analogy to that of roots, as it is not covered with an extension of the original cuticle. It is singular that the proper membrane of this cell when attached, often branohes out altogether independently of its contents. This lower cell never seoms to give rise to a new cell. It will, however, be better to give the author's comment in his own words.
"The branch, therefore, is developed within and ander cover of the orginal enveloping membrane of the entire plant, whilst, on the contrary, the organ which represents the root of the higher plants is not covered by this general integument, but so soon as it has emerged from the surrounding wall of the cut cell, continues to elongate itself in the water quite free and unolothed.

We here find, therefore, in the development of these two physiologically different organs a similar phenomenon to that which obtains in compound plants; for all those parts of vasoular plants which belong to the ascending axis arg olothed during their development by the epidermis; Whereas this covering is wanting to the root, whose divisions are invested with a layer of tissae analogous in many respects to cork, even at their growing extremities."

It is curious that the two new cells to which the joint gives rise should thus preserve their polarity. Prof. Karster brings forward this polarity. Prof. KARstics brings forward this
end of the embryo in Phronogams is always turned towards the aperture of the ovule or mioropyle by which the pollen tube enters. The pollen tube may be considered as the radical end of the germinating pollen grain, and by communication with the embryo sac aral cell which is polarity of the indifferent or neutral cell whimately to give rise to the perfect embryo. It ultimately to give rise to the perfect embryo. It both in the animal and vegetable kingdom, consists of some polarising process.
We have said above that out of several cells
ontained in a joint, a few only, whether two or more according to the nature of the plant, are developed. The rest are either completely absorbed, and supply nutriment for the nascent cells, or some traces of them are left between the mother cell wall and that of the new cell. Prof. KARSTEN brings forward some examples of this. An admirable illustration will be found in the genus Ascobolus, in some of those speries (as for oxamole in A. Kerverni) in which the sporidia are developed in a separate saio which fills up only a portion of the ascus, and where there is a great space between the sporidia and the mother-sac. M. J. B.

When Mr. Rimmel, Dr. Piesse, and Mr. WarRICK were a few days ago delivering lectures on the history and manufacture of Perfuna fashionable audiences in the large conservatory at South Kensington, there was a plant close by silently illustrating the subject in its own way. This plant, which as Moore sings of the JasmineLet the delicious secret out To every breeze,"
was the beautiful Luculia anatessima which had been in full bloom for several wreks past in the position just referred to.

In the dull days of winter, when many of our trees are leafless and our flowers comparatively few; when even the Chrysanthemum has gone out of bloom, and the Camellia, the Azalea, and the Hyaointh have not yet come in, any plant which comes naturally into blossom has an especial value, and if its blossoms are sweet-scented, its value will, on this account, be very much enhanced. Such a plant is the charming Luculia gratissima. It produces its flowers in the depth of winter, the plant is highly ornamental in the conservatory, and the flowers are deliciously fragrant. When we take all these things into consideration, one is apt to wonder it is not more commonly cultivated in our greenhouses and conservatories. Perhaps the reason we see it so seldom may be, that it is not such a rapid grower as many of our ornamental plants are; and it is not every one, apparentiy, who can succeed in its management. But its requirements are simple enough, so that any one with a conservatory and a little patience, may easily have it in a high state of perfection.
Luculia gratissima is a native of the Nepal and Khasya hills, where the olimate is temperate, being neither excessively warm in summer nor cold in winter. It is, therefore, not hardy in Eagland, but it requires only the protection of a conservatory from which the frost is excluded. There is one peculiarity about it which it is of considerable importance to know, if we would wish to succeed in its cultivation, and so have it in its most perfect condition, and that is, that it requires plenty of pot room, ot, what is better, should be planted out in the border of the conservatory. It appears to be easily injured by sudden changes of moisture or dryness at its roots, and hence it is very apt to get sickly when grown in a small flower pot. When planted out in the border, as we recommend, it escapes a danger of this kind, and as we shall have in this way studied its wants, it will be found to
repay us with fine healthy foliage and abundant heads of blossom. We may add that it delights in a light loamy soil enriched with leaf-mould or other kinds of manure.
The Luoulia belongs to an Order, the Cinohonaceæ, which "contains a number of plants remarkable for the beauty or fragrance of their flowers, and unsurpassed in the vegetable kingdom. As a proof of this we may name the Gardenia, Irera, Bouvardia, Cinchona, and Manettia, and there are many others of equal merit.
In our enthusiasm about new plants we are sometimes apt to overlook the good old ones. On this acoount we have thought it might prove useful to draw attention to the charming Luculia gratissims as a valuable ornament for the conservatory during the winter months.

We regret to have to record the death of Mr
Conrad Lodigers, which took place at his house at
Hackney, after a week's illneas, on the 20 th inst. Mr.

Lodncess was in the prime of life, and though he for some time ceased to take any very active part in Horticultural pursuits, yet from his conneetion mith the once world-renowned establishment which owed its origin to a progenitor bearing the same name, the sad intelligence must arouse the sympathies of thoee who had no persoual knowledge of the deceased gentleman, and his many excellent qualities. To quath local contemporary :- "One of Nature's nobilit himself, and descending from an ancestry of whid he might well be proud, Mr. Conrad Loddiges lived in the warmest affections and most devoted attachment of all who knew him."

- It will be remembered by those who hun made use of the Chiswick reports, that the than Marbled Pelargoniums has been applied to one of the sections of zonal varieties of that flower. The group thus indicated, which is marked generally by the: pale green centre of its leaves breaking outwands in irregular blocks or marbly patches, and by the pallid colour of the footstalks of the leaves and flower trusses, and also of the stems, and which is well represented by the variety called Sheen Rival, appears to deserve more attention than has yet been accorded to it, and this we are glad to find it is now receiving of the hands of Mr. Hally, of Blackheath, by whom mo have been furnished with examples of some three or four novel kinds which he is cultivating under the name of Winter Variegated Pelargoniums

Mr. Halli remarks of the Pelargoniums belonging to this section, that contrary to the usual races of Variegated Pelargoniums, instead of losing their colour in the winter they become brighter and more effectire, and it is to the development of this character that his efforts are now being directed. The lighter tints, th reanarks, instead of being in these cases on the outaide or margin of the leaf, occupy the centre, and forms paler-coloured star running out more or less into the sone, and where this happens, revealing the bright mid tipts, to which, however deep it may appear when blended with the deeper green portions, the zone is in reality owing. As there is only a partial instend of a total absence of chlorophyll in the discoloured path they are very hardy and vigorous in constitution; and at this season, while most other variegated kinds out of condition, these are in their best dress, and very pretty as decorative plants for the conservatory. It is added that
The new varieties which Mr. Hally has forwarded, are called Monitor, Marie, President, and Prinem Arthut, the first perhaps being the best, if the specimens bofore us are fair illustrations of the genend appearance of their foliage respectively, for in this there is a good deal of red evident in the zone, in their present state thoy are not to be compared fh the Miss. Pollocks, the Lucy Grieves, and the Lady Cullums of the golden tricolor-leaved series, but they make a pretty variety, and we think give promise of considerable increase of brightness if their breeding marbled series well followed up. no reason why the hybridist should not realise leaves with a clamrar yellow centre, a brighter red zone, and a deep grean margin ; sund such would contrast well with the varieties we already possess.
We may mention that the varieties having this pule green marbled centre to their leaves, though usulit we remember always so, for in the Cailed. Dayspring ii which it was entirely wanting; and though doubtion those with a red zone are to be preferred, especially in the prospect of securing its increased brightness y the leaves of this Dayspring had a very pretty very distinct appearance.
Mr. Halis has communicated a further mon randum, in which he remarks:- - bserved as a rale in in those case as a ruie in variegated planus, consis of a lighter colour (never quite white), proceeding from the centre, the light colour-or rather want of colour, is continued in stripes down the outer side of
the leaf-stalk, and diffuses itself on the outer side of the alburnum, giving a delicate tinge to the young atem. Some of the new golden-blotched Japmer Euonymuses are good examples of this. On the othes hand, thowe with light (generally white) edged leares, have the stripe carried down the inner channels of to stalk, where it may be traced through the alburn the edge of the pith, but never altering the colour different sets of chlorophyll celts, either set respectivel becoming partly or wholly obstructed or paralysed

## FILLING PLOWER BEDS IN WINTEB

ALlow me to claim space for a fow remarks bearing on an article on this subject by Mr. Thomson, of keith, in your last number ( $\mathrm{p}, 51$ ). Much to my regu I whs from home the afternoon on which Mr. Tb called here, and the gardener having only been year with us, Mr. Thomson was thus led into the following mistake in his notice of our winter viz., that it had "been for years furnished
shrubs at an annual cost of some $50 l$. or $60 \%$."
Those who will take the troable to ref
article on Wiuter Flower Gardening, in Nos, 6 and 7 of your volume for 1863, will see that the origiual outlay, 16 years ago, was what we considered "very con-
siderable," riz, from $18 l$. to $20 \%$, but that was a first sud last experiment. Our present system requires "a few shillings, not yearly." This season we have been estravaganit, and spens, for the sake of experiment and naw cty, but this was not necessary. It would take bove 70 and 49 of your Volume for 1862 . So much for Noe 48 and 49 of your Volume fo
Owing to our now having a larger stock of self-saved seed, and last summer, so trying for many plants, beving kept the Cabbages from growing rank and coarse, our beds are better than they ever have been, and are prono however, to improve them still further next season
Enclosed is a notice by Mr. McNab, of the Royal Botanic Garden, which gives further
${ }_{w}$ It is parhap not generally kays:the Cabbage fumily can be turned to good account for the winter decoration of flower gardens. The varieties Gorman Greens are now endless, varying from pure white, through every shade to dark purple, almost approacling black, and running through every tint of pink and green, many of the varieties being beautifully edged, and deeply indented. The crimped margins of the white varieties are delicately laced with green, red, and pink; while the pink varieties are edged with green, white, and dark purple. Others, evidently crosses between the German Greens and the Savoy, have their outer leaves green, while the inner ones run through every shade from a dark purplish pink to a ight centre, giving them the appearance of huge Roses Miss Hope, of Wardie Lodge, has the merit of being the first in Scotland to apply coloured Greens for garden decoration, and perhaps in no garden at the present day is winter garden decoration carried to such an extent. It may be stated that the coloured Greens are sown and treated like ordinary winter German Greens and Saroys, and when sufficiently strong are planted out in the open field, where they leep dwarf. It is of the utmont pen airy place, so as to prevent them being in an up, their greatest benuty being in the dwarf compact state. After the summer flower borders ngured by the autumnal fosts, the beds are and prepared, and then planted with the Greens, arranged so us to give an artistic frect to each clump or bed. Some of the beds bave
 dark pink, and centred with dark purple; white others
have the outer rows dark, and gradually lightening to white centres. The collection of these Posy Greens, as arranged in Miss Hope's garden at Wardie, is well worthy of a visit, and few cultivators will go without profiting by it. The coloured Greens are very hardy, the winter months, aud can be removed in time to receive their summer occupants of Scarlet Pelargoniums, Verbenas, \&c. Various plants have been tried to give the flower garden an attractive look during winter, but nothing up to this time, for simplicity and cheapness, hen the time arrives for the removal of the coloured Greens, the fimest varieties should be selected for seedbearing plants. Such plants should be put at the base of a wall, where they will perfect their flowers and ripen their meed. Care, however, should be taken to cover them with a net while the seed is maturing, to prevent the seeds being carried off by birds. It is not necessary that each variety be kept apart, as the greater are the chances of new varieties being produced by having them together while in flower. Those not required for seed can be usefully employed for feeding cattle.'
Economy and cheapness are indispensable if a system to be popular. I hope to live to see our public parks and gardens no longer the deserted places they are at present in winter. That "there is nothing to or avoiding them; but to see the false, untrue taste for chromatic gardens" increase and spread among ns every true lover of Nature will deprecate. The argument in favour of that style that has always been used 0 me and considered unanswerable, is, that in winter you can have no colour, save that produced by dif-
ferent tinted gravels and cinders. The Kails do away with this argument. I own it requires a much higher grade of observation and cultivation of the eye and taste to find pleasure in form rather than in colour, but 1 maintain that for one person who will be found in our public gardens admiring and studying the various and gracefal groups of Conifers, there will be a hundred of Crocuses, Pmonies delight, stand enjoying a blaze colour alone we can, at first at least, attract the non gardening masses
Why should Battemea and Kensington give delight to thousands, and olevate and purify their tastes, and bring them ont of their hauses only in summer? The triumph of skill and knowledge, as displayed in the sub of the beds at Battersea, is not required for the growth of forms and colouse in its endless variety and beauty of forms and colour, and what wholesome pleasure it
would give to those who cannot have a sight of the admire in their own public Parks and Gardens at that admire in "heir own pubal season,"

For the sake of all let a true love of a garden be encouraged, more particularly among the young in our towns and cities. The town child cannot have Daisies and Buttercups, Heather and Gale, but it need not have man's bricks, cinders, and glass in its gardens, and may have Nature's handiwork to look upon there even

I leave alone all the present writing and talking for arainst the bedding-out gystem, the old-fashioned botanical and herbaceous border, the subtropical plants, sc. It is well there are such varieties of taste; let us all please ourselves in what we grow. I care not whether it be Mosses or Palms;' Bulbs or forest trees, flowers or foliage that are cultivated and preferred, only, I say, let III have real plants to work amongst; only let us in "trim gardens (not brickeries) take our pleasure," and if possible, keep Truth in them, and not merely in "our wells." I.J. H., Wardie Lodge, Edinburgh.
notes on gardens.-No. XXVII.
The Dubize Phaeix Park and ite Gardeysa,
THE Marden of
THE garden of the Viceregal establishment is, of arse, the Frogmore of the Green Isle; and naturally one would expect from this premise that forcing and
all its conconitants must be seen in it in a high degree of perfection. The largest expectations would not. be disappointed, for it is a really great fruit-growing garden, and scarcely lens inferior for its plant-growing, considering that money is not granted for the purchase of plants rare or valuable, and that the Superintendent himself has to purchase novelties and young plants when he wants to add to his exhibition groups. This, of course, precludes the cultivation of Orchids, or expensive plants to any extent, but their absence is well
compensated for by fine and numerous examples of softwooded plants generally, greenhouse aud stove plants and most others that oan be obtained at a reasonable rate when young. A long look round here could not but afford intercst and instruction well worth recording, but having "gone in" for a thorough overhaul of Mesars. Bain \& Moare's domains I had little more than an hour to spend with Mr. G. Smith, the very able gardener to his Exoelleacy; and this, of course, was spent upon the most salient points.
The chief sighs in the Vioeregal Gardens is not afforded by the flower garden or ornamental department, but by a curvilinear range about 500 feet long, and by ribbon borders in front running 100 feet longer still, in a straight line. A very wide horder in front of this long range was planted with popular bedding plants in simple straight lines rather far apart, so that each line was quite definite for the 600 feet. Then a wide wall, and then another immense ribbon border, with the plants gradually rising to hide out the culinary aspects. The visitor is introduced to this scene from its western end, and, as will readily be inagined, the effect is very gorgeous. When people first see it they are delighted, though of necessity the interest is not lasting These bordera have
been for some years the wonder of most Irish bedding-out people. A Connaught gardener would pronounce them "splindid;" a Hielandman who had not seen on his way some of the great bedding places, would no doubt ejaculato- "Ah, man, it's fine!" Hundreds of Englishmen would expatiate learnediy on "the bringing out of the colours," \&c.; and most of us on first seeing such a display would feel equally enamoured of it: but, brilliant as the systom is, and much though the skill and labour expended on it be, I caunot but think that a change to a higher and truer style of garden decoration must soon take root and grow rapidly; for we can no more find real pleasure in a garden displaying countless numbers of very few individual species, than we could in a museum arranged on a similar plan, a picture gallery with the pictures all alike, or a country with hills and vales, all, or nearly all, of one pattern. Mr. Smith deserves great credit for having brought this bedding and ribbon system to so high a degree of perfection in the Phoenix Parls, and there oan be no doubt but that, if another mode of arrangement were adopted by him, it would be equally well develaped.

The fine range of honses fronted by these borders have nearly all undergone a great improvement, i, $e_{0}$ having the back wall taken back 6 feet, the old root being left as fornerly, supported on pillars, and connected with the antilators are fixed. This of course throws abundance of light into the houses, gives more efficient means for ventilation, and a great deal of additional space for plant-growing. When this improvement is effected throughout the range, it will probably be second

Vines occupied almost every house in this range, and uspended abundant crops of the finest fruit, sufficiently plentiful indeed to make one wonder how one establishment could ever consume it. One house reminded me of that which shelters the great. Vine at Hampton Court. In it were 500 bunches of Grapes, weighing from $\frac{1}{2}$ to $1 \frac{1}{2} \mathrm{lb}$., all the produce of a single vine about
10 years oid, which now fills two-thirds of the house-

70 feet long, will soun fill it altogrether, and if it
shows a disposition to do more, Mr. Snith can eisily slows a disposition to do more, Mr. Sintls cur easily
knock out a partition and let it go alredd. Cuis Vine enters the house at oue end, is traiued longitudinally 7 rods pruned on the close spur system, filling the house from front to back. The roots feed both in inner and outer borders, and have, like the rod, been conducted lengthways along the border.
Hall and room decoration forms a chief item in the Viceregal gardener's daties, and in the graat rauge ware many indications of this. Among them were many score fine plants of Dracsena terminalis-not the finely coloured plant asually known by that name, but a much more graceful and free-growing plant, which does well in the large vineries, and is a most valuable plant for room decoration on a great seale. For the sare parpose Rassellia jnncea is grown, and surely nothing could make a more suitable drawing-room plant.

A curvilinear range for Peach calture, 220 feet long half a dozen plant houses, finely filled; plentiful accommedation for the smaller branches of forcing, Melon culture, foo, make up the remainder of the glass The the contente of ane two of thees puses I shall now allude
Pelargoniams are shown in London about three feet in diameter; they are anuually exhibited in Dublin by Mr . Smith between five and six feet across, full of blom, and of the most perfect symmetry, without a stake. How he produces these plants, which must be well remembered by all who have seen the Dublin shows, Mr. Smith has been kind enongh to infurn me "We start in March with a cutting, strike in bottom heat, pick out the point, leaving about three $j$ )ints ove the surface, grow on, freely shifting as required, and keep topping at every two or three joiuts. As the plants get large the shoots are drawn down to a string passed round the rim of the pot. When they get right angles, stretching some distance from the rim ; these being tied firmly to a string under the rim, a hoop of galvanised wire is attached the sticks at a distance of 3 or 4 inches from the rim,
and to this the shoots are tied down till the plant again gets too large to be tied to the hoop, when another is added further out still, and this the plant completely covers before blooming time." It looks then as untramineleu by a tie, as these are Showe, kinds being selected which, when grown in light, airy, and suitable houses, will support erect their own heads of bloom To form a plant 5 to 6 feet through, the stopping process is carried on to the third summer, and the plant grown away the whole time. The old phants were slightly cat in at once without being subjected to the usual drying and resting process, They of course out and very carefully repotted, kept in a gentle moist heat and shaded for about three weelks, and then gradually inured to light and air. The once into vigorous growth. Denser heads of bloom can be got in this way than from young plants, thouth the latter are the most robust and healthy.
plants in 10 -incl pots were 4 to 5 feet in diameter pots a size larger from 5 to 6 feet. I have seen most of the Pelargoniums shown in London during the past three years, but the very largest and best eveu of shown were for size much inferior to Mr. Smith which many exhibitors no doubt think exhausted. I'he fancy Pelargoniums, though well grown, were not nearly as fine as those seut to the London shows.

The culinary garden in which all these houses are situated, is divided by high walls into three compartments ; and both walls and gardens exhibited the best management. For the rougher vegetables there is another garden in a distant part of the demesne
A rather lofty stove poasessed more than usua interest from showicg many Bananas full of the finest ruit, but more still from being half filled with a plant f Bougainvillea glabra, which, planted in the bed of the tove, bad run up with a stem several inches in diamete to the top of the house, and there flowered in the greatest profusion. I could see many hundred twigs of bracts, but the sight as seen from the roof by a glazier must have been among those that are generally left to the imagiaation. It is worth recording that among the other well appointed garden offices seen quite a respectable building for the accommodation of the joung men was a noticeable
The flower garden proper (not at all so flowery however as the space in front of the great range in the culinary garden) is on the west side of the mansio which by-the-by commands grand mountain views) and is 4 acres in extent, obloug in outline, and into great squares by straight walks, with oblong beds filled with bedding plants along the sides of these, anc plenty of Trish Yews (which do so well in the neigh bourbood of Dublin that one would think "native air" was essential to their health) along the walks, excep on the side next the Park; yet the effect of this garden was most graceful and dignified from the wide breadths of verdant turf and the nearly due proportioning of
planted by her Majesty and the other by the late are Oaks and other trees in the grounds planted by her Majesty and other members of the Royal family. Majesty and other members of Nothing could be more creditable than indeed of all parts of the establishment.
To the north of the flower garden is the "wild garden," half pleasure ground, half wilderness, and in this is a little monument of peculiar interest. When Lord St. Germans left in 1855, each of his family planted a tree. The one planted her ladyship's death ccurring about the same time, the peculiarity of the circemstance induced Lord Carlisle to erect a little memorial on the spot where th
with the following inscription-

## Ponr tree ! a gentle mistrosa plactad th

To be the glory of the glade around.
Thy life has not survivod one fleeting year,
And she too sleeps beneath another mound
But mark what diffring terms your fates allow
Thine are the sapless root and witherd d bough),
Hers the green memory and immortal
These lines are now, unhappily for all those conoected with the late Earl's establishment, a touching memorial of the writer too; but his rule in Ireland has left a deeper impression than any memorial could convey, for he was universally popular, and by none connected with the Viceregal establishment and the Phoenix Parls, William Robinson.

ORCHIDS AND THEIR CULTIVATION.-No. III All exotic Orchids, whether eniphytal or terrestrial, an atmosphere somewhat foreign to their nature, even when best imitated, require more or less shade from a corching sun. The very plants that will thrive under variety of circumstances in the countries where they are indigenous, might succumb to similar treatment here. It is well enough to know-indeed such infor mation is most valuable-the range of temperature, the degree of moisture, the exposure, whether shady or open, of all plants under cultivation ; but it is not the precise habitat. For example, there are periods of drought and periods of deluge which occur in all tropical countries. In our systenatic way of treatment as to moisture or drought, as even takes place in our measure, and we ought to be, by maximum heat during a season of growth, and minimum heat during a season of rest; but were we to hazard extremes, either one way or another, in our artificial climate,
Again, there are somo epiphytes which, doubtless, are growing in their native country pretty much exposed to sun heat, as witness for example, R. H.'s
allusion ( 1864 , p. 1061 ) to Broughtonia sanguinea and some other species not named, which grow in Bring these home however, tie them upon blocks, get them as well estahlished as possible before you suspend them close to the glass, in the face of a full meridian sun, in; the months of June, July, and August-and rapidly from the leaves and pseudobnlbs, that you artificial climate fails to provide the necessary fond for assimilation, the leaves get scorched, and, if not, the chlorophyll is all but burned out of them, the plant sickens, and unless remedial measures be resorted to it may die. Growers of experience will never treat them so. Of course they tie them on blocks and hang them close to the glass, but they also take the precaution to shade them during summer for at least few hours in the day. Such is my practice, and they grow and bloom successfully. Seedling Orchids, like other plants propagated in the same way, are never exactly similar to one another; and it may be well to be explicit, and disabuse the minds of those who are apt to suppose that mere locality and exposure has lead us to believe. In our collection of Broughtonias we have them varying from a bright copper to a rich claret colour. This is a natural phenomenon, which those who buy half a dozen of imported plants can see for themselves. Not that I am ignoring the effects of light on colour, but it must not be accompanied by the influence of direct sun rays, else even the bright claret, which is the fastest of all the shades of Broughtonia flowers, will quickly lose its lustre. Most epiphytal Orchids do require light, and light in abundance ; but some slight screen must intervene between the sun and the plants that are grown under a glass covering, the reason for which must be obvious to the merest tyro in horticultural art.
Prudence suggeste, in basing any calculations on reliable data as to habitats, that the grower should already signified, it is possible to either over do, or fall short of any particular system of management. Generally speaking, light is of great importance to the well-keing of roany valuable Orchids-even the powerful
makes its appearance, if high in the firmament, shading of some sort is essential. But when we con light cannot be too highly estimated. It is the first requisite for promoting the health, and ministering to the flowering tendency of plants of every description. It is the gardener's first outcry, and it should be the architect's first consideration. This is why I have some objection to Hartley's rough plate glass for Orchid houses during winter. The numerous corrugations ver the surface disturb the action of light; and anything that has a tendency to modify light during wintry days, tells against the constitution of the of glass would require to be so low that the plants would not be more than from 6 to 12 inches from the roof. In fact it is observable, in dull foggy weather, that flowers are affected, in duration of bloom, under glass even of the finest transparency, which is dead proof against glass of an opaque nature. I would also object
to double-glazed houses on the same plea. There is, no doubt, all the benefits accruing therefrom that Mr. Bewley notifles in his paper read before the British Association at Newcastle-on-Tyne, as to economy of heat, natural dispersion of moisture on the plants during night, and freedom from drip ; but there is always the proportionate seclusion from light at a time when it is most wanted, that is not sufficiently counterbalanced by all the other advantages to be derived. The remedy for drip, so to speak, is in one's own hands, and the proper dispersion of moisture, in more money will provide the necessary fuel, but no human power can augment the light. Any reasonable suggestion that is likely to prove advantageous to the cultivation of Orchids should never stand unaccomplished for the sake of a few pounds extra expenditure; because they are a class of plants that grow ast into money, if under judicious management, but they retrograde in value much faster than they grow if neglected. As the maturation of the wood of the Vine, and other fruits, is one of the main conditions for ensuring a crop of fruit, and maintaining a sound constitution, so is the proper ripening of the pseudobulbs of Orchids essential to the development of flowers and the health of the plants. Of course this implies that a proper mode of treatment has been conducted all through, for to be successful with the cultivation of plants they must not at any time be too uch exposed to sufferance or surfeit
That the class of plants we are treating of will stand more fatigue than any other order is beyond question, but that is no reason why any grower should corture them so unnecessarily, iseeing that it may take years to put them into vigorous growth agaia. consider
why I wish to lay down, as a principle, what I conser the best medium for promoting healthful action of the plant, in all its stages. Light, then, forms an important element in"contributing towards success; therefore the less obstacle to its diffusion the better, more especially for established plants.
Plants, however, that are in a dried-up state, such as those imported, and auy that are sickly in collec tions, recover all the sooner under subdued light. It would be impossible to conceive a better medium than a double-glazed house for these infirm patients; for the light would not be too strong in winter, and were it so in summer a partial shading could be put up. In such a house the air would be a great deal more motionless, the system of the plants would undergo less fatigue, by means of subdued evaporation and
absorption, and health would more rapidly follow In these days, when imported plants form the staple of trade and auction sales, something of this kind would be very desirable for more quickly plumping up the shrivelled substanceless pseudobulbs and leaves-a desiderntum which I have always found it judicious to aim at effecting as speedily as possible.
One of the duties the cultivator has to observe in the annual routine of a plant's career-for by far the largest number of species only produce their blossoms once a year, and, if under systematic treatment, wil national into bloom year by year as rogularly as ou national holidays come round-is the length of time such as Saccolabiums, Phalænopsids, and Vandas of sorts, delight in shade during the growing season from seven o'clock in the morning to seven oclock a night ; or, more correctly speaking, for three months in the year, if the sun be brilliant, and proportionatel 80 in the beginning and latter end of the season. Others, again, such as Cattleyas, Lycastes, Odonto glossums, \&c., would be positively injured by such treatment, their leaves and pseudobulbs would be elongated without being properly consolidated, and consequently they could not yield such an array of Howers, and of such character, as those that underwent greatly modified treatment. That they require shade, and would suffer without it for so many hours of the day, we willingly concede, but not to'the extent that is sometimes adopted. So long as plants are not actually scorched, even although the leaves become pale green if they do not shrivel from the effects of strong light, all is well ; for they are not half so subject to decay and spot during autumn and winter, and then the leaves regain a colour of the despest green.
To sum up, it may bo averred that no Orchid wil
shading from sunlight, either in a greater or less degme according to the nature of the plant; and no plant io more impatient of shade during a season of rest, and in dull dark weather during the height of growth. This assertion, if correct, demonstrates beyond doub, the propriety of using the most transparent glass as command, so as to have light in abundance when light rection, the more suritable for the plants under in any os it is an easy matter to roll up and down canm, as circumstances demand. The system of shading in use in some places on the Continent, is s latting, work of wood, like an open gangway, which throws the rays of the sun obliquely on the glass, and does not darken the interior of the house so much as thick cotton cloth; but as it is a permanent covering during James Anderson, Meadowbank.

## Home Correspondence.

Winter Decoration of Flower Gardens. - I can almot imagine the impression made on Mr. Thomson on seeing the flower garden he speaks of at p. 51, plauted with Kail, and from what I have myself seen, Ifoed sure that the sight would be a pleasing one. The late Mr. Duncan (gr. to Lord Wharncliffe, at Wortley Hall, Sheffieldi) was passionately fond of winter planting of the flower garden, and as soon as the victims of John Frost were cleared away, the principal flower garden, which is situated in front of the mansion, was imme diately filled with the following plants, viz: :-Golden and other Yews, Variegated and other Hollies, Aucub japonica, Santolina, or Cotton Lavender, \&c. The varieties of plants used were not many, but with judicious arrangement they made a beautiful display during the dull months of winter, and I think I an say, without being ostentatious, that this attempt at decoration surpassed all that I have seen done in the same direction in other quarters. In the autumn of 1862 Mr . Duncan had the basin emptied in connection with a fountain, which is situated about the centre of the garden, and having erected a stage to the required height on which to place soil, some of the different coloured Kails were planted so as to have a gradual fall from the centre to the outside. The prominent position of this bed, together with the surrounding walks being of a reddish colour, iucreased the effect produced by most conspicuous. It was most amusing to hear tho various conjectures of visitors as to what sort of plants it cousisted of. How great, it may be imagined was their astonishment when they got near enough, to find thit it was nothing more nor less than Kail
ore, shall we say respecting a whole flower garden thus planted. It certainly may be considered a bold step to introduce the Cabbage tribe into the pleasure grounds; still the sight is doubtless a gorgeons one, especially when viewed from a distance. The plan of growing them in poor soil (as Mr. Thomson bas statace) is good; it will help them to maintain their colour, a should they get too robust, a cut round their roots with when required for planting. W. P. R., The Garden Shrubland Park.
Culture of Ancetochili.-No plants with which I am acquainted are more deserving of attention than thow, or have greater beauty of foliage. I am afraid, hom ever, that they are not generally well managed. I am
nevertheless convinced that they may be grown well mevertheless convinced that they may be gat purpooe for my experience is that the older they get the stronger they grow. I find them to do well under the following never earlier. The compost which I use is equal quantities of chopped Sphagnum, silver sand, peat o Cocoa-nut refuse. I place them singly in thumb-potor
with plenty of drainage; then I set them iu shallor pans and fill up between the jots with live Splagnaw putting a bell-glass over them, tilted so as to ada air, and keeping the glass as clean and dry as possid which they are very liable if not properly attended to Ithen place them in the East Indian Orchid hoon Where they get plenty of heat and moisture, setine ight but no sun. the growing season, but in winter only just enough seep them fresh. If they are kept too wet they are, I have already said, liable to dump; and if you allo them to get too dry they are apt to shrivel time to get them right again. I find keeping them nearly dormant as possible to be the best way The foliage should never be wetted more than avoided, as it renders the surface of the lear dim, March they will be strong plants. I then cut just below the first root, and pot them as pushes one or more gronths, which are remored potted not later than July as I find the better es c cause. To are before winter the less trouble permit me to give the sizes of a few of the plana possess:-A. Lowii has leaves 5 inches lou

3 inches wide; Lobbii has leaves 3 inches long and 2 wide, seven and eight on ${ }^{\text {a }}$ that; petola, which is
one of the finest, has from 10 to 12 beautiful leaves on one of the finest, has from 10 to 12 beautiful leaves on very fine, also a variety of Lowii, and several others.
E. Mitchell, Gr. to R. F. Ainsworth, Esq., M.D., Lover E. Mitchell, Gr. to R. F.
Broughton, Manchester.

Brownbervies.-I am told that in gambling houses the croupier rolls a ball, and cries, "Now, gentlemen, the croupier yome while the ball is rolling." An article on Strawberries acts on the nervous system much in the same way, and bestirs gentlennen to make their game. The time for planting Strawberries in spring-
the best time here, will soon arrive. February, March. April, or May will do when the weather is open and the ground in good condition. If runners can be
obtained in June, or early in July, of sorts that root quickly, and that make crowns speedily, they will with ballis of earth attached to them, obtained from nurserymen in the autumn, will also succeed, and jiell a good crop the next season. received in Angust from Mr. Turner 50 plants of Sir
J. Paxton, in pots, fine plants; and 100 plants without balla, quite as fine; but the latter are now very inferior to the former. I advise purchasers to pay a little more for plants and carriage, and to have them in pots
Angust is often too hot for plants without balls, and Sentenber, here at least, is too late for next year's satisfactory cropping. All Strawberry plants that winter badly, or are spring-planted here, are disfruited and deprived of runners-at any rate till they become strong; after a year's rest they become fine plants, crop well, and last long. Two or three crops may then be taken, seldom more. In the first place let me name a few of the best kinds of Strawberries, suitable only to first-class loams, unctuous, deep, and well drained. Foremost is still 1ritish Queen, which hates chalk, but does well in rich stiff clay, the stiffer the better. Then come Carolina Superba, Filbert Pine, La Constante, Myatt' Pine Apple, and Crimson Queen. The last, I believe
to bee more easily grown than any of the others previnusly named. It came out as Myatt's No. 3. My friend, Mr. Adolphus Kent, of Blechingley, lately spole of it in high terms to me. It is of no use whatever to
pat these into land of an inferior quality, with any amount of manure. They may now and then succeed, but failures will be more frequent than successes Therefore I propose to name, secondly, for the public at large, other Strawberriea, which in their way are all more or less, first-class varieties, and which being grow-
able with good cultivation and sure bearers, are, therefore, nationally the most valuable. Let beginners therefore, select those, of choose from those to which would recommend *alice Mande, Eclipse, and President. Strawberries that come in before these, are here uneatable. Let Mid-seasnn sorts be *Rivers' Eliza, *Empress Eugenie. Later kinds may consist of 'Wcnderful,
and later still, Boisselot's Seedling No. I. called La Vineuse. I am always pleased to speak well of a foreign Strawberry when I can. This is a very nice Strawberry, and possesses an iron constitution. It is sweet, level in berry, and has cropped heavily two years in succession. Sometimes it is earlier and sometimes later than the Frogmore Pine. Last year it preceded them ; so I put the *rogmore Pine a little later still. This is, I think, a wonderful productiou. It has superseded entirely al other late Strawberries that have any pretension to constitution. Out of gratitude, therefore, I must ask permis-
sion to subscribe to the Ingrain 'Testimonial. hear!] I like the Frogmore Pine better than any othe Strawberry here except the Royal Hautbois. White or rather amber-white and latish is *Bicton Pine, still I have cropped heavily last sumpery valuable. Chilians, vizo, Lucie and La Belle de Croncels, but I have thrown them away; the last is the best of the two, but they are not equal to, or even near to, Won-
derful and Eliza, Of Hantbois, "Rivers Rogal Hautbois, a great cropper, sure, early mideseason and late by far the best of all the Hautbois tribes that I have ever had. For beauty of plant and high flavour, but Tery small berries, the Black Hautbois is the best. perlaps, the best, and its parent, Relle Haubois is perliaps, the best, and its parent, Belle Bordelaise, 18 the next best to have. Of Aipines, *the Old Red
and White are favourites with me. Blanche d'Orleans is and to be larger than the Old White ; but probably this arises from its being more recently raised from seed. *Elton Pinerries for preserving whole I would choose *Elton Pine and Oscar; they are very firm and well well for jarts, *Sanspareil and Marguerite would do different beds of Eliza and others. Strawberries for foreng might consist of Alice Maude, *Keens' Seedling, nnd lecoq Pine. The last is the largest in berry, the heaviest Cropper, and best flavoured (highly Yined ham two peculiarities, $i$, stems of all Strawberries, and it retains (an unusual thing) its high Pine flavour in the forcing louse. (lut Pined. I sent it to Mr. Sturt's, at Critchill, where I tasterl it under glass. There was a very fine crop of Keens Seedling alongside of it, but they were not so abundant, nor so large or good, nor did their stalks
hold up their crop so well. Try a few plants of Lecog
under glass, and do not water the plants after the frui some Pined Strawberries lose under glass, The berries that I tasted at Critchill were somewhat dried, and had their calices reflected. I have no glass. My Strawberry plants of all ages out of doors, slightly
protected with leaves (but not maffled up so as to soften the crowns), were never finer. I may add that the two best novelties partially tried here last season, both very good, were Jolnn Powell and Lord Clyde, not yet let genial weather, the plants would be drawn out into premature bloom. W. F. Radclyffe, Rushton, near Blandford, Dorset.
The Barbarossa Fine on its oron Roots.-The subject of Vine grafting is now being treated in a way and at Thomson has alluded to this matter with a practical freshness that deserves our best thanks, and from him we look for still more valuable results in the sume direction. Speaking of the Barbarossa grafted, oue of your correspondents states that the Grapes on an ungrafted Vine were sharp and comparatively worthless, a statement which I think should not go forth maquali-
fied. A close acquaintance with this variety for 14 years proves to me that it is a most useful kind for ate leeping if we understand its treatment, 80 as to get such crops from it as we obtain from other good orts. Mr. Fleming, of Trentham, used to cultivate it successfully, and he would be the last man to send an nferior Grape to table. Colonel Tighe, than whom there is no better judge of Grapes, thinks the Barbarossa a good vinous Grape when kept till March, after which
we have had it with the leaves quite green. Last autumn I saw most of the best Grape.growing gardens in England, but only at Chiswick did I see the Barbarossa look well when grafted; there it was all that could be desired, but the leaves were shed in the early part of November. Your correspondeut " E ," noblc-looking innormes of last year respecting some will, I think, agree that it is worth further trial on it own roots. Chas. McDonald, Woodstock Park. [Fine Barbarossas were shown from Coombe Abbey last week, as reported in another column.]
Trees blown down in Somersetshire.-In a storm on the morning of the 14th January, a Beech tree was 120 feet in length circumference on the ground is swell of the roots, 14 feet; below the fork, which is 46 feet from the base, 9 feet 8 inches. In falling it over threw an Oak, which measures 25 feet to the fork, and 12 feet 6 inches above the swell of roots, and 10 feet 7 inches below the fork, from which rise two branches, each 9 feet in girth. In its fall it destroyed another Oak, which measures 50 feet to the branches, and 14 feet 10 inches above the swell of the roots. In the same storm a branch was broken off a Cedar of ference. 55 feet long and 6 feet 6 inches in circum ference. W. C. Trevelyan, Nettlecombe.

## Foreign Correspondence.

Royat Botanic Garden, Peradenta, Ceylon. The following passages are from the Report by the Director, Mr. G. H. K. Thwaites, as to the state of the garden from September, 1863, to August, 1864:-

Cinchonas.-Complete success is attending the culti vation and propagation of the different species of Cin plants chibi growe most perfect condition of health and vigour, and the number of each kind in the following list furnished to me by Mr. MacNicoll shows how suc cessful he has been in their propagation:-
Cinchona succirubra, planted out in the forest, 1345 (the largest plant being $13 \frac{3}{4}$ feet high, and the stem at the base $8 \frac{3}{4}$ inches in circumference); plants for talking cuttings from, 2380 ; ready for distribution, 42,450 ; in different stages of rooting, 32,800.
Cinchona officinalis, planted out in the forest, 1044 (the largest plant being $6 \frac{1}{2}$ feet in height, and the stem at the base $5 \frac{3}{3}$ inches in circumference); for taking cuttings from, 1934; ready for distribution, 58,747 in different stages of rooting, 47,400 ; of C. crispella not distinguishable from C. officinalis), 430
Cinchona micrantha, planted out in the forest, 300 plants for taking cuttings from, 320 ; in different stages of rooting, 229.
Cinchona Calisaya, plants for taking cuttings from, 82 ; in different stages of rooting, 24.
Cinchona Pahudiana, plants for taking cuttings from, 24 ; in different stages of rooting, 12.

It has been determined by Government that plants shall be distributed, to the extent they can be spared, free of ciarge, to persons residing in the Island. It is satisfactory to me to report that I have alreads received applications from 18 planters, and that the aggregate number applied for by them is 28,524:-0 this number nearly 9000 have been issued, and there will be no difficulty in supplying the remainder at once. I have reason to believe that I shall before long receive applications for many more plants, and I have no fear of being unable to meet them, as Mr. MacNicoll informs me he can furnish plants at the rate of 20,000 per month, if they are required.
The small number of plants of Cinchona succirubra growing in the open ground at Peradenia, are making great progress, and are in perfect health, though not so
robast in
A few plants of Cinchona officinalis, which were planted by way of experiment at Newera Ellis, were cold nights of February last, 24 Fabr. in one of the would not be safe to plant Cinchonas in the island much above the elevation of 5000 fet, of be liable to frosty nights succeeding the exceellingly hot days of the dry season.
1 have transmitted to Sir William Hooker, who has Kindly promised to have it submitted to analysis for
me, a small quantity of baric of Cinchona saccirubra from a tree three years old, and I hope to be able to communicate the results in a short time. Dr. de Vry, Professional Chemist to the Cinchona plantations of sava, who favoured me with a visit a few months ago, took to Eurcpe with him sone bark from a tree at Hakgalle whirh had died owing to the roots getting into swampy undrained ground, and he found, even in this unpromising specimen of bark, more than 2 per
cent, of alkaloids, and of this neariy 1 per cent, of quinine.
I regret to say that some seeds of Cinchona pitayensis, obagingly sent to me by Mr. Clementa R. Markham in March last, failed altogether to germinate.
Vanilla.-Nothing can be more laxuriant than the vines of this valuable plant growing here on trellia, and bearing an abundance of pods this season; thus proving he idea to be an erroneous one that the Vanilla will thrive ouly upon living trees. Notwithstanding the permission accorded to me to give plants to any natives expressing a willingness to cultivate them, there is, strange to say, very little inclination shown to pay attention to a plant promising such profitable return for the little trouble and labour required.
Tobacco.-A considerable quantity of reel of the three varieties grown here has been furnished to several persons applying for it
Cotton.-There has been a little more demanil for seeds during the past year, but there is no evidence yet of the cultivation of Cotton being taken up to any extent in the island.
Tea.-Some gentlemen interested in the cultivation of Tea in India have visited the Island during the past year, and have expressed a favourable opinion as to its capability to produce Tea of very excellent quality, with the likelihood of its cultivation being very remunerative. Having in view the probability of is demand being made upon these gardens for supplies of seed, I have directed that as many plants as possible be raised here, and I shall send seeds to Hakgalle for the purpose of having them sown, as some plants already growing there have a very healthy appearance
The Linnean Society of London has very liberally made a valuable present to this Establishment of the first 15 volumes of its Transactions, and of a large number of dried specimens of Indian plants, cillected other celebrated botanists-a most important addition to the library and herbarium of these gardens.
From Kew I have received a considerable number of dried specimens of Indian plants; Dr. Anderson, of the Calcatta Botanic Garden, has been a liberal contributor of specimens from Singapore and Java; many interesting species have been sent to me by Dr. F. Mueller of the Melbourne Botanic Garden, and by MM. Teysmann and Kinnendyly, of that of Java; and numerous specimens from Syria have been received from M. Lenormand.
The "Enumeratio Plantarum Zeylauiæ," in the preparation of which I have been engaged during the last few years, is now completed.

## Eactetizs.

Ropat Hortioultural: Jan. 21 (Weekly Show). - Violets were the principal subjects extihited collection consisting of Russian, Neapolitan, and what he called his Giant Violet, apparently an unusually robust variety of the Russian. A Seedling Violet named Czar, resembling the latter, but larger both in leaf and bloom, came from Mr. Graliam, of Cranford, who stated that it had been blooming profusely out of doors for many weeks pasto Mr. Aldred, of Kilburn, furnished various Seedling Cinerarias, among which
was the variegated-leaved variety, Lilium auratum, was the variegated-leaved variety, Lilium auratum, Fern-leaved and other Primulas. From Mr. Bull came three plants of Elæagnus, various Aucubas, some with berries on them and others with finely variegated eaves. Mr. Ingram, Roval Gardens, Frogmore, com municaled a collection of well-bloomed Primulas.
Of Fruit, Mr. Miller, gr. to Lord Craven, Coombe Abbey, near Coventry, sent six bunches of Lady
Downes' Seedling Grape, onc of the best late sorts in cultivation; and a similar number of bunches of Black Barbarossa, one of which weighed no less than 7 lb . Both these exhibitions were magniticent examples not only of skilful Grape growing, but also of the way in which Grapes may be preserved plump and sound, and covered with a fine bloom up to this late period of the season. Along with then was a plan of
the gardens of Coombe Abbey, a full account of which was given at p. 991 of our last year's Volume. From Mr. Bullen, gr. to E. Budd, Esq., Vale Lodge, Leatherhead, came three Queen Pine Apples. Finally, from Miss Harrington, of Brook Street, came a diah of fine.
looking Almonds, the produce of trees growing at looking Amonds, the produch Mall, ir Lancashire.

Jan. 2.f (Election of Fellows)-At this meeting the followin.f Catudidtes were elected Fetlons, vis.

British Columtia. An Essay by the Rev. R. C. Lundin Browa, M.A., Minister of St. Mary's, Lillooet. Priated at New Westuinster, $186{ }^{\circ} 3$.
From a notice prefixed to this pamphlet, we learn that the (iovermment of British Columbia offered prize of 5ul. "fur the best essay, setting forthe capabilities, resources, and advantages of British Columbia as ${ }^{2}$ colony for settlement.

There is nothing on the face of the pamphlet before us to show whether Mr. Brown gained either the 501 . prize, or that of 10 . for the secoud best essay, but valuable, and very justly so, by the authorities, for it hears the oflicial mark of approval expressed in the following words-" The Guvernment reserves the right of translation, and the lissay is pr
Royal kingineer Pres, New Westminster.

The introductory chapter informs us that till 1858 the colony was sulject to the Hudson's Bay Company, Who used it as a vast preserve of fur-bearing animals,
and a fine income was obtained by the purchase of these furs from the natives, in the way of barter. I that year the dii covery of gold on the bauks of the Fraser (the great river of British C'olumbia, which has a course of San Francisco. The home Governument then revoked the grant to the Hudson's Bay Coropany, appointed Mr. Douglas as Governor, and sent a body of engineers to act as the pioneers of civilisation,
constructing roads and bridges. \&c.
The second chapter takes the voyager through a narrow channel forced by the waters through the shoals at the mouth of the river Fraser. The entrance
is deseribed as sheltered from storms, and there is depth enough of water for all but the very larges vessols. Passing the fiats, one comes to forests of New Weatminster, the site of which was selected in 1859) ; and in less than four years this city contained 1000 inhabitants, with already three churches or other places of worship, a colonial hospital, and Government buildings. New Westminster has abundauce of room for wharves, and is an excellent port, notwithstanding there is a bar at the mouth of the river. A new comer is surprised at the exuberant fertility of the soil, but the very circumstance of its being so densely land hitherto

Sixteen miles further up the river is Fort Langley, and 35 miles higher is the mouth of the Harrison River, and the traveller can go to the Cariboo mines either up the Harrison, by Douglac, the Lakes and Lillooet, or up the Fraver by Hope Yale and Lytton. The word Cariboo, by the way, is said to be derived from the Carri-beruf, or reindeer, freciuenting those parts.

Miners will be able to obtain from this pamphlet much usoful information as to the route they had better pursue, but these are matters which, of course, we cannot enter into here.
A number of spots are described as admirably adapted for agricultural operations; some being suitable for corn and fit at once for cultivation ; others, and these by far the more numerous and extensive tracts, are fine pasture lands, often reminding one
of some gentleman's park, and often spoken of as excellent for cattle raisiog. There is also a peculiarGrass called liunch-grass, which is very useful to the drovers and teamsters: indeed, it is invaluable to the owner of cattle aut horses.
As to climate, that of Cariboo is severe, the winter lasting from Novernber to the end of April; yet the weather is usually clear and calm, though much snow falls in Junuary or E'ebruary. "But with the exception of
Cariboo, the climate of Piritish Columhtia is universally regarded as one of the finest in the world. Nor can the fact of its extremo henlthiness bo too much insisted on: cases of sickness are rare, and many who suffered at home from feelie heath havo here inhaled new li'e from the bracing mountain breeze."
British Columbia is pre-eminently a gold country. To this it owes its existence as a elony. The enou $h$ to swew by, is found in the pana after washiug
the earth from any part of the country the earth from any part of the country.
aries, the coarser the gold the Fraser and its tribuof the country expected to find it so. Where, they asked themselves, as they examined the fine gold of the Lower Fraser, does this dust come from? It must
be formed by the disintegration of coarser gold - where then is the coarser gold, and the quart $\angle$ veins whence coarse gold comes? So those enterprising men went up the fiver and its tributaries in chest of conrse galda Fiver, and later, in $1 \cdots 3$, tholowed the discovery of Tiver, all
As tho mountaus
of this comutry app an ath to the both th and south of Cariboo, nobody can possibly compute what may be the extent of these mines, nor the length of time during which they may be productive. Dearness of provisions has hitherto been the principal
drauback to mining operations, and this is just the favourable opportunity for the agriculturist to step in, and supply the pressing wants of the miner. Even were the gold mines to be worked out, there are abundant indications of other minerals-silver, copper tin, plumbago, galena (lead), iron, limestone, coal, dc. The question has been asked-can Britislı Columbia suppret an agricultural population ? Mr. Brown
thinks the countryabout the Lower Fraser is not by any meaus the locality where farming can at present be most successfully undertaken, but to reach the best agricultural lands we must penetrate further into the gitcrior. Ho states that at Lillooet, where he resides, and New Westminster, farms have produced 50 bushels of Wheat, 60 to 70 bushels of Barley and Oats, and 60 o 70 bushels of Indian Corn to the acre.
The vegetables of British Columbia are unsurnassed by any in the world, Potatos yielding on one farm weigh, on another 15 tons tornips, both Swedish and White, 25 tons to the acre, some of these up to 20 lb . weight; Onions 4 to 6 tons per acre, many of these up to $1 \frac{1}{2} \mathrm{lb}$. each; Cabbages and Beet equally fine. The orchard at Langley is a great success; Melous grow in the open air without manure, attaining great size and fine flavour.

The soil is adanted for Pears and Cherries, and probably the Grape itself would ripen on the sunny mark-like terraces of the Fraser. There is a ready In 1862 the price of Putatos varied at New Westminster from 6s. to $16 s$. per 100 lb .; at Cariboo the price was 101 . Where so many horses and mules aro employed, Barley will always be in great demand. Hithertn all the flour has been imported; the price at New Westminster has been 3l. per barrel, and in Cariboo 40l.-more or less.
British Columbia, Mr. Brown assures $\mathrm{us}_{2}$ " is perfectly able to maintain an agricultural population, and to grow grain tor the support of a large mining com-
munity," but for stock raising, and as a pastoral munity, but for stock raisigg, andis unrivalled. Cattle thrive better and increase more rapidly in British Columbia than they do in Lugland. For sheep the country is found to be admirably suited. Mutton costs 1 s . to 1 s . 3 d . per lb ,, and wool sells at San Francisco at 40 cents per 1 b . It was feared that the small Cactus wonld prove an obstacle to the raising of sheep: instead of this it is."
found to be " most serviceable for fattening pigs." These animals can provide for themselves in summer time, and bacon forms one of the gieat staples at the mines. On the whole, if the settler finds in the first years more hardships than in older colonies, in none will he find so sure a market, or such high returns for all produce, whether of the garden, the field, or the farm yard.
The coasts and rivers of British Columbia are abundantly supplied with fish. In Mareh the shoals of herrings arrive, in April shoals of houlican, a delicate fish, rather larger than the sprat ; from March to October species after species of salmon continue to enter the river. Trout and sturgeon abound: In the lakes and marshes ducks of various kinds, snipe, teal, widgeon, geese, and swans are numerous; in the woods there are pheasants, grouse, partridges, and prairie chickens.
The famous Douglas Pine is well known from the sections of a tree 309 feet in height, which was cut at New Westminster and sent to the Eshibition of 1862, Gardeners' Chronicle. The White Pine is also a very valuable wood for internal work. The priucipal berries are the Sallal, the Huckleberry or Blueberry, the Whortleberry, the Salmonberry, the laspberrs Strawberry, Oregon Grape. (fooseberry, Curraut, and Cranberry.
In the summer of 1862 the white population of the whole colony did not probably exceed 7000 ; in the winter it fell to 3000 . The Chinarnen numbered about 2500 . They are a peaceful and industrions class and have been considered a benefit hitherto; fortunately their numbers are not increasing
The two great wants of the colony are capitalists and labourers. It would be well that the latter skould not come without the means to maintain themselves for a time, in case of not immediateiy procuring work. We need not speak of the fichds of hbour npen to the
capitalist. Here it is pre-emmently truo that money mapitalist. Here it is pre-emmently truo that money
makes money. Nowhere can there be a liner openiug or men of muscle, as miners, labourers, or artieans. "To be a miner nothing is wanted but pluck, strength, and a good constitutiou. True, the novice does not know where to look for gold; he must therefore ally himself with an experienced miner; a good part
are many-bad weather, poor food, and sometimen swarms of mosquitos buzzing about him as he works, But he who means to succeed must set all these thinas at defiance, keen a good heart, and not be cast down by lardships or disappointments. I would also recommend him, if he hopes to be successful, to har nothing to do wid ruin alas of many. To take the trouble of going to Cariboo, to undergo ail the hard ships of mining life, and then to spoil everything by drink, would be indeed a pity." This is excellent advice. Supposiug a miner does not succeed at once in finding a claim: "First, he will try to hire himsel ont in the mines. Nor, if he is a man of sense, will he be too proud to work for another man. He who i not willing to take any honest employment that offers bread and wages, is quite unfit for the work of this colony. Such an one had better remain at home or emigrate elsewhere.
"If unsuccessful at the diggings, the miner is not eft without a resource; he can work on the publie roads, or engage in
in any of the towns."
Carpenters can get 12s. a day at New Westminster, $20 s$. in the central towns, 60s. in Cariboo; ordinar labourers from 12s. to 16 s . a day, at the mines 40 s On the public roads in the summer of 181,2 6l, a month and board was given ; for farm labour, 10l. and board, in the central districts. Wages are smaller at New Westminster, and living cheaper." This was written probably early in 1863, but things have not materially altered, we believe.
In the Appendices much useful information is given, such, for instnnce, as the "rules and regulations for the working of gold mines in British Columbia," \&c.
It is impossible to speak too bighly of this little pamphlet. Intending emigrants should procure and study it. It comes to us confirmed by the testiano of a resident in the colony, who has carefully uuder
lined many passages, and has occa-ivnally added liis own commentary. Not many days have elapsed since Mr. Lundin Brown's Essay came to hand.
Watts' Dictionary of Chemistry. Parts XX,-XXIII. Long:man \& Co
A splendid article on Lisht occupiea nearly the whole of Parts XX. and XXI. In this, the undulatory theory is applied to explain the phenomena of Radation Interlerence, Rellection, Retraction, Absorption, and Polarization. Fizeau's ingenious method of measuring
the velucity of light by means of a revolving toothed wheel, and another method by means of a revolving mirror, at the commencement of the article, will be read with pleasure by the scientific, and give a far sample of the skill which has been brought to bear apon this interesting subject-a subject to whiciu the highest mathematical reasoning and the most consummate ingenuity have been applied with marvellons success. We observe that Professor Stokes is frequently quoted in these pages.
Part XXII. hasa short article on Magnesium, a metal Fhich burns when held in the flame of a candle, with a dazzling light, so brilliant thatit has been used for taking photographs. Magnesium wire may be procured in the hops at about sixpence per yard.
We must pass over an article on Magnetism to notice one more suited to our
After touching briefly upon the researches ff Saussure, Davy, and Boussingault, the writer introduces us to a new era. "It was not uritil the year 1840 thab a comprehensive theory of plant-rutnition was pounded by Liebig, with such perspicuity ant an propo sition of that theory was, that the food of plants, materials from which the chief mass of their substance is prorluced in vegetation, consists solely of carbonic acid, water, and ammonia." "Under natural conditions these substances are constantly supphed to plants br the atmosphere, which contains them in small proay tion, but $m$ large aggregate quantity; by the decay by dead animals and plants; by rain, dew, de., and cono other means. But there are also other materid water, and ammonia, from which the plant constructs its chist substance. In almost all plants, and in every oryap of a plant, there are certanin substances, indest fanty by fire, which remain as ashes when plants are perfectio organisn by means of the roots and probabiy bies taken up in a state of solution.
Liebig came to the concla-ion that "the capability of land to produce crops was due to the presence in it of the ash-constituents of plants; that the assim the tion of carbon and nitrogen was dependent upa the presence of the ash-constituents in the soil. Aned a particular cron is raisel yern after year on the sumb land, was ine to the abstraction of ash-constitnents from tlie soll."
Following ont these viervs, Liebig taught "that thie be properp compration of manures for pants ashes, and then combinine the manure aceording to analysiss." He stated "that the exhaustion of the suced by successive crops, its decrease in fertility,
by the gradual removal of the mineral elements, in
of cur cultivatel plants. Ry a supply of manure they are :qum retanment he ram wed elemetts of the soil by mene supply persutheient : if the quantity talien away be restored, the erginal fertility reappears; if the supply be reater, the produce increases; a defective supply gives a sinaller produce?
Consequenty, the agriculturist was advised to "conand riving it the propit plysical condition, so as to reuler possible, and to increase, the assinilation of This theory of agriculture, or of manures, known as the matal theory, was received with enthusiasm in Enaland and Ameriea, and highly laudatory articles Were written in the journals.
When brought to the test of experience. however it is well known that Liebig's manures utterly failed article on manure.

Instead of reforming agriculture by his manures, Liebig caused them to demonstrate the incorrectness of his mineral theory of agriculture; and the failure of
these manures, from the application of which farmers had been induced to anticipate such wonderful results, maturally produced a revulsion of opinion, which was sometimes expressed in a manner not altogether free from exaggerated opposition to his views."
"The practical farmer accepts in its full significance the abatract theory of plant-nutrition, so far as it concorns him; he also looks for its application to the art in which he is engaged, and for rules by which his
prartice may be improved. There is probably no art in which surge etiong for improvement have been more acrerly acceptell during the past 20 or 30 years than in agrienilture; lout when such suggestions are tested and found wanting, the practical nature of agriculture demanls their abandonment." ${ }^{6}$ These are abstract scientinc questions of high interest for the chemist, and but thay do not concern the farmer, whose business is to proluce fond wi h such means as are at his disposal. It would be a vary illozical conclusion, that the facts ammonia and superphosphate upon the growth of corn aud root crops should be disregarded, because science is unable to explain the precise functions of those substances in vegetation ; and it is equally irrational to denounce, as a folly and an error, the application of those facts, so far as present knowledge will almit." Such is the conclusion of an excellent paper on Manure, looked at from the chemist's point of view
Catalogurs Rrobivibd.-Barre \& Sugden's Compendium to Seed Catalogue for 1865, a list of 96 pages, we notice the beautiful Lagenaria, shown last autumn at Kensington by Mr. Stuart, is offered under the name of Prince of Wales Gourd.-Charles Turner's
Catulogue of Seeds contains several of Dr. Maclean's new early wrinkled Marrow Peas, among which Premier is one of great, excellence.-B. S. Williams's Descriptive Cutalogue of Seeds, which is very full, embodies many cultural paragr whs ; amongst other novelties a Matchless Celery, sid to be the finest red in cultivation, is list of the choicer varieties of flowers and vegetables. -Charlevood \& Cummins's List of Seeds has, as its distinctive feature, an extensive collection of the seeds of hardy trees and shrubs.

## Garden Memoranda.

Missrs, Low's Nurserx, Uppre Clapton.-One of the most interesting houses in this extensive establishment, especially during the present comparatively Tree Ferns are , is that in which the different kinds of Tree Ferms are grown, a long cool house, in which are some magnificent specimens of Dicksonias, Alsophilas, ness, surmounted by wide-spreading heads of refreshing green leaves, producing an appearance more like that of summer than midwinter. These are associated with foung Camellias, of which many thousands may be cuund in other honses. Heaths and Fpacrises are most extensively grown here; all of them are well set with flower had, an! many of the former, sueh as hiemalis, variety there are stated to be no fewer than 20,000 plants in this establishment, a fact which speaks volumes A new of the usefulness of this particular kind.
A new span-roofed house, about 125 feet in length, is Heath put ap for the accommodation of specimen completed for Orchids. The latter is also span-roofed, efficiently heated with hot water, and neatly fitted np with slate tables covererl with gravel for the plants to except Calanthes, which have produced a magnificent Isimatodis resea since the begiming of last ()etover. have also beeu Sorphronitise been finely in flower, as Lowii, Stinei, and Hookeræ, and the rave Dendrobium inluudibulum, the charming white blossoms which, faintly flushed with rose, are very delicate and
pretty. Of the pretty. Of the orange-flowered Epidendrum vitelhum, Odontoglossum grande, Lycaste Skinneri,

Cattleya Aclandies, C. marginata, and Phalmonsis grandiltora, Messis. Low possess an exceedingly fine
collection. True, the plauts are small, but in health and vigour they fully tqual larcer specimens. Of Odontoglossums recently imported from New Gremata they have also several humireds, anouy which something have also several handrexs, amo
ow may reasonatly be expectet.
Of other novelties in the way of Orchids, the collection contains Dendrobium nodatum, a gay species imported from Moulmen, with slender stems, gouty at the joints; D. prinulinum, a tine kind, producing large priniosecoloured flwers, ani 1). Far:weri aureo-tlayum, hoth valuable species Houlmein. Saccolabinm Harrisonianum, a beantiful fragrant white-floweres speciea, ant.

One house we noticed full of small plants of Pampas Grass raised from imported seeds; another contained small Orange trees well furnished with fruit; while in a third was an interesting collection of all the finer kinds of Japanese plants, among which we remarked ariegated-leaved Carnelms, mymus and Arcuhas dishii, which has a fine appearance in Wardian sanAssociated with these was also Lomaria fluviatilis, with long narrow fronds, which when hanging over the edge of suspended baskets, intermired with the leaves other plants, have a highly ornamental appenrance.

Among other new Eranthemums in a collection of plants remarkable for the beanty of their leaves, such as Alucasia Lowii, and others, was E. metallicum, a kind with mediam-sized folinge, the upper surface of which has a beautiful metallic gloss on it, which gives the plant considerable value in an ornamental point of view. In banging baskets, intermixed with the rosy-veined $\mathbf{E}$. sanguinolentum, which it resembles in habit, it cannot fail to produce a pretty effect.

In other houses were large numbers of Araucaria imbricata, raised from seeds; and, in warmer compartments, Palms, Ferns, and fine-leaved stove plants in great abandance.

## Miscellaneous.

Cabbages v. Cauliflowers.-It appears from the daily papers that a singular cause has recently been tried betore the Imperial Court of Paris. The question to be
decided was whether Cauliflowers ary Cabbages, and it gave rise to a long and animated discussion. The question arose in consequence of the regulated price of the carriage of Cabbages by the Orleans Railway Company being much lower than that of more delicate vegetables. the market gardeners who forwarded
Caulidowers to the Paris market by railway insisted that they should be charged as Cabbages ; the railway company, on the contrary, demanded the higher rate. company, on the contrary, demanded the higher rate. and save judgment in favour of the Orleans Railway Company.
Mistleto on the Oak.-The following letters on this subject Thave recently appeared in the Times newspaper "The interesting letters which have lately appeared in the Times respecting this singular parasitic plant will naturally lead your readers to inquire why the Mistleto is never found growing on the Oak tree; almost every one who knows the plant will tell you that it grows upon the Oak, but I have never met with any one who can point out an Oak with the Mistleto growing on it. The plant is very partial to Apple trees, and its extended grow th on one of these trees verifies the correctness of which, by its growth on fruit trees, injures them. Our early botanist, Dr. William 'Turner, speaks of this plant, and says of the berries - 'The fowler maketh birdlime wherewith afterward he taketh the thrush. I never saw more plenty of right Oak Missel than Hugh Morgan showed me in London. It was sent to him out of Eissex, where there is more plenty than in any other place in Englaud that I have been.' Dr. Bulleyn, in his "Book of Simples," speaks of Mistleto, and aals-- What benefit hath that tree upon whom the Mistleto does grow? No more than any member of the body upon whom a cancer is placed, and will at length destroy altogether unless it be pulled from the may interest some of your readers to learn that in two localities in England the Mistleto may still be seen growing upon the Oak. are Eastnor Castle, near Ledbury, in Herefordahire,
and Hackwood Park, near Basingstoke; from each of these places I have received sprigs of the very Oak
trees on which the Mistleto was seen growing by the grees on which the Mistiemen who were kind enough to reply to my letters of inquiry. A few years ago I took some pains to investigate this subject, and, after corresponding with Professor Lindley and other eminent botauists, came to the conclusion that the growth of the Mistleto ufon the Oak had always heen the exception and not
the rule, and that, even in the time of the Druids, Mistleto from the Oak was invested with peculiar sanctity and highly esteemed for its rarity. Though generally supposed to be confined to the Oak, Apple, and a few others, the Mistleto is occastonally found
growing on the following trees:-Apple, Pear, Haw growing on the following trees:-Apple, Pear, Haw-
thorn, Service Tree, Mountain Ash, Hazel, Maple, Ash, Lime, Acacia, Willow, Yoplar, Elm, Oak, aud it is said the Scotch Fir." Beaven Rake, Fordingbridge,

Jan. W1.- "I shall he happy to point out to Mr. Beisly, Mistleto growing on an Oak on the estate of Lord somers at Fistnor, ahout five miles from this "Ince." J. A. C'o insey, The Lumikes, Materen, Jan. 10.met with the Nistleto arowing and the (O) alis In one case I marked the tree fur tale, and $\mathrm{i}^{-}$is now ent; it stond on the Tiwhbourne estate in this parish. In the cther instance the tree was makked for s!le. hut it wa spared at the request of the Rev. (riwree Wrod, recto of Shopwyke, near Chichentur, amd the tree is nuw
standing on the Berningtolic estate. Dunstold, Surrey standing on the Berningtolid estate. Ionostohd, Surrey,
now the pronerty of Mr. Lev land. Wonds, thas present High Sheriff of Sussex." Alfred Mellersh, Ciodalming Jan. 15.

Antiquity of Garden Plants.-. We have historical evintence that existing species have mot variel for several thousand years, and the reason is plain enough because the exterual circumstances in which they have
been placed have not varied. For all practical purposes, therefore, the characters on which species are foundel may be assumed to be constant; and a minute and careful description of a plant will suffice, not only for the present, but for many succeeding generations of
naturalists. But we have no warrant from nature to assume that such specific, or even generic, characteristics either have, or will continue to be, permanent for an unlimited period of time; that they will survive all future changes in the physical gengraphy of the planetary surface. We know that great chaiges may
be effected in a brief space of time in the organisation of piants by cultivation; and why should not an organic change be brought about in plants when their external cir cumstances are altered by nature in the course of ages This world, what is it but a great and ancient theatre where the scenery of life is ever changing! Look at that majestic and venerable tree; its present form appears
to be fixed, yet that very form is in reality as fleeting and cvanescent as all the other forms thromg which that tree has passed from its first life movement in the nature, is true of the whole of natore; the present appearance of nature now is no more unalterable than at any other geological epoch: it is the last of the many phases of creation, and equally flceting with all the others.
Artesian Wells.-It has been observed that Artesian wells can only be successfully bored where porous strata
are intercalated between impermeable ones. Where the are intercalated between impermeable ones. Where the
intercalation is often repeated, several distinct sources of water may supply a single well. In that at Bruck, near Erlangen, there are three such sources; in that at Dieppe, seven; whilat the well at Dulmen, in Westphalia, is supplied by no less than 13 strata, in a depth of 380 feet. The great distance from which the water
of an Artesian well may be derived was well shown by a boring near Tours, from which, when the borer was withdrawn, quantities of sand and small snail-shells were ejected, which must, without doubt, have found their way there from the mountains of Auvergne, 30 miles distant. A curious proof of the nceasiona direct communication of Artesian borings with super ficial accumulations of water was given by wells of thi description at Bochum in Westphalia, and Elbouf in France, in the water from both of which eels and small
fish have at times been found. Popular Science Revievo The Lignite Flora.-The sketch I am going to give refers to a remote, though not to the remotest period of our planet-one which, if not immediately preceding, at all events is very near man's appearance on earth. It has been named the Tertiary period, and is distin guished by its supplying us with the enormons masse of combustible materials preserved in argillaceous and arenaceous strata in the shape of lignite. There can
be no doubt that the geological conditions of our globe were at that time very different from what they are at present; and the surface of our planet and the elevation of the solid land must have essentially differed from what they are now. It is well known that in the beds of brown enal, when they hare not become a compact mass, we find fragments of a great number of plants and animals. It is highly interesting to cast a glance at this subberranean herbarium, and 20 years ago I eagerly studied this singular eullection the botanical treasures of the much ollur esal formation and of the later deposits lead boen investicated, but those of the lignite still remained a sealed book. As might have been expected, the study of these vegetable fragments made a deep impression upon me,
and caused me many a surprise. The plants and anima!s of earlier periods exhibit but slight analogy with those of the present. But here all was revarsed. In these investigations (often dificult) one frequentiy came across known forms, and sometines it would seen as if with indigenous and foreigu trees and shruis. The most surprising was, tiat a consilerable munher of these plants so closely resembled the trees and shrubs
now-a-dus growing in North America as to be scarcely distiuguishable from them. Justly attaching great importance to this fact, I may he pormitted to reter, in support of it, to a few fossils. One of them is a rather large $3-5$-lobed leaf, with toothed margin and long petiole. The leaf of only one tree now indigenous to North America resembles it entirely, or very closely, and that is the Amber tree (Liquidambar styraciflua), well known by the resin it exudes. That no mis-
take has been committed in this instance is more than proved by the fruit, which has been met with in a fossil state, and closely reseme fleaves submitted next, one of which has been found in Switzer and, the other in limestone beds in Sinigaglia, are instantly recognised as those of the North American 'Tulip tree (Liriodendron tulipifera). Though they may not be quite identical with them, they must, at al events, be regarded as derived from the nearest In Iceland, besides the leaves, the fruits (of the other fragments frequently found in lignite are branches covered with minute lancet or nearly needle-shaped leaves, pointing towards a Conifor which is not met with in Furope, but has an extensive geograplical vegetable monuments of that country, and is the
 point towards trees of which several species at present inhabit North America. They belong to the genus Nyssi. The fruits and seeds of Pavia and Robinia, occasionally encomatered, prove that these two genera, nowriens as exotics at one time flourished in Europe. It is well known that Europe is destitute of Walnuts, the one cultivated being derived from the woody mountains of the southern Cancasus. But a great number of different nuts are very common in lignite formations, and if compared with a large North American genns, their close resemblance at once becomes manifest; the so-called grey Hickory (Juglans cinerea) can scarcely be distinguished from the fossil Juglans tephrodes, Ung. I might enlarge upon the different Maples, Oaks, Poplars, Hurnbeams, Firs, and Yews of the lignite flora, the noarest allies of which are not the species still existing in Furope, but almost exclusively those in North America; and I might add a great number of
other details, all proving that the lignite flora had not European but a North American character. This conclusion, which I publislued about 20 years ago, has not heen shaken hy any subsequent investigations. ** These considerations force us to the cunclusion that there must have been a continental connection. In the Tertiary period, or at the time when lipnite was formed, Eurone must have heen connected with North America, and the Atlantic Ocean must have been divided at one place or other by a continent. Dr. F. Unger, in Journal of Botany.
Kingfishers.-"The poor kingfisher has at last fallen a victim to the "taste" of the ladies. Not content with having taken all our handsomest jays, magpies, the, numberless water-fowl who fall victims, they have now begun to use the skin of the poor little kingisher for the same purpose, so that in a very little while we shall be compelled to look upon these beautiful birds as indeed rara aves. All who have seen them, as I have," writes a correspondent of the Times, "flying swiftly along with their blue backs g!ancing brightly in the sun, are able to appreciate the beauty they add to the by their exterinination. If the taxidermists would only unite in not receiving the birds, the watermen would have other occupations to follow than turning their hands against our British heart to give their consent to this bird marder." One of their number is also reported in the same journal to have uttered this feeling complaint :We thought they liked to the ladies on our behalf. Thames, but we are dreadfully persecuted just now. I tried in vain for three hours yesterday to get to my feeding-place, on an eyot at Datchet, where a waterman was waiting for me with a loaded gun. I heard ladies' at gentleman that we were 'coming in for tilled several this week. Do, pray, entreat the ladies not to wear us in their hats, or we shall inevitably be exterminated."

## Calendar of Operations.

## (For the ensuing veek.)

Two of the greatest improvements in modern ornamental gardening are the slmost total repudiation of
mixing flowers and shrubs together, and of deep mixing flowers and shrubs together, and of deep
edgings to the outlines of walks. Nevertheless it will, we thiuk, be aduitted that a dark background of evergreens is particularly well adapted to exhibit gay flowers in mass. Where, therefore, bold walks possess an extensive and broad margin, much may be done in the way of decoration independent of the regular flower garden ; and if the nakedness of such borders in winter were an objection, it would be easy where plenty of labour is allowed to turf or plant Verbenas and Pelargoniums were over. For when decoration of this description many eligible plants offer thenselves-such as the common Wal-flower Anemone, Snowdrop, Crocus, and many others. Anernone, Snowdrop, Crocus, and many others.
Hundreds of these might be potted in due time, and well established for the purpose, added to which a nursery of Rhododendrons, and other dwarf shrubs, such as Box, Aucuba, Laurustinus, \&c., would be a
high hand, and presupposes considerable expense. A
much cheaper method would be that of using Kail, as much eaper method dessuer woll in the south as in the north. As regards single permanent specimens of trees or shrubs on lawns, much discretion is requisite as to their position. The immense acquisition of new plants, of late years adapted for lawns, has forced many into the dotting system, who formerly despised it; this is undoubtedly a retrograde direction, however, in point of taste. Such things, where space allows it, might, under feature without deranging tho general plan. In places of some extent, it should ever be borne in mind that the formal edges of shrub borders, which are absolutely necessary at first planting, are but means to a given end; therefore it should be remem. bered that no formal cut lines can ever produce so rich and grand an effect as the majostic sweeping rich outline, as well as varying tints, produced by such permanent and massive forms as full-grown Hollies, Laurels, Rhododendrons, \&c., fringed overhead occasionally with arboreous forms--such as the Laburnum, the Purple Beech, or the Hemlock Spruce. The introduction of floral decorations therefore into shrubbery borders must be done sparingly and with sound judgment and good taste. A little lighting up of the margin is in general all that is required.
flower garden and plant houses.
In accordance with the directions just given, improve as much as possible outlines of every kind, plant fresh masses or groups of shrubs where necessary, and introduce specimen plants only where fitting opportunities offer. Much mischief is doue by planting single specimen trees in recesses; these should be careiully preserved, as a general rule, to give deep shadows, and to throw the prominent features into bold relief.

Azaleas. - Plants that have been kept in heat to bring them into flower will now require pretty liberal supplies of water, and take care to keep them free from cold currents of air. See that young plants are clear of insects and in a healthy growing condition.

Carnations and Picotees.-Soil for these having been obtained at the proper time, let it now be occasionally turned, and kept dry for use when wanted. Take care that it is tree from wireworm.
Cinerarias.-Give a little air when favourable, but avoid cold draughts. Pick off decaying leaves and keep down mildew by means of sulphur. Thin out superfluous leaves and shoots, and continue to move at intervals a few of the most forward plants into an intermediate house for early display.
Dahitas,-Roots of these may now be examined preparatory to their being placed hereafter in heat. forcing garden.
Notrithstanding the changeable state of the weather, few seasons, on the whole, have been more favourable than this for early forcing, and it is surprising to find in most places just now such a searcity of floral beauty. Whereanything like proper atteution has been paid, oue would have thought that most things would now be in a highly satisfactory condition.
Caerries.-Advance steadily. Ventilate freely when the weather will permit, and maintain a moist growing temperature.
Cocombers.-Water frequently between the hills, and round the sides of the frame. Ensure a tempera. ture of $70^{\circ}$ night and day, allowing a rise of $5^{\circ}$ in the day if possible, and rising to $85^{\circ}$ or even $90^{\circ}$ during sunshine.
Peaches. - Trees of these and of Nectarines which have been forced for several years of tentimes produce a large excess of fruit buds, and this more especially on weakly trees; a natural consequence of allowing these to remain are weak blossoms and inferior fruit and wood. When, therefore, such is the case, the trees buds, taking care to leave the largest and such as are most favourably placed. Of course a considerable number should also be left to allow for casuaities Syringe twice or oftener daily till the bloom is ready to expand, when that operation must for a time be
discontinued. The night temperature may be perdiscontinued. The night temperature may be per
nitted to advance to $45^{\circ}$ with an increase by day, accompauied by a proportionately free admission of air whenever the weather is at all favourable.
Pines.-As a somewhat general shift should take place during this month or early in February, let us offer a little advice about soils. Our best Pine
growers adhere in general to loam. What is wanted is not a new description of soil, but good texture Few people use turf so fresh as they may and ought to do. Proper mecharical texture is the great fection in freah lorys may be obtained in per broken boues will add to its prosity, and also to its quality. Turf for Pines should be housed in septeruber in a dry state, and should bo chopped
into squares, or small pieces when dry. As drainge for pots we would recommend in addition to open crocks, broken bones and charcoal mixed; on this put a layer of fresh turf in lumps, and then the ball of the shifted Piue.
Strawberrirs.-To these give abundance of air when the weather is at all mild.
Vinss,-Difficult setters should be artificially fer
tilised, choosing the middle of a dry day for the operation. Grapes swelling should be thinned the moment the bunches can be handled. Many exhaust their Vines by deferring too long this important operm tion. Follow up the close stopping of all superfuous wood, provide plenty of atmospheric moisture, and do not be afraid to indulge in a considerable increase o temperature on the afternoons of bright days, which

HARD FRUIT AND KITCHEN GARDEN,
Whenever the weather is at all favourable, see to the due preparation of ground for crops in general, but beware of carrying on any operations when the soil is a wet state. Where kitchen gardens are composed of light sandy soil, they are better dug or"trenched some weeks before the ground is wanted for cropning
Cadliflowers. - Look carefully after those in frames and under handglasses, while cold weather lasts.
Letruces. - Plants of these in frames will also now require attention. See that they are not suffering from undue confinement.
Potatos.-Bring forward those in frames slowly them.
STATE OF THE WEATHER AT CHISWICK, NEAR LONDOM,

## MEETINGS FOR THE ENSUING WEEK <br> WeDngspar, Feb. $1\left\{\begin{array}{l}\text { Society of Arts (Mr. . . C. . Morton on } \\ \text { London Sewage -8. } \\ \text { Royal Agri. Soclety of England (Noon) }\end{array}\right.$

Mr. 'T. Dyer Acland has at length published the letters on Agriculitural Education, addressed by him many weeks ago to the President of the Royal Agricultural Suciety of England. They were printed for the information of the Council so long ag) as early in December; but though we have long had a copy of the pamphlet on our table, its non-publication hitherto has hindered any reference to it here until the present time. This is perhaps the more to be regretted because whatever influcnce it may be calculated to exert for the attainment of its object cau hardly be looked for through the official authorities who have hitherto had the exclusive advantage of its perusal. It is through Mr. Ridaway, to whose shelves it is now committed, that it will at length reach those who are really concerned ; and it is as an aldress to the general agricultural publie, who are interested in its subject, not as a letter to the Counoil of the central Agricultural Societr, that its facts and arguments will tell.
Taking advantage of a reference whioh had been made to the Society's duty in connection with the professional education of the farmer, and of the Committee of Inquiry into the subject which Mr. Holland had subsequently obtained, Mr. Achand is at once afloat upon the great sea of middle-class education. True, these hat no power whatever of right to launch him there; but his own tendencies, habits, and desires are irresistible. He is on the Cummission of Inquiry into the condition of middle-class schools in this country, and every movement necessarily tends
in that direetion. He has moreover had a distinguished share in getting the great educational bodies of the country to contribute of their immense surplus ability and energy towarls the education of classes which have rarely bect able to con
Add besides the action of the Universities he has, we presume through the Society of Arts, had some share in the credit, belongiug mainly to Mr. Habry Chister, of organising those examinations through the local societies in union, by which yet another contribution has of late years been made to the improvement of middle-elass edueation. No wonder then that a hohby ridden so effectively and constantly should carry bim wherever he may gono wonder that any suggestion or inquiry, however closely it may be limited to a well-defined and particular ohjeot, aeting as a spur withont a rein, should send his steed careering all over the midal coclass plain; or, if we must keep to our original comparison, aeting as imperative but ill-defined sailing
orders for his good ship "Eduoation," should send her abroad on a voyage of commeroe and discovery her abroad on a voyage of com meroe and discovery
over the whole wide ocean of the English middle class.

And this is what the recent movement of the Agricultural Society has really done, for although the pamphlet is entilled Agricultural Education, the adjective might have been omitted or displaced by nny other professional term without any glaring impropriety.
It seems to us that agricultural edueation and the education of agrieulturists are two altogether different things. The former relates to the profession, the latter to the whole human natare of the individual. It is the ohjeet of the latter to place the body, intelleet, and soul of man in cordial and intelligent relationship to the whole is the ohject of the former to teach only such applications of the traths thus conveyed as will tell upon the relationship of farmers to each other, to their landlords, their labourers, and their land,
Agricultural education in Mr. ACZaND's
pamphlet means " physios, ohemistry, physiology, meteorology, the laws of heat, geoloyy, botany, animal pathology, political economy," \&ce., \&c.-a medley of all the sciences. It is tn quieken power of observation, to confer alert vitality and wake-
fulness, to create habitual thoughtfalness, to strengthen resolution, to foster religious feelings and conviction. In the words of his correspondent -whom he quotes-it seems as if he would rather forget that his pupils are to be farmersa very great service indeed he will have rendered if, his pages being generally read by agriculturists, they shall be induced by them to seek such an education for their sons as shall implant these, which are the essential elements of ultimate character, the firm foundation of ultimate position, whatever occupation or profession they may afterwards adopt as their source of maintenance and livelihood.
Nor do we say that there is not much in these pages relating more directly to the merely professional aspect of a good agricultural education. Although the pamphlet might be as properly addressed, let us say to the medical as to the agricultural profession, yet there is much in it of assertion, argument and advice from which the future farmer especially may benefit. We do not purposs to-day to offier here any analysis of its pages, but content ourselves with a cordial recommendation of them to those alone of the agricultural world, to whom, as we believe, they have any business to be addressed--the young farmers and agricultural students of the country.
But the pamphlet is addressed to Sir E. C. Kerrisoy, Bart., iu his official eapacity as President of the Royal Agricultural Society of England, and its object mainly is to induce the English Agricultural Sweiety to come forward and assist the Universities, the College of Preeeptors, and the Society of Arts in promoting that gencral improverment of middleslass education, out of which alone good farmers as well as ycod commercial men, or grood professional men of any class, ean be expected to arise. We contend that the Society will be altogether forsaking its well-defined field of labour if it accepts this invitation. With the utmust confiuence, and unconvinced by the altogether iuconclusive reply in Mr. Acland's second letter, we re-assert:-
(1) That the only education with which the Royal Agrieultural Šociety has anything to do is 'professional Agrionitural Education;' (2)
that a 'General Education' is as much out o
its province as it is 'outside Apotheearies' Hall and (3) that if they had wanted to encourage agricultural education they would long ago have taken up Cirencester College.

Whether "the education of those who depend on the cultivation of the soil for their support," which the Charter directs the Society to take measures for improving, be a professional or a general education, and in what sense the nerglect of Cirencester College, of which the Society has undoubtedly hitherto been guilty, is to be considered as neglect of duty, raust be the sujject of another paper. But we cannot delay insisting on the truth of the parallel between the practice of Apothecaries' Hall and the allered duty of the Acricaltural Society which which Hr. Acland seems, in
to have thought he had exploded. He says:-
"The Royal College of Surgeons confines its own direct action as much as possible to professional elucadirect and professional examination, but, feeling the importance coneral education as an indispensable importance of general educatision of technical knowprevious condill, it absolutely requires proof that every candidate has passed sone preliminary examination as to his general education. For this purpose the medical authorities are so far from establishing a board examiners of their own, that they enumerate a number of University and other certificates which they are willing to accept, and only in the case of 'candidates who shall not be able to produce one of the foregoing certificates,' do ther require the candidate to pass a examination in English, Classics, and Mathematics.
"And how is this general examination conducter. Not by the Royal College of Surgeons itself, but 'by the Board of Examiners of the Royal College of Preceptors, under the did
College ' of Surgeons.
Surgeons is dictated by a clear perception of most
important principles; and making due allowance for the difference of circumstances, it is just the course which I desire to see taken by the Royal Agricultural Society."

It is difficult to read aright, and in their intended meaning, the words of any saving clause, and we hardly know what is the "due allowance for difference of circumstances " here referred to; but it seems to us that so far from the course of the Cullege of Surgeons or Apothecaries' Hall being exactly what Mr. Acland desires the Society to follow, his admission here is a complete abandonment of the argument addressed to Sir E. C. Kerdicn in his former letter. The examinations of the medical schools are essentially professional examinations; those only who have adopted the profession are admitted to them. It is as a test of professional ability that they are instituted. That is the purpose which they serve. The general education of which they require a preliminary proof, is not the object which they have in view and although it is the basis on which the professional knowledge required is necessarily grafted, yet it is the former not the latter which is their especial aim and end. And although it answers
Mr. Acland's purpose to play upon the words 'outside Apothecaries' Hall," yet virtually and really we repeat that it is just as general middleclass education is outside Apothecaries' Hall, that we contend it must be kent outside of the Royal Agricultural Society of England.
But what, on the other hand, does Mr. Acland declare that he desires:-
The Royal Agricultural Society may, as it seems to him at the present time, take three decided steps:

1. Diffuse information (on schools and general education) by its Journal.
2. Recornise a sound standard of general education.
3. Give prizes for eompetition, open to those who reach the standard, either for their general attaimments, or their proficiency in particular subjects.
It thus apmears plainly enourh that it is seneral education which the Sorietr is to reergnise and reward. Apothecaries' Hall accepts all iatending medical men whose general education is properl attester; it takes the preliminary list of medical students from the hands of the general examiner and tests them for professional ability and knowledye, and rewards them according to their professional standing. The English Agricultural Society, facenrling to Mr. Acland, is to prepare the preliminary list of candidates, and submit them not to a professional but a general examination br Cniversity and Cullege examiners, and to give prizes to those who reach their standard, not of a professional, but of a general education.
So far from being the cony which he would follow, the rule of Apothecaries' Hall is that which he directly reverses. And when his
the Cirencester College a great middle-olm school for Gloucestershire, and copied as a middh class school in every other county of the king dom; and we shall have the Royal Agrient tural Society, which might by a more fritnily relationship have preserved the professional staild. ing of the Cirencester institution, and sugrest others of a similar kind elsewhere, presenting is insignificant contribution to the stinulus and guidance of the general movement, altogether lad in the abundant energy with whioh the work general education, necessarily independent of any special body, is being oarried on.
Good middlemelass schools,
whether counts institutions or not, are very desirable tuiags in the interest of agriculture, as of any other profession. If only they can retain their is dividuality, and help to enoourage indepen dence and individuality of character in bon in spite of the overpowering organising and tralising tendency of the age, they are on every account desirable. The promoters of so desirable a movement command the heartiest good will. But when we hear of them anticipating tha degradation of the great professional College a: Cirencester to the level of a mere county sch and when we see them attempting to degrade the Royal Agricultural Sooiety, the great professions Corporation instituted for agrioultural imprope. ment, to the level merely of a middle-olass edu. tional establishment, we protest. And we ventere to foretell the failure of any such attempt. It is not likely that the 5000 members of the Agrien tural Suciety, who know very well iur was: purpose they are associated, will be misled. The practical and professional character of the socitt will be retained. Its members will discharf
their duty to the 'general edneation question io the same way as Mr. Acland, a meniber of the Council, thinks he has discharged his to the Agricultural C'ulliege question,
merely individual and personal inte., by theis as members of the Agricultural Sucicte, and is their corporate capacity, we venture to prelie that their action will be confined, as it ought th be, to the professional portion only of an agrieal tural education.

## UTILISATION OF SEWAGR

In consequence of some remarks which appeared recent Number of the Agricultural Gazette, I hre received numerous letters and pamphlets on the subjech from various parts of the country, and as I am unail to reply to them separately
A "County Magistrate" has obligingly formaride his pamphlet on "The Utilisation of Night Soil api" from Sewage," but as a resumé of it was recenilg giva in the Agricultural Gazette it will be unnecessary repeat the contents now. 2The author has, with mudad ais ne:s, published along with his pamphlet a report fros a borough surveyor, whose opinion he sought, and states that however applicable the author's pian be to villages and isolated buildings, it would be gh impracticable in towns and populons places.
Mr. Edwin Chesshire, a well-kuown surgeon Birmingham, has forwarded a communication ac3us panied by a pamphlet explaining his invention solving the difficulties of the sewage question. plan consists of an "iron catch pit," or intercipp tank, which is so constructed that it may be applia either to a common privy, in lieu of an ashpit, or 1 watercloset, at some point between the seat and ewer: and by means of a pertorated partition in ank the solid portion of the excrementious mad. retained, while the fluid passes away as at present 1 the sewers. The tank is made large enongit or an average household romoved, ani whtied is replaced. Theso tanks are in oneration Birmingham, and in some other towns, and an be successful in all that they seek to accomp.id great nojeetion to the plan is that the liguill valuable ammonia, is allowed to escin", an! along with it some of the most fertilning the soird matiter. It woul be ronk 59 as to allo of its being easily removed
A gentieman who writes from the neighborathan Cirencester, and who is evidently wel the subject upon which he writes, advocates the ap cation of the earth principle to urinals and cin. gives the details of a plan which be several years, and in numerous instances with lucoss. For urinals, he say any smell so long as saturation is no outdoor privies lue recominends
one advecated by Mr Munle, cesspool is dispensed with and in which $t$ seat, with a flap with, and a box formed taking the content acor at
and ashes are placed, and
s small shorel and brush being the only articles
required. I bave, myself, known this plan adopted in the country for years, and have always found the ashes
sofficient to absorb all moisture, aud prevent any officient mive 1 ma .
Suiveril writers have called my attention to the selfating dry earth closet patented by Mr. Moule, and
lear testimany to its success. There can be no question as to this apparatus being an improvement upus the ateation it will answer tolerably well. my omn expericnce has proved that unless due care be vercised in the meparation of the eartl the hopper anes; and all who have artenpted to carry ont

## atention on their part. The cost of the

## AGRICULTURE OF SOUTH WALES

## Thio tollowing tz apoution of Mr. Bueklia's lecture before the Carmarthenshire Farmers' Club, of which part was givo

arn week.
Ir will doubtless be unhesitatingly conceded that there are peculiarities about Wales in a farming point of view. The most important of these may, I think, be ranged under taree heads, viz., Climate, soil, and
the farming usages of the country. The two first are natural; and the third, although artificial, has been so long in existence that it has impressed a peculiarity of
a very disadvantageous kind on the farming of the a very di
(1.) Aud first as to our climate; we not only have more than an average quantity of rain, but our atmosphere is particularly moist, accompacied by a low ternperature. Uften for days together we have a thick drizzle from the sea, with searesly a sight of the sun, while at the same time the harometer stands high, and I have noticed, when that bas been the case, that it was confined to near the coast, and that to the east the weather was fine and bright. Receiving telegrams, as I do, from Loadon every other day (Sunday excepted), ruark the the weather and wind, 1 have been able to I could hardly have belicved it, but for the statement of the fact. Oceasionaily, for instance, when we have hiad a thick, wetting, small rain, with the wind from the south-west, my telegram has said, "weather fine, quence is that our corn crops, that look so green, lieilthy, and promising in the spring avd early in iumer, not nierting wi his hot, dry, sunny weather in tue later summer and autuman, so essential do not fulfil their carly nromise, and at harvest present us with a lean iumnture sample, defective in quantity is well as quality. How strikingly this was exemplified the in nitsters of this town, I an sure they will any of you that -hey conld scarcely get a bit of I larley in this becutry it ior miting, and that it could hardly have bern wores; shile at the same time, from all aloug
the lime of rail from Gloweester to procuring as fine, if not the rer to Reading, they were erocuring as fine, if not the rery finest, Barlegs they per masheinto malt. They weighed frequently 56 lb . per bushel, struck measure. And your millers will testify to the same contrast in the Wheats. You know, in fact, that many, if not nost, of our farmers had to
on several large farms in Warwiolshire, and the quality
of their Wheats really deserved of their Wheats really deserved the appellatiou of
splondid. We are in the habit frequently of getting a change of seed-of Wheat and Barley particularlyproduce falls off in quality, even in the first crop, and be recognised. This may partly be laid to the change of the soil, but the climate is doubtless the chief cause.
I should state that these observations do not equally apply to the growth and maturing of Uats, and that this grain should generally be sown in all our high, coarse, or damp land, there will be scarcely two peculianly unfavourable to the protuction of cora! and is it not cyualiy erident that it is highly favourable to the growth of roots and artificial Crasses, and to the
laxurinnce of owr natural green pastures and meadows It is plain that no skill or management cau altogether surmount this iucongeniality to the growth of corn, yet it may be considerably alleviated by ouly growing corn crops after roots of the subsequent Clover lea, in land under a regular course of alternate croppiner, putting iu the seed much earher than is ushal in this district. is obvious-tho sced fiuds a deep ciean bed under high cultivation, makes rapid growth, and acquires considerable strength and luxuriauce early in the season, and secures longer days and a higher sun to
mature it, thus becoming to some extent independent (if I may so speak) of the season. If these observa tions, thes, are anything like correct, our courso of hisbandry is, to a large extent, pointed out. That we should ouly attempt a very limited growth of corn and that always under a rotation of alternate crops, and that the great bulk of our land should remain in
Grass (as we shall presently point out) as productive pastures and meadows, appears evident. I would just observe here in passing that even under such restricted breadth of corn we should grow more in quautity and of far better quality than under the present system, in which nearly the whole farm is laid ender contribution for its production.
(2.) Our soil is also to some extent peculiar, lying as it does, for the most part, on the Silurian formation The surface soils on each of our various formations are of course of the same nature as the rock on which they lie, and have been brought to their present state by atmospheric and other uatural influences during the roll of past ages.
Wales is Wales, is the system of farming that has prevailed from time immemorial. What I have chiefly to
point out is, the usage of ploughing up periodically all the land upon which the plough can possibly be brought to work; that which is too high or steep, too low and boggy, or too rough and rocky, alone escaping (save perhaps a favoured meadow adjoining the home stead), aud taking out of it a succession of corn crops until quite exhausted aud foul with weeds; and then laying it down, or leaving it to rest as it is called, in other words, leaving it to be renovated by the slow process of nature, and when nature has accomplished course. By such a system, a larys proportion of the land is always lyiug in au unproductive state, and it requires a great quantity or breadth to return a smal result in produce. The stock kept are in consequence badly fed andinforior and everything in fact is but just above starvation point, and whatever you bring to such a system of farming deteriorates. It has the advan tage certainly of requiring but little capital or intelli gence, the payment of the rent being the ultimate plishod it is suffint certainly, that ot the beginning of some of these course of corn crops, the field gets a dressiag-sometimes a heavy one, dung and lime being tumbled on together (the one eating up the other); but then it is spread upon the land in so foul a state that it produces weeds and trash instead of corn. As to loaving the hand to rest, it is not at rest; there is nothing at rest but the farmer himself. The land is labouring to regain the fertility of which he has cruelly deprived it, while he is sitting by his fire-slde, with his pipe in his mouth, considering which field he will plough up next. That this is the general system of farming, in this part of Wales at least, will not be denied.
Of course there are some very pleasing exceptions If, then, there is any correctness in these observations, particularly as to climate and soil, to what course of husbaniry do they point? Do they not indicate that the first and fundamental work is draining, and then the improvement of our natural pastures and meadows in connexion with the cultivation of a limited quantity of arable land under alternate green and com crops, sufficient to supnly the stnck during the winter months with food and litter; and that the ploughing should be confined to such iimited quantity of arable land under a regular rotation of cropping, seeing tinat the brenking up of pastures or meadon greatiy ivjures its productiveness for a series of years and grain crops never grown, except alternately with roots or Clovers, \&c., and as part of a regular course Do they not indicate that this is a country for tlocks and herds, and that dairy farming, the breeding and rearing of cattle and sheep, is the legitimate business of the farmer in Wales, and to corn only as a
secondary and subordinate source of profit? Nothing,
I believe, has impoverished the Welsh farmor I believe, has impoverished the Welsh farmer so much as his constant unavailing effort to raise grain crops What proportion, then. of a furn as a general rulefor of cours. it must, vary - should we hiruken up and kept as arallo lazd? Miay $1($ not venture to say that not more than about one-fourth or one fifth, after taking out all such inferior land as is too high or pre cipitous, or otherwise not ploughed? On the old red sandstone it may be souethinig more, and on low grazing and alluvial lauds it will be less. Take then for example, a farm of 200 acres of available land 40 acres of it carcfully selectel as the most suit the to be kept as arable, and the remaining litio as meadow and pasture. irlatever altermate comse of cropining is pursued on the 40 acres-whether a four, five, or six-course shift, ahout one half of it will come into corn every year. 'lake, then, the foureourse shift, and
there will be, say, 10 acres under roots, 10 under Bariey, 10 under Clover, and 10 under Wheat and Oats, and if this land is of fair medium quality, and has been for some timo properly cultivated under such rotation, the average yield shumld be at lenst ahout 40 mashels per acre of larley, 30 hashels Wheat, or thl
to 60 ()ats (we will say it is in Wheat). There will then be brought to the stackyard each year (carrying two acres to each stack) 5 stacks of Barley containing 60 bushels each, aud 5 stacks of Wheat containing 60 bushels each, and taking it at 2 tons per acre, 40 tons of straw-a fair quantity for litter, the stock and other uses. This, although corn is only to bo considered as secoudary source of profit, is probaily more than the furm produced under the old kystem, when nearly the whole of the laml was kept in requi-
sition for that purpose chiefly. This estimate sition for that purpose chiefly. This estimate
of the produce of corn is not guess work, but taken from my own experienced realisation of many years. Then the remaining 10 acres of roots and 10 acres of Clover will be usually heavy crops in our soils and climate : the former 20 to 30 tons per acre and the Clover 11 to 2 tons each cutting for hay, affording a great quantity of food to assist the meadow hay and straw for wintering the stock. But, as I have stated, the principal returns will bo derived from the dairy and the rearing and feeding of stock, for which the largest possuble supply of food will be provided by the improvement of the pasturage and meadows, by means of thorough draining, periodical dressing of lime, and earth dry from the ditches, with which slight senttering of suitable Grass seeds should be applied when required, and by the application of suitable artificial manures, as guano, superphosphate and bones; the dung from the farmyarl not required for the roots, \&c., being taken to dress the meadow
and raise early and succossive crops of Rye, Vetches, sc. By the consumption of so large a supply ot food (especially in the winter, under proper accomenodation) by a large and thriving stock, so great an accumulation of farmyard manure will be produced as to keep the farm (with but small assistance from artificial manures) in a rising state of fertility. What may be done for Grass lands, by the means I have pointed out, would scarcely be believed without being seen. I can poin out a meadow that eight years ago was a poor clayey and p, producing oniy the coarsest, sourest herbage, parts with the finest Grasses, and well worth $3 l$ acre.

## Home Correspondence.

Painless Extinction of Life in Animals designed for Hwman Food.-I was very much interested by your Life in the pamphlet entitled "Painless Extioction of your judicious strictures upon it, and felt a strong desire in consequence to read the pamphlet for myself. I accordingly procured a copy from Messrs. Longmans (for which I paid $1_{8}$, enough certainly for 12 pages of not very closely printed matter), and have read it with interest, and at the same time with surprise that the author should put forth such statements as are to be ound at p. 10, that "blood is as wholesome and digestible as any portion of the flesh of animals," and that "the recommendation that animals should be well bled is merely a butcher's prejudice." It happens, very unfortunately for Dr. McCormac's theory, that the universal practice of enlightened and civilised society is in accordance with an enunciation of unquestionable authority. It was not always that the flesh of animals was permitted as food for mankind, and when at length the permission was given it was coupled with this proviso: "But flesh with the life thereaf, which is the blood thereof, shall ye not eat." Not as the arbitrary lecroe of sovereign was this prohibition given, but like all enunciations from the same authority, in most perfect accordance with reason and riyht. Farther on in the same fatultess code we read: "And whatsoever man there be *** that eateth any manner of biond, will even set my face against that soul that eateth blood, and will cut him off from amony his people. For the life of the flesh is in the blood" (Lev. xvii., 10, 11) That the speciality of the prohibition may not be misunderstood, we read further on:-"And whatsoever man there be of the children of Israel, or of the strangers that sojourn among you, which hunteth hall even pour out the blood thereof and cover with dust." Only once more, lest objectors should say
theee regulations were enacted for the observance of pecial people. We find that in the very first General Council assembled at Jerusalem, it was enacted, an made binding to the very end of time, that men
es keep thomselves from things strongled, and from "keep themelves from things strangled, and from
blond." The above passages, to which inore might be adderd, are tie authorities upon which the practice of
sheddins the blond of all animals intended for fool is shedidng the bhond of all animals intended for food is usages of Society, wherever the knowlelge of them has heen disseminited, so that "the recommendation that animals should be well bled," appears to be something more than a "hutcher's prejudice ;" at any rate, it is not a prejadice of recpnt date, but has descende through the fraternity of butchers for nearly or guite 4000 years. It is quite possible that our author has never taken the trouble to acquaint himself with these passages and others from the same nuthority, or we "The butcher's preiudice nbont well-bled meat is one which they have irebibed from their superiors, and has no colour of support, whether in renson or fact." A very of the prohibition which forbida blood as an article of food. Whatever is taken into the stomach should be of a natare to be eavily digested by the gastric juice thereof. Ordinary articles of food come within thi category, but blood being the life, in reality a living vital subatance, is on that account totally unfit to be ueed for the parposes of nutrition, because of the great diffienlty of digesting it. Fivery one knows that, powertal as the solvent juices of the stomach are in resolving every dead aull well masticated substance into the condition necessary to nutrition, they will not lay hold npon any living substance. If therefore blood is taken into the stomach it must remain there till its vitality is entirely deatroyert, before it can be redaced into chyme, and thereforo must be to a considerable extent a mosenges uph living principle, and that the life actaaly whole body is derived from it, is a doctrine of Divine Whole bonly is derived from it, is a doctrine of Divine
revelationt, and a doctrine which the observations and experimenta of the most necurate anatomists hav gerved at rongly to confirm."

If the eaters of blond in general knew that it affords a very crude, almoat indigestible, and unwholeanme nliment, they certainly Wonld mot, on these physical reasona, leaving moral to the consumption of that from which they could expert no wholesome nutriment, and which, to render it even pleasing to the palate, reguires all the skill o the cook." So writes Dr. A. Clarke. Dr. Hunter "iving parts of the body, and he demonstrated this by a preparation in which vessels were clearly seen to arise
from what hat been a coagulum of blood, for these vessels opened into the stream of the circulating blood. which was in contiguity with this coagulated mase." Another writer affirms: "Oue general law affecting all living bodies is, that they have a tendency to resist the action of those bodies which threaten their destruction. This is undoubtedly the effect of life in every case." (Dr. J. Corrie's Essay on
the Vitality of the Blood, Ed. 1791, p. 6.) Enough has probably been said to show the unfituess of blood as an article of food; and yon have dealt so ably, though briefly, with our author's comparizon of vivisection with the usual modes of slaughtering the animals designed for food, that any further notice would be superfluous, further than to say that your remark, "that there are numerous cases to show that instantaneous death from a blow is in all probability absolutely painless," is worthy of being pondered by our author, and by all who entertain similar views. The probability is, that
the common sense of mankind (leaving hivher motives out of the guestion), will lead them. along with the "prejudices" of the "butchers" to the very end of time. Willian Chitty, Stamford Hill, Jan. 16.
Effect of Irrigation.-In the las $t$ issue of the Agricultural ( ${ }^{2}$ azette Prolessor IBuckman's Table of Grasses inproved by irrigation must be a surprise to many of ynur readers; this table, as you suy, is "not consistant
with mniversal practice." I aver that it is the very with nniversal practice." I aver that it is the very
opposite. For 20 years I have studied the subject of natural Grasses adapted to pasture land, and seen much of irrigution on mendows of natural Grasses, as well as with Italian Rye.grasa, ath am unw engaged to im less by irrigation ; therefore, the subjoct directly in terests me, and I vill feel greatly oblig $d$ by any intormation as to the amount of irrigation which produced the results as statel iu Profersor Buckman's Table. The Pon trivialis is the only good Grass that I have seen increase by irrigation, and this was with spring water congener, the Poa pratensis, an upland Grass, is made to double: more remarkable, the Aira cæ3pitosa dies out! Charles M"Domald, Woodstock Park, Jan. 23
Yew." and the requested on the subject I beg to give you mine. In March, 1859, I had, with other young horses running in my park, a very fine two-year old colt, by Raby out of a Beeswing mare. One morning the colt was found dead on the carriage-road. There were no indications was buried. Some days after, however, horses' feet marks were discovered in the enclosed grounds near a

Yew tree, the twigs of which had evidently been the result of a post-mortem examination, performed by Mr. C. Stephenson, of Newcastle, veterinary surgeon, ave the most conclusive proofs of the cause of death. nsilerable portions of fresh green Yew being fuand in the stomach. A more detailed account of this case may be found in the "Veterinarian" for Jaly
Jas. Lnycock, Low Gosforth, Northumberland.
Fero and Colchicum.-I observe you inquire as to the effect of Yew and Colchicum on cattle.
weeks ago my heifers broke through into a neighbour. ing garden. In one corner, unknown to any of ons people, there was a little 8crubby Yew-one. 'There Was no doubt about the cause in each case. The leaves in the stomach of the cow were quite fresh. Two or three years ago, when Mr. Came to Frog Lane Farm, he found some of the fields covered with owsn. the ground. When withered his cows ate of it, several them died. It is undoubtedly a very dangerous pla John Thornhill Harrison, Frocester Court, Jan. 19.

## F'oreign Correspondence.

Ehe Downship of Dawn, Canada WestMechi has been sent to ns for publication. Per mit me to address a few lines to you from the backroods of America, and to inform you of a few of the reat hardships the poor emigrants have to contend with in carving out a home for themselves in this inhospitable land. I was induced, from the flattering accounts I heard of Canada, to make a trial at bush. whacking, or clearing up a hundred acres of forest land. I was insane in that respect, for it's a task no nue should andertake unless he has two or three sons to help him in his arduous task. I took a hundred acres from the Canalu Company at ten dollars per acre, that is $2 l$. terling. I paid 180 dollars down for the right of settling upon it as a leaseholder for ten years; the interest on the thousand dollars is $12 l$. sterling per
year. As I have been on it ten years withont being able to pay one penny, either principal or interest, and manylthousands more being in the same position, I think it is high time that so much clap trap that we hear about emigration to Canada was exploded. I think rior to 1845 that Canada did offer a home to the hard vorking agriculturist, but now it will hardly do that to a man of moderate means. What can a farm labourer do here when a capital of at least 800l. is too small to commence a bush farm? for it is quite by chance if he aises his bread and seed under ten years, and it is no small task to grovel through that long time and keep the bailiff from seizing your little property for the benefit of the storeseeper or the bootmaker. The new settler has almost insurmountable difficalties to contend with. First, he has five times too much to pay for his and, that is, what should be sold at 88 . per acre, he cannot buy under $2 l$. sterling. The Government lands are all sold to speculators, hence the enormous price asked for them, except those lands in the extreme north, which is fit only for the native Indians, as there are seven feet of snow frequently. I think they are not ikely to be cleared fit tor civilised peonte. Mr McIDougall, the Commissioner of Crown Linds, stated that the best lands were all sold, and it was unfair to set the poor enigrants down in the forest to starve. A sentence composed of so much truth ought to be printed in gold. That pithy sentence roused all the land speculators, your Streets, Hendersons, and the Canada Company's nominees, with a hoss of others, to fiery combat in the house of the Legislative Assembly; they at the same time asserting that it would direct the attention of the inteading emigrants either to the United States or some other Britisli colony. Why, sir, or the last four years we have had no emigration to Canada except a few poor Scotch fishermen, influenced by "Mr. George Brown, M.P.P. of the famous representation by popuation notoriety." What the people want is this, that it should be widely known that Canala does not offer a home to the sturdy labonrer and his family; to a few single men it offers more advantages, as single men get higher wages than in England-i Wages is thell object, as they must sacrinice all other com-
forts. I will coamnence with stock, horned cattle first: the new settler from Fagland generally begius with s ock. He must have four cows at least, besides others growing first seven to pine years: $s$ ome let it remain ten befo they attempt to plough it up, and even then the roots and stumps interfere very much. Well, what is the result of keeping this stock? why, simply this; they in nine cases out of tell all die with the murrain, and frequently for settler's ox team goes also. That is a ruinous affair, and the loser sacriferything rules, oxen are always dear, and the loser sacrifices every comfort, even necessaries year the other to buy auother ox; very likely next year the other one dies, then he mortgages his land, paying 10 per cent. interest; after that he works at ditching on the public highways to pay the interest, crose pily the little farm goes, and then he has to flutter in to the land where the Stars and Stripes to form a home under their banner, for thong again
worships the flag of Old England, though he admite the impartial manner in which she administers her laws, though lee reverences the name of Victoria, and would draw the sword or shoulder the musket, and take a determined stand to protect the honnur and dignity of that beloved land, yet you do not give hind farropportunity to live under your protection. He wants land sufficient to keep him by hard work, and he most go where it is to be had good and cheap, at nbont 6 , ment; and thus we are losing, and shall lose, half our population in Canada. But I have wandered a tell you that I have lost 13 head of cattle, wy simply among the number; I don't know how many sheep, bnt I know 27 died in one year; we take but little notice of pigs dying, as they never pay to raise. I have seen 14 bushols to the acre a croop in 10 years, and we cal 14 bushels to the acre a good crop. The fly destrovg
the Wheat, and there is a bug that breeds in the Pa and eats the inside out; and through the America war we are unable to selt our castle or pigs, as they bry everything we have to sell. Our markets are very lom in everything; I will be plain and state in English money:-Good beef, per 1 b ., $1 \frac{1}{2} d$., pork $2 d$. per 1 b , flour per 100 lb ., $9 s$., mutton 3 d . per 1 lb ., hides per lb , $1 \frac{1}{2} d .$, butter $9 d$. per lb . (I have known it sold for years
at $4 d$. per 1 b .), Oats $1 s$. $8 d$. per bushel, hay $2 l .8 \mathrm{~s}$ p per ton. Many of our children are nearly naked and bare. foot, owing to the high price of clothing and boots, -

effect of indueng provincial senools t.) (h)yove ottention to th
 provinces would necessitate a stafe fat beyond that
zight, if necoeseary, be stated against direct intervention in egminaries
mend that two prizes should annually on further to recommend th to the etudents who pass the best and the second best Examination
Mr. Nisbit Hamilion moved the adoption of the report. Mr . Elinot, of Wolflee, seconded the motion.
Mr. Mchagav, of Pumpherston, said: Yesterday he reccived a letter from Mr. Milne Home, requesting him
to express his regret at not being able to be present at the meeting that day; he had therefore requested him to bring his views before the meeting. Mr. M‘Lagan proceeded to read extracts from the letter; and which require the most momentous consideration. 1 , therefore, with great deference humbly sug. gest to the directors whether they ought not to allow the report to lie on the table in the meantime,
and bring it up for consideration at next meeting. I wish further to say that there are some objections of Mr. Home's to the report to which I give my most refers to the giving of diplomas. It is said in the report, I think, that there should be a certain number of marks required in giving the diploma, and that there should be money prizes given to those candidates who exceeded the specified number of marks. Now, I think that a diploma is the highest honour which anybody can confer upon a young man. It is a certificate of his proficiency, and it is the passport which he shows from one district to another. I think you should not depreciate the value of that diploma by putting some paltry money prizes above it. This is one point which I wish to urge upon the directors. There are other points Which I intended to advert to, but I shall not detain the meeting with them. I beg simply to reiterate the hope that the directors will take this point into their con-
sideratiou-whether they will press the approval of the report at this meeting, or whether they will allow it to lie on the table till next meeting.
Mr. B. Nicholson, advocate, and Professor Balpoun thought it was important that the meeting should proceed with the report and dispose of it just now. The
latter said the better course would be to adopt it in ite present condition and make alterations or improvement on it if necessary, as they received experience of it working. He considered the question of age a minor point, and was of opinion that they should not stop the prizes, he wished to remark that in the giving of these it was not intended to depreciate the diplomas, but that the prizes should be given in
addition to those young gentlemen who manifested a higher standard of excellence than that required by the diploma
Sir John Stuart Forbes baid he thought the report stoutd not-pat nither as the report of the result of the consideration on this subject by the Committee on Education of this Society. The Council was one which had been established by their supplementary charter, and it consisted of men of the highest
position and of the highest intelligence in the countrymen who were perfectly suited to deal with that important question in the most liberal and systematic manner. He thought, therefore, it would be very undesirable that they should throw open the whoie of the points of that question for discussion and for the at the moment, considering thatht choose to take it up at the moment, considering that they had that deliberate $H_{\theta}$ report in favour of the adoption of a certain course He was glad to think that the step which the and they had advanced within the last taken months to a point which he had never hoped Was anxious that they should not lose time. He was quite sure that details, such as the place of examinamittee when matters, will be dealt with by the comraitcee when they come to put the system into working
order. He for one hoped that the Society able to go a little further in the society might education. He was confident that when the system recommended was in operation, they would be certain nations of their elementary material for their exami Hations of a higher character than it was at present certain schools, which would enable young men to come forward and devote a good deal more time than they at present did to their agricultural education.
The Report was then adopted.
Mr. MéLacang is Mr. Milne Home's letter, of which

especially when coupled with the restriction as to age-to students of tho University of Edinburgh. It is not to be expected that young men would come up from privacial schools, or even from any other town the seat
of a niverity, and incur the expense of travelling and of lodgings. in Edinuburgh, merely on the chance of getting an money prizes.
The reporters apparently felt that this restriction wonld be it. They say that, the "learned Professors" give their examinations in Edinburgh;" but that "the extension of a system of examination to thn provinces rould necessitate
staff beyoud what it is in the power of the Society to organise.
In othe
In other words, hecause the Fdinburgh Professors are willing coufined to Edinburgh, the society for the saly when they ar conained to Ediaburgh, the society, for the sake of a paltry
saving, should deprive the students of the other scottish Universities and of all the provincial schools, of the necessar means of testing their qualifications.
The society sends judgeo ungrudgingly to distant parts of
Scotland to examine catto, pigs, and pnultry, and award prizee
to the most deserving to the most deserving, at a a e expense far exceeding what wroul
be required to send a competent person to examine candidate in te provinces who may wish to coompete for the diplomio or certiticate. I therefore cannot believe that the Society, if
sanctions the offering of prizes and marks of distinction to b only practicable means of carring out that object. "But if the Hichland cociety really think it impossible to vinces, another pian equally efficacious, and very economical may be adopted. Arrangements have been made by the
Universities of Edinburgh and St. Andrews to hold district examinations for awarding honorary certificates of classical literary, and scientific attainments to young men. These
examinations are to be held in such towns as Perth, Ayr. Stirling. Inverness, Oban, and Dunse. Now, there would conduct these examinations should at the same time vistit the schools which had signified a desire to compote for the Society's prizas and honours, or receive the echolars for examination
in the town where the other examinations aro being carried on.
A short time ago, having been invited to join the District tion in Berwickshire next sumaner. I had sent to mo by the secretary a list of the subjects which will be embraced by it.
Imong these suljects I find mechanics, chemistry, natural history, animal and vegetable physiology, which are the principal heads of unquiry in an exsmination for the Society's
diplonas and curtificate ; so that the persons who, on behalf of the Universities, are to conduct the district examinations,
would be quite compotent to aet in this matter also on behalf

On these grounds, I cannot concur in the propricty of any of the restrictions which are recominendeli to be annexed to
the prizes and marks of distinction specified in the report. If the directors really entertain the desire "to popularise and
oxtend the operaticn of the Society's Educational Chartor," earnestly hope that they will reconsider these restrictions. I hope, aliso, that they will ask authority from the general
neeting to arrange for district examinations being held, in the event of any provinoial or parochial schools intimating on the
part of their pupils a desire to compets for the society's prizes and honours

## Thave writen taus fally to you, as I bolieve you appreciat

To P. M'Lagan, Esq., of Pumpherston. Chemical department.
Dr. Andersor, in reporting upon the business done in this department during the last six months, stated that during the latter part of the year a smaller number
of analyses bad been made than during the first six months, when the traffic in manures was most active. They had, however, during the past six months had our usual amount of work, and great progress had been made. He intimated that experiments were being made in connection with the Bean orop, and also with Grams. Some of the experimenta alluded to in last Graport wore of thil going on, and he expected that progress would be made in them during the next six months.
Mr. Habvey, Whittinghame, said it had come to his knowledge that considerable adulteration had been dis covered in some of their feeding cakes. He wished Dr. Anderwon to explain how far this adulteration had come under his cognisance, and to inform the meeting Whether it was foreign or home-made cakes which were the more adulterated.
Dr. Avderson, in reply, said he was sorry to may that the adulteration of oilcakes was far from uncommon the present moment, and be thought he might venture to say that perhaps the adulteration was more common io the bome-made cakes than in the foreign. He might give one sample as an example of the fact. A dealer in oilcakes-a man who took great pains to obtain a first-rate article-recently obtained samples from four manufacturers, and the result went to show that three out of the four samples were grossly adulterated. One of the manufacturers when taxed with the matter, admitted point-blank that it was adulterated, but snid in extenuation that the price ut which these oulcakes were sold was such that he was compelled to adelterato them. In resaril to foreignmade oid-cakes, he believed there was a great deal o inferior and Turkish seed ased in their manufncture.

## PAPERS IN COMPETHION-TMET OF AWARDS.

unaltered; and atter a somewhat unsatisfuctory discussion of the differences between the directors and the officers and members of the Inplement Committee, arsing out of the late show at Stirling, the meeting ated.

Dubiam Countr. - At the recent annual meeting of the County of Durham, Sir Hedworth Williamson, M.P., was olected President for the ensuing year.-Mr. Stratton moved, and Mr. Newby seconded, that the meeting of the Society be held in the city of Durham for the ensuing year. Carried.-Mr. Stratton then said he had a subject of much importance to bring before the meeting so for as the farmers and graziers were concerned, and that was with regaril to dogs rumning after and preying on their sheep. As the law stood at present, if they knew a dog was destroping sheep they could not destroy it nor make the owner pay the damage done by it, unleas they coull prove tint the dog had been in the habit of killing shepp. The laws with respect to this were different in Ireland and Scotland. If a dig did an injury there they had nothing to do but find out the owner, and they could compel him to reimburse them for their losses. He thought they ought to petition Parliament assimilated to those of Scotland and Ireland. that they might appoint a committee to gain every future day and consider it some future day and consider it.-Mr. Johnson: And to inquire as "to the best mode of remedying the law on the sabject-Mr. Furness said perhaps the secretary of the Nor thumberland Society might oo-operate with them. Mr. Johnson, the vecretary, said he shoold be happy to do so, and he should mention the matter to the members for Northumberiand in order to get their co-operation It was agreed that the meeting be adjourned to that
day fortnight.

## hevictus.

The Jownal of Agrioulture, and the Transactions of the Bighland and Agrioultural Sociely of Scotland January, 1865. Blackwood \& Son.
The Journal contains pnpers on the agricultural nses o Corse, on Cofiee, on the Oat crop, on plantation roads, on water and its agricoltaral uses, on agricrltural education in rural schools with the agricaltaral
sammary of the lat quarter of 1864 , and with notes on
the turkey, wool, and coprolites, and various statistica tables. The Transactions inclute papers on horse breeding, on antumn and spring manuring, on mised plantations, on waste land reclamation, and on the action of uric acid as a manure. As a whole, the volume Part is a satisfactory number, and fall of useful information. The papers to which we shall at present refer are those on Gorse, on Agricaltural Education, and on Uric Acid.

The serviceableness of Furze or Gorse as ford for cattle is illustratod by several anthorities. So long ago as 1812 Mr. Frnser Tytler fed his horses on bruised Gorse. Along with this they had "as much straw as they could eat, and $3 \quad 1 b_{0} 2 \mathrm{oz}$. of Oats per day till the beginniug of February, when their
allowance of Oats was doubled. The quantity of allowance of Oats was doubled. The quantity of
bruised Whins given per day was found, upon an average, to be $18 \frac{1}{4} \mathrm{lb}$. The same system was continued in 1813. In the following year the stock of horses was reduced to eight, and a larger quantity of Whins was given them. Six of the horses got each 28 lb ., and the ther two horses from 20 to 22 lb . Corn was witheld from them during the shenod whater and in spring, as the days lengthened, and the wor became heavier, they got only half their former allowance, or 31 lb .2 oz . Notwithstanding that the allowance of Oats was thus materially lessened all throagh the season, the condition of the horses was equal, if not superior, to what it had been during previous years-the quantity of cora withdrawn appear to to be more than compensated by the additiona 10 lb . of Whins.

The expense which attended this mode of feeding, including that of collecting and preparing the Whins bogether with straw and Oate, was $43_{3}^{3} d_{0}$ per day for each of the eight horses prior to the beginning of February, when no corn was given, and $8 d$. per hosse fter that date, Oats being then added. When hay was given instead of straw the daily expense was 8. 0 d. . per horse

Some nonths ago "A Welsh Farmer" described hi experience in the columns of the Marl Lane Express. He said : -

As a proof of the great coonomy effected by the use of this food, I may state that I winter ten horees, which consume three and a-hatf cart loads per week. These cost from 18. 6d. to 28. per load; the cutting is done by the jot at $18.6 d$. per load, the man aleo assisting the carter in loading. It is bruised after field hours in the same time that would be required to cut the necessary amount of chaff. The cost of keeping all my horses is therefore as follows:-
Thre louls and a-half of Furze, at (say) 28.
Cutting and hadiul three and a-Half, at 1s. 61 .
Curting home, half dy each load, at $5 s$. per day

Not quite 4s. $1 \frac{1}{2} d$. per horse per week."
Again, in 1838, Mr. Robert Black, ol Loch ilsh, Rnssshire, described his success in the atilisati in of the plant.
"In the winter of 1835 and spring of 1836 I had ong of in sentcli acres cirained and dag over to the epth of 10 or 12 inches, at an expense of 6l. an acre The land at the time of sowing, April 1836, I con sidered in a very unfit state for sowing, as the raw peat had had no time to mellow down to anything like soil and the seed was consequently sown over a raw peat bog, showing symptoms of pulverisation only where th pat had happened to be more or less mixed with other matter. Contrary, however, to expectation, the seeds vegetated freely, and by October had reached the height generally from 4 to 6 inches. The severe spring of 1837 cut off by the ground many of the plants tha had been unnaturally drawn up by shading or other wise, but these all sprang again from the root, and are now the thickest ani most luxuriant parts of the field. "At the present date, 15th January, 1833, we has been cutting Gorse for two months back, and during that time have kept eight horses, young and old, wholly upon them; as also about the same number of cow partially so. The horses are in the yoke every day and are in excellent condition, although they have not tasted Oats this season. The cows have also improved both in milk and condition siuce we began to give them feed daily. From what I have seen of the feeding qualities of Gorse, I have no hesitation in saying that onsider it equal to both Oats and hay for work horse and superior to any kind of food that is usually given to milch cows in winter; the butter and mill from cows ed on it being equal to those from the finest old atures during the best part of summer.
The rector of Aghada, co. Cork, the Rev. W. R ownsend, and Mr. G. Bolster, a farmer of that county, are further quoted. Professor Blythe's snalyses are given, and varions machines are described for preparing The food, whose virtues they unanimously praize. Mr Walsh's frorne-crnahing machine, which hms bsen alrearly described in these columns, is referred to as she best of thein. The following ia the cuitivation of the plant as escribed in these pares:-
"The most suitable situations for growing Whins are steep banks anfit for regnlar cultivation, or thin roeky hand, which cannot be ploughed, and produces little in and onoe sown, and the young spots Whins will thrive no further care in in general neoeesarg firly established
nent crop-one of its great merits being that the seaco for using it is that in which other food is usually semen and valuable. The ground must be dug or plonghel and harrowed before sowing the seed-of whith th quantity allowed varies from 20 lb . to 30 or 35 lb . peo imperial acre. When sown in drills 10 inches wide, some reco:nmend, from 15 lb . to 20 lb , will be suff cien but when sown broadcast double the quantity will bo necessary. Thick-sowing causes the plauts to be dram up, and therefure tender, which is of consequence the shoots are more easily prepared for use as food The seed is sorm in April, amit the plants will be read for cutting in 18 or 20 monthe atterwards. The fire cutting is light compared with what will be obtained the following year. Some cut only half the plants it each year, while others consider this unnecessary ani bnt the whole of their ' Furze-meadow' annaally seed used for sowing is usually called ' French Furze? Mr. Bolster recommends ground bones to be appled a a manure for Whins harrowed in along with the seed and the analysis of the plant at once shows this to be suitable application. In localities removed from the

We ma author pablishes from an Irish farmer :

 gener.lly speaking, 2 to 21 stones ( 28 to 35 lb .) with 3 to
stones of roots, gand 3 or 4 lb . of meal of some kind. It found that the bost time to give the Furze was about an bour or two after the Turnips; if given before the roots they do not rich in nutriment that the stomach in satiatod, and instinctivel cattle they get it ad libitum.
uitable consider that, economically, there is nn food mor holds a mindle place between hay calves during winter. It woo dry and indigeabible for their young organs, and the oblo too laxative. Accordingly, they are ra

The writer gees on to praise ibs medicinal and cut tive properties. He speaks of its use in the stable with confidence; but says it 38 less adapted for sheep.
2. The arbicle on the possibility and desirableneas agricultural instruction in rural schools is, we beliere from the pen of the recently appointed Director d agricultural schools in Irehand. It argues the poo bility and the duty of tearling common thinge, and if of teaching the use of the needle to the girls, the the use of the spade to the boys. And not only th practical details of farming operations but the principle on which the failure or success of them must hing are also to be taught to the future labourer of country. "Over and over again," says Mr. Baldwin machines, which, if properly used, would have proved economical, but which were thrown aside as useless for want of knowledge on the part of master and man. I all these cases the money sunk in the machines wo regarded as a bad investment; the economy or mon which would have arisen from their use was lost, and agricultural progress retarded."
nd again
From
From a pretty lengthened correspondence with extensive employers of labour, as well as with men who view this subject from a philosophac point of view, and from my own independent observation, I am justified in saying that the labourer who understands something of the principles of the implements he uses, takes deeper interest in his work. He performs the worl with with more profit to his employer. Regarding the matter from this point of view, I consider that the employers of agricultural labour are most deeply generation of labourers."
This article is the first of a series on the subject promised from the same pen
3. Uric acid is the subject of a paper only partly published, in which field experiments are described by Dr. Anderson-Peruvian guano, guano ash alone, and guano ash with nitrogen equal in quantity to that the Peruvian guano supplied respectively in uric act and in sulphate of ammonia. The results upon the Turnip crop in plots of about 40 square yards apiect are described - those upon the Wheat crop are yo be given. The circumstances of the experiment appar to have been unfortonate, and the resultm sccordig. are somewhat contradictory. Speaking of the Iurai results Dr. Anderson saps:-

Comparing the result in each section with on another, it is to be observed that in every case he mixture of guano ash and sulphate of ammonia iven the best result. After it comes the guano thereaud then the uric acid mixture. The conclusion,
fore, is favourable to the ready formed ammonia source of nitrogen in this case; but, as we shadl mum confirm this inferpence, and it is necessary how far the particular circumstances under oxperiments were made may tend to affect tho te

## Farm Memoranda

Forfarshire Farm.-A few everinga ago, a farmor in Forfarshire showed us his bouks for the year 1891; and the close, and also one of his fatuer's for the and the contrast between the two was so striking
farm contains 180 Scotch acres of land, all arable. The farm is a free light loam, except a small portion, certainly less than 15 acres, which is inclined to clay. The aubsoil is the boulder drift, except a few ridges where the old red sandstone comes rather too near the surface. A gool part of it is pretty steep, but all has a southern exposure, and is thoroughly drained where this was necessary. It requires the labnur of three pairs of horses, and there is usually an "orra beast" besides, wages for each of the two years:

Thus in the items of rent and wages there is a dif ference of $162 l$, of which $42 l$. is in wages alone. But other portions of the expenses were in still stronger
contrast. In 1834, his father had paid 10l. for bonedust, while the last year's accounts for artificial manures amounted to $150 l$., and in one sense, he said it was too small. This raised the difference of expenses to 312l. We asked how he made it up, and will give his answer and the rest of this contrast as nearly as "Wossible in his own words :-
considered too dear-rake it up at all. My farm is not than some we know, bat I, amd it is certainly cheaper father wrought it on the six-crop shift-1st, Oats after lea; 2d, Green crop ; 3d, Oats or Barley; 4th, 5th, and 6 6th, Grass. He had thus 60 acres of corn, which would possibly yield on an average 400 bolls. I see rop 1834 stated at 420 bolls, tenth was Barley. Prices are entered from 15s. to 21s. $6 d$. per boll, but a very small portion was sold at the
latter price. My father's horses scarcely ever got any clean corn, the shag being thought sufficient for them; but they had less work, and were seldom out in bad weather. He had sold of this erop
225 bolls of Oats and 40 bolls of Barley, and the total sum received amounts, you see, to $244 l .17$ s. $6 d_{0}$ His receipts from cattle were not so favourable, but from the way in which this part of the book is kept it would require some time to ascertain them exactly. He usually reared from 12 to 15 calves, and fed from 8 to 10 builocks, which were four years old wher they left the feeding byre. The price rarely exceeded $12 l$. a head, and was oftener below this. Those not required were then plentiful and cheap-about 10s. per head, except very early ones. My father got a new lease in
1889 , and I succeeded him in the farm just at the time the whole agricultural interest was agitated by the Was now 1802. I got through the dull times which
followed these changes, and the failure of the Potato crop, without losing seriously; and the high prices consequent on the war with Russia were giving me agnin a balance at my banker's when my lease expired. per Scotch acre; and had prices kept an ordinary range, no doubt it would have paid me. But low prices of grain and Potatos, coupled with bad harvests, melting away much faster than it accumulated. I have altered my mystem of cropping a little-sowing Barley after all my green crop. This gave me too little Oat lea, and break up my Grass at tome oat crops after three. This gives me 90 acres of corn instead of 60 , one-third of the whole being Barley. By this mode of cropping and the liberal use of light manures, I can
grow in favourable seasons nearly 300 bolls more than my father did; but then at late rates it takes all this to pay the manure merchants. Of my crop for 1863, seed, meal qre, of Oats were soid, and the net cash received Take this from the amount of the rent, Wages, and manure accounts, and you leave a balance
of 2000 . against me. Nor have we here all, or nearly all, the expenses. There are Turnip and Grass seeds, dadesmen's accounts, money paid for calves, wages of ing in the aggregate to upwards of $100 l$., without those of my family. Now, let us see how this $300 l$.

When you pay 10d. or 11d. for a pound of ateak, and read in the newspapers that prime Scots are worth nat 6075 s. per cwt. in the Glasgow market, you very naturally conclude that the profits of the rearer and that more money was made by cattle feeding when
 prices for your calves ; and for one that died 20 pay two aqo you your lose two or three. Not only is this the case with the calves, but at every subsequent period of my father's tile are much more subject to disease. In teath trifing, and the menrest blackemith our only
doctor. Now, what with pleuro-pneumouia, the Grass disease, and the foot-and-mouth disease, \&.c., the vete-rinary-surgeon is almost in constant attendance, and
his bills form no inconsiderable item in our expenses. It is a very fortunate year, indeed, in which no deaths ocenr on a farm of any size ; and too often the stock is decimated by epidemics. I once lost all my cows except one-the
worst in the lot; and 3002 . Would not cover my loss by worst in the lot; and 300 . Would not cover iny loss ly ration in those which survived. In this way a large per centage of the price of our fat stock is swallowed up. On
the other hand, if, instead of rearing, you purchase your stock either as one or two-year olds, you now nay a price relatively fully as high as that of beef, and are still subject to loss from disease. Having less Grass than formerly, I now buy in a few bullocks for feeding;
and this autumn I paid 16l. 10s. a head for them. High as this price is, it would have been still higher had it not been for the large numbers of English and Irish cattle that have for some seasons appeared in our local markets. The purchase of these is attended with great risk, and several parties in our neighbourhood have got their stock tainted by them. The railway trucks get the blame of this, and probably not
without reason. The expenses attending feeding are now much greater than formerly; and you cannot get the high prices before mentioned unless you use something more than Turnips and straw. Only a few of our best cattle bring anything like the top you will often fiud a difference of $2 s$. per stone between the two extremes. This on an of of 40 or 50 stones amounts to $4 l$. or 57 ., and the animal may lave consumed nearly as much food as a high-priced one. If forced from want of keep or any other cause to send our stock to market before they will sell for prime fat,
they leave little or nothing for keep. Last season I received 265l. for cattle, but this includes the price of a cow which I had to replace. This is the largest sum I have ever drawn for them, for my Turnip crop was good, and I used the damaged grain freely. But, after all, it leaves a balance of 60 l . against me on the expenses already enumerated, besides what was required aay that I am extravagant in either, but I know that I am going back in the world considerably more than 100l. a year
To too many of our readers these notes will convey nothing new-nothing which they do not know by experience; but if they meet the eye of any of that tions for that of farming, it may serve to show them that even that healthful and much-envied employment has its

Tattrnall Hall, wear Chbster. - [This farm received last year the prize of the Manchester and Liverpool Agricultural Society, as the best managed following is the Inspector's report.]-Farm contains 322 acres, viz. $183 \frac{1}{2}$ acres in pasture; 22 acres Clover and seed, mown; 11 acres meadow, covered with dung water; 13 acres meadow, irrigated; 6 acres Wheat, after Beans; 16 acres Wheat, after Oats or Clover; 25 acres Oats, after Clover or green crop; 17 acres Barley; 4 acres Beans; 2 acres Potatos; 16 acres Turnips; 3 acres orchard, gardens, and homestead; $3 \frac{1}{2}$ acres occupation roads, plantations, \&ce.

Rotation.-Oats, Wheat, roots, Barley, seeds.
Live Stook.-6 horses, 3 nags, 4 colts, 81 dairy cows, 13 feeding beasts, 3 bulls, 18 heifers and stirlss, 142 sheep and lambs, 49 pigs, and 15 rearing calves.

334
Stock sept on roots and cut straw till calved; then cut hay, crashed corn, bran, oilcalke, with malt corning
added. Catting, cooking, and mixing done by machinery.
The farmyard manure is mixed as made, and chiefly used for root crops and Beans. Previous to 1857 all the pastures had been drained by me, and since then have spent over 100l. a-year on an average on boiled bones, and chiefly applied to seeds after Barley. About 15l. per annum has been spent on super-phosphates and applied to root crops with farmyard manure.
All the land has been drained; 30 acres of ol
Landlord has drained 215 acres with tiles, an orected an entire new homestead, filled up seven pits, and eradicated many miles of cld fences, spending a considerable sum, for which he gets near 5 per cento as ncreasedi rent.
The following has been done by me at my own cont, besides the draining and boning above-named:-Have filled up 32 pits, grubbed up many old fences, planted and kept clean over six miles of new ones, dandlord finding plants; carted all materials for new homestead; pulled up old foundations, and removed old materials to the new site; supplied timber and carpenters' work for a building containing $2 \pm$ feeding cattle, young stock and yearling calves. Supplied and carted paving stones and sand, and formed the ground for all the paving at the new homestead. Made 706 lineal yards
of new occupation road through the farm, of hard materials. Made over tivo miles of footpaths, with cinders alougside; straight fences. Made a lawn, and near four acres of meadow, out of the site of the old
of an acre, made out of a swamp. Levelled and laid out $1 \frac{1}{2}$ acre of meadow for irrigation with the wash from the house. The liquid manure from the other tauks is conducted into the middle of a 10 -acre meadow, where the liquid can be drawn off into the water-cart from a tap.-July 12, 1864.
This is a complete Dairy and Grazing Farm, and lies in a good climate, is well situated for good roads, and within two miles of a canal and railway. The surface is gently undulated, giving plenty of f.ll for the drainage; well supplied with pure water. The soil varies much from a good deep loam on a sandy subsoil, to a very tenacious clay loam on a solid clay subsoil The fields, roads, farm buildings, yards, dairy, and piggeries, all appear substantial and well arranged for convenience and lessening labour. 'The machinery for the various purposes of indoor and outdoor work appears substantial aud effective. The dairy arrangements appear complete. In the shippons each animal is supplied with water in the stall by pipes and troughs, We inspectors do not think much of this arrangement we think a walk to a pond twice a day, and a littl airing in the yard at any sason of the year, is of great rervice to an aninal in keeping it in bealth.
The new fences have been well trained and kept clean, and are now complete. Each field has one or two substantial gates and posts. The cecupation roads and footpaths through the farm are in good order
Swedes and Potatos bealthy and clean; the former short of plants in places. Wheat a good healthy crop and clean; half the Oats an average crop, the other half a¿ove an average; Barley a very promising crop Beans in drills clean, but not showing for heavy
produce; pasture, both old and new, produced good produce; pasture, both old and new, produced good
herbage, but wanted rain; irrigated meadows appeared of a fair quality of herbage.
Live Stock, mostly honee bred, and well selected for the various purposes required. The whole concern, including the dairy, showing no want of ability or perseverance in those at its head.

Chatteris, Isle of Ely: Jannary 23.-The wintar is rapidly passing away, and without much severe weather. We have occasional visits of frost, but they have not hitherto been of long continuance. Two nights ago wo had $12^{\circ}$ of frost, but there are indications of a change again, and the wind appears to be drawing back to the south. The Wheat seeding was generally late, and the land was in a very dry state. We hav however a good plant, although not so forward as is usualiy the case at this season. Some of the last sown will be in danger of being injured by the present dry frosts, having no cover of snow to protect them. A good rain would do good to all our fen moils, as it would help to consolidate them, and prepare them for the Wheat when the surfuce. Tho strize its spring is turning out as well as we expected, and equal to our previous reports of it. The price is very low, which prevents its being a paying crop, except in the case of fine white Wheats ; these are very scarce and remlise a comparatively high price, from 6s. to 10s. per quarter above ordinary runs. Oats are not yielding so well at was expected, especially Polands Barley is as good a crop as was anticipated, and is a very heavy sample but is realising a poor price, and is being much used for feeding purposes. Beans and Peas are only a poor crop generally, and are a slow sale.
Our winter food is being rapidly consumed. The and or colemeed were inferior, and eat away quickly, and Mangels, except on cool soils, were light. We have 400 hoggetts now in yards eating cut Mangels, Whee straw, quarterd 1b. Linseed-cake, and 1-3rd lb . Barley meal, medicated at'home, and made into a condimental ood,", and 1-6th Peas per day each. We bought our lambs in Lincolnshire at an average of about 34s. per head in August, September and October. They have been more unhealthy than last year, aud are yet
uffering from some irritation of the lungs. We have had more than our ustal loss both before and since they came into the yards. In other respects they do vell, and are quite free from lameness. We have 68 cots eating Barley, Wheat and Oat straw, with 1 lb Linseed-cake, 1 lb . Cotton-cake, and $2 \frac{1}{2} \mathrm{Ibs}$. Barley meal per day each, on which they thrive very well.
We have been engaged with cultivating our lands designed for Coleseeds and Kohl Kabi another year, and have also ploughed about 50 acres, part by horses and part by steam, from 16 to 18 inches deep. We have not grown Kohl Rabi jet, but intend trying about 26 acres this year, to test its suitability for our
fen lands, and its feeding value upon these soils. A. S. R.

Aston Parb, wear Nobthwior.-LA prize farm of the Manchester and Liverpool Agricultaral Society.] Farm contains 188 aeres. Of this, 83 acres is pasture, 33 acres meadow and Clover, mown, 28 acres Wheat after Potatos, 17 acres Oats, 4 acres Clover and Vetches, for atall feeding; 15 acres Putatos, 10 acres of these, early ones, and nearly all got up, and the land sown with common Turnips; 4 asres Swedes, 3 acres orchard and garden, 1 acre roads and waste.
Customary Rotation.-Roots or Oate, roots, Wheat, Barley or Uats, seeded down for six or eight years, sometimes varying a little as the case may require.
Live Stook consists of 5 horses, 1 pony, 1 colt, 54

10 rearing calves, total 109. In winter, generally feed sheep.
Stock kept on pasture and green Vetches in the summer. In winter, on straw, hay, roots, crushed corn, bran, and oilcake.

Make as much manure as possible, and chiefly applied to root crops. All the liquid mapure is made available. Daring my occupation ( 12 years), I have purchnsel 757l. 14.s. of bone manure, and applied it to Grass land and seeds; my landlord paying 250l. of this sum. Purchased annually near 3 tons of guano, and 20 to 30 tons of horse manure, and applied to root crops.

Have drained 74 'acres, chiefly with horse-shoo tiles on slate soles. Landlord finding tiles.

Have marled 50 acres, at a cost of from $5 l$. to 6l. per acre. Fillell up all the pits except those required for water, and made an easy approach to these. Made three ponils, one at the homestead and two in the fields.

Have eradicated 3350 yards of old fences, and planted new ones where required. All this at my own expense.
Have erected an extra pigcote, and made alterations in the old ones. Made a urine tank 90 feet by 5 feet, and 5 feet deep; landlord finding materials. Carted all materials for there, and for improvements in the honse and outbuildings; and the tiles for draining from two to four miles.-July 12, 1864.
(Signed) Samubl Hormby.
This farm liee at a tolerable elevation, but not in bad climate. A good road runs through it, and lies within three miles of a market town. Is a good soil for arable cultivation, or the alternative system. The hay, atraw, Turnips, and Oats, moatly consumed by atook on the farm.

The early Potatos are planted in beds, and Cabbaces planted in the furrows. After the Potatos are taken up. the Cabbbages are earthed up, and the beds sown with common Turnips. The dry weather much against the Turnips. The winter Potatos were healthy and clean. Swedes promising considering the weather. Headridges well fallowed, and all the root crops cleau.

Wheat, a thick strong crop, Oats much the same, and 14 acres of these, good seeds at bottom. Clover of flrut jear. mown once, a heavy crop, then pastured, was full of White Clover. Seeds, and pasture of older growth, produced good herbage, but were bare of Grass. One old pasture of inferior quality and bare of Grass.
The remaining old fences have been much improved by judicious cutting, and many new ones have been planted. The fields are much improved in size and shape. The gates, posts, and road, in proper keeping. The same remark will apply to the house, dairy, outbuilding, farmyard, rickyard, garden and orchard. The farm buildings are very spacious and well arranged,
although not new. In the dairy department, all the best appliances are adopted for reducing labour and manufacturing a good article, and the cheese room displayed no want of care or judgment.

## Miscellaneous.

Theory of Land Drainage.-A plant, thorigh spreading its roots to a certain distance all around it in the That is the first, and must have its food brought to it. That is the first main fact on whicl the need depends for a current of water through the land. Water, a powerfal solvent, brings substances out of the air which the plant requires as food, and these substances increase its powers as a solvent of other matters in the soil which the plant also needs as food. Moreover, water brings facturing food for the use of plants. On all these grounds, then, it is of importance that water stould go through the soil after going through the air. It becomes laden with vegetable food by passing through the air, and it becomes still more larien with vegetable food by passing throngl the soil, till, when traversing the soil, it passes stationary roots and enters them, and feeds the plants to which they belong. And there are specinl reasons why rain-water should bo induced to pass throngi the soil rather than lie otagnant on it. In the latter case it is not only useless to the plant, but
it is directly mischievous. By evaporation it cools the surface, whereas by percolation through the land it carrien the warmer temperature of the surface into the crops may be gathered from the is to the growth of autumn, which has been so productive of growth in our pastures to so unnsually late a season-not so much from the increased temperature of the air during November and December, which has been only about $2^{\circ}$ or $3^{\circ}$ above the average of the last 30 years, as from the increased temperature of the soil and subsoil at 1 and 2 feet deep, which has been $5^{\circ}$ and $6^{\circ}$ above the average of the past 13 years, during which observations have been made near London. And not only is it of importance that rain, by passing through the land, ghould carry the temperature of the surface, warmed by the direct rays of the sum, downwards, rather than by evaporating from the surface, it shonid carry the heat away and cocl the soil: but the percolation rather in the ne case air is the water is desirable, because in the nee case air is made to permeate the land, in the other it is excluded. The chemical changes which air produces on and in the soil are desirable, and result in the preparation of nseful food for plants; while by its exclusion, substances of a poisonous nature, especially moil, are formed. Morton's Farmer's Calendar.

## Calendar of Operations.

Juncant. - In the last week of this month we refer oo one or two points hitherto omitted.
(10) The Stable. -The following are the weekly rations collected by Mr. Morton from a number of correspondenta, as exhibiting their practice in the winter feeding of horses; and published in the "Journal of the Agricultural Society." In successive columns we have put, first, the number of the case ; secondly, the authority on which it is given; thirdly, the weight consumed per week of hay, Oats, Beans, roots, Clovers, and straw by horse ; and lastly. the caiculated weekly cost of so maintaining it. This cost is calculated at the rates of
maintaining it. This cost is calculated at the Wraky Fuon or

(11) The Pigstye.-The following memoranda are abridged from Arthur Young:- Mangel Wurzel, Carrots, Swedish Turnips, and Cabbages, must be provided for the sows and stores from October till the end of May, by which time Tares, Clover, Lucerne, should be ready to receive them, which will carry them till the stubbles are cleared; Mangel Wurzel will indeed be good food throngh the summer, so that the whole
year is filled np with these plants, together with the common offal of the barn-door and the corn-fields When the sows pig, meal must be provided to make wash, by mixing it with water. This, in summer, will be good enough for their support, and in winter it must be mixed with boiled roots, ground Oats, and thinned Pease meal in water, for the young pigs. If cows are kept, then the dairy-wash is to be used in the above mixtures.
In order to the highest advantage, the sows should pig but twice a year; that is, in March and August: by which means there will never be a long and expensive seasort for rearing the pigs before they are put to the staple food of Clover, Mangel, \&ce.
Upon this plan the annual sale of lean hogs should be in October, the litters of April being sold then as stores, and those of August kept till October twelvemonth, to sell for baconers, if the farmer fats none himself. The stock upon hand thes month will, in that case, be the sows, and the pigs littered in the preceding Angust; all which should have roots from the store, and run at the same time in the farinyard. In proportion to what they find in the straw of the barnyard, you must supply them with roots, giving enough to keep them to their growth.
It has been o!ten remarked, that winter pigs are anprofitable; and it is certainly true, if they are not kept with great care and attention. Where there is a dairy, the milk and whey may be so profitably applied to their use, that it should be preserved carefully for that purpose. Six pecks of Peas boiled in a hogshead of water till well broken and dissolved, and then mixed in a tub or cistern with dairy wash, or given alone, will wean them well. If dry meat be given in addition, or alone, it should be Oats, which do for young swine far better than other sorts of grain. Barley does not agree nearly so well with them.
As to selling stores, farmers should fat their hogs now that meal is cheap. There is no cheaper or more efficient way of manuring their land.
(12). Trrigation.- Meadows may be floated this month draining them at intervals of every three or four days. the rule is to flood the land until a scum appears upon (13) Woolland fot the water on in frosty weather (13) Woodland, fo.-The following memoranda are Thain quoted from Arthur Young:-
This montt: is generally a busy one in felling corpse : measure, or tale. In some districts the fanly paid by cut and laid in rows and sold in that mals are only rood; in others, the former in that maner by the proper use, and sorts it iner converts the stuff to its or hurdles : and this, I believe, most profitable way. I believe, will generally prove the
In cutting wools there is one point much disputed,

3s. a cwt. for hay, 3s. a bushel for Oats, 5s, a bushel for
Beans, 4d. a cwt. for Turnips or Mancel WW Beans, 4 . a cwt. for Turnips or Mangel Wurzel, Gow,
cwt. for Carrots and Clover, and without chare cwt. for Carrots and Clover, and without charge for
straw. Where an asterisk ( it is to be understood that the corn has been broien or ground, or the hay or straw has been cut into chat: where a dagger ( $\dagger$ ) is appended, the article so marken; has been boiled or steamed; a mark of interrogation (: indicates that the result so marked is uncertain, owim to some indefinitiveness in the account given. The priay adopted in calculating the cost of food are the marke prices of the grain consumed; and in the cases of th hay and green food, the value which it is supposed the might produce if given to other kinds of live stock the farm.
which is, the number of years' growth at which to ant Custnms vary from nine years to 27 , but generally about 12 or 14. I have seen many woods, in cuttien which one stem on a stool was left, to be of a dooble age at next cutting, in order to have some large wod in each fall. The question is, whether sucli stan draw from the root so much nourishment as to lewn the young growth as much as the large shoots ammat to? From viewing such woods, I have observed, the the part of 12 years' growth, among which mad some stems 24 years old, was as yood as othem where the whole was only 12. If so, the additional growth is nearly all profit; but if not, it certuinty makes the wood wh

In the Beech wools of Buckinghamshire, this system has been carried exceedingly far, for they are not cot till of 30 or 40 years' groswth; the consequence of which is, they are destroyed as underwood, aud noting appears but single stoms, which are successions of fourg trees. The way of cutting them is not by falls, 28 in common woods, but by singling out every year, the argest of the trees, and cuttin $\geq$ enough of them to por $12 s_{s,}$ 15s. (r $20 s$. per acre per annum, according to the goodness of the wond. These trees, thongh somed d them "hen cut would more than measure as timber are all eawn into lengths of 4 feet or thereabouts, and rived into billets for fire-wond for the London markeh being conveyed there by the Thames. Good Bead woods upon this system will pay 20 s . an acre clear o expenses, which is more than underwood would py upon the same soil. I believe it will generally be fonut that the older the growth, the greater will be tor profit. At 12 years' growth of Ash, the lamd musb very good to have a crop of Hop-poles; but at 20 gens growth, youl will have very tine ones, and pay g mach better than by the yonnger growth. $12 l$ an sam growth of Copse will be worth from 7l. to 12l. an a $\begin{aligned} & \text { gielding } \\ & 500 \\ & \text { to } 2000 \text { fagrota }\end{aligned}$ 100 to cuta and tio 2000 f

## THE PATENT IN-DOOR PLANT CASES

(to Which a phize was awarded at the royal horticultural boctety's exhibition)
SOLE MANUFACTURER,

## JaMES GRAY, Horticlltural Works, DANVERS STREET, CHELSEA, LONDON, S.W

The PATENT IN-DOOR PLANTT CASE is one of the most uscful of the Gardening Novelties of the day. It is a handsome ornament for the Drawing Room or Sitting Room, and at all times forms a fresh, pleasant, and interesting object to the mind and cye. It is always under command, and will preserve many of the most tender Exotic Plants through the severest winter with comparatively little of the trouble and annoyance attending the use of Lamps, Gas, and Heating appliances of any other kind.
To all who have a taste for the cultivation of In-door Plants, for raising Seedlings, striking Cuttings, \&cc., the Plant Cases will be found an inestimable boon
The Cases are highly approved and recommended by Professor Lindley, and by Messrs. Veitch, of the Royal Exotic Nursery, King's Roud, Chelsea.

Sizes and Prices on application

## HOT-WATER APPARATUS,

WITH TRUSS'S PATENT PIPE JOINTS.

## T. S. TRUSS, C.E.,

53, GRACECHURCH STREET, LONDON, E.C.

By means of these Joints the work is exceutcd in less than half the time required for Sorket Joints, and alterations can at any time be made, or the entire Apparatus removed and erected elsewhere with the greatest facility. A considerable saving in cost is also effected.

These Joints have been used for several years, giving entire satisfaction, and may be seen in use at the Royal Horticultural Society's Gardens, Chiswick, and many other places in Horticultural and Public Buildings. They are also exhibited at the Society's Gardens, South Kensington.

For a fevo prices, see last week's Advertisement,
estlimates, plans, and price lists forwarded on application.

## GREEN'S PATENT SILENS MESSOR, OR

## NOISELESS LAWN MOWING, ROLLING, and COLLECTING MACHINES.

by special appointment sole manufacturer

TO HER MOST GRacIOUS MAJesty THE QUEEN.

GREEN'S PATENT LAWN MOWETS have proved to be the best and carried off every Prize that has been given in all cases of Competition. The Judges af th Royal Horticultural society"s Show, held July 20, 186t, awarded them a Finst-clasis Certificate (No Prizes were given), and at the same time suggested a slight alteration which has been done. Messrs. T. Chmin di sor considor thcir MACHINLES now ay near perfection as possible, and in consequence have continued making them as uand they will have nearly 3000 ready for delivery at the commencement of the seasou, and they hope with their present facilities to be able to execute all arders on the by thoy are received.

Buth the HORSE, PONF, DONKEF, and ITAND MACIINAES possess orer all other Makers the advantage of Self-sharjening; the Cutters being steel on each side, thom they become dull or blunt lyy rming whe way romm the py linder, c:m be resersed, again and again bringing the opposite edge of the cutters against the bottom blade, whente Machine will cut equal to new. Arrangements are made so that the cylinder can be reversed by any inexperienced person in two or three minutes.

negitine poz the ensuman wher

Or a portion of a promontory, enclosed in the The river flows Seine, is the Bois de Boulogne. The river flows along the western boundary of its race ground, beneath the opposite village of ${ }^{\text {St. Cloud, then curves back again past Auteuil and }}$ Passy, where, bending, it straightens its course parallel meet with it again shooting off at an angle parallel with the Place de la Concorde. Thus the Western side is bounded by the river, the eastern by Auteuil and Passy, the northeri by Neuilly, and the south side by the village of Boulogne, whence
it takes its name. The forest was originally of
far greater extent than at present, and was known as the Bois de Ruvray, or Garenne de Rourray, afterwards changed to the Bois de St. Cloud, from its vioinity to that town; while its present same is mentioned as early as $141 \%$, although it is occasionally referred to as the Bois de St. Cloud till about the middle of the 16 th century. Charles IX. had a country seat here and Francrs I., after his defeat at Paria in Italy, was so captivated with his prison accommodation in Spain, that on his return he adopted it for the model of a new villa, called the Château de Madrid. This, with many of the finest trees, fell viotims to the Revolution. On the approach of the Allied armies in 1814 many more trees were felled for the construction of the palisades ereoted in the defence of Paris; and in 1815 the British army of occupation, when building its encampment of $\log$ hats, cut down the survivors, and added the finishing stroke to the general desolation. The présent state of the Wood is copselike and most deplorable from the timber; the stools having reproduced, like the Hycra's head iu the fabie, and grown into a mingled mass of confusion
Two main roads pierce through it, one, the Allee de Longehamp, from Porte Maillot to the racecourse, and the other, the Allée de la Reine Marguerite, communicating between the little villages of Boulogne and Neuilly; and besides these, drives and wallss, countless as the meshes of a fishermau's net, lead through the Wood in all directions. The fashionable and nearest entrance is, however, by the Avenue de l'Impératrice, starting from the Arc de l'Etoile, as the Porte Maillot is further down the road that continues the straight line of the Champs Elysces.
Descending a gentle gradient, wooden barriers separate us from a space reserved for horsemen ou one side, and foot passengers on the other. These again are margined by gardens, with Cedars, Firs (Spruce and Silver), Cypresses, and deciduous planting, massed or dotted over the lawris. To the right in the distance frowns Mont St. Valerien like a broken crest of wave terminating a longbacked sweep of hill, with a few Lombardy Poplar in the foreground, towering thinly over the sky line of distant bloom. At the end of the road ar gates, which, folding to accommodate thei immense width, form the usual entrance to the Bois.
Entering, and winding through a mixed wood of Elm, Ash, Beech, Maple, Aoaoia, and Oak, we emerge near the N.E. corner of Lake Inferior, enlivened by a neatly-painted fleet of pleasure boats, and swans sailing about, and groups of water-fowl dabbling and quacking. Keeping the road to the left-past the Pare aux Daims, a cleared piece of ground-woods of Pine and Birch, beds of foliage and flowers dress the sloping banks of the water; soon divided in its length by a long island, in its turn bisected by a cut, which is prettily arched over with a rustic bridge. On this side of it is a Swiss restaurant enwrapt in a grove of Scotch Pine and Birch. Ferry boats take you across, and numerous walks thread the shrubberies, which can boast of better trees than are to be seen on the mainland. From here the banks get gradually steeper, till their height at the end tar exceeds the proportionate width of the water, and no amount of after-thought seems capable of compensating for this constructional error initio. The waut also of an indicated waterline is sensibly felt, as the banks slide into the water with graceful hollows suggestive of the aneient bed of the lake, such as may be seen at the Lake of Langern, near Lucerne. Rugged and careless banks, with Rushes, Willows, Alders, Poplars, and Dogwood, are less insipid on a large scale and less difficult to keep than smooth shaven lawns; and it becomes a further question how far the gardenesque and formal treatment of the details is in unison with the rural character of the scenery. We can only answer, "La oritique est aisée, mais l'art est difficile;" but before quitting the subjeet will quote a passage from Sir Uvedale Price's book "Oa the Pieturesque," a work somewhat difficult of access, but which might easily be reprinted, as every gardener should have some knowledge of its contents.

After the improver had settled the principal points where he would either add or take away earth for the sake of picturesque effect, he would then begin to dig out the soil that might be necessary for completing the form and size he wished to give his lake. In the management of this part, whioh must be entirely formed by digging, lies the great difficulty; for if the line be exactly
in that direction to the edge of the future water, perfect monotony will as usual be the consequence. The art here consists-and it is by no means an easy one-in preserving a general play and connection of outline, yet varied by breaky and inlets of different heights and characters ; it consists in a voiding sameness and insipid curves, yet in no less carefully avoiding such frequent and distinet breaks as, from a different cause, would distigure the outline.

Then, alluding to natural banks, he says, Let us suppose then that all the trees, bushes, and vegetation of every kind, were to be taken from such a" (i, e. a natural) "bank, what would remain?-a number of rough unsightly heaps of earth tumbled into irregular shapes, with perhaps several stumps, roots of trees, and large stones in different parts of it. If these also were removed, nothing would be left but broken irregular banks of earth. The prophetio eye of real taste might. indsed, even in this rude chaos, discern the foundations of numberless beauties and varieties, but the rash hand of false taste would destroy that foundation by indiscriminately destroying all roughness and inequality."
A dam crossed by a road separates Iake Inferior from Lake Superior. The latter, on a higher level, is a large open ponl, with a quiet refreshing look that pleases at the first view. K-oping along its shore and past a meadow enclosed in triangular roads, we ascend towards an open platform of considerable elevation, with a Cedar of Lebanon, and seats round it, in the oentre. Through a straight gap in the trees to the left is a glimpse of Meudon, the seat of Prince Napoleon, and in front the village of Boulogne, and beyond that again St. Cloud, hidden by the trees. The fort of Mont St. Valerien, once a convent, but now the strongest military position round Paris, orowns the hills to the right; and looking back down the lakes is a oharming reach of water, which might be considerably improved. by removing some sorubby trees to the left, and leaving a rather file gronp of Oaks near the water's edge to create a subordinate vista.

Starting again through the Wool th the right we wind towards the Allée de la Reine Marguérite, a mixed avenue of trees, and crossing to the road in front of us come out near the Porte de l'Hippodrome, close to the village of Boulogue. Climbing the hill opposite is the village of St. Cloud, studded with trees, among which lie concealed the Chateau and its park, where the Emperor ordinarily resides in preference to the more stately Palace of the Tuileries. The place is well worth a visit, especially on Sundays during the fêtes in August, when the waterworks are in full play, and the people crowd here from all quarters of Paris to enjoy themselves with characteristic vivacity, the more striking as compared with the quiet prevailing at similar gatherings in Holland.* There is the usual amount of extraordinary humanity, some without leas, and some without arms; Balancés-but beware, ye bad sailors, for the downward swing is strangely suggestive of sea-sickness; wheels of fortune, and many other sights and amusements. Brass bands by the dozen, drums ad libitum, bells ringing, people halluoing, volleys of musketry fro.n some adjoining. Malakoff oaptured every ten minutes, and occasional stunning reports like the diapason in a convert resounding above the general Babel of tongues. Every "chevaux de bois" has its musioal organ, and should you prove venturesome, and entrust yourself to the back of one of the steeds, circus-like revolving, the roar increases as you come opposite the band; the work of a huge musoular peasant grinding at the bell handle, as though in training for the labours of a Hercules. Men, women, and children are blowing long tinselled pipes, like a screeching Hock of macaws, or a fallen host of Cherubim and Seraphim, though if this, like the feather that broke the oamel's back, prove too much for the nerves, you oan ascend the Lantern of Demosthenes, and, supremely elevated above the vulgar herd, ascertain the time by the church olocks in Paris, oriticise the horsemen in the Bois de B sulogne, or note the details of the Pantheon-all through a telescope for one penny It is not so long since horses, with riders of 10,11 and even 12 stone, might have been seen ploughing the sandy plains of the Champ de Mars. Turning to the right we have the race-course, the scene of our recent defeat, between us and the river. It is a large undulating piece of ground, with bunches of planting in parts of it, and at the further end, right under Mont St. Falerien, is the grand stand,

The Kermi
a long low building, somewhat resembling a river teamer. In the centre is the Emperor's pavilion, Swiss coltage surmounted by a Gothic tower, and on either side covered stands for the tribune, and beyond these long open seats for visitors. At this end of the race-course there is a pretty drive past a windmill to a suspension bridge over the river to Suresnes, and just opposite, set baok a little from the road, is La Grande Cascade.

From the yawning mouth of a large cavern, placed over another and deepor cavern, Hanked on either side with a small cave, a thin stream of water issues over a straight ledge of rock into a water Little tributary streams concealer by rockwork trickle over the stones at right angles to the rain fall, in front of which is a wee island of tussooky Grass with a small bush on it, which looks as if it had tumbled out of the big moath. The effect of the tributary streams is to disturb the surface on either side, and thus counteract the intensity of dark contrast to the spray, by destroying as much as possible the refleotion of the eaverns. There is a path through the caverns behind the fall, and although it is rather damp for a prolonged stay, still looking at a landsoape through a dazzling veil of water has a ningular effeot, as all will allow who have seen Hardrow Force in the North Riding, or the dreamy visions that colour the trembling rush when standing behind the third fall of the Giessbaoh in Switzerland. But it is as well, before judging of this cascade, to have read Rosirin's faithful painting of Sohaffhausen, or the subjoined ideal of Schicurr from his ballad of the "Diver;" a remarkable proof of the poeta nascitur, as his only knowledge was drawn from Homer's description of Charybdis:-

> And it bubbles and seethee, and it hisses and roars, An when fre is with water commixed and contending: And flond upon food huries on, never ending, And as with the swell of the far thuoder boom, Rushes roaringly forth from the heart of the gloom."

What a grand conception of a whirlpool! Although a large body of water would render it not at al inapplicable to what the cascade might have been, had a river instead of a leakage from a reservoir falls at Chatsworth and Virginia Water, but it is an open question how far episodes like the ruins at the latter place, though real and picturesquely grouped, or Carmontel's pagan temple at Monceau, are appropriate in English park scenery, since they are deficient in what most interests us, the history in their association. Features, on the contrary, like our old abbeys, are preserved not merely for their beautr, but for the from their association with past ages, as monuments of bygone generations, and silent witnesses of customs, habits and deeds, known only to us through the dim haze of history. Such heirlooms are national relios, but in sham temples, grottoes, and "s other toys," there is
nuthing that interests us, nothing to claim our sympathy.
Leaving the Grand Cascade, we proceed on our way to the Allée do Longchamp, a five old Acacia avenue, with side avenues shading the parallel walks. Long streaks of sunlight streaming through the feathery foliage brighten the road, and a little way up we again cross the Allée de la Reine Marguérite, while to the left from here a road leads to La Bagatelle. Taking the road to the right, we come out near the Cross of Catelan, now only existing as an obelisk, though a beautiful mass of greys and brilliant Moss patches in relief against the surrounding trees. been perpetrated here some 500 years ago on the persun of a vain though inoffensive troubadour, who was murdered for his supposed wealth by an escort sent for his especial safety. Close by is the Pré Catelan, still a celebrated resort for holiday makers, for on Sundays at times as many as ten bands may be heard clashing their harmony, while a Swiss dairy and numerous cafés provide kind of open theatre, surrounded by pavilion arbours and summer houses, which in its palmy days must have been very pleasant to sit in.
Serpentine walks sweep through the grounds, and there are beds of foliage plants, as Wigandia, Sulanum Balbisii, and large masses of Portugal and Common Laurel, Privet, Chinese Arborvitæ, Yew, Mahonia, and Box, all mixed up together and struggling for existence. There are also handsome single specimen plants of Abies Pinsapo, Wellingtonia gigantea, Magnolia grandiflora, and
Golden Iew, which "shine like good deeds in a
naughty world," and show how favourable the soil and climate is to the growth of trees, if only allowed room to develope themselves.

From here we return to the western side of Lake Inferior, and see it to better advantage than on our ascent. Fallow deer are feeding in an enolosure on our left, and at the end of the island the water becomes a broad expanse, but little below the !evel of the road, with a background of trees all round it, and the boats in the corner, and the dueks still at their gambols. Taking the road at the end of the Lake, which sweeps round to the left, we arrive at the Jardin d'Acolimatation. If the animals from the Jardin des Plantes were brought here, or the Jardin des Plantes removed here, and its space relaid out as a Zoological Garden, with the Jardin d'Acclimatation as an accessory, it would form a very interesting feature, and save us making two bites of a Cherry. The principal entrance is near the Porte des Sablons from the Boulevard Maillot, from whence a carriage-road loops round a large irregular oval, meeting and continuing straight again to the opposite gate. In the centre, like a conneoting link between the straight roads, is a piece of water, swelling here and pinching there, with basins for moor hens, coots, cormorants, sea gulls, pelicans, and many others of the web-footed tribe. There are also alpacas, llamas, sheep, and goats, while variously plumaged birds are perched about the lawns, and the conservatory, aquarium, and litt'e quivering suspension bridge, are all objects of attraotion.
Nor let it be thought that time is wasted in studying the beanties and wonderful mechanism of Nature, in the gorgeous array of the peacock, the subtle colouring of the dove, or the proud grace of the swan. For if the lessonsunconsciouslyimbibed in the contemplation of the blending hues and appropriate harmony that spiritualises all her works fail in learing their impress on the mind-an impress, we mean, of infinite consequence in preserving the purity of taste-there must be a fault somewhere, reader; surely not in the seed sown by the Teacher but rather in the quality of the ground on which that good seed fell. Z.

We invite the attention of Lady Cultivators to the Ladies' Prizes for Indoor Gardening, which are offered by the Proprictors of this Journal, as announced last year.

The object of these Prizes, as we have formerly intimated, is that of exciting and fostering amongst ladies a taste for the cultivation of plants such as they would introduce for the decoration of their drawing-rooms, and of inducing them to realise the additional interest attaching to such objeots, when reared by their own hands, and under their own especial care. Plant culture in living rooms is now rendered easy by means of modern appliances in the shape of plant-cases-of which, all points considered, that contrived by Miss Maling is the most useful ; and, moreover, it affords a fund of interest to those who engage in it; for as remarked in the very useful guide* this lady has prepared, not only may the poorest and darkest room thus find some plants to lighten it, but "the gayest and gaudiest drawing-room can find some to tone it down and touch it with their refinement."
Two prizes will be submitted to competition. One prize of 10 . is specially offered for the best Orohid in bloom grown and flowered in a room. The other prize of $10 l$. will be given to the best flowering plant or foliage plant of any kind, oultivated in a room, which may be presented. Now that the ice has been broken, and distinguished individuals of their own sex, like Mrs. Ellis, have expressed satisfaction that an opening has been made for ladies to compete for distinction in a department so appropriate as that of floral exhibitions, we trust there may not be the same hesitation as was manifested last year, but that a spirited competition may take place; for of the faot that ladies can and do grow plants in every way worthy of such rewards as are offered, there can be no doubt whatever.
The competition will take place at the exhibition of the Royal Horticultural Society which is to be holden at South Kensington on June 24th; and notice of intention to exhibit must be sent to the Garden Superintendent at South Kensington not later than June 19th. The plants themselves must be sent in by 9 o'olock on the morning of the exhibition day, and must be ready for adjudi-

* The Indoor Gardener, By Miss Maling. London: Long

The conditions to be complied with by tbs 1. The competition i ladies only.
The prizes are offered for the best single plants, examples of actual indoor-cultivation ; they must, therefore, have been grown in a room for at least six weeks previoua to the time of exhibition, during which period they must have been under the management of the exhibitors themselves.
. The plants are to be such as are suitable fot drawing-room decoration.
4. Flowering plants and foliage plants competo nn equal terms for Prize No. 2, therefore the best cultivated specimen produced, of either class, is to win.
5. The plants may have been grown in pots or boxes, or baskets, or aquaria, or in any other convenient and suitable contrivance, so that they comply with condition 2.

Tere ranks of science have sustained a hean loss during the past week in the death of $\mathrm{D}_{\mathrm{r}}$ Hoem Falconer, which took place in London on the 31et ulf Dr. Falconer, though perhaps little known to the general public, had a great reputation amongst men of science, by whom he will be deeply regretted. Ho was one of those many distinguished men who har won laurels in India, where some score of the bet years of his life were spent, in the service of the East India Company. About ten years ago he returned from India in shattered health, and has now departed from amongst us at the age of 55 . His chief field a studyiwas palæontology, out he was favourably knom also as a proficientin botany and natural history generally,
The official appointments in India through which b became best known were those of Superintendent al the Botanic Ftarden at Saharunpore in succession to Dr. Royle, and afterwards of that of Calcutte. It mim to information supplied by Dr. Falconer that we om the cultivation of Tea in N. W. India; and it has dlo been mainly through his suggestions that the Cinchoni plant has been introduced into India, with a com. pletely successful result. Dr. Falconer has moreores been one of the chief instigators and directors of the inquiries which have recently been made as to the antiquity of man. It is truly remarked by the leading daily journal in announcing his death, that "all thom who had any knowledge of him will deeply feel his lom?

We resume our notice of recently gathernd varieties of British Ferns, with a few mem
80 l or
which it is proposed to call Baycie, is of Irish extrec tion. It was found in Wexford, by Mrs. Barle, has been forwarded to us by Dr. LyELL. It seems in combine in some degree the peculiar features of plu mosum and gracile. The fronds we have seen hav been small, of normal outline, and with very acelta pinnæ and pinnules, the latter agaiu divided into man. acute awned lobes; the basal pinnules are quite pin nate, and the pinnulets separate. The texture appears to be rather thin ana papery, in which respect, and tha deep lobing, it approaches plumosum. Another, is to be called Acroris, has also, like the last, affinity with gracile, but it is larger and more appronch ing to aculeatum in the outline of the pinnules, have not only a very sharp spine-like point, but a very sharply-pointed auricle or ear; the large bas pinnule is deeply lobed, but less so than in Baylie,
the pinnæ themselves are much acuminated. For the pinnæ themselves are much acuminated still larger form, but also with acutely-spineswat pinnules, the name stimulans has been proposed. this the pinnæ and pinnules are distinct, the than tirt, long-stalized, trapeaif two or three fin teeth, one of which is awned; and the aper bot the pinnule and auricle with a long spine-like t distsimilar texture and ${ }^{2}$ with the pinnules sin distant is a variety proposed to be called DoLabs FORME. It differs from the last in the blunter, and more hatchet-shaped pinnules, which have lobed auricele rounded, the margin abo oud, except in the basal ones, which have abo rounded lobe on either side, and the spinescear very little developed. These th
Quite distinct from the foregoing, 'and one of th most beautiful forms of this polymorphous species have yet met with, is the variety Pabvissmud, was first observed as a self-sown seedling in the Feruin of Mrs. Head, of Alphington, was brought into by Mr. R. J. Gray, and is now, we believe we know. The fronds, which are thick and of green colour, do not appear to be large; have seen are 8 to 9 inches long, with an apex, and numerous pinnæ, which are crom blunte overlapping pinnules, the fure, and that they do not measure more than a line direction. It resembles the variety called s but the parts are much smaller. This eaturo be a fixed characteristic, as the fronds of two

## KENTISH ORCHARDS.

A short time ago an art:cle appeared in your Paper (see p. 1203, 1864,) by "A Kentish Fruit Grower," commenting upon a system of growing fruit on very small
trees planted very closely together. At p. 7 of your "present volume a reply to that communication by stand, supported the plan of growing fruit on these diminutive trees, although the more especial object of the writer seemed to be a tirade agaiust the mode of fruit growing adopted in this county. As your reader may in some degree be misled by both communications, in growing fruit for the London market, to state a few plain facts on the matter.
In the first place, I may say that "A Kentish Fruit Grower" was much too liberal in his ideas of spreading the cost of fruit trees for a supposed miniature orchard over 10 years. The custom of this neighbourhood (the banks of tife frees that have been planted more than six years, and as little or nothing can be expected of fruit trees the first year, the first outlay ought to be dividel
by five instead of 10 , so that $72 l$. per annum, instead of 361 . ought to be charged upon the profit for the expense of the trees, supposing them to have cost 1s. $6 d$. each, which is the price quoted by the principal London nurserymen for such trees, and which a friend bridgeworth. If the Surrey nurserymen sell thens cheaper, the more honour to them ; but supposing that only 18 . each was charged, there would still be an
expense of $242 l$. per acre for trees alone, to plant this orchard; and spreading this outlay over five years, the charge of $48 l$. per annum must be met for this alone. "T. R.'B" idea of expecting an allowance to be made for fruit trees at the expiration of 30 years, may be very pleasant, but where is the landlord that would do it ?
The mode of dwarfing trees by hand pruning my grandfather speak of cutting and mutilating trees into many fanciful forms in his'early davs, which would he very near a century ago, and I have seen scores of on these trees however, than never saw better fruit winter they were extremely ugly distorted things. If the mode of pruning now recommended affurds fruit of so much better quality than that zrown on full. sized standards, I for one would be glad to learn the secret. At the same time let the grower of such fruit
state the result of his practice fairly, that is to state the result of his practice fairly, that is to say, the picked out from a hundred, and producing ouple of trees of fruit which might be sold to a friend, il no criterion. Let us have the whole, so that the readers of the Gardeners' Chronicle may judge for themselves how far point out a way whereby we can obtain more for our fruit than we now do, without incurring an expense greater than the expected increase, there are plenty give us more satisfactory his advice, but he must give us more satisfactory examples. A siugle bushel much 100 bushels were sold for.

I believe your Kentish Correspondent's report of the confirm lis views that these correct, and I can also complained of, as they pay. lndeed the fruit season of 1864 may be regarded as a favourable one. In my own market ticketa, and I find that up to look over my had sent 2874 , bushels find that up to December 31, I say sieves) to the London markets, and the sum total, exctusive of commission and rail carriage, will average any siuce the and $1 s .2 d$. per bushel. I have not sen some tolerably good Golden Knobs and Nonpareils, and at the marks not quite 1s. $6 d$. If "T. R." will look for Apples the notes in the Chronicle, he will see that all very well frice is quoted at $1 s$ s. to $2 s$. Now it is necessity well for a Horticultural writer to urge the as to improve thing the trees and thinning the fruit so perk could be done to ensure an increased price of $3 d$. per cent. If the buds on each tree have to be looked at too much. My obj. R." suggests, 10 s. a bushel will not be but to ask for pluin Ihare of experience in fuit acts ; and as I have had a fair improving right to expect that others who write upon some extg Kentish orchards will point out examples of I leave "' $T$ whicl" are better managed.
fruit grower and a fruit cultivator, after between a
suaded the trees plane landlords to make an allowance for fruit London markets, years. With regard to the different to Spitalfields for I may say that I have not sent any Garden and the some years, but send to both Covent Notwithatand:"g "T. R.'s" with about equal results. orchards, my rimm belief is that if he will go into
Covent Garden of the ten best linderrow and inquire into the history find (barring foreigu productiong) hees there, he will from Kent. Then if one of our large trees of them come more bushels of truit, it is certange trees yields us 20 or
that quantity from 40 or 50 small trees. The largest
tree 1 have produced me 43 bushels, but some of my neighbours' exceeded this. Of the 287 t bushels noted above, 253 were gathered from very young trees that were from growing under different circumstances, years old, and average of slightly over 6 bushels eacis tree. Of the treatment they receive I will siy something hereafter. one else, will show by facts and figures how much return a diminutive orchard bas ever made for the outlay incurred, giving market not nominal prices in support of his views. W. C. Springett.

LEAF-SPOTTING AND LEAF-BURNING
I fear I shall not be able to do much towards cith solving the difficulty of accounting for spotting on the leaves of plants, or doing more than hats been done in the classification of probable or well azcertained causes in your able article at p. 1178 (1861). I have had frequent opportunities of observing the scorching produced by lenses, at long distances from the glass; and remember a case in which a number of Pineapple plants-by no means the most sensitive to the action of intense light were so thoroughly damaged, I might suy perforated as with red-hot irons, that another kind of glass bad to be substituted in order to prevent further injury. I by lens-light, and no doubt every practical man has experienced the same evil, and adopted meaus counteract it.
I ain not at all sure that the scorching supposed to be produced by the action of globules of water is due to that cause. I have seen a large collection of store plants, including Ferns and Orchids, engined overhead repeatedly in bright sunshine, when thousands of drops of water must have fornaed lenses on the leaves, and I
have looked in vain for any evil consequences. but the have looked in vain for any evil consegueuces; but the glass, and hundreds of small openinys old-fashioned accumulation of hot air, which the modern system of glazing does not so readily permit to escape. This occurred most frequently when the foliage was youngest and without shading. In this case, too, the whole
collection of plants being subject to the same conditions, sun spotting ought to have been very prevalent, yet I seldom have seen a collection of plants more free from this disfigurement than that alluded to.
I bave at times looked for sun-scorching when visiting aquatic houses, and have seldom seen instances of scorching in those structures, but not having a hous of this kind, I am unable to say, from personal obser vation, what effect the copious supply of humidity exercises in preventing scorching. I have, however,
frequently seen leaves touching the glass, or exposed to frequently seen leaves touching the glass, or exposed to leaves have been destroyed as if by the action of sulphurous acid. Some plants can endure a very dry atmosphere with apparent impunity, and yet lose their leaves in time without showing any scorching, th leaves falling while still green, I have seen a case of this kind in a Vanda tricolor, lept in a very dry house in the resting season. I think however the peculiar disease called "spotting" is quite a different thing from any of the cases above mentioned.
Again, I have seen Orchids in the most robust condition, thoroughly healthy and full of life; and on these a spot has appeared, succeeded by others, until the result has beeu the complete disfigurement and death of the plant, the roots all the time having been not only abundant, but in a healthy state, and the plant potted in the best material, and in accordauce with the most scientific principles; where, moreover, no cold draught of air or the use of cold water have been ever
permitted. I admit however that no one could say no single drop of cold water had ever fallen from the root otherwise, on to the plants.
This however is not all ; for where spotting begins it does not confine itself in all cases to one plant, nor oo one particular species of plant, but will often attack have seeu a single leaf on a healthy plant attacked, and ail the other leaves perfectly free, and this in cases where neither sunshine, cold, lens action, nor insects could well have caused the mischief. I am perfectly satisfied that there is some other cause beyond these. To keep Orchids wet in winter, and allow the atmosphere to become cold at the same time, will produce spotting, unless the remedy of a dry warm atmosphere is promptly applied. But whether the cold produces stagnation of the sap, and causes the tissue which is least perfectly developed or vitalized to decay; or whether some insidious Fungus is developed, I am unable to say, though the latter is very probable. A brisk circulation of heated air frequently changed and renewed, with a good share of daylight, is the condition least likely to produce spotting in Orchids. I apprehend the same atmospheric conditions are the least favourable to the production of Fungi, while a moist stagnant shady state of the atmosphere favours the production of these parasites.
Too much importance cannot be attached to keeping the leaves of plants in a healthy state. Whatever disturbs their functions must act detrimentally, not only on the surface, bat on the entire development of
flowers, seeds, or fruit. So much is this the case, that
no mau's skill and ingenuity is sufficient to overcome unfavourable conditions either of houses or climate, sources of evil. For instance, if an artificial these phere cannot be kept sufficiently humid to supply the wecessities of such things as "itcher plants, no sply the management, can make up for the incessant wast of the pla by the continuous drain on the vital juice meplant. I think that if, first of all the requir ments of certaiu classes of plants'were well studied, an houses built which would supply these wants ; and then houses and showing houses, made between growing greater success in plant culture than there ever ha been. There would be less damage from the attacks of insects, and there would be less spotting.
foproper methods of heating and ventilating have bud to do with these disfigurements, as well at ris management. And besides these, impmritie arising from different sources may so pollute the canosphere that the conditious of healthy leaf-action camot be maintained. We have a case in illustration of this point here. In one of our houses which wi
freely ventilate, on accoumt of the goniums, de.) reguiring plenty of air, some sivem yma cince we grew remarkably fine specimen shrubby Calceolarias. Now we cannot grow them in thi same place, although we have the same: varinties as ditierly, and the same treatment is given. The con identic and skill being the same, a similar, in fact an leaves become ought to follow: but instead of this the infested with red spider, fur which insect I lave in vain sought with high maguifiers. There is in fact no insect life to account for the misfortune; but we have belical manufactories now in action around us, and I believe the noxious vapours from these pollute the air Puyne, Gardenere of this kind of spoting. William

## NOTES ON GARDENS.-No, XXVIII.

The Dublif Pegenix Park and its Gardens.
Nexr in importance comes the Chief-Secretary' de:mesne and gardens. "The kitchen garden of th. Chief-Secretary's lodge is reckoned one of the bust managed in the county of Dublin," wrote Loudon, 40 years ago ; and the description is even more applicable to it at present, for the chief proructions of the kitchen garden, more especially Grapes, are as well done as they are in Ireland. The garden has for many years been in the hands of gardeners of the first class. to was here Mr. Niven laboured betore he was appointed fo Glasuevia; and good men have worked the place gardener, Mr. McNeill, who is more auccessful both as an exhibitor of fruit and plauts, than any of his prede. cessors. Here, large Pelargoniums, similar to thosealluded to in noticing the Viceregal gardens, are grown, quite as well as by Mr. Smith, but it is only fair to say that first shown or grown in Ireland. Now, however, Mr first shown or grown in Ireland. Now, however, Mr
McNeill is giving up their culture to some extent, wanting the roou for his choice greenhouse plants. The two gardens being so close together there is riendly rivalry between them, and indeed the productions of both are so much alike, that what is said of one may almost suffice for the other; but withal there
 of course a much greater extent of glass and me ms, and very good specimen greenhouse and stove plants
too, yet the "Chief"s," and Mr. McNeill, have it all their own way with other specimen show plants.
Here it was that great specimens of Chromemax, Pineleas, and such like stove and greenhouse plants wer first shown to the Dubliners and to Irisla gateners gene rally.(who previously, like other people, hal been accus tomed to see, and to bring to shows, a croup of stov and greenhouse plants all nicely massel un. basket); and from this garden still g.) to the "Dublin shows the filust specimen plants. Fine as they are they are grown under some difficulties, ant to a larg extent under Grapes and Peaches, as the chief crass i an iron range 100 yards long by 5 wile, which is al may, Mr. McNeill stows all his larger specimens, many of which would attract more than ordinary attention even where Messrs. May and Whitbredd compete. have nothing peculiar to report, as in the case of the Pelargoniums, about the stove and greenhouse plants, but if I mistale which is now so generally understood, not common to not there were subjects among then plants as Posoqueria longiflora and Tristamia nereifulia of which there were graud specimens, while of plant better done than I have noticed them at the London shows, Acrophyllum venosum, Rogiera cordata, Steno carpus Cunninghami, and Heterocentrum roseum may
be naned. Rhynchospermuin jasminoiles be named. Khynchospermum jasminoilles was plenti fully grown on huge trellises, and far tinur than it has been shown by London exhibitors-who indeed tis no seem to be aware of what the plant is capable. Heath were also finely grown; but the same is true of all Mr. McNeill's plants, and pre-eminently so of his Chry santhemums, which are trained, without sticks, in the
and perfect did they look that I have little doubt stoke Newington would be asteniahel could it see them Mr. Suith grows his Chrysanthemums in this way ton The Grapes were of the first quality, particularly Muscuta, and the Granalilla was well fruited; but perhaps the most distinet aspect of the great range was afforded iny Banamas half arehing over the main passaje. In the buok wall were arched recesses, planted with the Musa, and thus yon passen honses for of them as it were. There are in adtition honses oung, sprecimen phinnowe hous.", and a new Mulon house-a sort of "rice the the by, which appears to be superseding the ol Melon frama about Dublin.
Here ugain, as at the Lord Lientenant's, were mmense ribbou borders in front of the main range and mmence naren uis in tact a hlaze of colour, but there is little gother thower-gardening in the place; and if there wvere, thsulid be on an cmurmous scale to look anythime after these wide, wide bordess, 180 yards in length But thes borlurs hore were differently arranyed from these at the Lord's, i.e., in circles and paves, with considerably more variety, and the soil in th back parts of some of the borders thrown into flattish pyranide to give diversity. It is, however, not so much the arrangement that wants altering, as the plante -the plants. Grace and verdure, two smentials of all vegetable beaty, are wanting, and they must he freely introduced. The quality known ss "effest" was of conrse as well developed as could be desired. I was rather surprised to find that the Centanreas, which have dome so much to vary and heantify bedding, were the Plimaix Park. At Mount Merrion (the late Lord Herbert's place near ()ublin), however, they are freely used by Mr. Walah (who is perhaps the most alvanced of the Dublin colour-culturists), but very sparingly in other gardens. The Seoteh, led by Mr. Thomson, have taken a derided march ahead with these Centaureas.
The great quantity of Verbenas used here are all
atruch with case in prans of sasd and water. This reminds me of the quantities of bedding Pelargnniums I saw at the Vieuresal dodep, freely struck in beds in the open air, with about as much attention as is usually given to roung Cabluge plants, and also how advantagenus to the reading garilener must be elahorat essuls on "the propagation of bedding Germiums." It woulid searecely he fair to Mr. McNeill to omit mention of his w. Il cared-for walls and wall-trens, hut
more than anything else do I wish to record that he possesses in no common degree a vein of the milk of human kindness and gnodiess, equally appreciated by better sizn still, hy the less fortumate, and often umfirsuate $j$ - $n$ rusuman gratener who visits the Chief Secretary's gardens during those lapses that oceur between the relinquishing of one lucrative situation and the getting of another. I particalarly allude to of Britin there are of Britant there and that there are snme who measure their ability hy the
amount of work which they can get out of, and the abuse which they ean play upon the often badly-fed and badly-housed journeymon gardener. It is very gratifying to kuow that gentes treatment of young Mr Mre Well capalile of vielding the be turessful of the leading gardeners of Ireland. Win. Robinson.

I consider that by judiciously asing a portion of shrubs along with variegat greens, a good and at the same time a most economical arrangement might be accomplished in the way of meny Park Cardens.

Wine Cork Fungus.-I believe that the curious Zasmidium cellare (see p. 6) is "an abnormal state of nme common Fungus," but that its remarkable form is due, not to any of the favourahle circumstances suggested by your correspoudent "M. J. B." as attending its growth in a cellar, but chiefly to the presence of alcohol. I have seen it extensively developed in an old vanlted cellar in the north of England, and have always observed that it flourishes most about the corks of bottles containing the stronger wines or spirits. Gin one shelf, ou which have been standing, perhaps for more than a century, a number of bottles which once contained some German or Dutch spirituous liquor, the entire space between the heads of the bottles (standing upright) and the shelf above is filled with a mass of it; and 1 have little doubt that one or more of the elements of alcohol, as it slowly evaporates through the cork, has been arrested and assinilated by the plant, and perhaps a chemical analysis of it wouid throwsome light on this fact. We can scarcely inagine that the plans bas ouly come into existence since man commenced the manufacture of alcoholic drinks, but must rather suppose that it is merely, as suggested by "M. J. B.," an abnormal development of a common Fungus, due to certain favourable circumstances; and that perhaps, by careful observation of its first development, the normal form might be discovered. I shall be glad, slould any of your correspondents desire to make a chemical analysis of the Zasmidium, to supply a quantity of it, and also one of the old bottles just mentioned, with remains o the liquid which supplied nourishment to the plant with which it is crowned. W. C. Trevelyan, Seaton,

## Axminster

Eariy Grapes.-Would you kindly allow me the means of akking parties who have produced Grapes a they have succeeded in continuing the early forcing of the same Vines for any length of time, and if so, with what result? I tried a house of Vines here, and ripened a crop in February; next season the fruit ripened at Christmas, the next crop in November, and so on till the Vines have gained one reason, it being impossible to keep them back to the desired period, viz., about Auguat. At the present time the same Vines are pushing again, to all appearance bidding fair to produce another crop under circumstances more natural to thei nature. Notwithstanding this severe work these Vine are strong and healthy, though not so strong as others planted at the same time in other houses; but from the thet of their being so unstationary in regard to starting, it is not my intention to force for Christmas fruit again, unless my olyject in writing this is served by eliciting some plan for retarding the Vines. Shading the house in my case did not suffice; and I confuss my pets were very near!y getting a cooling down by way of ice, only I was afruid I should be obliged to do th same thing too often. They were most impatient th second season, starting into growth in the middle of
June; whereas, in the previous year they were fore duntil August for the first, crop. It is only in haces where there are several vineries that very ear freing can be practisen, and even in these it will be hest left alone if the Vines cannot be kept to a settler ime of starting. J. Roberts, Charleville Gardens, Tullamore.
False Alarm respecting Bees.-On the 13th of December last, Mr. Wood bury stated in a contemporary hat the consmaption of food by bees during the two that he had alreads November, hed been so rapid, fine stock from shee atocks up to a suffieient weight in October to ain his whinter. Now, it is olvious that some mistuke have been conmitted the mither stoek in question atter he lad ful it or in wigh the make it af anf are heally did have been olo whe wit must of bees had consumed nearly 15 lise of that any stoch required to insure the quantit 15 lls , of food (the in October and Novemher preservation over the winter writer ought to bave known that he never had a stock that cousumed that weight of food during these two months.

The statement has however created so much alares that I have received numbers of letters solich ing information respecting the consumption of ton from bee-keepers who knew that I have kept min register of the loss and gain of my bees during erery month, for a number of years. In order theref) ereery allay misapprehension, I send yon the exact loss in weight of 20 stocks of bees that were weighei on the last day in each month specified :-

Mean average
last 10 years
It will thus be seen at a glance that there is no cares for alarm, as the actual consumption in October man
$8_{3}^{3}$ ounces per stock less thau the average of the his ten years. In November, however, the loss was abon: $4 \frac{1}{4}$ ounces per stock greater than the average. My bea food from Borage, Mignonette, and French Ponnie in November they were also out frequently and Ian in Novearryiug pollear into their hives as late as the als them carrying pollearlinto their hives as late as the als
of that month. William Carr, Clayton Bridge, Wentas Heath, near Manchester

Our Interests in China. A Letter to the Right Hon.
Earl Russell, K.G. By Horatio N. Lay, C.B., Jate Inspector-General of Chiness Customs. Robert InspeotorGeneral of Chines
Hardwicke, Piccadilly, 1864.

## Mr. Horatio Nelson Lay, the author of this letter to

 Earl Russell, is well known as a Chinese scholar of a very high order, and perhaps the most perfeet speaker He rendered good service to the late Lord Elgin He rendered good service to the late Lord Elginduring the last Chinese war, and for this he was madea Commander of the Bath. At this periad he had already left the Queen's service, and had been
appointed one of the Inspectors of Chinese Customs. It would appear that his facility of expressing his ideas in Chinese, and his thorough knowledge of thet language, combined with the strictest honesty the Ministers of the Emperor of China, and enabled him to attain an influence with them which probably no other foreigner ever attained before. In 1859 he
was raised to the rank of Inspector-General of Chinese Customs, and the direction of all the ports open to foreign trade was placed in his hands. Enfeebled health, from severe knife wounds received in an emigration émeute at Shaugbae, when he interfered to proteot the life of a sailor, compelled him to return to he appears to have been held in the highest esteem not only by the Chinese Government but alae by the representatives of foreign Powers resident in the
Chinese capital, and to have possessed a great deal of influence with both parties.
Shortly after Mr. Lay arrived in England, Mr. Hart, who had been left in China as his locum tenens, wrote progry that the alarm in Peking, occasioned by the tion of a European naval force, under Imperial authority, was not improbable, and that Prince Kung, to hism the matter had been recommended, was now
disposed to act frankly upon the advice which had hisensed formerly act fiven to him. Later letters from Mr Hart authorised Mr. Lay to purchase vessels of war in Englaud, and to engage the services of English officers and Enslish crews. Captain Sherard Osborn was realiers will remember that the expedition, and our discussed at that time in our public journals.
The naval expedition in question was to be quite be under the control of the Imperial Governate alone, and Mr. Lay was to be its director. through Mr. Lay; and the latter ceutleman but be allowed to be the judge of what orders should
ie given and obeved. Mr. Lay must have felt he Was treading on dangerons ground, and that it was
throngh? rear only that the Chinese Government passaces frought to agree to such a compact. A few he quote I to show this:- "On the 15 th of March I innate, 'If Priuce Kung sends money for gunboats, he mingt send me a carte blanche. He must send so it in the best manner that my jurgment may dictate. This is gecessary for my mafety. \#\# \# You muast send nodertakiog to agree to andch from Prince Kung conditions as I may arrange with Captsin Osborn and bo full and exact," Thake care, please, that its wording In May Mr. Lay reoeived a remittance and an official Prince Kuag had authorised "the construction of a
steam fleet, for the police service of the Chinese waters to act in co-operation with the maritime customs under Mr. Lay, He therefore replies :-"Any ofticial dispatch from you, even with authority, would no I hade me to disburse any portion of the money until Thad the proper auth wity under Priuce Kung's seal. heet what it will be necessary for Prince Kung to send me forthwith, and please do not let him take word therefrom or add a word thereto, or the lawyers will be telling me that it is not safe for me to act, an l I shall havo to refer to Peking again.' We must refer ur readers to the pamphlet itself for the document in question
In the meantime various letters were received by Mr. Lay from Mr. Hart. In one he says, "I have he has memorialised, and that theEmperor has directed him to carry out the proposal with all speed. ** A letter ust received from Wade says, 'The chief [Mr. Bruce] writes to the Admiral to assist them in chcosing teamers of which to make war vessels.' So we will ave Mr. Bruce's support. Another, a third despatch rom the Prince has reached, enjoining haste and telling me to get as much money as I like; so pray
hurry on-hurry on. ${ }^{*}$ * You may start the keels of four gun-boats and two despatch boats veithout any fear Ishall get more money without difficulty, so that the leet may be four despatch-boats and six gun-boats. I got another despatch yesterday from the Prince about these steamers and money. He's in an awful hurry and tells me to do whaterer Iike"
Without further hesitation, the Queen's licence being promised, Mr. Lay 'proceeded: with the building' and purchase of vessels, and could have diapatched
at once three which he had purchased from the Admiralty, but he determined to detain them until he should be in possession of authority that would legally warrant his siguing the necessary agreements with the officers and men. The authority in the lesired form came at last, and when it was submitted o Mr. Lay's legal adviser, an opinion was given that under the circumastances Mr. Lay might act upon it Tith safety
With the
y Captain Opatch of the steara fleet to be commanded frst scene of the drama closes, and Mr. Lay returns to China and reaches Peking on the 1st of June, 1863. And now his troubles were about to begin. From what e tells us it appears that a remarkable change had come over the Prince of Kung and his Government
during his (Mr. Lay's) absence from China. "When left China," he says, "the Emperor's Covernment under the pressure of necessity, and with the beneflcial terror established by the Allied foray to Peking in 1860 fresh in their recollection, was in the best of moods, willing to be guided, thankful for counsel, grateful for help, and in return for that help, prepared to do what was right by the foreigner." The face of things now was completely changed. "There was the old insolent demeanour, the nonsensical language of exclusion, the open mockery of all treaties, the declared determination to yield nothing that could be evaded. In short all the ground gained by the treaty of 1858 had been frittered away, and we were thrust back into the position we occupled before the war-one of helpless remonstrance and impotent menaeo. I cannot tell my grief and mortification when I beheld the labour of jears lost, and through egregious mismanagement.
For this state of thinge Mr. Lay blames the earele indifference of Sir F. Brace, Her Majesty's Minister at the Court of Peking, and the inexperience of his loowm tenens, Mr. Hart, who had, despite many warnings, says Mr. Lyy, "permitted himself, during my two years' absence, to be assigned a very subordinate position." Prince Kung was not now so accessible to foreign ministers as he had been. "He professed to be engaged with more important mattore than foreign affairs
And now Captain Osborn's sterm fleet comes upon the scene. It will be romembered that it had boen arranged that Captain Osborn was to be entirely independent of the provincial authorities, and was to receive all his instruetiona through Mr. Lay, and through him only. The Foreign Board now informed Mr. Lay that most satisfactory aryangements had been made
with Sir F. Bruce, according to which our military with Sir f. Bruce, according to which our military that, of course, he would not object to the naval officers being placed in the same position. Mr. Lay protested against this arrangement, as it was not in accordance with his agreement with Capt. Osborn and his officers, nor with the British (doverument, who had given the icence to serve the Emperor of China alone. He nuthority of Prince Kung, he laid that authority on the table before them, and remarked that its validity could not be impeached.

Oh never mind that authority, and if Captaiu Osborn offers any objection one else." In vaiu Mr. Lay addressed Prince Kung upon the subject, formally enclosing the agreements. He could get no answer, although the Prince addressed him regularly on other business. Finally, in order to remove all ground of refusal to ratify the agreement, between Captain Osborn and himself, provided it was

Inderatood that the foree should be under the Imperial Government. The Board will not agree to orders, and not in concert with, the provincial autho rities, and he must undertake, in writing to accept this position." Such was the decision of the Yrince of Kung As Captain Osborn was of Mr. Lay's opinion, and would not consent to serve under the provincial decided the dissolution of the force wes then decided on. In justice to the officers and mea who hast come out so lar upon his representations, Mr. Lay lost no time in endeavouring to secure them against
pecuniary loss. In this matter the Chinewe Gjarnment would seem to have ace 1 honomrably enough
Upon the authority of Prince King Mr. Lay handed Captain Osborn an adrance of about Tol (i,0), and the ships and crews mere dospatched without delay. ships on account of the (hinese (ruvermment, and so he whole scheme, which hud takeu so long to mature suddenly came to au abrupt termination. A few days afterwards Mr. Lay received a curt lotter of dismissal, and thus his nine years' connection with the Chinese
In the pages of the marrative muder our notice ther are two or three aneedotes which are rather amusing a his being . When Mr. Lay received the intelligenc the members of the Foreign Board. "Oh," they observed, "we could have given you honours," and with mock gravity continued, "We are making orders jus mike that which we are giviny as a reward to your
military officers who are pesisting us at Sianghe? Oh, exclaimed one, "ours is a verynice order, mitation is it not?" and then, no longer able to restrain heir merriment, they burst into a seraam of laughtor another, to add to the joke, exclaining, "This is what It appears it ing mor
ficial to be tor any Chinese member," says Mr. Lay, "just before I left China to return to England in 1861, when it was thought tha I should visit Puking, a high official thus addressing me, "When you go to Feking, upon no account say a word in my favour; rather disparage me than otherwise; you understand?
An aneclote is relatel to show that Sr F . Bruce simulated more or less friendliness even to the date of his (Mr. Lay's) leaving China, which one would think will afford some amusement to Sir Frederick when he seas it in print. "He affected interest in may future and wished to know how I proposed employing myself, as he might perhang be able to give me some assistance There is one thing I wish you would undertake for me when you get down to shanghae," he said, as I wa leaving the noom; 'if you meet Sir Macdonald him tephenon, as you probably will, choke him off ; tel want any Mr. Ley concludes his letter and railroads.
somo general remarks upoter to Earl Russell with evidently thinks we are drifting back to the old state of affairs which existed before the Chinese were brought to our feet at the close of the last war. For this staie of things be considers that Sir F. Bruce and the other representatives of foreiga Powers are greatly to blame He also is far from thinking that we have heard the last of the rebellion in China. He feels assured that any attempt to suppress it simply by the sword will be
found ineffectual. Crushed in one place, it will spring ap like a weed in another, because the causes of it are to be found not in the people, but in that nest of corruption at Peking.
Mr. Lay tells his story fairly, and we must say With much ability. In so far as his charges agninut Courts are concerned, there may be, of course, two sides to the question, and we have only heard one. This is not a political Jouraal, and we do not venture to express an opinion on our policy in China, but from the perusal of the Letter before us, and from other circumstances which have come under our notice, we cannot help thinking that it is bad policy in our Government to give any encouragement to its officials 0 take service in the Chinese Customs. Since tho office of Foreign Inspectors has been established, there have been three men of mark who have left the Queen's service for that of the Chinese, pamely, Mr. gentleman having resigned his appointment some years since, is now acting as her Majesty's representative at the Court of Peling. The system has a tendency to lower us in the eyes of a semi-barburous people.

## Garden Memoranda.

J. Day's, Esq., Tottranham-Among the many magnificent plants in this establiahment in the way of ronderfully fine specimen of Colous atese is suring 4 feet in diarueter, and about 2 feet in height, and ornamented with 60 flower spikes, on each of which there are from three to five yellow.stained ivorywhite blossoms. Among winter-flowering plauts this must ever occupy a prominent place, its glossy dark green foliage setting off the light-coloured bloswoms to much advantage. The large white-llowered Angrecum sesquipedale is also now in flower, together with the
charming Sacenlabium violaceum, S. Harrisonianum, charming sacconaum one or two others. From, different kinds of Calanthe, including the handsome bright rosy-flowered Calanthe, including the handaise Leilia anseps, autumnalis, and others, which have been lately in great beauty, the blooms have been removed on account of their being required for in-door decoration.
The whole of the plants in the East Indian house have just been repotted, rearranged, and otherwise put in order for the growing seasou, and viewed as they now stand, when even fow are in bloom, they have a very pretty effect. Aerides, Vandas, and Saccolabiums are prown in roof of this and other houses, and suspended from the roof of this and other wrous growth in this way Mr. Stone gets more vigorous growh be obtained by any other course of culture. Dendrobium macrophyllum thus managed has shoots 4 feet in length; two plants of Dendrochilum glumaceum similarly situated liad last season each 20 spikes of bloom on them; I). filiforme was equally satisfactory; Larlia prastuns, a charuniay species in thas blossomed splendidly in way; and marginata, has bulossomed stlendialy in trand acquisition, has growths $3 \frac{1}{2}$ feet in length, well set with flowerhas growths $3 \frac{18}{\text { f feet in length, well set with fower- }}$ buds; othors in baskets are also growing with unusual buds; others in bakkets are also growing with unusual thick as one's finger.
In pote, we noticed a magnificent mass of Arpophyllum giganteum, which last year was ornamented with 16 closely packed spikes of little shell-like rosecolourpd flowers, and even young offshoots separated from the parent plant exhibit indications of blossoming. some four dozen plants, most of which differ someWhat from one another both in colour of the flowers and in marking or variegation of the leaves. One of
the bost as to flowers has its foliage nearly wholly the best as to flowers has its foliage nearly wholly Among thene sotne are throwing up stout flower spikes, from which issue as many as five laterals. Wheu in full flower therefore, so fine a display as these must make, must indecd be a sight well worth seeing. Dendiobium heterocarpum blossomed well here last year, as did also Cymbidium oburneum, which is this season throwing up fivo flower spikes.
In a cool house placed against a north wall, in which the winter temperature varies from $45^{\circ}$ to $50^{\circ}$, the glorious terrestrial Cape Orchid Disa grandiflora is growing freely. Several plants of the brilliant orangescarlet Sophronitis granditlora are at present in bloom, Iare also Lacelin prostans with unusually fine colour, Skinueri, Epidendrum vitellimum, and Epidendrum
Skioneri. Ucher kinds for which a cooll temperature is evidently well suited, are the beautiful Odontoglossurn Pescatorei and navium; Anguloa Clowesii, Laelia superbiens, Souralia macrantha, and Calanthe veratrifolia, all of which exhibit a freshness of appearance and vigour of constitution which these plants rarely poasess in warmer houses. Lipageria rosea, trained along the roof of this house, produced last year no fewe
than 80 of its haadsome crimsou bell-shaped blossoms. than 80 of its handsome crimsou bell-shaped blossoms.
Of Odontoglossa imported from New Greuada, Mr Day has a fine collection, iu which are doubtless O Alexandre, gloriosum, and others. Of the last named, one plant has already sent up a flower spike 10 inches in height. From this batch some novelties are expected.

A small frame full of variegated Orchids which we found here in one of the houses, is perhaps a matte worthy of mentioning now, when such things are al but lost iu some establishments. Those in question seemed in perfect health, some of them, such as intermedius, measuring 5 and 6 inches in height, and well furnished with charmingly veiued leaves. Let us hope that Mr. Stnue's success witis those under his care, may bestir others to again pay that attention to this charming class of plants to which the unrivalled beauty of their leaves entitles them.

## Calendar of Operations.

## (For the ensuing veek.)

Now that the weather is again favourable, all opera tions in arrear in the shape of pianting or other
alterations in the way of ground-work should be proalterations in the way of ground-work should be pro-
ceeded with without delay. It need seareely be stated that the principles of correct planting in the open ground are the same as those which regulate pot culture, allowance being made for the altered circumstances of the plants. Indeed, good planting is even more necessary for plants in pots than for thoso in the open ground. since they are so artificially situated, and have so little chauce of being liberated from the bad A tree or shrub man, by any kind intervention of Nature. A tree or shrub may possibly get on, in spite of the wan of bkill in the planter, because the soil being favourable the roots may escape from their pent-up position, and abundant rains may re-dispose the clods so unceremoniously thrown upon then. But let a plant be once badly potted, and its chance of flourishing is gone indeod. The pet presents an impassible barrier to the compact, aud lesar applied ouly makes the mould more outdoors and in capable of fulfilling its office. Both outdoors and in pots planting is, therefore, an operavegetation, greatest importance with regard to healthy Wholly entrusted to iuexperienced or careless hands.
flower garden and plant houses.
The winter, with one or tivo exceptions, has as yet been so favourable for indoor plants generally that comparatively little fuel will have been required in conservatories or greenhouses; 2 slight increase of warmth may soon, however, be indulge but let the temperature sink at night again to $45^{\circ}$ or $50^{\circ}$
Auricuras. - There has of late been sufficient Adricolas. - There has of late been suffient
moisture in the atmosphere for these plants, butas the days lengthen more water will be required. Towards the end of the month they may be placed on blooming stages. Keep tham cool during the firsu two months of the year, in order that the plants may swel gradually and not be brought prematurely into bloom. Topdress and keep them clear of insects and dead foliage Carnations and Picotees.-Owing to the mildnes of the season, some of these are starting into growth be, however, sparing with water for a time, but towards the end of the month let them have a good soaking should the weather prove dry and a mild rain should happen to fall. Let frames in which they are kept be open as much as possible. As potting time is at hand, it get too wet. Early potting is desirable, but planting in beds must be deferred until March.
Cinfrarias.-Plants for flowering late may now be re-potted and stopped. 'Tie out the side shoots of such as are approaching the blooming season, and by means of frequent fumigation endenvour to keep them free from green fly.
Dahlias.-Cuttings of these will now or soon requive to be struck freely, but roots placed in the forcing house should not be purhed so rapidly as to exhaust them too much, as March is the best time for obtaining healthy plants without much forcing. Pot roots should cortainly not be started yet for a month or so

Fuchsias.-Push forward autumn-struck plants let them have sufficient pot room, and a moist growing moderately warm atmosphere. Pinch in the young shoots be shaken out and re-potted, and put in cuttings for blooming late in the autumn.

Pansies.- Re-pot such as are intended to bloom in pots. A month hence will do for planting them in beds.
Pelargoniums. - These will soon be beginning to grow, and in watering them take care that the soil is well soaked down to the bottom of the pot. Tie out the side shoots as they lengthen, and stop young plants from which late bloom is expected.

Verbenss. - Cuttings of these put in now will be found to make good plants, either for pot culture o bedding purposes.

## FORCING GARDEN

The keeping up of regular supplies of Seakale, Asparagus, and Rhubarb will now require considerable attention. Owing to the changeable character of the weather, night coverings will have to be resorted to, especially in the case of pits, in which an even growing temperature must be maintained. This will diminish the amount of fire heat employed, which should be no more than is absolutely necessary. All glazed frames or pits at work must be kept washed and thoroughly clean; the importance of this in early forcing can never be overrated. Where a better method is not employed, hang mats or other,coverings upou rails free from dirt. Keep at all times plenty of leaves and dung well blended, and in a state of high fermentation, ready for new beds, linings, \&c. ; a portion should bo mixed once a week at this period.
Mflons - Make a second sowing of these for fear of disappointment. Any surplus strong plants of the early sowings may be planted in large pots or boxes, and placed in a light part of any warm house; $70^{\circ}$ of heat, and abundance of atmospheric moisture night and day, are indispensable.
Peac'h House.-Trees in flower should have as much air as possible whenever the weather is favourable. Pines,-Proceed steadily ; if pits are at liberty, and provided with permaneut bottom-heat of say $80^{\circ}$, it would be a good plan to shift a small portion of the plants into large pots in the expectation of their producing early fruit. Where a constant succession is required, let the final remoral into the fruiting "pots take place successively; no doubt this influences in a
considerable degree the period of fruiting. Young stock which has thoroughly filled the pots, might also have a liberat shift, provided pit-room is at hand. With young plants an early growth, with a long summer before them, is important. In all potting, use good turfy loam, the newer and the rougher the better; when the precis in a proper coudition, water will pass through precisely where it falls without puddling the surface.
Potatos.-Some Ash.leaved Kidneys
Potaros.-Some Ash-leaved Kidneys may now be put into pots and placed in heat to bring them forward
for planting out into frames and pits when the latter for planting out into frames and pits when the latter are ready for them.
Vinis.-Proceed as before recommended; lessen the and allow plenty of day heat with a lively circulation of air.

## hardy fruit and kitceen garden.

Nailing must now be pushed forward with vigour. Cret all planting of fruit trees finished, and stake and is this advice more necessary than in the orchard;
although Apples and Pears are fond of adhesive solls,
they will never prove profitable where water is allomel they will never
to accumulate.
Catliflowers.-Get hand-glasses ready for sue plants as are to be turned out of pots ; enrica the stations for them, adding fresh loam also if at hand Turn out four strong plants-one under each angle of the glass; the soil stould be well soaked with liquid manure previously to their being planted.
Horse-Radish-- If not already done, this may nox be planted; dibble in the sets or crowns in light rics soil from a foot to 15 inches deep.
Reubarb. - Get both this and Seakale for nezt year? forcing planted immediately on rich ground, trenched throw a hillock of old tan, ashes, or sand, round ead crown to coax it on through the vicissitudes of that weather during this month and March.

MBRTIVGB FUR THE ENSUING WBEK

Monday, Feb. $6\left\{\begin{array}{c}\text { London Farmers' Club (Mr. Edmuads on } \\ \text { Middle-class Education } .\end{array}\right.$

We direct particular attention to the announce ment made above-that a Meeting will be held in St. James's Hall, on Thursday next, at noon, under the presidency of Lord Portanan, for the purposs of appointing a Committee to obtain subscriptions towards perpetuating, in a suitable manner, the memory of the late John Fowler The readers of this Journal neerl no testimony o ours to the worthiness of this object, and we fee certain that all the success that oan be desired will attend the effort that will at once be made to hand down the memory of so great a benefactor to English agriculture as the late Mr. Fowlef, during his short life, proved himself to be.
At the close of this Meeting Lord Kinvaisd will preside over another, when the question whether locomotive engines shall be prevented from travelling on the highways excepting between midnight and dawn will be considered and a deputation will be named to wait upon Sir Georgr Grey with a memorial upon that subject, The Home Secretary has announced that he will receive this deputation at 2.30 P.M. on Friday, Feb. 10th.

Mr. Acland's Letters on Agricultural Edecation* :-We return to the consideration of this pamphlet, addressed to the President of the Royal Agricultural Society, and originally printed by the author for the consideration of the Council
Perhaps the first idea occurring to any member of the Counci! on a first perusal of his copy of it must have been that the author had adopted a very unusual course in thus forestalling the delibera tions of the Committee (himself a member) to whom the subject here discussed had been remitted for consideration.
The Council had committed the consideration of the duty imposed on the Scciety hy their Charter By T. D. Accand, Esq. W. RIDGwAy, 169, Piccadilly.
to a limited number of their body, in order to the collection by them of information and materials jor a report for the ultimate deliberation of the entire Council, and it certainly seems to be a very promature and irregular proceeding for one member of a Committee so appointed to print and circulate amongst the members of the Council his own peculiar views of the subjeet, in a very early stage of their deliberations. Indeed, it appears, in the first page, that the writer had himaself entertaiped some such impressions, which however had been overcome by the great personal interest he had taken in the subject. And in a quasi apology for an unusual step he declares his object to have been without delay to elicit the opinion of those who take a similar interest in it, as to the general end to be arrived at, and to offer something tangible for their consideration.

We are glad to acknowledge in the outset his concurrence in au opinion which has long existed as $t$, the amount of good which might be accom plished by the Royal Agricultural Society, poseessing great influence in every part of Englaud, "if the Council now dealt with an objeet of its Charter which has hitherto lain dormaning as to writer proceeds aileged good which the Society may effeet, but his grand result points only to the foundation throughout England of public schools for the middle classes, in conjunction with landed proprietors and other capitalists. He then asks, "What is the right position for the Royal Agricultural Society to take up in reference to this national muvernent?" There can be no hesitation in replying-"No position at all." Such a movement is quite outside the well-defined field of its labours.
After passing over much matter that does not appear to have any bearing on the real question before the Council, which is- "To consider the measures which nught to be taken by the Sooiety for the irurovement of the education of those who depend upon the cultivation of the soil for their support," Mr. ACLAND asks:-

1. What is the agricultural education which the Council desire to improve? Is it a knowledge of What is called practical and soientifio agrioulture;
2. What steps cin the Counat take with a good prospect of succesi, to improve either the one or the other?
In his seoond letter on these points, he observes, there is not a word about agricultural education in our Charter," and we may add, with a someWhat stricter interpretation of terms, not one word about the "general education of the middle
classes." We take the general education of the middle classes in sohoots devoted to that purpose, to comprise the training and instruction which are generally deemed essential for the prosecution in after life of the endle-s variety of occupations open to young men at the close of such a course of
instruction. That period is the usual time for the determination, in the case of every individual, of the occupation by means of which it is proposed for him to obtain his ultimate support; and it often happens that the choice is entirely different from that which was contemplated by the parents or the youths themselves in earlier years. But there generally occurs an interval of some rears between the completion of the general education and the responsible entry on the special occupation which has been deter:nind on.
Now at the date of the Svciety's Charter, obvious means existed for prosecuting the special studies applicahle to most of the ulti-
mate occupations in life which may have been selected by individuals; but it was no doubt seen by the Privy Council, that practioal and voientific agriculture was an exceptional case at that time. They availed themselves therefore of the opportunity of the application fur a Charter by the Suciety, to require them to supily that want. To say, therefore, that there is not a word in the Charter about "Agricultural Education" is really a puerile mystalication of Words.
We are therefore justified in passing without tional passage here and there, and divers quotations of letters from writers of whose oapacity for enlightening us we know nothing, the author which is now before the Society. But there is towards the close of the pampblet, an entire letter which Mr. Acland especially recummends to our attention. So far as it relates more particularly to the subject under our consideration, the
following passages are more ad rem than Mr. following passages are more ad rem that Mr.
AcLaND's 40 previous pages.
"As to whether any theory of agriculture could be successfally taught in ordinary schools, the circumstances being as we have deseribed them, wo are deci dedly of opinion that any efforts in that direction wonl for futile. Let the farmer's son, and the him have the best his parents' means will permit; let that education best his parents ${ }^{2}$ means will permit; let that education be, whatever its extent, solid, and accurate (and such edu-
cation, we are convinced, is edeily obtainable now-a-days by all who will be at the pains to inquire); let the boy's school life be extended to five years, from 10 or 11 to 15 or 16 ; then, on leaving school, he wonld, ceive, bring to the mastery of the details of agriculture a mind well disciplined, and one fully able to cope successfully with its problems. If, however, he could then be sent to an Agricultural College, and coula oljemistry has upon tillage, and other kindred subjects, no one can doubt but that it would be highly beneficial But to attempt to teach agriculture to a boy at 13 years of age would br, we thmk, no wiser than to train a boy of like age for a lawyer's or a grocer's lite.'
liather than incumber this notioe with any further extracts from these letters, which are of little value for our purpose, we only add Mr. Acland's own very candid summary at page 42 :"The preponderating opinion is that special agricultural knowledge can only be conveyed with advantage to those who have already had a good general education ; that any attempt to teach it at school or college should be postponed at least till after the age when steady habits have been formed, and some actual experience gained."

Such having been the rational and generally received opinion amongst the best informe agriculturists, the earliest attempt to supply this want was the fomudation of "the Arricultural College," incorporated by Rayal Charter. Of that Institution a history and a full aoount of the course of instruction provided at it will sonn be given in the Journal; and but for the somewhat depreciatory allusions to it contained in Mr. Acland's letters we should not reter to it here. He observes:-" I do not deny that a young man who has received a good general education, and who has formed steady habits, both of thought and onduct, may gain much useful information at a well-conducted Agricultaral College; all I say is, stitute for general education, for practical ex. perience, and for wholesome training of habits.'

Can any one reading these observations draw any other inference than that this Institution, in this year 1865 , does not comprise the class o young men described, and that they have only such advantage as special leotures may afford-no practical experience, or wholesume training of bebith. With a pertect knowledge of the administration and teaching at the Cullege, we venture to state that sueh an inference would, in every partieular, be at variance with the facts
Mr. Acland further on observes that he has taken the warmest interest in this College-that he has paid frequent visits to it, and that he has communicated frequently, and confuentially, with more than one of its principals, \&e.
These remarks led us to inquire of the present authorities at the College what suggestions may have benn offered to them in the way of an and we were rather management by Mr. Acland, not had the honour of a visit from that gentleman during the past six years, nor have they heard of his having been at the College during that time.

In another place Mr. Acland observes: "Such an Institution, if it really offer the training and instruction which, in the opinion of intelligent landowners und parents, is best adapted to prepare the British farmer fur his future life, can surely may contidently put it to the Conncil of the Royal Agricultural Society whether it is fair by them, to say nothing of this Institution, for a gentl-man referring to it for the purposes of their deliberations on Mr. Holland's educational motion, to prelude such observations by an expressiun of hi Warm interest in the College, and by references to
his frequent visitations to it, when he has not his frequent visitations to it, when he has not been heard of within its precincts for five or six years Had Mr. Acland's interest in this College led him to make those personal inquiries there which w have made, in reference to peouniary poeulte, he might no doubt have been permitted to inspect, as we recently have, accounts very carefally prepared, which would have shown him that the College had not "languished for want of pecuniary support: "- On the contrary, that with the exception of a few of its early yeare, daring which an expensive staff was maintaned, betore its advantagen, and almost its existence became
known, the annual income of the College from students has, with one ezception, considerably exceeded the annual expenditure on their account and that though the Council of the Institation have been appropriating from 1000l, up to 12001 , per annum more recently, out of that income provide first-class instruction for their students Such a previous inquiry would have saved Mr Acland the trouble of propounding to the Counci of the Society the " obvious alternative,"* to which he calls attention on page 28, inasinuch as no foundation exists for either member of it.

Mr. Acland seems to estimate the possession of College Diploma as of very small vaiue to soung farmer. He would find that at Ciren cester considerable exertions are made by the most energetic students to obtain one. These exertions are beneficial even to the unsuccessful, and ther operate beneficially for the successful, as candidates for appointroents. A case of this has recently come uader our knowledge. A gentleman in distant county advertised one of his farms to b let by tender. Amongst numerous applicants wa a very assiduous student who had obtained the Colle re Diploma, and who had proposed that as a qualitication. On a survey of the tenders, the owner said, "that is the man for me," and he was at once offered a lease

Let us add that this pamphlet concludes mit the valuable suggestion that our Siciety should provide exhibitions, besides prizes of small amount to stimulate the efforts of agricultural students But how are they to be awarded? The Suciet or their Council, it seems, are deemed incompetent They cannot judge of the competency, proficienes or excellence of agricultural qualification. The are merely to furnish a list of the candidates fo these prizes to the Universities, the Society of Arta, and the College of Preceptors, and the pro fessional status and ability of the young firmers literame before them is to be deterinined b
[iWe add that the Education Committee of the Society met at Hanover Square on Tuesday last and recommended the Council to vote a sum o money to be placed at the disposal of the committee, to be given in rewards to the successful candidates at examinations of such a kind, and to be held at such times and places as should hereafter be determined. At a conference subsequeztly held with rep:esentatios of certain examining bodies in general and literary education-the Universities, the College of Preceptors, and the Society of Arts-it was ascertained that these bodies are willing to eooperate with the Rogal Agricultural Society; and that they will com municate to the Council a report in detail on the attaiuments of any candidates iracluded in any list forwarded to the:rn by the Council
At the Council meeting on the following day, discussion ensued on the Committee's report, and resolution was ultimately carried, which virtnally
postponed the consideration of it till the nex postponed the consideration of it till the next policy of confining the action of the Suciety to the professional part of an Agricultural Education.

We also oall attention to Mr. Edmunds' paper on Middle-class Education to be read next Munda before the London Farmers' Club.]

Baron Liebat has addressed a long report upon the Sewage question to the Lord Mayor of London for which we hope to find roos next week. Mean while, on this subject, we at prosent merely sud that the discussion before the Society of Arts, on (which is reported at length in another page), was Rugbed almost exclusively to Mr. WALKER, Rugby, and Lord Robert Montagu. The forme manarement, especiaily on the part of the R sal Cammissioners appsiated to inquire into the sub
ject. He had let portions of Grass land to them which had suffered exceeding,y in tieir hand. He quite believed, nutwithstauding the luth expersence hithertn, that sewage mitht be prolit-
a.ly used on land, notwithstading cost of engines, pumps, and pipes.
Lord Robert Monragu followed Mr. Wargat with an elaborate and hostile oritiesm of the lecture, quotiug largely the evadance taken by bis using committee to prove that the proper way meaduws, but in a much more careful and econ mical manner, at the rato of a fow hundredso
*The altornative is abvious: either it must be proved that College life, or the syatem has to percelve the valus of suited to their the systom bas yot to be matured
tons instead of many thousands as at present annually per acre． report next week．

## THE FARMER AND HIS INSURANCES．

## In these days of low－priced grain，the farmer naturally

 tries to reduce the cost of production．But now that thebalance is on the wrong side of the ledger，it is more than ever necessary that he should exert every meaus to secure his property fro：n the destroying elements，and from unfor seenmisfor tume．Among the many advantages culture，the means of insuring farming property against loss by fire and hail are not the least．Fire insurances
bave long been known，and those means of security are very generally，I might say universally，adopted by
farmers．On the othhr lhand，I learn from the repor of the（ieneral Hail Storm Society that not 1 acre in
12 （we presume of corn）is insured against hail．Why I would ask，is this？Why does the farmer show such indifference to secure himself against the damage of against fire？Many persons would answer，that a fire although occasionally caused by lightning，much more generally results from the wickedness or carelessness of man，whle hail is always the act of God．At no period
of the year are we safe from fire，but hail seldom visits us earlier than May or later than September，and if it did，would do very little harm to the farmer．And again，when a farmer insures against hail storms， corn and pulse crops，while fire secures the hay and the live stock，as well as the grain，straw，
and chaff．Hail storns，when they do happen，gre sometimes most desolating and destructive，but happily they ravely occur．Fires on the other hand are of weekly occurrence．If the two cases of fire and hail Were put before a man learned in calculating risks， whinch would he say is the heaviest and should pay the
lighest premiun？Surely he would gay fire．And yot the occupier of an arable farm who has half his land under grain crop，pays 50 per cent．more for insuring live and dead farming stock against fire．The report of August，1843，＂hundreds of thousands of pounds＂of pro－ perty was destroyed on that one day．If we can tax our awful storm was stated by the appointed valuers to be something above 30,000 ．Ten years later Sir
John Walsham stated that over 430,000 acres of corn were annually grown in our county．Supposing that all $6 d$ ．per acre（the price now charged by the hail－storm societies），the farming interest would have paid for
that prutection upwards of 100,000 ．Of course it was a？l guess work when Hall Insurance Companies were first establiched as to what premiun should be paid，
and certainly Gid．per acre seems a very smali sum． But 6d．to insure 92．（the average worth of an acre of
corn）for four months is in reality $1 s$ ． $6 d$ ． twelve，and that $1 s$ ．6d．would for à year iusure over the difference，and this is one reason that they don＇t insure more generally against hail．Certaiuly 45 per cent．，which will be a return of something like last four years．If only 1 acce in 12 is insured，I risk of the Society would be just the same，provided that one－twelfth of the arable land was equally distri－ who live in Norfolk it is not．There are certain parts and it is in those districts that most of the farmers values the benefits of insurance more than I do，or feels
vore more kepnly the necessity of such wise precautions．I
aim，quite as much as any director does，to extend the blessings of insurances，and I fancy that much good
would result from thinking a litle less of the reserved fund and a little more of the insured．If all our corn in Nerfolk was insured at 3 d．per acre，that wnuld give
an anuval revenue of upwards of $5000 l_{\text {o，}}$ and taking
the aver the average losses of the past 20 years，there is no the hai．－sturm damare the farming interest has sustained． would not prevelyre many more insurers than trying to frighten us farmers hy telling us that when the next
hailstorin comes we＂s canot aild，viluntary rates，and other sympathetic con－
triburnons to our losses．＂I have constantly per farmers，especially needy ones，to insure acainst hail cost．Onee a large necupier replied，＂If I objection of against wind and rain as well，I would willingly pay
2s．ful．per acre．I have lost tho long lite from storms of wind and rain，bat I never And it is well known low remember，from hail．＂
there has been little hail it is，when
wind，to say at good deal of wind，to say how much of the damage resulted
from the wind and how little from the hail．
I ame quite sure that the farmers would，if they could，
gladly repeal the duty on fire insurances．It would they could then truly vastige when they ask for the abolition of the malt tax，that though the land pays chief part of the local burdens of the country，the farmers have
not a single examption from Imperial taxation．After not a single exemption from Imperial taxation．After
all，iu this matter of fire insurance，the trader who pay the duty is not much worse off（as far as regards cost） tocks now cost 5s．per cent，for insurance，and house hold goods 4s．6d．Still，it does seem monstrous that is s． $6 d$ ．per cent．should cover the risk of fire，Govern－ ment slould step in and tax the provident man just
double the cost of his insurance，the duty being 3 s．for double the cost of his insurance，the duty being
every 100 insured！A Young Norfolk Farmer．

## LONDON SEWAGE

## From the Agéictlutural Point of Vibw．

The following Paper，by Mr．Jorn C．Morton，was read last
Wednesday before the Society of Arts．］
I aM perfectly aware that any service to be rendered by the Society this evening towards the atilization of London sewage must depend principally upon the dis cussion which is to follow the reading of this Paper．I
shall，therefore，not occupy your time for more than forty minutes in stating，as an introduction to this discussion，those data and conditions on which agricul． ture，as I believe，may be able to offer a solution of the difficulties which surround the subject．
Earlg last November，before the Metropolitan Board of Works had decided what to do，and while the public papers，stirred up by the report of Lord Robert Mon agu＇s committee，overflowed with controversy on the sewage question，I suggested to Mr．Foster that ad
vantage should be taken of the acricultural week in Dage showl te taken of the agricultural week in eubmit some of the schemes which had been pro－ pounded before that Committee to the test of such criticism as they would have received here from an gricultural audience．The Wednesday in question had，however，already been allotted，and that is how delayed till now，and left for me to introduce．
In this paper then on＂London Sewage from the Agricultural Point of View，＂I not only mean to exclude the engineering and sanitary aspects of the question，but，while discussing the merely agricultural aspect of it，I wish to coufine myself and you to that view of it which it presents，not to rate－
payers and enthusiasts，but to farmers．Of course everybody knows that there has been a great
deal of wild enthusiasm and speculation excited by both newspapers and cumittees；and even agricul－ tural journals have been＂bitten．＂I suppose that if a sober view of the agricultural value of sewage manure Was anywhere to be expected，it，would have been in the the clever Editor of that agricultural paper say？He declares that recent experiments，discussions，and discoveries have thrown so much new light upon it， issue，that an altogether new leat in the book of agri－ cultural progress has，in fact，been turned；and there－ fore，if any one siall hereafter quote any of the former leaves of this book－any of the older blue books， whether cortaining evidence or writings of his own or others－in any future discussiou of the subject，a vat of the very richest of the stuff is to be prepared，and he is，
in short，to be ducked in it

Now having unfortunately given evidence before Dr． Brady＇s Committee，aud having used at intervals during several years what opportunities occurred to me of presenting the facts and stating the arguments which have year by year accumulated as the urgency of the question grew，it might to avoid the fate which my kind friend and brother Editor had prepared for me．In order therefore，both to escape the ducking，and also to give the most recent evidence of an eye－witness，avoiding all reference to last few weeks spent a day at Rugby and anocher at Birmingham，a couple of days at the Craigentinny meadows，near Edinburgh，and a couple of days at Croydon．I have also spent a week with Mr．Harrison， M．Inst．C．E．，of Frocester Court，Gloucestershire，in Sonth Essex，clown at the Dengie Flat，the Maplin Sands，
at Burnham，Fouluese，Ravleigh，Stanford－le－Hope，and other places，trying to find ont in what relation the present circumstances of Essex agriculture stand to the suhject．And we paid visits to the home farm of the Earl of Essex at Cassiobury，and to Mr．Blackburn＇s farm at Aldershot．And I propose to tell you what have seen and heard withn the last two months at all these places．
Of course the evidence of an eye－witness accus－再过 to the inspection of farms and to the examina－ gion and discussion of both ordinary and extyordinary gricultural exper：ence，who has made it his business to examine afresh in this way alnost all the places where contribe is now being utilised，must oe a serviceable contribution to the discussion of the general subject， provided only that it be impartial．And if it be schemes for using London sewage，that any one who has committed himself to a particular view of the subject pronounced alroady prejadiced and partial，then
it must be at once admitted，that an acquaintance both with agriculture and with sewage has led me long ago to a definite opinion of the right way to convect provious inspection of most of the places named，it was with some confidence in its soundness that I recently camined them again．
This I presume is what is meant by prejudice．Allow me to say that there is no word used by amateurs in agricultural discassions that is more maltreated and abused．A man－of course I do not mean the profes－ sional agricultural chemist，who often works as much n the field as in the laboratory，but－one who takes his facts exclusively from the laboratory of the chemist，who deals with soils or with manures on atter papers，in bottles，and in crucibles，or with plants in fragments and in flower－pote，is allowed to expatiate unquestioned，and of course，we all gratefully acknow． ledge，often usefully，upon the policy or impolicy of the various operations of the farm；but he who has witnessed and directed the operations of chemistry and of life for years and over acres，who has long annually furnished the material and gathered the fruits of these operations over whole flelds and farms， has his doubts or his convictions attributed to＂pre－ applicable to whatever either of credulity or of doymatism on any subject precedes experience，it can be least frequently applicable on agricultural subjects to the farmer．He at least comes to any agricultural dis． cussion with experience to guide opinion；and he has， as I think，cleaner hands，on the score of sobriety and impartiality of judgment，than the enthusiast who charges him with prejudice because he does not believe， to put it shortly，that the profits of farming depend simply upon the atomic theory of the chemist． I at once confess that the analogy of agricultural ex－ perience，both of costs and of returns，leads me to prefer those plans for using London sewage by which it is applied to land in quantity，as in water meadows： and I have found that the experience of sewage farmers hitherto does generally sauction these plans． Still further 1 may confess that，havinir inve atigated pretty fully both at Foulriess，Dengie，and the Maplin sands，and through the line of country thither，the plans of Messrs．Napier \＆Hope for using London Sewage there，I believo them to be consistent both with ordinary agricultural experience and with that of sewage farmers generally．With this＂prejudice＂it was that I revisited the different places I have named， and，finilly dismissing these personal explanations， it is with this＂prejudice＂against me，I have now，in rder to an agricutcaral view of the sewage of London， to tell you what I saw and heard upon my tour．

1．First then of Rugby：－Here the washings of 8000 people，in a town which is，I understand，very fully supplied with waterclosets，are drained into a tank in the valley below，and thence continually，excepting
nights and Sundays，forced by pump through several miles of underground pipage to one or other of various exits，some of them a mile away，on land probably 60 or 70 feet above the level of the tank；and thence sometimes by hose，and elsewhere by mere surface runnels as in ordipary irrigation，the sewage is dib－ tributed，a plot or ridge at a time，over the Grass land， until the whole sarface of a field is overtaken．I am told 50 l．a year are paid to the town as rental for the manure－3s．or 4s．a day，or，including expenses of distribution and interest of capital，altogether probably 30s．or 40s．a day for some 200,000 gallons；and 1 am told that none of those who rent it are satistied the sewage is sublet，fails of a profitable result becanse he cannot get the sewage when he wants it，nor enoug of it then．Mr．Walker，over whose land most of it is poured，is dissatisfied because of the injured quality of his pasture lands，where it has been applied in large quantities．I have seen heavy and early crops ef Italian Ryegrass，at least 10 tons per acre，in the month of April，grown bere on rather unkind land，chiefly by the aid of sewage；and we all know from the published reports of the experiments superintended by Mr．Lawes，that the produce of the ordinary Grass fields upon the lias clay land here has been wonderfully in creased，and nearly in direct proportion to the quantity of the sewage applied．But it is worth noting that although the manare is hero applied upon the land at the cost of leas than $\frac{1}{2} d$ ．per ton，and not much more than 1s．per head per annum of the population who supply it，I did not meet with any one who was satisfied that it was agriculturally profitable．Let me mention here two other noteworthy things：－I saw coarse，conchy，weedy－looking stutble of Grass，origin ally，I was told，goo：grazing ground，which had been sewaged，and which alter varous mowings had latterly down．And this latad had been lately valued for the purposes of ordinary agriculture as having been injured to the ertent of 20 l an acre，I think，in selling value， by being sewaged．And I saw good grazing land， which had been also sewaged－and was being sewaged when I walked over it－as full of Clover and sweet short Grass，and as abundantly producing first－class feed as any pasture I was ever over．Both had been sewaged －the one had been mown，and mown，and mown－and the other had been fed，and fed，and fed－the latter kept firm by the treading，and aho no doabt
replenished by the droppings of the cattle which lay thickly on the ground, hal retained the original qualit the Grass, which is generally, an at Iave said, injured by the sewage irrigation where only for ordiuary ayriculturai purp)ses after the use of sewnge-it is plain that any figures so ootained must be taken according to the atrict meaning of these words. The agricultural valuation of land must be mane to learn lately, not for any special purpose,
whether any profit or loss has beeu sustained.
2. At Birmingham, the sewers which drain the two valleys over which the houses of 300,000 people are here distributed unite in tanks at the confluence of these valleyg-for the settlement and deposit of their mud viletere the comparatively clear water is allowed to ft w before the comparatem again. Some 30 acres of land bave been here purchased by the Corporation, and this have been hoped by Walker's diaphragen pump to one and amother section of this acreare, and as it dries it is dug out and carried away. This is creating such a nuismee, that at length they are pumpiag the sediment iuto barges on the canal which passes a few hundred yards away, and taking it to the various farmes along the canal ; in neither case however does he value received repay the costs connecter with the proctass Birmingham sewase is going down the river as before. And as the water closet systern extends, b. th the nuisance of the tanky and the wastefuluess of the overflow from them will increase.

The level lands near the tanks are occasionally flooded from the sewers as they were formerly from the river and with about the sane effect as formerly, according to the tenant, who denies the right of the Corporation to charge a rent upon bim for this water, wiver water alleges, no etronger than the orimully the water lyin on the land has killed the Grass instead of benefiting it. This is a contingeucy which may, I suppose, be sonetimes lowkeal for from the washings of a manufacturing town. It will be cquated by the advocates of acancy dressings as a risk to which those who use large quantities are especially liable. It appears to me to have been due to the dit surface, on was allowed to impertect

Mr. Councillor Walker is arging the distribution of the overtlow of the sewage tanks here, and declares that their $20,000,000$ tons of it per annum would, a even fd. a ton, yield a monstrous revenue beyond have here an example of a central delivery of a great rapidly extendin, which is ready for being turne pinedutely to arricultural accuat It is howeve fair to mention, that several of the leading medical men in Birmingham recommend cuttiag off a portion of the supplies from the sewers immediately below
the water-closets. Both 1)r. Bell Fletcher and Mr. Chesshire recommend contrivances by which much i retained, as in portable closed cesspools, for collection at monthly or half-yearly intervals by night carts as formerly. And this practice, if it sbould extend,
3. We now come to the Edinburgh meadows. The principal facts are that at Lochend and Craigentinny on the North-east, at Grange upon the South, and Dalry upon the West, there are some 350 to 400 acres of Grass land, over which the filthy natural drainage the town is poured as in ordinary water meadows. The lands are geuerally sloping so as to enable a rapid flow, Edinburgh is spread, receiving the drainage of it houses, are of sufficient volume, together with the artificial water supply by which they are thus supplemented, to give an abundant irrigation to the lind. From
10,000 to 20,000 tons per acre annually are thus distributed in one or two floodings during every interva between the cuttings of the Grass, of which three and four, and more rarely five, are taken in the course of the season. Perlaps the best illustration of the productiveness and value of the Grass thus treated in and around Elinburgh and Leith fed from the nendows during summer, or neariy six to every acre and that between the mitdle of April and the end of October, they will ou an average consume from 80 lbs . to
120 lbs a day apjece, along with about half a bushel daily of spent malt from the distilleries. If the consumption of these rows be put down for 180 days at 100 lb . apiece, the produce of the acre
which kecps six of them unust be close on 50 tons a year, and for this the average price paid is $23 l$. to $25 l$; intelligent man, who kreps. 24 cows in Leith, that he has usually purchased at the soring nuetions, when the year's growth is sold, 4 acres for his 24 cows, paying
about $100 l$. for them; and this perfectly tallies with the average result alrendy given.
Some of the plots-(the Grass is let or sold by auction for the year in acre and half-acre plots)-are let or suld for as high as 40, the innper acre. The worst pieces are thee flateest and un-
drained, which are thus incapable of getting a
flow either over or through the land. The best pieceg are those whela face the south, which have a sufover the surface, and which are of s) ope: a texture a to permit a good natural drainage through the land. I is worth noting too that while the inferior bits have by arainage been thon ; it is alinens particular apo always remain thest, soil, and abuudant supply of irrizatiou, are earliest ready abun the seythe, that command the exceptional prices which are sometimes quoted as if they were the average yield of the much as 1 s. per c.w the field and cut it for himself, although the averay hroughont the year is not worth much more than $6 d$ and that is how those early pieces fetch so long a price, It must also be understood that while Grass-milk bein 10d. a gallon in the Eiinburgh trade-is worth 6 ac. cont. or more, perhaps, upon an average, to the cow keeper to cut and carry a mile, or evan two or three, ye it is not worth so much for any other purpose. horses
unswer for feeding neither cittle, sheep, nor und thus it is that it is just in proportion that the demand there or not. 'The prices named that the price is maintained or not. The 20 years ago as now. There were then were haird tewer cows than now, but there were just about one-third fewer acres then as well. As the demand increased and prices rose, more acres have been added. Italian Rye-grass, broken up every third year and resown after taking a Putato crop, has been grown at Lochend, even above the natural fall of the strean, nd, wored by gelf-actine pumps driven by the stream tar it fotcho noarly then loes, does not reach the m

At Dalry, too, and the Grange, natural Grasses, chiefly Rye-grass, have been sown along with in places topdressings of chopped Couch, and watered by the foul stream, and equal productiveness has been soon acquired for newly laid down pieces. Whatever Grasses are sown originally, Poa trivialis, Alopecurus geviculatus, and Glyceria tluitans, with Cuuch Grass, Crowfoot and other weeds - and where the land is best
dramed and driest, Rye-grass, Cat'sotail, Coc's'soot, \&c., ditimately form thie pasture. Aud it would be pronounced by any one as I saw it last month, a wonder ully thick and luxuriant grassy surface, nothing like coarse and weedy generally as the Rugby meadow, to which I have just referred.
At Craigentinny, too, the meadows bave been added to occasionally, and pumping engines have been erected to extend the limits of the area
commanded by the stream; but they are no longer used, for it has been found here more than once that if but a few acres in excess of the demand are brought into the market, the average price of the whole at once drops. I cannot too strongly impress upon promoters of schemes for utilising London serwace, that this is a very important part indeed of the Edinburgh experience for them to read. 350 to 400 acres of this sewaged Grass suffice for 2000 cows. The people of Edinburgh and Leith are far better supplied with milk thau those of London; but evea there one cow suffices for every 100 of the population. And the 30,000 cows required at this rate by the metropolis, would all be fed during summer, according to the Edinburgh rate on 5000 acres of Grass. If there be any considerable increase of the supply near London beyond the Edinburgh rate, then it is plain from the Edinburgh ex perience that the Edinburgh prices will not be main tained. Probably, the chief way out of this difficulty may be to copy Lochend in growing Italian Rye-grass, for which there is a demand other than that of cow keepers, but I cannot doubt that the marketing of the enormous Grass produce wnich we shall obtain from Loudon seware will for many years be the great difficulty in the way of a profitable result. Without discussing here, in detail, the quantity of sewage to which the Edin burgh results are owing, it may be said that the drainage of an area cuvered by more than 100,000 people is spread ver 350 or 400 acres (we cannot, of course, infer from this that the waste 1 nom all these people retches the land) luat six to ten floodings are given during the year ic 10,000 to 20,000 tons or more per acre per inaum; of feeding 6 cows dun the sump it is bought by men who are at all the expense of cutting it and carrying it a mile or two home themselves five $23 l$. to $25 l$. per acre on an averace, exceeding $35 l$. and even 40l. per acre in particular plots. It may be also said that much of the land yielding nearly the average price is the poorest seaside sand; and that a great deal of it, watered with tail water which has alteady gone over hand above, is just as grod as the rest.
It is all mowed and mowed, the produce being carried wholly away, and it maintains its productiveness year by year under this abundant sewage irrigation, notwithstanding this inmense draught upon its resources One fact more of great importance:- The land, not withstanding the immense supplies of this mauure, i not enriched; a grain crop following the heaviest crop of Grass on the sandy soil will fail unless it be itsel heavily manured with cart dung ; the Potatos follow ing the Italian Rye.grass at Lochend require to
be most liberally manured. The Italian Rye-gras
 and dressed as it will soon the with sewage from then puaps, at the rate of athousand tons or more to erers cutting-a good dea: less than is poured on naturall commands-it may be worth 20l. an acre during th coming summer. In 1866, too, it may be worth much, but this growth and value is wholly owing the supply month by month of the manure, not at all to the land, which is no richer at the en
So much for the Elinburgh meadows :-If the gros ruceeds of the land be put down as 8000 l., thero probably as much as $2 s$. a head obtained from so manyol he population as contribute to the result, and dilut s it is (much of it, too, being used twice), I do suppose that more than $\frac{3}{4} d$. per ton is obtained from the sewage. The Elinburgh results are obtained fro the use of very dilute and already putrifying sewage in large aunantities over slopes of light and well-draiued land Aad poor though they be as compared with the result and definitions of aualysis, they are the most profitable results that have yet beer any where obtaiued.

Compare them with the results on farms nea London.
(a.) Near Croydon Mr. Marriage deals with the sewage of 20,000 people, in a stream of $1,000,000$ gallons sewage of an extent of about 250 acres. He uses the water a second or third time. His fields vary from 300 to 530 yards long. The feeders are 15 yards apare and the "panes" or beds between them sink sram versely at once from these parallel feeders across the brearlth of them; and they sink, on the whole, in the length of them, about 1 in 400. There are no inter vening drains, but any cubic inch of sewage may lear the feeder at the upper end, and, if it be not previousls absorbed by the gravel subsoil, trickle over the who length of the bed to the transverse drain across 400 yards off; or it may leave the feeder 10 yards fr the end, and trickle ouly 10 or 15 yards to the dra close by. A very close and thick growth of Grass, wit Clover appearing in the autumn, exists in the upp fields of natural pasture, which has come of itself af the Italian Rye-grass without any direct sowin of seed, after the latter had died out, as
gradually does, after the secoud or third $y$ Italian Rye-grass is sowa in autuma, and keeps domn two or three years, and is then broken up for Man , Wurzel and followed by Putatos, and theu is soma down again. A cutting of 10 or 12 tons of Grass ii May is followed by others of about 7, 4, and 3 or t espectively, so that upwards of 20 and up to 25 toms of green food are got for use. This, however, is certaing less thau might be expacted. Mr. Marriage deciaro that there is no good derived from drainage; mere surface feeding as it flows is depended on; but the gravel subsoil here does supply a natural drainage tos certain extent, and the ditches are deep enourh to advantage of it. Land in the neighbourhood, and this and before sewaging, was worth 22 . an acre; Marriage paya $5 l$. and seems in good spirits. I hope he is here to state his experience to-1ight.
believe, upwards of 20 s . a ton for Grass in tomn 10 miles off, and 12s. to 14s. a ton for if the ground, his own men mowing it and weighing it. Sewage helps the earty growth amatugs the interval being five or six weeks, and the latter o the two dressings being often among the tall Gas when it is quite as efficient as elsewhere. It is on for 30 hours at a time. The main fact
that the sewage all goes on filthy, and that the water leaves the farm cleau and limpid; ani mixing up Mr. Marriage's plans fur the futim what is experience available for it the following produce: -150 actes 0 Italian Rye-grass at 20 tors $=3000$ tons at $=18002$. ; 50 acres of Mangel Wurzel at 20 tons $=100$ tons at 20 s . $=1000 \mathrm{l}$. 50 acres of Potatos at 6 toni 300 tons at $70 \mathrm{~s} .=1050 \mathrm{l}$. In all (under rotation three years, Italian Rye.grass, Mungel Wurzel, am Potatos) $3350 l$., or about $15 l$. per acre. It is plain in quantity of the Italian leye-grass; and that a market has beeno obtained to

解 for the Grass. making. Now there terable difuculty and but only aneven supply. The second and third cattings year suffered from the drought, and under a to throm en it seemed that the tendency of the Grass
(b) At Cassiobury, the experience of the Earl Essex, which is longer than that realised at Croyd may be also named. There is here, from Watford, sewage of 4000 people, and 200 acres of land provided with pipare to receive it • but I mider that his lordship has learned by experience paratively small value in small quantities all over only 7 or 8 acres of Itahan leye-y summer, cutting 30 au.i 40 tons per acre annually,
over 30 to 40 acres of his Park-land during wint
(c) Mention must be made of the Camp Farm, at Th hot, where 10,000 to 12,000 mea use the litripes and

Whole of the stuff is to come through 18 -incl pipes of earthenware down gravelly sandy heathery waste. 160 acres of here is only in estimate and anticipation as The subject here is only in estimate had experience elseyet, ait, by which he is guided both as to plans and expectations. Some of the stuff will flow over part of this, and that part will always be available for the overflow of any remainder, left un-delivered by the overflow of apparatus. Mr. Blackburn will pump by underground pipes to the centre of every obels to the thence deliver through sariace-pipes on wheels to the centre of every $1 \frac{1}{2}$ acre, and
will tius deliver, it is said, 400 tons a day, and 200 tons are expected to be a dressing for an acre Drainage is obtained naturally through a gravel subsoil, and it is intended that none of the sewage shall flow away oft the surface, bo used on a minimum quantity o land in the first place, until that is got up to the right standard of fertility, and then the work will be extended. Italian Rye-grass will be followed every third year by Potatos. Sixty tons per acre of the Grass is the standard of produce to be aimed at, and some 20 acres only are being prepared. The plan here $i_{s}$ to pat the sewage on before it has time to rot, and to use it by hose and jet at the rate of 200 to 400 tons to a cutting. There is a quantity of water in land ordinary surface irrigation is not the plan advocated by Mr. Blackburn, he holds that only as a second resource. It is with pipe and hose, and with an
economical use of the fresh material, that he declares to win.

It is plain that Mr. Blackburn's plans are directly Edinbargh result, which is due to irrigation in quantit with dilute and putrid sewage, and to a feeding not of the soil but of the plant.
These, then, are the facts, wholly agricultural-for have not referred to the chemistry of the subject at allon which theagricultural view of London sewage depends. The waste of Loondon differs from that of Rugby and o case there are from 40 to 60 tons of water to the annual waste of every individual of the population. In every case, as water closets come more generally into opera tion, this filthy water will become more fertilising, surely is the proper quide for estimate and foresight lere. If we had 15,000 to 20,000 acres of light sewers, this agricultural experience would point once to a very easy solution of the problem. pump the whole of North London sewage ( $100,000,000$ tons per annum) 50 or 60 feet, and let it flow aloug a culvert down to Foulness and the Maplin Sands, where some thousands of acres, partly perhaps by purchase and partly by embankment from the sea, can be obtained, over which it may be poured, and ther
produce the 40 to 50 tons of Grass per acre which are got at Craigentinny. This will be the almost immediate result, and in the meantime, year by year, on believed a demand for course of the culvert, it supplement the deficiencies of Essex agriculture.
suppose that in suppose that in che mmediate opporturity which thus afforded of using all the sewage at the very outset, whether or not in an outrageously extravagant and wasteful way, as some people think (at all events very much after the way in which Craigentinny is at present afforded for the gradual extension of a more economical and considerate use of the sewage all through the lower part of Essex, on its way to the final out-
fall-this scheme has the advantage of its rivals. It certainly has the sanction of the agricultural view of the subject which Rugby, Edinburgh, Croydon, and Cassiobury present; and while Aldersinot, with its proposed economy of the material, is still a problem, yet, if that should succeed, it too may be copied easily
and perfectly. I prorfectly.
I propose now to devote the short remainder of ihis agricuiture along the line of the culvert together with the Maplin Sands at its termination offer for The of London sewage.
is proposed to Sands, a considerable width of which it sand, not sufficiently inclined for catch-water irriga feeders of "sloped probably enough for the ridge line angles from the shore; which "lands" might be laid out with sides sufficiently steep and with intervening drains also having fall enough; and several series of seawards, might be yards long apiece, all pointing he cross main-drains of the first series collecting the and ther used there for a second use over the third series and the tail water of the second series being used upon below high,water mark. The island of Foulness, all comparativewater mark, is on the side next the sunds a comparatively light soil, in places shallow upon a sandy of beingoil, and quite suitable for irrigation, and capable of being laid out for it without much expense.
gian over a tract near Stanford-le.Hope, where the all along South Essex, westward from Foulness, is stiff clay soil. Most of it is arable, a proof of dey climate. Anywhere else than Essex such land would be in pasture, and if ever the rainfall be supplemented by even so sunall a quantity
sewage, it must be pasture here.
be utterly unmanageable as plough land if frequently soaked either naturally or artıficially. The drainage o the country is almost wholly a surface drainage: narrow ridges, the width of harrow, drill, \&ce, are worked by horses walking in the furrows, and these furrows are sowing machine, and they are then connected by cross cut furrows cleaned out by hand where necessary Steam cultivation has been adopted in places, and
probably deep draining will succeed after it, It is Wheat and Bean land, with occasional Vetches and fallow; straw is sold into London and dung brought back at about the cost of the straw. The whole country is the London-clay and arable, growing corn and straw for sale, and buying dung. There is hardly any tock
And on Foulness the sales of straw to the bargemen and purchases of manure fro
balance each other in the year.

It seems to me that in the barren slope of worth less sand at one end of the line, in the immense scope which exists for an extension of the milk supply, of which I hope we shall hear something more this evenof an extensive tract of arable land without stock of an extensive tract of arableland without stect, whose
straw is at present sent 20,30 , and 40 miles, and straw is at present sent 20,30 and 40 miles, and
manure brought back as far, we have all the elements required for the profitable conversion of $100,000,000$ tons per annum of North London sewage.
At the outset probably the detoand for sewage along the line must not be connted on. Thisn, these sands come into use. In the outset, too, we shall probably be overstocked with the produce of $t$
and hay-making may be required.

Of course it is impossible to make 30 or 40 tons of Grass peracreinto hay while the sun shines upon the land which grows so much. But I think it may be possible to make it artificially. Twenty-five tons of well-grown Italian Ryegrass which may make only $12 l$. or $13 l$. as green food, will yield probably 5 tons of hay, worth more than 20l. In the manufacture of this quantity 20 tons of water must be driven off, and if this can be done for 6l. or 7l., there will be a profit on the process. The bands or shaters, from the top of a shatt or building to which it had been lifted, and might during its passage downwards be subjected to a current of hot dry air upwards, so as to come out dry enough to stack; or it subjected to the same influence, entering it green and emerging dry. There does not seem any difficulty on the face of it in thus dealing with that large surplus of green Grass, which will certainly in the first instance be on hand. And if 6 or 7 tons of hay per acre are thus obtainable, the revenue should be even larger than though a direct sale of Grass were had for all at 10 s. ton.
The books tell us that 6 to 10 grains of water would be taken up by every 100 cabic inches, raised from
say $60^{\circ}$ to $180^{\circ}$ or $200^{\circ}$, even supposing the space, or we may say the air which occupied it, had been sulurated at the lower temperature. To take up 20 tons of water in this way then, we should need a quantity of air equal to from two to three millions of cubic feet, and raise it from $60^{\circ}$ to $180^{\circ}$ or $200^{\circ}$, and keep it
at that temperature while it was pissing through a shatt or passage for long enough to get saturated at the higher temperature from the moisture of the green Grass as it was being brought along the passage. Can such a shaft or passage, siy 4 feet deep and 10 feet wide, be kept at the temperature in question, and have air heated to that temperature driven along It at the rate of about 800 yards an hour for 21 hours, by the consumption of say 5 or 6 tons of coal
can, then hay can be artiticially made at a profit. And although the sewaged natural Grass makes soft and worthless hay, that from Italian Rye-grass is perfectly good. The conversion of the green Grass into hay, is a market and which will spoil if not immediately used, to goods for which there is always : A demand, and Which can be stored. And believing, as I do,
that the immediate effect of any great extension in the neighbourhood of London, of such an experience as that of Lochend or Craigentinny, or even that of Croydon (the only profitable examples by the way which we have to follow) would at once glut the market, and altogether overflow the demand for its produce, I believe that this question of artificial haymaking is of great importance.
Whatever may be the schemepdopted, there is no difficulty either on the score of engineering, or, where the abun dant method of irrigation is adopted, on the score of the chemistry and composition of the material to be anticipated. Neither is there any difficalty in the agricultural aspect of it, so far as the certainty of a croo is concerned; but I believe that during the first years of our agricultural experience of it, we shall be puzzled by a
market; and it will be some time before the cow-keeping business will be transplanted from the grooves in which both food and trade have run so long, down to a new region of food, even though more cheap and plentiful; considerable importance during the period of change.

There is, however, another opportunity of a market afforded by the circumstances of South Essex agriculture Almost the whole of this district is arable growing corn and straw for London, and fertilised by London dung, often at about the cost of the straw sold. There is, you may say, no stock. It is probable that it Grass were supplied to the farmers here they would consume it in yards at home, and send milk or meat to London, making manure for themselves, rather than a great labour and expense send straw to London, and cart back the dung. And this, if it could be carried out, would be the best way of disposing of the produce of the sewaged land. The Grass would be sold, it cheap enough, more easily than the sowage; and if it can be carried for $1 d$. or $2 d$. per ton per mile, I believe Green food properly consumgh to tempt is trade.
freed upon the land even in ordinary to sso a tou to feed upon the land even in ordinary agriculture near London, with a ready and numediate disposal of milk, it is worth from 15s. up to 20s. a ton. It is hardly possible to doubt either that cowhoness on a larga scale, well situated near depôts of Grass in country "where there is a great demaud for dung and ample supply of straw, and where winter food may easily be grown -with ready access, too, to the London milk market-would at once be hired and worked; or that under such circunstances a considerable change in the style of agriculture of the district would gradually grow; more stock would be kept upon the farms, and the London milk trade would extend over the plongh lands of South Essez

Laslly, there is the opportunity offered to the tenants of all such lands as lie near the culvert, to use the sewage on their own lands and grow this Grass them-
selves. I presume it is part of any and evary plat selves. I presume it is part of any and every plan of using the $100,000,000$ tons per annum of the London sewage to pump it into reservoirs on hill tops or rising grounds wherever a local demand for its use occurs. Thence it may be delivered by liydrants or in runnels over the surface of the field to be watered. I confess my strong preference of the latter to the former. There is all the difference between them that exists between labour-needing and self-acting machinery. And while the plan of course is cheaper, it may be also quite as economical in the nse of the material. If I had only 10,000 tons of the stuff per annum to pour over 10 acres on a slope (and this woind, I presume, be thought a reasonable allowance even by those who advocate small dressings), I should prefer pouring it all over the highest by ordinary surface flow, to an equable distribution owe by ordinary surface flow, to an equable distribation over
the whole from equidistant hydrants, each of which must be managed by hand, delivering no more at a time than would sink into the land and there be alt used. If, however, occasional reservoirs existed whence this sewage would be available in either way in different localities, we may safely leave those who have to make a profit by its use to sheir own devices as to its management. Anyhow, if by the use of surface irrigation great crops are obtained, and the water at a
second or third nse is perfectly clarified, then it is plain that the whole attainable result is attained; and great expense in hydrants and in detailed distributio will in that case be an expenditure for no useful end.

I believe I have only one additional remark to make and that hinges on the conclnsion here asserted-that if the water leave the land perfectly clarified, the whele attainable result is attained. This will be at once disputed, and is perlaaps not absolutely true. In a dry season, no donbt, water, though free from fertilising matter, is itself invaluable, and in a drought it would often pay for pumping and for distribution; but when there is a question of gradually altering the whole style of agriculture of a county, I do not believe in this extra value of the mere water by which enthusiasts, in the adrocacy of particular schemes, add on so many additional thousands of pounds to their anticipated Wo
We have in this country varieties of rainfall amounting to 3000 and 4000 tons of water per acre per annum ; but the value of the land depends very little upon this; the various styles of agriculture resulting from these differing circumstances do not as a rule differ materially in the quantity of rent which is possible under each. That depends on the composition and quality of the land, on the cheapness and abundance of manure; and on the neighbourhood of good markets.
On this subject, however, I must not longer detain you, and I will conclude by naming the results to which this discussion of the subject has hitherto led. Collecting these nearly into one, although I have not beea able to overtake within the allottod time all the grounds on which an opinion mast be formed, yet the conclusion to which I believe that the agriculturist is led after a study of the subject is, that Grass as the produce and ordinary irrigation as the method-both, as involving a minimum of labour-are the proper agents by which the conversion, which we all desire, of London se
obtained.

Certainly, on the clay lands of South Essex, to double or (quadruple the present annual water supply be a sufficient application of thas sewage cirans. On lighter lands with natural drainage, such as ultimately on the Maplin Sandt, it may be prssitule to use the diquid to take the growth of Mance or other of these crops under arable manugement one or triennial succeasion with Italian Rye-grass, but elsein triennial saccession with where it muast be Grass, anl only Grass, that is capable where it must be Grasa

Another principal conclusinn is that the profitable conversion of the enormons addition to the Grasi growth of South Essex, which will follow the use of London sewage, can be expected onty therengio a great London matk traile.

Accurding to Mr. Lawes, we can depend on a ton of Grass from every 200 toms or thereabout; and to this agrees the experience at Edinburgh. What London, $200,000,(6) 0$ thas, thanging loth north and sonth London, of senarge ammally be comerted lyy-ande is grood for which aceording to tine Craigentinuy rule is foor have a haruly anything (irnss to eat-enough for 50,000 coms, in aldition to the supplies already grown for the number by which London milk at present is provided.
Lastly then, as a help out of this-0, ef of the main diffeulties which threaten the inmedinte profitableness of any scheme for using London sewage - I hope that experiments may bo instituted as to the plosibility of artificinl hay making.

It will have heon observel that in the emrse of this pmper I have male no reference to Mr. Moule's carth bystem of dealing with howse waste. as wedl as to other scleatines for connstrained by the terms in which the that I am constramei by the the subject is London Sewage. And we are, therefore, shut up to the discussion of how to use $200,000,00$ or $300,000,000$ that of filthy water per annum. That is the probem for cousideration; and thus the discussion of
for single houses or for villiges is excluded.
Agann, I have made no refernce to the nuisanc which may be expected from that arricultural use of this sewatge whieh experience elsewhere seems to have recommended. I believe that the efficacy of the sewage as a manare will be dependent to some extent on its heing already in a putrifying state; and no donb
a ceertain nuisance will be created. But, if any alarmist here, ready charted with a demmeiation of these phans on this account, be about to frighten us all with accounts either of putrid miasma and resultant fevers, or tilthy Grass unlualthy colv-, and unwholesone milk, ar thas to find thetr bome in our bodies, hreeding discas and death-I hope both he and all of us may bear in mind that 400 acres of land, treated more wastefully and filthily with sewage than any London sewage under the very noses of the Eslinhurgh people, who have, morcover, been fed fur generations on mik from cows fed on this sewaged Grass. If any evils of the kind alleged are in the least to be as expected, they must have declared themselves long ago in the death rate of so large a town, which howev.
as that of any in the country.

Lastly, it will of course be pointed out that I have named one only of the rival schemes for using london sewage. In fixing on that one of the munber for any particular applicatiou of the general rules of practice to which I have been directing your attention, I bave followed the example of the shrewd and intelligent representatives of Lomdon who constitnte the Metropolitan Board of Works, and who caunot be supposec or the special interests of the rate-payers.

## Home Correspondence.

What Meal versus Linseed Cake.-As one prompt word may be seasonable, I send yout the result of my weeks. Limsect-cake.-Five Down Shearling gain 39 d lbs. ; five Fast Down Hoggets, 42 lbs . Wheat Meal.Five Down surariugs, fots lis.; five East Down instend of Cabhage; the Shearlings eat. 6 stone per pen per day; the Horgets 4 stone. P. H. Frere, Jun. 27. We presume this is the experiment refercel to at p. 13, where the "pens" are five sheep each, They get they will cat, amd one lot gets 1 lb . of Linseed-cake apiece, and the other 1 ! Ihs. of corn, and ! 1b. of Cottoncake apiece. Each lot of five had been found to cat 6 stone of Cabbages per day when fel on Linseed.cake, and only 3 stone per day when fed on enrn and Cottoncake.]
Poisonous Properties of the Fers,-About eight months ago there was an account in the West Surrey Times of the death of a valuable stallion belongine to Mr. Collins, lanilurd of the Cucketer Man, Riphey
from eating twigs off a Yew tree to which he was tied from eating twigs olf a sew eree to which he was tied While the man

Farming is a $\mathrm{T}^{\prime}$ radt, and must be so consintered.-If man enters upon any haminesa, a certain capital should
be available to euable him to carry on the undertaking
he will also require a knowledge of the occupation he intends to foliow. The average cald, though generally Ireland is below that of England, though general Irish farmer labours under difficulties peculiar to his country, and not the least is the smaliness of his boiding, which craups his energies, aud prevents a profiterg tilled, and provide a plentiful supply of food for man and beast, and at the same time establish a manure haup, without which it is in vain to expect average crops. Artificial manures are most vall kept "mixen." It is necessary to adopt a course system o tillage, varying over a certain number of years, in order to bring land into thorough bearing condition To do this elfectually a man must have cash at command, as the farmer has other speculator. A his outhay longer than any other speculator. Dr. and Cr. account cannot be purchases and sales tine land, aud the fluctuations of the veighbouring markets, seasons, dec., a shrewd guess may be made o the annual income to be expected from a farm. Profit will always depend more or less upon the demand and supply of food. Lossis from carelessness, mismanage aupply of food. Lessance, shonld not be considered ment, and extravagance, against which conmon foreaight mirht have guarded The ignorance of the correct meaning of tenant righ is another source of discontent amongst the Irish agn culturists. A prevalent idea exists that a farme having oceupied and rented a farm for some year munot be removed by his landlord. Tenant rigut doe not give a man my privilege of this kind, without special agreement under a farm by the tenant, and improvements made on the farm property, for which compensation is to be received unler the usual arrange ment between the parties. The whole system of lettim and sub-lettins laud in Ireland appears faulty, and until a different plan is anopted, and farms increasell in ize, little permment inprovement can be anticipated. Falcon.

ROYAL AGRICULTURAL OF ENGLAND
Monthly Couyctl: Wednesilay, Feb. 1, 1865.-
Present, Sir F. C. Kerrison, Bart., M.P., President, in The Earl of Shrewsbury and Talbot, Lord Feversham, Lord Tredegar, the Hou. A. H. Vernon Sir A. K. Macdonald, Bart.; Sir T. Western, Bart. Mr. Leland, Mr. Barnett, Mr. Barthropp, Mr. Buwly Mr. l̉urgess, Mr. Cantrell, Colonel Challoner, Mr. Clasden, Mr. Deat, M.P. ; Mr. Druce, Mr. Fisher
Hobbs, Mr. Holland, M.P. ; Mr. Rigden, Mr. Thompson, M.P. ; Mr. Torr, Mr. Wells, Mr. Frere, Prof. Simonds and Dr. Voelcker.
The following New Members were elected:-

\section*{Adams, George, Collaton, Kingsbridge, Devon <br> 

Fincivers.-Mr. Fisher Hobbs presented the Report from which it appeared that the Secretary's receipts during the past two months had been examined by the committeo and by Messrs. Quilter, Ball \& Cu., the Society's accountauty, and were found correct. The balance in the hands of the baukers on January 31 was 11341.10 s . Sd. The balance sheet for the quarter ended lecember 31, 1854, and the statement of subseriptions and arrears, were laid upon the table; the amount of arrears then due boing $\$ 311.221$ neembers have given notice during the past year of their withdrawal from the Suciety. The sum of 2000 l. received from the local committee at Plymouth had been placed on deposit with the Society's bankers. An account exhibiting the whole of the receipts and expenses of the Newcastle Meeting to this date was laid on the table, showing a balarice in favour of the Society of 1312l. 6s. 6d. This report was allopted.
Plymoltir Miefinci-Lord Feversham, Chairman reported the recommendation of the committee that Mr. Moon be appointed Steward of Forage, and that Mr. Bowly be appointed a siterard of Live Stock. Also that there should be duplicate metal numbers for all horses and cattle; that prize animals should be dis tinguished by rosettes-white for 1st prize, red for 2.1 prize, blue for 33 prize; and that the prize cards now in use should be issucd to winners in duplicate This report was adopted.
Edccanion Commitee.-Mr. Hollaud, M.P., Chair

Council to vote a sum of money to be placed at ath disposal of the Committee, to be given in rewarde is the successful candidates at examinations of such kind, and to be held at such times and places, as shall here. after be detercained; and tuat all candidates for such examinations shall receive a certificate of nomiuation from some member of the Society. They reported that the Rev. Professor Rawlinson, the Rev. Dr. Temple, members of Delegacy for the local examinations Oxford ; Professor Liveing, one of the Syndicate for the local examinations, Cambridge ; Mr. Hepwood M.P., one of the Senate of the Uuiversity of London Rev. J. Constable, Royal Agricultural College, Ciren. cester; Rev. Canon Brereton; Rev. Dr. Jacob, Dean of the College of Preceptiors ; Mr. Robson, B.A., Secretary of the College of Preceptors, attended the conference on the invitation of the Council in accordance mith the contents of the following letter:-
"December 9, 1864 .
Sir, - I have the honour, by direction of the Cuuncil of the Royal Agrrcultural society of Eugland, to inform you that thay
body, haviny in view the 7 th nutional object set furth in it Charter, namely, 'ty take measures for the inuprovecment of
the education of those who depend upon the cultivation of thy soil for their support,'-bearing also in mind the great effort made both by individuals and by learnad and sciuntitic bodies in order to extend and improve the existing nueans of educs part, is desircus to obtain further information before it decide Agricultural suciety to initiate or to promote. munication with those educuating or examining bodies whic have devoted their attention to the present stat,e of education
as regards the class in question, with a view to obtain th as regards the cire experience und counsel.
"The Conncil have appointed a Special Committee to carn on the recuisite communications, instructing them to exprens hope that the Universities, the Society of Arts, and the Roga
College of Preceptors will do them the favour respectively The Committee propose to meet on Tuesday, the 3 lo Square. I am directed to request the favour of an intimation resent on that oczasion. "H. Hall Dare, Secreary."
(Signed)
Mr. Harry Chester, deputed by the Society of Ant was umable to attend in cousequence of illiness.
It appears that all these bodies are willing to or operate with the IRoyal Agricultural Society of Eingland, and that their several examining Boardsan dieposed to communicate to the Council a reporti detail on the attainments of the candidates included in any list forwarded by the Council.
A discuesion ensued, in which Mr. Thompson, MfP Mr. Holland, M.P.; the President, Mr. Acland, yr Torr, and Mr. Ciayden took parr, after which tue report was adonted; and it was resolved that tho report 1 a MP Mr Pall and Weils be added to B M.P. ; Mr. Randell,

Country Meeting Queries.-Mr. Fisher Hobbi reported that the Committee proposed to introduce clause into the queries requiring the local authond to confer with the directors of railwaye, and to sale the terms on which stock and implements would be conveyed over the Companies' lines. The schedule of implements for trial in 1866 would comprise only those which could be tried in the Show-yard; thereforeno land outside the show ground would be requiren. This report was adopted.
The name of Mr. Fisher Hobbs was added to the list of the Railway Communications Committee.
Mr. Torr having uoved that the Implement and Stock Prizes Committees meet at the Novembe Council, and prepare a draft of the Prize Nheoder thas sent to ench member of the Committee in or Neer. the same may be reconsidered at the December ing, the motion was seconded by Mr. Clayden ai carried.

A Select Committee, consisting of Earl Cathorn Major-General the Hon. A. N. Hood, the How, Vernon, Mr. Fisher Hobbs, Mr. Randell, Mr. Thomp son, M.P., and Mr. Torr, was appointed to take inh consileration the subject of the contract entered wotse with the contractor for the Society's Show- Yard noll for Tradeler from the Commitural Meeting at Stetie was read, enclosing a prospectus.

The Trustees of the Melbourne Public Library the colony of Victoria, having applied for the fort coming volumes of the Society's Journal, the granted.

The Council then adjourned to their Weekly Meetim on the 8 th inst.

At the Weekly Council on the 18 th inst., Mr. Iame will open the discussion on "Sewage."

## 

Outlines of Modern Farming. By Robert Scott But Vol. V. Vit
noster Row.
The present volume of Mr. Burn's compilation studenta of agriculture includes the subjects ond Sew we lrana first of these subjects is represented by evidence, and reports of Liebig, Lawes
Voelcker, and Way. Mr. Alderman Mecti, Voelcker, and Way. Mr. Alderman Mecti,
burn, and Messrs. Hoffamand Franklin ar upon for evilence, and thus most to the understanding of the subject aro
visited most of the localities concerned, and gives his own notes of Croydon, Craigentinny, \&cc. The general subject of irrigation is discussed in the second chapter subject of the volume. The author has studied both this of the voiume. allied one of Embankments practically subject and the alled on of Continent and in England,
and in detail, both on the Col and we have accordingly a great deal of useful information. Moreover Mr. Pusey, Mr. Keelhoff, Dr. Voelcker, Captain Baird Smith, Mr. Cuthbert Johnson, are all made to contribute of their experience and information, and the chapter on Irrigation is thus generally satisfactory. Excepticn must be made, however, to the botanical information; the letterpress at pages $8!$ and 98 , giving the botanical names of various weeds and Grasses, does not seem to have been "read" before publication. We quote the following reference to the utilisation of drainage water for irrigation purposes:«In many districts boggy lands lie at the foot of hill ranges. Now, a double benefit might in such cases be then applying the waters thus obtained to irrigate the boggy lands. The quantity of water obtained will be boggy lands. The quantity of water obtained wimple quantity, and draining from Grassgeverally hill-sides will be of excellent quality. The probable quantity will be roughly estimated from the rainfall of the district.
"The late Lord Hatherton, in Staffordshire, showed what could be done by the drainage waters of high land. He collected it in ponds, and led it off in the first place, to work a water-wheel, affording power for the labour of his farm steading ; and in the second place, after working thus, he led it off to irrigate extensive meadows. Drainage water is, in fact, peculiarly valuable for irrigating purposes, containing, as it does, so much fertilising matter. We believe that in the collecting and utilising of drainage water coming from land high enough to give a moderate fall, lies a power of the value of which farmers have generally little idea. The following note from an agricuitural periodical, on uniting irrigation with drainage works, will be suggestive on this point now under consideration :-
"There are many thousands of acres of deep-drained arricultaral land in different parts of Great Britain, where the outfulls of the drains are at sufficient elevation, and in suitable places, to allow of the water drawn off being used for purposes of irrigation. Lands, to be deep-drained, may also be laid out so as to work the snlsoil water of the upper portions over the surface and throurh the soil of lower lying districts. No available depth of drain yields pure water, and it has been long proved by analysis that water from a manured field contains soluble salts of any manures used; it must evidently be an advantage to pass suc.'. water over and through other lands. We throw out the hints for what they may be worth; we think deep draining and irrigation may work together with advantage.'
The quotations as to the quantity of water used on the Craigentinny mealows are not perfectly accurate.
"It appears, says Mr. Cuthbert Johnson, from the report of Dr. J. Siark ('Statement on Sewer Manure,' p. 49), that the celebrated Craigentinny Meads are annally irrigated with the city sewage about 18 times. For instance: a certain plot was watered in its turn in 18.4, May 3 and 14, June 3 and 20, August 15 and 31, October 8 and 29, November 24, December 31; in 1346, January 30, February 18, March 5 aud 22, April 2 and 13.
"Now, if we calculate that on an average of months 500 tons of irrigation water would suffice to saturate the soil (always partially and sometimes thoroughly previously moistened), then it would require 9400 toris of water to give these 18 irrigations to an acre of land. 1 deem the quantities I have stated as likely to be an average amount of sewage-fluid required for the irrigathe report of Mre Grassland to be nearly correct. In the report of Mr. George Buchanan, Engineer to the Irrigated Meads of Craigentinny, to the Commissioners of Metropolitan Sewers, he states the quantity of water fluid of $3^{3}$ acre to be equal to a stream of sewerfluid of $3 \frac{3}{4}$ cubic feet per minute for 12 days of 10 hours each. Now, this I calculate to be equal to $3 \frac{2}{4} \times 60 \times 10 \times 12=23,400$ cubic feet, weighing $62 \frac{1}{2} \mathrm{lb}$. per cubic foot, or $62 \frac{1}{2} \times 23,400=1,462,500 \mathrm{lb}$, or about sewans. It will be remarked, however, that the sewage-fluid in this case had to sustain the soakage, leakage, and evaporation during 13 days of the month of May. This slow irrigation is far from being the most economical mode of applying the sewage-the more rapid and copions application being to be preferred, as affording little time for the soakage into he substratum and the drains."
Tbe land is not irrigated so often as 18 times in the year, and very much more is put on at a time than is here named. If ever there are 18 applications per 30 thonse the total quantity applied is more likely 20 or chousand tons per acre, though on an average the quantity applied may not really be more than 10 to 12 housand tons.
The third division of the volume relates to waste land reclamation, and here we bave descriptions of Heath, and on varions Ireland, in Lancashire, Bugshot Heath, and on various moorlands in different counties.

## Calendar of Operations.

Febrüary.-Spring Wheat, Beans, Peas, and Oats raay be sown this month.
Beans are to be sown early in Febraary. Manare
either in drills or broadcast if not already done. The land is to receive either a light ploughing, if manured broadcast, or a scarifying if it has to be drilled up to receive the manure; and the seed, from 8 t, 10 pecks per acre, may be placed in the ground, either on the manare in the furrows and covered by splitting the intervening drills, or by sowing in every third furrow
of the plough; or by the Suffolk drill in rows 18 to 24 inches apart; or by hand, either hoed in or dibbled. Dibbling may be cheapened one-half by the use of Sigma's dibble.
Peas may be sown on the lighter soils. Use the common Saffolk drill, the coulter levers being well weighted, in order that the seed shall be deposited at a sufficient depth. Sow in rows 12 to 18 inches apart -3 bushels per acre. After nowing the water furrows are to be cleared out.
Oats may be sown in rows 9 inches apart-10 to 12 pecks per acre on ploughed Clover stubbles of the past year (which, however, in England are more generally sown with Wheat), or on land that has borne any other green crop, that was ploughed in autumn, and has been well harrowed since winter. In exposed situations the sowing of (ats should be deferred till the end of March, and in Scotland gemerally they recommend upwards of 4 bushels to be sown per acrobroadeast.
Clover, Grass, Carrot seeds, Mangel Wurzel, and Turnip seeds of all the required kinds must now be procured. Purchase 12 lb per acre of Clover seeds, and 1 busbel per acre of Grass seed for use with the Clover; 3 bushels per acre of Italian Rye-Grass, if for use alone; 5,7 , and 3 lb . per acre respectively of Carrot, Mangel Wurzel, and Turnip seed, for the extent of land on which you grow each.
Manures should be purchased; guano and other fertilisers for grain crops, superphosphate and othei manufactured manures for green crops.
Draining, Road-Making, and othier extraurdinaty winter works should be finished.
Grass Lands.-Trampling from stock during these wet and cold months will seriously injure the herbage and at the same tinse be of little benefit to the animals; they should, therefore, be all in yards.
Live Stock.-Calves will be arriving. A sepatate crib in a well-ventilated house should be provided for each. Undiluted milk is the bost food; but after the first three or four weeks it must be supplementel by Linseed cake and sliced Turnips to admit of a larger number being reared to each cow. Yellow or late sown white Turnips yield more milk than Swedes, and should therefore forin the stapie food of the cows at this time Horses must be put on full allowance of food of all kinds, as they will soon be required to work the full period of time. The ewes being now far advanced in Wurzels or Turnips upon their pastures. They must on no account undergo any sudden change in keeping or management, as it tends to affect their constitution, and cause dauger in lambing. Lambs and fatting sheep must have their regular increase of food, their sheds littered, and their feet frequently examined. The lambing season commences as early as January in many districts, especially such as are near good markets for early lamb.

Dairy Farm.-The food of the dairy stock should be gradually improved. When a sufficient number of cows have calved commence cheese-making; cheese is more profitable than veal. As the cows calve their food is changed to the best hay, and the warmest courts are allotted to them. Butter, on most dairy farms, is still the principal manufacture.
We shall refer to the several topics more particularly daring the four following weeks.

## Notices to Correspondents.

blubber in Composts: Scalpel. The use of blubber in composts will be fuud largely recommended in old books on
agriculture; but there can be little doubt that ita value as a manure has been overrated. The object is tum get it to rot and help rot otuer things in comp st with itself. To this end mould, dry peat, do.-and.turn it over frequently uncil it was beginning to rot, and thereatter add to the compost so much lime as would, witn the quantity of the heap you intend to apply per aere, make a fair acreable dressing also, of the lime.
Depend upon mixture with the fibrous vegetable matter, and on repeated turnings, in fact upon the access of air, to the heap for getting it rotten. Lime is a good thing to add
along with the prepared compost of this vegetable and along with the prepared compost of this vegetablo and
animal matter; but it is not of much service in preparing the compost for use.
ART Horsss : Rusticus asks our Correspondents to inform him what they cuastuer to be the proper allowanee of food for cart horses at this season of the year. He gives his
chopped Oat straw and Oits but no hay. ald should be glad to learn from others what proportions of each will keep cart
bores in fair working condition. [see page $\$ \$$.] DISEAses of Wheat ; $A$ Z. There are three principal diseases by which the graing of Wheat are attacked :-1. Bunt,
which is at once known by the grains being filled with dark pwoder, which bas a disayreeable fishy odour. 2. Ergot. in which the graiu is mure or leps eularged, an the nterual
substance white and solid. 8 . Earcockie, in which the substance white and solid. ${ }^{3}$. Earcockle, in which the
altered grain is smaller than the sound. These graing aro altered grain is smaller than the sound. These grasing are smadl, black, and rounded, consisting of a thicl, hard
shell, whose cavity is filed with a white powder. This powder contains no trace of fecula, but is exclusively cotuposed of mierocoopic thread-shaped particles, which are in fact little dry, rigid worms. Wheu immersed in water
they are seen by their motion to by allve. Besides these the they are seen by their motiun to balive. Besides th.
ordinary smut and mildew must of course be named. ordinary smut and mildew mut or course be named. and sorts next week. We recommend paring and burning and ofd peaty sward rather than attempting to reduce it

OUR Indian letters give us a sad account of the effects produced by the late fearful Cyclone upon the Botanic Garden at Calcutta. The valuable collection of trees and shrubs which had been brought together there from all parts of India and from many other parts of the world, has been greatly damaged, and many of the plants are entirely destroyed. Stately trees have been torn up by the roots, or have had their leaves and branches stript from their stems, and noble avenues, the work of many anxious years, have been all but demolished. The Eagre, or, as it is called in India, the "Bore," came rolling up the Hooghly on this occasion with a force whioh was almost overwhelming. Usually this tidal wave is only a few feet in height and comparatively hurmless, uinless to small boats, which generally contrive to get out of its course, but during the Cyclone it formed a wall of water fully 30 feet in height, breaking over the basks of the river and sweeping the country bare. It will take a century to replace many of the grand old specimens, and to make the Garden what it was on the eve of this remarkable torm.
The Calcutta Gardon is situated on the right bank of the Hooghly, a Ehort distance below the town. It was established by the East India Company in 1768, asd liberally supported by the Company up to the time when the English Government took India into its own hands. But although the country has ohanged its rulers, the Botanic Garden at Calcutta is still appreciated and supported. Bishop HebER, who visited it amongst other remarkable places during his tour in India, gives us the following description of it :-" The Botanic Garden at Calcutta is a very beantiful and well-managed institation, enriched, besides the noblest trees and most beautiful plants of Tudia,
with a vast collection of exotics, ohietly colleoted by Dr. Wallich himself in Nepal, Pulo Penang, Sumatra, and Java, and increased by contributions from the Cape, Brazil, and many differeut parts of Africa and America, as well as Australia and the Soutin Sea Islands. It is not only a curious, but a picturesque and most beautiful scene ; and more perfeotly answers Milton's idea of Paradise, except that it is on a dead flat instead of a hill, that anything which I ever saw. Among the exotics I noticed the Nutmeg, a pretty tree, something like a Mrrtle, with a beautiful Peach-like blossom, but too delicate for the winter even in Bengal, and therefore placed in the must sheltered situation, and carefully matted round. The sago Palm is a tree of great singularity and beauty, and in a grove or avenue produces an effect of striking solemnity, not uulike that of Cothic architecture. * * These different establishments [Indian Botanic Gardens] used to be all cultivated by convicts in chains, of whom I have already spoken. In the Calcutta Garden their labour is now supplied by peasants, hired by the day or week; and the exchange is found cheap, as well as otherwise advantageous and agreeable ; the labour of freemen here, as elsewhere, being infiuitely cheaper than that of slaves."
To the many remarkable plants which grew in the Caloutta Gardens we may add that there were examples of the Amberstia nubilis and Jonesia Asoca, the latter being one of the must beautiful flowering trees in Southern Iudia. There were miny Palms of great interest and rarity; and the Banyan tree (Ficus indica), of which there was one fine speoimen in the Garden, was widely extending itself and affording a delioious shade by means of its spreading branches, and dark green, shining foliage. Some years ago Mr. Scott, the head gardener, was most successful in the cultivation of the Amherstia, whioh had proved somewhat difficult to manage in Calculta, and doubtless there were very flae trees of this plant in existence at the time of the Cyclone.
In this country, and throughout Europe, we owe the Calcutta Garden a debt of gratitude for many of the fine plants which adorn our stoves and huthouses, and which yearly find their way to our great Exhibitions. The East India, Company was in the habit of sending these things home in the most liberal way and with no grudging hand, a proceeding which redounds to its oredit, and we hope the good example thus set will long continue to be followed by its successors. Many of the captains of our "Indiamen," as Captain Nisber of the "Nile," for example, uecd to take great interest in bringing home Ward's Cases on deck filled with most valuable plants, and we belleve often freight free. Such liberality in a Government, and in individuals, deserves to be made widely known, and to be long rememtered.

The Calcutta Garden, like all the Indian establishments of a similar kind, is of great value to the country itself. By its means blauts are istroduced, propagated, and distributed all over India. Productions of mercantile, and even national importance are received, taken care of, and forwarded to their destination. The Tea plants which are now covering maly of the slopes of the Himalayas, and the Cinchonas which are likely to prove such a boon to buth foreigners and natives in that country, were sent, in the first instance, to the Calcutta Garden. The Directors of the Caloutte Garden have always been men of great soientific attaimments, ard atdent lovers of botany. Roxburgh, Wallich, Falconer, all now alas! no more-and Thonson, are names of well-knuwn men, under whose care the Garden has been siuce 1793 ; and Dr. Anderson, who has charge of the Garden now, is proving himself a worthy successor to these eminent men. We doubt not the latter will do all in his power to renovate this useful garden, and although it will Lake years to replace mauy of the specimens which heve been destroyed by the Cyclone, yet the value of the establishment, both to Europe and to India, may be but elightly impaired.
We fear the Garden of the Agri-Hortieultural Society of India, which is also a most useful establishment, may have been severely handled by the late storm. It is, however, more inland, that is, farther from the banks of the Houghly than the Botanic Garden, and may not have suffered so severely as the latter has done.

A memoir was read before the Academy of Sciences at Paris, by M. Naudin, on the 21 st of last November, on Hipbridity considered as a Cause of Variability in Plants, of which memuir an

THE GARDENERS' CHRONICLE AND AGRICUITLRAL GAZETTE
abstract is given in the Reader for January, 1865. "Althongh hybrid plants, when endowed with sufficient fertility to propagate their kind beyond the sfcond generation, frequently and speedily revert to the type of one or other or the original species, nothing is more
find that certain individuals not only persist in their divergence frum both the primary typos, but nctually depart still more widely from the oripinal parents, and even in some cases present considerparents, and even in some casses present consider-
able differenoe from the first generation of hybrids."
In elucidation of this doctrine M. Naumin has proceeded with his experiments on several hybrid proceeded Mith hilis, \&C., and he has kindly supplied us with seeds of three hrbrid Dature, together with those of a hyhrid Mirabilis and Cucurbita. The seeds yielded last year an abundant orop of
like M. NAODIN's, presented plants, which, like to mese intermediate states, reversions to the parent appeared quite abnormal, in exact accordance with his latest observations. In
the caso of the hybrid Cucurbit of which we lately gave a figure, and which we expected to have bitter fruit, there was not the slightest bitterless, though the habit was not that of the parent Melon; und it is probable that the seed will yield some hybrid Dinturm there were individuals with both purple stems and flowers, while others had green stems and white flowers.
M. Naudin believes that in diffioult genera suoh as Salix, whioh abound in doubtful species, a multitude of anomalous forms oocur in consequence of cross impregnation which become fore bear upon analogous phenomena in the animal as well as vegetable kingdom, and present a very interesting field for observation. M. J. B.

It will have been observed, from the letter published at p. 1157 of our last year's volume, that the arrangements for the Soutir Kexsing ton Hor-
ticutcras Exhidions in the present year have ticultrial exhibitioss in the present year have
proved distasteful to the great body of Exhibitors; and it will, therefore, excite no surprise that the latter should have memorialised the Council of the Societr under whose auspices the shows are to be
earried out, with a view to their modification. A and we have been favoured with a copy of it, and of the reply, which want of space prevented us from noticing last week.
The mennorial itself sets forth the "very orjectionable arrangements" for $186 \overline{3}$ as having been "condemned by the entire hortioultural and
florioultural press;", as "diametrically op-
posed to the inlerests of "exhibitors, as well posed to the inlerests of "exhibitors, as well
as to that of the society;" and as "totally adverse to the practical purposes of horticulture., The memorialists go on to say: " "It is not our object or wish to dictate to the Council. On the
contrary, it is our earnest desire to co-operate with them if they will meet us in a practicable form; but with the arrangements as they at present exist we must most respectfully deeline to exhibit at any of the Royal Horticultural Society' exhibitions for the year 1865 ; and we feel it our duty as horticulturists to communicate this intention to the Council without delay." They also state that at a recent meeting of the Exhibitors' Society it was resolved that:-" In consequence of the
programme of the Royal Horticultaral Society for the sear 1865 being so diametrically opposed to the ioterests of exlibitors, the members pledge themselves not to exhibit at any of the Society' exhibitions unless the arrangements are modified
to a practicable extent." This document bears to a practiable extent." This dooument bears
between 40 and 50 signatures, amongst which
ocour such names as BAKER, YovNa, Chilmas, Peed, Penyy, Cabson, Kaile, Whit pread, Page, Pottle, Btllex, Maf, Moyle, Perry, Refnolns Hole, Radclyffe, Ballet, Stevers, Howado, Lane, Wiliams, Henderson \& Co., Dobson, Cutbusi, Turner, \&ce-all well-known exhibitors; and it appears that others
who have not signed, agree generally with the who harialists.
The Council has, as we are informed, returned the following reply, addressed to Mr. 0 . RHoDEs, Secretary to the Exhibitors' Society.

Royal Horticultural Society, S. Kensington, W. 25 th January, 1865.
Sire, - I am directed by the Council of the Royal
Horticaltural Society to actnowledge the recipt of Horticulturnl Society to acknowledge the reeeipt of a
memorinl, which, on behalf of certain exhibitors at thm Society's former olows, you have done me the honour to transmit for the consideration of the Council.
The Council desiringe me to express their regret that
the arrangements they have made in respect to the
exhibitions of the ensuing season should have proved distastefnl to any exhibitor, but as the programme has already been made public, they fime they would observe to adhere to it. Al the bamer themselves precluded from that they will not consider themselves prectar that introducing any modification or alle be desirable.
experience may hereafter prove to be desirable.
It would appear fro'n the memorial and 2 d , to the day taken-18t, to the special great and special shows are to (Saturday
be held.
a held.
As reg
As regards the first, the Council have only to remark that their object in establishing wat they have termed special shows was to give a fresin to particular tribes of plants; and as regards the secon l ohjection, they have only to remind the remonstrants that in making choice of Saturday they are but reverting to the practice of Chiswick in its palmiest days, when the facilities fo ocomotion were infinitely less than at present.
The Council desire me, therefore, to express their hope that those who lave signed the remonstray intend reconsider their decision as to the course thay int,

Andrew Murray, Assistant Secretary
The present Cusncil has, no doubt, sufficient easons for adhering to the programme it has announced; but seriously, in the interests of gardening and gardeners, and in the interest of the Society itself, we put it to the new Ccuncil which in a few days will be elected, and to whose hands the affairs of the Society for the next twelve months will be committed - Whether, since the
Saturdar meetings prove to be as distasteful to Saturday meetings prove tollows as to the complaining Exhibitors, it would not be beneficial to the Society to make some change in the arrangements that will be agreeable to all parties. Experience has surely already proved that such modification is desirable.

IT will be seen from our advertising columns that the Royal Horticultural Siciety has taken a first step in the matter of the EDUCATION OF Gardeners, by offering through the Society 0 Arts five prizes of the respective values of $5 l ., 4 l$. $3 l ., 2 l$., and $1 l$. , to those persons, being gardeners, and gaining certificates, who stand highest at the examination in Botany which that Society holds towards the end of April next. We understand that this course has been adopted on the recommendation of the "Education of Gardeners" Committee," the season at which the Suciety of Arts' Examination is held not allowing the candidates sufficient time to prepare for the more special examination which we believe is to be instituted, and the marhinery of that Society affording the most readily available means of bringing the prizes within reach of gardeners throughout the country.

The Red flowered Locust tree-Robinia Pseud. CaCIA Decaisneana-which we briefly mentioned at p. 579 of our last year's volume, is now being sent out by its raiscr, M. Villevecles, of Manosque, in the form of one-jear old grafted plants. This distinct variety was raised in the nursery of that gentleman in 1862, and has all the habit and general aspect of the common Robinia, but in addition is covered with long clusters of flowers of the finest rose-colour. M. Decaisne, after whom M. Carrieze has named it speaks of it as likely to cause a revolution in the ornamentation of promenades. The rose colour of its flowers, he remarks, can only be compared with that of the most brilliant varieties of Robinia hispidn, and would give to our parks a new aspect at a time when ornamental trees have already lost much of their beauty. M. Carriere says it is destined to play an important part in the ornamentation of gardens and public walks, for which purposes it cannot be too much recommended as the tree is vigorous and easily managed. The appearance of R . Decaisneana, he continues, will proand open a new field of interest amongst hardy trees, combining with rosecoloured flowers the distine habits assumed by varieties already known. The origin of this new Locust tree appears to have been quite accidental, but it will not be the less welcome on that
Th describing the Jalais Nectarine in a recent Number of Revue Horticole, M. DE Liron D'Airoles, Peach and Nectarinc on the same branch presented to the societe Centrale d' Horticulture, and mentioning the Horticultural Society of In in the Transactions of the Horticuitiral Society of London, remarks that amonget find the orrais sudies, he has searched ruitlessy to Nectarise, he observes, was produced from a kernel of a Nectarine, and its kernels have given birth to other 1863 Nectarines, amongst which, however, he observed in of four years, and possessing and fertility at the age of four years, and possessing so agreeable a flavour that he was indaced to name it Jeony de Thouaré.
came nearest to the Peach. Opinions will be dividod he thinks, as to whether this new form was the roalk whether it is a hybrid or a germinal sport; but at leat he is persuaded that it throws some light on the origin of the Nectarine. For myself, he goes on to say, am very much inclined to believe it to be an anomals produced by a disease of the sap, and fixed by gratting.

THE PINE STOVE AT KNOWSLEY.
Knowsiey Park, which I propose by and by to speat of in detail, is the seat of the Earl or Derby, a nobleman commanding universal respect on account of his mond as to the extent and character of his private establibh. ment must be therefore more than ordinarily interestion to the general reader. Nothing would be calculated is give more pain to lovers of gardening than to know that one so prominent should all but ignore their favourite calling. Fortunately, as I shall bo able to prove, before I have exhausted my notes on the gardem and pleasure grounds, his lordship, who has all along been the friend and uacompromising advoato of agricultural interests, has done something, in his on right, for the advancement of gardening.
Rarely, indeed, does it happen that the practical man who always intuitively assumes the capacity of critic, finds himself agreeably disappointed with the extent, management, and character of any place d notoriety; but here the garden establishment, frou whatever point of view you examine it, clearly enoogl demonstrates that it has latterly been well appointo True, there are many things left undone during the lan half century which might have been accomplished his proper representations been made. Here, as in mus other places, judging from present appearances, the progress of gardening depends more really upon gardener than his employer. If the supe londend any establishment rests contented, aimply and abo plately refusing to throw out suggestions for enlargin the sphere of his department, his employer cannot be blamed for not taking the initiative. Dozons the I know, hundreds I should say, of horticultural ati blishments, are chiefly enlarged at the instance, or by the reiterated suggestions of the gardeners who sppa intend them and this is the principal reason woy body of men are almost universally esteemed
plodding, industrious, and intelligent class,
Greatly indeed was the writer pleased to find the Knowsley represents gardening so well, and that this fine old establishment there is accommodation fu the cultivation of the king of fruits of a kind wid must command universal admiration. All ye alle vators of the Pine-apple! who have been growing 80 fruiting your plants in holises of $30,40,50$, and 60 lea long, and who may still bo considering that you pow housee, plants, and fruit of an unique deseription, an your eye upon the woodcut--lonk there for extantit and quality of the fruit

The horise is 100 feet long and 26 feet wide, contimi ing as near as may be 600 plants. During the tims a my visit, in the latter end of October, there mer 170 Black Jemaicas swelling off their fruit, and in wad condition as to excite the wonder of even the mat st. lid observer. It is not an unusual occurrence to a dozen or two of that variety, in the early par winter, probably about 4 lbs . Weight; but gether, according to my notions, an unpreced
example of cultivation to come in contact with 170 frit example of cultivation to come in a giving an average weight of $4 \frac{1}{2} \mathrm{lb}$. I give the ways is
upon the authority of Mr . Freeman, who say largest fruit of this sort weighed 5 ib .120 mm , judging from the eye, I can thoroughly endors statement. Such an array of fruit, so uniform ither ind and handsome in outline, in long lines on either ibme the centre path, like stripes of fowers in border, was a sight of itself worthy a special friik Here, indeed, were numbers of that luscious condition for table from November to sufficient to regale not only the palate of Wales and his retinue, had his promised visi place, but also the whole Conservative party
there are no better judges of fruit than noblemen country gentlemen, we may state that Lord D prefers the Black Jamaica to all other kinds winter fruit, an opinion pretty generally Some exceadingly handsome fruit of the Hurat Seedling, of outline so exactly pyramidal as to ap have been turned out of a mould, were also in rip. the largest of which weighed 7 lb . In flavour, winter, it cannot bear comparison with Black dan ont I have heard it more than once maintain that there is a degree of uncertainty ruiting which, if satisfactorily proved, wis at some years ago, it seemed to bc a wonderful both as to habit and fruit-bearing tendencies.
There is something very grand in possessing for Pine culture of this extent; but ainst its utility. What is the nes of 600 or even 400 may be said, subject to the same treatment grided according to the
made upon it. This much I may say, that if ever there certainly this is the house. The principle is good, and certs of adoption; the size and details can be modi fied according to circumstances. Any lady fastidious abcut her person und dress can walk through, inspect, and admire this house quite unconcernedly, so very different is it from all older sty le of bouse, where the narrow passages and whitewashed walls are always a serious obstruction to capacious skirts. It searcely need be said that the old style of house does not find much favour with either ladies or gontlemen, unless their enthusiasm for either fruit or flowers exceeds common bounds. It is a Jesirable object, therefore, to possess an unobjectionable medium for the cultivation of plants, and at the same time have ample walking space for those who desire to examine them.
A glance at the woodcut will show that the principal and central path is 4 feet wide, the beds ou either side 7 feet, and the path by the wall $2 \frac{1}{2}$ feet. Bottom-heat is mainly, if not altogether, supplied by four rows of pipes, which are covered over with rubble for the diffusion of the heat. The space between the rubble

$$
\text { scole of }{ }_{5}^{5}{ }^{4}
$$

little less firing. There are 1480 feet of piping in this house, attached to a saddle boiler erected by Meredith. and heats an early Peach house 80 feet long as well. A side shelf all round the house is filled with Frencl Beans for forcing, and keeps up an adequate supply The ammonia tells beautifully upon the foliage of the Beans, which during short days are not usually of a very dark green hue. In this case, however, they come very highly coloured, and not so subject to the attacks and depredations of insects. Huge blocks of stone, the largeat of which mensure 7

## FRUIT GROWING.

On reading the heading of the article in No. 5, p. 101 quite hoped and expected that some experienced Kentish fruit cultivator had been stirred up to give us some hints on fruit culcure, or to deseribe some mode of cultivation superior to that of common standard orchard trees; in other words, to describe fruit cultivation and not fruit growing. I have, however, been much disappointed, for I find only a repetition of the language of the " Kentish Fruit Grower," as given at p. 1203 (1864), and a sidiculous calculation based on the price of Apple trees at $1 s .6 d$. each, reminding one of the country grower Who, on giving 3d. for a Ribstone Pippin at one of the fruiterer's shops in the city, went home ani valued his own as worth at least 30s. per bushel. An Apple tree occupying the ground as a scock and tree for four or five years is cheap enough at $18.6 d$., but if a contract were made for 5000 or 10,000 the price would be widely different. This supposed heavy expense fiction I have already disposed of at p. 7, and Mr. Springett ahould read the remarks there made his calculation is alike absurd and ridiculous.
The only matter of interest I find in Mr. S.'s letter is that in which he tells us of that most arbitrary custom (surely it cannot be true) of Kentish landlords not allowing the value of trees to an outgoing tenant that have been planted more than six years. Why it is nipping an orchard in the bud, and must be rainous to a tenant; no man of capital or judgment would take Kent ought to resist it en masse. it seema growers of the "Men of Kent" even to ; it seemy degrading in unjust arbitrary custom to exist. The remedy is, however, easy; men of capital should become their own landlords, and then exercise their skill in cultivating
H.

How langhable it seems to $m e$ to see a sensible man write abort "cutting and mutilating trees into many one's mind , as if that were cultivation; it brings to one's mind the old topiary method of mutilating evergreens, when many gardens were not thought complete unless they had a percock cut in Yew or Box on each side of the garden entrance. I know of a farmer's
and the surface is filled up with leaves, and, I think, the whole top-dressed with sand, which gives the surface a neat and tidy appearance. There are taree principal rows of plants something after the style indicated in the elketch, which form those intended to, and in, fruit. Of course, in suoh a large house as this, there will be always a number of succession plants planged in to take the places of those that are cut, and the front rows can never be so uniform as the artistic eye might desire. There is little, however, to take excep. tiou to in this way, as there is an admirable stoek of succession plants in other houses ready for transter. The plants, moreover, are clean, and, as I presume has been already surmised, in the very best of health. Surface heat is kopt up by means of six pipes, the flows having large evaporating troughs, which are kept continually charged with moisture. The atmosphere is largely charged with ammonia, eriden: to the sense of smell as one enters the door, proceeding from manure water emptied into the troughs.
The command of heat is excellent, although the addition of two pipes more for surface heat would more evenly balance the bottomoheat, and cause a anternate tree, but for several years I shall have crops from these trees, and be able from their occupying such a patch of ground to give them very superior culture at a small cost.
At this moment they are in a most promising state, literally covered with blossom buds, and owing to being in a snug sheltered spot they will doubtless Lear as fine fruit as when they occupied some 10 or 15 acres. These rees are on the Quince stock, and when 1 phanted them the wiseacres all prophesied they would not tive five years. From these Pears my attention was drawn to Apples, and I then found that a plantation of 400 trees from 12 to 15 years old, subjected to summer pruning, were in a heulthy bearing state, althoush only from 3 to 4 teet apart. I then saw that planting fruit trees conparatively thickly, might be reduced to a segular system. If Mr. Springett reads this he will see that my deductions have not been made hastily. I may by the way mention that I have a piece of ground a little more than one acre occupied with Plum trees about 15 years old, very slightly pruned in summer; the crop has made more in one semson than 2000 bushels of $\mathbf{M r}_{r}$ Springett's Apples. "So much for methodical"calture as standard orchard trees. standard orchard trees.
I do not by any means despise etandard orchard trees-they are beautiful things, and their fruit is valuable to the poor and to make cider of, also to give pigs the stomach ache; but as the prices given by Mr. S. show, they are not calculated for a large wealthy class of fruit consumers, annually increasing ; 18. $6 . d_{0}$ per bushel is quite enough bowever, for Golden Knobs, which require iron teeth and a leather stomach, and are only fit for Kentish boys.
I have some 400 or 500 bushels of Sturmer Pippins. Now these sent to market in April and May will make from $3 s .6 d$. to $4 s$ s the half sieve, and pay well tor growing; last spring they made 10 s. the half sieve. I mention the above facts about Plums and Apples, at the risk of being thought egotiscic, merely to show Mr. S. that I am not what I daresay I have been called by the "Men of Kents," a "Cabbage garden experimenter." I assure them I am not so, for there are here 100 acres, nearly all more or less under fruit trees in all stages of their growth, and if he will come I will show him not "a couple of trees picked out of a huudred," but some interesting experimental quarters, among which a snug plantation of Cox's Orange Pippin of 100 trees on the English Paradise stock, were last autumn perfect pictures of fertility, as they are now pictures of promise. There is much yet to learn to bring fruit-tree cultare to perfection. Old as I am, I can see that we are only commencing to know the effects of different kinds of stocks, the improvement to be made by grafting, by the adapting the modes of protection to trees while in bloom, \&c. In short, when I reflect on what may be done, and the little that has been done in fruit culture, I feel surprise at the past, mingled with hope for the future. As to the planting an orchard of standard trees in a fine soil, and waiting till the trees bear, and wheu they overbear never thinning the fruit, the Devonshire and Herefordshire rurals have done it for many generations, and, like their brethren in Kent, they are satisfied: "so mote it be."
Mr. Springett seems to think that dwarf trees must always be "diminutive trees," for which he appears to feel the sort of contempt displayed by a Newfoundland dog for a small cur. He seems to furget that a tree, whether a dwarf or standard, it decently treated, will every season increase in size, so that dwarf or pyramidal Apple trees grafted on the Paradise stock, and Pear trees on the Quince stock planted 3 feet apart, in a few years become fine fertile trees, and by the time Chey are fit to thin out to 6 feet apart, are capable of bearing large quantities of fruit. It is not however so much the large quantity, as the superior quality, of fruit grown on trees well cultivated, making more than donble the price of common fruit; and here I answer Mr. S.'s question: " How much of such (I presune suminer pruning) work could be done to ensure an increased price of $3 d$. per bushel?" I have received this morning (Feb. 8), a note from my saleeman. telling me that my Wellington (!umelow's Seedliug) Apples made but $3 s$. per bushel-thy were sinall and gathered from standard trees overloated with fruit he adds, "had they been larger a higher price would have been !obtained. I am now selling very fine Wellingtons as much as 78. per bushel." Now, here is a difference, not of 20 , but of more than 100 per cent. a difference, not of 20 , but of more than 100 per cent.
betweeu growing Apples and cultivating them. The difference between a fruit grower and a fruit cultivator exists in about the same degree.
I give the above particulurs to enable cultivators to form a correct idea of what may be expected from what Mr. S. calls a "diminutive orchard ;" he seems to forget that his standard trees when first planted were diminutive trees, and have only become full-grown by culuure and care. I may be wrong, but it appears to me, from Mr. Spriugett's letter, that he has never seen a dwarf or pyramidal Apple, Pear, Plum, or Cherry tree on their proper dwarfing stocke, so as to make them fertile and adapted for superior culture; and that be, Jike the rural orchardists of the West of England, exists in a pure, happy, unsophisticated state of mind, beautifully ideal, but not calculated for new phases of fruit culture

I have written no "denunciation of Kentish orchards." No, I pointed out the advantages that
miglat be derived from improved frait culture in Kent, and warned the growers that they must expect sharp competition.
I was prophetic to a greater extent than I thought for, I have just learned that a fine spot of 200 acres near London is at once to be appropriated apples will be coltivated to a large extent, and Kentigh Golden Knobs not allowed an entrance. I have only to add that you are at liberty to give Mr Springett my address; I shall at any time be glad th give him a lesson on fruit-tree stocks, and the soils they atfect, and endeavour, as Paddy says, to insense hesesity as to the benefits of summer pinching, and the necespom Sir W. Napier's "Apple Pie Poem,"
"Next in your mind this maxim firmoly root,

## Home Correspondence.

last week of this beautiful Cologyne now flowering at Mr. Day's; it is one of the most magnificent winterflowering plants in cultivation, its lovely blossoms being unrivalled in excellence by those of any other Orchid with which I am aeqnainted. When seen in masses of from 8 to 10 feet in circumference with from 150 to 200 blooms on each mass, such as may now be met with in the Orchid houses of W. Jackson, Esq Scrnton Honse, Yorkshire, they present one of the richeat floral treats that can be met with a from the Land's End to John o'Groat's to see. The reason of the Coelogyne in many places not being seen in such perfec tion as it is capable of is its being too generally kep in the cool Orchid house; for I have invariably foun it to thrive hest in the East India louse with plenty of
When I first had the management of Mr. moisture. When I first had the management of the growth and flowers they produced were very meagre After howtver bring treated more generously, the change in their healch was something wonderful, and
there are now specimens in the collection just named, such as are seldom to be met with in other establish ments. George Gordon, The Elms, Hampton Wick Middlesex.

Trade Lists.- Whatever is a poor gardener to do in these sensation days with all the soccalled new things that are being sent out, and more especially this year? He is considered quite behind the age unless he has tried somebody? Atlantic Cable Cucumber, cr who-18-it's
Pneumatic Pea, or some other such vast improvement on all existing varieties. I have heard some people say think that we garleners have to put up with more than our share of it. In my young days very few published a printel seed list, but now-a-days every seedsman sends out his "Little Book," "Vude-Mecum," or "Amateur's Guide," and he is not content to have and make up a bools with illustrations, testimonials, de. of some 80 or 100 pages. If we examine the lists of some of our largest advertising houses, We find that vegetables, while another directs attention to forty-one new varieties of esculents. Now, see what we have to try in order to keep pice with the times; there are five new Peas, one Bean, three Kails, five Broccolis, three Sprouts, four Cabbages, three Cacumbers, one Lettuce, five Melons, two Onions, four Potatos, three Turnips, and a few others, ill stated to be novelties, making up 41, which, be it observed, are reported to be a careful selection worthy of special attention. I verily believe early Peas than in that of other seeds; formerly seedsmen were content to produce Expreses, Racehorses, No. l's, Morning Stars, \&ce, but these have now First and liest"," Early Peas, "First Crops," and haust my subject, for nearly every other vegetable is stated to be either improved or ennobled. I heartily gardeners, and stick to common sense in all matters relating to seed lists. Surely no man calling himself a gardener would think of lonking into a seedsman's catalogne for what soil the Carrot "delighted" in, or with regard to illustrations, with the exception of plates of knives, they are in general of little other use than to give children to play with. I am sure that large catalogues are not priated without great expense, way of quality or price. What gardeners want is a catalogne of really good things, with perhaps a few brief descriptive notes respecting the seeds offered Tiale lists will soon be an intolerable nuisance if they continue to grow as fast as they have done during the
past few years. Let us hope, however, that they may diminish rather than increase. $Q$.
Black Alicante and Royal Albert Grapes.-It is said that there is nothing new under the sun; but whether this is true or not I do not now stop to inquire. It is a singular fact, however, that the Grape which is extolled this year above all others (and deservedly so) is two varieties of thed years old. It is true there are certain, and I am backed in this opinion by Mr. Peed,
gardener to sir Edward Walker, who is well known to be a first-class Grape grower. How such a Arape as the Alicante should have so long been almost lost seema mal probability had it not been for Mr. Mredith Mr John Cox of Crown East Court, Mr. Meredr. it would have bean but little known even in the present day. My object in referrinc to this Grape is twofold. see in many of the trade lists sent to me that it is termed the Kempsey Alicante, and in others Kempsey's Alicante. Who Mr. Kempsey is it would be useless to ask-suffice it to say that in some instances the prefix bothers purchasers, making them believe that therc distinction between the Black Alicante and Kempsey's Alicante; and as we have two Alicantes already, we have no occasion for a third. I have previously stated in your columns how the word Kempsey became first attached to this Grape. There are, as I have said, two varieties of Biack Alicante, believe the true one, was known more than 100 years

And in the Vineries of the late sir Ofley Wakeman, Bart., Ferdiswell Hall, with whom I Fived upwards of seven years, there are vere oll labelled the Liverpool Grape when first I took possession of the place; this goes to prove that it is not a new introduc tion. My object however in referring to the Vines at Perdiswell, is to speak of a Grape called the Royal Albert. I have never seen this varie colude that it is in any list sent requires to get into some good hands, like the Alicante, to bring it into notice. This Grape very much resembles the Barbarossa; its bunches are very large, it is a strong grower, and the berries are ex ceedingly large, the largest I have ever seen; it is no however one of the most prolific, but for alarge lrape called on me just at a time when a large bunch was hanging by the don of the Orchid house that prevented my opening bespoke every eye, but unfortunately my 'foreman got them mixed with the Barbarossa, so that I could no send them as I promised, and my employer dying th same autumn, which caused me to leave the neiling $\mathrm{Mr}_{\mathrm{r}}$ Maule's request. The following season however I sent to the person then in charge of them, asking ar a few eyes, but the reply I got was, it being variety worked on it. From that day to this I hav never heard of such a Grape as the Royal Albert. Now as large bunches of Grapes at the present day appear to excite admiration, this variety should on no account be lost sight of. Doubtless it is to be met with in some out-of-the-way place, and let us hope that it will find its way into Mr. Meredith's establishment; when, under so skilful a cultivator, it would not only be brought to light, but astonish the admirers of large bunches and fine showy Grapes; and while Mr. Meredith would reap honours for successfal cultivation, I should be content to know that I had partly been the means of hringing into notice another old Grape worthy of extensive cultivation. Edrod. Bennett, Gro to
Roljambe, Esq., Osberton Hall, W orksop, Notts.
Rough.plate versns Sheet Glass. -In the instructive
papers on Orchid Cultivation now appearing in your columns, the question what glass admitis the greatest number of rays of light is incidentally raised. Years ago this subject was most ably discussed by Dr. Lindley, and Mr. Hunt's valuable paper, which also ppoared in the Gardeners Chromite, was most important contribution to horticultural science. At the time when rough-plate glass came into use, the late Mr. Charles M'Intosh, then at Dalkeith, had a set of lights glazed with it, and with the glass in common use. I attended to the plants under those lights, and the result was most decidedly in favour of rough-plate during the dull winter months, and fully confirmed Dr. Lindley's words, viz," II believe, indeed, that light passes through it as freely, though not so directly, as through transparent glass;" and again, "This glass is prepared by rolling, which destroys transparency without diminishing translucency." This is the trath and essence of the subject, and I have acted upon it permit I have advised its nse wherever I have had opportunity of doing 80 ; and for all important purposes of plant and fruit calture I would use no other glass. Mr. Anderson cites Mr. Thomas Bewley's houses in illustration of this subject; tibose who have seen these splendid houses and magnifficent plants, will admit beyond doubt or question that under rough plate glass the highest success is attained. It is only of recent date that gardeners have begun to study seriously the importance of light in glazed structures The velocity of light is computed at $12,000,000$ of miles per minute; the rays proceed in straight line through the air until intercepted by a denser medium when the lines become bent or refracted. A straight rod held in a pool of water will very simply illustrate this point. In treating of the quality of glass, a most important point is the angle at which it is to be erected. It is most unfair to judge of the merits of glass without correctly considering the angle of eleva tion; in accordance with this, glass may be condemned in one case, and praised in another. When a ray of ligh passes from a rarer into a denser body, the refractio
is towards than the angle of incidence. is less than the angle of incidence. The sine of th angle of incidence antas a constant ratever be the inclination of the incident ray to the surface. Of rough-plate. Anderson says, "the numerous corrugations over the surface disturb the action of light." Dr. Lindley it simply aids in diffusing it. The prism does not distarl light, nor do we find that ridge-and-furrow houses diaturl it in passing into their interior. The elaborate expation ments of Mr. Hunt determined that glass of a pale yellon greer gave the most satisfactory results. In sabstan and colour Hartley's rough-plate is the best yet pas duced. Charles Mc Donald, Woodstock Park.
Spring Bulbs.-The announcement of the disple intended at the Horticultural Gardens of 50,000 balb is quite startling. We shall indeed have an oppor tunity of improving our minds and our spring garden What becomes of the bulbs after flowering? Are the kept to be served out to country customers the next
seamon? If so, some of ns may further improve ome knowledge as to the difference between home an foreign-grown bulbs. Caveat Emptor

Alanuel du Tigneron: Exxpose de divers Procédés de Culture de lit ITigne et de la Vinification par les plus renommés, d'où l'on a déduit, à l'aide d'une longue pratique. la methode rationelle, Par le Comte Odart. Paris, 1861. 8vo, pp. 548.
This is a charming little book, whioh, though its principal object is to show what the anthor considers
the most rational mode of proceeding in and after the vintage, treats at such a length on the cultare of the Vine itself, that it is of great interest to the Horticulturist as well as to the Wine-maker. scientific man, and therefore we may easily pardon his constant rubs against the chemist, some of which are
just enough, while others are devoid of all reason. We may also pardon a little patriotic amour propre.
But withont allowing that the red wines of Roussillon are equal to those of Oporto, or that F rance can produce such sherries as those of Spain, or Madeira equal vins de liqueurs, as they are termed, which at all approuch them, our principal object here assuredly is,
if possible, to get some hints at Vine-growing. The if possible, to get some hints at Vine-growing. The
cultivation, however, of Vines in the vineyard is so Very different from that in an artificially heated house,
that we caunot expect to gain much, and some of the that we caunot expect to gain much, and some of the
favourite processes we must look at with amazement if not with distrust.
It seems clear, however, that the soil which in general suits Vines best is one of a tolerably free a hot country retain moisture when the surrounding
a soil is dry, and which cannot be yemoved without inaterially affecting the Vines. It is, in fact, the same
condition which exists in some of our light lands, which condition whic' exists in some of our light lands, which
lose their fertility almost entirely if the stones are removed. What Vines seen to suffer most from is a soll which sets hard when exposed to the sun, or
beaten down with rain, or a stiff tenacious clay Which will not suffer the roots a free passage, An
impervious subsoil, if it is not too hear the surface, and dnes not prevent proper drainage, does not seem to bo injarious, though in some cases it is recessary to enttings are often made very long, with a view to prevent their drying up too rapidly before they can the production of roots from the base, but ratner from sub upper portions of the rods. In soils which are
subver to be beaten down into a solid mass, it is found
advale adviable to use sometbing by way of mulching, either in the more ordnary form, or in the shape of soil which
does not set. Various manurea are used, either properly so-called, or in the shape of top-dressings, but the one stable manure, which can scareely beything else is raw materially affecting the quality of the vintage $-a$ good Gireen crops are often sown, eoarse putrescent dressings. ins, and even the niatural weeds are in some cases thonght beneficial, but some aromatic plants are carefully extirpated, from some notion that they impair the bouquet. like to admit in the garden. When the cattings are
planted, a quantity of Heath or other slowly-decaying
shrub, as Broom or Cistus, is previously buried in the soil, with a view to supuly br itg decomposition a slight degree of heat, and in the Vineyard itself large quantities of Reeils, Sedge, and other planta, or bundles of twigs are buried in trenches between the rows for the double purpose of supplying warmth and nutriment, but, as might easily be suspected, the Viues often become unhealthy and perish without the Vine dreaser suspecting that the white fungous spawn which he sees has destroyed his plants, has really originated from some of these concealed faggots,
It is curious in open air cultivation to find the Vipegrower complaining, like our own gardeners, of a variety of ciseases, such as ruat, shanking, abortion, scc., and attributing them more frequentiy to the right cause.
He knows that some kinds are more subjeot to parti. He knows that some kinds are more subject to partio
cular forms of these diseases than others, and that even in the safeat varietion much depends upon season and individual constitution. The misohief in the Vineyard is by no means over when the Grapes are ripe, for in the preparation of some kinds of wine an over maturity is necessary, or an artificial treatment after the Grapes re gathere, in the course of Whioh in some weasons some varieties will shank without attaining the state of desiccation which is requisite, wo that instead of the berries approaching the condition of raisins they become sour and quite unfit for the wine press.
In general, Vines like a perfect drainage, and therefore cceed better on a slope than on flat ground, and though great deal depends on aspect, good wines are made on particular parts of some hills which have a northern exposure, though this is the exception rather than the
We are glad to see how completely the Vine mildew yields to the sulphur treatment, the sublimed sulphur
being generally mixed, for the sake of economy, with quicklime.
In conclusion, while we see the importance of caltivating only the best varieties, proper attention being paid to the necessities of the pecaliar district, and of may feel surprised that our gardeners do not pay more attention to selecting those especial varieties which mas suit their soil and appliancea the best, while the frequently combine in the same house sorts which are utterly incompatible, and are surprised that they shoul wet, they cannot expect to avoid shanking and other diseases, nor can they be surprised if the berries mould or pass into a state of fermentation. As a general rule difficult to find two which will not at some periol of growth require a dufference of treatment. We
are convinced that if this simple rule were attended to, we should have far fewer complaints and disappoint ment, both on the part of gardeners and their e mployers.
-Exposition des Produits de l'Horticulture à Caen du 15 au 18 Juin, 1865. Programme. Pp. 12. This is the programme of the Central Horticultural Snciety of Caen and Calvados for the current year. The rules and proposed objects of exhibition are of course inuch the same as in other meetings of the same kiud. We observe, however, one excellent rule which
is not always adopted in country horticultural gatheris not always adopted in country horticultural gatherprizes are determined. There are three prizes which are to be awarded by the Lady Patronesses, who themselves provide the medals-one for the most beautiful collection of plants, a second for the best bouquet, and a third for the plant which is considered to possess the greatest merit. They are to be assisted in their award by the President and two of the members. Prizes moreover are offered for the best cultivated gardens belonging to market gardeners, as also tor the most profitable cultivation of any kind. The particulars, however, which are required for the determination are of too searching and inquisitive a nature to suit Enghish taster. Any ohject of art or any new implement or mechine connected with horticulture is admitted, and a prize awarded according to the merit it may possess at the discretion of the judges. This, under proper regulation, might form a very intereating feature in such exhibitions,

Time was when the Royal Hortienltural Society enjoyed, and deserved, a high repatation for the ex cellence of the papers (dissertations) that were published in its Transactions, and the care and skill with which they were drawn up. A glance at No. 1, Vol. V. of its present Proceedings, which has lately been published, shows that no such merit is now displayed On the contrary, the new Number is a pitiable exhibition of negligence and ignorance, such as we should call unpardonable in the proceedings of the most obscure garden periodical. We take bnt one class of examples, that of bad spelling, which is worthy only of a dunce, and we do not presume to have exhausted even that sehoolboy subject:-p. 2, Jan. 20, will he a ballot for

## po 23 ? Moreover, though this is the first porti new volume, it is without any proper beginuing

Cataloaurs Received.-Francis \& Arthur Dickson I Sons" Catalogue of Vegetablo and Flower Seeds,1865, is a very amplo list, containing a variety of useful revegetables the First and Best Farly Pea is very higbly spoken of.William Woed sons Catalogue of Seeds is another very full lisk, with useful oultural hints. Amongat the novelties we notice Lenormand'e Caulillower, a large Frenol variety, said to be earlier than our English kinds ; and an improved Tariegated Kail, which is highly spozen of for the winter decoration of gardens.-Chivas and Weaver's Cetalogus of Vegetable and Flower Seeds has, in addition to a good selection of these, what is called a monthly companion for ama-teurs.-Lucombe Pince \& Co.'s Seleot Catalogue of Seeds is a summary of the choicer kinds of vegetables and flowers. We observe amongst Marrows a new sort called the Chusan, described as a oompact shrub, produoing an abundanee of pale long green fruit, requiring little space, and being highly ornamental.seleetiong seleot Cabrlogue of Seeds comprises a yood amongst Melons a new hardy Ridgo Melon from the Ionian Islands, with favour "quite equal to Melone grown in a pit," also a descrintivelint of New Jopanese plants.-Richard Smith's List of Plants of the Hir Pribe is a sort of garden cyclonmatia of Conifera, containug a descriptive account of a very extensive colleotion. Mr. Smith's Seed List is of the select class, with much information relating to garden and farm seatrered throughout. -R. Taylor's (Malton) Catalogwe of Fruit, Forest, and Ornamental Trees", offera a meleotion of good useful plants. Among fruite we notice a tolerably full list of Coosoberries. Mr. Taylor's Seed Catalogue is also select.-F. G. Godhoin's C'alalogue of Kitchen Gardew Seods is confined to the more important varieties. The Myton Hall Cucumber is mentioned as one of the best sorts in cultivation.-Flintham's (Rotherham) Catalogue of Seeds is a select list, and is supplemented by the "Useful Garden Almanae."-R. H. Poynter's Retaib List of Seeds is of moderate extent, and includes a calendar of operations.- W. H. Rogers's Catalogue of Nursery Stock is interspersed with many useful dea criptive observations.-Hfnry Brown's (Lirerpuol) Descriptive Catalogue of Seeds is a very nicely arranged full list, with a variety of hints on cultivation and other information on various subjects. Among Pees, Brown's Early, Ezhibition is said to be the earliest in cultivation. - S. Ponsford \& Son's Select Retail Catalogue of Seeds is what its title indicatea, and contains cultural hints for the principal subjects--The London Seed Company's General Price Cwrrent is a full list of Joĥn Keynes's Descriptive Catalogue of Dahlias offers a score of novelties, along with a select general collection. Most of the former, we observe, have won Firstclass Certificates.-Hooper \& Co.'s General Spring vegetable seeds and roots, amongst which we notice a separate list of aquatic plants. Messrs. Hooper also offer Etruscan Pottery in considerable rariety

Of Scottish Catalogues we have before us:-Peter S. Robertson's Sonoer's Guide, an excellent and correctly got up list of farm and garden seeds, accompanied by descriptive notes and cultural hints.-W. Drummond \& Sons' Descriptive Catalogue of I'egetable and Flower Seeds, another good descriptive list, select yet ample, with very useful notes. Their abridged Selection of Flower Seeds, with directions for their culture, is a sort of "haudy-book" of the most popular flowers, chiefly annuals.-Smith of Simons Cultural Guide contains the most ample information of any cata-
logue we have met with, and deals the most unsparingly with the uselessly long lists of varietios one often meets with, both as regards vegetables and flowers. Besides the general list of azmuals, there are six separate selections for different purposes, prominently introduciag about 10:) of the best sorts.Dmonis Laird \& Laing's Select Seed List discards all inferior sorts, and offers amoug other things some 40 or mare of "highly omamentrl foliage plants," such as are used at Battersea, in Paris, and elsewhere.-J Stewart of Bons seed Catalogue is less deseriptive than most of the foregoing; their Rose Cataloges is full, and gives the usual information.--Roughead if Park's (Haddingtom) Solect List of Soeds is confined to the Borts most worthy of recommendation.- Thomas Kennedy of Co.'s (Dumfries) Forest and Ornamental Trees, and Select Vegetable and Flower Seeds, afford ample choice of materials in these respective departments. The varieties of fruits are very fully described, and the seed lists are extensive, with directions for cultivation.
Of Irish Lists wo have, in Thomas MoKonrio \&s Sons ${ }^{3}$ (Oork) Vegetable, Flower, and Parm Noeds, an ex. ceedingly neat and well got-up list, with dencriptive particulars and culturel hints. It also contains numerons figures of horticultural implements.
Of Foreiga Lintry Vilmarios Andmious et Cie.' Catalogue des Graines arbres at arbustes offers an M. Filleviolld's (à Manosque) Extrait des PrixCowpants is priced summary of his collection of the new rosecoloured Robinia Decaispeana

## Miscellaneous.

Mr. Miers. - We learn from the A thencoum that the Emperor of the Brazils has nominated Mr. John Miers a "Commendador," or Kuight (of the highest class) of
the Order of the Rose, aud accompanied the insignia by the Order of the Ros
Mushroom Beds.-In the formation of Mushroom beds, it is necessary to imitate as far as possible the conditions under which they are found growing naturally. In summer, beds may be made in any shed or cellar, and even in any shady situation out of doors,
if covered with thatched hurdles to keep out the rain. Beds out of doors should be made deeper than those in a proper house, and they will be more lasting if the droppings are mixed with one fourth part of mellow turfy loam. In forming the bed, collect sufficient resh horse droppings, spreading them out in any airy shed to dry, and turn them frequently, not allowing them to heat or ferment to any extent. After they
have been so turned and dried as to prevent the possibility of their heating too violently when put together, make them up into a bed about l foot deep, been carefully prepared, gentle fermentation will soon commence, and by inserting a thermometer, the rise or fall of the temperature can be ascertained. If it rises too high, the surface of the bed must be loosened with a dungfork, and when showing symptoms of declining must again be beaten firm. When the temperature of the bed is from $75^{\circ}$ to $80^{\circ}$, with no danger of its rising higher, put in the spawn. This is
done by making holes about 4 inches deep, and 9 inches spart, inserting pieces of spawn abont the size of an egg, and covering with the dung, pressing it closely about the spawn. It is of the greatest importance below $70^{\circ}$, nor rise above $80^{\circ}$ for a month after spawning, and it must be closely watched, lowering the temperature of the house, or covering the beds with mats, or straw as may be necessary. Within a fortnight after spawning cover the bed about 2 inches thick with good soil a covering of about 2 inches of cowdung (in about the same state as to moisture as the soil) is spread over the bed, it will last longer, and produce a larger crop of Mushrooms than if covered with soil only. After the bed has been made up and spawned, keep the house shut up, excluding the light, and use the syringe
occasionaly to keep the bed moist. This will be all occasionally to keep the bed moist. This will be all
the attention required. The most suitable temperature for beds in bearing is $50^{\circ}$ to $55^{\circ}$, as a high temperature causes the Mushrooms to come small; and watering the beds wheu in bearing causes the young Mushrooms to be productive, using water about the same temperature as the bed. Cure must be taken in gathering the crop, so as not to dislodge or destroy the young Mushrooma. Dickson \& Sons' Seed Catalogue.
Apples.- The Dorchester magistrates have decided that Apples are notagricultural produce, and therefore not exempt from toll whe
Age of Vines. - The age to which the Vine continues to bear well ranges ordinarily from 60 to 70 years, often more, and under favourable circumstances of site and soil it is long lived. In the Gironde, when properly attended to, it will last from 100 to 150 years. In the commune of Pauillac, in a gravelly soil, there are Vines 200 years old; whilst at Pessac some are shown of a yet greater age, planted, as is there traditionally
believed, in the 14th century, during the pontificate of Clement V. A Vine in Burgundy is credibly recorded to have lived 400 years, and in Italy plants three centuries old continue to flourish productively. Denman's Vine and its Fruit.
Servian Flora.-One peculiarity of Servia, Mr. Denton says, will not fail to be noticed by an English traveller. The Flora is almost entirely English. The banks skirting the roads which wind through the forests are carpeted with the wild Strawberry, and the open glades which rur into the woods abound with the wild Raspberry; the thin soil on the steep sides of many of the hills is covered with the Whortleberry; the weeds and wild flowers of the fields also are those which are commonly met with in England; Violets and Daisies, nots and Speedwells, Orchises of all shades, and wild Garlic, Meadow Saffron and the Cuckoo flower, or Ragged Robin. The hedges are powdered with Honeysuckle and the Clematis, and fringed with yellow Broom, with Bramble bushes, Dog Roses, and the White and Blackthorn. Trees, indeed, that are comparatively rare in England are met with in profusion in Nervia. The wild Pear and Cherry, the Plum, and the Apple, may be seen in great numbers in the woods the Acacia and Laburnum are met with by the sides of
the roads, and Lilacs abound on all the hill sides. the roads, and Lilacs abound
Quarterly Review, Jan. 1865 .

## Calendar of Operations.

## (For the ensuing week.)

Tre necessity of acting on physiological principles in all gardening operations is now pretty generally acknowledged. Nature works by rule, as "surely as the expert artisan or mechanic, and our wisdom consists in
first finding out her methods of procedure, and then imitating them. By a long course of experience, guided by a habit in time become skilful; but there is a more compendious method by which much time will be saved, and that is by reading the results of the observations of others. Let us recommend to every young beginner interested in plant culture the importance of studying well Dr. Lindley's "Theory of Horticulture. Many have acknowledged that they $v w e$ much of the pleasure and success which they have found can gardening to the perusal of that book; and no one can e ignorant of first priacour of years will be superseded morncurs acquainted in this easy manner with the discoveries of others, and with the great laws of vegetable growth which the collation of those discoveries has brought to light. A man may indeed be a great reader, and yet not a practical gardener; but a
judicious application to books will always shorten his judicious application to books will almays shorson why certain mode of planting and potting is more efficient than others, it is very desirable to know on many accounts, and a man must either discover the theory by extensive research or learn have named will prove a safe guide.
flower garden and plant houses.
The weather being still favourable for carrying on out-door alterations, soils for flower beds may be prepared, and digging and trenching where necessary may belpushed forward with advantage. The propagation of plants for massing must also now receive attention. Stock in pits should likewise be looked over, and any should be to there there is a gentle heat, to force them into growth for cuttings.
Auriculas. - Whenever the weather is favourable et these have as much air as possible.
Bedding Plants.-These, if in pots, must also have
ir whenever the weather is mild, but means of protec tion at night must be at hand.
Carnations and Picotees.-Draw the lights off these in the day time when dry, but let them be put on again at night.
Cinerarias.-Secure these from frost, from which they are very liable to suffer. Strong growing plants may now require a shift, in order that their pots may
he well filled with roots by flowering time. When fully established they may have an occasional watering with weak liquid manure.
Forced Flowers.-Successional batches of Roses and Dutch bulbs may now be placed in heat. Among Tulips one of the best for forcing is Samson, a handsome variety, belonging to the Van Thol section Where pots are scarce, bulbs of all kinds beginning to push may be advanced without injury by being placed thickly on soil under a greenhouse stage. They can afterwards, whon convenient, be taken up and potted. Plants in pots of Lily of the Valley and of Weigela rosea should now be placed in heat.
Pelargonidms.-These will now be growing slowly therefore in fine weather let them have as much air as possible, consistent with the proper temperature Fancy varieties may be kept a little warmer tha

## ordinary kinds.

Primulas.-Water those in bloom with very weak liquid manure occasionally, and bring others forward for succession.

## FORCING GARDEN

## High' temperature must still be avoided, or unhealthy

## growth will be the result.

Asparagus.-Prepare a new bed to succeod that now becoming exhausted. On fine days give as much air as possible consistent with maintaining a proper amount of heat.

Carrots.-Sow a little Dutch or Early Horn in a 2-light box on a gentle bottom heat.
Cucumbers.-Worn out plants in houses may now be rooted up, the beds renewed, and their places filled with young plants.
Peacees.-Admit air freely whenever the weather is mild, and keep the atmosphere moist, maintaining a steady night temperature of about $50^{\circ}$. Very early
houses in which the fruit is set should be afforded a nice growing temperature, syringing liberally to prevent red spider, and keeping the border in a healthy state as to moisture to secure a vigorous root action,
Pines.-If not already done, young plants growing in beds that have been some time planted will be benefited by having the soil loosened up as deeply as can be done without injuring the roots, giving it a liberal soaking of tepid water if it be found to be too dry. The water should be applied by means of a pot with a rose on it, and not so fast as to flood the for if this is done the soil will be rendered almost as close as before forking up; indeed, careless watering is the great cause of the surface of the soil becoming
close and hard, and should be carefully avoided. Endeavour to afford a nice bottom-heat, with a thoroughly moist atmosphere, and keep the plants growing as freely as may be consistent with preserving them dwarf and bushy. Have a constant eye to maintaining a succession of fruit, or securing a supply at the season when it may be most wanted, and let the treatment of the plants be regulated according to circumstances; this is a matter which demands considerable
forethought, and which can be successfully manage
Potemos. If not a ready done let som
a frame on a gentle bottom-heat a frame on a gentle botom-heat.
Vines.-Be saisisfied with as low Gre-heat as may be considered safe, but shut upe from allowing the thermometer to rise cont shut up early, will to some extent economise fuel, and will be mued more congenial than having recourse to much fire-heat
hardy fruit and kitchen garden.
Digging and trenching may now be carried on with activity, and, where necessary, drains may also still be put in. Wheeling should, if possible, be kept for hard weather.
Apples.-Pruning and thinning of these must now be pushed forward with expedition. Where necessary, root-pruning may also be performed ; but this kind of work is best done in the autumn.

Pears.-The observations made in reference t Apples also apply to these.

## The $\mathfrak{a g r i}$ ultutal $\mathfrak{G a t e t t}$.

SATURDAY, FEBRUARY 11, 1865.

The past week has been of unusual agricultural interest in London. On Wednesday a large and influential meeting assembled for the adoption of resolutions deelaring the unfairness and misohievouaness of the Malt duty; and a deputation on the following day waited on the Chaveelior of the Exchequer, to urge the propriety of redueing or removing this tax. The renly of Mr. Gladstone was couched in the most general terms, and merely stated that if , at the end of the financial year, a surplus of revenue should appear, it would be the duty of the Government to apply it towards such a reduction of taxation as would benefit the whole community alike, and the agricultural interest therefore with the rest. If, however, the present duty, as is alleged, has
hitherto pressed more heavily on the agricultural than on any other interest, it appears to us, notwithstanding the apparent fairness of this reply, that we have that priority of claim on Mr. Glad sToNe's consideration which he denies.
On Thursday a meeting was held in St. James' Hall, to raise a fuad for the establishment of a Charity, to bear the name of the late Joun Fowler, on behalf of labouring men and their families injured by field machinery. Lord Fayersiian presided, and 40 or 50 gentlemen from all parts of England were present to testify to the great national loss which the death of Mr. FowLer has inflioted. Lord Portman and Mr. Holland, M.P., were detained from the meeting by illness. Ample testimony was borne by Mr. RUCK, Mr.

Willians, Mr Satiders, Mr Eddisont and otbers, to Mr. Fowler's distinguished public services, and to his high-minded personal character. In particular, a most eloquent eulogiam was pronounced by Mr. Eddison of Leeds. And we cannot doubt that in honour of a memory so worthily held dear, not only over the country generally, but in the large town where Mr. Fowier had latterly resided, a sufficient sum will be collected to establish the proposed Institution, by which his name will be most appropriately handed down.
On the afternoon of the same day a meeting assembled in the same room to consider the state of the law with refereace to the use of the public roads by travelling agricultural engines. Lord Kinnaird presided; and it is a great proof of the interest which the subject excites that several hundreds of agriculturists should have assembled to discuss it at the very time when the deputation on the Malt Duty, which must have taken away so many, was engaged with the Chancellob of the Exchequer. Mr. Calthobp, M.P., and Mr. W. Martin, M.P. moved and seconded the first resolution-the latter relating the history of one of the first orders which the Home Secretary had issued to forbid the travelling of these engines except during the night; and showing how it was the work of a very small minority of the residents in the district affectel by the order, and in fact ultimately the work of only one, and he a man who had to confess that he had never met or seen one of these engines in his life. A dozen or more gentlemen, not only agriculturists, but men iuterested in mining operations, for whom these travelling engines are of the greatest importance, bore testimony to the stoppage of all work which must fullow these orders of the Hoare Sechetary. Mr. Harrison pointed out that the clay land of the country, generally in small holdings, is dependent on hired machines for any share it can have in the advantages of steam cultivation; but hired machines will no longer be workable at a profit if the daylight is not to be available for shifting them aud placing them. Mr. Nicuols, of Ilchester, has four of these machines, and has travelled 600 miles of road with them, and had never yet met with an accident. If however he is driven by the law to travel in the night, this is not likely much longer to be the case. It was on all hands agreed that the danger of mischief is in fact much inoreased by insisting upon travelling by night; that by daylight it is nothing; but that anyhow a horse now-a-days cannot be considered fairly broken in until it is broken to steam.

A Deputation from this meeting waits on the Home Secretary as we are going to press.

The disoussion on the Agricultural Utilization of London Sewage lasted over a second evening before the Suciety of Arts. Last Wednesday Dr. Voeccier, Mr. Sidney, Dr. Gilbert, Mr. Alderman Mechi, Mr. Rawlinson, Mr. Bowing, Mr. J. T. Harbison, C.E., Mr. Stuart Barker, and Mr. Bachoffner addressed themselves to the subject.-Dr. Voelcker's speech discussed chiefly the influence of the varying character of soils on the question. He showed that light and sandy soils are the only kinds adapted for dealing with the enormous quantities which constitute the drainage of London.-Mr. Sidney entered on a general discussion of the experience of the different towns where attempts had been made to deal with it, and showed that heary dressings of it offer the only instances of profitable experience.-Dr. Grlbert offered a defence, which seemed to us complite, of the Royal Cummissioners' proceedings at Rugby, which had been attacked by Mr. Walker.-Mr. Alderman Mecei defended Baron lifebig's recent letter, which he declared to be "exhaustive and conclusive" of the subjeot. - Mr. Rawlinson showed that the cost of the small dose plan is altogether fatal to it. - Mr. Bowing criticised Mr. Morton's paper in the interest of those schemes which propose to deal with sewage in small doses.-Mr. Harkison dealt with Baron Liebig's argument that the utilization of sewage is the salvation of British agriculture. On the contrary, even on the most extravagantiy small dose plan, it would not overtake a tithe of the area of English agriculture, so that nine-tenths of that area are still certain, on Lifbrg's principles, ultimately to go to "rack and ruin."-Mr. Stuart Bareer in particular defended the Carlisle experience, which he declared to be encouraging in the highest degree; and

Dr. BACHOFFNER argued in favour of the large dressings rather than the small-in favour of the allopathic rather than the homoopathic treatment of the soil.

The discussion was thus slmost entirely in favour of applying sewage in quantity, as in water meadows, not by pipe and hose in small dressings. The Chairman, Mr. CEadwick, however, evidently favoured the latter view, and alleged instance, whether of a farm or town, by aotual experiment, even in flower pots and with water pots, certainly with water cart and small field plots, before any particular plan of operation is adopted. He concluded by emphatically declaring that on this subject he could not take the opinions of the farmers, for their practices and
prejudices all ran connter to the use of liquid manure.

Now there was one point that cropped out occasionally during the debate, and which is WICK's, on which a reply ought to have been made, and would have been made, had it not been for the lateness of the hour to which the discussion reached. The ground on which Mr. absolute sovereignty of agricultural experionce in the decision of all agricultural questions.

This is not urged as a doctrine, but as a fact. It is not that so it ought to be, but that so it inevitably is. Where can we find a better illustration of this truth than Baron Liebig and his letter give us? If ever there was an autocrat in science, or one whose mere authority would carry everychemistry ; and yet he is of course as helpless and as powerless as a child in anv attempt to disprove facts or thwart the course of Nature. He confesses simply enough that he tried it once and failed; and the great German philosopner fonnd that he covild no more thwart the course of Nature than the old Danish King could stem the tide. It will be seen, however, in his letter, whioh appears in our columns to-day, that this is really what he aqain attempts to do, He declares that according to all the lights of science guano is worth rather less than 8l, a ton. Is it therefore worth rather less than worther more than $12 l$. a ton. This, indeed, he calls a "fancy" rice. On the contrary, it is the real price, as any one going into the guano market will find. Agricultural experience of guano during 20 years of a trade exceeding $1,000,000 l$. per annum, and over an acreage of probably more than 1000 square miles every year, has determined its real valuer of chemical authority to upset it.
And so with other points and topics in the agricultural field: once get the agricultural verdict fairly and it is final-it must be the true one. Whatever may be the prepossessions of the man of science there can be no appeal. Hence it is that if we can show how the analogy of ordinary agricultural experience bears upon the sewage question, and still better, if we can quote the records of actual agricultural experience of sewage elsewhere in illustration of the treatment of the question at the metropolis, we shall have thus obtained the only safe guide through its difficulties. And this was what in Mr. Morton's paper was attempted. Lord Robert Montagu does not indeed see how the analogy of agricultural experience leads to the conclusion that it is the best policy to put sewage on Girass land in quantity as tbat the farmer puts on his manure sparingly, carefully calculating how much the crop willppay
for and not putting more. But if agricultural experitnce proves anything, it proves that plants must be treated according to the nature of them. A rapid succulent growth, which is what we want in Grass, is obtained by excessive manuring. The London market gardener, as we showed the other day, applits 60 to 80 tons of solid dung per acre to the Cahbage crops of a single year. Aod it is consistent with this that the grower of a single aore of Italian Rye-grass, where succulent growth is also wanted, should put 10,000 tons of sewage on it in the course of a single year.

But we are not dependent only on analogy ta guide us here. They have for years and generations been putting 10,000 tons of sewage per acre over many hundred acres of poor land near Edinburgh. Here is a case which, as it seems to us, fairly closes the door on any further discussion. If ever there was a satisfactory and conclusive bit of agricultural evidence on the subject, it is this. Three hundred and fifty acres in extent, and 50 to

100 jears in duration-it is altogether unassailable. By the use of sewage in quantity, these 350 acres are made to keep 2000 cows during the season of growth. They must yield 50 tons of Grass per aere to do it-or a ton of Grass to every 200 tons of the stuff poured on. This, however, the advocates of minimum dressings declare to be a poor result. All we know is that there is nothing ike it anywhere else in England; and taking the character and continuance as well as the quality of the produce into account, we don't suppose that there is anything like it anywhere else on the face of the earth.

Add to this result the one which Mr, Lawns observed at Rugby, and the argument in favour of abundant dressings appears to be irresistible. He found that the increase of produce under sewage was very fairly in direct proportion to the quantity of the stuff put on. Lard Robert Montagu indeed denied this, and quoted-whence, we know not-figures declaring that while 3000 tons of sewage per acre raised the growth of Grass from 9 tons to 22,6000 tons added only one-third more, and 9000 tons only one-fifteenth. That would be $9,22,29$, and 31 tons per acre for " nothing," and the three successive dressings respectively. The figures, as we read them in Mr. Lawes report, are not $9,2 \%, 29$, and 31 , but in one instance $9,15,27$, and 33 , and in another $9,16,23$, and 27 tons per acre for the successive dressings.
The successive steps were not 13, 7, and 2 tons of increased produce as Lord Robert Montagu alleged, which would have justified his assertion of diminishing effeot from an increasing application, but 6,12 , and 6 in one case, and 7, , and 4 in another. Putting the two cases together, the Grass which grew where the heaviestdressings were applied was 3 tons 13 cwt. for every 1000 tons of sewage, and where the least quantity was applied it was 3 tons 15 ewt. yer 1000 tons. This seems to bear out the assertion that the Grass produced is in direct proportion to the sewage applied. And this (with the Edinburgh results) is about the whole of what has been accurately ascertained upon this subject. We contend, in conclusion, that we re only safe, as we stand upon these, the actually aohieved results of agricultural experience.

## PRESENT POSITION OF THE FARMER

I should not have ventured to trouble you with any comments of mine on Mr. Williams's lecture to the Hungerford Farmers' Club (p. 58), bad it only appeared in our ocal journal-it bears so much more the appearapce of a political squib than a contribution to English farming. But as you have given it a leading place in the Agricultural Gazette, I think it right in the interest of all the farmers in these southern counties to protest against the assumption therein contained, that at the present prices of corn and meat, a tenant farmer on good stock land can make only 8 per cent. of his capital-that on 400 acres of land, worth $1 l$. an acre, or 30 s., including tithes or taxes, he can only grow $1300 l$. worth of corn, or keep more than a flock of 300 owes-and that his only refuge ip to "eft solitary" and bemoan the present times (times of unexampled prosperity to every one else), to quarrel with the fixed payments of rent, tithes, and tazes, and to raise some vain expectation of a "good time coming," through endeavour to show that things are not quite so bad as they seem to him; and that the tenant of that model farm of 400 acres which he has instanced, ${ }^{\text {e might under }}$ preserit prospects and present prices have presented to the listeners at Hungerford a much more prosperous balance sheet, and thereby lightened the sombre cloud
which must have overcast the conviviality of their which m
Xou are quite right in characterising Mr. Williams as " \& gentleman of well-known ability in the agriculand power of stenm. Had he not been biassed by his preconceived opinions he would have made good uee of it in drawing up his model balance-sheet, instead of putting it apologetically in a postscript, "fearing he might be thought to teach radical priuciples."
Had he done so he would have debited the yearly expenses with a higher sum for steam-engine, and less than 13 horses' keep. His ploughing would have been better and deeper, and the total annual outgoings perhaps quarrel, but with these items I have no fault to finch quarrel entirely with his receipts. I have bad the pleasure of riding over that neighbourhood frequently grod Wheatan hounds. I know it to be a generally vated of growing 5 quarteif clean and moderately cult that in fiair seasons, and with proper attention, it wiil bear good crops of Vetches, Rape, Cabliages, Swedes, and Beaus; and I contend that by a proper application of these crops to feeding his stock fat instead of selling it in store condition, le would reap from his 92 acres Wheat at least 450 quarters $=9002$; from his Barley 1728l. instead of $1319 l$. In addition his cory receppt
instead of an average of $26 s_{s}$, making a return of twis in lien of the 220l. credited, and cattle and pigs in like proportion ; but I will not add any portion of the stock receipts to the the for corn. Supposing tha
stock to realise only the same sum beyond expenser, and deducting the $1663 \boldsymbol{l}$. annnal there will still remain to our model tenant the some balance of 6406 .-bore than 20 per cent, on bin capital.

To prove the accuracy of these figuree, I am aman it would be necessary to prove correct the two folloming theorems:-18t, That the food consumed in fattomes animal from store to fat condition will be paid for 4 present prices of meat, not by the increased valne o described will, if properly cultivated and quanty abor 5 quarters of Wheat to the acre, or an equiralent spring corn every alternate year. Should any one dem spring corn every alternate year. Should any one dem
these propositions (which I believe are now these propositions (which I betieve are now acceptad b
most thoughtful farmers) I would refer them 10 some articles in your Paper last summer on Condition in land, wherein I endeavoured to prove both theoretically in practice the truth of them-the proof of them mor were far too lengthy for this article. I will men mention the great saving of expense through menty cutting and pulping machines, and of cartage thrond portable grinding mills, which have been of mant introduction, as additioual evidence of the former, in the continualiy reported superiority of the effecto d corn and cake-made dung over the application of rothan and rain-washed straw as confirmatory of the lither proposition. In fact, Mr. Williams quotes an fatang of a neighbour of his who has adopted this plan rith success. These are evidently times of transition. prices have passed away ; new prices have not 5 settled down. How much more worthily might
Southern counties' farmer take a leaf out of the 1 Lothian Club's book, where rents are much higher than here, and yet they look hoperully on the future. much more sensible were it to employ his energiesia growing more wool and fatting more meat, now tha the prices of these products are so tempting. Tue increase of corn will follow as a mattor of currse, and ? after a time prices should retura to their former lereh he will be prepared to reap the full advantagn
Invoking Hercules in the shape of the Chaucellor of tie Exchequer will never be half so profitable as prim his own shoulder to the wheel. J. B. M.

EXPERLMENTS ON GROUND COPROLTTES
In the Gardeners' Chroniole of Nov. 22, 1861, Itw the pleasure of laying before your readers the rand of some experiments on coprontes (gro in favo their value as a manure. The pluts then experimentad on were considered too small to obtain trusturatity results, therefore in the following season one-eighth il an acre was taken for each experiment.
The field in which the experiments were tried w the same as on the previous occasion. After as whit fallow it was ploughed and managed in the usual wi. A prece of ground was measured out througa centre of the field, and divided into six equat palar one-eighth of an acre each. The malures usel
bone meal, ground coprolites, bone aslh, dissilved bons, and dissolved coprolites. One plot remained anut nured. All the manures were mixed with dry aum ashes, and sown by hand, an equal quautity bem measured out for each drill.
The quantity of manure used, and the cost peem will be seen by the following Table:-

Plot.

## Bone meal Bone-ash

## Bone-ash Unmanured <br> Caprolites (ground)

Dissolved bone
Each plot had 52 drills at 18 inches apart, and h seeds were sown with the manure on the 18th of dos appeared very resular they were then hoed thinned in the usual way.
As they advanced in growth they ran a great dent necis, the buibs being very irregrular in size. most regular crop in appearance at the time of euse was that on which th3 ground cenprokics In Norem ber they wenerally was of a fair averalid, an, weighel In Plot No. 1 all the roots were wei hed,
The following Table will show the separate regutit o the weighing:-

## wedes manu ef with ground coprolites have given the

 weatist yield per acre. LThis must be altogether erceptiona!.] Those manured with bone-ash are second ercoptiond those manured with dissolved Loves stand next. b. That and nortion meanured with dissolved coprolites, That pertion little hetter than the mmanured portion, the reason of which may be this: the dissolved coprolites were iresh made, and there might have been a little frue awid present, and this have injured the ycunc plant; or the plot being somewhat shaded by an archard, the plants might have been checked in that way, as I wherved that the remaining Swedes in that what grew much larger afterwards, the season being olot grew mid.The above experiments were carried on under my own superinterdence and with the utmost care. The own suphers haid before your readers, they can draw their unn ent!clusions from them. The experiments made the following year I hope to have the pleasure of s.muling to yni in the course of a week
Kensington, F.C.S., Mloolham, Somerset.

## REPORT OF BARON LIEBIG ON METROPOLITAN SEHAGE.

TuE following is the communication from Baron The President of the Royal Academy of Science at Munich, on the subject of the utilisation of metropolitun sewage, which was read at the Common Council last week. and referred by it to the Coal and Corn and Finance Committee for consideration:-
to the might hon. the lord mayor of london
Mr Lorn. - In complianee with a request on the part of

 than comcty at large nend the towns which furnished it. apokelu on this question leads me to believe that the and npuen of persons in England, even the more enlightened,
num upon sewage as a nuisurce; they thiuk it ought to be緊 14 of iy iny me ms, and the more qumekly the better. It dress my remarks, and if my endeavours to convince them or thus prevent over-hasty gtops being taken, the task I have
set tujself woold be fullilled.
These questions therefore, which have been elucidated already

 point, namely, for certain calculations, in order to reduce to e more taugible forme tho result of my inquiries. These figures are not put forth as absolutely correct; indoed, in the present
state of the roatter no person in the world is sbje to state them with perfect accuracy.
Whoover is conversant with the history of agriculture will
know that in the later trat of the that contury preotioe found a means by the cultivation of Clover and othor fodder for putting of rotation of crops. The restilt was an increase in the agrioul
 the more flesh the more manure, the mere manure the
more qrain,",
At that time no one bad any correct idea of the cause of the fertility of the soil or the effect of manure, nor did it then occur to ang body that the fertility of the Clover fields would ever have
an end. The whole system of farming was based on the pro duet in cf farmyard manure by means of fields of fodder. That

 Thans dited away; Turvips, too, would mot thriver any more as
they bad done. The very expreasion, Clover sickuess, showed that the cause was not supposed, to lie in extbuustion
of the soil, as in the case of cornfelde, but was thougbt to aries from the thield being ailing.
a doma tbat the producibleneas of a farm could be lastingly monhtine: hy the proper rotation of crops without a surply

Ne know the cause of the efficacy of phosphate of fertility lies guano. We know with certainty that the cause Ior the tormation of the body of the plants, of the roots of
the leavies aud fruit. is very limaited; and that man, with all his ant and skill, is
unable to get fruit from a field when such constituents are
wanting. These, as long as they are in the ground, are called "alimentary matters." but out of it " manures." Both names signify the same thing. products which the farmer brugs to market he sells a part of the active ageuts of his fields, and that, accordingly, the harvests must gradually grow loss in
The following Table gives a summary of the matters which are drawn from the soil in different crops

## Potash

Phnsphoric acid

## 

A glance at these analyses of the ashes of phants aud the
ashes of flesh suffices at once to make intelligible the effect of phosphates (bone-dust) and of puanco. Both restore to the soll two conditions of fertility - phosyhoric acid and nitrogenwhich it had lost by centuries of cultivation and removal. The stores ; but which, on being uugmented, again put tho field into its former state
The inhalitant of the town comsumes in the bread, tlesh,
and vegetables which ho eits the connponent parts of the-e and vegetables which ho eits the counponent parts of thee
fi elogs, whence these differeut fuods sprung, and whicle wore the conditions of their growth. Hence all these accumulato towns in the fluid and solid roidings of the inhabitants. of the following analysis it will be ssee that the excrement
ond those of another (II.) who feeds on meat and lut little bread, represent a mixture of the incominstible parts of their food:-

Potask
Plosphoric acid

| I. Individuab. | $\begin{array}{\|c} \text { II. Indi. } \\ \text { vidual. } \end{array}$ |
| :---: | :---: |
| Total |  |
| 23.69 | 40 |
| ${ }^{35.62}$ | 31 |
| 35.19 | 29 |

The relation of the town to the country, or of the phace
f consumption to that of production of food, is thus made of consumption to
intelligible at once.
In the English towns in which water-closets are introduced, these matters form the princinal ingredients of the in the streets "r stables, containing the constituents of their fonder ; becides thiq, the constithents of the fond brought
from the ocean; and, finally, the rinings of the atelyen, and yart of the blowd and offal of the slanghteren animals. The ingredient, do not enter the sewers, being applied to warious
purposes.
Thus it will be easily understnod that if a possibility is offered to the farmer to get back, as sowage, those matters which vegetables, and if he gives bis ficld the sinue, tinth in quantity and quality, as that he took from it, then its fertility way be assured for an enilhss number of years. with cunstancy if the causes of it are fllctuating, and that :
field cannot constantly yield crops if the conditions of their growth continually decrease.
There is, perhaps, no land where the truth nf this simple law of nature is so patent as in England. The British farmee has been euabler to win from his fields crops surptising thise which have ever been gained from a like superfizies; not, houl ever, because he is more skilful or diligent than the husvani
man of other tiands, but becauce lie acts more in hurm he law on which production depends. In no ciuntry a Sngland, is the faruer so

without their audition it would be iop possible to preserve for
continuance the present high produce of his fields. But, con sideriug the neeans by which they are obtained, ti e high cenps
are not signs of a lasting store of their conditions in che fields are not signs of a lastiug store or the British farmer considers an outlay for manure not as a dountul experinitura, distioguishes the farmurer from the manu'acturer is that the former is not so accustomed to calculate as thy latter. The rately the raw material which he intends to whrk ip with his
machines; while the farmer, in the chnice of fitting mavures machines; while the flismer, land, is gnided by vague untions which he calls has experience. He mu-t wait for his crop to see it be has colls him which pariures and in what quantity his field requires, he is as yet unacquanted with fand this is the
rasan why he is almost unable to estimate the worth of sewage. This, however, he will sonn appreciate when
experience teaches him iis effects. Un to this monen

 ond, and a glance at tye following analysis of boues and guano ashes shnws that in one there is no potash, that in the other only traces of it are

Potash
Phosphoric acid
Lime, magnesia

I shall show that the soware is especially rich in by the trade : and that when it is emplojed, then only is the system of culture a rational one.
We will now examine more attentively the different matter which sewage contains; and bv determining their trade valu
we shall be better able to julke what may be tine worth we shall be better able to julge w1
The matters contained in sowage of most value for husbandres are ammonia, pctash, phosphoric acid. But besides these there is a large amount of sulphuricacid, lime, magnesia, irou, and cowmon sult; all which arc also aliments of plants, but which I will not furtber allude to hore
manuring purposes, they are not articles of trade. Ammonia. - This is prasent in lages quantity in the
voidings of men and anmals. When manufactured it is voidings of men an water and animal seffrase (horns, hoof
obtained from kas
bones, \&c.), and is sold as sulphate of ammonia and sal
ammoniac. The manufacture of those salts camot be
extended beyoud a certain limit, as the raww naterial is not to be obtained in unlinited quantity.
The best sarts of Peruvian guano contain st per cent. of inmouia: thus, a yearly importation nt 300.000 tuns of guano is a quantity representing luo, ©ov of sulphate of anmonia.
This is more than could possibly be manfaetured in two years in all England, France, and Gंermany togethor. Salts of ammonia are used as mamure onily in small quantity for the cumparatively luw price arises from the suiall demand to be iurposes of busbandiry. When Peruvian guano ceases to be imported, the price of salts of ammonia may considerably
rise. The present price of culphate of ammonia, contaiuing
2. 25 per cent. of pure nummana, is $15 . h$ lut. ; ; p pumd of ammonia
would thus be worth Ploop,horir Acil-This acid is found man all parts of tho world - in Engiand min cuproites. in spain, Canada, the Antilies, tce,

The phosshorie acid in the Ihosphates can ouly be reckonod

late salts. - oo ashies are the chiet source of potash. O late saits of potash have boen manufnctured from sea water
well as from the upper stritn of ruck sait near Stassurt, but does not seem that either yields so much as was expected, and the manufacturing cost of pure potash salts leath ona to think that it will not bo possible to supply it at lose than ity presout
price. The purest sulphate of protuan tronghtit to marhet ewon
 These, tue market pricos of ammonia, phosphoric acid, and potash, I shall take as my guite in estimating the worth of
sewage ; but I shail enuploy them first to fix the worth of Peruvian guano
The best sorts of guano contain on an average $8 \frac{1}{2}$ per cent. a insoluble) and 0.6 per cent. of putash, aud accurdingly the value of 2240 lb . is as follows:-
One ton of Peruvian guano contains-

|  | . | penco. | pence |
| :---: | :---: | :---: | :---: |
| Ammonia | 190子 | at 6. | 1257 |
| Phosphoric acid | $\left\{\begin{array}{l}\text { fir soluble } \\ \text { cie }\end{array}\right.$ |  | 215 |
| Potash .. | 181 | \% 8.84 | 51 |

This is the real value of 1 ton of Peruvian gun $15 i 5=-1$. 148. This higher price that the farmer pays for it (13t, 100.) is a fancy price, which by some agricultural chemusts 1 sent main-
tsined to the evident detriment of the farmer. Thesc calcula-
 fuow in, that the resilne of Pornvion gatmo ther lixiviation

These figures show, therefore, that were a solution of those jet, over an acre of land in Bogenhausen, a 4 -inch stratum of 1910 lb . of potash, and 888 lb . of plosnluoric acid; and that not a pound of ammonia. potash, \&c., would penetrate
tbe upper 4 inches had been siturated with them. In the year 1955 the absorbent power of siils had not yet
been discovered. Tve doctrine at that time was that plants derive their nourishment from a solution of ammonia, potash,
\&c, formed by the rain in the soil ; and this opinion, gene
, goin rally admitted, led me to commit an error in the compzsition
of an artificial manure, which circuobstance was most unfor
ond tuanate for the priacipestion of their trath was thus retarded
inasmuch as the recognition many years. Greatly as I have suffered by it I do not now
regret the error, as it was not so much mine as that of the time; and because without it the great natural law would not
so soon have been reconised, by which all doubts respecting the utilisation of sewage have been removed, and the I gave
of all the questions concerning it assured. At that time gifferent a recipe for a manure which was to restore to the soil different
matters in the proportion in which they had been drawn from it in the crops. According to the former erronena the potash
the kreatest dificulty seemed to lie in preserving the
in the upper stratum of the soil, for being extremely soluble it the upper stratum of that, with the first shower of rain, it would be washed into the ground at a depth beyond the reach of the roots. My manures contained the component parts of the
most effient artificial manures at present in use, in the tions for obtaining the wished-for crops but I had rendered them ineffective by purposely dopriving bility. It seemed to me that a link was wanting in the chain of conditions of organic life, and my temerity in wishing to mprove the Diviue order of things met wit it a severe punish necessity, and had given the earth the wondorful property o
drawing towards it, just as the loadstone attracts iron, all the drawing towards it, just as the loadstone attracts
elementa indispensable for the maintenance of life.
elementh indispensable for the maintenance of life.
Out this point $I$ said in my book, p. 113 :- "With the natural of the earth which is exposed to the suu, is most intimatel connected the power of the fragments of that crust, whic form the arable surface soil, to collect and retain all those nutritive substances on which life depends. A plant is uot food and make it ready for absorption. This prenaration of the nutriment is assigned by another law to the fruitful earth
itself, which in this respect discharges the functions perfor by the storoach and intestines of animals. In perforning this function the plant-baaring earth constitutes for the use of ma
and beast an immense purifying apparatus, whereby
removes from the water all raaters hurtulul to the health removes from the water all suatters hurtful to the health o
animals, and all the products resulting from the decay and putrefaction of deceased generations of pants and ammats."
A series of experiments with an artificial sewer-water provel that a dilution with water, as great as that of th effect of the soil. I found moreover, last summer, by experiments regarding the growth of plants, that a soil completely saturated with naanuring mater, did not further, as might be supposed, the development of the piant. In such earth Salad Potatos, and fPulse were scantily developed; their leaves acquired a light yellowish hue, and after (a)
plants died
But the same soil luxuriantly.
I further found the
roots is an almost conmon turf, which for corn and Beetmost excellent one for them by adding to it changed into a quantity of manuring matter (ammonia. potash, dre.) which crop was thus when completely saturated. In a trial field 29 tons of leaves par acre. At last it was proved that turf (bog
turf) in coarse powder, when thoronghly turf) in coarse powder, when thoroughly saturated with manuring matter, as might bo done with sewage, can employed, like stable dung, for manuring fiel
weight, exceeds the latter in fertilising effect.
stable manure consists as every straw and vegetable and animal residues inows, principally sition, and is soaked with a liquid which contains the com ponent parts of sewer-water. The effect of stable-dun depends chiefly on its component parts being gradually solved by rain and distributed throughout the soin. Io we calculate the degree of andion a liquia composed of the most by the rain falling during one year over a whole acre of land the result is as follows:Voelcker's analysis), contains-ammonia, 330 lb ; phosphoric If we 200 lb . ; potash, 220 lb
If we take, on an anverage, 2600 tons of rain per acre, we have
colution containing-

Yew, Colchicum, and Ergot Poisoning.-It is now more than 20 years since this subject was ventilated in your columns, and as a generation of fresh readers has since arisen, perhaps the following resumé may be of
some use to your present inquirers, and lead to fresh pome use to your present inquirers, and lead to fresh
facts which may help to elucidate the mysterious nature of the poison of the Yew. Fefore I go on with it, I Would however first get rid of the Colchicum and
Ergot; which latter I bave added, as I believe the harmlessness of both arises from the same canse. 1 feel convinced that immense injury would arise from aboonds, it is always in grassy meadows, and the cattle carefolly reject it when browsing. The hay upon such land is not generally cut until after the Colchicum seed is ripe and shaken out. In many meadows the plant is so abundant, that if the hay was cut before this takes place, there would be a fearful dose of Colchicum, in its
most active state, in every meal taken by cattle or
horses. No doubt much of the seed would also horses. No doubt much of the seed would also get
shaken out while putting into the rack. The same shaken out while pusting into the rack. The sam cause prevents Erzot doing injury. I have seen
abound fearfully in Rye crops, and at first wondered did not destroy the people and cattle who fed upon them. But 1 observed that upon a very slight shake with a stick, the Ergot generally fell off, so that it difficulty that I could get good specimens adbering to the Rye. To this I attribute the immunity which I have seen follow the use of liye very unuch affected by
the ergot. It falls to the ground in cutting and harvesting the crop.-Now as to Yew. The subject largely entered upon in jour volumes for 1843-44. In p. 807 the prisoning of two ont of three horses is In p. 142 of the succeeding year, a case is mentioned of four bullocks dying from cating Yew some days after it had been cut down. In p 235 I mentioned my own experience, which had been pret y considerable, with
regard to the Y'ew; having lived from a boy at a house where a large square stable-yard was bounded on two sides by a high hedge of Yews, and where there were many trees in the grounds, in the pasture fields, and churchyard, all with branches to the ground, and where without any injury. In the same place, however, I remember several valuable cows being killed by eating the withered shoots trimmed from a hedge. In p. 364 I called attention to the fact that at a large $⺊$ rasey valley near Chichester, calied Kingley Bottom, there are numbers of Yews scattered most picturesquely pointed out that I had several Yews to which cattle had access, and which were eaten by them. In p. 172 withered Yew, and a pony eating the branches, green with impunity. In p. 284, "George Crompton" gives a clear case, where two horses were killed by eating young green shoots, and where two more horses were
apparently saved by taking castor oil. In p. 324 , "A Subscriber" mentions a flock of sheep getting into a plantation abounding with Xew in a snow-and several dying in consequence. In p. 395, "Alfred plant possess much more activity at some times than others-and that this may probably be the case with the Yew. He also gives the probable reason for the withered leaves being more poisonous than the green. In p. 417 "W. P. Keane," of Seybourne Grange, mentions an extensive pasture land near 'Town Malling, as having many old and young Yew trees in it, and that neither cattle, horses, nor sheep, ever suffered any ill effects from eating the green branches, but that when Auother Correspondent "H. T," states that the reason Another Correspondent, H. Nitnesses aries from or the discrepancy between the wineses arices rom one party describing the consequences full stomach while the other records the consequences upon an empty one. Twenty years ago I felt no doubt that green Yew only wronld never hart any cattle. Bat all these facts convince me to the contrary. It is clenr that there are circumstances under when Yew is evidentiy poisonous when resi-tionguit. The experience would cia to a cottled, is-under what questionstances is fresh Yew harmless, and when poisonous? There is no doubt that withered Yew is decidedly deadly. "H. T.'s" observation is well worth consideration, as to whether fullness or emptiness of stomach valuable as to the time of year making a difference in the poisonntrs nature of the Yew-making it more intense, "G. Murray," in p. 60 of yonr Number for Jan. 21, 1865, gives a very strong case of two cattle dying in September from eating the green shootso in any other notices sent on the subject, the time of jear, whether the cattle were fasting, and whether they were accns tomed to Yew in their pasture, would be desirable. The subject seems mysterious. That in many districts al kinds of cattle eat it with impunity, is clear. That in others they are poisoned by it is equally clear. Can of ratiference arise from the first being in the habit mall shoots sparingly at a time a sort of relish while the latter not being in the habit of eating it at their leisure, have taken a large quantity on breaking into a plantation, when pressed by hunger. A large dose of poison will of course kill where a amall one right do no harm. This would account for almost, only satisfactory solution of the case I can come to. This view has been strengthened by several cases sent to me since I before wrote on the subject. A herd of bullocks in a frost broke into a plantation in Ireland where there were many Yews, and several bullocks were found dead in the morning, evidently after feed ing on them. Two out of three Dromedaries travelling with a circus in Cheshire, died very shortly after browsing a Yew tree by a public house, at which the whole pp. 807 284, and 324, and in that of G. Murrav" it would be natural that the animals would eat greedily of what would be a great treat; and hence I imagine that quantity of the poisonous food is the real cause of its deadliness, just as large doses of Vinum Colchici, or
Ergot, would destroy the livee which they now so often
save when given in moderation. I hope that I shall be forgiven this terribly long and prove communication, which I conld not shorte. W. D. Foz:
Flax in Ireland-Your agricaltural readers will be interested in tho following extract frow the Armagh Guardian newspaper:-"Enconragement to Flas growers. During the last week the acutch mill of C Carson in Marlacoo has been employed in scutching 260 stone of Flax of fine quality and great length, grown by the Rev. J. F. Flavell on his farm at Mullabrack. Thit crop was the produce of somewhat less than 7 buthels of seel, aing an average of 33 stone to the buasiel. which brought $8 s, 9$ d. per stone." "xeption an 60 stone, crop was crown upon somewhat miore than $3 \frac{1}{2}$ acres, and realised (as you will perceive) $117!$. The seed was sacrificed. The question whether this can be done in England, and "if not, why not $P$ " is one that may be asked by others besides Your Constant Reader
Live Fev Poisonoms to Callle.-There is no quedion respecting the poisonous qualities of the Yew, in either the green or dried state, although there is atill mystery respecting the different effects it has on animals-killing so ne, and proving quite harmiess to others. How can this satisfactorily bo accounted for?
Very conflicting statements have at timea appeared on Very condicting statements bave at times appeared on in both the greell and dried state. And I confens I was at one time under the impression that live Y ew was not so injurious as it was supposed to be ; having noticed so many Yew trees growing on commons, hedge.rows, and church-sards, where cattle have free access, there always appeared something mysterious to me as to the cause of death of animals stated to have been poisoned by Yew. But this doubt is now clearly proved to me by the death of one of my employer's horses, which unfortunately broke loose into a shrubbery near the mansion, composed chiefly of Yews; and within one hour and a half from the time it got loose it was lying dead on the road; the horse seemed perfectly well up to the moment of its death, which was instantaneon-one squeak only was uttered, and it fell dead. When opened, the stomach and every
part was found in the most healthy condition, and there sppeared to be about as much live Yew in it as would fill a half-pint pot. There cestainly appears to be something mysterious respecting the poisoning of cattle by Yew. Although I have always believed live Yew to be poisonous, I was under the mpression that cattle would ander my charge bite deal, Yo breles turn them orer a few times in off the Yew branches, turl them full the round their mouths, and then let them full to the ground therefore I came to the conclusion that instinct would teach them not to swallow enough to do them any Next comes the question that more cattle do not get poisoned, for we frequently see Yew trees growing by the wayside that have heir bear of deathe from chis call now refer to a case quite the opposite to the one above. Last autumn, during some extensive alterations in the pleasure grounds here, the temporary fence was left unsecure, and some catle got ity freely pleasure ground and regaled themselves pretty freely on some Yew-trec brancles. There is no mistake about this-they were found eating at the trees These beasts were driven into a part of the park there no water could be procured by for mome hours: and allhoug her than the horse not them. Allow me in conclucion ate the Yew on an empty stomach, and was fed and watered after eating the Yew branches. The cattle, we may naturally suppose, ate the Yew on a ful stomach, as they had the run of a large park; the latter for some hours at least were kept from any water. The horse died from eating Yew in the month of March; the cattie were The question is, did the cattle sarvive through being lept from water, or are Yew branches more dangerous at one part of the eason than another I am inclined to thirk the latter. Edecard Bemiett, Gr. to G. S. Foljambe, Eeq. Osberton Hall, Worksop, Notts.
Cultivation of the Cattle Melon.-After some year: experience and careful attention to the cultivation of this fruit for cattle-feeding purposes, 1 am enabled no only to say that the Cattle Melon, as selected and regetable cattle-food of the farm, and more particularly to the occupiers of small farms, and cow-keepers, wher the production of milk and batter is a considerabio tem-but that it is easily produced, a ch colt rat with as little expense as the ordinary crops of roots upon the farm; and it is eupecially adapted for smal occupations or large gardens, in fact anywhere where apace enongh can be found for the bine to extend becange in almost any soil where moisture enough is obtained to support the plants immense crops can be grown and will be available at the season when Grass is scarce, and before root-crops in general are ripe. The value of the crop is therefore very great, particularis in cases where only two or three cows are kept; for the Melons will grow upon any border near hedges and dang for each plant will give an abundant crop, and the land and adjoining hedge will be often loaded with fine
fruit. The woodlands, too, where not over crowded with timber trees, the first and second season after cutting the underwood, particularly in shat vege valleys where the callen leaves, \&c. table moul, offer a capital opportunity for their grems of under woodlands where the soil is godis these wood are always found farthest apare the Melon cede will be found ample room for planting the Melon seeds, and the first year after removing the underwood, Grasi or weeds seldom appear to interfere with their growth. By digging a space about 2 or 3 feet across a circular moand may quantity of Peravian, or indeed any of the guanos, or a spit of dung, the plants will thrive trail between the underwood stems without injury to its growth, and the produce will be very fine owing to the favourable combinations of soil, situation and climate. The farm labourers and nttagers generally, if encouraged to do 80 , may grow ine crops in any odd corner of their gardens, affording an edible vegetable whilst for the pis, particularly when boiled and mixed with meal, in the same way as Potatos are often used for fatting purposes. All soils snitable for the production of root crops where the climata is fivourable are well adapted for the growing of the Cattle Melon. In preparing the land for them it is only necessary to cultivate in the same manner as for root crops in genera; ; ammomacal night roil, and rich town or yard dung. The Cattle Melou is best grown ns a mixed crop (in open field cultore), in order that room may be obtained for its trailing hakit of growth, and it should be grown between Mangel Wurzel, Pctatos or other root cros. Two rows of Mangel or Potatos on the ridge should be taken 2 feet apart, then dibble the Melon seed on one ridge the same width as two ridges of Mangel ; tras rowing alternatcly two lincs of Mangel and one ine of Melons; the mannre shonld be burien in the centre of the ridge, and the Melon sceds dibbled $1 \frac{1}{2}$ inches deep and $2 \frac{1}{2}$ or 3 feet apart directly over the manure. In case, however, it is desired to grow them alone, the rows may he placed about 6 feet apart. The uses of the Cattle M. lon are varions; they are excel lent food for cows, sheep, and pigs, and when ripe they are used abroad for many purposes in cookery. The French in particular use them in soups, \&c. A friend just
returned from the Continent, informs me that the working people of different towns in Italy consume the seeds in large quantities roasted and slightly malted. For cattle feeding I have foumd them very advananalysis, which I obtained from Dr. Voetcker, made from part of a fruit weighing 16 lb . in the unripe state:

## omposition of "Cattle Melon," sent by Mr. Blundenll, of Burg- ledon, \&outhatapton, analysed ly Dr. Voelcker, Consulting Chemist to the Royal Agricritural Society of England :-

100.000

This analysis, although taken from a fruit before the seed was formed, shows nutrition about equal to the common Turnip, and I hope to get the analysis of ripe fruit this season, when I have no doubt a much higher
feeding value will be obtained, owing to the rich flesh and solid seeds which they contain. The expense attending the cultivation either in labour or manure is the same (certainly not greater) than required for Mangel or Potato crops. The Melon plants whilst young being so wide apart ample space is allowed tor horse first that the interculture may be continued for a much longer time than is the case with Mangel and other roots. When the plants, however, begin to spread, they grow with such rapidity that all the land is covered with laxuriant foliage in about three weeks and aboat five weeks after the blossom, the fruit will weigh from 30 lb . and npwards. The weight of crop in my case amoanted to 40 tons per acre, but I am firmly persuaded that a very much greater weight may be grown under more favnurable circumstances, for it
must be borne in mind that I treated the crop precisely as other roots in order that I might obtain the compara tive value of each in open field culture. The last week in April and first fortnight in May is the best time for dibbling the seed. Joseph Blundell, February 4.

## Farmers' Clubs.

LONDON: Reb. 5.-Middle-class Education. - Mr DMUNDS delivered an able address, from which we give the following extracts:- He said: No apoloxy is education into this room. If the question is at home anywhere, it must be at the Central Fariners Class for the farmers, without doubt, form the largest
followirig any one Labouring class.-Two hundred years ago, they who

the register. In ISB2 it was reduced to 23.7. Annong women
the difference was even greater. In 1811, 48.8 per cent. of minors were unable to write; but in $180^{2}$ there were ouly
25.5 per cent. In 185.5 , the number of schochls inspuected was
3853 , aud the number of children the schouls could accom modats 714,495 ; whilst in 1863 the schools inspected nimm-
bered 6237 and they could accommodate $1,315,988$ chilfren. The Parliamentary grants to popular education,
which a mounted to 30,000 . in 1840 , rose in 1862 to 774,7431 Rather more than ne-third of these sums was spent in the pecial instruction. From the report given with the estimates that the grants for popular to neation from the year 1839 to
 in 25 jears, mure than eight millions of public money on
popular education. To this should be added also the sums raised by subscription in each parish, and then it will be seen how enormous is the tatal amount that has been spent anon we could have expected, there is not one of us but can and rought in the ge nate; and the next generation will perceiv greater and greater still. The leaven has been introduced, and, depend upon it, it whll wark until the whole is leavened. A strong man is a most usen he has a maind possesses! But however we may differ in opinion, the one fact remains undisputed, that through this action of the
Government on popular education the artisan and the labourer have the meams of obtaining a better education than many of our grand-fathers or fathers obtained, or could at that
ime have obtained, except at considerable expense. If $m$ asked, "Has a corresponding advance taken place in the No; although the next greatest movement of impartance has been the success obtained by our public schools. These, by by an improved system of tuition, have so raised their posftion as to take them entirely out of the hands of the great middle clase, and have caused tbem to be almost monopolised by the education are said to be so unsatisfactory? I shall not here attempt to define who may be called the middile, and who the
uper class; but will take a test which will be quite encongh question of means. Those who can afford to pay from 100l. to
120l. per annum for the eaucation of each of their sons, 120l. per annum for the eaucation of each of their sons, can to 30 l , a year for a boarder, must I think, for the present seni their children to the Government schools. But the class for Whom a proper provision is wanting is that large class which the amounts last mentioned ; but which finds neither the education within its reach, nor the facilities of oltalning it so good es what they ought to be.

Middle-class Schools.-Let us now try to learn what is wanted, and how that want may be supplied.
What is a school? It is, or ought to be, a training ground in which the mind is exercised and led on, step by step, to
develop itseif. The word "training" conveys fully what shonld be the object of all education. There is a great outcry about teaching something userus. "Crem them with f. stuff that can be of no wee to them in after life use this language confounding the end with the not those who proper education is the train ther formin ceive and acquire useful knowledge. Schonl, as it were, only year by year, and that nceording to the diligence and capacity of the gatherer. The Rev. C. Lake put this in its proper light
when lately speaking at the Devon County School, where he had been examining the boys; and so full of truth are his
words, that I cannot refrain from quoting them. "Ho thing difficult, som them the necessity of learning some
their energies of mind. which would tax them tom all utmost; and if they did this, it would onable them in mistaken on this point. The education of their sons did not
consist in what was called useful knowledge only ; it consisted of the youthful mind. He would saty to all concerned in the subject, that if they wanted to help in founding a great spatem He did not care what it was, so long as it was something difficult. It might be mathematics, or Latin, or French ; but hard, in order to get the mastery; anil a youth who do work wonll? acquire a power which wruld be to him of tlig greatest principles upn which all education shonld be conducted. It
has taught all of us that there is nothing, worth having, to be of the mind can be silvered and enabled to take a true impros public schons alone can give. Of all the systems of edrcation
this one seems to liave the preference. So great has boen the
sncess of the public-schonl system, that it is said that they snccess of the problic-schonl system, that it is said that they
who have been educated in any of our great schowls caan reeng
nise each other nise each other as sonn as they are called nean son to act together,
as they ften are, in the army and elsewhere. It is acknow-solf-reliance, that quickness of can our youth aequire that

authorities are self-constituted, and have therefore nup to grant their particular degrees, if degrees they may beca.

The Agriowlural Society.-Now, to as sist in previd. ing this instruction is, I think, the only way in wl ich tie Royal Agricultural Society can help the farmer in the question of education. To establith colleges to found colleges for grocers or any other trade.
Faining, or the science of agriculture can only be learned Fi, ruatuis: fot if auy busiuess can be called practical it is the
iltivations of the soll. It ought to solve the problem (and I Cirencester the cost of instruction and the length of time than and obtain the college diploma are too great, for the expense is about 900 . per annum, and the thome required two
rears. Hence you will perveive that this is

.
 tienlties there aro, and difficulties there will ever he, in the
Way of prughes. It may be that mon them fof scienthice chlocYuar as schonis arise, int wheh it berter ulivoution in inppartod
than there is at present, the want whil nowo and more bo felt,
and the Rogal Aaricultaral doatety would do well to provide somo distinctive mark of position, to which the riging genora-
tion might in $k$ furward, and in the obtaining of which there be every rearomablo 10 contenided has not suffered from the wave so feebly adrocate; and if our discussion to night does but in some sinal degree rouse the midule classes to the children, it wall not have been in vain. All would be indignant if charged with neglect in providing for is the mind more than the meat! I pray them, as thi $y$ if ueed be, to give thie education to their children. They will then give them what even the reverses wo which al are liable cannot take away; and they will be adding, as it were, living stones to the hilding up of the future prosperity of their conntry. This, rest assured, is the true Reform Bill: for to give power into the hands of the ignorant is like entrusting fire arms to those who are unaccustomed to,their use, and who are consequenty quite as likely to injure their fiends as their foes; but to give it into the hands of the ellucated, is to give it to those who know its value, and who consequently will
ase it for the beneft of the community, as the only true way of benefiting themselves.
Bath and West of England: Counoil Meeling, Feb. 4.-The Finance Committee presented their avaual
statement. The Societr bas now a fanded oapital of 4923l. $12 s$ s, and the value of the plant, after making the usual allowance for depreciation, is 3084l. 5 s . IOc. The sulisbury Deputation reported that the site and every member of the deputation was impressed with the extraordinary determination of all they met, to rendar the Salisbury meating (1866) one of the very necessary to have a larger area than that appropriated to the purposes of the Royal Agricultural Soctety on the occasion of their visit. The proposed site was not more than a quarter of a mile from the city, and it would be only s
ment trial felde

## Calendar of Operations

Fibroary: Pea Culture.-The following is abridged from Morton's Farmer' Calendar (Routledge):-
This is the season for sowing the harly sorts of Pea may be sown. The Pea can hardly be called an ameliorating crop, but admitting of cultivation in the wide intervals between the rows in which it is u-ually sown, and afterwards covering the ground with a bulky sinothering growth of haulm, it is, when well cuitivate a fallow crop. The land should thus be left cleaner after Peas than it was; and as the crop yields in its heap, a frequent crop of Peas is no evidence of cross cropping. It rarely, however, forms a regular part the rotation, being taken now and then, iadaion fit for it, or unfis for the crop which it is talken to displac

The soils best adapted for it are the lighter loams Which are hardly stiff enough for Beans; and calcareous soils are especially fitted for it. Pen straw contains in its ashes from 35 to 1.0 per cent. of lime, a kind of soi which the plant rcyuires. Peas need liberal treatment and gool cultivation like any other crop, but bad frill yiell too apt to som they have and will yield notbing else. Tbey have a proverb among them, which sionsifies that the season docs for Peas as
inuch as good hisiandry; and they from theme take care that goorl crops shall be owing to season alone Hence atises the reneral idea of leas being the most oown on land that is not in good order. Let the careful busbandman lay it down as a maxim, that he should
sov no crop on land that is not in good order; nut merely is reopect of fine tilth at the time of sowing, but also of the soil being in peod heart ond clent of wre.s. Peas will admit of cleanis! ahile they yowo On that Accolnt, if a farmer comes to a liced which his pre decessor has filled with weeds. a horechoed crop of Beans might bo expedient, when Barley crop would be utterly improper. Pens, when managed in a spirited manaer, will not have the reputation of being so very mucertain a crop, for this chararter hons in some measnre been owing to ill conduct.

Peas ofter Clover. - The white boiling Pen, of many sorts, and ander various namer, is more teader than the greys and various kimds of hog leas; but I have many times put them into the ground in February, and thongh very sunart frosts folloned, they reoeived no
jurs. I fanc unifurmly found that the earlier they were sown the better. There is also a particular motive for being an enrly as poesible: which in, to got them ofl in time for stubble Turnips. If they are anon in this month, and a rght surt chosen, thry will be off the lind early in July, wo that Turnipe ansy follow, at of early Pens shaculd be cultivated vin dry souls ouly. Upon sanda, dry sundy loame, gravels, wad chalke, they Broad cast Pens are to be utterly rijected in every case. The only queation that can arise in their culture determined on, the land should have been ploughed in autumn with the skimeulter. The surface being possible after winter, drilling should directly follow. If dibbling is determined on, the lund, if afready clean, necd not be plonghed till winter time or alter it, and a heavy roller follows the plough. Dibbling Poan on a Clover layer generally reanits in a good crop.
It is the practics of some farmers to manure for Pess. If the land is in heart, and they are pat in on a luyer, they do not wont manure. A very good crop mayy he gained without it. I have had five, and cven five quarters and a half an acre, without any manure applicel for this crop. Dung makes them rin to long siraw, ud that is not favourable for podding productively. Bea's will henefit from it heavy dressing of dume, lut
with Peas the case is different. There are very few situations in which the furmer can have such a command of manure as to give him a suffoiency. It is therefore of mach consequence to him never to spread a load but where it will be sure to answer best. Every man complains of a want of dung; and he should be careful therefore to give it to the crope that will pay best for the expense
As to cistance between the rows of Peas, the practice of various farmera difiers exceelngty. Fquidistant
rows from 9 to 18 inches are common. I have seen them at two feet, and even at threa. In dibbling it is common in Norfolk and Suffolk to put in a row on every flag or furrow-slice of nine or ten inchel lureudth; and I liave known very good crops in most of thene distances. If horse-hoeing or much hand-hoeing is intenced, double rows at nine inchen, with intervals of 18, do well; but the greatest crops I luve known lnve been from jlanting every furrow-itice. Where drilled in rows, the interval of 15 to 18 inchres is to be preferred. This enables an efficiot horsednosing of the land during the early stages of their growth.
From two to two buehels and a half per acre is the usual quantity when planting every furrow. If they are drihled at greater distancee, six or eeven pecks will do. Some have trusted to one buahel per acre, but that quantity is too small.

Peas after a stabble orop are sown by the drill after the harrow apon land which was cteaned, manured, and ploughed tho previous autuinn. The manure this lying some mouths in the gruund bicomes mose likely to produce too grots and leafy a growth. The sorts sown may be (1) the early Grey Warnick, which, however, being of more rapid growth, is adapted for March or later sowing; it is not 80 productive as other sorts, and is especially adapted for late districts and land in good condition ; (2) the common grey field Pea later, more prolific, yielding a very bulky straw, and better adapted therefore for dry soils and districts, and for land not in such rich condition; (3) the l'artridge Pea, or Grey Maple, very prolific, yielding plenty of straw, and better adapted than the last for a lave country; (4) the winter ficld Pea, sown in autumn. There are also several white boiling Peas adapted for field culture which may be named, as (J) the Early Charlton, of medium bulk as to straw, yielding ma
abundant crop and tolerably early; (6) the Curolina abundant crop and tolerably early; (6) the Carolma
Pea, later, cqually abundant; (7) the White Sicklp, a Pea, later, equally abundant; (7) the White sickip, gonan the nthers.

The place of the crop in the rotation is cither after Clover, as already named, or after a corn stubble ; and in the latter case it generally takes either the nlace of Clover in cases where there is believed to be a liubility to "Clover sickness," or the place of Turnips in cases where there is believed to be a liability to the "finger-and-toe " disense.

After autumn culture, as already described, the lard ssoon as dry in February, is either scarified or merely
per acre, is drilled in rows, 15 to 18 inches apart, permitting the subsequent use of the horse-hoe. The ground is then again harrowed, and the field is shut up till the rows appear.

## Notices to Correspondents.

Barking Trees: $X$. Kill the bares and rabbits. If you may not, take as much thor,unghly skimmed milk as required, and paint over the tree with a whitewash brush. It lasts well one season.
Condition of East Lothian Labourers: Agriculturist. Mr. G. Hope thus describes it:- "The hinds and ordinary workmen live in separate cottages with their families. A cottage and garden firms part of their wages, wind of grai and Potatos, or a piece of land wrought and manured for the growth of the latter. Each of them has a cow, which is their own property, graked and kept on the farm , they are thus enabled to feed a pig. The possession of a valuable cow sing pig not only enables themto rear their famocilal respectability, bur hear of a man who owns a con it is selg a poacher, or being guilty of any of the minor offences against law and order.
Corruated Iron Rooping: BD. Can any of our readers give their experienco of this rooting for farm stanlid
especially for cow byres, feeding houses, and stable
Drainage: Inguiver. The following are Mr. Balley Dentor'a lines:-

When land is drained no furrows keop,
But lay it flat and plough it deep.
sow your seed scon, wide in the row,
Ere the last sheaf is off the ground
Let the broad share begin ics round,
With sun to scorch and wind to dry,
In earnest plough and fcrifiyth ryin,
Then your labour is worse than vain
For ev'ry footmark shod or cloven Only stamps the folt or sloven.
Hay: Jutia. Cowe in millk, of ordinary size, need 30 lb . of good hay dally each. Further next weet.
Hoose in Calvzs: $\boldsymbol{A}$ Sufferer. Mr. Spooner describes it as a disease of the windpipe and air passages, in which are found aumber of small worms which produce a troublesome cough, and is often fatal. The disease is aigu ned poverty or wait or tonetsupply; the eggs of the worm are probably taken with the water. To prevent the disease, give the calves some oil-cake or rape-cake during the winter, in comfortable yards. To cure it. give the following:-Linseed oil, 4 oz . ; ofl of turpentine, 1 ozz ; oil of carraways, 20 drops, to Three domee may be given.
Hoven: Cor. This is owing to greedy feeding on green and Fucculent frod. The following is Mr. 8pooner's instructions:-re-agents. The probang should be passed into the stomach, to that the gas may eccape: give the following draught:-

Powdered ginger
Hartshorn
3 drachmos
Water
1 ounce
If these are not at liand, give lime-water, or two drachms of follow with a purgative, to restore the digestive organs. anmetimes it in necessary, in order to save life, to relieve the distension by making all incision in the flank, on the lef side, between the last rib and the hip-bone. A pen-knife and a quill, or stick of elder, inserted in the wound will suffice. The wound may be esed with a plaster.
Manuers: $\boldsymbol{X}$ :-

| Name. | Applied to | Welght per acre. |
| :---: | :---: | :---: |
| Guano | All crops | 1 to 8 ewt |
| Superphosph. of lime | Turnips | 3 " 5 |
| Common salt .. | Grain crops, Mangels |  |
| Boot .. $\quad$ - | Crain Potatos, sce. | 30,40 bushels. |
| Sulphate of ammonia | Grain crope | $\begin{aligned} & 1 \\ & 1 \end{aligned}$ |
| Nitrate of moda | Ditto |  |
| Rap ; cake | Gra | 6"8 |
| Bo co dust | Tumips, Grass lavd, | 12 , 16 bashels. |

All soluble manures should be applied during the season of growth-all others some weeks before the seed-time.
Mr. Gant's Thicory: Exhbitor. It was fairly discussed in the "Veterinary Review" at the time, which said:-"Assuming, for the aske of argument, that fatty degeneration of the heart is a common fact in a fattened beast, does not that prove how, in spite ot such fatty degeneration. an animal may thrive in an extraordinary degree; and the fatty heart itself may, for aught we know as physiologists, be as explains how fats are digested, and no man of science beiore Mr. Gant ventured to assert either that a tiasue ic from the mere fact of its being fatty, unfit for human food, or that a farty heart is so far unequal to the performance of its functions as to unfit an animal's flesh for nutritive asoimilation.
Oats : W G. The Potato, Hopetoun, Flemish, and Early Angus Oats are suitable for the best qualities of soil in gnod Blainslie. Grey Angus, Lato Angua, Puland, Friesland, Shirreff, dec, are suitable for intermediate soils and situations Tue Kildr'ammie, Strathallan, Black Tartarian, Barbachlaw, are suited for high altitudes and exposed places. So sajs the writer of an arcice in the cur Probabls the Quarterly Journal of Agrichture. Probab
Tartarian will best suit your peaty soll.
Pulped of Whore Roots: Feeder. Mr. M'Laren's experiments gave 78.4 dd . per ton for whole roots, $58.2 d$. per ton for pulped
roots, given fresh with straw chaff; and 68 . 11d, per ton for pulped roots given fermented with chat. The process is nevertheless extending. There is an economy of roots obtained by 1 ; ; and the siogie experimenta of Mr. M‘Laren are not an unquestionable guide.
Sbort-hori Bremonva. Stoclemastar. Mr. Willoughby Wood has well illustrated the right policy for you. He argues against the prevalent practice of rearing al pure-bred that at present there are many blanks in hull breeding to one prize; and, 2, that if our beat herds were annually to send a number of well-bred fat oxen to the butcher, farmer 3 generally would have oculur evidence before them of al thowe ad vantages of procolity and ecomolical foodigg which Witll their own cows Wheats: Foung Candion Wheat, and may be Bailett' is a coarse brown white cha

## THE PATENT IN-DOOR PLANT CASES

(TO WHICH A PBIZE WAS AWARDED AT THE ROYAL HORTICULTURAL SOCIETY'B EXHIBITION).

## SOLE MANUFACTURER,

## James gray, Horticultural Works, DANVERS STREET, CHELSEA, LONDON, S.W.

The PATENT IN-DOOR PLANT CASE is one of the most useful of the Gardening Novelties of the day, handsome ornament for the Drawing Room or Sitting Room, and at all times forms a fresh, pleasant, interesting object to the mind and eye. It is always under command, and will preserve many of the most tendExotic Plants through the severest winter with comparatively little of the trouble and annoyanco attacth the use of Lamps, Gas, and Heating appliances of any other kind.
To all who have a taste for the cultivation of In-door Plants, for raising Secdlings, striking Cuttingh, be the Plant Cases will be found an inestimable boon.
The Cases are highly approved and recommended by Professor Lindley, and by Messrs. Veitch, of the If Exotic Nursery, King's Roud, Chelsea.

Sizes and Prices on application.

## HOT-WATER APPARATUS,

with truss's patent pipe joints.

## T. S. TRUSS, C.E.,

53, GRACECHURCH STREET, LONDON, E.C

By means of these Joints the work is executed in less than half the time required for Socket Jointen alterations can at any time be made, or the entire Apparatus removed and erected elsewhere with the grain facility. A considerable saving in cost is also effected.

These Joints have been used for several years, giving entire satisfaction, and may be seen in use th Royal Horticultural Society's Gardens, Chiswick, and many other plaers in Horticultural and Public Buildingo are also exhibited at the Society's Gardens, South Kensington.

# GREEN'S PATENT SILENS MESSOR, 

## NOISELESS LAWN MOWING, ROLLING, and COLLECTING MACHINES.

BY SPECIAL APPOINTMENT,
TO HER MOST GRACIOUS MAJESTY THE QUEEN.

GREEN'S PATENT LAWN MOWERS have proved to be the best and carricd off every Prize that has been given in all cases of Competition. The Juiges at the Royal Horticultural Society's Show, held July 20, 1864, awarded them a First-class Certificate ( N 0 Prizes were given), and at the same time suggested a slight alteration, which has been done. Messrs. T. Green \& Son consider their MACIIINES now as near perfertion as possible, and in consequence have continued making them as usual ; they will have nearly 3000 ready for delivery at the commencement of the season, and they hope with their present facilities to be able to execute all orders on the day they are received.

Both the HORSE, PONY, DONKEY, and HAND MACHINLS possess over all other Makers the advantage of Self-harpeming; the Cutters heing steel on eadh side, when they become dull or blunt by running one way round the cylinder, can be reversed, again and again bringing the opposite edge of the cutters against the bottom blade, when the Machine will cut equal to new. Arrangements are made so that tho cylinder can be reversed by any inexperieneed person in two or three minutes.

Illustrated Price Lists Free on application.

EVERY gardener complains of the Srot IN OrCHIDs, bat no one seems to know how to prevent it, and few are agreed as to the cause. The most probable opinion is that it arises from a conabination of cold and camp. Most certainly however, it is not precisely the same thing with common spotting, and there seems some reason to believe that it is contagious, or at any rate that there is little chance of getting rid of it without cemoval into another house, when it has once got complete possession anywhere.

Leaves of 10 different Orchids, variously affected, have been sent to us, as mentioned in $p .148$, and as it seems olear that there are three distinot forms of disease, it may be well to call attention to them, though unfortanately we have no suggestion to make as to any remedy.

The first, which we have seen on many species of Orchis, and of which a very perfect example is sent us on Dendrobium apeoiosum, is charaoterised by deep pits which extend to half the thickness of the leaf only, or have communication with similar though not striotly correspondent pits on the other side. There is in general, no previous discoloration of the unaffected parts of the leaf, the chloronhyll being often as healthy in the interstices as in the pits. The withered part is a pale nmber brown, or more rarely black. Sometimes however the affected part is chlorotic, as in a leaf of Aeriles Larpentro, where the evil is confined to the very base.
The second form, whioh exhibits broader blackish blotches, which are often superfioial bat sometimes much depressed, is generally preceded by a pale chlorotic discoloration. This form sometimes ocours on the same leaves as the former, and often runs over the pits, while it more or less completely penetrates the leaf. The two seem so distinct that we are inolined to think them different diseases.

They certainly do not arise irom the attacks of any Fungus, or from thrips or scale, thoush the unoffending insects are often brought forward as an excuse for an evil which does not apparently depend upon any culpable want of skill in the cultivator, as the very best seem sometimes quite helpless.

A third form, perfectly distinet from the others, occurs amongst the specimens sent, on Odontoglossum citrosmum, and another species of the same genus, of which we can at least speak positively that it is due to a Fungus- the second form of disease also occurring, in one instance, on the same leaf. The leaves are more or less chlorntic, and the firat atage appears under the form of large oblong spote which look soft and pulps, and of different concentric tints, olive green in the middle being succeeded by one or two shades of reddish brown. The central part is covered with little granulations, each of which is a little cyst. On examination the substance of the spot is observed to be traversed everywhere by a delicate branched mycelium, and ench eyst is surroumded by a bread delioate fringe of cilmured jointed threads. In this condition we have observed no perfect fruit. After a time the central part becomes strongly bleached, and is surrounded by a dark brown border, whioh is sometimes narrow, sometimes extremely proad in parts and irregular. The cysts have a more or less concentric arrangement, and the spores, whioh are colourless and byaline, are cblong, rather narrower at one ead, and have a single partition in the centre. We have not, howerer, seen the Fungus in its nost perfect state, the soft spots being too young, and the bleached patches too advanced. The spots in an incipient state are not depressed like those of tise two furms of disease mentioned above, and we, therefore, do not believe that the Fungus and either of these forms have any dependence on each other. In one specimen there is a pale yellow irregular shade beyond the spots occupied by the Fungas, which looks exaotly like a sunburn. M. $J_{0} B$.
Botanical Congresses have long been in fashion on the Continent, and have done much towards the promotion of science, by the interobange of ideas between persons having the sam scientific purzuit, and the general diffusion of knowledge. It is now proposed in Germany to have similar hortioultural meetings, whioh com prise the usual routine of hortioultural shows, and at the same time discussions on questions previously proposed. It was determined at a meeting held at Mayence in the spring of 1863 , that the second Congress should take place at Erfurt next September, and the proposition was cordially accepted by the Erfurt Horticultural Society.

As regards the exbibition itself, which is open to the whole of Germary for competition, the prizes embrace agricultural as well as garden produce, including flax and hemp; and trained trees in pots or otherwise are invited amongst other objects of oulture. Especial attention more over is direoted to plants calculated for table decoration, as well as groups of flowers, ornamental baskets and vases, or in short any objects of art which may seem to enhance the beauty of the garden, or the conservatory and its surrounding pleasure grounds. The King of PRUscia offics as the lst prize a gold medal for the most striking labours in the province of Hortionlture.

The peculiar feature, however, of the Congress, is doubtless the proposition to discuss matters of horticultural interest, and a question accordingly has been selected with reference to each of the sections under which the exbibition is arranged. These sections are six in number, and comprise1, Vegetables and agricultural produce; 2, Fruit and fruit trees; 3, Plants in pots; 4 , Cut blossoms; 5 , Objects of decoration; 6, Implements, machinery, \&c. Corresponding to these, the following six questions are offered for deliberation:-

1. On Darwin's theory, especially on the production of new races of plants by selection.
2. On the most important operations in the production of recrular trained trees, with respect to the different kinds of fruit, as well as the site and nature of the soil.
3. What are the best means of modifying difficulties which arise from diversities of nomenclature and terminology.
4. The history of the develoginent of some important flower, as the Nitcck, the Aster, \&c., from the first beginning to the present condition of its varieties.
5. On the choice if picturesque plants, as regards form and colour, for the ornament of buildings and their environs.
6. What implements during the last ten years have been most worthy of commend
and have most promoted horticuiture.
An additional question refers to the schools for the improvement of gardeners, and within what limits theory and practice should be taught in them.

Something of the kind is most desirable in this country, but discussion is useless without a sound scientific foundation. We believe, however, that in consequence of the measures which have been taken at Kew for the improvement of the men, and in some private institutions, as in that of
Miss Burdett Coutts, a race of gardeners is springing up amongst us, who will have something more to depend upon than the mere rule of thumb, and who will, both by example and precept, improve the present somewhat empirical system. M. J. B.

Wr announce with deep regret the Death of
Doke of Northumberland, which took place at the Doke of Northe mberdand, which took place at
Alnwick on Sunday last. His Grace was born in 1792, Alnwick on Sunday last. His Grace was born in 1792,
and was consequently in the 73 d year of his age. Lord Algernox Percy, as he was then called, entered the navy at the usual carly age; and many anecdoter are still afloat of his youthful spirit and gallantry. One of our daily contemporaries relates, that on one occasion a case of great distress was made known to the ofticers of resolved upon. The paper was handed round among young nobleman he put down his name for $1000 \%$. The captain of the ship, startled at this display of princely liberality, wrote home to his father upon the subject. The answer of the DJER was prompt and decisive-that
he would honour his son's draft to any amount. The he would honour his son's draft to any amount. The manifest a warm regard for the shipmates with whom he had ever at any time sailed. The DuKer did not however follow up the active duties of his profession, though he never formally retired from the service.
The late Doke was in 1816 created a peer in his own
ight by the title of Baron Prudhoe. He never showed right by the title of Baron ProdHoe. He never showed
any disposition however for public life. His tastes were more for antiquities and the fine arts; and he was
among the first to explore the interesting remains of among the first to explore the interesting remains of was by no means so safe as of late years it has become. He was, however, a steady member of the Conservative party, and daring the brief administration of Lord retired tastes he had so long caltivated, and to accept the
office of First Lord of the Admiralty. Since that time he has taken no active part in political life.
In 1847 he succeeded to the dukedom on the death of bis elder brother. As soon as the estates were in his own handr, his Grace commenced a series of improvements, which, chiefly carcied on at the family seat of
Anwick Castle, extended over every portion of his extensi
Alawick Castle is one of the few perfect specimens of the ancient feadal fortresses still preserved in the lingdom; and may rank with Warwick, oreven Windsor. But it had been neglected by its former owners, and it was reserved for the late DUKE to renovate the Castle from
foundation stone to battlement, and to carry out all In restorations in leeping with the original buildings. In the interior his Grace pursued a different course. While the exterior presents the grim and frowning the Scottish invaders, the interior is fitted up with all the luxury of modern taste. Moreover, a moderate fortane has been spent on the building of cottages.
The late Doke was a liberal patron of Gardening, and it is in this character more especially that we have to fine specimens of hardy exotic trees, and their choice collections of tropical rarities, afford ample evidence of given at Syon to the growth of rare tropical fruits is
also well known; and our readers will recollect that also well known ; and our readers will recollect that at 650 (1864) was obtained the first example of the fruit of the Cocon-nut grown and ripened in England, or, we believe, in Europe. It was in the garden of his Grace, then Lord Prudhoe, at Stanwick Park, that the Stanwick Nectarine was first fruited, and we have only to quote a passuge from our volume for 1848 ( p . 587) in
connection with the distribution of that most excellent fruit, to put it beyond doubt that by the death of Algernon, Duke of Northumbrriand, gardeners
have lost a true friend. The public, we then wrote, have lost a true friend. The public, we then wrote,
" will naturally be anxious to know how and where to procure snch a Nectarine as this. For their information we have to state that the plants are exclusively in that his Grace has ordered them to be zold either by public auction or private contract, as may appear
most advisable, for the benefit of an excellent though most advisable, for the benefit of an excellent though
ill-supported Charity, HHE GARDENERs' Benevolent Institution."

Towards all objects of a public nature the liberality the large number of lifeboats he presented to different
stations along the rock-bound coast of his native county, which munificence was acknowlelecting him
Royal National Lifeboat Institution electin their President. He was mainly instrumental in carrying out a survey of the old Roman wall which ran from the Tyne to the Solway ; and the beautitul and
highly valuable results of that survey were published at highly valuable results of that survey were published at
his expense. And within the last few years, when the spiritual destitation of the country was more especially brought home to the owners of property, his Grace was one of the first to recognise the obligations that rested charches on his own estates, the greater portion of which he lived to see opened.

The note on Spring Buibs from a country Correspondent, printed at p. 126, seems to indicate the existence of a misconception amongst inexperienced
cultivators, as to the habits of the Tulip as used for garden decoration, which it may be useful to show has no substantial foundation. Indeed, the very circumstance that the varieties of the more delicate breed of florists' Tulips are grown year after year withont loss of vigour, as hinted by another Correspondent this week,
may be taken as a pretty good indication of what is to be expected in the case of the hardier or more normal. conditioned varieties which are employed in flower gardens.

We have, then, no hesitation in stating our own conviction-and we are confirmed therein by that of a cultivator of great experience in this matter-that
Tulips can be as well grown in English gardens as in those of Continental Europe. Our correspondent "Caveat Emptor" is perhaps not aware that good one-year-old offsets of these early flowering Tulips bloom as uniformly as the largest and most exuberant bulbs, and hence he may bo relieved from his apprehensions as to the quality of bulbs to be supplied in future years. In all good soils the bulbs of early-flowering
Tulips continue to oloom and enlarge until the Talips continue to oloom and enlarge until the
third or forrth season, when they maltiply or throw off their increase- not uniformly but according to the constitutional vigour of the variety, and the fertility of the soil. In some instances indeed the largest bulbs may give the largest flowers, and very often, indeed generally, they, will yield the coarsest. The most perfect and aniform development of bloon will be, as a rule, secured by an average degree of vigour-in the Tulip an in other plants. This is well illustrated by many kinds of florists' flowers, in which, as is well known, the most perfect proportions and the purest strains of colour are generally the concomitants of an average degree of vigour in the growth of the plants, and by no means necessarily accompany either size or exuherance in the
plant-that is, provided there is a healthy development. A striking example occurs in the case of the Hyacinth, in which it is not the largest bulbs but the most perfectly matured of average growth, which produce the finest spikes of blossoms.
To sum up, then, it is quality and not size, perfect maturation and not mere bulk, which are the conditions requisite to ensure fertility, whether that be sought in the form of blossoms or fruit from either bulbs or trees.
We ought perhaps to add that the 50,000 bulbs We ought perhaps to add that the 50,000 bulbs understood to be but a moiety of the collection from which they are to be furnished, and which has yielded a display of a similar kind to that now anticipated at South Kensington, as we can testify, for some cight or 10 years past, and latterly on a very large scale.

We invite the attention of our readers, and of exhibitors generally, to an Advertisement which appears in another column, announcing a change of date for those Sprive Shows of the Royal Horticultural Society, which had by some mischance been fixed for the same dnys as those of the Royal Botanic Society. The special show of Hyacinths and Camellias, announced for Murch 18th, will therefore take place on March 25th; and that announced for the 8 th of April, ou the 15th of that month.

ORCHIDS AND THEIR CULTIVATION.-No. IV. One of the greatest of the enemies that creep in. sidiously into our Orchid-houses is Fungus. It appears in a variety of forms, at least it acts on the system of the plants in a variety of ways; and as stove plants, and plants in general, are more or less subject to one or other of the forms of it, it may be of some interest, to illustrate a few examples in detail. I purpose, then, to submit some leaves affected by, what I consider to be, parasitical Fungi, and some whose lamina I have no doubt will causes, to "M. J. B." who what the diseases are, and the best means, if any are known, of preventing their increase.
The first example illustrative of an attack of para. sitical Fungus, in its most aggravated form, is a leaf of Aerides Fieldingii (Foxbrush). The malady only shows itself here in an incipient stage; but if the leaf had been allowed to remain on the plant a few weeks longer, it would have become quite putrescent. It is when the from a common centre irregularly, in all directions. The normal colour of the leaf is a fine shade of deep green, but the affected part is as near the colour of
the leaf is paralysed, and nothing that I have yet trime
will arrest the progress of the malady will arrest the progress of the malady. This is the most destructive of all Fungi, because it invariably plant, and is apparently as incurable as cancer in the human system. The Aerides from which the le was taken was attacked in this manner, and perceiving its approach, I beheaded the phant
much further down than a novice would deemed necessary, and used antidotes, which siall hereafter speak of in detail-all to no purpose. Some of the lower leaves on the plant are still quite good, but the disease is in the system, and the plant will eventually die in spite of all the
remedial measures I can adopt. Corroborative of this I may state the history of a Phalzenopoin amabilis, which I had grown to a model plant, ing $10 \frac{1}{2}$ inches by $5 \frac{1}{4}$ inches. In the autumn of 1861 the same disease, which I was then a stranger to, mad its appearance on the centre of the youngest leaf. sulphur, but the running sore of health. I appliod sulphur, but the running sore rapidly grew wome Judge of my chagrin to be obliged to cut the leaf of
for although diafiguring the plantit seemed morapmen for although disfiguring the plantit seemed moreprudand Fo do this than run the chance of losing it altogetion For a month afterwards all went well. To my
dismay, however, the disease was still there, for in day or two the leaf on the opposite side shoned similar symptoms. The almost imperceptible spert grew into a putrid mass, and leaf after leaf fell victim to its influence. The stem during this time appeared to be perfectly sound, for young leaves grem out of the crown, of course with abated vigour. I had the roots of the plant examined, and, strange to sy, there was scarcely a dead root in the mass-and thene were above 100 of them-notwithstanding all the havoc on the leaves. I was in hopes that by reducing the size of the pot, and keeping the atmosphere aftar. wards a little warmer and dryer, that the malady might be overcome. The plant grew quite as well as one could expect any plant in like circumstancos, but all my practical knowledge and care, as will soon be told in few words, was baffled. The affected plant kept growing from the autumn of 1861, was attachod with spot, made other leaves, got spotted again, and
ultimately died upon a block in December, 186 , II "M. J. B.," whose scientific accuracy is admitted on all hands, can help us out of this dilemma, a very grant service will have been rendered. If some antidote could be found out to arrest the disease in its incipient stagu, the lives of such plants as are affected might be surnd
The second kind of spot is a very common one in
The second kind of spot is a very common on
fact I have never seen a collection of any size
pletely clear of it. The leaves of Aerides Larpetite Dendrobium densiforum, and Cattleya Leopopdi, sufficiently illustrate the form of it. The leaf of the Aerides is attacked at the base. The progress of tho disease has been stayed for more than twelve mont of the leaf is destroyed, with the exception of s litt each margin, the other portion does not show symptoms of distress. In the Dendrobium, althoug unaffected marked all over irregulariy, vigour. The Cattleya has been more recentily attack showing the disease in an active state, and from the other two examples in not having the lamina on the under side of the leaf. It has have grave reasons for doubting this; for although circular or semicircular lines here and there over the surface of the leaf, which invariably characteriee this spot, give a sort of colour to the idea, many ot things interpose, pointing quite in a different diral
tion. In such plants as have thick succulan tion. In such plants as have thick
leaves, a careful observer will see the spores of Fungi, or whatever other name be proper to give them, in the tissue of the learee some days or weeks before they break out. More than that, and by indisputable evidonce, any on predispose this race of plants to the spot
heat at one time, and too much cold at another, mill do it; too much moisture at one time, and too maid drought at another, will also do it. Watering tr air, chilling the system, want of proper ventilation and insufficient maturation of the pseudobulbs, wil have a tendency to propagate spot. I have a We could not get the case of Dendrobium spec adopting extreme measures. It was taken from to a tropical house, and back again to a house all summer to a very liberal supply of sun This treatment had the desired effect. of flower, but the sudden variations induced virulent character. I believe that it is this same of spot that occasionally attacks Pelargonium, cellaneous stove plants of a succulent nabure
Another form, something similar to the above, bil more general in its ravages on the plante, leaf of Vanda tricolor. I never knew thi entirely to destroy any leaf or plant. The parts fected are more longitudinal than circular; and
presents an appearance very similar to the human is, at no period of the disease, however, any eruption. The fluids seem to dry up, and the affected parts are
destroved. There appears in such instances to be a destroyed. There appears in such instances to be a
general weakness in the system, as the distemper acts general weakness in the system, as the distemper acts
uniformly throughout, and is probably engendered or brought about by an improper mode of cultivation. The Vanda which was infested with this kind of spot When a very young plaat, is now producing young "M.J. B.'s" opinion, that this is an instance of spot mainly arising from constitutional weaknees, and must eventually be overcome by skilful treatment.
The fourth ind of spot which I shall refer to is and in others of $O$. Uro-skinneri, and Trichopilia tortilis. These leaves are injured by fumigation. The
spots are black enough, and do not differ materially, to the uneducated eye, from some of the other examples adduced. In fact, a burn arising from fumigation sots on a succulent leaf, where the fluids are
rapidly circulating, very much in the same way as the rapidly circulating, very much in the same way as the
worst form of spot first spoken of. It differs, however, materially in this very important particular-that it is only partial in its effects. If mischief of this
kind las been done, it will show itself speedily, without communicating any bad effects to leaves uninjured. Severe fumigation under any circumstances is highly injudicious, but when you come to locality the Orchidere that belong to a temperate trary, however, the great majority of high-temperature Orchids are not easily injured nnless the leaves are in an early stage of development. Odontoglots, Lycastes, and Trichopilias, will not stand even cautious doses, if repeated, with impunity. This sort of burn is the under part of the leaf being injured in the highest degree.

Burns cansed by the sun's influence need not be specially illustrated, as the practical eye can detect them on the most cursory examination." Spots arising
from or occasioned by such causes, merit the least consideration, because it can only be from want of attention, or probably by experimenting too far, on the gardener's part, that such accidents can occur. :All plants requiring shade can be inured to a certain amount of suulight; and if the gardener in the exercise of light and shade, so much the better for the health of the various plants with which he has to do. I look upon : that sort of spotting, occasioned by sunburns, either through defective glass, injudicious syringing or M. Neumann in the article translated at p. 1180 (1864), as the most simple of all forms of spot, and the easiest thing imaginable for any gardener to guard against and avoid. Very different, however, are the kinds of spot routine of cultivation. They try the metal of the practical man to a very high degree, and often appear on plants subjected to a course of treatment precisely side, in the highest the same kind, growing side by In the case of bitate of health.
In the case of burns, the constitution of the plant is not affected to a high degree, unless the accident be a severe one. It is only part of the structure of cutaneous accident to the human body. In the other illustrations of spotting to which I have alluded, the constitution is affected, and the plant is more or less which it is afflicted. S, far as form of disease with yet led me to forns conclusions, the parasitical Fung are clearly generated in the atmosphere, else the disease would affect both root and leaves simultaheonsly, and every cultivator can attest that this never able to fulfil their functions after every leaf has been destroyed. It is quite another question, however, whether the disease is carried throughout the roots to leaves. The vegetable physiologist will be Meadowbank. to solve this enigma Jas. Anderson,

## WEATHER OF 1864 IN LANCASHIRE.

January. - This was a cold dry month. The mean temperature was $35^{\circ} .03$, or $2^{\circ} .098$ below the average of
the last ten years, and $5^{\circ} .62$ below January, 1863. The
7 whas tore being only $19^{\circ}$ cold day, the maximum temperathe 24 th and 25 th of December, 1860 , it is many years 1.21 inch, being cold a day. The amount of rain was the last ten years. It fell on ouly seven days, whige of 6.8 days lens than the average. The barometer at higheat on the 4th stood at 30.55 inches, which was the The prevailing winds were from the day in the year. February.-This was again a very cold most.
the averaperature was only $34^{\circ} .74$, being $2^{\circ} .478$ below and $6^{\circ} .4$ below February of last year. It

17 days it was below the we have had since 1860. On of yain was 3.45 inches, or 1.639 inch more than the average of the last 10 years. It fell on 13 days. The March. Winds were from the east.
March. - The temperature was still below the average of the last 10 years, $1^{\circ} .449$; the mean temperature
being $39^{\circ} .48$. Rain fell every day from the 4 th to the 14th, when the weather improved and we had some beautifnl fine weather, with frosts at night, so that by the end of the month gardening and farming operations were getting in a forward state. The amount of rain Was 280 inches, being 0.065 inch below 'the average. The prevailing winds were from the east.
April.-This was a very dry warm month; the average of the last 47.63 , or $1.536^{\circ}$ above the once indicated as low years. The thermometer only night of the 13th. Rain fell on only eight days, the amount being 1.26 inch, or 0.815 inch less than the average. The prevailing winds were from the west.
May.- This was the nost remarkable month on days, from the 15 th to the 21 st , On the thermometer days, from the 15 th to the 21 st, the thermometer
indicated $81^{\circ}$ in the shade and $127^{\circ}$ in the sun, which was the greatest heat ever known in May. The nearest approach to it was in 1858, when the thermometer indicated $82^{\circ}$ in the shade and $116^{\circ}$ in the sun. This great heat brought vegetation very rapidly forward, but the frosts at the end of the month dispelled all calculations of an early harvest, and did very serious damage to the Potatos, Kidney Beans, \&c. The mean temperature was $55^{\circ} .87$, being $2^{\circ} .241$ above the
average. The amount of rain was 3.66 inches, or 1.456 inch more than the average. It fell on 12 days, but only on one day from the 7 th to the 27 th. The prevail. ing winds were from the east.
June. -This was a wet cold month, and the frost on the 1st cut down the Potatos, and even the young cent. The greatest cold registered before in Jine since 1791 (taken at the Royal Society and Royal Observatory), occurred in $1797,40^{\circ} ; 1802,40^{\circ} ; 1841$,
$40^{\circ} .3 ; 1848,38^{\circ} 7$; and $1849,38^{\circ} .6$. The mean temperature of the month was $58^{\circ} .32$, being $0^{\circ} .302$ above the average ; the day temperature being $10^{\circ} .37$ higher than June, 1863. It rained on 20 days, the amount being 3.98 inches, or 0.495 inch more than the average. The prevailing winds were from the west and south-west.
Jump.-Ture was a dry warm month. The mean temperature was $61^{\circ} .95$, being $1^{\circ} .555$ above the average.
Rain fell on only 6 daya, which was the least number of duys in any month during the year. The amount was 1.59 inch, or 1.278 inch less than the average. The very light on some grounds. The prevailing winds were from the south-west.

August.-This was again a very dry month, but the temperature was $1^{\circ} .581$ below the average nf the last
10 years; the mean temperature being $58^{\circ} .47$. Rain fell on 12 days, the amount being only 220 inches, or 1.98 inch below the average. The drought was very severely felt in some parts of England, many brooks and aprings being quite dry, that had never been known to be dry before in the memory of man. Water was sold for a penny a gallon, and cattle driven some miles to water; mining and other operations being almost at a Lincolnshire the Grass was almost burnt up ond of Lincolnshire the Grass was almost burnt up, and they had to feed the cattle with the crops that were growing
for their winter supply. The corn harvest was secured in their winter supply. The corn harvest was secured in prime condition, bat Turnips were quite a failure in west.
September.-This month we had in Lancashire copious supply of rain, which fell on 22 days, the amount being 3.39 inches, or 0.043 inch less than the average. The mean temperature was $55^{\circ} .12$, or $0^{\circ} .484$
above the average. The prevailing winds were from above the aver
the south-west.
October.-This was a very dry month. Rain fell on only nine days, the aunount being 1.88 inch, or The mean less than the average of the last 10 years. average. The prevailing winds were from the east.

November. - This was a very mild wet month. The Dallias and other plants received no check until the night of the 2 d of November, when they were all cut down with the frost. The temperature on three nights only was down to freezing point. The mean temperaaverage of the last 10 years. Rain fell on 15 days, the amount being 2.97 inclies, or 0.639 inch more than the average, it being the first month the fall of rain was above the average since June. The barometer fell to 28.48 inches at 4 P.M. on the 14 th, which was the lowes point it reached on any day in the year. The prevailing winds were from the east.

## Home Correspondence.

Tine Grafting.-I am glad to see that this important suhject is attracting the attention which it deserves as from my own observation I am fully perwuaded that character and quality of the Grape worked eft upon the is to such men as Mr. Thomson ond othera who large opportunities for making trials of stocks, that we must look mainly for information in the matter. I feel, by rever, that all who have a worked Vine may assist have come under and I most willingly furmish what inarched a cioiden Hamburgh on a Chasselas Musqué, and find no tendency to crack in the berries. The bunches are very compact and abuudant, and the berries are medium sized, of a fine amber colour, and of good flavour, ripening a fortnight hefore the Black Hanburgh in the same house. We have the same kind worked on that I Hack Hanhurgh, and it has been so mnsatisfactory andria, and I shall be curious to see what the effect of this double working is. I ought perhaps to state that his Vine is in a late house, with an east aspect, where I lave some diffculty in ripening the wood; and as this stock has suited the Golden Hamburgh so well elsewhere, I must attribute my own want of success to the canse just named, as the wood was particularly gross. an bery loose and fre the The Black Prince appears to suit as a stock exercises little or no influence over it, except that of giving the berry a more conical form, and in inducingr the frnit to ripen a werk or so later. Willmot,
Black Hamburgh makes no appreciable difference on the common Black Hamburgh, except perhaps in tho foliage, which I think it thickens. I should strongly recommend badding in preference to grafting, as the operation is more certain, and the union much neater on large stocks than grafting, but for this purpose the bud must be ripe and inserted in the Vines when the bark runs freely. Before closing I would suggest trying some of our late keepers -such as Lady Downes, on stocks that send up their sap late, in order to see how far that would prolong their keeping. J. Sheppard, Gardener to J. Berners, Esq., Woolverstone Park.
New Mode of Selling a New Rose.-I have been much amused this season at the sbarp practice of one of the French Rose growers. He has, it seems, either Rose, which be extols as the wonder of the age, and equal, if not superior, to the Cloth of Gold Noisette, which is to be proved. Well, he advertises his intention of selling this Rose on the following terms:-The price he fixes at 25 francs per tree, but he will not sell enthusiast wishing for the Rose must expend 150 francs or 6l. This seems hard, but then mark his proposal-he will not sell one tree, but if you buy his 20 frace seeding Roses, all new, at an average price of Roses, so that in any yive yoll one of his new yellow Roses, so that in any caze the yellow Tea Rose must cost you about 150 francs, for the "eight new Roses" are Hybrid Perpetuals, and neither rich nor rare, either in colour or quality, (and therefore but of amall value in the eyes of the true amateur. Verily they manage these matters "cutely" in France, for only imagine one of our respectable florists selling a new Pelargonium on the same conditions. The dodge is ingenious. Rosa dumosa.
Black Alicante Grape.-I did not see what Mr. Bennett had previously stated in reference to this
Grape; but I conclude, from using the, prefix ' $M$ r.' to the wcrd Kempsey, that he has not correctly stated how Kempsey became attached to it. I know that the Alicante Grape existed at the late Rowland Lenthall's, Esq., of Kempsey, Worcestershire, in the year 1847, which I think was some time before Mr, 'J Jhn Cox (now of Crown East Court) became gardener to that gentleman. At that time thir Grape was well known not certain whether or not it was held in much estimation by them. Its history was considered doubtful, but the connection of the Grape with Mr. Lenthall's place is unquestionable. In course of time Mr. Cox took clarge of the place, and by his ability as a gardener he very soon developed the valuable qualities of this Grape, to the great astonish. ment of Mr. Bennett's predecessor at Perdiswell, and many others. It was also I think produced in excellent Guildion at the last flower show held in Worcester Guildhall. This may be set down as the coming out of the Kempsey Alicante (not Kempsey's), for the gardening world, and as Mr. C. was well known and withal good natured, he kindly distributed it to most, people who asked for it. To Mr. Cox, therefore, belongs all the credit of first introducing and disseminating this Grape, and I have no doubt could : Bupply correct information as to the origin of this Grape. My impreasion is that it was a 10 pro.
miscuous seedling," or that Mr. Lenthall "picked it up in some of his travels," but not 100 pears ago.
May not Mr. Wennett's Royal Albert be $\Omega$ sort of Hamburgh they have in some places about Worcester, called "Chmmpion," which bears immense berries of good flavour but of bud colour, and bunches compact and large? R. II. Poynter, Taunton.
Spring Bulbs (see p. 126).-Your Correspoudent, Mr. "Caveat Emptor," lad better ask the florists what they do with their Tulip bulbs after flowering. Now, as
they grow a moch mure delicately constitutioned and they grow a much mire delicately constitutioned and
ligh.bred race of Tulips than those which are employed for bedding purposes, and bloom them with equal suecess-barring accidents of disease or errors of latter may also be grown in the same way; and such in fret is the case, as your Corresponcient may learn if is rather late to set about it now for the present year's is rather lute to set a
bloom. Oculis Solis.

Eugenia Uyni.-This is grown at Lower Knowle, Kıngsbridye, in the open air, and it is trained against a south wall, where it receives no protection. It is in fact quite hardy in Devoushire. In summer it is large Black Currant. It is my impression that the Engenia will become an important plant, and that it will be much valued and cultivated for its fruit alone. We have this season preserved four jars of the latter and it is suid by all who have tasted it that it is the richest and best preserve ever eaten-it has a delightfiri aromatic favour, whic! partakes something of that of a Pine Apple. Even when gathering the fruit a rich odour is left on the fingers. S.s freely does the plant hear, that I have even seen bushes of it only 1 loot in height, with fruit on them. James Hyne, Gardener, Kinysbridge.

Royal Albert Grape.-Mr. Bennett, I observe, has made a few remarks in your colouns respecting a Grape
ralled Royal Albert. Whilst living with a gentleman in South sitafordshire, some 12 years ago, I fruited a Vhe which bore that name. It was growing in an early Peach house and ripened its fruit in May; it is a skin, and rather inferior in flavour to the Lhack Hamburgh in general cultivation, which it greatly reaembles in appearance. The foliage suffers a little from hot sin1, and requires a slight shade under sheetglass. I think it would make a good stock for grafting with other kinds froms some of the L.unden nurgeries Henry Beddard, Gr. to J, S. Basset, Esq., Tehidy Berberis asio
Berberis asiatica, - Is this shrub likely to prove
hardy in the south of Norfolle ? [Yes] hardy in the south of Norfolk? [Yex] Is it left exmolested by hares and rabbits, and likely to rival or gratefal for the mames of any other distinct species of the same genus (evergreen) that promise to form good cover, and are easy of propagation. Diss.
The Knowsley Pine Stove.-I haveread with amuse. ment "J. A.'s" duseription of the Pine stove at
Knowsley (p.125). I heard of it last sumper and aent onse of my men over to look at it, but his report convinced mo that we, swho raise frnit for the market, neei be under no fear on its acesunc, but that Lord Des by would have still to buy his Pines at she season of the year when I shall try to have the most of mine ripe, there was a moriel house for the cultivation of the Pine, certainly this is the house." A model house should be as perfect as man knows how to make it, and we know that good Pines, of from 4 to 5 lbs . each, cannot be ripened so as to satisfy the taste of good julges,
withontan atmosplieric lieat of $90^{\circ}$. I am certam from the pipes shown that this honse will fail to keep up this amount of leat during five mouths of the year. It would take hearly three times as many. Therefore end of November till May. Are there none that will? So much fur top-heat; let us examine the bottomheat. Pipes will not do much gool without they are hot enough to evaporate water in pang placed on them. All gardeners agree on this point. Then are these four rows of pipes intended to keep sending up moistute into not more and something like boiling Potatos by ateam. G. II,
Scentless Mignonelte.-Can the fact that some very fine lookng Mignoncte in pots does not emit any well for the last six weeks, and is well blown and fine looking, but without fragrance. There are many pots of it, and all without scent. Are there different kinds of Mignonetite, some less fragrant tiasu others? The seed cane from that which did well in the open ground last summer. J. W.

## £ocietics.

Rofal Hormicultural: Feb. 11 (Weekly Show).The weather being unfavourable, very few sabjects were produced. The only Begonias which were the subjects specially invited to be shown on this occasion, cawe from the Saciety's garden, and were confined to one or two well-known kinds of the variegated-leaved Mr. Bull sent

## th <br> they scale atter

Cookii, Bidwillii, and Rukei, together with four pretty plants of Libocedrus Doniana. W. Mercer, Esq., Staplehurst, had Eucharis amazonica ; Lady Caroline
Legge, two red-coloured Cammellias; Mr. W. Smyth, gr. to Lord Sondes, Ehmham Hall, a very good specimen of Epacris, and two plants of Ardisia crenulata covered with fruit; Scarlet Nonpareil and Boston Russet Apples, and Beurré Rance Pears were also shown by the same exhibitor. Major Trevor Clarke had one or two Roseberry, Dalmeny Park, sent his Inproved Hardy Autumn or Winter Broccoli, a good white self-protecting kind.

Feb. 14 (Anniversary.)-Lord Henry Lennox, M.P, It having
It having bcen previously announced that Mr. Godson had sent in his resignation as a member of the Council, it was now moved by Mr. Weston, and seconded by
Major Phipps, that that resignation be not accepted. The motion, however, was lost. Scrutineers having been appointed to report the result of the approaching ballot for Comncil and Officers for the ensuing year, the late Assistant Secretary then read the Annual Report as follows :-

1. The Councll hive the satisfaction of being able to announce to the Fellows that the number of members of the Society continues to increase. On the 1st January, 1864, there
were 33:36 Fellows ; on the lst January last they amounted to
2. The Council als? congratulate the Fellows on the success of the important works undertaken jointly by Her Majesty
Conmissioners of 1851 and the Society. The Commissioner works, and the convenient access which these works have
given to the Conservatory through glazed and warmed arcades.
and the Orchard-bouses which connect them with the new and improved entrances, sre i
counpletion of the Gardens.
3. The improvements carried out by the Sostety have given
genieral satisfaction to those who have of late visited tho Gardens. These works have necessarily entailed considerable

The Councilas. to state thet her Majesty contia ul

The adoption of the Report having been moved and soconded,
Mr. Gopsox, jun, moved by way of amendment, that a committee to consiat of five membert, with porer to
add to their number, be appointed to investigate the affirss of the society, and to report what is is it true financial state ; what were the circumstances under
which snch an extraordinary expenditure has
been \#hich such an extraordinary expenditure has been and that the balanee sheets of 1864 and 1865 be laid before the Cormittee. Ho then at some length criticied the accounts, With a revenue of something
like 14,0002 he said, the Society had spent 20,000L, and yet it was said to be a succeess. Amonge other things he complained that an item of 5000 , due for sculpture in 1883 , had not been paid, but carried over to the following gearis account. The receipte from the annual extibitions had fallen off from last year. He denied that the accounts placed in the hande of the Fellows represented the true state of the Society's financial matters. In 1861 they had the "aseets and liabilities," which showed That they poeneseded and what they owed. In the following yerr that was eliangeato "proitt and loss," Which alo alowed the etate or anfirs , but last yenr and this,
When there was a great deficit, it would not do to
 Society was nearly 10,0002 . in debt. In 1881 there
was a balance shown in favour of the Society ot ${ }^{10,0000, \text {, } 80}$ that in four years over 20,00001 had dis. appearect. There was one item of 25001 , for improve. mint for hie part hens. Hhought the "was a matter of taprovements", would have been more appropriate in Brompton Cemetery. ITe contended furthermore that the manner in whith
the Conneil had dealt with the Ilfe composition holders mas not that which should be expected on the part of an honeat gociety, and that it was aleculated to drive hand annual subseribers. The prospects of debenture
holders, he sidid, were very bad indeel; and wulless the Committee for which he moved was grantel, or some similar action were taken to remely the present system or management, at the end of 10 years the Comuris.
sioners of 1851 would
dwn Sioners of 1851 would swamp the Society.
Mis samer Parprs seconded the amendment, but at views expressed by Mr. Godson. Ho knew the the Sxeiety was considerally in delet, and that many fellowe were withdrawing their subseriptions ; nevertheless he sam that the Society had spent 14300' for a tent! The greatest calamity that ever befel l bes Society had been, he Commissioners of 1851. Puublic opininon lad bsodeen Iouxily on this subjeet through the prese, but owiog to thlis union with the self-atyled patrons of the Arts and
Sciences, they had aecrifeed the Mr. Coire rendied to ticeed the Society.

Major Pritps again said that in in rising to second
amendment, he had no desire to impute motivest to any one. All he wibed to do was to express his sentimentes, and he considered that the Horticultural Society had done wrong in conneting itself with the Commiasionero
of 1851 . He thowndt
 place for hortien ture, while sonth K Kensin
Mr. Batesarar said he was glad that Major Plipps had taken occasion to diselain particiepation in the re. markz of the mover of the amendment. The previous
speaker had said that Chisick speaker had said that Chiswick was the place furt
horticolture. Well, certainy Chiawiek was in a most efficient state as fart as, and in connection with those circumstances in which, its elfioiency coald be maintained; and his own feelings wore entirely in favour
Cliswick. But peonle conld not do iny slint their eyes to the clhanyes which weres takinee, nor in horticulture in Eng land generally, and in this metropolisi in partionalar. There were four aspects ander whint Cumiek might be viewod: frat, as an experi-
mental garden ; secondly, as is inneleus from which new plauts miqhht be distributed; thirdly, as an arboretum; fourthly a a an arena for great stows. He remuenlbered the Arst exlibibition held there. It wasa poor affirir,';but still a
heginning as to ming, and thees sliows became at leng th so poprlar the proance a very large, if not legitimate portuon of then Councile expressing his fears that such a precarions source of income might be buddenly stopped. For
several years, huowerer, the shows had gone on incereas. ing in popularity, until on one memorable occasion the admisisions, by tidetet at 5 s. each, numbered 14,000. This
naturally caused
reat the Botanic Gardens in the Regent ${ }^{2}$ Park were onened and then it was seen that the Clitiawick exhibitions conld no longer be relied upon-there was an end of thent Another point was the arboretum, where egpecialy y hardy plants could once be seen in the
greatest perfection, This, he was of opinion, coold do Tonger be the cise, owing to the infuences to which the plats were now subjected there owing to the encroachment of London; beside, what could they be expected to do in their 20 atres in comparison with the Tmperial estallishment at Kew? This he said with pain As to the third point-Chissrick as a nuelens
or the production and disemination was this, he beliered, which first gave Cliswioks its prestige, and as long as the rare plants of America,
India
\&ce, remained to India, de., remained to be disovered, and as long as
the zanlous collectors of the S Sciety continued to send hiem over in such profusion, sol long was that prestize maintained, but now nearly the whole world hiad been explored as fur as hardy plants were concerned. Rocky $\mathbf{3}$ there were still some in the passes of the some doubtless also on the snowy mountains of Africa,
 jealousy, that no European lad been pernitted to seale their ficees. Their collector in Brazil had been
suceesstul in sending over syme rare supecimens, but it must be remembered that tender plants were only for the enjoyment of a few, and the Society would not be justified in spending mucli money to procure them. He was of opinion, however, that Chis yick was still
 plants. Referrring to chiswick as an experimental garden, lie said it was never before in such a satisfactory state
as at preesent. He was happy to say that the Rev. Mr. Borkeley had consented to jofin the Society as con sulting botanist, and to conduet the Journal. After alloding in commendatory terms to certain prizes that have been offered for window gardening ammg the poor of London, Mr. Bateman conelnded by supporting ne aloption of the annual Reert and ac:oonts.
Mr. Edg $A \mathrm{~B}$ Bowriva, while agreeing that the accounta might have been presented in a mure simplified and intelligible forma, denied the justice of Mr. Goison's
deductions. He deductions. He explained the exact relation of the Godson's fears as to the latter swamping the Society at the end of 10 years were quite groundless; that in fact, from the nature of the agreenent between the two bodies, such a thing was almost iumposibles
The noble Charman then briefly expressed his
 Society, and his hopetulness for its future eareer. He
reminded the meeting that the position of the Cound was a dificerlit one for centlemen to holld, and lic trusted ed that in labouriug for the best interests of the Scieity its members would have the hearty stupport of the Fellowa. Mr. Godson's amendment was then put to thé meet. ing, and was loast by a large majority, only three hands The oriziniat motion for
rep rt and statement of accounts wis then put and carcied unanimonsly.
Some remarks were subsequently made with reapect
arising from what was formerly a private day Satur-
day, being now converted into a pubbic Sbo $\begin{aligned} & \text { dy d }\end{aligned}$, the interfering with their privilege: The Chairnan intimated that this matter would reccive the atteontion the Council.

it may be coufidently stated that Nature provides work enough for hawds that do not like to be idle, of which the present berutiful volume is sufficient proof. No one with a micuscope of common power, such as may be
bought at Smith \& Beck's or olsowhere for soine $5 l$. or 72 need want rational ambsement if they will but hunt the first flold or hedgerow for microscopic objecte auch those which Mr. Cooke has introduced to notice, and when his volume is exhausted, a luot of similar objects M obluer branches of Mycology will still remain.
Mr. Coole shall however gpeat for himeelf
Mrr. Cooke shall however ppeak for himself as to the
"Mildew is just one of those loose terms which represent no definite idea or a very different one to different individuals. Talk of muldew to a farmer, and instantly he seampers mentally over his fields of standing corn in search of tbe brown lines or irregular spots which indicate the anwelcome presence of Puccinia before him as mildew. Try to convince a Norfoll farmer that anything else is mildew and he will consider you insane for your pains. Speak of mildew in your own domestic circle, and inquire of wives, or daughters, or servants, whatrit means, and withuut hesitation another and oven more minute species of Fungus which attacks damp linen will be indicated as true mildew to the exclusion of all others; and with equal chaims to antiquity. Go to Furnham, aud any other Hop-growng dietrict, and repeat there your question-What is mildew? -and there is every probability that you will be told that it is a kind of mould which attacks the Hopplant, but which differs as much from the mildew of the farmer and the laundry-maid as they differ from each other. The Vine-grower has his mildew, the gardener his mildewed Onions, the stationer his mildewed paper from damp cellars, the plasterer from mildewed walls; and in almost every calling or sphere of life, where. ever a miuute Fungus commits its ravages upon stock, erop, or chattels, to that individaal owner it becomes a bugbear under the name of mildew
A great deal of instruction will be found under each head un a variety of subjects most interesting to the apply to the others, and Mr. Cooke has wa cirious subject of dimornhism ainongst others has received due attertion, on which new light will undoubtedly be thrown by the third volume of the Carpologia which the Tulasnes are at this moment actively preparing While on this subject we ought never to forcret that it was Fries who called attention to it more than
40 years ago. By mere intuition, before the modern improvements of the inicroscope, which have dene 80 much for science, he saw more or lesa cleariy the connection of many supposed genera, and announced facts which modern observers have either confirmed or
dilated. The elder Sowerby's observations in Englie\#

Fungi on Reestelis cancellata are another instance of act in a very obscure subject.
As regards the important matters contained in Mr. Cooke's volume, we need not advert to them particlilarly here, as most of them have from time to time veen recorded or is so reasonable as regards price that there is no volume is so reasonable as rega the original,
excuse for not referring to the original, which who recommend to the notice of all horticulturists who
wish to know something of a very large and troublesome class of diseases.
The Appendix contains a classification of all the species hitherto known as British, which will no doubt eceivertunity for the record of new species will be given in some future edition of a work for which we foresee a considerable demand.
Le Jardin Fruitier du Muséum. By Prof. Decaisne.

## (Continued from p. 1256, 1864.

Pécher Ispahan.-Leaves finely and sharply serrated, without glands; flowers large. Fruit small roundish kin yellowin red next the sun. Flesh parting from the stone, or coloured next the stone, melting, with an acidulated sugary, slightly perfumed juice. Stone elliptic. Ripens at Paris about the middle of September. [This Peach, from the country of which the Peach is said to be a native, is not of much merit at with that of the plant as it existed in the garden of the Royal Horticultural Society. Nevertheless some particulars relating to it as found in Persia, and to its introduction to Europe, may prove interesting.] It was supposed that the Ispahan Peach might be the patural typeoren to Europe the multitude of varieties, and of which Duhamel described more than 43 of the more remarkable for their beauty and excellence ; but this shrub, or bush, has not been found wild in Persia, only in gardens. We ought therefore to suspend our opinion on this point till under longer culture its variations have been observed. We owe the tree to the voyage of Bruguière and Olivier. They found it in the gardens of Ispahan, where they frequently met with it abandoned to Nature, without having been . They thought the fruit possessed an agreeable flavour, and although it was in the month of November, it was scarcely ripe. They collected some of the stones,
which formed one of the 738 kinds of seeds which they collected during their interesting voyage, and with which M. Olivier (whose companion perished) enriched the Museum of Natural History on his return in 1800. Five of the stones were sown, none of which rose the first year, but three came up in the spring of 1801. The difference in the period of ripening which we remark between the fruits seen at Ispahan and those
which were gathered at Paris, is similar to that which Professor Decaisne has stated to be the case with the Angora Pear. This variety ripens in fact several weeks earlier at Paris than in Asia Minor ; but presents all the characters of a continental climate.
Pêcher Bourdine.-Syn. Bourdin, Incomparable de Narbonne, Pavie Admirable, Pêche blanche, Pê:he Bourde, Boudin, Pêche Royale, Pêche de Zwoll, Pêche de Narbonne. Leaves crenated with globose glands flowers small. [Fruit so like that of Téton de Venus, that many consider it the same, even among French authors themselves, born at Montreuil, where Peaches are more especially cultivated, where their cultivation forms the chief employment of the inhabitants, and where, consequently, they must be practically well acquainted with the varieties they cultivate. The Royale is also considered to be distinct from the Bourdine by many; but the fruit from trees obtained by the Horticultural Society under both names proved the same; and the fact of their being so, is corroborated by the following quotation from La Bretonnerie, Ecole du Jardin Fruitier, vol. 2, p 272, 1810; p. 389, edit. 1784 :-

Boudine or Royale are the same, whatever may be said by nurserymen, and stated in all the catalogues. This Peach was not known, when one of the cultivators Louis XIV. This Prince had the variety introduced into his gardens, and he esteemed it so much that it was named La Royale. Tbis fact, on which I can firmly rely, has apparently been ignored by those who make two varieties of identically the same thing under different names. The Bourdine is an excellent Peach ripe the middle of September [end of September or beginning of October in England]. It does not commence to bear so early as some others, but when it does begin, it bears abundantly. It is the best of late Peaches." To the latter remark of La Bretonnerie, made in 1784, there is perhaps scarcely an exception at the present day.]

## Miscellaneous.

London Street Nomenclature.-Streets called afte trees, flowers, and gardens, are more numerous than might be supposed, and may be presumed to have derived their names from the open spaces of cultivated ground by which they were originally surrounded
one near Regent Street, called after the vineyards which had previously occupied the ground. From many names of a similar character, which occur in all parts of tie town, but eapecially in and about the cry which it would are selected as illustrations of a the idle antiquary to investigate a little farther: Elm Tree Court and Garden Court, both in the Temple; Flower-de-Luce Court, in Fleet Street; Green Arbour Court and Break Neck Stairs, where Goldsmith Lodged once, off Farringdon Market, but now removed to oblivion; Hatton Garden, called after Sir Christopher; Hay Rag Fuir ; Saffron Hill, happily vanishing into brick dust; and Willow Walk, in Pimlico. Leig Hesi held, as an article of faitis concerning green leaves in London, that there was not a single street in indications, of which a tree was not visible. From his creed was not
there may have been a time when very wide of the truth. Reader.

## Calendar of Operations.

## (For the ensuing week.)

Whice the ground is white with soow, as it is at present, little can be done in the way of out-door work. Many in-door plants will however soon require attention in the way of potting; everything therefore necos sary for the proper carrying out of that operation may now be put in readiness. and constant care bestowed stric tly kept in check, and constant care
upon the timely performance of routine work.

FLOWER GARDEN AND PLANT HOUSES,
regards the Conservatory and Show-houses, the obtaining Spring bulbs, Chinese Primulas, Begonias, and other plants in flower from forcing pits or other houses, and the removing such as have done blooming
to other quarters, will now be the kind of work to other quarters, will now be the kind of work requiring most attention. A temperature ond from $50^{\circ}$ to $55^{\circ}$ during the day time, is aig this time of the year sufficient in Conservatories, even in houses in which plants are in flower.

Carnations and Picoteer.-Planting time with respect to these is now approaching; therefore bestow great attention on the proper preparation of soil for them, as upon that much of the after success depends.
Orchids. - If not already done, re-pot such kinds as require that little water since last autumn, and may have recos be very dary. 1 wili also be benefited by being subjected to the same process. Syringing may soon be resorted to early in the afternoons on fine days, and other conditions favourable to growth may more generally be put in force than would have been prudent during duller weather.

Pavsies.-Beds for these are best made in the autumn; but where plauts have been kept in pots during winter they may be planted out with their balls entire on richly prepared soil as soon as the weather has become favourable for that purpose.
Pinks.-As soon as fine weather has returned, these ought to be carefully gone over, slightly forking up the surface soil and applying a top-dressing of ligh rich fresh mould to the depth of say half-an-inch all over the bed.

FORCING Garden.
Cucumbers. - Follow up former directions, regu larly stopping and often sprinkling lightly with water round the frame.
Fias.-As soon as the young shoots are four or five joints long, commence stopping them by equeezing them flat between the finger and thumb; this is one of the principal secrets of success in Fig management. Ensure a steady degree of moisture at the roots. Figs are very impatient of drought-a very short period of neglect in this respect mny prove fatal to the crop.
Kidney Beans.-Give liquid manure to these, and make sowings for succession as required.

Peaches. - As before observed, suffer no gross shoots to push above five or six eyes without stopping; this will do more to equalise the sap than any mode o winter pruning. If the trees are properly attended to n these respects there will be little left for the knife When the fruit is as large as marbles, commence thinaing, taking only a few at a time. Give air freely when the weather is favourable, and syringe liberally with some force in the afternoon.
Pines. - Do not allow the bottom-heat to rise too suddenly; when much new tan has been added in consequence of recent shiftings or removals this may readily take place. Constant attention to the trial sticks is therefore now necessary, in order to ensure success. F'or general purposes $80^{\circ}$ or $85^{\circ}$ will be sufficient. Let atmospheric moisture be in proportion to the natural increase of heat and light, and give air freely "early in the day on all favourable occasions, shutting up a good amount of sun-heat whenever a chance of doing so occuss.
Vines.-Attend regularly to the disbudding or stopping of superfluous wood. Take good care of bunches that require shoulder tying. A brisk heat rate at night ; let $65^{\circ}$ at that period be the maximum. Koep up a liberal amount of moisture independent of Koep up a hberal amount of moisture independent of
the syringe. As soon as succession houses are closed
for forcing, be careful to secure a thoroughly mois state of the atmosphere by frequently sprinkling the floors and every available surface, but a regular mois state of the atmosphere is most effectually secured b means of a slight bed of fermenting materials in th house, which will also afford a little warmth, and th moisture from this is much more congenial to vegeta tion than anything that can be effected by the mos careful use of either syringe or evaporating pans.
hardy fruit and kitcmen garden.
As the period for sowing seeds of some crops will soon be at hand, see that everything is in readiness fo that purpose; never sow, however, until the ground is sufficiently dry to bear treading on without dis advantage, and otherwise in proper condition to receithe seed. Much mischief is committed by inattentio to these particulars.
Beans.-Sow Early Mazagan as soon as the ground will permit.
Carrots.-Sow also Early Horn on a warm border, Wall Trees.-All pruning and nailing must soom be brought to a close.

## The agxitultural Gatette.

sATURDAY, FEBRUARY 18, 1865.
ON Wednesday Mr. LawEs opened a diseussion on the agricultural value of town sewsge by an address before the Royal Agricultural Society, in which he disoussed some of the points which are touched by Liebig in his letter to the Lord Mayor of LONDON, at the same time desoribing and defending the Rugby experiments. The lecturer is just the kind of witness whose evidence any student of this subject would desire to hear. Everybody declares that the testimony of the chemist is necessary to a right understending of it, and of course agrioultural evidence is required and Mr. Lawes conbines the knowledge of the chemist with that of the practical agriculturist more perfectly than they have ever hitherto been united in one man. Baron Liebig does indeed descend to the suggestion that being a manufacturer of manure his evidence on sewage is untrustworthy, but it so happens that the conclusions which the German chemist adrocates, and which Mr. LAwes opposes, are those which the interest of the manure manufacturer would lead him to adopt. What magnificent scope for the indefinite extension of the artificial manure manufactare would there not be, if, as Liebig indicates, every farmer's modicum of town sewage delivered on the land should receive that preliminary supplement of soluble phosphorus, of potash, and other things which it requires to make it perfectly adapted to the crop! Mr. Lawes, to whom considerations of this kind have obviously never presented themselves in the same manner as they have to Liebig, simply desires to ascertain and state the truth; and in order that it may be useful truth, it must be true not only in the abstract, but practically-it must be truth not only scientific, but, as it may be called, commercial. The value of the material must be determined not only by its constituents, but by the condition in whioh
they are presented. It is frequently the case that a mass of rock examined by the ohemist may prove to contain $1000 l$. of gold; but the ore is so scantily distributed that it would cost more than 1000l. to extract it. To the chemist it is worth 10001., while commercially it is valueless. And this is very much the case with sewage. It may be worth $2 d$. a ton on the one view-it is actually worth barely a halfpenny a ton on the other. And just like Liebtg's assertion of the value of guano, the former of these assertions is good for nuthing in the face of rotual experience.

This experience is now large and long enough to be trustworthy. Thanks to the Rugby investigation it is also detailed and accurate enough. In eramining Liebie's recent statement, Mr. Lawes particularly pointed out his error in supposing that the ingredients of so much of a crop applied to the land will produce the quantity thus indicated. On the contrary, all experience proves, that in order to place a certain quantity of any substance in a plant, you must apply many times that quantity to its roots. A manufacturer will supply you all the ingredients of a billings morth will nor a shilling; but this shilling's worth will not when applied to his land
produce the extra bushel which it represents. And it is found practically to take 6000 tons of sewage to do that which Liebig declares 2000 will suffice to do. And as to the distribation of sewago over arable land for just the purpose of supplying the ingredients which the crops remove, it appears that ploughland under an ordinars rotation, when no mauure or cittle food is bought, loses only 7 lb . of phosphoric acid per acre annually; and $11,000,000$ acres of it would be needed in order to that scientifio distribution of the sewage to just meet this exhaustion which Liebig recommends. Of course the cost of such a distribution would be altogether fatal to the plan. And even if only the 600,000 acres be sewaged, which the London Corporation recommend, it would need a price of more than $2 d$. a ton to overtake the expenditure of distribution over so large an area as this.
But can the farmer afford $2 d$, a ton? That is the question. And Rugby experience decides it. The owner of the sewage there offered it to the Commissioners for 1d. a ton, knowing that he could make no more of it, though all his land is piped for its distribution. And they gave $1 d$. a ton, though they barely realised $\frac{1}{2} d$.
The following are the figures representing the experience of the last four years.

| Year. | None appliod. | 3000 tons applied per acro. | 6000 tons applied per acre. | $\begin{aligned} & 9000 \text { tons } \\ & \text { applied } \\ & \text { per sereo. } \end{aligned}$ |

A study of this Table shows that the inoreased produce follows the increasing application of sewage ; and it oroves that up to a certain point the result of applying a large quantity per acre is as profitable per ton as when a small quantity is used. Mr. Lawes conoluded by warning the promoters of any of the schemes for using London sewage, that they must not expict to realise more than had been realised at Rugby; for the experiments there were perfeotly trustworthy.
To the discussion which followed Mr. Lawes' paper, Dr. Voelcire, the Earl of Longford, Mr. Morton, Dr. Crisp, Mr. Fawcett, Sir E. Kerrison, Mr. T. Scott, Mr. Acland, and Mr. Blackburn contributed. Dr. Voelceer corroborated the remarks of the lecturer on Liebig's faulty estimate. Dr. Crisp pointed out the real danger, as he asserted, of an increase of parasitio creatures in the bodies of those who shall be fed on sewaged produce; but as he alleged of a particular white "worm," which it seems is especiaily to be dreaded, that in all probability it was already flourishing in the bodies of half the gentlemen in the room, who certainly had not been feeding direotly or indirectly on sewaged produce, one does not see the connection between his fears and the subject
of the leoture. Mr. FAwcext spoke of his ex- and excepting the reception and delivery of goods, perience of liquid manure on Grass, which the whole process goes on day and night continually answered very weli in wet weather, but spoiled the growth in dry weather. Sir E. Kerrisons asserted that ample experience already existed, both as to extent and as to duration, of the proper way of turning sewage to agrioultural account. The Edinburgh meadows and the guide. Mr. Scott described the experience at Wimbledon, where a pipage distribution had been abandoned as too costly, and the simple gravitation system had subsequently succeeded. Mr. Acland called attention to the need of examining the experience of ordinary waterwith sewage.

The debate was closed by Mr. Lawes, who pointed out those difficulties conneoted with a practical dealing with the question which arose from the enormous quantity and constant mow of made the subject of remark hereafter.

We have more than once presented in these columns remarkable examples of the food manufacture of the country. Only the other day the farm at Plashet Hall, East Ham, where labour to the extent of $6000 l$. per annum is directed chiefly to the provision of vegetables for London, was described. Last year the farm near Woking, where ten to twenty thousand "score" of bacon are every year sold off four or five hundred acres, was referred to at some length. And occasionally examples have been given of the subsequent undergo before they are ready for the kitchen or the cupboard. Thus, an account of the great bacon-curing establishment of Messrs. Hilliter, near Stroud, will be found in our last year's volume. And we propose to-day to give some account of the largest flour-mills in London.

The difference between the weight of Wheat and the weight of all that the miller obtains from Wheat is generally found to be one pound in a busbel. Add all the flour and biscuit middlings, the coarse and finer Pollards, and the bran into which Wheat is converted in the mill, and it will he found one pound per bushel less than that of the Wheat from which these articles are obtained.
Where the fine dust of the flour from the mill stones is drawn awry by exhaust pipes and colleated in a "stive" room, thence to be taken for sale to those who use paste and batter for cement or starch, or perhaps to be remixed with the manufactured flour before delivery, there is a smaller waste than in ordinary mills. We have now to describe an establishment where every known method of economy is employed, and where this only. The flour and other goods for sale contain less water than the grain bought. The latter is reduced from berries weighing perhaps 10,000 to the pound to partioles of inappreciable size; and there is involved in this process an enormous extension of surface laid open to the drying infraence of the air, and as a considerable increase of temperature takes place during the grinding process, of course there is a certain loss by evaporation from the particles whose surface is exposed. It is a striking illustration of the magnitude of this establishment and of the quantity of its operations that the Ioss of this kind which is suffered in the yedr-the difference, due almost wholly to evaporation, between the weight of Wheat which is reofived and that of flour and meal and bran sent ont, amounts to 380 tons per annum.

If this be, as we may assume it to be in the present ease, not more than one in 80 or 90 of the grain which passes here through cleaners, fans, and miluthones, silks and siever sod sacks, then the quanitity of Wheat which is here manipulated must amount to 32,000 or 34,000 tons per annum, or considerably more than 100 toms a-day. This tallies perfectly with the actual performance of the mill in question, which, when driven to its utmest, is capable of delivering 1000 sacks of flour a day, corresponding to 1500 sacks of Wheat, and does aetrally upon an average convert 500 quarters of grain dally. This quantity, though so much below the possibility of its performanoe, is still largely beyond the ordinary experience of flour mills when compared with the means by which it is achieved. It is accomplished by an expenditure of about $14 l$. a day in wages, and a consumption of about 12 tons of coal a day, producing 400 horse-power, and driving 32 pair of stones, of whioh four or five at lenst are of course always out of work and in
the luuts of the drewter. The whole machinery,
superintended by relays of men in attendance on engines, millstones, silks, \&e. The arrangements for hoisting grain from barges outside the building are oapable of lifting about 90 quarters an hour suffieienoy of vans and carts, equally eapable o vertaking during even short winter daylight the requirements of so large a faotory, whioh is otherwise continually at work.
The City Flour Mills were ereoted by Mr tames Ponsford in 1851; Mr. Bramwele, brother to the present Baron Braywhll, being the architect and SWAINE \& Bovill being the mill engineers. They were worked first for five or six years by Messrs. Ponspord, Curais \& Whicit. Every known appliance and arrangement was brought to bear apon the attainment of an economical and profitable resalt-exoopt we prosume that business tact, promptitude and ability, without which all other helps must fail; and after heavy losses of money (counting both the original "investment and the annual expenditure) had been incurred, the factory was let to Messrs. Hadley. It stands, one end and side in the river, and the other end abutting on Thames Street, about 370 feet long and 60 wide; a building seven stories high, one of the most striking on the river side below Black friars Bridge. The lowest floor,one-half only of the length of the building next the Thames, contains coalhouse and bnilers. The next is on the level of the top of the toilers (seven in number, of which six are continually in work), and is oocupied by the two engines, together 400 horse-power, which have lately been supplied with second cylinders, on the principle referred to at page 12, by which the same amount of power is derived from a con sumption of 30 per cent. less fuel than formerly. Towards Thames Street on this floor are delivery stands for waggons, clerks' offices, counting house, \&e. Mounting from this floor to the third, we are in a room 90 yards by 20 . The whole power of the engine, which is centrally placed, drives here a central longitudinal shaft extending about halfway towards either end of the building. There is thus scope beyond for a further extension of the mill to the extent of nearly doubling the number of mill-stones at present used. These are arranged on the floor above, in efghts, along the sides of the wall, and about 5 er 6 feet apart. Anid on this floor are the arrangements for ariving them, together with the sorews and lifts for taking the flour from them. All the stones are driven by straps from drums or riggers on the central shaft, and the vertical
motion of these drums is converted itte the horizontal revolution of the several riggers, or drums, on the shafts which carry the upper mill-stunes, by the intervention of a wheel at each, carrying the lower strap, which both lifts it and directs it aright, so as to suit the position in which it is required to worls. It results buth from the upward lift of this lower strap as it leaves the central shaft, and from the atones driven being parallelly arranged on opposite sides of this eentral shaft, that the shaft itself runs almost lifted and pulling equally on both sides, almost without friction in its bearings. This arrangement of driving straps, though we are informed it is no new thing in other manufactures, is, as applied to the driving of millstones, a part of Bovill's patent, which has latterly so much engaged the attention both of the law courts and of the trade. Another part of the patent is seen in operation on the 4th floor, to which we next ascend. There are here the 32 pair of stones, arranged 16 on either side of the floor, and about 2 yards apart, concentred at the middle of the floor, leaving ample storage room at either end. Mr. Bovill's patent consists in the combination of a blast operating at the eye of the upper mill stone, with an exhaust operating all around the circumference of both mill stones, by whioh the flour and bran as made are drawn and driven tinough, and so hindered from ologging the surfaces by which they are being made. We understand that a blast alone and an exhaust alone have been each before employed; but that the combination of the two is new. The arfaces of the millstones are thus lelt the cleaner for their work; the power spent in driving them is unwasted by the clogging effect of the flour made, which it unremoved creates much useless friction in ordinary mill stones; and the grinding surfaces are the more efficient for their work, by the flour being rapidly removed from between them as it is made. It is perhaps partly owing to this, but ohiefly owing to a heavier grinding as indicated by the unusual horse-power employed ( 12 horse-
of stones will generally grind about a back pert - 12 quarters during the 24 - the 28 pair of sto which are here generally at work get throw
500 quarters in the day, which is at least jo cent. more than is the average rate. Another effect of the blast is that the flour is delirem cooler from the stones, and thus less hablo toing during storage.
It may perhaps be worth while to describe here operation of a pair of mill stones. They are cire 10 inches thick) burr (abont 4 feet across and 9 10 inches thicks, pieced together and held in one by
iron rim. Their surfaces are made perfetly planes; they are pierced at the centre by two cir
eyes about 6 inches in diameter. The law eyes about 6 inches in diameter. The lower one; fixed and firmly bedded; the upper one he balanced on cross bearings on the end vertical shaft (passing through the eye of the lo one), by which it is driven. It is furnished 4 leaden plugs around its upper circumference addition to which it can be accurately balane and the slaft is then lowered until the two surfacen an on the point of touching one another. The grain ed into the interval between them through the erea the upper stone, and the centrifugal teudency on sequent on its revolution, together with blast exhaust respectively where BovisL's patent is employ drive it from the inner to the outer edge of the gin ing surfaces, and it is reduced to flour and bran on ito m In order to the accomplishment of this result
surfaces of the stones are furrowed, so that both rolite and cutting are combined in the process of griudiug. In the first place each surface is scored m 10 tolerably deep equidistant radial grooves, and thons after the singular sections thus defined are tooted nt straight and equidistant very close and shalinw femm chipped out, which are mt radial, but which are pridild to the foremost of the radial sides of each section whir whole revolves, when this one surface revolven on the other, which it does at the rate of 120 revolution per minute-the scorings of the under and uppore aces cross one another and produce a cuttiug as mell a rubbing of whatever lies between them. And the action tends somewhat to sheck the rapility of centrifugal action upon the still unground fay ments of the berry of Wheat which have to be reduced to flour. A week's grinding so it obliterates these markings on the stones as to retum them to be re-dressed; and thus, of 32 pairs of 11 m shere are always 4 or 5 under the tool; and 11 m out of the 61 men and boys within this factory constantly employed at this work: edge is used by which to make wood latter when thus made absolutely trie and indicate by mean of paint any faults of vurthe both the stonee, and thus in re-tooling the scare प पp the stones security is taken for the perfect tran the surface employed. We understand thit a g stone will wear not more than an inch in seven renm
To return to the mill we are now As the flour and bran leave the stones upon fourth floor they fail down a tube into the below, and the whole is then received by a hor zontal tube with screws, which couveys it along $p$ the various lifts by which it is carried up intol apper floor, where it is dressed, and whence. whops into the flour rooms in pastries, which it drops into sacks. Tho exried with the flour dust, which it saves, into 1 danvas - walled room or "stive," where deposited.

In the fitth floor these "pastries" are situate. and here, too, are the Wheat scrubbers, sieves fans by which any bunt is broken and r:w and dust and dirt is taken from the grain bel it reaches the hoppers (one to every 4 pair) the mill-stones.

On the sixth floor are the dresseris- 14 "sil -oylinders of silk, of varying texture, long, and about 3 feet in diameter, stretoan ootagonal frames, revolving at the rete per minute-into which the whote meal into and through which the flour passes ived pastries" below, while the bra shoots and carried is lifts,
stored, whence it is delivered for sale. way the whole produce of the stones is separ into the various sorts and qualities known market, which have been dlredy y enume this tloor, too, are the fans, fed frough triple canvas for the per of London smoke and soot, which create the and exhaust respectively by

The last story is where the corn is reoeived couple of lifts, with a couple of men to each oontinually hoisting grain from thie barges for object and judgment of the matter, and the ris shoots are fed on this floor with the mixel to thence passing through sorubbers and fans hoppery over the towes, and fhenee by so

Is to the silks, and thence by its own weight, and ins lift when neetssary, to the sacks which slide onn to the waggons waiting to carry the goods of the merchant or the baker. The grain is lifted 0 the merchant wheeled along by han 1 in bags for rirture, tut never touched again. The process is the seafter carried on be machinery, and the whole in one of the most striking examples of well devised and economical organisation that we know. The fuil is economse of the steam which it produces. $P$. a ar is is econnmised both in the gearing and in the stones liga reduction of friction at the bearings of the central shaft, and by keeping the rubbing power of the stones to its proper purpose, not suffering the then when once it bas been made, to remain and clog the surfaces. Labour is economised everyWhere by putting screw and lift to do the work of handa. And over all are the trade arrangements by which 500 quarters are delivered daily to the mill, and the corresponding quality of flour (some 660 sacks) are delivered daily to customers in all Farts of London; and thus the mill kept going withnut excessive storage being required.
The topmost floor is generally a good museum of all the various sorts of Wheat known, whether to the Iuglish farmer, or the miller and importer. The very bast white Wheats from Berkshire, and the coarsest from the Fens, foreign growths, all sorts, pass through daily, and are mixed according to the judgment of the miller for the production of various qualities of flour for which he knows there is a market. Sampl-s of grain and flour and bread in the counting-house below are the data on which large bargains are made. And in this way the material is provided fir nearly lalf a million quartern loaves per week. And here, in this one mill alone, there is ground the produce, year after year, so far as Wheat is concerned, of probably 300 square miles of arable land.
It does good ocoasionally, we believe, to the quiat homely farmer, when he is induced to look over
the hedge, not ondy at the energy displayed, Whether successfully or not, upon a more bustling neighbour's field, but alno at the power and energy displayed in those manufactures which are enpocially connected with his own occupation ; and hoping that some such may read these notes, we have at the City Flour Mills
doings at

We are hindered this week by the pressure of other subjeets from giving that fuller discussion of Mr. EDMCNDs' extremels valuable paper on Middle-class Education, before the London Farmers' Club, which it so entirely deserves, and which we hope it will yet receive from our cirrespondents. We hope next week to direot aspen to EDMONDs' recommendations, with especial reference to those on the same subject Which the Council of the Royal Agricultural
Society are about to receive from their Committee on Education.
-The Mark Lane Express has, daring the fast two weeks, fabulated an immense mass of information on the character of the last harvest. The following Table, in which the figures represent the number of the reports received, gives the principal results of the inquiry. It gives a condensed view of the general results of the harvest, and in doing this it is necessary to say that the averages of grain are assumed to be as follows:-Wheat 4 qra, Barley 5 qris., and Oats 6 qris. per acre. us; but this is of less importance, as not more that three or four of the returns mention the amount, merely naming "average," and "over," or the table of the aotual may be. The following is table of the aotual results :-

eports, the following figures give the number of regardo the grain oropt:

Oar own reports in August last, though from a
much smaller number of correspondents, may be compared with these by a similar per centage table. And there is a sufficient resemblance between them to show how fairly the character of
the crons may be estimated before harvest by any one acoustomed to such work.
Per Centages of ter Reports to the " Agricoltural

## Whest Barley

The principal discrepancy in the two Tables exists in the returns of the Wheat orop; and those at the time of our publication last summer were declured to be less favourable than had been confidently expected. And shortly afterwards it was pointed out that a wonderfilly fine harvest time had undoubtedly improved the orop beyond the character given of it by our correspondents: as indeed the reports to the Mark Lane Express prove to have been the case.

An International Agricultural Exhibition at Cologne, under the patronage of his Royal Highness the Chown Prince of Prussia, is announced to be opened on May 15,1865 . It will embrace Machinery, Implements, and Productions of Horticulture, Agriculture and Forestry, together with objects of farmers' and foresters' household economp. All manufacturers and producers of such subjects are invited to contribute to the exhibition, which is to comprise the following principal divisions:-

## Agricultural profuctions, including collections of any

Implements and machinery for agricultural purposes, materials, household furniture, working implemente, victuals, and objects employed for the proparation and use of the same.
Productions and implements of forestry and sport as
well as collections relating thereto
b. Productions and implements of horticulture and garden architecture, including garden furniture, statue,
Questions and letters to be addressed post paid to the HortiUltural Society "Flora," at Oologne
The privy counelllor Dr. Hartatoln, Director of the Agricul tural Academy, and Mr. Von Rath. President of the Agricultural Associatiou for the Rhenish Provincos,
Bonn, will gladly answer tochnical queations.

## REPEAL OF THE MALT TAX

As a class of men the farmers are blamed for their indifference to the repeal of the Malt tax: the majority, however, feel very btrongly oin the subject ; yet for the want of union very little has hitherto been done. Perhaps something will be allowed for their isolated position, as compared with the inhabitants of towns. It bas long been the opinion of many of the most eminent statesmen that when the Corn laws were repealed the Malt duty should certainly follow, and that its ultimate repeal would simply be a work of time, and the recent roeasure introduced by Mr . Gladstone would seem to imply that the period has fairly arrived when the obnozions tax inust be dealt with. That measure, however, being so clogged with restrictions, and next to useless to the farmer, he remains in much the same position ns before, and this benefit of the farmer only is impracticable-alike selfish, inconsistent, and entirely opposed to the doctrine of free trade. If this is what Mr. Cobden means, when he states that he will be ready to give
his support when the farmers come forward with a straightforward and honest policy-and as stech policy is now admitted to be a total repeal remitted by instalments, we shall ever feet mott grateful, and shall be anxiously looking for one of hid powerfol ard telling speeches on the subject.
That the Malt Duty in anjust in principle; being ntterly opposed to the free trade policy of the times; that the farmer is thereby debarred from the privilege of using his own corn in its most approved state for the fatting of his cattle, and the demand for a most important portion of his produce is thereby most unnaturally curtailed; that it inflicts great injury to the working classes, enhancing the price of the people's beverage from som enfori by encouragite or leading them indirectly to comfori by encouraging or leading them indirectly to injuring the public generally by contributing to make both beer and meat dear ;-all these are ohjections well known and generally admitted.
Having to deal with a period of low prices for all kinds of corn produce at the present time, the position of the farmer is one that requives much consideration on his part, if not some anxiety; it is not necessary, however, that he should look on future prospects with
a gloomy view because prices happen to be low. Why should the business of agriculture be exempe from those changes which beset all other occupations $P$ Low prices may coutinue or they may not; all past experience would tend to show that we now nothing prices are beyond control, thanks to free trade in corns
though not in meat), and the point for consideration is, what system of farming is best adapted to meet $\ln \pi$ prices? We have heard a vast deal of information lately given upnn this important subjeet, such as laying dwn hind to permanent pasture, \&cc., for the purpose of more stock keeping. In this particular respect, how. ever, I am extremely glad to find that 50 good an
authority as yourself cannot agree; but in the rearing and keeping of as much stock as possible to meet the increasing demand for meat, the feeling appears to be well understond and manimons.
It has ever been a matter of regret to all those farmers especially interested in the fatting of bullock: and sheep, that the feeding with malt should be im. You have only to wall ine ante tion because of the Excise. You have only to walk into the various markets to see large quantities of Barley vers low in price, and of ex. cellent quality, apparently wanting customers, for there stands in the eample sacke, woek afcer woek, till one is positively tired of looking at it.
And in the same town or strees an active demand exists for both beef and mutton at high figures, aud nany of the animals about half fat. Why not turn some of that beautiful Barley into malt, and fatten your cattle, asks the consumer, and benefit jourself and me too?
Well, my friend, I shatl be extremely glad to don an, as soon as I get the chance and am permitted; but so long or reason to complain, even though the price of meat should wise to $1 s$. per lb. Has it never occurred to your moind what a very large amount 1 d . per lb . tax on meat vould raise?
The Chancellor of the Exchequer professed to be astounded when some one or other of the deputation who waited upon him last year, informed him that it cost many millions to collect the five raised by the Malt tax; but as you and I are not exactly qualified to enter into statistics of that description, in lien therent let us take a retrospect of our respective meat bills for the past twelvemonth, and see what that would come in a quiet kind of way.
In the mean time will yon join with me in endeavouring to obtain, by all proper legal and constitutional means, the total repeal of the Malt duty, because if you will I have no doubt we shall succeed, and the farmer will do his utmost to provide you with meat of the best quality and at the cheapest rate, to say nothing of the mariy opportunites afforded of providing yourself with pure and wholesome beer. W. Simmonds, Guildford.

## PAINLESS EXTINCTION OF LIFE

## It Atrivale Desionsid ron Hugar Food.

Lise my excellent neighbour Mr. Chitty, I aloo was interested by your notice of the pumphet by Dr. McCormack, and as the subject is strictly
withn the province of Jomrnal devoted to the withn the province of Jowrmal devoted to the trust I may be allowed to make a few femarle in reply to those by my friend. I am anxiot to break a lance with Mr. Clintty, becanse the line of argument he adopts is one calculated, even if fallacious, to have great weight with many excellent persons, who would countenance waste, and worse than waste, rather than violate a Biblical precept which they suppnse to be binding on them. Mr. Cliitty represents the oljections to Dr. McCormack's as of tivo kinds, theological and physiological ; that the eating of blond was prohibited by the Mosaic Law is most true, but are we bound by that law in these times? It is generally agreed that we are not; else we must abstain from labour on Saturdays; we must abstain from certain kinds of fish; we must abstain from pork \&ec, \&e. Mr. Chitty says: "it was not always that the flesh of animals was permitted as fuod for mankind," and in this he is prubably wrong, for though there is an explicit declaration in Fien. ix., 3, thas "every moving fhing that liveth shall be meat for you," yet in Gen. ivo, 2, we read of the flocks of Abel ; in Gen. iv., 20 , of the flocks of Jabal, and in Gen. vii, 2 , of the distinctions between clean and unclean. Nevertheless the eating of blow was prohibited: "flesh with the life thereof, which is the blood thereof, shall ye not eat." If we comeider the prophetic nature of many of the earlier precepts and injunctions of the Oid Testament, I think it will appear that this and similar passages are not intended to set forth any physiological truth whatever. Suppose, for instance, we find that the blood is not the life; what will Mr. Chitty and those who hold similar views say to it?
Nevertheless, by taking a higher, that is to say a spiritual and not a carnal view of the subject, we may under tand that the eating of ood whe was the symbol of the precious blood was herearter to be sied for the salvation of the world. If I may use the term without irreverence, I mny say that it was a necessity of the Mosaic dispensation that blond should be considered sacred-most sacred; elso what impression could the sprinkling of it in sacrifces make apon he mat declara prombition an of the Leviticai ceremonies, but is it not just such an anticipation of them as we have in Gen. vil., 2 , where
there is a diatinction between bensts clenn and un. there is a distinction between beasts cienn and uno
dean? Not only did the Levitical law forbid the eating of blood, but it enforced the prolibition by the poantry of deathy and in Lev. in, , 17 , the eating of

Levitical Law binding in these matters, he is prepared to pratensis, which, thongh a Grass which in some state or enforce the penalties for disobedience, and whet the rhe himself is an abstainer from fat. Bat beside the sacredness of blood in former times as representing mystically the life of all flesh, and typically the plan and purpose of is probable that the interdiction of its use might derive force from the practices of the Those who are familiar with the Old Testament will be able to call to mind many prohibitions that have no meaning whatever except in bearing on the tendency of the Jews to become idolators. For altar, \&c. In Psalm xri., 4, and in Ezekiel, xxriii, 25 distinct mention is made of the eating and drinking of blood by idolators, and that is alone sufficient to render perfectly intelligible the proscription of blood to the chosen people.
As for the New Testament declarations, they appear to represent the remaining prejudices of declaration on the subject, and the Apostles were greatly influenced in their views and teachings of Christianity by their Jewish training and habits; so much so indeed, that a vision from Heaven was needed to show to Peter that the distinctions between clean and unclean had passed away. As respects the Biblical argument, probably the whole matter is summed up in 1 Cor. viii., 8. "Meat commendeth us not to God; for neither, if we eat, are we the better; neither, if we eat not, are we the worse." As in many other matters, it is doubtless left to us "We are not under the law, bnt under grace."
As for the physiological part of the subject, it is obviously one for further inquiry and experiment. If animals can be killed instantaneously; if being so killed we can obtain from their carcases a larger amount of wholesome food, then let us follow Dr. McCormack, and suffocate instend of bleeding, and having done so, eat the blood. I dare say I shall be called a beathen, and something worse, for putting
the case in this way; but I will risk all that, and maintain that if people like black-puddings they may eat them without violating any law of God, and perhaps without imperilling their powers of digestion. Mr. Chitty objects, because "blood taken into the stomach must remain there until its vitality is entirely destroyed;" but this is assuming that painless extinction of animal life is to be followed by the quaffing of bumpers of blood, hot from
the bullock, which I suppose Dr. MI ${ }^{\prime}$ Cormack does not propose. In plain truth, Mr. Chitty's physiological argument melts into "air, thin air," before the fact that the blood when removed is no longer a vital substance; It has no more vitality than a finger nail, a body, a lock of hair, or a slice of flesh. The life of an animal is not result of the combination of these various constituents of the creature, and their combination under certain conditions. Dr. A. Clarke was a good man and an able theologian, but lis authority for regarding the blood as
possessing a living principle" is of no value whatever; and as for the quotation from Dr. Hunter, we must know more about the experiment referred to, to accept it as evirence. Is the quotation from any work by the great John Hunter, and in what way, when, and where was a coagulum seen to become vascular? Mr. Chitty has dealt with the subject in an able and spirited manner, but I think he fails to establish that th Biblical declarations have a physiological meaning, and I am sure he is wrong in assuming that if blood is taken into the stomach as food it must be taken while it yet has life in it. I suppose Mr. Chitty refrains from eating hare soup; for all cooks say that unless the blood is saved in dressing the animal, hare soup is not worth eating. Shirlsy Hibberd, Stoke Newington, $A$ Feb. 1, 1865.

## Home Correspondence.

Effects of Irrigation. - Your Correspondent Mr Charles McDonald wishes for information as to the amount of irrigation which produced the results observed by me and recorded in the Table quoted in reply that the Table January 28. To this I would of Grasses, and a subsequent one the same for other plants in a field after four years of irrigation. It is in a position where there is perfect command of the water, which was let trickle through, not upon or ove the mpadow, three times a year. The water was that which is employed in irrigation for many miles of it course, and so successfully as to have made land otherwise only worth 30s, an acre now let for 52 , an acre. From Mr. McDonald's observation I almost incline to the belief, that, notwithatanding he says "I aver that it, that is, the Table, is the very opposite of universa practice" (qy. experience) - that he has had more as Poa trivialis will certainly increase where water at all stagnates, but under proper irrigation sounder and better herbage takes its place, and amongs
apondent, in which he is is cease to that atated by your correspondent, in which he is "engaged to improve a meadow
where the herbage has become worthlest by irrigation,"
other may be found almost everywhere, is still not entitled to be called so exclusively an "upland Grass," It is viewed as "more remarkable" that Aira crespitosa by one, too, who has studied Grasses for 10 years ; but I would observe, as the result of more than 20 years o study of the Grasses both at home and abroad, that if Aira cæspitosa occurs in any quantity in a meadow ander irrigation, it is itself the best eridell-informed drowner* knows so well, that whenever he traces a single tussack away from the water-courses he knows the water stagnates there, and at once makes a new that irrigation and flooding are too often confounded. In a good irrigated meadow the drainage should be so perfect that when the water is stopped one should be able to walk over it clean and find it sound in less than 24 hours, to which end there should oe perfect command of the water to get it distributed and and equally so to get it drained off. I am now the lack both qualifications; they are on a sluggish stream liable to floods, and some parts are so low that they cannot be drained; the consequence is that here and there the water stagnates, to the delight of Aira cajpitosa, Rushes, Sedges, \&c, In some portions that can drain these are quite absent, and if we could improve the whole we should look for the evidence of our success n the gradual dying out of these weeds, and a substitution of better things - and this much upon the principle recorded in our Tajle, which by the way we must refer to our Natural History of British Graases published by Hamilton \& Co. James Buckman, Bradford Abbas, Jan. 30.

Utilisation of Slewage.-As this question is one of the greatest importance, and as it is most desirable that no call attention to the following serious oversight in Baron Liebig's estimate on the subject. I may remark, en passant, that having years ago, when greedily 302 . not. in the purchase of 3 tons of his manure, I lost that the great chemist was not infallible ; and he has since still further lowered himself in my opinion by the pertinacity with which he clings to his inorganic manure theory, though scientifically refuted by Mr . Lawes, and practically by every farmer in the country; but I suppose the greatest minds do not like to own to a mistake. In the present instance the error to which I propose to call attention is the following:-Baron Liebig calculates the value of the excreta of $2,000,000$ in the London sewage; and we gather from the calcu. ation that 3-5ths of the phosphoric acid, 11-12ths of the potash, and nearly all the ammonia are contained in the urine, and these are the only three substances valued in the estimate. In a subsequent part of the report Baron Liebig refers to a now well- Known fact, and states, that "where water and earth are brought in contact with each other, the manuring matter goes no further, but remains there." Now, of course it is impossible to calculate correctly, but every one must be fully aware that a large, if not indeed the largest, portion of the urine voided by man and beast is mmediately brought in contact with earth, and consequently robbed of its manuring matter; some perhaps may only be partially so, from flowing over the surface into the drains ; but much more only finds its way into them some day the soil of Lund though it may be argued that some day the soil of London will be saturated, so that it can retain no more, that day must be very far distant, and for present purposes cannot be taken into account. I also observe that in estimating the value of guano, Baron Liebig refuses to attach any value to the uric acid and urea contained therein, though in valuing the urine he estimates the full value of these its principal contents at their ammoniacal value, which no donbt they fully contained in then it is inexcusable to ignore them when contained in guano, especially when, as you have fully has bee yourleading Article on the subject, that value agricaltural experiences" H.C.

Wheat a Drug.-Wheat is certainly, at present, drag in the market. Beef, matton, pork, poultry,
butter, milk, and cheese however pay well. There will be changes in the prices of various articles of human country, rise and fall in value commodities, in a free country, rise and fall in value, according to the supply and demand. Men lave no reason to complain, if from their foresight or speculation they happen to have in be. if whes an article not so profitable as it used to the expense of growing, let it be either used in pay wher way, or less of it sown. Crushed grain and chaff with the addition of a few roots, will fatten sattl rapidly in the stall, and leave in the yard a splendid related to the vegetalle will bear alnost anything contin to regetable kingdom, but if farmers will remur tulvate quantities of that which will not * The them for their trouole, they will have themout the conduits and directs the flow of the whater in

 am certain we sham anagement. At the same time, to show
tical points of farm mane we aspire to embrace, I may, phint out
the freedom of range two or three subjects on which I believe there may be I difference of opiniox, at east in regard to which the interestis of
landloris aud teants, at first sightt. appear to diverge. First, thero is the important question of the Law of Hypothec, which 18 at present is denouncect by some and praised by others, it wust exurcise an Important influence, oither for good or evil, on
practical agriculture. I have no doubt, when once the labours of the Rogal Commisslon now sitting are fairly over, sud you
have the evidence taken in four hande, you will disouss the surject; and the opinion of the members will be taken as to whether it should be maintainen, modited, or aboiished. There may come before us: for instance, the game laws and the premarvation of game, by whicl I apprehend many tenants suffer gn iniuriously. I am glad to hear that of late it is difficult to
find tenants for farms near preserves, except at very small rents. find tenants for farms near preserves, 'except at very small rents.
Again, there are the terms of leases, the rotations of crops frequently prescribed, and the conditions, generally, on which it in his power to lay down the terms on which he will part it in his power to lay down the terms on which he will part is at full liberty to farm it himself if he chooses. I Iearn this
bas boen of late extensively done on ehire. I hope that discussions here may bring out clearly and estisfactorily what is the right and reasonablo thing for land-
lords to ask-that they will find it to be their intereat to lords to ask-that they will find it to be their interent to
bargain only for such terms as clear-headed business men will be willing to agree to. I have of late seen some leases so out ragoous that I can only wonder they were ever offered for
sigosture to sane men. The truth is, a tenant so very rarel sibmite a lease to his own lawyer, that I believe a charge o revising a lease ofr a tenant of agricuitural subjects has no Mlace in a lawyer's table of fees. So much evil has arisen from
this, which has lately come under my notice, that I wish to this, which has lately come under my notice, that I wish to
call spocial attontion to it. It is all very well so long as a
tenant pays his rent and remains on the farm. but lat him lease, or if either landlord or factor take offence at him, on
many eatates he is wholly in their power, from the impcsibibility of farming without breaking either one clause or anotherto be reduced, or which no right-thinking landlow himse to be reduced, or which no right-thinking landlord should
desire. Beeides these questions, there are many others which may come before Parliament that may require attention on the part of the Cbamber, as involving the interests of practical
agiculturists. I allude particularly to all assessments that may be laid on occuplers, such is poor-rates. for the main-
tenance of roads, or, it may be, for new or increased rates for
national edncation. I am far from saying that occupiers should national education. I am far from saying that occupiers should
not bear their fair share of these burdens; but what I contend
for is that they should have an opportunity of first considering them, and of being satisfied that they are called on for
no more than is justly exigible. For the regulation of fairs and markets, also, I cannot imagine a more suitable body for
giving advice than the Chamber of Agriculture. And there are many other questions I have no doubt your committee
will take up. When it next moets, I hope it will be divided welvemonthsi I trust we will be and when we meet this time towardsbip. Gentlemen to, seeing there was some little difference of opinion in regard styled "The Scottish Farmers' Club." What have not yet had ecured excellent rooms in this hotel, which; is most have her the numbers can at all times most freely resort, and the most reasonable terms. I am confident we obtained on useful part of privileges to pronnunce the club not the leas Inth to make our programme. For myself, I intend hence hope to meet our roomere gentlemen from all parts of Scotiand, the can be of service to any member, in regard to and if ever Contlemen otherwise, it will give me the greatest pleasure potico the I cannot conclude without bringing under your tion of our Association by Mr. M'Lagan of Pumpherston. our honorary secretary, he has bestowed on it, demand, Warmest tbanks. I have no hesitation in saying that to him is He assuredly deserves to have occupied the place which I hav except the fact that Mr. M•Lagan has the misfortune to pa no rent, but happens to be owner of the fee-simple of the name with the toast, and to give it thus-" ${ }^{\text {Succes}}$, to join his the health of Mr, M'Tere and the Scottish Farmers' Club, with

examined in reference to the Sewage of London, mittod to the Metropolitan principal Schemes sub Retractsfrom Evidence, \&c. B. Stanford, 6, Charing Croes,

## We merely name these publication this week-the

 contain a pamphlet. Together we may say that they contain nearly all that exists of well-determined infor of Mr. Menzies deals vith tom them both. The bookhouse by house; the anonymous pamphlet deals with it in the mass after it has, in fact (to speak of that of London), been turned out of town as a nuisance, and is running to waste at Barking. We shall next week give an analysis of the contents of each of these works, and make such critical remarks on them as they appear to deserve. But we do not delay this mere announce ment of their publication, as they both directly relate to the subject which is just now one of the greatest importance in the agricultural world : the latter in particular, as it appears to us, concentrating in readable and accessible form the whole of the evidence by which
decision of the town sewage question unust be determined. It includes a discussion of the experience of all the towns where sewage has been applied-refers to the artificial manure trale in connection with the subject-describes the several methods proposed for dealing with town sewage, and advocates, as all those who have had any practical experience dc, the treatment of the land with it in quantity as in ordinary irrigation.

## Farm Memoranda.

generally considered an unprofitable Farming is very now when all grain is at such a low price. I have lately taken a farm in the Weald of Sussex, and will give a short description of it, and the manner in which it is proposed to manage it, both as to stocking and cropping, and then ask whether the manner proposed can be carried out-if the calculations are anywhere near right and such as are borne out by practice, and if so, can the resulting balance be considered satisfactory ; and if not, what other mode of management can be recommended which shall produce better eturns
The size of the farm is 208 statute acres, lying mostly to the south; the fields are large and unencumbered with hedgerow timber; all the arable ground that requires it is drained well, and water lays but a short time after rain has ceased. The farm is divided as follows :-

> Arable land Meadow for mowin Pasture.. Roads, woods, \&ic.

## 15 ares 35 25 208 208

The soil is all of a description upon which roots can be grown, not strong land, but nice working, though with rather a tendency to run together and paste. After heavy rain, especially if worked fine, the subsoil is very various, as is the case in the Weald, veins of sand, marl and clay occurring all through it. None of the
farm is what can be called lilly, and the buildings are so situated as that most of the manure carting can be done with one horse in a cart.
It is proposed, then. to mow the 35 acres of meadow land every year, and of course to pasture the pasture, and to crop the 115 acres of arable land as follows:-

## 23 acres root crop (lst year). <br> 23 acres- $11 \frac{1}{2}$ Clover, $11 \frac{1}{2}$. Beans (3d year)

115 acres.
The description of stock to be kept is to have 12 cows and to make them bring up 50 calves during the year, which is rather more than four each, the
calves to be kept until two years old. They will suck the cows for two months, one calf at a time, and gradually weaned in that time, then putinto a box and fed with hay, meal, roots, \&ce, until two years old, not leaving the box until fit for the butcher,
there will thus be 38 calves to buy, and each corr's there will thus be 38 calves to buy, and each corr's
calf will bring ap the number to 50 ; there would thus be from 80 to 100 animals always on the farm for which to provide food. I consider the number of boxes required for these would be 50 of 10 feet by 9 feet each, that is 20 boxes with one animal in each, 30 with two each, and the remainder would be in a large loose box or boxes during the time they were being suckled, the cows to be in a yard. The question is how to find sufficient food for this quantity of stock, and I give the quantities I imagine would be sufficient, and when I am wrong in this should be glad to be set right.
Number of head of stock always on farm would average 90 , for which food must be provided.
Quantity of food possible to provide-

## 33 acres of root cr <br> The root crop woild have to be begun in 23 hay

 and last until the middle of the following June-meren months and a half, or say 230 days. From the middle of June until 1st November, four and a half months, the 12 cows would be in the pasture, and the rest of the stock would be in their boxes, fed on Trifolium, Tares, and Rape, cut green. The bay crop would have to last the same length of time as the root crop, that is 230 days.40 Beasts
40 Beasts

12 Cows to have per day ach 8 lbs, of hay fur 230 days.
so Beasts

The remaining 10 tons of hay would be required for the farm horses, of which six are kept.
As the land of the farm cannot be called a good Turnip soil, tie Mangel and Swedes would always be taken after the Tares, \&c., and so as to insure these crops as far as possible, the land would be got ready for them as soon as the Tares were cut, and be land where the Trifolium was grown would white Turnips, which the cattle rould consume during half of August to the end of October; this land would be sown the following year with Swede
Turnips. Thus there wonld be rather more than 23 acres of root crop to sow cvery year, and tho land for the principal root crop having been got ready the previous year would enable it to be sown as carly as desirable. At any rate it is calculated that having 23 acres of land ready for sowing with roots and a goor half of another 23 acres to sow with Rape, Cabbages, $\& \mathrm{c}$, there wonld be no difficulty in growing the guantity of frod stated above.
Supposing the above food supply to be correct, we now come to the quantity of corn or cake T5 stones (of 8 lhas.), by the time he is 2 years old. This I would put as follows. Each beast is not to eat more than $6 l$. worth of purchased food during the two years.
 880
340
$=880=$
ture-
I now use as a fattening mixture-

The above are present prices of grain, to which add the grinding, and it will cost in all about $8 l$. 10s. per ton, so that each animal, eating 14 cwt . in the two years, will cost as nearly 6 las as possible. The question is, will the above quantities of roots, hay, and grain, fatten an animal up to 75 stones in the two years so as to make him tit for the butcher? -if so, at present prices he him tit for the butcher? -it so, at present prices he
would be worth $20 l$., beef in this neighbourhood readily fetching $5 \delta .4 d$. per 8 lbs . The roots would be all pulped, mixed with the hay cut into chaff, and also with as much Oat-straw chaf as it was found the beasts would eat.

As it may not from the above appear very clearly as to how the green food and Turnip ground would be managed, I will just state it as shortly as I can.

We begin with the close of harvest, when there would be 46 acres of ground to be looked after for the
food supply reguired; 23 acres of it would be Whent stubble, which would be sown as follows: -3 acres with Rye (manured with farm dung), 4 acres of Trifolium, 5 acres of Tares, all to be put in as soon after harvest as possible; then 5 acres more Tares, sown about six weeks after, 3 acres of winter Tares, sown as soon after Christmas as practicable, and 3 ncres of spring Tares, to be sown in April. This food should last the beasts from the time Turnips and Mangel were done up to the middle of August. As soon as the Rye and the Trifolium ground and a portion of the Tare ground was cleared, they would be sown with Kape, planted with Cabbages and white Tarnips, to be used for food from the middle of August to the 1st of November as before stated; the remaining Tare ground would be ploughed and worked as cleared, and got clean and in as good state as possible for next year"s Mangel crop, and the rest of the land that was sown with Rape, \&cc, would be for the next year's Swede crop. It is espected by thus managing the land intended for the principal root crop, a crop of roots may always be grown, as there would be scarcely any work to do in the spring beyond a scarifying and
harrowing, \&c., for the Mangel ground, and an additional ploughing for that intended for Swedes; the farm-yard manure would be carted on this root ground during frosty weather, ploughed in deeply and then left until time for sowing the respective crops; the land not being a Turnip soil upon which sheep can be fed in winter, could not be cultivated in the ordinary way, and so make as sure of a crop of roots as by the method above stated.
In addition to the stock to be kept as described, it will be possible to keep also from 60 to 80 sheep for a year, to be bought in as lambs, and allowed to run over the pastures, meadows, and stubbles, getting what they can in this way, and sold as lean or store sheep.

I will now state the returns expected to be derived from the above mode of management, giving the real rent and taxes paid. I do not enter at all into the question of the moont of capital required; it will be seen I have not charged any thing for interest of capital, as I do not desire to go into that part of the question. I merely put down the expenses and returns, and the balance left after deducting the expenses must be charged by any one as they think fit. All I wish to elicit is-can the system proposed be carried out in the why stated, and, if so, are the returns put down in the way they should be? -1 mean as to the amounts. It will be seen I have charged for 50 calves to be bought;
this I have thought necessary, so as to allow a margin this I have thought necessary, so as to allow a margin
for deaths. I would explain also that the 100 p put
down for trade bills and artificial matnures would be down for tradn bills and artificin mamures
sufficient to pay also for all seed to be bought.

## Miscellaneous.

The Preparation of Animals for Show.-This was referved to ly Mr. Hannomd at a meeting of the Norfolk Agricultural Society in a very amusing way. He shid :Who were the great winners at the Roval Ayricultural Society's meatings? - they were Lorl Walsingham, Lorit Berners, and other lords. From the newaspapers one wonk fancy wod wablime in pulling hairs out of their cows tails, or clipping their sheep. The principle which had been very much repudiated in Norfolk, with regard to the exhibition of aumals, was a very correct one. If he had to get up a young lady for a show, he should put as much bustlo on her as she required. And so it whs with sleep; the only difference being that as little "bustle" as possible was taken off them. Gentle men should he left to bring up their animals as the fleased, and to look the best they could; for the tuphirer was a fool who was deceived by a little millinery
Food in Blood.- When we recollect that we tak from 5 lh , to 35 ib . from a slueep or from an 0 x , aud multiply that by the number of sheep and oxen killed in the course of a year, you will find that it amounts to something which is quite frightful to contemplate Now, I have no hesitation in sasing that the blood you take away is just as good as the blood you leave in, and that you would do much better to leave the blond in the :mimal. There are other ways of killing animals than bleeding them to death. These are unpleasart things to think $0^{\prime \prime}$; but after all, we have no hesitation in erting the mutton and beef after, it is plain, and we ought to be able to give a renson or our
extravagance. We in mot take the blond away from hares and rathits; they are brought to the table and eaten by the most tastidions. so also with birds, phearants, and partridges: we do not bleed them; and Itell you more-1f youdid they would not be so pleasan
to eat; they would lose some of their gamy flavour to eat; they would lose some of their gamy flavour
i) the great loss incurred in the present moninted out animals, and suggested a mode of killing them by which a large portinn of the blond was saved. Mr. Carson, son of the late Doctor, was kind enough to send me a quarter of a sheep which had been killed in this one and all pronounced it delicious. Economically this is an important question, and it ought to be a consideration whether we are justified in throwing away so
large a guantity of this nutritious albumen. Dr. LanNester on Food.

## Calendar of Operations.

Febrtary. - Bean Culture.-The following, extrected from a former volume, describes the process as cirried on in Galloway
We are now necupied with Bean sowing, which is performed in the following manner:- The land, which was trench-pho:ched in antumn, from exposure to the weather now breaks down hefore the drill nlouch, with out any other previous operation ; six drill plonghs, making 12 drills; a drill barrow, which sows three drills, then enters, and at a "bont "f inishes Rix drills By this time the six nloughs have again drawn six
drills, and on returning up the fieh, they cover the first six drills, now sown. Thiry then draw off six new drills, and again cover six on their retnen, the drill barrow goine at the same rate, and sowing at a 'bout six drills also. A space of 12 drills is lefc between the opening and covering, which gives plenty of room for the working of the barrow and the passing of the horses. The drills are 27 inches wide, and are made across the winter furrows. Part of the land was dunged on the stubble, butt the part* which was rot dunged is dressed with three cwt. of guann mer acre, sown in the drills by hand, and covered in with the seed. Two and a-half hushels of Beans are sown per acre, and with this force we get over from 10 to 12 acres a day. An expeditious plan at this season is of the greatest consefor Beans taking advantage of a favourable seed time for Beans

Or, if well plonghed and manured in autumn and harrowed down now, the seed may lie sown by drill in
rows 2 feet apart. - Or the seed may be ploughed in the hean harrow finlowing evary thirn are the proper lean soils. The following sorts may be namen:(1) The Winter Kean, a small oblong kind-two hushe's containing seed enongh per acre-wey light very well, often 7U ib. per hatuma sowing. (2) The common Horse Bean, a good deal larger, needing two to three hushels or more is the seeding of an acre, and requiving to be sown in spring on stiff soils. (Brolific, two bushels containing seed enough per acre. (4) Heligo land Bean, a plump, round seed, adapted for gool soils; int so large as the Horse Bean; two bushels or ten pecks containing seen ennugh for an acre. Pot-a name for many amerents requiring fertile land, in good order, for their efficient culture. ( 6 ) Mazagan also as much of a garden Bean as the Long Pod, but yielding a valuable produce per acre in fieids well cultivated and in good condition.

Barley. - On this crop we may quote the following Marticntars from Mr. Randal's paper
The common, or Early Finclish Barley is the one The commonly cultivatel through the kingdom; and athough from time to time many other varieties have been introduced, it still maintains its position. It is sutable for light lands where the prartice of sheep. folling prevaik, and also fir a greater range of soils than many other varieties; it has the advantage of coming to maturity earlier, reguiring ouly from 14 to 16 welks to perfect its growth. The Chevalier Barley is a Barley land answers the farmer's purpose very well but it is not in every district that so many hushels per acre of it can he grown as of the coarser varieties. must he sown rather eariier in the season, as it require a longer time to ripen than some of the more common sorts. The Leghorn Barley is a qood sort, very fairly productive, and a good malting Barley, and it is orter worth several shillings per quarter more than the coarser Barleys. The Amnat Rarlpy is one obtaining
now a very wide reputation; but has not attained the now a very wide reputation; formalting urposes. It is
productive on sanciy loams. The Nottingham Bariey makes a fine sampe, but it is also considere coarse ; it is cenerally of a good colour, and works we in the malthouse, and is sown rather largely in the north of England.
In the cultivation of Parify, nne creat object to be attained before sowing it is to have the land perfectly clean and dry; and when Barley follows the Turnip crop it is well immediately after the Tumips are fed off, either to rut a scarifier across the field or to plougha it very shallow, for by sn doing we get the s'reep droppings more intimate'y mixed with the soil, and also prevent the dung being washed away by the rain, especially in the hilly districts. Shallow or thin plough ing for the Barley crop is considererl beneficial to the growth of Cl ,vers, which, like Wheat, thrive and stand the winter better on a firm subsuil. In most rotations of crops Barley follows the Turnip crop, anit is succeeded by Clover. If the Turnip crop, to which a liberel amount of artificial manures has been given, all fed off on the land, and the soil be further eurichea by oil cake or corn given to the sheep, the land may be sometimes left in tno high condit'on, and the Barley will grow ton !uxuriantly, and be laid, and the consequence is a very inferior sample of corn, and most likely the Clover plant killed. To remedy this, a certain proportion of the Tursins should he pulled anil carted away for feeding elsewhere. Su.ficient attention is not always paid to seed Barless,-the temptatinn of the higher price often takes all the beat grain of the farm to the market, and the farmer then contents himse? with snwing the best tailing. The seed nught to be of the best quality, fully matured, quite tree from injury, and true in its variety. In sowing it some use the Suffolk drill, others prefer the old-fastimed plan of sowing broadcast. The drill is to be preferred, as it not only depnsits the seed at a: uniform depth, but also puts it ont of the way of the birda, and effects a
considerable saving in the quantity of seed required Very eariy in the season three bushels per acre, or even less, is quite sufficient; but, as the senson advances, small addition to the quantity is required.
Mr, Randal adds,-"The casly-sown Barley is always the best. I think we ought, if possible, to get the greater part of it in in the month of March, the earlie in the mant the better; even the last wepk in Febrnars If our hill land will work free, I do not think too eariy on begin sowing."
The following further particulars are taken from Morton's Farmers' Calendar:-

- Spring Whents may be sown this montlo nn any lond adapteri to them, either Clnver lea which has not been phonghent in time tor an eartier sowing, or land whiel has borme a green crop-eithor pulled and carped awa or fun on the lam by sheep. The Tatavart Wheat is one of the hest for sowing at this time, though alinost any of the sorts usually sown in sutumn will do very well. Later in the season the so-called April Wheat, red-beardei sort, is alone fit for use as seed, and deserption of it will ancordingly he given hereafter
Top dressings.-The present is the hest time of the
as guano, soot, rape cake, \&c., and 2 or 3 cmt. of th
30 or 40 bushels of the second, and 4 or a cat third, are a sufficient dressing per acre. It crrt. harrowed in as snon as possible. The more manures, as nitrate of socia and sulphate of am are better sown somerwhat later in the season, growth is more active, and will more rapidly mak: of what is within its reach
Vetches to come into use for feeding during may be sown now, as much as are likely to be me in that month. Three bushels per acre on any mes land of a clay3y soil are sown in rows eight in thereabonts apart, and will yield very valuable fo sheep and cattle, and be cleared away in time for of good stubble Turnips.
Sainfoin, too, may be sown towards the end a month, though it is more usually sown in March, its cultivation is described
Seed beds for Cabbages and Kohl Rabi show解 this month for transplanting in May int felds where they are to be grown. The sem should have been cleaned and manured and is utumn. Three or four ounces of seed should be on each square perch of the prepared nurser raked in, and then a peck of soot sown over eac A Cabbage nursery cannot be too good, nor or wards thinning carefully.  meetings fur the masuing wber
While there is much speculation abroad as to the proper treatment of what it has become fashionable to call Coor Oremids, and much misapprehension in certain quarters as to the capability of endurance possessed by many of them, it is quite certain, as Mr. Bateman has shown, that a considerable number of species do really prefer a much more moderate degree of heat than it had been the custom to afford them. It is, moreover, equally certain that experience is the only safe guide to the grower as to how far the declension of heat may be carried in the case of any partioular species, not only as regards that which it is able to endure, but also as to that under which it will thrive and bloom in a satisfactory manuer.

The attention which has been directed towards these beautiful plants has led to the issue of a very excellent descriptive Catalogue of Cool Orchids by the Messrs. Backhouse \& Son, of York. In this brochure, which is now lying before us, and which may be cited as an illustration of the axiom that demand induces supply, we fiud some introductory remarks bearing so forcibly on this point of endurance, and recording so clearly the experience of these gentlemen in the matter, that we gladly transfer them to our columns for the benefit of such of our readers as may be now only beginning to devote attention to the subject; for as Messrs. BackHOUSE observe, we doubt not that the culture of Vinery and Greenhouse Orchids will beoome general when their beauty and ease of culture are known The remarks to which we refer are these:-
"New Greneda, Peru, Ginatemala, and Mexico are all hot tropical regions; The 'Equator of heat,' or line of highest mean minual temperature, passes close along
the northern coast of New Grenadu. But although the northern coast of New Crenada. But although
these countries are, by their geographical positions, these countries are, by their geographical positions,
subjected to a very high temperature in low and flat districts all the year round, yet their elevated regions
afford a widely different climate. Vast mountain chaine, which occupy a large portion of the whole, rise far into the regions of eternat ice and snow. On the slopes of there, and on the immense table lands that stretch for bundreds of miles, a cool and genial climate is found not very unlike our own, though rarely if ever presenting the extremes of heat and cold that oscur in England. In the vast forests and humid ravines of these mountain regions, Orchidaceous plauts of surpassing beauty abound. They have for 20 or 30 years past heen imported into Europe in very limited quantity, but, as a rule, were at ouce subjected to a close and stitling heat. Becanse they were from the tropics, whether (in reality) from the chilly slopes of a snowy 'Sierra,' or from the hot janglea of India, it was all the same. Nature rebelled, and the plants died! Within the last 12 or 18 months, thanks to the perseverance of Low, Veitch, Linden, and other eminent narserymen, many of these beauties have again been imported. They hate being dragged down from their cool mountain homes, and cuoped up in a box for six or eight weeks in the hat and humid climates through which they must pass to reach us; amd therefore few, comb-
maratively, survive of sione of the very finest, paratively, survive of some of the very fimest, making these still both rare and expensive. Others,
scarcely less charming, travel well, and are now offered at far lower prices than have been usual hitherto. Somre of the finest of the New Orenada Odontoglossums and Oncidiuas ocour in districts that are liable to extreme cold, and may yet be found hardy enough for the winters of some parts of Eugland. We lean from the fine work on Orchids of the late M. Pescatore, of St. Cloud, near Parie, that a very beautiful Orchid was met with in an Oak wood, 800 feet above a village where the snow was lying 6 inches thick, and the thermometer indicated $8^{\circ}$ of frost ! (three below the freezing point of Reaumur). The"grand Lacolia majalis, in Mexico, is said to bear several degrees of frost; and Cattleya labiata and Sophronitis grandiflora, from Brazil, have been found not unfrequently with the hoar frost upon them. We ourselves have had icicles hanging abundantly within a few inches of Epidendrum vitellinum, which was placed in a niche of rock-work during the frost of last winter. The plant was in no way injured, and grew finely all the summer. There is every reason to believe that many, and perhaps most, of the Orchids from Brazil, Mexico, Peru, New Grenadu, Nopsl, Khasya, China, and Austradia, will bear a tomperature close upon the frezzing point without injury. Not that we recommend this to be tried, any more than we should with a Cineraria! but we are Batisfied that a greenhouse temperature (which is never safely alloweil to fall much below $40^{\circ}$ ) is not ouly abundantly suf ficient for them, but likely to induce a far more vigorous growth and abundaut bloom than the usual warmth of 'Orchid houses' in winter will effect.
"We have consequently placed a large portion of our collection in houses where the winter temperature falls to from $35^{\circ}$ to $45^{\circ}$, associating them, in fact, with 'greenhouse plants.' That they will bear this, and Laxtia purpurata continued growing out of doors in after the frost had cut off Kidney Bean tops, \&c., in the adjacent ground, and were only taken in after the thermometer registerel $28 \frac{1}{3}$. This temperature severely injured one of the young growths of Cattleya Mossix, but did not hurt two others which had been formed almost winter killed Odontoglossam grande. Threo and a half dogrees of frost ( $28 \mathrm{t}^{\circ}$ F'ahrenheit) very slightly spotted its leaves. It destroyed the leaves (only) of Lyeaste Skimneri, and did not hurt in the slightest degree the glorious Laclia superbiens, all of which were side by side out of doors. Now, if Cattleya Mossim will bear this, all Cattleyas will (?) except Cattleya superba, as with this exception they come from conler districts than Cattleya Mossiæ. It must, however, be borne in mind that an Orchid wintered in a warm house $\left(60^{\circ}\right.$ to $\left.70^{\circ}\right)$ will searcely stir if placed out of doors or in a greenhouse the following summer, even if the temperature be $80^{\circ}$ in the shade during the day. They will have a second nap! The coolness of the aight temperature, and free circulation of air, more than neutralise the high day temperature. Plants so treated will rest for months with the thermoneter at $60^{\circ}$ to $80^{\circ}$, and begin to grow in autumn when their sleep is over, even with the thermometer at $40^{\circ}$ to $50^{\circ}$ ! This clenrly proves that to get a free and vigorous summer growth in a greenhouse, or out of doors, our plants must be wintered at a pro portionately lower temperature ( $40^{\circ}$ to $50^{\circ}$ ). It is no easy to accommodate recently imported ones to this wholesome discipline, beeanse the great heat of the voyage, \&e., often stimulates an untimely growth which you cannot cheek severely without endangering your plant It must, however, be aimed at as tar as your plant. of our finest species the short stiff leathery leaves and weh purple tinted stens, \&c., which we find in the imported specimens, healthily developed in thei ane mountain climate. We have yet to learn that mere airs is not the standard of excellence in an Orchid's stem or belb any more than in cattle
"There are many Orchids which will bear greenhouse troatment when the growths have been well matured daring the mamener in a cool and niry situation, whioh
will rot directly if placed in a greenhouse when they have been grown in a moist and close house with a temperature of $70^{\circ}$ to $80^{\circ}$. We may be able to see no difference before the two are tried, but we shal soon fiud that they have very different constitutions.

As a rule, while these plants are growing freely they should have an abundant supply of water Odontoglossums should never have the soil dry, but they like air in constant motion, and a bright sinn position in winter. In summer, they shou'd be carefull shaded from direct sunshine, and a very humid atmos phere maintained, combined with very free ventilation day and night. At that season the night temperatur should be 15 to 20 desrees lower than the day tem perature, so as to cover the plants with dew. In winter, and especially when the temperature is very low, little or no water should be given, and the atmosphere should be kept as dry as possible. The pseudobulbs are the natural reservoirs for moisture, so that if plump and well maturd, the plants will require no water for weeks or even months while at rest during the winter and this is, in fact, the only safe condition atmeter period. Air win $40^{\circ}$ but will be advantageons, when the sun shines and there is little wind, for an hour or two t midday the thermometer being at $45^{\circ}$ or more outside in the shade."

For a list of the speoies whioh have been subjected to the treatment thas sketohed out, the interested reader sho

We alluded last wreek to the formation of a new Sooiety, under the name of the United Horticultural Society; and we now add a few particulars respecting its main objeots and intenions, whioh, according to the rules which have been placed in our hands, are as follows:

The objects of the Society shall be to promote the practice, study, and advancement of horticulture in all its various branches; means shall be especially taken for the examination of plants, flowers, and edible fruits, their nomenclature and synonymes, establishing their relative merits, investigating their physiology and diseases, their uses, properties, cultivation, and improvement; also to facilitate the formation of a fund and aring sickness, calamily and old age; such fund to be managed by a sepater a separate code of rules.
"The operations of the Society to embrace periodical meetings at which members are invited to proluce new plants, flowers, fraits, and other nbjects of interest; committees to be appointed to adjudicate upon such $3 d$ chass, at the discretion of the committers, such certificates to bear a money value to be determined by the general committee at the end of the year, necording to the amount of the funds then in hand; also the reading of papers, lectures, and discussions thereupon the original papers, reports, \&cc., if so deternained by the members, to be printed and sold for the benefit o the Society.

At any ordinary meeting committees of members may be appointed for the investigation of special invectigations as soon as may be convenient

All surpias monies remaining at the annual moeting, after all the debts of the Society are paid or allowed for with the exception of $5 l$. to be reserved, shall be handed over to the trastees or committee of the benefit fund proposed to be formed in connection with this Society.,

We learn from Mr. Marshall, of Enfield, a gentleman who has taken some interest in the organisation of the Society, that its intentions are not at all antagonistio to any existing asscciations; and hence it is intended to obtain for the Committee powers so to arrange the meeting days, which are fixed generally for the first Tuesday in each month, and the third Tuesday in June, July, and August, that they may not clash with those of the Floral Committee at South Kensington.

Mr. Marshacl further explains that the original and principal idea was to form a Society which would enable practical gardeners to meet and
discuss the value, merits, and uses of the varions novelties and other objects of interest that might be brought before them. No existing Society, he observes, offers any facilities to them in this matter. "It is likewise proposed to form a fund for the benefit of gardeners, from whioh they might rceive assistance during sickness or calamity or in old age. This however is to be managed by a separate Committee, its only conneation with the Society being that it will receive all surplus funds after the current expenses of the year have been liquidated."

We merely add the remark that the object of meeting for the acquirement of information on matters relating to their daily occupation is a members; and that there can be no good reason Why persons thus assembled should not pass judgment upon objects brought before them for
that purpose; but we are rather inchined to question whether it be good policy to attempt to establish the benefit fund, which is one of the objects set forth, inasmuch as suoh a cours must inevitably lead to a division amongst horti culturists detrimental to the interests of the Gardeners' Benevolent Institution, an association which is already doing a great amount of good for gardeners, and might accomplish much more and perhaps in a better way, if it were better supported.

The admirable account given by Mr. Anderson in our last wreek's Journal of the different forms of Spot in ORcHIDS, which was prepared quite independently of our leading article on the same subject, except that the materials for observation were the same, leaves little room for comparative remarks. The two are singularly in accordance with each other, Mr. Anderson noticing a fourth form of spotting, derived directly from fumigation. We have, however, never seen in his sesond form, that of which Dend robium speclosum afforded such a striking example, any appearance of fungous threads at any stage of the disease, a very important point to settle, as, if it at all arises from a Fungus, a remedy is almost hopeless. We may sometimes contend with superficial species, but seldom with those which are essentially internal. Our attention shall be direoted particularly to this point. As regards the Fungus on Aerides Fieldingii and Odontoglossum oitrosmum, there is either a misprint or slip of the pen in our leading article, where it is said that the fringe of the oysts is coloured, as it is perfectly hyaline and colour less. The soft pulpy condition of this form of spot will distinguish it at once. The third form on Aerides suavissimum is much less formidable. As there seems such good reason to believe that the seoond form arises from sudden changes of treatment, it is very possible, if our notion is correct that there is no mycelium in the affected leaves, that a well-conducted series of experiments may lead to some bencficial result. The first step owards the removal of disease is an accurate notion of its nature, and we feel much indebted to Mr. Anderson for the nice discrimination he has shown in indicating the very different diseases rom which Oruhids have lately suffered so hopelessly. We recommend his paper to the especial notice of cultivators, for it deserves a very carefu perusal. M. J. B.

THE Gardeners of Scotland have determined to hold in Edinburgh, in the month of September next, Great International Fruit and flower show in connection svith the Horticultnral Society of Edinburgh This"exlibition is fired for the 6th of that month, an the schedule of prizes, now before us, is on so liberal scale that a fine gathering may be anticipated. In the class devoted to home-grown fruits the principal prize are 15l. for a collection of 20 sorts of fruit; 10l. for collection of 16 sorts, excluding Pineapples; 10l. for two bunches of each of 8 varieties of Grapes; 101. offered by the Proprietors of this Journal, for a collection of the best 6 kinds of choice fruite, including 2 Pineapples, 2 Melons, 4distinct sorts of Grapes, 12 Peaches, 12 Vectarines, and 12 of any other fruit; $5 l$. for two bunches of each of 4 varieties of Grapes; and $5 l$. for the best collection of fruit shown by fruit merchants. In a class provided for fore'gn.grown fruits $5 l$. prize are offered for collections of Grapes, of Pears, and of Apples coming respectively from France and Italy, Austria and Russia, Germany, Molland and Belgium, the United States, British North Anerica, and Turkey and Fgypt. This ought to bring together materials for a fine display. Prizes are also offred for plants, flowers, and vegetables, sufficient to make up nice Autumn show. In the class devoted to home-grown fruits, we notice, there are 54 prizes offered for Grapes
14 for general collections of fruits; 9 for Pineapples 14 for general collections of fruits; 9 for Pineapples should be worti a journey to Edinburgh to see.

## culture of A.nsterdam, which las been alread

 announced in general terms at p. 1130 of our las volume, is fixed for the first week in April nest. The abjects of exhibition are to be sent in from the lst to the 4th of Aprid; the International Jury assembles on the morning of the 5th; the grand opening takes place to the 7 th; the pablic are to be admitted from the 8 th to the 12th; and there is to be a Bale of plants on the 13th.We understand that since the original programme was issued, prizes to the amount of 1800 florins have been added, bringing up the total to 15,000 floring The gardeners of foreign amateurs who exhibit will be rewarded in the same manner as the actual programm promises to the gardeners of amateurs in the Nether ands. One of the rooms of the Palais de l'Industrie Where the exbibition is to be bolden, will be warmed for the reception of hothouse plants. After the closing
of the exhibition there will be the public
alluded to of such plants as may have been exhibitw with that object. Part of the expenses of transpont
will be reiubursed to the exhibitors, and foroign tributionabursed to the exhibitors, and foreign con. Such are are the recently issued.
Those persons who intend to exhibit are required ive notice to the Secretary, Mr. Kbelage, of Haarlem before the 10th of March; and lists of the articles to be sent are to be forwarded to the Assistant-Secretar), Mr. H. Witte, of Leyden, before the 26th of March
Concurrently with the Horticultural Exhibition Rotanico-Horticultural Congress is to be held; a already notice has been received of many interesting questions which will be discussed. The Programme and regulations will soon be published. Upwarde of 200 botanists and horticulturists have signified their adheion to the Congress, of which those persone who form the Internaticnal Jury will be considerod meinbers.

We beg to call attention to the subscription list of the Ingram Testimonial Fund, which appean is another column, and to remind those of our reanden who have not yet contributed, that they will not lone have the opportunity of doing so, as the list muat mom be closed. Mr. Ivaram is too well and too favourath known in the profession to need that we should add one word more in commendation of the object, which is do honout to one who has known how to merit it.

## New Plants.

284. Corylopsis sproata, Siebold and Zuccarini 20 Jap. 47, t. 19; Hooker, Bot. Mag. t. 5458.
The generic name sufficiently indicates the aspect d this now hardy plant, which is that of a Nut bush (Core lus), its habit being deciduous, and its leaves long stalked, acutely heart-shaped, strongly feather-veined mucronately-serrated, and having above a pubescent green surface, but beneath being somewhat hoary. In its native country it is said to form a bush of somio 3 or 4 feet high, flowering before the leaves are producod

It is this early. flowering character which will give its chief value in our Euglish gardens, to whichin been introluced from Japan, both by Mr. Fortane Mr. Veitch. The plauts introduced by the format gentleman flowered last spring in the nursery oik Standish, by whom they were shown at south later fornished the specimens from which the figure Botanical Magazine was made.

The flowers themselves are rather small, regular, ail five-petaled; but they appear profusely in conspicuab racenes before any leaves are put forth, laden with them must have rather an
appearance, sufficiently so indeed, to make it occupant of the front ranks of a shrubbery bor blossoms are pale yellow, and issue singly fro axil of a greenish yellow bract, some eight to 12 bat produced in a raceme. They have moreover drooping the bracts ample cordate or ovate green, the lowest ones largest and not floriferons; calyx has a short turbinate downy tube crowned ive ovato-lanceolate subincised erect segments; corolla consists of five oblong-spathulate retuse crect petals; and the stamens are hive in as long as the petals. Within the stamens sta erect oblong subulate seales or glands arranged in ring around the two-celled ovary. These p
will enable our readers the more readily to unders the accompanying figure, which represent It of a flowering twig.
It may be added that the genus Corylopsis belongo
the Hamamelidacese or order of Witch Hazels, and
that five nectary scales are attributed to it by its
leamed founders, who understand them in Chis case to learned be bifid.

NOTES ON GARDENS.-NO. XXIX.
Titi Dublif Pheentx Park and its Giboens. (Concluted from y. 102)
Nixt comes the pleasantest portion of my Phcenix Park experiences. I have to describe the home of Mr.
W. S. Wilkie, clice bailiff and superintendent of the 1758 acres. His house is a Gothic one, but of what the whils were made, if I wistiad by Roses arowing out their they were hidden by Wistaria, by Roses growing oun cheir
own roots, and of great climbing capability; by Abelia floribunda, whicit formed a charming wall covering, Was fall of flower, and had been fur years on the wall;
by the best forms of Clematis; by Clianthus, Habrothaunus elegans, and Swainsona galegifolia, which was flowering beautifully as a hardy herbaceous plant, having beens planted out for some years. The Lodge is a tasteful and very suitable one; but what hive I to do with buildings? should not mention it were it not clothed
Mr. Wilkie's little demesne is about 6 acres in extent. About 2 arres of this are devoted to ornamental pur-
poses; the remaining 4 acres in part to a Strawberry ground, and to a compact and well cropped fruit and vegetable garden, with neat Vinery and greenhouse, frames, pita, dc., some of these being filled with Oamanthises, and rare Pines not yet proved hardy, Onmanthases, and rare Pines not yet proved haray, ont; so, as they are no donht intenderl by Mr. Wilkie to be planted out, he will, if they succeed, be in advance of most persons with good specimens, as he already has the best plants of some older favourites.
The pleasure-grounil occupies about 2 acres-a comparativelg small garden, but if measured by the amount of pleasure it has given to lovers of plants and garders -amongst them some of our greatest statesmen and But who are these
Bat who are these admiring the beautiful Pines? As I live, the very high priests of Irish and Scottish merely recorded of the place, that I had seen these gentlemen in this lonely part of the Phoenix Park, the old proverb which tells that it's not precisely "for nothing the cat winks," would surely help curiosity on the walks and banks into two scenes, each distinct, and yet having much in common, for the finest and rarest Conifers, in the greenest health, are the chief features in
both. That farthest from Mr. Wilkie's house is almost exclasively given up to beautifully developed Cypresses, Thojus, Junipers, and rare Pines of all sorts,
dotted about singly on the turf, with here and there an enormous plant of Pampas Grass, and raised banks all around with Cyclamens in flower near the margin; plenty of spring bulbs asleep around them, and belind anil on the top rare evergreens, and deciduous shrubs these, such plants as Pyrus vecatita, a great-leaved specing from the Himalayas, about 25 feet great-leaved species from the Himalayas, about 25 feet high; Paulownia;
Acer colchicum, upwards of 20 feet high; Quercus glabra, \&cc.; and near the winding entrances, very perfect specimens of the Weeping Ash, formed by framework into capital tents, with a close row of sawn blocks around inside for seats. This part of the garden, which has been named the "Happy Valley" by some of Mr. Wilkie's noble lady visitors, is oblong-oval in outline, and Among the by walks.
Among the trees which divide this from the more
varied and flowery part of the garden around Mr. Wilkie's house there is one very iuteresting plant, almost hidden by others. It is Whately's Tree ; for the great Archbishop himself gralted it, and always called Lord Carlisle, He was fond of the garden, as was and used frequently to visit it. One summer day, years ago, he came to Mr. Wilkie and told him he attonishment, but his Grace took a phial of water, and old plant of end of a scion in full leaf, taken from the of thant of Pyrus vestita, attached the scion to a stock of the common Pyrus, and eventually succeeded with his graft. It must be geatifying to all gardeners to pow that men of Whatoly's stamp could thus find pleasure in their work. This Pyrus vestita would be The certing treasure in any garden.
most delightrul sorts delightful kind, for he is fond of plants of all bodding plant as and ahrub as well as the herb, the fally arranging well as the Pine; and by mott tastegraceful whing all so as to produce a picturesque and graceful whole, and at the asme time infinite variety visitors est of detail, gives himself and bis numerous ing as is hardly a concentration of the pleasures of gardenNear the Lodye elsewhere to be found in a similar space. tifut specimen of Tha quiet corner, stands alone a beau. by the late Lord Carlisle, whea, 10 feet high, planted deeply mourned by those, whose loss must have been whom his mood by those connected with the Park, to and near it is the Wellingtorure was so well known But though is the Wine llingtonia previously spolen of
course equally embellished the scene at all seasons, ye their aid ou little irregular beds-full of flower to be sure, bat not masses of one flower. Thus Mrs. Pollock Pelargoninm and Centaures ragusina were
twined around by the Japanese Honeysuckle, and periaps flanked by Salvia patens and Dianthus superbus, with its delicate fringy blossoms. When plants of the elegant Thujopsis borealis, 10 feet high, had been admired near the rising boundary of the lawn, I had merely to turn round and survey a bed of Souvenir de flower, and mixed up with Gladioli, which had been for sewer, and mixed up with Gladioli, which had been for
several years undisturbed in the rich bed; while round the margins were single plants, such as Solvia argentea, the silvery leaved Centaureas, and great rich tufts of garden would be as charning in April as in August, as every garden ought to be. What a fine comp ict Lurellike shrub is that Quercus glabra, 8 feet high, near a nass of the white-stemmed Rubus, and how graceful are those inmense plants of Pampas Crass in the moist shel tered places! A pair of Cupressus Lanbertiana, each 28 feet high, and each more than 100 fept in chenam. frence, were nobla objects on the lawn, and seemed
to glalden the heart of Mr. If Nab , connoisseur as he is of such plants, but he was equally delighted with many
others, and avowed that at least five of the Conifers were the most perfect of their kind in the country.
Apart from the intrinsic beauty of the Pine3, not few of then were most interesting in a commemorative sense, being planted oy men of mark who had been
attracted to the garden. Thus the sons of Burns hid planted a Picea Nordmanniana, and there was a heautiful Thujopsis borealis, which General Lord Seaton
planted in 1860 . In the garden, too, are the now monu mental plants of Lard Carlisle, who, if report speaks true, was fonder of the garden than of any otherplants which a year or two ago many doubted not but
he wonld live to see well developed trees. Piceagrandis was of Archbishop Whately's planting.
reland are supposed to be the dense spreading specimens on Mr. Wilkie's lawn, about $2 f$ feet high; and there are healthy individuals over 20 feet high of Cedrus atlantica viridis, and C.
atlantica argentea. The Douglas Fir and Picen nobilis, lise all the other Pines, are in the freshest health, aud 30 and 15 feet high respectively. Bat how exceedingly tasteful and refreshing are these irregular masses of bedding plants-Salvias, Fuchsias, trailershere and there amoug the shrubs and taparing young Pines, and how well some of these old root-stumps of great trees that have been blown down in the Park look with the lieads planted in the ground, and the
old ront basin or basket turned up to act as a vase, filled again with nixixed bedling plants, Alpiues, Centaureas, and in fact a little of almost every fivourite plant. Some of these upturned stumps looked a little too long in the leg for a garden in which no gewgaw rusticity of any kind was attempted; but then the varipgated Ivies and Honeysuckle, Virginian Creeper, \&cc, wer Cupressus funebris, 15 feet high; C. macrocarpa 26 feet; C. torulosa, 20 feet; C. seinpervirens, 22 feet Libocedrus chilensis, 9 feet; Pinus taurica, true, 18 feet, and 56 feet round; Picea cephalonicr, 30 feet; Larix dahurica, 16 feet; Juniperus excelsa, 13 feet; J. recurva, 18 feet; and Picea Pinsapo, were all rising specimens in the greenest health. A plant of Thujopsis borealis had been planted by the lite Countess of by the late Earl of Eglinton when Lord Lillongtonias by the late Eart of Eglinton when Lord Lieutenant of
Ireland. Most of such trees, which may now be called monumental, had neatly written labels with the name of the planter and date of planting, in addition to the name of the plant, upon them. Mr. Wilkie's best Araucarias, and some other valunble Pines were killed by the great frosts of recent years. The soil and air of the place are of course favourable to the Pine tribe, but I think the densely covered banks by which Mr. Wilkie has skilfully shaitered his garden, must to some extent help in producing the fich health and verdure displayed by these plants.

The banks were quite as interesting as the lawn, for in front of Paulownia, Weeping Holly, Double HorseChestauts, \&res, were quantities of climbing Roses in profuse vigour, running as best they could among Clematis rad Cutoneaster, while in front the common Brake, Alströmerias four or five feet high, Phloxes, and Epilobinan avgustifolium had a most romantic struggle for mastery. On the margins of some borders Gentiana acaulis was most luxuriant, and I understoon the same borders were covered in spring by the flowers of bulbous plants. Salvia patons and some of the Fuchsias are found hardy, and are taken advantage of accordingly. Moutan Pæonias, mixed with Lilinum, \&ce, were doing freely, and only require protection in winter from Laurel branches.

One of the best autumnal plants in the garden is Clematis Flammula, which runs freely over the banks and staunps, and is much sought after for cutting. It is strange that this plant, which is capabie of doing alnost as much for gardens in the autumn as the Hawthorn does in spring, is not more used than it is.

In Mr. Wilkie's parlour I hail the honour of "handling the spade," the aristocratic looking spade, which had been used by her Majesty, by the late Prince Consort, and by other very great people when planting
trees in the Park. Ah! my poor blue aprons, thought but Royalty deems itself nobly emuloved in handlin, Hur "chict arm." Itself nobly employed in handing in print to the swearing betting horsey-man, or the dame that feeds the dncks. But great men have put good and creditable things on record about yon, and so you can afford to let the coarse sneer pass.

Why talk so much of so small a place? " some one with half a.dozen acres of unrelieved bedding staff may of how very mach could be done to form the most beautiful of garden scenes with hardy plants alone and while wandering about and enjoying fresh views and beanties at every turn, I could not but conclode, though resh from the astonishing display at battersea, that if the "subtropical" plants of lialfad dozen botanical gardens were "stood nut" for the summer, they conld not produce so charming a scene. But Mr. Wilkie could add with hardy plants the very aapect which many of these tender plants are placed out to afford. What pot plant for instance could give a better effect of the sort than the splendid specimens of harily Yuccas which stool last summer-and no Chelsea? Nome. With the horticulturists of Dublin this garden is only se
and dignified founder.
'Twould scarcely be wise to wish that everybuly slonuld imitate this or any other style of gardeniug; but it is much to be desired, that, as great interest anl variety of some sort should be seen in most garilensmuch to be desired, that paople who devote their means and attention to open-air gardening should enjoy ss nuch of flowers and trees at all seasons without any "derrible interval between spring, sum ner, or antumu
"den Mr. Wilkie does. Still more isit to be desired that the owners and managers of gardens should act as independently of "fatshion " in gardening as lhe leading ; and instead of copying the "effects" ot the leading gardens in their vicinity, give 13 somethind fresh iuterest in gardening which wo now find in books and in all other works of art wrought for our delight. Wm. Robinson.

## Marte guisse pear

This new Pear, figured in the Revue Horticole for January 1865, is very handsome, and has a remarkably rich warm appearance. The fruit is middle-sized, or rather large, obovate; colour, well russeted golden yellow. Fiesh melting, rich, norfumed, excellent. Season, March and April. The tree is described a being very vigorous aad an abuadant bearer. It is As is ofton the case with seedliug Pears whilst young many of the branches are yet spiny. It was raised From seed of the Saint-Germain in 1834, at Jussy, a first time in 1857 ; in 1860 it produced nearly 600 Pears. This variety was obtained by M. Guisse, of Sainte-Ruffine, and is named in compliment to his daughter by M. Hiva, an old mayor of Cassy-les Metz, and a distinguished Vine prower
It will be observed that the seedling just named was 24 years old before it produced fruit; but this may be accounted for by the circumstance of the tree having boen grown in rich soil, 7 feet deep. In such deep soil, the Pear is long before it commences to bear ; but Pear trees similarly situated have lived and borne for huudreds of years. Should this variety be as good in our climate as it look s, and as it has proved o be in the finer climate of the Moselle, keeping also till March or April, it will be a valuable acquisition. Some good late kooping varieties of Pears are yet desirable.

## Home Correspondence.

Spot in Orchids.-While admitting that Orchids,
like other plants, have their periods of youth, maturity, and death, I still believe that their lives are shortened by bad management quite as often as they perish fro $n$ natural decar. I have plants which were intro luced into
this country froun 20 to 30 years ago. To put plants into urs ritable houses is bad m magement. lijuave erred much in this respect, for out of 10 houses severai are not so fit for Orchids as they would have been if built expressly for them. Adverse circumstances will sometimes occur; as, for instance, a pane of glass may be broken or cracked, and not observed until the plant immediately below it has received its death stroke from cold or drip. Cold wind is often the cause of one soit of spot, and 1 would urge on any one erecting Orchid houses not to have them less than from 17 to 20 feet in width. In a narrow house one has not that command of heat which is desirable. If you give air to such honses it is ten to one that you give too much, especially in winter, and the heat is driven out before the gardener perceives it, if he has many houses to attend o. If you do not give air the plants grow watery, and are thus rendered still more liable to disease. It may
be said, why cannot you give just sufficient air and n , more? The answer is that to secure such accuracy too much care and time would be required, especially in large establishments. Houses from 17 to 20 feet wide, and 10 feet high in the centre, contain a large amount of heated air which is not speedily acted on by
cold-a point of great importance, especially in winter. With me one canse of spot has been too free flowering, which has impaired in some cases the vital energies of the plants, so much so that they have gradually sunk. Allow for instance, Phalænopsis rosea to flower as march woull advise ail Orchid grovers to pay particular attention to the ventilation of their houses, as I believe it wall be fouml that there is more spot in dark, dull, damp close houres, than where light and air are ajoundant. There are some few exceptions, but I am inclined to think the main points in Orchid culture to it. Rovert Warner. Broomfield.-I am not learned in Orehids, but I have found the fillowing abstergent lotion to be very effectual in curing white Fungus on Roseleaves :- Dissolve 2 or or of in
vitriol in hot water, then put it into a stable bucket full of cold water. I do not know whether this would be too strong for the follige of Orchids or not; but spreal Iasidly, and therefore should he got off withont delay: Prolully removal of the incipient bloten by the diseased Orehids mine, I should try bath plans. The lesves migto be eponged both on the upper and Fungus. If lefto on long it stops the pores of the leaves, and does the same mischief as the Fungus. Moreover, if the sum is very hot, sulphur will burn the leaves.
Pontuhly some is Mr. Anderson's Orchic leaves were burnt in this way. If the disease does not arise from Fingua, but, prosporls frome conalitutional chuses, the likeliest way of arresting the malady. Let me hope that the above plane, one or other, may be of service to Mr. Anderson. W. P. Radeluffe.
Seen/less Mignonette. The deficiency of fragrance in your Con respomdent's 1 ingonette doubt less arises from
low temperature. I have sur pral phats precisely in the same condition, in a pit the lomp rature of which is just sufficiently ligh to keep nut frost; other plants of Mignomette raised from the same packet of sead were recently placed in a nit where the temperature never falls below $70^{\circ}$, and the frigrance of these is all that ould be desired. M. A., East Malling.
Trade Lists.-Your Correspondent "Q." deserves credit for his efforts to reform trade lists. If, however, existe in the seed trade, why does he not stick to oidfashioned things instead of bothering Jimself about What even our "largest ailventiving linnses ammonce." after, seedimen would not offer the:n, and the same remurk equally applies to bonk catalogies, "Q." must
mot imaque thit, all garleners sarorn the artinn of looking into a trade list for the treatment of particular things. My own experience as a seedsman convinces me that they do co
Black Alicante and Royal Albert Grapes.-Mr. Poynter (see p. 149) is mistaken in conch lirg that 1 18 years I lave contriluted to your. Journat, my paragraphs have alwass related to sulijets which I have
well umberstonl, and I may assent that that on the Grape in 'queatiou forms no exception t.) the rule.
Mr. P. concludes from my using the prefix 'Mr.' to the word Kempsey that I have wet correctly siaterl how Kempery hecame attached to this Grape. What I did say was, "I see in many of the trade lists sent me that this cirape is termed the Kempsey Aliente, and in others Kempsey's, but who Mr. Kiempsey is it would
ho useless to inquive," meaninд, as a matter of course, ho useless to inquire," meaning, as a matter of course,
that there was nos such person. For further remarks by me on this part of the suligent I beg to refer My Poynter to your wolu ne for 1562, pp 1149 and 1197; I was shown by Mr. C $x$ under the name of Kempsey Alicante was snue eight or ten years ago at one of the $P_{\text {meetings of }}$ of that Pomological Society in London. as the Kemplisey Alicante. Mr. Cox then gave many No show within my remembrance bas been held in the Gnildball. Worceater for many yeare, and although this venture to say that it was not until Mr. Meredith Mr. Cox exhibited it at the International show at sonth Kensing:on in 1962 that it hecame generally known. As a pronf of Lhis, examine lists of Grapes previons to foand to have Alicante iu it since that date. Mr. Poynter says his impression is that this Grape was a promiscuons reedling, bat, as if in contradiction to that, he states that Mr. Leclitimil (which should have heen ever, Notaif) pickerf it up whe travelling: not, how statement wound imply that the Alicaute part of his known 100 year amply in a work I bave ly me, how"ver, edited by thie leve. Wia. Hanbury, vol, iii, p. 779, your Currequident I will quote part of the description. thiuly on the bunches, which have large berries, placed and leavy ; the leaves are said to die off the top, long in the autumn. This work was written in 1771 , which
p. 763, it will be seen that more than 40 years agn, the Aeante mow advert to the Royal Albert, with my accunt of which Mr. Poynter also appears dissatisfiel. The Grape I allude to under this name is
not the Champion Harnburgh, Datch, Mill Hill, Wilmot's, or any other Hamburgh. That grech a Grape as the Royal Albert does exist, Mr. P. will find if he will look in Your Paper for the year 1812, p. 742, Royal Horticultaral Sncinty's Procvedlings:-"Menticn was also made
Royal Albert, received on the 13 th of October last, from Mr. J. S. Brock. The bunch sent weighed purple, and possessed a five bloom. The skin was morlerately thin; flesh juics, with a little crispuess, but could perhaps be grown to equal perfection with that variety." This is the Grape I wrote abont last week, and one, if I mistake not, which will soone later be found worthy of all I said of it. Poynter-quite as much as uis statements about the Alicante have astonished me. Edward Bennett, Gardener, Osberton Hall, Worksop, Notts.
Pine Growing.-I have for some time past been inqniring why Pine Apples are not grown as commonly ${ }^{8}$ Graper, and the answer I generally receive is-that they are liable to the attack of troublesome insects, accordingly more expensive. It occurs to me, however, that there must be other reasons, and one of them is that the treatment necessary for the snccessful culciva less secret among gardeners, and that amateurs have never hind the courage to try and penetrate the mystery. If any of your contributors would correctly enlighten your readers on the subject of the growth
of Pines from the commencement to maturity, ace mpanying their remarks by stating the size of stove or fruiting them in, a description of succession pits, and or number, and at the same time indicate tie canse would not take long before Pine-growing became as much a mania as Cucumber-growing. Why should not Pines be grown in open borders in the stovehouse mstead of in pots, and fruited in 12 months from lanting the offset? A. P. Q., Chelmsford.
The Knowsley Pine Stove.-"G. H." is evidently one those individuals who can see nothing good nut of his own immediate circle. Surely it would have been ast, if not generons, before placing upon record the conclusion of "one of his men," and his ownadverse opinion cunded on the woodcht and the disinterester reinark Kuowsley occasionally between the months of "January and June," to see with his own eyes the failure he anticipates. Mere assertionz, it must be remembered, carry very little weighto J. A.
Crategus orenulata.-Does this plant require a wall ? And is it more ornamental thin C. Pyracantha? Diss plant, in which position is is a very beautiful brightooking evergreen, which we are surprised is not more generally met with.]

## Forainn Correspondence.

Gastrolobium grandiftorum.-This year large docks have started for the Flinders, and on the road out have It is It is most destructive, and for a death dealer I do not
think it has been surpassod. It is fatal to cattle as well as sheep. Some drop as soon as they eat it ; others dask inxuly into the bush and are seen no more; hut fter them show ho sy raptocas of it till the hundreds. F. M., Melbourne.

## Eocietics.

Lifnean: Jan. 19.-G. Bentham, Esq., Presiderit, in the Ciair. Archibald Campbell, M.D., Lient.Col Scott, R. E., and J. L. Stewart, M.D., were elected Fellows, Letter from Mrp. W. I. Brewor, State Geologist to the Survey of California, on the Forests of Sequoia (WellingOn a new Banana frome Tropical Africa, by Dr. Kirk Enis plant, whiseh was evidemty chosely related to Musa Encete, was proposed to be colled sinsa livingstomiana Nudibran the Anatomy of Doridopsis, a genus of Feb. 2.-G. Benthana, Esq, President, in the Cuair The Rev. R. W. M'All and Capt. Douglas Galton wer elected Fellows. The following papers were read:-1 On the Movements and Habits of Olimbing Plants, by
C. Darwin, Esq. The ints three groups, namely, divided climbing plants climbers, nad tendril-bearers, and detailed ats, great length his observations under each division. In his concluding remarks to nhsurverl thit it might bo presumed plants beeome climbers in oriler to reach the action, and to that of the surface of leaves to its effected by climbing with wonderfully little expen-

Which essen
masua habit are furnished with revolving intervoder. It phe next group the possession by a plant of ith with their petioles or tips sensitive, and with the very little use unless associated with revolvina be ch nodes, by which the leaves could be brought into intewith surrounding objects, though on the othentac! revolving internodes without other aid suffice to give the power of climbing. Unless, therefore, we suppose the leaf-climbers simultaneously acquired both cappacities seems probable that they were at first revalvens and couid thus climb, and that subsequently they beam
capable of grasping a support. From analonno reasons it is probable that tendril-bearing planta mone primordially twiners, that is, they are the descendanten plants having this power and habit; for in th inajority the internodes revolve like those of trining plants, and in a very few tho flexible stem retains th Wapacity of spirally twisting around an upright stick. With some tendril-bearing plants the internodes have lost the revolving power, which has passed into the
tendrils. These teudril-hearers have undergone mose more modification than leaf-cliunbers; hence it is $\mathrm{no}{ }^{\circ}$ rurprising that their supposed primordial revolving and twining habits have been lost or modified more frequent's than with leaf-clinbers. The three great temdil-bearif families in which this loss has occurred in the mat marked manner are the Cucurbitaceæ, Passifoment and Vitaceæ. There is abundant evidence in the whols gronp of leaf-climbers that an organ still subserving its proper function as a leaf, may become sensitive to 1 leaves may acquire all the leading and charactarition qualities of tendrils, namely sensitiveness, spontanemas movement, and subsequent thickening and induration. If their blades or laminæ were to abort they would fon rue tendrils; and of this process of abortion ener stage may be met with. According to these view, lef. climbers were primordially twiners, and tendril-bermon (of the modified leaf division) were primordiaily lerf. climbers. Hence the latter stand between twiners and tendril-bearers, and ought to be related to both. This proves to be the case, for the several leaf-climbing gpecinst the Antirrhineæ, of Solanum, of Cocculus, and of Giorios re selated to other genera in the same family, or eran to otber species in the same genus, which are to twiners. Oll the other hand the lear-climbing spee of Clematis are very closely allied to the tendrildbearina Naravelia, and the Fumariacea include closely aliel genera which are leaf-climbers and tendril-baren. Lastly, one species of Bignonia is both a lexf-climbor and a teudril-bearer, anil closely allied species are winors. Tendrils ennsisting of modifieed Aoner perluncles likewise afford many transitinnal saxa The common Vine gives every possible grade, from grandly developed tendrils to a bunch of thom Some tendrils their nature, and it might bave been expected they would present some differences of function, the is not the eas on the contray they pred most perfect idontity in their several characteritio The most interesting point in the natural history climbing plants is their diverse powers of The most different potiole, midribs of the leaf or leaflets, and apparemil reivial roots, all possess these powers. Climbing parme continued the author, ale so numerots as to Ther conspicuons section of the vegrtable orders.
belong to many and widcly-different order some crude idea of their distribution in the Kingron,", which inciude plants in any divisions of twiuers leaf-climbers, and tendriblhearers and these (some at least in each gromy) al bave the power of spontancons'y revolving divides planerocrmic plants into 59 alliances, andeftres 36 (thove half) include climbing plants-h root-climbers heing excluded. To these a fer Crmin gamic plants must he added which climb by retation When we reflect on the wide serial p:ants having this power, and when we know positæ, Rubiacem, Scrophalarizcex. I
three genera alone out of the hoat of $g$ capacity of acquiring the revolvin. most climbers depend, is inherent, tho in almost every plant in the vegetable kinginm athor thus concluded his reunarks:-The periet br the organisation of plants is forced on our m ns linat study of the many kinds that climb. climbers. done its work, and done it in an admirablo manner. 2. Note on the genera Darooinia and Bartlingia, by the Preident. In this paper, Mr. Bentham showed that the later ones: Genetyllis of De Candolle, Hedaroms of Tindley, Polyzone of Eadlicher, and Schuermannia of F. Mueller. ()wing to Rulqe having overlonkel the E. Mueller. of the structure of his Darwinia, it was generally referred to Monochlamydex, and hence was overlooked by D Candolle when working up Myrtacess. The latter over-
loo'ed the staminodia, distingnishing his Genetyllis from ('hamalancinm expressly ly their absence, and hence Lindler established Hedaroma, giving to it characters Whieh are really common to DeCandolle'sand to Rudge' Darwinia thus extended, Mr. Bentham noticed 23 species, which he distribntes under the sull-zenera Hedarom with 11 species, Genetyllis with 6 species, and Schuermannia with 6 species. Bartlingin founded on apecimens of Sieber's, and inexplicably retained in
Mntaceax by Schauer, Mr. Bentham finds to be none other than Pultenæar oborata, with the buds in the young stage when the sepals and petals have not grown into the irregular form characteristic of Papilionacer.

Royal Hortioultural: Feb. 18 to 22 (Weekly Shoro).-Major Trevor Clarke furnished for exhibition on this occasion some very pretty cut flowers of forced
Chrysanthemums. From Messers. Lee came the handsome winter-flowering Coelogyne cristata, Dendrobium cocrulescens, Double Chinese Primulas, and one or two Finter and early apring-flowering Heaths and Epacrises. Six sunall houquets and a box of cut Camellias were plants one or two examples came from Mr. Bull, who hadfalso Imantophyllum cyrtanthifolium, and various little Standard Orange trees. From Mr. Hall, gr. to
II li.H. Prince Fdward of Saxe Weimar, Molecombe, near Goodwoo1, came a very pretty basketfol of Violets, and with them some pendent
fustic decorations, consisting of blocks of wood covered with Moss, from among which peeped intermised with living fronds of British Ferns, a extremely good effect. Mr. Tillyard, gro to J. Kelk, Fsq., sent beautiful examples of Muscat of Alexindiria and West's St. Peter's Grapes, still in a state of excellent preservation. From Capt. G. H. Clarke came a PinePernambise. Finally, from Mr. Fraser, Lea Bridge, came examples of winter-flowering Heaths, Logether Hovea pungens, one of the purpl-si-violet bloswomed ornamental of early hardy greenhouse plants.

## Notites of 300

A Monograph of the British Spongiada. By J. S. Bowerbank, LL.D. Vol. I. Published for the Ray
Society. 8ro, 1864. Pp. xx. and 290. Tab. lith. 37. If every branch of science were overwhelmed with a nomenclature similar to that which prevails in this volume, its study would indeed be the pursuit of knowledge under difficulties. Such terms as bipocillated equiauchorate, floricomo-hexradiate, and a hundred equally overpowering, might well be a heavy blow and
strong discouragement at the very outset. In many cases we think that matters are not facilitated by this new nomenciature. Such terms as expando-ternate do
not to our apprehension convey any definite notion, and many of them are certainly framed in opposition to all received rules of etymolngy. They may be incenions, bat it is ingenuity which is almosts on a par witi that the different forms of generic and specific names to fore, we think, much to be regretted that a work Which has so much to recommen it sioulid bo over Whelmed with such a mass of ill-looking, and, we think, needless phraseology.
The geagh we protest so far, we wonld not detract from work, of which we lave here only the firat instalment The figures ar3 extremely well executed and very and excellent account of all that js known of the structure and physiolozy of these very curious produc tians. At present but little has been ascertained in in spite of the apparent excessive simplicity of strucure, except as regards the skeleton, all are really The skeletnn is of three kinds, calcareons, siliceous or nasmene the most strange and varied forms, which would astonish us the more were we not apprised of the very by the Foraminifera, coverings which are elaborated by the Foraminifera, beings quite as simple in strncture The mes: know, as the Sponges the:aselves.
equally with th. Furaninitera is the whin sponges
 regetable as well as the animat ascenined to cceur in the "It is," says our author, speaking of.
in Sponges, "a pellucid, semi-transparent gelatiuoid
substance, variable in colour and insoluble in water It dries readily, and its physical characters are reatored
by immersion in water with little or no apparent by immersion in water with little or no apparent
alteration. When separated from the living Sponge it bas at certain periods an inherent power of locomotion small detached masses of it may be observed slowly but continuously chauging their form, and occasionally
progres-ing in lifferent directions. It is usmaty spreau progres and rather evenly over the internal tisgises, but the surface is rarely perfectly smooth; sometimes it abounds in obtuse elevations, and occasionally separate naturally into innumerable irreqularly round
masees which are excuedingly varialite in si\%."
mases wheans of a double set of porea, a constant com munication is kept. up with the surromanding fluid: the for:ncr of these are minnte, anl often when closed invisible to the naked eye, and through these nutritive matter contained in the water is imbibed; the latter ambibed water anl any tal matter are expelled, to gether with in many cases reproductive bodies.
It is not clear how these apertures open and shut. In some cases cilia have been observed, and it is
probable that they exist in every case, and very possibly on the whole surface of the sarcode, which seems to answer the purpose at once of nutrition and aer ration
So few, however, of the inarine Sponges have been studied immediately on their removal from the water, that little positive is known on the subject.
The reproductive bodes are of various kimis; some-
The reproductive bodtes are of valuns inds; some complicated ovaries; sometimes propagation is carried on by gemmnles as they are called, secreted within the Spnnge, or produced extervally ; and sometimes by mere be able to live at its own expense and to reproduce the specips. The gemmules are bo lies of a doubtiful uature, and if they are of two kinds, one of which bears sperma toz a, they must be of a higher character than mere uds.
N.
Mr. Carter, who has made such valuable observations on Sponges, as on other aquatic productinus at Bombiy, makes the following statement:-"When the transparent spherical capsules which contain the granules within the seed-like bodies are liberated by breaking open the latter under water in a watch-glass, their firs act is to burst: this takes place after the first 36 lonurs, and thair granules, which will presently be seen to be the true ova of a protemiform infuanium, varying in diameter from about the $\overline{\text { s.ob }}$ th part of an iach to mere point, gradually and untormly become spreal over che surface of the watch-glass. On the second or third day (for this varies) each granule will be observed to he providen with an extensible pisud - pediform base; and sing by its aid or gliding over the surface of the watch
glass in a globular form by means of some othe glass in a globule
"The trutt appears," says Dr. Bowerbank, "simply to be that any minute mass of sarcode, whether
separated voluntarily or involuntarily, has inherent life and locomotive power, and is capable of ultimately developing into a perfect Sponge, and in the course of this process the dermal membrane is produced at a very early period.'
r. Cuter's description, he says, is strikingly simila to his account of the masse; of sarcode separated from the sarcocions lining of the interstitial cells of Spongilla but it must be observed that, in the development of the egg, the first act is to liberate itself from the mem branous envelope, and the contents thas hatehed become moving masses of free sarcods, but without the locomotive cilis that are found on the so-called ova or gemmules so minutely and accurately described by Dr. Grant in his papers on the Structure and Functions of the Snnnge, in the Elinburgh New Philosophical Jonrnal.
Both these modes of propagation occur in tho samo species, but Dr. Bowerbant has never seen them both well developed in the same indivicual.
The subject is of peculise interes: to the batanist, becanse of ita bearing on the mode of reprometionit the minute Puffbills belonging to the order Myxonasres, in which proparation sometime; takes place by an Amochoid boty proceeding from the interior of a spore and which cannot be distinguished from a true lufin sorium, while in other cases the spores germinate lik ordinary spores. It is only an a liditional instance in proof that vegatuhle and animal li"e are not two distinct thinga, and that the two kingto:ns are far from being acutely separated from each other
Many nther matters of importance might be noticed but we have quite reached our usuil lunits. It seems very ungracions to find any fauit where we have so much to interest ns, and where we ought to teel so much obligation for collecting such a mass of informa tion on a point which cannot fail to be attractive. It
is, however, a great olject of the present day to siunplify science quite as much as is compatible with perfect truth, and to avoid as mirn an massht, anytuing which cin prove repulvive. 'The great drawbaek to Wallroth's bonk on Envopean planis, was a moancmelature which was not familar, un eonseqnemer of which: : mass of most valuable mformation on Cryptog mic phats has been almost miversally negleeten, and we have fears of ammilar consequences in the crase betore us. With this apology, if we may so call it, we conclude onr somewhat
desultory remarke, at the same time expressing a hope
that the descriptive part relating to the species may very shortly follow.
M. Muquardt, of Bruseels, aunounces a magnificent folio work on Java plants, entitled Flewrs, Fruits, et
Fewillages choisis de la Flore et de la Pomone di Th de Fewillages chousis da la Flore et de la Pomone d' Tho de an Nooten. The work is published in 10 parta each comprising four plates, richly printed in colours and nachel with thr pencil, with four leaves of Freuch and English text. Mr. G. Severyns, of Brassels, has been encaged in the production of the phates. The prospectus ells us that the author, in a touching prefaer explains he painful circumatances wheh induced her to seek in these studies the means of bringing up her family, in the accomplishment of whien sacred duty she has had the consolation to find in the study of Nature a he satisfaction of propucinme magnificent alhum, which will form an indispensuble supplement to works already published on the same subject.

Cathloguts Reonived. - E. G. Homderson and kiteluen and of Seeds is a well prepared auple list besides some very useful observations on Seod-sowing, on Manures, on Dostroying Insects, \&\%, as well as a set Golden Rules for Amateur Gardeners. Amonget specialties we observe Hombersnns Perfection Sweet
William, which is deseribed as the last improvament on Mr. Hunt's celebrated strain.-Jolun Salter's Deseriptive Catalogue of Linglish and Foreign Ňveltiss contains a large assortment of Chrysanthemums, inclading apwards of 30 novelties, and many other interestiog subjects, amongst which is a most extensive collection
 Garden Seeds is a neatly arranged enmpronncine list. Countess of liglinton, a hew mave heding Vorbena, Choice and Rutre Seeds is a most comprehusive list Of the beautiful feathery Celosia, 12 distinct colours are offered, including rose, crimson, carnine, orange,
pink, and yellow. Mr. Stuart also offers seeds of the beautiful perennial Lagenaria, of which fruit was shown last antumn at Sonth Kensington.- William Knight's (Hailsham) Catalogue of Nursery Slock is a genera ist of shrubs, frnit-trees, and Roses.-William Thomp son's Descriptive Catalogue of Elower Seeds is a well arranged select list, amongst the novelties in which we
notice Waitzia aurea and W. corymbosa, two species of a genus of Everlastings, which are likely the prove Deseriptive Priced

## hist; Meredith's Pewsin! Hybrid is rucumbiniel as

 the best Mrelon grown,-Lamoureur. C'l. ik of C..'sGeneral Price Current is a full seed list, with useful notes and cultural hints. There is also a calendar of
operations. Among Po!atos, the Creeper Kidney is mentioned as one of the very earliest, and as the sort Covent Garden Market.-Diummond Brothers (Edin. burgh) Priced List of Garden Seeds is a condensed list, and seems carefully prepared.-Haaj
(Erfurt) Catalogus of Seeds and Plants is most claborate, the numbers of the seel list alme reaching over 8000 ! of which more than 1300 are seeds of trees and shrubs, abont 50 of aquatics, anid over 200 of succu-lents.- Vilmorin-A ndrienc \& Cie.'s Extrait General des Catalogues is an albridge! list, with several wondent
illustrations.-William Davidson's (Edinburgh) Select Lists is chiefly devoted to farm seeds.-Downie Lairc - Laing's Descriptive Catalogue of Elorist's Flowers is chiefly deroted to such subjects as Pansies, Folly hocks, Phloxes, Pentsemons, \&-., of which a vary extensive selection is offered

## Garden Memoranda.

 Essex.-Alreaing are the show huses in this wellknown establishment quite a blaze of floal beauty. Prominent among plants employe! in protucing this display are Azaleas, both red and white, and thododendrons. Wurthy of especisl notice among the later is a rose.coloured variety of caucasicum, which is stated to fores with great facility, while in point ot appearance it is greatly superior to its parent, Double blossomed Cumese Peaches are also at present in great beauty, and varying as their blozsums do in colour fro.n snowy whiteness to rich deep crimson, they havs a striking and highly ornamental effect. One variety moreove has carnation'-striped blossoms. Considering the ease with which these double-blossomed Peaches can be had in bloom, it is a matter of surprise that present bestowed on them for purposes of early spring decoration. Among Cyclamens, which are now bloomins in protusion, the little kind called Coun is atilt deservedly a favonrite, on account of the beanty of it spring-Howering Heaths are also at pres ment o.jpets of interpst, carecrally the sorts catled E. Peserminans himualis aracilis, melanthera, and a bew oth res as ane aks) Epaerises, Boronia pinnata, Tetratheen ericitolia and certain oiler early-flowering grewh use shrats, on account of the beauty of it peculiarly rich violet
purple blosoms. Anong Correas, cardinalis is a fine
kind, its blossons being ricts searlet, tipped with preen the two colurs producing a charming con grast. Crocuses consisted of potsful of the common large yellow kind; a white wort called Dians; and Orondutes, purplish violet, and one of the largest varietios in cultivation. Of atriped kiaus with which is one of the very best, while for the ease with whichis may be forced it has few equals. Narcissi likewise same a good display, as did nhso Deutzia scabranand Tulipe, Among lilacs was one named Charles X the blossoms of which when out of doors are of the deepeat purple; but when forced they come nearly white. This is stated to be the variety employed abou Paris for producing white fluwers when forced in dark nesa. As far as fine effect is concerned, few plants equal the common Guelder Rose when forced here we noliced standard specimens of it, loaded with balls of snowy whiteness, which, contrasted with rose Ledum paluatre, a well-known forcing shrub; Chines Primulas, and Duphues are likewise at present in fine llower. Of Camellia, Mr. Fraser has on extensive ascortment, and as covering for walls they have fow equals. When traiued in clonoly, as they are here, they oceapy little room, and fower profusely; whin extremely ormanemtal baekground for other plants.

To the growth of Pelargoniums several houses are devoterl, and selfon have we seen more promising plants than those intended for the forthcomng exhiattention here, and to their propagation and growt many long span-roofed houses are appropriateit. One , wholly set apart for the cultivation of ixoras, contained a fine collection of these showy sirnbs associated with a few plants remarkuble for the brauty of their leaves; while in a forcing house were Lilies of the Valley, the new Double White Almond, just coining into bloom, apparently a valuable acquisition both indoors and out; the blue-flowered Exacuin zeylanicum was also in flower, and is worth growing on account of its colour. Un the ingide roof of a comparatively cool house Lapageria rosea blooms beantifully every year, and produces abundance of seeds from which multitudes of young planis liave becn roised. It may be worthy of remark that the Howers proluced towards the end of the season are those which furnish secds most abundantly, the early blossoms being nearly or in most cases wholly barren. Neapulitan Violets, now blooming in great perfection, are being removed lrom frames in which they have been wintered, and potted preparatory
to being placed in the show honse.
Rlow and froit trees aro beoming important features of this nursery, both indoors and ont. Under glass some of the nowest Roses are coming into bloom and even grafts put on suce Christmas are furnished with flower buls. The respective merits of the different sorts now on trial will therefore soou be in som meature determined. Some of the better known kinds of Teas now in blossom are nucommonly sweet-scented a quality belonging to them even more appreciated nov than liter in the season.
Orchard-houses are annually stripped of thei eammer stock on the approach of winter, and are con verted into hybernatories for other isinds of plants Among the hater we noticed Lilies which suceed admirably in houses such as these. Of L. auratum Mr. Fraser has several hundreds, most of which flowered beautifully last season. Coniferous seeds also germinate freely in houses of this uescription, which, bowever, to be useral, should always have a hot-water pipe run round them-as is the case here. The frait trees in pots with which they were filled last season are now plunged out of doors, and have their pots covered with Cocoa-nut refuse, a cheap and useful material for such a puripuse, as well as for plunging pots in in pits.
Vine eyes in great numbers are being started into growt h in heat, and of the collections of specimen plant and large Azaleas, for which this nursery is celebrated, it is impoesible to speat in terms of too inuch praise On these, however, we shall doubtless have to report more particularly on future occasions.
As far as can be ascertained at present, the Japanese Retinosporas, from the late severe weather, which has also had no ill effect on the bright yellow blossoms of the Winter Aconite, several beds of which are now in great beanty

## Miscellaneous.

Sale of Bulbs of Lilium awratum.-An importation of these, together with some sceds of Wellingtonia and a few plants of Tree Ferns, was sold the other day by Mr. Stevens, and realised large prices, especially the Lilies, which although in many in stances only presumed to be L. auratum, fotched Wellingtin from $2 s$ s. to 8 s. apiece. The seed of Wellingtonia fetched from 15s. to 25 s. an ounce, and the Ferns from $1 l$. to $4 l$. per plant. Altogether, a sale some 425 lote realised the sum of 420 l .
Uses of the Vine. - When in tlower the Vine exhates an agreeable odour, and there is no part of the plant Switzerland the leaves to some usefal purpose. In
surgical nses. In cuta and green wounds they are estecmed a sovereign remedy: decoctions of the juice Wher the yild ail reate but Qage. When boiled they yield an agreable tea, but more astringent than that of Chinas: it is much iked
and thought very bracing to the nervous system. The and thnught very bracin, to the nervous system. The The leaves and teadrils bruised, and the juice fermented, afford a pleasant light drink of a vinous character. The leaves form also excellent fond fo cattle when fodder is scarce, but they are of too much valus in the vineyard to be often spared for tha purpose. In such cases they should not be taken til they begin to fall off. They are then collected, put in a dry lott, and sometimes salted, pressed and left to ferment. In some places they are alternated with fodder After the vintage, animals are often turned inlo the grounds to browse on the leaves. Vine branches furnish potash and salts when burned; basket work is made from them; and the bark is used for bands to tie the Vines to the props. Denman's Vine an its Fruit.

## Calendar of Operations. ( Kor the enswing week.)

Dubina the present changeable weather great atten tou will be required in the way of maintainiug proper temperatures, and the requisite amount of moisture in stoves and other plant houses. Spare no labour to keep :up a gay appearauce in the Conservatory and everything be kept scrupulously neat aud clean.
flower garden and plant houses.
Look over beds of Crocuses and other bulbs to see that they are not thrown out of the ground by the late frost. Also inspect half-hardy plants that have been closely covered up, in order to see whether or not they are necure from injary, or suffering from con finement.
Aubiculas.-Now that mild weather has returned, let these have as much air as possible; they dislike confinement.
Carnattons and Picotres.-Draw the lights off these in the day time when there is no frost or heavy rain, but let them be put on again at night.
Pelargoniums.-Those for purposes of exhibition will now be in their pots in which they are to be bloomed, and will be growing'pretty freely; therefore whenever the weather is fine, let them have as much ai as possible, cousistent with the proper temperature. As has been stated on former occasions, let Francy varieties be kept a little warmer than ordinary kinds.

Roses.-Another batch of these may now be placed in heat to succeed those coming
Tulres.-Place in heat potsful of bulbs to succeed those now in bloom, and see that the latter are not allowed to droop from want of water

## FORCING GARDEN.

Asparacus.-A bed to come in in succession should now be made. On fine days give a little air, to keep the heads from becoming too much drawn.
Cherrirs.-Force slowly while the weather is com paratively dull. Syringe the trees occasioualiy, an keep all Hoors and other evaporating surfaces moist.
Cucumbers.-Where necessary fill pits and frame with young plants. Cuthill's Black Spine is as useful as any to plant for ordinary purposes
Melons.-Sow now ; pot in small pots wheu strong ensugh; keep near the glass, and either plaut out or pot into large pota, using properly warmed, rather strong turfy soil. Suw for succession at intervals of about a month until May.
[Peaches.-Admit air freely whenever the weathe is mild, and keep the atmosphere moist, maintaining in which the fruit is set about $50^{\circ}$. Early house in which the fruit is set should be afforded a nice growiny temperature, syringing liberally to prevent red spider, and keeping the border in a healthy state

Pines, Young plants in beds that have been some time planted will be benefited by having the soil oosened up as deeply as can be done without injurin the ronts, giving it a liberal soaking of tenid water it it be found to be too dry. Endgavour to afford a nice regular bottom-heat, with a thoroughly moist atmo sphere, and keep the plants growing as freely as may be consistent with preserving them dwarf and bushy Have a constant eye to maintaining a succession of fruit, or securing a supply at the season when it may be most wanted, and let the treatment of the plants be regulated according to circumstances; this is a matter which demands considerable forethought, and Which cun be successfully managed ouly by careful observation and attentiou.
Strawbrardes.-Put sufficient of these for a second crop into a Peach house or Vinery, and place them on $a^{\text {shelf }}$ near the glass where they will have plenty of ligat. A fresh supply of plants should be afterwards placed under cover every fortnight or so. Let the emperature be low at first, and even afterwards force gently and give all the air possible, or the flowers will apt to become "blind.
Vinss.-Take adrantage of all favourable oppor-
tunities to admit resh air as freely as can be droe wo safety, and be satisfied with as 10 a a temperature fro gre-heat as may be considered safe under the shate the Vines, but shut up early, allowing the thermone to rise considerably. This will to some extant ese mise fuel, and will be much more conemial 1 , fire-heat, Except where Vines are in flwe strongs atmosphere moist, but the foliage should almp the allowed to become perfectly dry in the course the day
hardy fruit and kitcuen gardex.
Digging and treuching may still be carried on wis achive. All wheeling win, as a mater of course, hat done during the late hard weather
APples and Prars.-Pruning and thinning of these Beave Broad Windar
Beans. - Broad Wiadsor and Johnstone's Wondati may be planted as soon as the ground is in a fit athe or their reception.
Parsnips.-Seed of these should be sown as noon as possible. Had the weather, indeed, been thromen able, it should have been in the ground befone the Pe
Pras. - Make a sowing of these as soon as the grome fit to receive the seed.
Potatos.-Early sorts should now be plantod wite out delay.
Spinach.-This will doubtless have suffered in some places from the late frosts. A sowing to supply coly plants should therefore now be made.
Radishes.-Let a sowiug be made on a warm borla

## GENUINE GRASS SEEDS.

PERFECTIIS FREE

Direta the ofurial attention of intending purchasers to the following VERY FINE MIXTURES, which ue gicaranters are not to he surpassed in quality and selection.
III whlering Gramepa a deecription of the I, and to he laid down is very necessary, that a suitable Mixture may be supplient.
MIXTURES for PERMANENT PASTURES and MEADOW LANDS.
Containing only the finest suitable Grasses and Clovers.
25s. to 30 s . per acre.
MIXTURES for IRRIGATION or WATER MEADOWS.
Specially prepared from those kinds of Grasses most suitable for moist situations.
258. per acre.

MIXTURES for PARK and FIELD LAWNS. l6s. per bushel.

MIXTURES SUITABLE for SHEEP WALKS.
being compmeed onl! of hinds which thrive on poor soils.

$$
25 s \text { to } 30 \text { s. per acre. }
$$

MIXTURES for RECLAIMED MARSHES or HEATH LANDS. 208 . per acre.
MIXTURES for GARDEN LAWNS, PLEASURE GROUNDS, GRASS PLOTS, BOWLING GREENS, \&c.

18s. per bushel, 1s. per lb.
This Mixture has been most carefully prepared from the finest growing kinds, and cannot fail to give satisfuction.
MIXTURES for RENOVATING OLD PASTURES.
(Sow 10 to 12 lbs . per acre). Price per lb., 9d.

## MIXTURES for ALTERNATE HUSBANDRY.

These Mistures are formed of the best Clovers, Fescues, Bye-grasses, \&cc. \&c., according to requirement. for either One, Two, or Three Years' Pasture or Hay.

16 s , 188 ., and 20 s . per acre.
In ordering this Misture it should be stated whether it is required for One, Two, or Three Years' Lay.
Where large quantities are required, J. V. will feel pleasure in quoting apecial prices.
Euteh kind of (irass and (lorer Sced supplicd sepurately if required.
Full DETAILED CATALOGUES of AGRICULTURAL SEEDS will he furwarded (Post Free) on application.

SATURDAY, FEBRUARY 25, 180.5.

> MEETINO FOR TBE BNGUING WERK.
> W:DxElpay, March 1-Royal Agrl. Society of Rngland (Nion)

Have the members of the Royal Agrioultural Society at all considered what the Educational Committee of their Council are recommending that body to do? On Wednesday next a decision, adjourned from the last mecting, will no doubt be declared upon a proposition which really has no claim wha!ever upon the consideration which it will receive; and certainly none upon that favourable consideration of it which sonse enthusiasts desire that it should have.

It is proposed that 300l. of the Suciety's funds be voted for prizes to be annually awarded to boys, the sons of farmers or of members of the Societs, who shall pass, with the greatest eredit themselves, the local University examinations or those of the Collerge of Preceptors. In addition to these bodies the Sucicty of Arts liad been origimally asked to co-oparate, but its examinations, which alone have any direct reference to agriculture, are now exclade 1 from the scheme. And it curiously illustrates the same tendeney on the part of the promoters of this plan that a proposal that $25 \%$. should be appropriated for a special paper on Mechanics as applied to agriculture, which is the only professional ftature it possesese, is expressly declared to be contingent on further negociations with the Universities.
All this, then, is in discharge of the duty connected with egricultural education which the Charter of the Society imposes! It is plain that agricultural education-" the education of those who are dependent upon the land for their support"-so far from being promoted by this seheme, is altogether ignored. The class indicated by the words of the Charter are not the sons of farmers or of members of the Agricultural Society - but those, whether sons of farmers or not, who, entering agriculture as a profession, beoome depeadent on the cultivation of the land for their
sopport; and it certainly may be fairly conoluded that the education referred to is that prolified to education by which they become qualified to abtain a maintenance in this way.
In place, however, of any examination which, by testing so much of this qualification as is capable of being thus tested, shall stimulate young men to seek a thorough professional aqked to do is to agriculturists, aht those who satisfied a merely literary board of examiners. It is not a knowledge of the art of agriculture, or of any special applications to it and plants and animals-with the practice of the field, the fold, the farm-with the experience of the agriculturist, or with the explanations given of it by the man of science-hut a kn wledge of spelling forsonth:- of Arithmetic and Geography, of Grammar, linglish Histors, and Writing; Latif, Greek and Fernch; of Drawng, Mathe of England is desired to stimulate and reward!
Let it be clearly understood that there is no question raised here of the importance of any or all of these departments of what is pronounced by do we at all deny the serviceableness of ayy of these studies as real educators of the mind. Nor is there any displeasure because of the amount of mones which it is proposed to appropriate EDMUNDs, might very properly be dorot Mr the promotion of agricultural education. The question raised is whether the funds of the Auricultural Society will be spent in accordance with cilher the intentions of its founders or the grod will of its members, if voted for the purposes which the Committee have thus indioated. We admit that they are perfectly consistent in putting " music" and "religious knowledge" apon thei list of studies; but if the mention of either of these subjects do not awaken the commun sense of our leaders to some perception of the grotesque unfitness of the course on which the Agricultura Society is being asked to enter, nothing can be hoped to do it.

Does it not seem plain upon the very face of it that the Agricultural Society, if it interfere directly in the subject of education at all, must first place it is novious that to do what it is asked to do for the promotion of general education will be a umpless flinging amay of money; for it is utterly visionary to suppose that the few pounds placed at the disposal of the University examiners will be felt as any additional spar whatever by candidates for the status, place, and literary rank, which, as as arded by a public board of such high standing, are the real objects actuating them. -In the second place it will manifestly be an indefensible wrong doing ; for the modey for whi they are petitioned is not at the disposal of It is at their disposal solely for the agricultural objects which are specified in the Charter; and general middle-class education certainly is notone of them. - And in the third place it will be a most mischievous mistake: for it will close the door on the effort which might and could and should have been made for the promotion of professional and ggricultural training. The duty specified in the seventh clause of the Society's Charter will be declared discharged; snd the subject will altogether dop.
We submit to those who are really interested in the promotion of agricultural education that this is a most serions and weighty consideration. There certainly are a large number who sympathise in the efforts that have been made to induce the
Council of the' Society to an effort in connection with this subject. They may rest assured that if that body be misdirected now on to the wide field of middle-class sohooling, nothing will be done for the special and professional object in which we are concerned.
It is earnestly to be desired that no rash step taken now, and retraced under directions from the general meeting of members next May, shall result in a distaste and indifference towards the whole subject, so that the professional education which alone is the proper object of our efforts, shall be left altogether in the lurch.
Is there no middle term on which the advocates of this middle-class movement may agree with us? Why should not the conduct of Apothecaries Hall towards candidates for the medical degree, to which Mr. Acland gave his adhesion in his letters to the President, be our guide? Let the candioiates
exclusively, if you will, those who have already passed the mid ile-class education tests; but on the other hand let them be exclusively intending agriculturists, and let them gain their places on our lists by the test of agricultural examination alone. It is idle to say that nothing can be lations by such a test. The practical men who say that the real test of agricultural ability is only in the field and in the market are quated with approval by those who are nevertheleas their very antipodes on the educational subject. Their judgment Firtualiy misrepresented. There is not one of them who does not form a judgment of the servants whom he bires by just such an examinaion as he is here asserted to despise-nor one of them whose son at the Agricultural Collega does not derive periodical guidance and incentive in just this way.

Agricultural education is a definite thing, and many of its results can be tested by examinations. To its prometion we eordially hope that the educational efforts of the Agricultural Society may be directed and confined. These efforts are the more likely to be efficient and successful if the field of their operation be thus limited. They win be utterly lost if thrown into the great sea of
middle-class schooling; where Mr. Actand, middle-class schooling; where Mr. Acland,
according to his pamphtet, strives to send them. And it is moreover well worthy the consideration
of the Council whether they will not thus be misappropriating the funds which are placed at their disposal for agricultural purposes alone.

## THE PRESENT POSITION OE THE FARUER.

[To the napers on this subject read before the Hurgerford
and the East Lothian Societies respectively, and lite's aneorted fou our columne, we now add another, or rather an
address, spoken by Mr. Grey, of Lipwod-John Grees, of
addren Slub, of which he was the founder, and has long been the President.]

1. The Corn and Meat Produce of the Farm. place in the prices of agricultural produce ave the place in the prices of agricultural produce, and the
means which we may be able to devise to meet that without the ruinous loss which attends the raising now of the produce of grain." Ten or twelve years ago he took the liberty of suggesting to the large importation of looking abead, an which wenld greatly interfere with the markets of our nwn produce in this country. At that time it was obvious to him that the great increase in the importations would be in the articles of Wheat and other grain. That had enme about. They would recollect that they used to calculate on 60 s. per qr. as an average price for Wheat, and now it was down to 40 s. or less. On the other hand, they used to reckon butcher meat at an average cost of $5 d$. per 1 b . and thought themselves well-off if they got $6 d$., while now it had gone up to 8 d . and $9 a$. 1 seemed quite olvious that, loosing over the world and seeing thin population of many other countries, and considering that Wheat could at all times be conveyed from one part of the world to the other upon that great highway of nations-the sea that divided them from other countries-and hy means of those lines of railways which now intersected the globe in all directions-it seemed quite obvinus that Wheat sliouli be the article they would be likely to be inundate with, because it conld be put on board a vessel or truck and conveyed from place to place with very little cost or diminution of value. It required no feeding and attention like cattle; there was nothing of that required for such cargoes as those. Not only did cattle require both food and water on their way, but they were liable to loss of health and the risk also of lisease, and consequently great depreciation in valuo would be sustained. That had come perfectly true,
and the recommendatiou which he tnok the liberty to hestow upon them then had been in the right direc tion. He told them generally, at that time, that he would judge of the conlition of a farmer by the
extent of the fluck of ewes upon his farm, and the condition of his live stock. That generally had held gond. Another thing showing the very great importation of grain and its i:creased consumption in this conntry, Wheat into England was about a million and a half quarters ; now it had risen to between seven and eight millions; and on one occasion it had reached as hight as
11 millions. That proved not only the great increase in the population of the country, but, what he rejoiced was also a fact, that the poor-the labouring classesof this country were better fed than they used to be in the earlier days of many of those present-and better fed than any other class of labouring perple in the world. Those circumstances proved the great chinge that laad taken place in the market prices of the pr
duce of their land, and it might point out them the necessity of accommodating themselves, as well as they conld, to a different mode of cultivation, which would tend to modify, in some degree at least

When he asked what was to be done in thes? people said they must lay their land to Grass.
was a very easy, but a very fallacious solation question ; because they knew that if they not land to Grass they could not possibly maintain husback that could be kept under another come husbandry.
aware, that there were cortain portions of land ther mas? on almost every farm which, from its rempoto siturip:
steepness, or the pecular quality of its Boil,
laid out to permanent Grass than in

 he agreed upon the prouriety of lajing into permaneen:
such fields as he had describan - he hid allowed him such fields as he had describan-he had allowed himet:
of the lime required to be applied to the land, and he of the lime required to be applied to the land, and he is
the Grass seeds required. That was a course which requently failed, and consed him to doubt the wisdom
so Tho failure, perhaps, was caused by the want of
l-dge, want of experience, and want of care in som:
for permanent pasture those very small, those for yermanent pasture those very small, thons serery it would not be out of place were he to detail to then
the result of a set of experinents he recollectel being many years ago for the Highentand So recollectel beina
they would find recorded in that very of Sentland, agriculture, by his frien perdia of Agriculture."

2. Rotation of Crops.--s, fir, then, as rea agrain, they must extend their view beyonl: because as practical farmers they were mp. required for the consumption of the comntr paying their rente unicss they had a coner bave a rotatiou of crops and must have litter. traw, and manure as well as root crops to keep rmount of stork. But it was quite pessible to that object addicted to.

3. Cirass Lambl Farming.-These were plans which 1 at by th-ir own scise teaching then-by their own that that Clah, atm the varines clubs of a similar chad been. It was nut merely the cultivation of the land that neerfed attens of the land. He hoped they tion also of the occuniers of the land. He hoped they
had there a useful librury consisting chiefly of agricul. turul bove, and he trusted they ronld take out those huha which womlil teach them theoretically that which they mint work nit fractically by their own thought anil julument. There was, however, a description of
firming which was exmpt from the depression which had been brought over the corn-growing of the cmntry -he mennt those farms already found in pasture

 matter, and one in which the greatest care had to be taken to
ronder it a proftable pursuit. But there were many mountain

 yearsago The sheep now came much earhar to maturity and the tme reforred to. Those gentlemen in the poseoseion or ather so foltipnate in their exemphion from the tronbles of
 evily m monged because it was ail Grass. Now he was of a different opinion, for instead of being more easily managed, he thought
the krentust amoment of jindament was necosiary to nanage
well and to the beat advantage, the stock alone. A man must know not only the descriptioa of stook best suited to the soil, malluse tiat stnck so as to make the most of it. Instead o it wha yust one of those situations which required a very great
4. Land Agency. - But no man deserved to be, indeed, no mane could be a successful manager of land it he was wanting in judgment, or wanting in industry duke extolled as being a very good landlord, who say, "Let me see his tenants."

## In entering pon thi discusion, to

reluctantly, as he considered that he had retired from public life. But still he confessed that he had very grad to seasure in coming again among them, and he was an interest in maintaining the Hexham Farmers' Ciub Ile did not pretend to dictate to them his opinions or assertions, but rather to endeavour to bring forth their opinions in connevtion with the subject, and their exoehoped would was great-into the discuesion which he

STATISTICS OF LAND DRAINAGE.

halance of undrained at 10 million acres. He says that
there ar, however, 11 millina acres of undraingl chays there are, however, 11 millinon acres of undrainmid clays
alone. His calculations run thus:- The extent of (irat alone. His calculations run thus:- The extemt of (ireat
Brit uin is $56,352,000$ acres, of which there are ahomut $29,3910,000$ wet land capalle of improvement by trainage, but the extent of lamel alrealy permanently drained thoes not exceed $1,700,000$ acres, so that there remain 33 millions consist for the most part of froe soils naturally dry, which absorb and infiltrate to various depths heyond the reach of craporation from one-half to
one-third of all the rain that frlls upon the surface, the remaining portion of the rainfall being taken up hy vegetation or evaporition or passing of the surface f.alls. The residue of this of heavy or suddell rainmonntainous lands of rock formations, the surface which, having rapid slopes, throws of the rainfall in very large proportions, viz., from one-half to four-fifthe of the rainfall. Within the bounds of these stecp lands there are bogs and moors which catch a large quantity of the water thrown from the mountain slopes, and gire
off by evaporation much more mojeture then the rain that falls directly upon them. The extent of the sarcharged free soils drained or requiring draining is about
$12,000,000$ out of $23,000,000$ wet lands (adding in the drained), leaving of clays alone ahout $11,000,000$. The Private'Moness Acts, and under the several Drainage Company's Acts, does not excecd as yet $1,100,000$ acres, at least the total outlay $n p$ to this time does not reach $6,000,0001$; so that at the prise $t$ rate of progress may be fairly considered that it will sake a century to complate the nider-dramage of the country. Now the
number of pipeyards or brickyards making pipes in Great Britain is estimated at 2800, and assuming the number of pipes made at each yard to be on the average 150,000 a year, the number made annually may be taken at $420,000,000$. As 1250 pipes are used in underdraining an acre, 336,000 acres may be drained annum; but a large number of pipes are applied temporary unconnected purponses that cannot come into this computation.
2. Legislation on Drainage. - It is important to know precisely what are the provisions of the Act of 1861, and how far it is or may be found available to remedy a pressing and threatening evil resultirg
from increased drainage. For the first time power is given to two-thirds of the lower land proprieturs of any district so injured to o mpel the remaining third to join them in the expense of getting rill of obatructions to the removal of the upland waters existing in the shape of mills, dams, weirs, \&ec, wherely the passage of the upland water is interrupted in its way to the main
outtalls; to which powers are super-added powers of eompalsorily obtaining land in order to straiten or deopen old rivers or watercourses, and to make new cute. The Act is divided into three parts. Parts I. and II. refer to district drainages, requiring combined works, and comprise no fewer than 71 clanses, including some provisions of a new and highly practical charaster. It would appear that a comparatively small proportion -one-tenth of a district even-may set the measure afloat, whilst the dissentients must amount th at least one-third before the project can be rejected if approved of by the Inclosure Commissioners of England and Wales. Part III. refers simply to outfall works to be carried out by private proprietors, such as easements for the passage of drainage waters throngh the lands of lower owners, and the deepening and straitening of watercourses. It must not be concealed, however, that the means of attaining these orjects are attented with an expense considered by Mr. practical men to be even greater exercise of the same powers partially existing under Part III, of the Act is in fact to be paid by the applicant for the improved outfall, and any adjoining occupier through whose land it is necessary to pass may offer objections and employ counsel as in the case o Railway Bills, and the Act declares that all "reasonable" expenses must be paid by the apppica the right of landowners to discharge injurious waters through the interposing lands of their neighbours has been egalised.
There is, linwever, a mirhty power in England known as the Commission of Sowers, and in all modern Acts of Purliament relating to drainage saving clanses are inserted, preserving entire the rights of these Conmissioners, which may in no way be inal the chief are those of the Romney Marsh in Kent, and those of the Great Bedford Lovel: of the new outfall and others in the fen country, and counties of Cambridge, Northampon, Jincoln, and Norfilk. But the powers of these corporations, referring as they do not only th sea walls, rivers, streams, and waterchursea, but to banks ditches, gutters, sewers, gotis, calerea, bridges trenches, "outrageons springs," mills and milldams, weirs fish-gartha, kedels, gores, flod gates, locks, and ponds and as they are specially reserved in every Act o Parvament, are very apt to interfere with draingge Drainage Acts was to confer pinwers on tenatuts firt life, and others, to improve ratates in which they were interested, and these Acts were e.rtainly of grea
benefit by promoting improved cultivation; indeed, i
is their having proved no benefiolal that has lod to an extensing of their powers. The first Drainage Act,
$\mathbf{8} \& 4$ Vict, wae repealed by 8 \& 9 Vict., 56 . Under this last An an powers a diven to borrow, but the Act 9 \& 10 「ivt., c. 101 , nuthusisel the Commissioners of the Tremsury to adrance a sum mot exceeding $2,000,000 \mathrm{l}$. for Great Britain, to be ontained on application to the Inclosure Commissionors, who were appointed to carry out the Act, the charge upon the land to be $6 l .10$ s. par amnum, payable for 22 years, Srbseqnent, Ants have been passed to faclitate drainage
operations, and it is not a little remarlable that whilet Enclish land whers remened generally apathetic, the Scotch grapped at once at the Government grant, and certainly got the lion's share of the money. wickohire albut the period to Berwickshire and Northumberland. In 1848 the frst of the Drainage Companies whose enterprise comes now 80 materially in aid of the Government grant, wat incorporated by Act of Parlinment as "The West of Fnylind and Smeth Wales Draining Company.' The 19 the Sonttish Drain wen and Improwement ( (omphany, and
 An Act for the Incorporation of the General Land Datinage and Inprovement C mpany, and for facilihowever, can be tnken by this Company, except with consent of the Inclosure Commissioners. It must be kept in view that whereas the uagge in regard to
drainage lonns has been to pay off princinal and interet drainage lonns has been to pay off principal and interest
in 22 years at $6 \frac{1}{2}$ (now 71 ) per cent., some Companit now offer to do it on permanent loana, not rempable The Act 16 \& 17 Vict. c. 154, is nu Act ineopmating the Lands Improvement Company, and extends to England, Walea, and Scotland, affirding farilitios for the improvement of land, hy enabling the Company same Company obtained another Act in 1839, and can now aftora great assistance to tranding and improving their estates. Mr. James Sanderson, now of Westminster, in a report on the Agriculture of Berwickshire and Rosburgh hire, just published, thus speaks of the Scotch run upon the Government loan:- It was not till the Government grant was given in 1845 that drainage was carried out on a gigantic seale in the two counties. Landowners and farmers, already cognisant of drainage being the basis of every agricultural improvement, alike cagerly sought the Government money-the former merely lay, and the latter readily paying the required interest. lay, and the latter readily paying the required interest. son, or one from which accrued so many banefita. Land.
owners in some cases had theif catates creatly increased in value without any oukdy; and farmers, though pay ing a little interest, became occupants of a workable not to seek for labour, and all classes of the community became sharers in au increased production of food. The writer adds that he can furnish no reliable dala as to thie amount of Goverinment money expended in Berwick and Roxburgh ; but this, he says, must be great, as
$50,000 \mathrm{l}$. was spent alone in the western divisinn of the 50,000 . was spent alone in the western divisinn of the
last-named county. Subsequent to it not concurrent with the Government loan he states that a fresh impu'se was given to landowners and farmers to expend counties very large sums heve bern expended both by andlords and teuants. Ite subsequently explains that in the district in question the arrangement is such that the landlord is generally at the expense of opening trains, the ternant cilher furnishing the files an closing the tenant is charged a percentage on the total ous jay and arain in others the tenant is at the sole expense. have never seen farming enterprise I must say exceen the spirit with which they prosecute their calling, shall just adduce an instance out of many given 'oy Mr.

"The farm of Woodent, Danse, is," he says, "a singular, it might be said unprecellented example of expeditious inpprovementz, The farm contains 900 arable where the firmers mostly act more like landlords than teuants, keeping their carriages and their bailiffe, and calling in the latter merely to point out upon the plan
of the farm the operations for the day). But to return to Mir. Sanderson: "The soil," he says," is chiefly of a loamy character. The fields vary from 20 to 60 acres, and are well laid ont with straight fences. The farm especially, the tenant, Mr. Logan, is mot surpassed. Mr. I agan entered on a new lease of the furm at Whitsuntide, 1859 , little more than two years since. During the first year he limed 700 acres, at a tntal cont of no joles; all the lime having to be drawn from the other side of the Tweed, a distance perbayis of 20 or 30 miles, from the Northumberland and Nirth Durhann cation in Berwickshire is the destitution of it in the siii). "In the same year Mr. Logan drained 600 acresthe drains 3 feet deep and 30 feet apart-at a cost of
chis was not all-for) "Simaltaneously with these outlays Mr. Logan was engaged in driving carrians for teadings, which cost the proprietor 1000l." When Mr Sanderson wrote, Mr. Logan intended still to complete the whole drainage and liming of the farm in another the whole drainage and liming of hie these were accom plished the entire outlay on improvements on that farm plished the entire outlay on improvements on that arm pretty sure that Mr. Logan knows well what he is about.

THE PRESENT POSITION OF THE BRITISH FARMER.
HAD your correspondent " J. B. M." in a late Agri ultural Gazette been a farmer, which I am confiden he is not, I should not have troubled to make any reply to his statement, bul have left it to stand for what it is worth in the oyes of all practical unen; but as 1 believe him to belong to that class, whose income is so graphically described by the late Lord Herbert of Lea "as the surplus, after all the other expenses of the farm bave been paid," I an not surprised to find him attempting to put a better face on matters in I Iour Journal for a reply, or the landlords may suppose that my igures are incorrect, and that his are usanswerable.

Your correspondent asserts that my paper "bears more the appearance of a political squib than a contrithe steam plough, I could have made out a ketter case Now he is wrong in both instances ! When asked by the committee of the Hungerford Farmers' Club to give them a subject for discussion, it struck me that the "position of the British farmer" at the present time was such a peculiar one, so unknown to haif the world, that it would be instructive and set people
thinking, if it were properly and trut? fully illustrated. I therefore suggested it, nnd have, as far as my ability permits, given as faithful an account as 45 years impossible to give a fair description of farming by taking the extremes either way so I 400 acre farm of medium quality, and as near as I could, this year's average of quantity and price that each crop produced. But your corre spondent protests against the amount of produce I have given, and against the idea that a tenant farmer can only make 8 per cent. with the present price of part of my paper, he will see that I gave the tenant armer nothing, much less 8 per cent. If he has ridueu over the Craven country this season he must and Turnip fields, and how few and far between, and mall also, are the hayricks; and if he had only though earth even the 400 sheep I have mentioned are to be kept, together with the 20 bullocks and 13 horses, except by artificial means. This will settle the 8 per cent., and I again assert that the inajority of the farmers this year, when they have paid every one else, must reep house and pay their own expenses out of their capital.

Following the Craven hounds does not give man that practical experience which a life devoted olo the
business is able to attain; as a proof the following quotation will conifrm. "I quarrel entirely with his receipts. I have had the pleasure of riding over tha neighbourhood frequently with the Craven hounds I know it to be generally good Wheat land, capable, if clean and moderately cultivated, of growing 5 qrs to the acre. I also know that in fair seasons, and with proper attention, it will bear good crops of Vetches Rape, Cabbeges, Swedes and Beans; and I contend that by a proper application of these crops to feeding
his stock fat instead of selling it in store condition, he would reap from his 92 acres Wheat at least 450 qrs $=900 \mathrm{l}$. ; from his Barley and Oats 81 . per acre, or 8000 ., making his corn receipta 1728l., instead of $1319 l$.
"In addition to this he would sell his tegs fat at or after Christmas at 50 s, each, instead of an average of 26 s ., making a return of 450 l . in lieu of the 220 l . credited, and cattle and pigs in the like proportion but I will not add any portion of these stock receipts to the 17281 . for corn. Supposing the stock to realise
only the same sum beyond their expenses, and deductonly the same sum beyond their expenses, and deduct-
ing the 16631 . annual outgoings, there will still remain to our model tenant the handsome balance of $640 l$. more than 20 per ceat. on his capital.

The theory of the writer of the above is much fines than his practical knowledge. Would that it could be realised! My paper is headed "The Present Position of the British Farmer," and he has entirely forgotten, or even taken into consideration, what is to keep the 180 wether lambs, in addition to the 400 stock ( 1 sheep to an acre, besides the lambs through the summer), till they are worth 50 s. each ! He seems to have thrown all the fat on their backs in five minutes, taking credit for 2301 . without any cost, as the whole produce of the farca will not maintain those that I put there, viz, a breeding llock! It is as a rule the duty
of those who do not breed to fatten and make off the tegs for market. But the 5 quarters of Wheat per acre puzzles me! I bave lived in the Craven district nearly all my life, and most of the farmers would put the average at 7 sacks per acre; but I fearlessly assert whole Cushels per acre is the very outside that the whole Craven district can be put at on an average of
seasons. I have put it above an average, vizo, 32
bushels. Then again your correspondent has added that to my account for Barley and Oats, assuming am certain that they do not exceed 6l, per acre nor do I believe they average that sum. After show ing the position of the farmer I analysed his case himself. I would advise your Correspondent to read that part of iny paper again, and unless he is a large preserver of gam. But should be be one of those who are satisfied to eat up their tenants' crops with rabbits and hares, and theu sell them at $12 s$ or $15 s$, per dozen, which I have known done, then he will not agree wit
my statement, and I shall not sympathise with him,
With respect to the steam plough I should have as in England it is the exception rather than the rule And I know that three-fourths of the sets made by Messrs. Fowler \& Co. are for foreign service. Tha effects from its use in Egypt and India are perfectly marvellous; and the English farmers whote with the extra produce therefrom. But I am taking up to much of your space, so will conclude by subscribing myself. J. A. Williams, Baydon, Feb. 16.

## Home Correspondence.

The Weald of Sussex Farm.-Your correspondent Leisurely" evidently writes with a view of eliciting what he proposes is the system of working a clay farm to the best advantage. (One important fact he cer tainly keeps in view, and that is the necessity o keeping a large head of live stock. We, however,
doubt very seriously whether he will find the plan which be proposes succeed so thoroughly as he seems to expect, juilging from his somewhat sanguine bilance sheet. In the first place the rent and taxes of the land only amounting to 30 s. per acre, hardly warrant, at lenst for some years, the estinated number of cattle which your Correspondent proposes to maintain ; 80 to 100 cattle and 60 sheep seems to us a very heavy winter stock for a farm of 300 . per annu an of rent,
tithe, and rates, consisting of wealden clay. Starting with this assumed number, your Correspondent next asks the most necessary question as to how he has to find food, not only for keeping them in what is usually considered store condition, but to fatten at leas 40 of them. Now, if 23 acres of strong land can be made to grow a sufficient quantity of roots to feed 40 cattle, maintain 40 head of young stock in a healthy state, and 12 cows in milk with regularity through a series of years, your correspondent has gained his point,
That $\operatorname{si} 345$ tons of roots, 35 tons of hay, and 23 ton of Clover hay" will do so, we doubt altogether. It is not to be expected that " 42 lb , roots, 4 ll , of hay, nn 3 to 4 lb . of meal per day," will in any case turn off cattle at two years old of the weight your Corre spondent looks for ( 75 stone of 8 lb .) Let him double his allowance of roots, and let the meal and hay remain andiminished, or, let him add 4 or 5 lb . of oilcake per day to his bill of fare before he need expect to turn a beast off his farm fit for a butcher to look at. He, of course, must be the best judge as to whether the land is capable of growing roots profitably on the whole of the fallow break; the term Wealden clay, and the ten dency of "running together," do not sound encouraging and we (with our small experience of clay-land farming albeit well drained) would rather suggest a less acreag of roots, with an increased breadth of Beans, to be used as a means of maintaining stock. It is also a question whether a few of the fat beasts would not be well exchanged for a "lot" of good in-calving heifers, to be so!d at the London market before calving. These would be maintained at a much less cost, would not need so many roots, and leave, we feel sure, a zood return. Although differing from your correspondent, we cannot but admire the business-like way in which he sets to work to "count the cost" before he com mences his career. May he be successtul is our earnest wish! In haste.
Mangels.-This winter has taught us all a lesson, and I believe you will have the largest sale of Mangel We have now discovered that the pulping of Mangels with a mixture of Clover and hay charl is the best possible feed for cattle and sheep. We shall, therefore all of us grow more Mangels. If people would give good order for Mangel seed and plant that, they would be very much more advantaged than by attempting to feed stock on malted Barley. I farm nearly 700 acres of land, and I would not use Malt if I could get it duty free. Beans and Mangels are the food for fatting stock. We never remember their feeding so fast on any kind of food. I have now about 600 sheep, and with lambs shall soon have 900 sheep, so I must know something about it. [This has been sent to us by Mr Sutton, of Reading; being an extract from the letter of a Correspondent.]

## 

Agrienlurral Education (Pamphitet). By Edward Holland, Esq., M.P.
This in a reply by the Chairman of the Elucation Committee of the Royal Agricultural Society to letters on the educational subject addressed to the President subsequently published. Mr. Holland represents the riew that the professional Society should
confine its effurts in this field to the promotion of professional education. Mr. Acland, as our readers are aware, knowing that such an effort
will be useless excent it be preceded by a sound general training on which professional efficiency must be grafted, contends for the whole force of the Society's Universities bing thrown along with that of the general scheme of middle-class local literary examinaof cours which these learned bodies periodically conduct. Of course, Mr. Holland, with every other intelligent
man, holds as strongly as Mr. Acland does, that a good general training must precede a good special or profesinnal education; but he believes that, thanks to the existing examining bodies, and thanks still more, let us say, to the intelligent convictions of the general middle class of this country, this general education is already effort by the Society to more so every day-that any efiort by the Society to promote it would, in fact, be altogether lost in the great movement on this subjeet Thich is just now actuating every class of society-but
that whether it would or not, such an effort would be quite out of the field which is clearly marked out for the Society's operations by its Charter. He believes, moreover, and so must every other intelligent man, that the
belongs to the Society is large onough and well-defined enough to make those labours which it ought to undertake both efficient and important. The class whose special education it might test and stimelate is conwhich the preliminary education it already receives confers. Let however a certain standard of prelininary ability and intelligence, the results of good general edacation, be required before any the spur which the professional Society may very well the object great enough, to be well worth the labour the Sjeciety might thing undertalk.

These are the corsiderations which apparently infur ence Mr. Holland in his reply to Mr. Acland's letter His judgment will undoabtedly be received with that respect which a lifetime spent in the promotion of t. And it is the weightier and more trustworthy for its entire coincidence with that which the Agricultural Society of Scotland have already acter $n$ in connection with the subject. We extract the following parsage desirable or possible to test a knowledge of practical agriculture by examination. Mr. Holland suys:-
"I look upon this as the crowning examinntion of it is not teac!. ing practical agriculture that I ask you to entertain, but to take a test for its having been tanght. At Cirencester agriculture has a certain number of marks allotted to it; Practical Agriculture absorbs a certain number of these, and the way of proceeding there is most satisfactory. We secure the services as examiner in practical agriculture of some noted man as an agriculturist. Last year Mr. S——, from Wiltshire, was kind enough to render us his services. The mode of proceeding was as follows :-The Principal introduced to him the candidates for diploma, with some such words as these : 'Mr. S.- it these are candidates for the diploma, to obtain which it is necessary to gain such and such a dictated to you how you are to examine them, but proceed with them to the farm and keep them there three, four, or more hours until you have satisfied yourself as to their respective attainments. Do not conine your examinations to the state of the farm, the nature of the crops, their rotation and so forth, but ascertain what these young men know of cattle, sheep, implements, management of a farm.' The examiner did so, and I understand he has been since pleased to of practical knowledge di-played. Now, why should
not the sane results follow from evamination not the same results follow from examinations in practical agriculturs when the competitors for our
rewards come off their fathers' farms, or from farms on which they are gaining practical knowledge as pupils? I will not consequently yield this matter of examination in practical agriculture; I look upon it as the crowning act of our proceedings."

We sincerely hope that the author of this pamphlet will carry his views in the Council next Wednesday; and that the governing body of the Royal Agricaltural Society of England will see their way to the adoption of such a plan as may lead to the improvement and
promotion of a sound professional agricultural education.

## A Treatise on the Sanitary Management and Utilisation

$f$ Servage, \&c. By W. Menzies, Depaty Surveyor numerous Drawings. Longmans.
We have here, issued in a style which does great credit to the publishers, a small volume profusely illustrated by lithograph drawings, which contains a full account of the methol by which Onborne House has been drained, and by which its drainage water has been utilised; as well as of the plans by which the same system has been carried out Criminal Lunatic Asylum ; with details of the methods by which the author proposes that the sams idea shall guide the utilisation of both house waste and town sewage everywhere. Beginning with a particular account of the best construction for water-closets and of the necessity of ventilation, and of various devices for ensuring it, the author proceeds to insist first upon the need of keeping the rainwater out of the house drains, and secondy upon the need of filtering the contents of
those drains before attempting to pass them through pipes on to the land. The upward filtration adopted by the Prince Consort at Osborne is described, and the entire merit of first perciving the principle of upwari filtration, and of designing such a tank upon that principle as would continue to act, is ascribed to his Royal Highness.
Then follows a chapter on methods of irrigation: and a very sensible chapter it is; expressing a preference for sandy slopes and a small area of Grass land and ordinary surface gravitation and putrid sewage, to extensive distribution by steam power and subterranean additions to the liquid: a preference whtch has long been asserted and defended by all practical men.

The full development of the plans which Mr.
Menzies recommends for dealing with town newage is
possible only in the case of those (almost) towns which sometimes arise around new manufactories where cesspools, filters, \&c. might all be provided before the new streets are built. For existing towns it is inpossible to attempt any such plan of cesspool filtration, or of restricted water supply as he requires. Excessive water supply, and frequent and abundant flushing of all drains, are a part of the sanitary arrangements of those towns which they will not abandon. And any plan for utiliaing drainage must take these as an inevitable part of the circumstances with which it has to deal. Mr Menzies accordingly, as the matter at present stands, believes "the utilisation of London sewage upon a perfect scheme to bo hopeless if any adequate return is to be obtained for the outlay necessary to make either the solid or liquid parts available." But we learn farther on that he is not aequainted with the circumstances on which the utili/ation of London sewage must depend.

He says:-"As I have not examined the country round London, I am not prepared to any that there is sufficient land suitable for the parpose to warrans a system of irrigation, even upon the principles I have advocated, being undertaken on economical principles alone. It would require a very long investigation waste of time to go into the matter, unless a complete change is made in the syatem of towa drainage
It is however right that Mr. Menzies should know that the country around London has been well examined, and that nthers are "prepared to say," \&e.upon the subject, and that in pact 80,000 , has already been deposited as a guarantee that the plans devised shall be carried out.

It is, indeed, unfortunate for the author of this work, that there can be hardly any reader of it who will not see at once how deficient it is in the ncknowledgment which is due of what las been already done in connection with its subject. The whole of the chemistry, and the whole of the agriculture of house and town sewage have been already long since worked out by well-known labourers in both fields. These labourers are, however, all unnamed in these pages And even as to some of the details of house accommo. dation, in which the strength of Mr. Menzies' pub lication lies, there is a similar forgetfalness of the just claim of others to the credit of inventions which the reader is led to believe original. Thus, a method of flushing out the curves of the drain pipe for a closet is both represented and described withont any acknowledgment of its real authorship, Which however may be learnt from Mr. Rawlinson's Report of the Sewerage, \&c., of Windsor Castle * (1863) thls book is taken. And even on the origin of the Osborne filter tank, whioh is so exclusively at tributed to the late Prince Consort, further details might have been supplied with more of that justice to the claims of
other labourers, in which this book is certainly deficient.

As another example of this same fault, it must be added that the earth-closet system, which is certainly the best plan of dealing with the nuisance in the case of detached country houses, is named without any mention of the Rev. H. Moule, to whom, as our readers know, the credit of it is due.
A Reviewer who has no professional interest in these matters, around which capitalists are now jealous for the reputation which is all that mere thinkers and inventors are likely to get ont of them. And it is impossible therefore to conclule this renerally commendatory notice of Mr. Menzies' able work on the domestic "and field arrangements required for dealing with sewago house "by house, without pointing out the undue self-assertion which toe author exhibits, and the lack, we do not say of generosity, but of just and candid acknowledgmeat, which it displays towards his predecesrors in the field.

The Agricultural Value of the Sewage of London, Fxamined in Reference to the Principal Schemes Sutmitted to the Metropolitan Board of Works, with Extracts from the Evidence of Chemists, Engineers, and Agriculturists, \&c. E. Stanford, 63 Charing Cross, S.W.
In a well-packed pamphlet of 78 pages, an annnymous author here very compendiously arranges whatever rustworthy evidence exists upoa this most important subject. In successive chapters we have from him a history of the rise of the portable manure trade, and of the origin and progress of the liquid manure theory; the evidence of chemists, engineers, and agriculturists on town sewage; and then a discussion and defence of the decision of the Metropolitan Board in favour of the Napier-Hope proposal to utilise the drainage water of the metropolis upon the Maplin Sands and along the line of the culvert which is to convey it there.

The time has passed for theorising on the value and use of sewage. There is in existence a sufficient mass

disposing of the sewage of London, keoping in view three important conditions:-

1. That 277,000 tons, amounting to about ten million cubic feet, and capable of alling a lake 75 aeres in superticial area, and 3 feet deep, must be received and consumed bythe contractors every day in the year. secured from pollution, and the inhabited districts socured from pollution, and the even thance of a nuisance.
2. That the Metropolitan Board should obtain, without involving the ratepayers in any risk, a fare full rent, increasing as the field for the use of sewage is increased."

These three conditions are shown to be compatible with the Maplin plan, aud with no other that has been yet proposed; and no one, we venture to say, who reade the evidence here epitomised can come to any other conclusion. It establishes, as the author here puts it
"1. That the Hquid sewaze of a great eity may be made to
produce a considerable profitif it bo applied by gravitation in
 the more barrent the ture thot table will be the apphe ttion. fow of sowage (too great to be stoved for occational use), "4. That the most ec, nomical and profitable application is
 oxhanated.
ordinary crope fin arnble farm, such as cereale, roots beana dc., as woll as Grass intended for hay in times of drought; and would be worth a very much higher rent, elthos por ton or por Thut liquid sewage can

 cannit be employod to rercive the volls of a constant sumpel) would, durlog many months of the year, be damaged by either
 mades

The fith of these conelusion rests upon a smatler body of evidence than the others; burt it is hardly possible to doubt that in exceptional seasons and at exeeptional times it will be possible to raise a considerable reverue from sewage applied in this way to arable land near a runuing strean of it. It is, however, by the abundant irrigation of Grass land, as at Rugby dealing piofitably with an snormene constant daily flow. This is the problem which is offered for solution and the following is the Napier-Hope plas of dealing with it, as described in these pages:-

A culvert will be constructed ten foet in diameter, which
tap che Northern Main Outall Sewer of the Metropolitan Will tap the Northern Main Outfall Sewer of the Metropolitan
Board at Abbey Mills, three miles from London. This culvert
will run for will run for a distance of three and a-half miles, with a fill of two feet per mile, to a point where the levels of the ground
will require it to be lifted 20 feet. The discharge will then conkinue in a culvert of the same dimensous, sometimes in of the navigation of the river Crouch, at Battle's Bridge, in
Ensex, 28 males from the commencement at Abby Mills, The ${ }_{\text {Ensex, }} 28$ milles from the
a-bale miles. The object of these lifts is, bosides increasing tho nuch as posaible of the surrounding country by gravitation. smaller ones, ruanning on the north cart south sides of the rivo
Crouch. That on the noth will be 18 miles long, terninating on the Dengif Flats that on the south will be 16 and a-quarter miles long, terminating on the Maplin Sands. Both these places are extensive foremhores on the east coast of Essex, dry at low
water, and several miles in width, by about 20 milles of
aggregate lenyth aggrepate length These vast plains are to be reclaimed from
 20,000 aeres will te enelosed. There is scarcely any popul tion
at present along theese ureary shores, which, huwe wer, will
become, if the project is carried nut, the most highty-furiliet

 a. year.
"Frotu the nature of the sands there is no doubt that if
 ans per annum, of $10,000,000$ cubic feot daily, could be
absorbed upon them, ; and therefore there e not the slightest
azzard that when? structed, the Metropolitan Boar
by the pollution of the Thames.
"But it is not the intention, and it will not be the interest

 tion of cabbage or Manger, or or other marting, or for transplanta- Weill exoed 80,000 acres; but if sowage be anything like the
walue which some persons believe, it will be hasy, by bhort
vind

This is the plan by which in three or four years we may hope that Londou fith, which is but imperfectly removed even by the millions which have been spent on draining, may be expected finally to disappear-ith form of London milk.

## Miscellaneous.

Death of Mr.W. Steevens.-It is with unfeigned gret that we announce the death of Mr. Steevens, Well-known as an exhisitor Agricultural Society; and in particular as the inventor of a plough and cultivator for use by steam.

He died (we quote from the Mark Lane Express) on Wednesday, Feb. 15, at his residence, 6, Godolphin Roal, Haminersmith, in his 56 th year. Beinc a strong-built mau, be might have reckoned on iving many years longer to pursue the labour of love and hope which he long aqo began; but he had con racted a chronic pulmonary complaint, which told on him, as these diseases ever do, when the wind was in
the east and the thermometer falling. The present xtraordinary season of chopping winds, rain, frost, snow fog, and spring temperature all in one week, told heavily on his complaint. But although his cough had been severe for some days, he was, from being under the lever surgical treatment which had frequently relieved him before, in his usual buoyant frame of mind up to
the day of his death; but in the evening of that day, while in the act of handing back a cup from which he had just drunk, his head drooped, and he had departed without any signs of additional suffering. Mr. Steevens was at the Fowler Testimonial and other meetings in St. James's Hall on the previous Wednesday; and it was then little thought that one among us in his usual health and spirits would, within a week, have lost al interest in worldly affairs, from lying in the iong sleep
of death. Mr. Steevens attended, we believe, every Royal meating but the firit, and had, therefore, been in some conspicuous position here and elsewhere for 25 years. From heing endowed with \& powerful mechanical mind, and a quick imagination, with muct improvements in implements which bave been adopted by agricultural and other engineers.
Couch Grass.-At the meeting of an Agricultural Society in Northamptonshire the harmony of the proceedings was disturbed by a speech from Sir H.
Dryden, who said that, amongst all the prizes, he was surprised to see they land no cups for Twitch, Dook Wistles, and Nettles. "What! no prize for the staple ambodity of South Northamptoushire- He hay been through England, Ireland, and Scotland, and he must say that that district (South Northamptonshire) was the worst farmed and Iowest rented of any in her Mujesty's dominions." Sir Heary Dryden was tamely under the slur that had been cast unon then by Sir Henry Dryden's imputation, and he did not hesitate to say that lis insinuations were utterly false and

## Calendar of Operations.

Febreary. -The Cow Byre.-The following, on the management of calves, is from the pen of Mr. Wilson, of Edıngton Mains:-It is desirable to have all the cows to calve between February 1 and April 1. If earlier they will get almost dry are the Grass comes, and calves later than this will scarcely be fit for sale with the rest of the lot. When a calf is dropped it is imme diately removed from its dam, rubbed dry with coarse eloth or wisp of straw, and then placed in a crib ia the calf-house among dry straw, where it receives a pertion of its own mother's first mi'k. For a fortnight new milk is the only food snitable for it, and of this it
should recerve a liberal allown showld recerve a liberal allowatce twice a day; but means should after this be used to train it to eat Linseed-cake and sliced Swedish Turnips, and the mouth immediately after getting its milk, as it will then suck greedily at anything it can get hold of. By its trough, it will usually take to this food freely; and whenever this is the case, it slould have as much a as it can talre, go that its, allowauce of milk may be diminished to meet the necessities of the younger calves which are coming in succetsion. This is of the greater importance that it is always nost desirable to avoid mixing anything with their mills by way of uelping the quantity. When a substitute must be resorted to, oatmeal porridge mixed with the new milk is perhaps the best. The sour sinell invariably found in mixed calt-honse when porridge, or jelly of any kind, is mixed with the milk, is prool sufficient that indigesallowance ionsequence. An egeg put into each call's the hand, and mixed with the milk by stirring with with this exception, it is best to give acills warm and unadulterated, however small the quantity; and along If moras dry farinaceous food, Turnips and hay ad lib. If more liquid be needed, a pail with water may be put
effects of mixed milk. Indeed, it is beat $t$, ieep
elosely as possible to the natural arrangement to which the calf takes its suck at first frequecorrie, then at longer intervals, as it becomes anle to ar co same food as its dam. The diet of the c3m Turnips yield the richest milk, but it is too sca aives fed on it are liable to inflammator $G l o b e ~ T u r n i p s ~ s h o u l d, ~ t h e r e f o r e, ~ f o r m ~ t h e i r ~$ food during the spring months. Care should al
been taken that they do not get too low in been taken that they do not get too low in cond
the autumn and winter; and for this put them dry at least three months before Some may think this long; but on a breeting mik is of little value at this season. Th dry, are kept at less expense, and by this period of heir constitution is invigorated, greater jartice domen the footus now rapidly advancing to maturity, mall nuch more mil
The Sheepfold.-Mr. Ruston thus described experience of teeding sheep instead o! bullocks in man uring winter:-1 have now tried sheep in yaris? ve years. Last year the lang disease appearing in ot Seots I had, excited my fears lest it should appe and decimate another lot which I had just receiven fic
Scotland. I therefore determined at onee Sootland. I therefore determined at onee to send th hose in which the disease had appeared me to the necessity of purehasing nearly 400 lants the purpose of consuming my hay and Mangele and manufacturing my straw into manure. I made close observations, kept a diany of all necessary pur culars, valued them inte the yards, and valued themm O Grass with the dates of going in and ouf; calculer heir cost for axtificial food, noticed very nampor what quantity of straw they made into manure, 1 also the quality of the manure, 衫 fout 講 appeanmec nabled me to judye. From close and careful oberr inn last winter and acain this-for I have now betm 300 and 700 sheep in yauds -1 find six lambo trend down as much straw, and make it tite ant my ordinary fold yards, and always calculdte six sure to one hullock; so that where I should have 10 ballond put 60 sheep. During the whole of hast minte. don't suppose I had more than a dozen lame s.e. whilst they were in the vards; and there lave bentia less cases in the yards than there were previons: their coming in. I find it is very essential to keep thin layer of dry straw over the yard. In wet days on fitter them twice a day, and on fine days onee, ban $m$ only use a small quantity at a time; this just heo the heat of the manure from rising to injure their fete ond prevents them also treading on wet straw during the day. When they first come into the yard, and indeed until the end of February, when the days bsi oo lengthen, we give them a larger quantiyd practicable have a stack or good heap in the yard un to; we also cut them chaff, hay and straw toget and feed them several times a day with i.. hem a Mangels twice or thrice a day, quantities sufficiently large to make them as the days lengthen we increase the quanlid an aress
sind reduce the supuly of dry food. I find an Mangels of an average crop will carry 25 sheep20 kanbs-during the weeks they will December begin or middle of April. old sheep would cons: more, and 20 per acre would be a fair calculation.
I will now present some details in connection ${ }^{5}$ my last years experiments. The 371 lamb whe in the yards last vear were bought durmy he inder of August and September, and were keph Grass-keeping without artificial food, win hell they were consigned to their witer, but at : few of them were los to Grass the fol ind of the winter when the results:
$\begin{array}{lllll}\text { The whole } 877 \text { lambs wero valued } & \text { t } & \text { s. } & \text { d. } \\ \text { into the yards at }\end{array}$
They cost for arttificial food

## to the acre, at 122. 110. 2fd per

if you take 2 acres more Maugels, and call the told quantity 17 acres, it will then give
riner as the more correct calenlation.
This was an instance of exipaordimary retorill in Mr. Ruaton's case it was contrastet wis in cattle fueding with mhish be ha
chagan's experience in carly lamb,
week's Scoltish Farmer:-As an instance
can be made out of sheep when manased year already realised for lambs out of two 00 guinen. He has boen selling lambe
hrofond their way to the butcher from any breeder - Scotlind. Latterly some of these lambs have been in sootho high as 49 so ; and even at the beginning bringing a meighed s mue 7 or 81 lb . dead weight. The tney each which Mr. McLagan obtaised these lambir are of the Durset breed, which appear to be a haredy and tolerably prolific race, and have the reputation, which is fully justified by the butchers' experience of Whe lambs this jear, of being "capital killers." These the ambe twice a year; but Mr. McLagan, in order sirep, frat in the market, and like the early bird to catch the worm, only takes one crop of lambs from liem. This year he was rather too early; lamb apparently not being coneidered a luxury in Scotland, ur, at all events, not being deemel a profitable article of sale by the butchers at Christmas or New Year's Dav. Next year, therefore, Mr. McLagan proposes to keep lis lambing time back for about three weeks, as be calculates that he has lost something like that a mount of keep on them this year. Instead, therefore, (f haring them lambing in the end of October, he (f laring thee them back until the third week in Yoposes to keep the the score ewes for which Mr. Murember. it dhould be stated that these were the product of 35 owee only; the other five, having been injured by trasitit on the railway from the south, did not yield offepring. Up to the time of lambing, the ewes receired nothing beyond Grass, Turnips, and such hay as was cut from the roadsides, ditchen, sc. The cest of their heep for ten months before lanbing is estimated at abont $6 d$ a week; and for the two menths they remained with the lambs, when they were supplied with oilcake, corn, and anything they could eat, about $15 s$. or 16 s.- that is altogether for the year about 36 s. Truis, multiplied by 40 , the number of the ewes, gives "घ $72 l$ o, whel, deducted from $105 l$, the value of the lambe, leaves 33\%. of clear profit, or 16 s . 6 d . per head. Not a bad profit, surely, when it shall have been sugmented by the value of the wool and the manure.

## Notices to Correspondents.

Bes- Sir. Weigh the hives, and shonld they be each 20 lbs . groes weilght thero will bo no occasions to feed thom. The this reason soreens aro rccommended to prevent the sur thinfug on the hives in the cold season. We recommend a intich hork which contanins, most nsefol hints to a boe keeper, entitled, "Bue Keeping," No. 3, by the late J. H. Payne,
 alreasy given a great many instances of this kind; and it is generally understood that the seed sent out last year was unfortunatoly not sufficiently ripened to be good. But knowing Mr. Blundell, we are able to assert with confidence faith: snd that his statements of his experience are trustmorthy. for " singular" read "angular," and in the fourth line from the bottom, for "matter," read "miller.
Falcove: Odd Sub. Fallow is held in scontland, by a recent decision, tor inclu ie lan i, labour, and duns, and the fallow Libour free, but the appellant is bound to give the dung als). Gris fur Sea-shore: R. Psamma arenaria, Sea-mat Grass; Elymus arenarius, Sea-lyme Grass; Cynodon dactylon, Creeping Dog-tooth Grass, are among the moot useful Grasses Horss Shors: IV $B$, ordinary of sand-banks Honss Shoks: J W $B$. Ordinary plough horses wear shoes
weighing $2 \% \mathrm{lb}$, apicee. The shoes of a saddlo horse again do not woigh 1 I 1 b . ; bub the custom of different localitios is exceedingly various. Where flint is the common road Haraterial. shoes are made thicker than elsewhere.
Horges: : Julia. You will see the rations allowed to farm horses
during during winter by a number of Correspondents given at p. 88 . euffice for carriage horses, with access to straw and water. Nem Marube : $A$ subscriber from No. I till now. The new Prench manure is, we believe, in the nature of a steep for thic seed, and therefore altogether untrustworthy. We have net seen the announcemont of an agency in London ; but Ororiandiva: 1 Thention of it ray bring it to us. obliged if your Young Gardener says : - I should feel greatly has lately writteu iu the Gerdenere' chronicle "Ou Orchard Minagetrent." Wwitd kindly dus .er the following questions through your columns. We have bought a fine lot of Orechard Apple trees, with capital stenus 6 fieet long, 4 inches in cirshoots ( 2 to 3 feet in splendid heads, consisting of 12 to 15 strong The trees are planted as directed but of last yoar's growth wish to know is, if thooe shoots should be shartened or headed down this season? aud what should be the subsequent lanagement in pruning for the next year or twa? [The and hence been sent by mistake to Mr. Cox, of Longrord, Rend bence the delay of its prablication. 1
atributed by the Rev, M. J. Berkelcy the ne thed has been Fungi on deeayng matter of the previnis crop attacking the Fung plant. He eays:-It is acknowledged almost univerprostably succeed Wheat. The same may be assume $i$, from mixed with Clont, respecting Wheat after Italimn Rye-grass may be good, after. In the time case, thengh the cocome blighted in parts in here, agzin, we hume pateches becorae sighted and die. Wo do not assert that we bave satisfuct rivily traced this to and aning (fr(in) decaying vegetable mattor attacking the gics, that if the blichwever, so far as nur own experience enernht if the blighted straws are split up, there will very SThernily be found traees of fungous mitter.
s.rong clay smil, Jond do not need auy tanure at stl Tillage not manure, is wanted in such cases. A dressing of common int tonds to strengthen straw ; from 2 cwt . on stift soils up Wrem r 5 on light soils are a common dressivg.
dra mage, close masturapastures weeds are discouraged by porseveraneg in sputating or pulling top-drespiugs, and by easons of the year, espocially in the spring and summer and before thair your, tima. If theos mpang and suramer, dom and must be ploughod up, well fallowed, and laid

THE PATENT IN-DOOR PLANT CASES
(to which a frize was awarded at the royal hortictltural soctety's exhibition).
SOLE MANUFACTURER,
JayEs gray, Horticultcral Works,
DANVERS STREET, CHELSEA, LONDON, S.W.
The PATENT IN-DOOR PLANT CASE is one of the most useful of the Gardening Novelties of the day. It is a handsome ornament for the Drawing Ronm or Sitting Ronn, and at all times forms a fresh, pleasant, and interesting object to the mind and eye. It is always under command, and will preserve many of the most tender Exotic Plants through the severest winter with comparatively little of the trouble and annoyance attending the use of Lamps, Gas, and Heating appliances of any other kind
To all who have a taste for the cultivation of In-door Plants, for raising Seedlings, striking Cuttings, \&e. the Plant Cases will be found an inestimable hoon

The Cases are highly approved and recommended by Professor Lindley, and by Messss. Veitch, of the Royal Exofic Nursery, King's Koad, Chelsea.

Sizes and Prices on application

By means of these Joints the work is executed in less than half the time required for Socket Joints, and alterations can at any time be made, or the entire Apparatus removed and erected elsewhere with the greatest facility. A considerable saving in cost is also effected
. Joints ber mation and mation in use at the Royal Horticultural Society' Gardens, Chiswick, and many other phees in Horticultural and Public Buildings. They are also exhibited at the Socioty's ©iardons, Bouth Kensington.

For a fow price, sue layt wok's Adoortisemant.

EALING NURsERY, G. CANNON, MaNaomb.
Ten minutes' walk from the Ealing Station on the Great Western Railway Main Jine.
FRUTT TREES, ROSES, and SHRUBS, are here extensively and sucenssfully cultivated in some of the finest Loam in the county.
FELTHAM NURSERY, R. HIGHAM, MANAGEr. Ten minutes' walk from Feltham Station.
EVERGREEN and DFCIDUOUS SHRUBS, and CONTFER $\mathbb{A}$, are here largely grown in a free Loam, well suited to their habits.
At SION LANE and WOOD LANE NURSERTES, ISLEWORTH,
ORNAMENTAL TREES are in a healthy and thriving state, and GENERAL HARDY PROPAGATION is here carried on.
The Stick in the above Nurseries is well worth the inspection of purchasers. The prices are very moderate, and the Plants are frequently transplanted to ENSUREE SAFE removal.

The following CATALOGUES are published, and will be forwardeci Post Free on application :CATALOGUE of KITCHEN GARDEN, FLOWER, and AGRI- $\mid$ CATALOGUE of FRUTT TREES And FROIT TREES in POTSS

# GLADIOLUS BRENCHLEYENSIS (True). <br> ROYAL NURSERIES, <br>  <br> GREAT YARMOUTH. 

Colour "Vermilion Scarlet," the brightest variety known.
Flowering Bulbs, 3s, per dozen; 20s. per 100.

## YOUELL \& CO.

Have much pleasure in submitting the following Report from the Editor of the Gardeners' Chronicle:-
"Glabiolds Brexchlritests.-We have recoived from Mesesm. Youkir \& Co., of Great Yarmouth, some specimens of this plant, the gorgousu apoaranoe of hiran caniot be spoken of in terms of exngeration, The tall robust habit and intensely bright scarlet fowers place
it at the head of all the hardy flowerro of the autumn "The grecimens are masnificont ; we have seen as set nothing of the kind so handsome near London. It is undoubtedly the most

It was exhibited by them in their Collections which obtained the Three First Prizes at the Royal Horticultural Society and the Crystal Palace; also the First Prize at the Royal Horticultural Gardens, Kensington, Crystal Palace, and Brighton.

## GLADIOLUS, the most choice Show Varieties to name.

For which they were awarded the Three First Prizes at the Royal Horticultural Society, the Crystal Palace, and Brighton, Yourle \& Co. beg to intimate that they are in a position to supply the most choice kinds of this beautiful tribe, in strong flowering Bulbs, as follows:-

Fine Solections will be supplied at 6s., 9 s., 12s., 18s. to 50 s. per dozen.
Strong Bulbs of unbloomed Seedlings, sared from the finest named hinds, 4s. per dozen; 25s. per 100 . CATALOGUES can be had on application.

We have just received the first report of the Committee of Enquiry on the ravages of the Whitr Ant In St. Helens, institated by the present Governor Sir Charles Elliot. We have little experience in this country of the destructive powers of ants, though they prove ocoasionally a source of considerable annayance in houses, where they are very difficult to extirpate. It is mostly in our woods that we see what pwers of destruction they have when once they attack a tree, which they soon reduce to the appearance of a coarse honercomb. In one or two localities however on the coast of France, a very small species has proved extremely destructive to wooden structures, so much so as to cause very serious apprehensions, and Myrmica domestica, an exotio epeoies aceidentally introduced, has occasionally taken possession of houses at Paris. In James 'lown, St. Helens, the white ant has prevailed to an extent seldom heard of in countries ahounding with that scourge. It appears to have been introduced into the island about 20 years ago, but it is only within the last 10 years that its ravages have
inoreased to such an extent as to make some attempt at extirpation a matter of necessity. ${ }^{\text {" Churches, }}$ schools, oftiees, and dwelling-houses of both rich and poor have been equally attacked. Goods in warehouses of various kinds are destroyed Goods in Warehouses of various House is invadedwine casks are destroyed; the corks of wine, beer, and spisit bottles eaten out; bouks, cluthing, and furniture in dwelling houses are nowhere safe, and the logs to the inhabitants of the island is of an immense amount, and the expense continually incurred is enormous.'

Under such circumstances it was obvious that full inquiry ought to be made as to the most probable means of prevention, and the kinds ol wood most likely to eseape. For this purnose information was obtained from various quarters by
the standing committee, and amongst others Sir W. J. Hоoker sent specimens of various woods most likely to resist the plague. All the softer woods, as might be expeoted, more or less rapidly fell a sacrifice, or if from some accidental or unknown circumstance, some particular piece had escaped for jears, when removed to another situation it was quickly destroyed. Ttak seems less subject to attack than other woods, and in the course of the experiments Myrtacer seem in general tohave resisted better than woods belonging to other natural orders, though some, as the Blue Gam (Eucalyptus globulus), perished. A fow hard Brazilian woods also escaped, together with a few other kinds, as Mammee, Hymenæa Courbaril, and Cedrela odorata. In some cases, where specimens were not attacked at first, they did not endure a longer trial.

It was hoped that the processes whioh have been adopted with a view to prevent dry rot, as those of Sir W. Burneit, Jackson, KYan, \&c., might either prove destructive to the insects from the large quantity of poisonous metallio salts with which the wood was impregnated, or, at least, be distasteful ; but in general complete impregnation proved no less inefficacinus than partial coating. Sulphate of copper, chloride of zinc, sugar of lead, arsenic, corrosive sublimate, carbolic acid, and creosote, all in turn proved useless, and in some oazes the destruction was tutal. Mr. Langton's charring process was not more successful. One of by Lieut.-Colonel Baker, late Garrison Engineer at Lahure, which consisted of rosin and arth rubbed into charred wood while hot. Col. Baker reoommended also, but less successfully, sulphate of copper, in the proportion of a pound to 8 gallons of water. Deal and Ash, which are peculiarly according to the first process, but the solution sulphate of copper, though at first apparently hopeful, failed.
The hard woods which seem the most capable of resistance are in general expensive. The great point is to find something whioh will render the softer woods, such as Deal or Pitch Pine, safe, and it is to be hoped that some modification of Col. Baker's process, in which the wood mar be impregnated after Boucherie's method, combined with external charring, will prove a perfect remedy. Metallic salts seem useless, and resinous matters with petroleum and its allies, on the contrary afford the best hope of protection, though all have occasionally failed. M, J. B.

The following brief notice of the destruotion of much of the noble Calcotta Botanic Gaeden, from the pen of its able director Dr. Andenson, has been forwarded to us by Dr. Hooker, We may shortly expect more detailed information through the same channel

The garden here is ruined, as you know, by the Cyclone. I do not yet know what the losses have been, but 950 large trees are uprooted and prostrate. Many species are lost. Of 67 Mahoganies in the garden, 31 have been blown down. The storm Wave reached to the Agri-Horticultural Society's gardener's house, and carried a large piece of the helm of a ship to the foot of the large Gmelina arborea opposite to it.
'The plants on Wallich's Mount are all gone, except a few trees ; a fourth of the great Banyan is also gone. My house has received most serious damage, and is still soarcely habitable.

Bengal is now covered only by Endogens. Palms, Bamboos, and Musaceæ, have suffered the storm. In the Teak avenue, near before Monument, two shattered stomus, near Kyd's remain. The large Adansonia is down. Happily the nataral order groups are almost nninjured and looking well: they were all set up tho day after
the gale, while the ground was wet. In low places, where they were under water for four or five days, they have been lost. I am preparing a full report on the storm and reording $t^{\prime}-\theta$ loss here, but it is meny trees I knew so well."

Ir has been the fashion with most Myonlogiste, in consequence of the difficulty of the subject, to oharacterise Parasitic Fongi rather by the plants on which they are developed than by any good distinctive characters. $\begin{aligned} & \text { onnsequence been made in two directions, either }\end{aligned}$ onnsequence been made in two directions, either
distinguishing furms where there are no distinctive characters, or confounding matters which are really different. Within certain bounds, however, the same species affects in general plants which belong to the same natural order, and sometimes wanders to those of neighbouring orders with or without any marked difference.

We have a very striking instance of this in the curious parasite of which we are able to give a figure from the pencil of Mr. Broome.
Dr. Leverilé pahlished in the "Annales des Sciences Naturelles" for April, 1848, a parasite under the name of Triphragmium echinatum, which was discovered hy M. Prost at Mende in the department of Lozère, on Meum athamanticum; and specimens have since been published by Rabenhorst in his collections of dried Fungi. The rimary spores of this species are globose, but divided by septa into three equal parts, and supported by a hyaline stem. Each of the divisions is armed with two or three simple or branched processes, which give the plant a very curious appearance under the microscope.

At a later period Mr. Thwatites forwarded to us from Ceylon, a parasite on a species of Hedera

(H. Vahlii) agreeing with the parasite on Meum in every particular, as Mr. Broome has observed, except that every process is either bifid or tricid, the
short divisions bring strongly reourved, whereas in M. Leverclés plant the spines, if forked, have the divisions much shoiter and not in the least reflexed. Few objects oan be more attractive nuder the microscope; and such highly developed ornaments are so rare amongst Pucoiniæ, as to make that before us one of peouliar interest in itself, part from other considerations.
We have then a parasite on a plant belonging to the natural order Araliaceæ, distinguished only by a slight difference of character, not sufficient to justify the proposition as a distinct species, from a parasite on a plant belonging to Apiaceæ, a circumstanoe which, were it needful, would tend etrongly to show the justice of the close approximation by authors of these two natural orders.
Our plant may be regarded, then, as a marked variety of Triphragmium echinatum, oharacterised by the recurved divisions of the spines, and may hear the name of T. echinatum var. Thwaitesii, The diameter of the spores, inclusive of the spines, varies from $\frac{1}{500}$ to $\frac{1}{550}$ th of an inch. Our figure represents two of the spores of the Ceylon plant and a spine magnified, as also a spine from one of Rabeniorst's specimens, to show the difference between the Ceylon and European plant. M. J.B.

Mr. R. Warner has kindly sent to us a leaf of Dendrobium densiflorum, which exhibits a very curious form of Spot, which may bo identical with Mr. Anderson's No. 2, but if so it is a very ourions variety. Like that, it does not seem to be so injurious as two of the other furms. The leaf is two years old, and the younger leaves are not at present affeoted. In Mr. ANDERSON's case the spots are very irregular in form, and pretty uniform in colour, but here the spots are more or less shaded with brown, and are distinguished by their having a broad orbioular pit in the centre, surrounded by three or four concentric depressions. In some cases where the spots at their commencement have been near to each other, the spots are still
surrounding they The spots do not penetrate the leaf completely though there is a slight indioation of the concentry rings on the under side. The appearance is quite new to us, and we are very happy to place it o record. M. J. $B$.

In the last Number of the Proceedings of th Royal Horticultural Society is an announcement of the more extended scheme for the Exaxination or Gail DENERS, which has been under the consideration of the Society ; and which we mentioned at p. 124, in allod ing to the more limited scheme adopted for tho present year. The Examinations Committee appears, recommended the Council to request that the Society of Arts would cause a special paper to be pre. pared, more adapted for Horticultural than Botanime Examinations, the prizes for which should be provided by the Horticultural Society; and also that the Socies of Arts should be requested to co-operate in adding scheme for Examination in Practical Gardening, to it other examinations, in future years. With regard th this recommendation, which has been duly submittod to the Councils of the two Societies, Mr. Fostra's letter of reply announces the willingness of the Society ef Arts to include Practical Gardening among the sabjecte for examination in its future programmes; and will this view the Council of that Society invite the join committee to embody in a paragraph the particulars ol this additional item of examination for insertion it the next issue of its programme.

The disease which has attacked the Mulbery Silkworm has for some time past attracted the attention of the Government and of the learned Societies in France ; and the discovery of a New Sillswoby in Senegal has been one of the results of the ioquine instituted to remedy the distress caused by the disenas. A note on this insect, the Saturnia Bauhinix of Guizn has recently been presented to the French Acmem of Sciences by M. Guérin-Méneville, who propoem to found thereon a new sub-genus under the num of Faidherbia, in honour of General Faidgerbe, the commander of the French military expedition in the district of the Senegal, through whose instrumentait the silk-producing qualities of the insect have been made known. Specimens have been sent to Eurpo and from a report addressed to the Academy it appar that the Senegal silk worm will live in France, and the the silk produced by it is much more rich than the produced by any silkworm hitherto known. A cocoon spun liy one of these silkworms contains 633 mill grammes of silk, those of the common yulberry silkworm containing only 290 , and those of the ilik worms of the Ailantus and Ricinus only 255 and $1 / 4$ respectively. It is proposed to introd
tion of this new silkworm into Algeria.
$\Lambda_{6}$ an illustration of the EFFECTS Or Draindal we may mention the substance of a paper recently addressed to the Munich Academy of Scienceis Professor Vogel on the alteration of the vegeataion
produced by this operation. The details of some expenin ments on a moor, made on a large scale for the pa pose of excluding 'accidental irregularities of toe chosen, are interesting. The produce obtained fram ne Bavarian morgen, 40,000 zquare feet, under mopres diferent conditions, was as follows:-From $A$, rep. senting the moor untouched, 7 cwt ., but full of from $B$, ooly fit to be used as straw, and not saleable; from $C$ representing the moor drained, 11 cwt.; and foum the produce in both the latter cases being also giv as food.

- The National Auricura Show is fired to th place this year on the 26th of April, at Cambilitan a connection with the Horticulturamad Howbri Esq if Esq. If we may judge from the interes ars at the London spring shows held during the past making way in presume that the amongst its admirers caunot do subscriptions in augmentation offered on this occasion, so as to out their plants, and thus to keep ali the annual gathering of the growers.
information may be obtained of Mr. Douclds, Gate, York, to whom subscriptions should be sea

Dr. F.C. Schubecer has recently been romit nated Professor of Bot

We learn from the Revue Horticole that Dr Maximovicz, who not long since returned to s. of whe burgh from Japan, with a very large collectio Imperit plants, has been a
crarden in that city.
Models, illuatrative of an ingenious mood SHADING greenhouses and pits, have been Kinspection by Mr. M•Kbllab, of we aro kingston-on-Thames. The plan, whim only simp apparently effective in it action; the opert
at one end of the louge, heing able to raise or lower the roller, which is outside the roof, equilly ht both ends

## WINTER FLOWERS.

frzbeary day among the london nubseries. Tae snow is in the fields and parks, its black sludge in the strects; frost, sleet and rain succeed each other rapidly and regularly, Out-door garden attractions scarcely be philanthropic to induce people to take their "pleasure" in "trim gardens" at this most wretched quarter of our generally wretehed winter-except such pleasure as may be derived from briskly walking where a varied collection of deciduous and evergreen trees and shrubs display their forms. The plants of spring are in the grip of ice, and there is naught in flower out of glimpee of better things, for though the snow and smut come down as the "water comes down at Lodore," there is at Chelsea some of the fragrance and beauty of myotery" to the inhabitants of this great city, yet there are charms of the Mediterranean shores expanded at St. Joln's Wood; and though the weather is undoubtedly that of the "region of Ork and Birch," yet the verdure and elegance of lands beyond the Line waves comfortably in the northern district
metropolis several hundred miles "too far north" fo bethought me therefore-when frozen out-to have look at some of these, for though it is a notoriously bad season for flowers, and this almost the worst end of it, attention to the production of spring or late winter flowers, yet I fancied I might find, besides those commonly grown, some interesting plants for the season, to the manner born as it were. So off to northera side first.
Here I aun much too early to see the display made by the elnormous quantities of popular flowers that are
grown in houses worthy to accommodate the finest grown in houses worthy to accommodate the fines
specimens sent to our shows, from their size and excellence; but Cinerarias are already hlooming in quantitr, as are other common flowers of spring, and than 150 feet filled with early Pelargoniums inst beginning to open. Albion, Mr. Woodroffe consider work, but he has other fivourite sorts, such as Florigreat. quantity here, but suld as soon as it comes into fower, proving that the people have not yet lost all will have us believe they cannot be attracted by anything is rather auundant here and in full Hower beima much used for cutting ; and Acacia Drummondii is flowering nicely, and is useful for sale in a small state, but these are only casual thirgs flowering here now; by-andby the epread of bloom will eclipse that of any of
the great bedding-places; and yet a little later the plants will bearry sweet pleasures to a hundred thousand non Lomes.
Messng. A. Henderson's Nersert, Pine-apple Place, always to me most interesting from its age, hat ing associations, and even its very name, slows attention is paid to the bloming of winter and farly and thongh there are 200 plants out-lending beauty to London lialls and draving romems,-yet there is a very gool display in the show-house, nicely arranged and matted comfortably. The Tussac-grass in flower other subjects in in unison with the weather than many it was very striking before the flowers began to fade; recently, is very neat in habit and exquisite in colour. ware poets of mixed bulbs-in rustic and other earthenbeing pots-look very pretty, Bulbocodium vernum,
which is highly a few days after Christmas. But the sweetest and ercentina mul ornaments of this show-house-not even symmetrical standards of double-flowered Peaches, are compact sheet of fragrant white blossoms - a firstuseful to the gardener, as the decoration, and doubly good an effect on terraces, \&ca, during the summer for furnishing subjects which are grown in tubs solely in the best ing. Had I a large conservatory to decorate Btandards manner, I should regard a batch of these fine here as indispensable. The Camellias are very beautifal white from the newer ones being Pizano, a is an excellent winter-flowering greenhouse plant that greenhouse things in many weeks. Among other Dioama buckoo $($ ? $)$ in bloom, Styphelia tubiflora and though mach cut at all seasonsed, while the Lapageria, are the swect Daphnes too, among them being Dowers, as marginata, with large and pale flowers, intermediate
between rubre and alba, but harger than either. In is of course one of the best plants for the season, and very useful for cutting. The Hebecliniums are coming in flower: there is a scandent Begonia-Comte Lim filipes -chiging to the walis in frower; and Cytisu graceful beaut
Messbs. E. G. Henderson's Nursibrx, Wellington Road, at once rewarded me for an Arctic ramble, by the bloom of a probably unequalled collection of Cyclamens, Cyclamen Atkinsii, Coum, and other species
are flowering beautifully, and there is an enormous stock of the seedlings of C. ivericum and mistures coming into flower in the frames; but the frames and pits, here and elsewhere, might be mistaken by the uninitiated for the longitudinal root and Potato pits of some giyantic farming eatablishment, from the covering up material heaped upon them; and getting a peep at the earliest flowerers of the very extensive and excellent collection of choice berbaceous and Alpine plante thorist's fiowera, \&c., cultivated here, is out of the question,
though hibernation in a house devoted to Cyclamens and very delightful. Cyclamen garden, is quite possibl and very delightful. Cyclamen persicum in remarkable rose and purplish crimson-is the chief attraction in the Cyclamen house; and many of the plant hav been in flower for weeks, though the greater number have not yet unfolded a flower bual, but will burst int blooin by-and-by. Cyclamens are by far the best of all dwarf and easily cultivated winter end spring blooming plants. In some places seedlings of d
ibericam are now in flower out of doors. Nice bloomins plants of the best, C. persicum, may be bad ind 18 months from sowing the seeds; they are in fact invaluable, and though popular, not nearly so math grown as they deserve to be, and will be. Andromed phillyreafolia, an elegant white-flowered species Acacia, or I should say, the best winter species, though a vile odour may sometimes emanate from it; and Echeveria secunda, a neat useful winter-flowerin succulent, (which I was pleased to see in several
places, as it is one of the hundrel succulents that, paid as much attention to as commoner plant generally recei-e, would well repay it, are blooming n the greenhouses. Also Schizostylis coccinea, which proves to be "a really good thing;" and Aucuba aponica vera, with berries of surpassing brilliancy ongrdens. In the stoves, the Cypripediums ar abundantly in flower; and in cooler houses a nicely
growing stock of Cephalotus, with the Dionem, and growing stock of Cephalotus, with the Dionæa, and pubescens, afford additional interest.
Mr. Williams's Paradise and Victoria Nurseries, Holloway, the first of which is vastly improved since I first saw it some four years ago, and it every day becoming more paradisiacal, though the Victoria Nursery is rapidly alvancing to surpass it, aftord some choice things. Among Orchids, of which of Dendrobium nobile-which, by the by, will yet be grown by the dozen in places where choice spring
decoration of the indoor department is practisedcalled intermedia is very delicate and pretty, as are two other distinct and desirable vars. Deadrobium Pierardi, Coelogyne media, Phalænopsis several species, and Cypripediams may be named as the best; though nere, as in most other nurseries, it should be observed, sizes, not the proluction of flowers at this or any other season: that of course falls to the private gardener, The Sarracenias do very nicely here, particularly S. Drummondii, and its white or pale variety-the beautifully marked pitcher-lids beirg well-developed and more attractive than many flowers. Astrapma Wallichii is just gone out of bloom, and that on a plant ouly a foot high. At the Victoria Nursery one of the most remarkable sights is, at present, the number of foundations that are digg out,
preparatory to almost covering the phice with glass, but the clay of Holloway in icy weather is not The pleasantest compound iu the world to louk at, and G. A. Sala does not retain a more fearful respect for for the clay of Holloway and its neighbourhood. For his hardy plarts Mr. W. purposes making a new nursery a little beyond the London clay and London very fine house-full as it cana be of vaiuable plants, There is a good deal to be seen and a good deal to be learnt. I cannot say enough ahout it now, but, that a conservatory in which the night temurature descends below $40^{\circ}$ in this cold weather, and warms up when the sun does come out to a comfortable 60 -average such plants as Theophrasta imperialis, Cyathen medullaris, Todea africana, Palms, Zunias, Dicksonins, Marattia elegans and Gleichenia hecistophylla, flabellata and dichotoma in duplicate and as large specimens, is too importaut to be passed by. Some of the plants are much the better for passing ths whole year in this of the same age; one passed the last summer in a stove, and its atipes might furnish crutches for a veteran,

12 months, is not one-third so tull, but much heallhier and very neat. There is a bench in this house 100 feet Draceenely flled with the finest Agaves, Yuceno reminds one many of their allies as to habit, which house at Kew, and which augurs well for our soon seeing many of these fino things in general caltivation. Most of them, while second to none for producing striking effect indoors, are also the very best subjecti
for placing out in summer in flower gardens or on erraces.
Messers. H. Low \& Co.'s Nursery, Clapton.-I had hoped to reach Chelsea by the erening, butharing opened the day among the fair natives of Cyprus and Suathern Europe at St. Jhin's Wood, I was obliged to cry peccavi in a veritable grove of Tree Ferns at Clapton, amongst the intermimble Orelid and other houses in this nursery. So far I could never have got cent. of the limitless parallel lines of pits, the way, and spread out here by the furlont. Any. boly writing of antipodal scenory without having the aivantage of travel anong Dicksonias, should at once Ferns in a long house will afford a must of Tice perspective. Looking lengthwiso or sideways the effect is remarkable. It would be pardonable absentmindedness in a man to peer through the stems for $3 n$ aborigine and his "gin" or squaw, in this houe was on the point of doing so, when my eye caught the pello an adj,ining house, and the illusion was die pelled. Bigger Fern trees I should not have wondered at, but when the number seen together much exceed 100, then you get something uniqua? for a northern clime. Of course the meadows of II eathe and other hard-wooded plants grown here are, as a rule, in too youthitul a state for flowering; though there is one species-Erica hiemalis-in flower in great forco20,000 to 25,000 plants in 60 -sized pots. If there is such thing as a gardener who does not decorate his greenhouse with this plant in the early spring, "let him Horea it." Among grewnhouse subjecte in flower, Hovea pungens, very deservedly praised of late; Erica white Labiate - Epacrises lifia, a very pretty little mure, candidissima, and Copelandi bein, among the beat Grevillea rosea, and Ceratopetalum guminiferum are among the most noticesble. Among Orchids, Den drobium barbatulum and sulphureure; the Cypripediume particularly the fine C. Stonei ; Limatora very extensive batch yet in flower; and lastly, deliciously sweet-scented Orchid from

## Home Carrespondence

Tagetes pumila and ofter Bedding Plants.-Some three years agro, in emsequence of the Calce thua failing in so many places, it was fearel that its calture would have to be nartially given un, an ? that something must be found as a substitute for it that could be depended upon with more certainty. Alchough many thinga were recommended and brought under notice at the time, yet as a yellow bedding plant the Calceolaria stands unrivalled at the present day. It is true there are as $Y$ anicties of that caanot be depended upon, such \& . fear of failure, such as Gaines's Seedling (one of the neatest growing Catceolarias in cultivatin), amplexicaulis, integrifolia, dece; these and some few o:hers can be depented upon, and we have at prasent on the whole nothing to decidedly supersede :T... Cilceularia. As peoples tas' es vary however, and as we must keep
progressing with the times, wo hail with delight any introduction that may be found useful in the flowe garden. One of the best things which have come under my notice for some time is Tagetes pumila. I have seen nothing to surpass this annual when well managed its neat habit, serratel foliage, profusian of bloom, pretty orange-c)loured flowers, and long dura:ion, stamp it at once as one of the most useul bellane plants we have. Last season this was fumishel by my
seedsman, with a stroag recommembation to tey it. In May I planted out a row in order to pire it a fair trial and although I fitter myself that I have the geas of the bedding plants (and shall bed out this season nearly 40,000 ), Tagetes pumila was considered by all who saw it at Osberton during the past summer to be the second best thing grown there; the cream of the bedding being four large circular beds of Amaranthus melancholicas ruber, edged with Cloth of Gold Pelar gonium-these beds were the admiration of all. Both the Amaranthus and Cloth of Gold do well here; but I feel certain that the Amaranthus will he eclipsed by
the introduction of Achyranthns Vircelhaffltii into oar flower garden. I look upon this phat as a great boon to the flower gardener. The management of Tayctes pumila is so simple and easy that any en noments upm its cniture would be superfluous; sulfie it to sty the fliage should be thinned, in order
dxuriant growth, and to permit the phants th thoos ap to G. S. Foljambe, Esq., Osberlon H lll, Worisop, Notts.
The Black Morocco, alias the Kempsey Alicante Grape.-Neither alr. Poynter nor Mr. Bennett seem

Kempsey Alicante Grape, which, if my memory serves me correctly, is as follows:- -Some few years ago, at one of the meetiugs of the British longer exists, Society, wath bome Uliack Grapes of enormous size were exlibitited. My recollection of them is very vivil, for I thaught them like oval Orleans Plums. Nell, Worcester said to have come from hempsey, and all were
siaire; no one knew the variety, and
 were compact, and the berries regularly set. After some inquiries made of the grower-I think Mr. Cox - it was lecided ithature bearethe name of the Kempsey Alicante (I am not quite certain if it was Kempsey Alicaine (he name of Alicante), and that the not sen the phace should be attached to it to dis. naine of the pace should kinds known wider the linguish it Aliemte. In common with other members I received some cuttings, and in process priso I found it to set badly, and the buncles to be rather long aud loose. The berries, instend of being oval and swelling out like those exhibited, were long and al:nost cylindrical, some of them very large, the majority small and stoneless. I confess that I was staggered, and thought that the wrong sort had this was not the case. Soon after seeing my Vine in bearing I happenced to be at Chiswick- 1 think in the autumn of 1863-mand there I saw my Kempsey Alicante in fall of Speechly's Grapes, and a very old variety), which it uudoubtedly is, for not only in fruit, but in foliage and habit the Kempsey Alicante agrees with it, Mlack Morceco in the bunches and berries of those sent to the Pomological Suciety nuder the name of Alicante was made the subject of a rigid inquiry, the result of which, as far as I recollect, was found to be the treat ment of the bunches by MIr. Cox, the gardener, whio of some otlier kind of Grape. If so, it seems to onen ap a new feld of inquiry. Can the size and form of the berries of Grapes undergo so great a change by carefully fertilising their flowers with foreiga pollen,
i. e. with polien taken from other kinds of Grapes? so, we have much to learn. T. R.--The name of Alicante Grape has been familiar to me for 20 years, black Prince, till I called on Mr. Ingram, at Bultcr, near Grantham, six years ago, where I saw splendid crops of a Grape hud never seen before, and on inAlicante. I at once saw that this was a most distinet Grape, and asked for cuttings of it, which Mr. Ingram sent me when the wood was ripe. In the course of a couple of years Mr. Meredith oegan exhibiting his fine samp'es of what was called "Kempsey Alicante;",
thinking this wight be a distinet variety from Mr. Inzr.m's', I wrote to Mr. Meredith for cuttings of it,
which he kindly sent me, I have fruited Mr. Ingran's, but not Mr. Meredith's, but judging from the foliage they are identical. Now, these Viues of Mr. Ingran's had al! the appearance are the same variety as Mr. Mereditu's and Mr. Cox's, the Vine must have been in the country for many years. I hope Mr. Ingram will tell us what he kows or learn from a neighbour of his, that he had splendid crops and bunches of it last year. I gave a neighbour some Vines to plant in a new Viurery four years ago, amongst them one raised from Mr. Ingram's Alicante; and both last year and in 1863 he cat Black Hamburghes out of his small house in the areond week in June, and Black Alieante on Christmas Day; the latter would have kept till March hall it been convenient to let the bunches hang. $I t$ is not a little carious that it should be so difficult to trace the origin of so many of the new Grapes that have of late ye urs come before the public. No one can raise a Seedling Vine and grow it till it fruits in a nobleman's or gentleman's garden without its coming under the constant notice of many individuals, some of whom might be reputed origin of a Vine is called in question, as has been done in more than one case withiu the last half doz'n years, I certainiy think that purchasers are entitled to evidence that what they buy is what it is ropreanited to them to be-not only distinct, but new. Wm. Thomson, Dalkeith.-With me the Black Alicante is a great favourite. I have often said, and I am still of the same opinion, that it is the very best late black Grape in cultivation, and I predicted that when its good qualities became known and its proper treatment better understood,
every collection, particularly where late Grapes are in request, a prediction which, thanks to Mr. Meredith and one or two others, is being verified. As to how the prefiz "Kempsey " became attached to this variety, I must refer your readers to the Transactions of the Pomological Society for the years 1857-8. John R. Cox, Crown East Cowrt, near Worcester
Microscopes.- A lens of the extracrdinary power of 1.50th focal distance has recently been manufactured f the highest known lens previously made, namely 1.25 th of au inch, described in last years Proceodiug
of the Royal Society. The new lens ponsesses a magnifying power of 3000 itear measure, and has been
secure 1 by the Radelifie Trustces for the Ner Maseum at Oxford. I. O. Weste sod.

Impressions of Plants.-1 few dags ago I was Impressions of Plants.- A few dass ano whe shown some impressions of sing like it, and were very beautiful, and perfectly white. How is it accomplished.
One of the old School. [Can any one inform our One of the Old School. [Can any one inform our
orrespondent?] orrespondent? Lileocedrus Doniana.-It may interest some opinion eaders to learn that this Libycedrus-in my opinion proved itself to be perfectly hardy here this winter, aving stood out without any protection withough the changing the colour of one of severe we have had in he south of Ireland since 1855 , or for 10 years. When visiting the principal nurseries about Exeter some two years ago, I! saw at one of them in all of them were in large pots or tubs, and on inquiring why they were not planted ont, $A$ wat stand out during tho wher cover when some frost set in. Nall much resembles that o the south of Ireland, I hare always hitherto protecte $\mathrm{m}_{y}$ plant with a large pot inverted, or a straw cap during the winter months, but having omit this specie his year it is a great pleas was led to expect-a fac which when will, I am sure, lead to its more general cultivation; its presumed delicacy, when its greal beauty is considered, being, as far as I can see, the only reason why it is not more generally met with i collections. W. E. G., Belgrove, Queenstown. Co. Cork
Royal Albert Grape.-Since my last communication ppeared in your columns respecting this Grape, I have received, amongst other letters on this suljpect, one from which I venture to give the following extract:-"The riginal Fine (says the writer) was brought to this island, Guernsey, many years ago by the late Mr. France. It was first fruited in Mr. Brock's Vinery at Detroit, Guernsey, in the year 1842 or 1843, and some bunches of it of immense size were sent to Prince Albert on his birthday; hence the name of Royal Albert. Being a very shy bearer, and equiring totally different treatment from any other Vine grown in Guernsey, it has never been cultivated there, and by mere accident only the original stock has escaped destruction. Another Grape was worked upon gardener, was curse of time that, through a change of niginal stock clit back, and a cane grown from the year. In this way only hae the variety been preserved Some eyes fron the Royal Albert were sent in 1816 by a gardener here to a nurseryman at Leamington, from whom the Vine at Perdiswell in all probability was procured. The Royal Albert requires heat later in the season, and more of it than we ever give to othe Grapes: in fact, it wants a house to itself to do justice." These remarks bear out exactly what I have previously stated respecting this Grape, and as we have thns discovered the spot in which the original Vine is known to exist, and as there is a possibility of getting an eye from this Vine, I am pleased to think that my efforts in its behalf bave not been made in vain Edward Bennett, Osberton Hall Gardens, Worksop, Notts. - Mr. Bennett is quite correct in all that he has written respecting this Grape. That there is a variety of Vine in cultivation under the name of Royal Albert, is well brown in this neighbourhood; it was grown at Kent's Green, near Worcester, the seat of William Morton, Hsq., and was exhibited in splendid condition at a horticulturai show in the Town Hall, Worcester by that gentleman's gardener, Mr. Willian Coliins, in or about the year 1845 or 1846. One bunch of it I believe, weighed between 5 and 6 lus. The origin of this Grape-at least its first introduction into this country, is well known. In the year 1840 Mr . Jones, of Birmingham, was erecting a Vinery at Kent's Green, and amongst other places he was also putting up some glass structures in the Island of Jersey; there he saw this Grape growing under the name of the Prune d Hiver or Winter Plum. He procured a couple of plants, and brought them with him th this country; one was sent to Kent's Green, the other, I am informed, went to Frogmore, where after some few years it likewise produced its fine fruit, and was there named Royal Albert. These two Vines, if in existence, will no doubt be the two oldest in the kingdom. The one at Kent's Green was grown for some few years, but not being much liked by the proprietor it was cut down and another kind was worked upon it, so the old root is still thereat least it was so some few years ago. When I entered upon my situation at Kempsey, under the late Robert Nuttall, Esq., in the year 1847, I found a small plant of this variety there, which had been procured from Mr. Cullins the previous summer; this produced some very fine fruit for several yeare, but not being considered equal in point of flavour to other varieties then in cultivation, it shared the fate of its parent, to make room for a more approved kind. It was a very strong grower, producing large foliage as well as large bunches and berries, and was indeed very similar in general
appearance to the Barbarossa of the present day, which

I have always corsidere
variety. If I understand
is a seedling raised at or near, however, Barbure some 10 or 12 years ago; and if such is reallon-Aro it would tend to confirm Mr. Bennett's opphe they are in reality two distinct kinds. John $R$. Crown East Court, near Worcester.
Walnuts.-Some time since one of your $C$. dents asked the best way of preserving Walnoth send you a few for trial. If you think them good the last week of February, you can publish my ceeping them, which is, simply, in a large pan alternate layers of Wilnuts and sea sand. I got p little too long), I put it in a heap to run dry, and the packed my Walnuts. I put them away as they came from the outer husk, without wiping or drying ; hence, from the sand adhering, it is necessary to soak them a fer minutes and wash them before putting them on the able. I think you will find the:n plump, and that ber tion, and the flavour excellent. We shall be glad tom the Figs at the proper season.]

## Proctical Tratise in the Cultirntion of the (irupe Tine. Dr William Thomeon, Gardener to his 'irace F:lition. Elinturgh and Londua: Blackwoul \&

 EifitionSons.
The isene of a fourth edition of Mr. Thomson' Treatise on the Vine so soon after its first appearance is the best of all practical commentaries on its merits, to which we have adverted in former notices. In the present edition, such further information as experience has suggested has been added, and as a sample of this new matter we may quote what the author rays on pianting young Vines :-
of lanting ard treating foung Vines, from my own experience of it in the past season. It is, probably, in its details new, bat it only requires to be described to matters. I had a large house to plant, chielly with Muscate, in April, 1864. I hnd a stock of one-year-old plants in 8 . inch pots by me; I cut the rods back to 4 feut in February, and allowed them to stand in a border was ready for their being planted; I shook all th.o earth from their roots, and spread them out on the soil of the border, 'one Vine to each rafter, and 5 fect apart, covered the
with 6 incties of soil, and gave the whole a watering, with water at a temperature of
and covered the surface with an ineh of dry soil, to frevent to some extent the escape of the heat communicated to the border by the warm water. The Vines were just bursting their buds when planted, and instead of adopting the nsual practice of stopping or to grow, and tied them carefully to the wires; by this means I had in somo instances 10 rods to one Vine, all of which have, during the season, run to the top of the
house, and partly down the back wall-a distance of 30 feet, and many of these rods are as strong as ever I had previously seen a single rod from a Vine the first year it was planted. At this date (January 6, 1865) perfect thicket of wood. I will shortly cut back all perfect thicket of wood. I will shortly cut back all these Vines to within a foot of the front sashes, and train up two rods from each this season for fruiting in
18.36 ; and I need not tell those who know that a plant makes roots in proportion to its leaves, that enormous excess of roots formed in the border as compared with others treated on the one rod and pinching system, and that the bearing-rods they will make this year will be in proportion to the extent and vigour of
their roots in the soil. I have just measured one of ther that when planted in April was not thicker than a writing-quill, and I find that it is now $3 \frac{1}{\frac{1}{2}}$ inches in circumference, and has 10 rods perfectly ripe to the
top of the rafters, 8 distance of 21 feet. If, instead of permanent vigour and productiveness, an immediate return were the object aimed at, I have no hesitation in saying that such a Vine would yield 50 lb . of Grapes this autamn."
We may add that those who have not yet consulted Mr. Thomson's book may do so with the full confidence that the lessons they are taught will be those of a master

## The Principles of Biology. By Herbert Spencer. <br> It in only to the 8 . 1865 . No. I-13.

important publication that we purpose to refer on this present occasion, and this because it treats on the Morphological Development of Plants. Mr. Herbert Spencer is well known as a profound and original thinker. No one can be in his company even for a few
minutes without hearing something in the way of minutes without hearing something in the way of some of his questions may be so profound as to require a month's labour to give anything like a satisfactory Asswer, if it be possible to give an answer at all.
his work before us, No. 13, much to call for deep reflection. In a great deal of what he says we cordially concur, and where we differ, we do so with somewhat that $\pi$ cell in ounnot own conclusions. We quite agree phataiological mit. There are conditions of plants as well as animals in which no cell can be discovered, Which consiat apparently entirely of the gelatinous membrane, called sarcode, which, conened by no investing vitality, and seems to perform at once the functions of aeration and nutrition. Mr. H. Spencer therefore first order ratheellular plants as aggregations of the Cell is, rather than as units.
direction then added to cell, first in a longitudinal as tranaverse division takes place longitudinal as well definite, a kind of axis is formed, and thus through order, fiom which we proceed tgates of the secnnd Ash-leaved Seawecd, Delesseria sanguinea. "The fronds of this plant, quite regularly slaped, have their parts midribs grow other frouds, which are and from their
 phological units which we distinguish as aggregates of
the secomid order.* And in this cate, two or more sucti aggregates of the secomil order, well individuated hy their forms and struectures, are united tomether; anch the plant composed of then is thas rendered, in so fut an aggregate of the third order."
From Algge our author proceeds to Hepatice, and in the most ingenious way traces the morphological development of a bramehed Jungermannia from one of the fromdose ones. The mode of doing so is scarcely
capable of being clearly explained without figurea, capable of being clearly explained without figures,
aut much less can we dispense with the figures when he proceeds to show that the type on which an Endogen
and Exogen are formed is merely a mocification of that which prevails amongst these humbler plants.
As a part of his theory he considers the axis to be leaf
primordial form being an integrated series of folia (or leavcs); and the development of that part by which these folia are held together at cousiderable distances taking place afterwards; it is inferable from the general principles of embryology, that in its rudimentary
stages, the phænogamic axis will have its foliar parts much more clearly marked out than its axial pat to."
He explains in a very ingenious way the identity of the monocotyledonous form of embryo with the dicotyledonous, by supposing one of the cotyledons to have the outer edges united so as to form a cylinder, and thus to prevent the equal development of the next leaf. The gies of the leaves of Phæuogams with those of Acrogens, and even "ith the superior Thallogens is excellent, and well worth an attentive consideration.
We do not think that he is equally successfnl in combating Goethe's doctrine of potential buds in the axils of leaves as accounting for many morphological structures. His illustration from Umbellifere fails, hecaus? w see the spokes of the umbels often developed trom the nothing or entirely obsolete in the same plant. We cannot regard the spokes or rays as metamorphosed leaves without some much stronger arguments. We are the active cellular tissuc is present, and we should no more wonder to see flowers occasionaliy produced from parts to which they are in general strangers, than buds from the edges of leaves.
The objects of our Journal forbid us entering more minutely into the various matters brought forward, but we can assure those who are not disinclined for a little stiff reading, that they will not consult our author
without deriving some new ideas from his disquisitions.

## Garden Memoranda.

The Eabl of Drrbs's, Knowsley Pabk. Knowsley Park joins the extensive park of the Earl of Sefton, at Croxteth, the mansion itself being about eight or nine miles distant from Liverpool, and some two or three miles from Huyton station, on the Liverpool and Manchester line. The house is situated on sloping ground, and is commanding in its position, and
at the same time so surrounded with plantations of considerable age as to be sufficiently sheltered from the violent storms that prevail in the district. There is no want of timber on the estate, but it does not, as in the boles and branches of many of the trees, not remarkable for size, being carpeted over with Lichens and Mosses, evidently showing the unsuitableness of the locality for promoting a high order of cultivation
One of the finest features in the park is a lake 90 acres in extent, which furnishes, and is furnished in turn with an ample supply of water to form the little river or stream that meanders through a portion of the grounds, flowing past the mansion, and forming the most natural of all boundaries for separating an extensive deer park from the dress grounds and artistic flower garden. Had Knowsley been a castellated structare, with the appurtenances of that atyle of architecture such as they were in the Norman, Tudor, or Elizabethan eras, then the stalwart forms of the red deer, with their huge antlers, sending forth their wild croaking cry,
would have been in keeping with such a building, eren had they browsed up to the very castle walls, as is the case in the magnificently wooded part that surrounds Raby Castle. Knowsley, however, has no pretensions to any of the orders of architecture. The building is a simple parallelogram with a few relieving points, and is constructed almost entirely of brick. It has never been remodelled in any way to please the æathefic eye,
although there has been an addition made to its size. Some of the older portions are hidden from view by the trees which are growing almost close by its side. It is of very large size, and the interior must be very commodious.
Park scenery, with specimen trees and clumps of evergreen shrubs in the foreground, bound the mansion on two sides; in fact, it may be said to entirely gardens, which lie in immediate contiguity on the other two sides. Evergreens, Roses, and bedding plants of sorts grow wild with vigour, and such as

Lac an do so etfectively. The flower gurden by the sulue
of the house is a square panel, the proundwork of which is frase. This patel is divicul inand foun, and again subivivided into a serics n! irregular heens. Eit:odsd whins and standated foses are l-redy yend as individual plants for prominent positions in these beds, and must have been grand while in flower; while the massive darkogreen folinge, indicative of high during summer and autumn. Bedding plants afould be weli contrasted with shrubs, and a variety of other thing that are ever suggesting themselves to the observant and educated cye. Such is by far the most celling and consistent style of geometrical flower gardening. Some may run riot with discordant glaring mixtures, but there can be no doubt that of all the styles yet intro. duced for flower gardening purposes, there is none so effective, and in fact, none so capable of being made to suit the various kinds of architecture, or different characters of scenery, as a well balanced ajstem of massing. All the opposition that has been brought to bear upon this style has but pointed out defects in
detail, and the only remedy that has hean surgented bina been a return to the old ayatem, which was simply no Not that I wish to advocate the expulsion of herbaceon plants, but this much may be said: that any arrangemeut of a mixed character, such as the make-up of the old lierbaceous border, must ever be subsidinry in purely ornamental gardening. The flower garden at Knowsley make the design striking, and enough of individuality to satisfy the eye while passing from one object to another.

The flower garden is bounded, on one side, by a large conservatory, some 120 feet by 24 feet. This house is divided across the centre; one part forming a stove, and the other a greenlouse. A collection of plants in flower is always lept in these holses, with a few choore specimen plants in the centre, which at all seasons form fine examules of Cycads, Musas, Crotons dise were some fine examples of Cycads, Musas, Crotons, \&c. ; while the Greenhouse division contained some good specimen Camellias, and numerons standard plants of IIelintrones and Coleus Verschaffeltii, which looked handsome towering over the heads of dwarfer plants, and inaking an admirable contrast to the Capsicums, richly clad with scarlet fruit, which formed the most prominent feature at the time of my visit. At the end of these houses stood a large collection of Zonate Pelargoniums, in splendid bloom, with colours varying from pure white ap through the various ahades of rove to a rich scarlet, all of which come in well for indoor deenation- not the least importar:t part of Mr. Freeman's duties.
This conservatory, is constructed after the same loftier building, and a little more pains has been tuken with its architectural decoration. The paths are beautifully polished, and marked of by a rounded kerb stone. The plants in the centre appear as if they were planted out, the pots being plunged in the soil; while those in front stand on a stage raised after the usual fashion, and are easily inspected. The honse forms a nice quiet resort for Lord Derby's family and frieuds; and being in the highest order of keeping, and having ample perambulating space, and seat accommodation, must be often visited.
Ascending the wooded slope towards the kitchen garden, we pass a pond of irregular outline, bounded with rockery, and ornamented with evergreen shrub3 picturesque residence and resort for the fine collection of ducks that move listlessly, but gracefully, upon the water. A great deal more interesting is the aviary close by, being probably the most extensive thing of
the kind in the country. It covers a large space of ground, and is completely enveloped with hexagon wirn netting, appearing in the distance like a huge canopy of gauze. The iuterior arrangement is such as would excite the admiration of any ornithologist. The ground is somewhat ondulating, and is laid out into clumps divided by numerous curvilinear walks, so that the fancier may have the best opportunity of $m$ thing a thorough inspection. These clumps are planted with
evergreens, 1 Portagal Laurels predominating, the darl sombre tints of which are vastly relieved by the diversiffed plamage of the collection of birds naturalised here, which may be said to include all that is beautiful and interesting, from the handsome prattling cockatoo to the modest and sweet-toned camary. This I understood has for many years been a specialty with the Derby family, and only requires to be seen to enamour the wost listless spectator
The kitchen garden covers an area of 18 acres, and is surrounded and divided by brick walls. The walls have
been long built, as the appearance of the bricks clearly enough indicat, as the appearance of the bricks clearly ing. This is partly attributable to the greater portion of them being faced with a wooden trellis to farten the trees to, which does away with nail holes and shreds, always more or less a harbour for insects. The Peach wall is covered with a collection of trees in splendil bearing order, and apparently free from the least
aymptoms of canker. In fact I do not reeollect to lave elsewhere 'seen such a fine lot of trees unprotecteri, nnless it was many years agn at Piukic, near Edinburgh, where there was a very lofty wall partly trellised, and in splendid bearing order; but that wall was heated with
a flue. likely anomgh these time trees were ail but deatryei in the were wimter of ' 61 , which has not hat Knuwhiny, wise as tmay be parly attributable to thie

> (To be continued.)

## Calendar of Operations.

## (For the ensuing week.)

Thes strong gales lately erperienced in the neighbonthood of Lomlon and elsewhere lave, we understand,
been very destructive to aged timber trees, in some instances blowing them down altogether, in some inflicting on them partial injury. In both cases, there. fore, see that the damage done is repaired with as little delay ns possible. Roll walks and clear lawns from in proper order for the scythe or machune. Most kinds of hardy annuals may now or sonn le sown; as hovever in disappoutument fronn of this nyeration often ends in disappnminnent from the seeds not germinating, we would advise the inexperiencel in such matters to wait until the soil is not only sufficiently dry to berr
tramplang upon without iujury, but also
perature has been somewhat ransed by means of iucreased
sim heat. Tegetation will then push onwards nackecked flower garden and plant houses.
Many phants, as for instance Pluloxes, Asters. \&c. iniv up too many floweriug shoots; where such is the case, thin them out 80 as to obtain unt only fine heads, to bloom but increased strength in the remance from stakes, enable them to staud with less assist stroug winds, and Secure all newly-planted
mulch well over the roots.
mulch well ovar the roats. AORicis.- Mo fore protect them from frost amewn fryuntly, as well as more liberally and water more frepe a week will strengthen the weak liquid inanure once a whe fumirate occasionally trusits; give plenty of air, and fumizate occalowall
green-fly generally appears wrowing plants liberal shifts
Azaleas.-Give young growng phite sand suits them dinirably, but for stronger kinds a small portion of loam may be used with advantage. When potted the plants sliunld be put into a nice moist growing atmo phem 0 d ther chould have a temperature of from $55^{\circ}$ $060^{\circ}$ by ni and $65^{\circ}$ to $70^{\circ}$ by day; give air freely in fine weather, and attend regularly to the stopping hinning, aud training of the sloots. Large specimens will now require more water.
Bending Plants- - Push on propagation of all kinds, in oriter to have thoroughly established and well bardened plants by May. Pot off autumn-struck curtinge at present in store pans.
Cafceofartas. - Any plants struck during the winter should be repotted into 4 -inch pots to succeed the first plants. If not so large, they will make compact Inndsme bushes for purposes of decoration; it is not ton late to strike cuttings of the best shrubby kinds for bedding out, such as Aurea floribunda, Pince of Orange, King of Sardinia, Pallida, Beauty of Montreal, Kayi, Diopmore, and Orange Boven.
Carnations and Picotees. - Strong-growing varieties may now be put into larger pots. If there is any green fly on the plants, give them a good smoking with tobacen or tobacco paper before taking them from the pit. The latter end of the month will be soon enougl) for planting out in borders.

Cinerartas. - Such plan's as are intended for exhibition should now have their anull leaves and super fluous shoots removed, to admit light and air; tie out as thinly as possible, and keep them as near the glass as mav be convenient; fumigate, so as to have them thoronchly clean before coming into flower, and sulphur wuch as may be affected with mildew. Seedlings will now now bo may appear should bo watched so as to select for preservation colours.
Dablias.-This is the best month for propagating these; cuttins struck 10 w have time to make fin plants ; thereforo propagate freeiy, and when sufficient cuttings have been taken, divide the roots to make few strong early plants.

Priks.-Tup-dress with half-rotten manure, mixed rith rich loamy soil
Telips, - Protect the best bed with canvas, Frig Domo, or mits, whenever there is much frost or exces sive rain. Do not, however, keep it so close as to excite weakly growth.

## ORCING GARDEN

Cocumbers.-Maintain for these a stealy heat of $65^{\circ}$ or $70^{\circ}$ at night. Give air on every favourable opportunity.
Figs.-Kpep the shoots thin so as to expose the foliage to light and air, and persevere in the use of the syringe to prevent red spider. Give air freely on right days, sluutting early in the afternoou after syringing the house,
Peacires.- Proceed gradually with the dishuddin of the early house, and where the fruit is very thick portion should be removed as soon as fairly set.
Pines.-Lonk ovor young gt.ek, occasionally examining and repotting such as is fonm to be in want of more pat roum. The temperature may bo slightly advanced as the amount of light increases, but this is a matter in which the state of the plants will be the beat guide. Aim at securing strong dwarf plants, with a rea habit of growth; and if this is obtained, it is immaterial whether the night temperature is $60^{\circ}$ or $70^{\circ}$, and very much will depend apon circumstances as to which will be proper
Stramberries. - Continue to bring on succeigion plants very gradually, and afford those in bloom rather dry atmosphere, with a free circnlation of air, as they set their fruit badly in a noist close atmo sphere. Plants swelling their fruit must be liberally supplied with clear, rather strong, manure water; and f tine large fruit is expected, thimning must be resorted to inmediately the berries are tairly set.
inss- See that Vines starting into growth are tied liable to be brakeno the shoots get so long as to bo frequently until the of in the operation. Syringe requently until the leaves begin to unfold; but use the syringe sparingly after that time. Where the buds do not promise to break regularly, bend the Vines so position to thoo that are backward in the mont likely posicectly to cany indications sap, and this should be done are obearyod if if of their not breaking regularly where stoning has been finished, bunches in houses
this be done at once.
hardy fruit and kitchen Garden
All pruning and nailing should be brought to a close as soon as possible. Make timely preparations for pros tecting wall trees. Be sure that everything is in reid: ness for that purpose, su that the material to be ubse can be put up in a short time when it is needed. Carrots.- A good breadth of Early Horn shoold by got in about this time, to succeed those sown on hem last month
Catliflowers. - When large enough, and th weather bas become warmer, these should be caref i" pricked out, either in gentle heat, or on a warm in tered border; if the latter, they will require protectic until well rooted.
Leeks.-These should now be sown.
Turnips.- Sow Early White Dutch on a gente bottom-heat, and also a good supply for succession ind warm border; dress the beels with dry soot and ashes occasionally

SATURDAY，MAR（H 4，1865．

meeting por the fnsuing week．
Mowdix，March 6\｛ Londo Farmers Club（Mr．Stearn on
－The Essex Reclamation Bill，giving power to a Company to embank at Maplin and at Dengie，and to convey the sewage of Nurth London to fertilise a large tract of foreshore there which is now oovered at high water，was read last Monday before the House of Commons；and，after an unsuccessful attempt by its opponents to post－ pone its consideration，it has been referred to a Solect Committee．
－The Committee appointed to confer with the Home SechbTany by the general meeting which was held last munth，abont the travelling of locomutive engines on highways，resolved that＂it will be sufficient for the protection of the public， under the Locomotive Act，1861，if Sir G．Grey requires the owners，or persons in charge of sueh engines，when travelling on the public roads，to have some person to accompany or precede the engine，whose dutyit shall be to signal the engine－ driver when he deems it necessary to stop or slacken the speed of the engine，aud who shall be instructed to assist horses，and carriages drawn by horses，passing such engines；and as a further precaution，it is recommended that the speed should be limited to four miles an hour．＇＂
This resolution was communicated by Lord Kinnaidd to Sir Geohge Grey，who has replied as fullows：－
＂My Lord，－I am directed by Secretary Sir Georae Griy to acimowied ge the receipt of your lordship＇s letter of the Itth inst，for warding a cong of a resolation of the Agricultural Loconotive Committeo in reference to the use of locomotives on
high－roads ；and I am to inform your lordship that Sir G Forae high－roads ；and I Rm to inform your lordship that Bir Grorg
GREY does not think he is empowered by lav to impose on the owners of loconotive traction engines regulations of the nature proposed in the resolution of the Committee，but that he would suggest that theowners of such engines，in any distric in which a restrictive irder is in firee，sinould give public notice that they are willing to adopt such regulations，any SO as to admit of a revocation or modification of the order． so an to＂I havo the honour to be my lord，
＂Your lordship＇s obedient servant，

Your lordship＇s obedient servant，
Under these circamstances our readers will be glad to learn that Mr．Hollayis，M．P．，has ob－ tained leave to bring in a lill which may under necessary restrictions give to Steam Cultivators the relief they require．
－Our readers will observe from the report in another column，that the Council of the Agricul－ tural Society have again postponed for a month their decision on the Education question．

The paper on Egyptian Agriculture in another page will we are sure be read with much interest．A country where steam oultivation is probably more largely adopted than it is any－ where else－where hundreds of linglish loco－ motive threshing and ploughing engines are already employed，must certanly excite very cor siderable nterest ：among abreulturists．The authur of the account which we this day give
of it in Mr. W. H. Delaro, one of Messrs. How IRD's staff. He is now again on his return to Eigypt, but any inquiries will reach him whioh are addr

Is the Ayriculthoral riasette for October 31, $186: 3$, will be found the results of some experiments on the germination of Wheat, which for the 42 samples operated upon may bo summarised as under:-

In 10 s.mples the seed failed from 52 to 92 per cent
In 13
18 to 48
In 19
2 to 12
an average of 25 per cent Nuw these experiments were appealed to as showing, intic alic, the great importance of a trial of seed l. fire s.,wing, and alse as estublishing the fact that if sed of it low germinating power be employul, thase by whom it is used are really "thin sceders." The facts upon which tirese simple conolusions wers based are so incontrovertible that one in at a lues to know how they could have been denied on the whe hanl, or how the reasoning founded upon them esul: h have boun disputed on the other.

Nutwithatuadug the terrible onslaughts which the firmer series mad to bear, we still continus our exprements; and as a further contribution to this subject, beg to submit for consideration the fol-lowing:-

If then we sum up our general conclusions with regard to the Barley, as in the case of the Wheat, they will be found to be as under:-
In 7 samples the sced failed from 16 to 30 per cent. In 14

8 to 10
0 to 4
In 25
Now, on comparing ", an average of 8 per cent obtained in the germinating of with the results found that the market samples of the two kinds be grain varied immensely in germinal power, result being greatly in favour of Barley. With regard to the latter, every one practically acquainted with the subject will know that the veriest starvelings among its grains will germinate however poor the "tail" of Barley may be it will grow, and it is even asserted by some that poor seed is the best to som ; and in rare cases this may of a cold $n$, where the poor sample is the result
if it be used in a good Barley district it bud soil, as
changed as not to be recognised. We last year owed 50 aores of such thin seed, said to be Iinerican (No. 23 of our Table), at the rate of jpecks to the acre, the general rate of the district being a sack to the acre.
But now, without asserting that this poor seed is as good as that of a plumper description, the question arises whether we did not sow almost as many seeds as our neighbours, a point which will be made clearar from the following calculations:-
Take three examples of Barley,-1st, a light thin ample labelled Odessa; 2d, the American sampl reviously referred to as being sown by us; and 31, the growth from this, which we this year sold at 30s. per quarter. In these samples every 100 seeds weighed as follow:-

## Odessa <br> 2. Anerican <br> 3. Own Grown

$$
\left.\begin{array}{l}
\text { grains. } \\
48 \\
50 \\
80
\end{array}\right\}
$$

$$
\left\{\begin{array}{c}
\text { The proportional numbers } \\
\text { of seeds according to } \\
\text { measnre were }
\end{array}\right\}
$$

181

Thue, 89 seeds of Yo. 3 and 150 of No. 2 oceu 89 he same space as 184 of No. 1. Heace, then, the better sample is nearly twice the weight of the poorer, and contains more than donble the number of seeds.

Puor, then, as were the seeds of No. 2 (23 o Table), they seem all to have germinated; the crop we obtained was very good, and it was after Wheat, but it is questionable whether, if we had sown less, we should not have had a better crop, and yet we have shown that this is really thick seeding.
Take, now, the converse. We sowed at the same rate, namely, 6 pecks per acre, 50 acres after Siwedes of a stout Chevalier Barley, such as may be ompared with No. 3 as above. Here the produce was less, which it ought not to bave been after ruots ; the quality is certainly superior, but all our reeighbours concurred that the field would have been larger with more liberal seeding, and we have great respect for our neighbour's opinion, especially when we see that kis double seeding really gets him a few more bushels per acre.
But the truth is our crop was lessened by our being obliged to wait for some of the Turuips to be eaten off, and here is the inportant matter to be considered: The extreme of thin seeding presupposes the extreme of good cultivation, land in good heart, of a fine tilth, and all done up to time, such as we have no doubt is fully followed out by some of the advocates of the system. But if under the present cultivation all eases were treated with the like inlinitesimal dosing of seed, we cannot think that the general results would be so good as at present, for in a poor soil with a late climate, where probably from oircumstances the grain is not got in early, there is only time for the growth of a single stem, tilleriug is out of the question, and therefore each stem yields no more seeds at some inghes from its neighbour than it would at half the distance.
But, say the advocates of the extreme of thinseeding, "What sense can there be in sowing thickly if the land is not strong enough to grow enough of a plant when sown thinner?" The truth, however, is that in many cases neither the soil nor the time allotted for growth is sufficient to grow fine stools of Barley, while it can grow single ears, which may be put as thick as we please, as for each one of them we require a distinct seed to be sown.

Nevertheless we confess that too much seed is sown as a rule, but in so saying we would respectfully dissent from the sweeping assertion which would accuse all men of folly who do not content themselves with the use of pecks of seed where they now employ sacks.
In some rich lands we have seen much straw to follow as the result of thin-seeding, but reither good grain nor a large yield. During the past year we sowed six and eight pecks of White Oats to an acre in parts of a tield-the former made straw nearly six feet high, but only yielded 30 bushels to the acre; the latter a short straw, as much as 40 bushels.
It seems then to us to follow that there can be no absolutely fixed rule as to seeding; and though we believe that improved farming will require less seed, yet we are also sure that as things are, many thick-seeders find their account in their seeming
prodigality. $B$. prodigality. $B$.

## AGRICULTURAL EDUCATION.

Mocit as agriculture differs from many occupations, It is not an art or pratice a general resemblance. dexterity, and art or practice requiring mere manual imitation, and which may be learut by observation and divinity.
It has by common consent been allowed to cont of two parts: Practice and Science, a combination existence of which is strikiagly shown at the an t exhibitions held in the Royal Agricultural show ground, and the union of which has beenf furt sanctioned by that Society adopting it as their fursep It is unnecessary for me here to enlarge upon the fie depth and height of meaning contanined iu thesef words. They are the fundation of amriese tre adrancement-the two strong pillars upor whici agricultural knowledge rests.
$t$ is in this fundamental truth that we trace 1 . analogy of agriculture to other pursuits. The surgem for instance, must be thoroughly conversant with art, firm of hand, steady of purpose and able to guis his kuife, so as to effect his purpose, and pot injuring important arteries and nerves, important is his scientific knowledge, not Equal: qualify him for following his profession, but to to bim in those numerous difficulties which are give stantly to be met with in exceptional cases.
The engineer also requires to hare cases.
The engineer also requires to have a good knombelo of the uses of tools and machives, aud the generi
details of his business. At the same time he possess a thorough kuowledge of the application physical and mathematical laws to the various branelo of his profession. In other words, he should knit both the practical and theoretical parts of the occupation.

Tow, the same general rule applies to agriculture A good farmer must know the daily routine of farm work; but to be accomplished in his business he shonit know the why and the wherefore of those daily open tions-or the Science of farming.
In considering, therefore, the best mode of eduating young man so as to make him a good farmersuch, I take it, is the only object which rational agricultural educators should have in view-it is enis wise to consider the methods which good auth nick sauction, and succes; stamps as the best meani; acquiring a good knowledge of the occupations aboret mentioned.
Without going into wearisome detail, it will be enough to state that the means used in both cases an similar, and embrace, first, a thorough knowledge ci details, obtained by a regular course of instruction is the workshop or the dissecting room ; and, seondly, a knowledge of the theoretic part of their professions attained by atteudance on lectures, and the perusad of the best books on the subject.
Agricultural education must be gained in the same way: first, by a knowledge of details, attained by care. ful observation on a well managed farm ; secondly, by a careful stuly of scientific works and agricultural literature, and attendance at lectures in a good scientuit school or college. Such a course of instruction moun doubtless give all the information necessary to mase a good practical and scientific farmer, just in the sme way as a course of instruction in other subjects, ©ar. ducted on the same principles, sends out good surgens: and good engineers.
It is protessional education we want. Agricullure ' becoming more scientific than agriculturists, and it: most desirable that farmers should keep up with the: business. The farmers of an older system did rent well for that system-but now they begin to find ther deficiencies, and to ask for some better instruction tion their sons.

It is encouraging to see that this general crif: knowledige is being responded to by the Rogal igri. cultural Society of England, and that a committee es been appoiated to consider this important subjecto
If however the intention of sound profesionis agriculcural instruction has to be abandoned for scheme of middle-class education, because an enarace mind is necessary to the right understanding scientific teaching-then may agriculturists mait, 10 wait in vain, for the knowledge which they now the need of.
It will be little less than an insult to the agriculana community if oven the Royal Agricultural socie? thiuls fit to withhold its encouragement from special professional knowledge, and to bestow it upon a muw general and elementary education, on the grom the young agriculturists of the present day are a fit state for the reception of such knowlejge much to be feared that such is the tenuesubice leaders of this Society. Leaviug the seaten cheoretical and practical agriculture, and che achan sciences of chemistry, geology, botany,
applied to agriculture, there is great danger money of the Society being thrown away attempt (as far as an agricultural society is to raise the general education of the country prizes for English literature, classics, Seriptur drawing, and music. Without the slightest of education, no mese important and equ if the infu of education, no one can help regretting ind Society and wealth of the Royal Agricultural to
diverted into such a chavnel rather than urgent wants of that part of the community which represents. No one will deny the fact that use teaching chemistry to a man who does uo understaud his mother tongue, and who is d the elements of education. First, however, Io
welthy and leading farmers; secondly, that it is to
thin very class of farmers and their sons that we must this very claes of farmers and their sons that we must look for further prog for scientific knowledge.

It will be beginning at the wrong end if the Ryyal Agricultural Society first try to elevate the whole agricul
lodge.
The right principle to go upon is to encourage leading agriculturists and their sons to further attainments ; to give encouragement the sonks of farmars engaged in agriculture the attainment of which shows and competeredge on agricultural subjecte, and to make the possession of a prize, or certiticate, or diplom?, stamped a testimonial showing their appreciation of his egricultural knowledge.
It must have been gratifying to all who are interested in agricultural caucation to have witnessed the interest which has of late been excited in this powerful society mortifying indeed if, after all the talking and writing upon this subject, men who have shown a proficiency in classic3, Scripture history, drawing, and music. X. Y.Z.

## THE MALT TAX QUESTION.

Trie malt tax yields to the revenue nearly $6,000,002$ ? annually (which cannot be spared). By whom is it driuker ; by the consumer. This tax is paid, in fact, by those who drink the beer. There may be a little extra charge upon ma'tsters for capital, and interest Government, but it is all put on themalt, and the consumer pays it all. There is no respect or favour paid to classes here. The mechanic and the farm-labourer are upon equal terms as consumers, and each pay the tax, according to the quantity they consume.
What advantage would these classes derive by its redaction or total repeal? The reduction in the price of beer would be considerable. In the event of the
total repeal of the tax, it would be something like 22s. per quarter tax added to 32s. per quarter for Barley-total present cost 54s. per quarter, exclusive
of maltster's costs and profit. But a quarter of good Barley will make rather more than a quarter of malt, but as the duty is always charged from the couch, or in its most swollen state, it may fairly be taken as I have
put ito Well, talke off the $32 s$. tax, we have again 32 s . for the Barley, to which add 68. per quarter for malting
and costs of sales and delivery, \&o., and 15 per cent. for maltster's risk and profit, i.e., 5s. per quarter: total cost of the quarter of malt is 43 s . The account then the preeent price for good malt. The difference thus shown then proves a reduction of about one-third in the price of malt by the ropeal, and of course a cor-
responding reduction in the price of beer; good beer, therefore, instcad of being a 1 s . per gallon, may be as profitably sold for 8 d
But would not the total repeal of the duty enhance the pricz of Barley? So the advocates of repeul say, butwhy should it? At least to any extent? Inferior
Barleys might advance a trife, but no one thinks that Barley will outstrip Wheat in price. The two are now nearly upon a par as to price per stone, and no one
would think of putting inferior Barley thruugh the expensive process of malting, to say nothing of the maste or loss by so doing. Good Barley, weighing 32 stones per qr., will not produce 25 stones of malt, inferior still less proportionately.
Buppose the duty off, then there would be no restrictions, and every farmer may make his own malt.
That would be folly indeed. Malting is of itself a peculiar business, requiring consummate judgment and coustant watchfulness. No novice or unpractised man
can male malt. He may wet Barley and dry it again, after a fashion. You want the greatest proportion of malt from the steep. It must be all properly grown, or it is merely wetted Barley dried
men of great experience can do this.
But, after all, it is asserted that it is a most burdensome and obnoxious tax, and wholly opposed to the principles of free trade. This is by no means clear. Free trade means unrestricted commerce, no tax upon
importation. A taz upon imported Barley or malt importation. A taz upon imported Barley or malt
would be in direct opposition to free trade; but this is an internal tax, a tax upon Barley converted into malt the chief a species of manufacture, a tax upon one of beverage, and therefore obnoxious enough, and in that view altogether indefensible, and cannot be too strongly reprobated. No one approves the tax, except as a dire
necessity for the public payments. What ffect would the payments.
condition of the working man? Beer would become and great measure his substitute for tea and coffee, and sugar and milk. The poor man, be he me banic or labourer, has generally to depend upon his cup of on his return fromee it. This he takes in company with
his family testimony. The tea and the coffee I know, from good
and cheap. In like best or strongest ; it is weak Weak and cheap, for it can be brewed at almost any
price; I therefore take one to be as good as the other,
the difference being in the tea, coffee, sugar, milk, and the beer he may take in substitution. I certainly from experience, hold to the beer after a hard day's toil, but I don't match a quart of beer amainst a cup of beer will be an inmmense boon to the poor working man.
What effect will the total repeal have upon the employers of labour? Very great indeed. It is not
often taken into account how much the cost of labour is enhaliced by the quantity of beer consumed under the varied operations performed by workmen daily. A farmer will find his beer bill amount to from 3s. to 4. per acre upon his occupation. The master mechanic, the builder, the manufacturer, the ship-
wright, the miner, the foundry master, the railway manager-indeed every employer will find that from 5 to 15 per cent. and more of the wages paid is for
beer. What a tremendous account!-and yet this national beverage is kept up high in price by this most obnoxious tar. All necessaries for and personal comforts required by the numbers ought
weigh most with righteous statesmen.
What taxes are to be substituted to enable this large sum to be repealed?

The first undoubtedly is renewal and further charge upon property and income the scale to descend much lower than heretofore as return for the boon. The foolish bugbear of it being a war-tax is no longer tenable. Only just let one of the Powers of Europe insult us grossly, provocative of war. The Chancellor of the Exchequer need not
hesitate - he may lay on what tares he likes, and where he likes; there will be no grumbling, but here is a heavy tax upon one of the actual necessaries o
British life. It must be repealed or greally reduced. British life. It must be repealed or greally reduced.
Next, there is a new and most powerful interest come into being within the past 30 years or so-the railway interest. I am not sure it has contributed its share to the public treasury. It has occupied our senators above all | others; it has possessed itself of our fields, our homes, our trades, our shipping, our everything, on which it is flourishing amazingly. I think this interest might contribute something both by passenger and
luggage traffic. Wines and spirits might again contribute something more-they are luxuries, no necessaries. Tempting beer shops are opened every where. A higher licence might curb this "eocial evil, and add a trifle to the revenue. Joint stock Cual pater prise. Leet them pay a tax for their immense monopolies and privileges. If the tax is to be taken off

## who manages our Exchequer from doing it. O.F.

NOTES ON EGYPTIAN AGRICULTURE.
Amongst all the cotton-growing countries called to sudden prosperity by the American war, none have sacceeded better in the art, whether for quality of stapie or quant:ty grown per acreage of arable surlace, han the fellaheen for the present demand by his various enactments for the cultivation; and amongst all his various schemes for making Egypt great, glass mannfactories, spinning, weaving, dyeing establishments, salt-pits, arsenals, foundries, sugar factories, \&c., will parowng has proved mores Cotton cro of 1863 . Egypt received over 12 millions; for that o 1864, she will receive over 20 millions, as the notice in the Times of "gold withdrawn for Alexandria" daily testify.
The writer, after completing an agricultural tour in Spain and Portugal, started for Eyypt in November 1863, and remained there travelling abjut the agricul tural districts till June 1864; and perhaps his brie superficial notes on Egyptian Ag
In the autumn of 1863 things were very queer in Egypt; the extraordinary inundation of the Nile spreading for miles on each side of the river's natura bed, had drowned the crops and broken the railway communications. Besides this, a violent murrain tha seemed like a second Mosaic plague desolated the country ; the native oxen and buffalos, as well as those hastily imported from the coasts of the Black Sea, Trieste, Spain, Purtugal, and Fating down the swollen waters of the Nile ; carcases lay on every road, and in watery field and ditch. In fact, so rapid was the course of the malady, that even the polyglot Earopean speculators of Alexandria, neglected for a little while to buy up the hides and hoofs for exporto
The natives were in despair, and bewailed their splendid osen with many bitter tears ; the oniy available animals left were the camel and donkey, both better suited for carrying than for draught, as the Arab horses,

* With reference to the murrain, well-known literary Bey
 or chiof of a village, rendered public praise to Aliah for that it
had pleased him th confound the iudidel Cotton growers of
 selfishnoeso of
the murrain.
all thorough-bred, are little fit for agricultural pur poses. A sight pretty commonly seeu at this time was and the muck enduring Eisyptian doncer stepped tugether (the yoke at an angle of about $60^{\circ}$ ), draccing the simple Egyptian plongh, the industrious fellah encouraging them from the plough handle, who would mideed, have scratched up the hand with his fingers ather than miss his crop. Meanwhile, the Government of the Viceroy set to work to right things; duble pay was offred to all the railnay employés to get the line in working order within a certain time the drowned Cotton was dragged up, and the land replanted with Flax, Indian Corn, Wheat, and Burseem, or Eggptian Clover ; and as no draught animals were orthcoming, large ordera were given to Howard and Fowler for steam ploughs.
In these brief notes modern agricaltural Egypt will be described under the four following heads: -1 , the Soil ; 2, the Produce; 8, the Animals ; 4, the Men.

1. Soil. The arable Innd all over Egypt is for the most part loam, entirely free from ntone, with a heavy clay subsoil, the latter strongly impregnated with salt; I. H. Halim Pasha, the whole soil is a heavy clay, to makes very superior bricks.
It is generally supposed that the water from the Nile during its rise deposits the rich fertilising mud wherever it flows: this is far from the case. It is only for a short dist ince on each side of the banks that the deposit takes place, and the rent of land there is exceedingly high compared to that at a greater distance; the water conveyed by canalisation to the lands of the Deita is perfectly limpid, and merely used for sinple irrigation. It is only on the immediate banks of the Nile that the fellah may be seen when the waters rpcede, wading up to his armpits, sowing his seed broad cast on the ooze, casting his bread upon the waters which he will find after many days. It is frequently supposed that the land is inexhaustibly fertile; it is no so however, as has been amply demonstrated by the liberal-minded Prince and agriculturist before named, who planted two fields side by side with Flax, the one dressed with superphosphate, the other left without manure. It is no exaggeration to say that the Flax reated with the manare grown under the superin tendence of H. H.'s English gardener, Mr. Wm. Chapman, had double the thickness of stalk, and was mearly double the height of the other; in fact, the difference between the two samples was as striking as anything could be. This enlightened Prince has since ordered 300 tons of guano and superphosphate for his different estates in Egyp

The fellatieen are also alive to the value of manure, and epread on their fields dust from old ruins, abounding in the Delta, which contaiu a great deal of
lime. The dung of the camels, oxen, buffaloes, horsen, lime. The dung of the camels, oxen, buffaloes, horsen, who compress it with their, hands into a bun-lik shape and stick it on the walls of their hats, where it dries and is used for fuel, there being little wood and no coal or lignite in the country. The land is broken up to a depth of about 3 inches with the Egyptian plough, partly from the want of proper implements to go deeper, partly for fear of bringing up the salt subsoil. The Egrptian plough is like that used in India spain, and Purtugal, a mere iron point or pick adapte to a wooden frame-work which scratches up the land as a one-tined scariber would do, so that to get anything like a tilth, the fellaheen must plough and cross plough at least five times. They then drag a large flat smooth frame-work of wood, on which the fellulb stands, over the land to level and pulverise it, after which, with amall short-bandled broad-bladed hand-hoe, the blade making an angle of $45^{\circ}$ with the heft, they set up the and in ridges and arrange their water furrows for irri gation, at which they are very clever. Tuis hand-hoe, called a "fass," is the national implement, and
About the only other implement in use is the native threshing machine, a wooden framework, or chariot, running on sharp iron discs or skeiths, which they drise orer the grain and straw in a circle; the action of the discs and of the animals treading bruises and cuts up the straw in short leugtha and insufficiently threshes the grain, the whole is then piled up in the middle of the circle and a fresh supply strewn in the track of the charioteer. To winnow the grain they take a heap of the mixture and toss it up in the air with a wooden shovel, when the wind blows the straw chaff and cavings to a little distance, the grain falling straight to the ground. The chopped, bruised straw, de., , good deal of grain fodder, whilst the grain, with a good deal of dirt in is garnered or sold without further operation. The Arabs bad carried the same methods to the prement day, so that owing to the demand for chopped bruised straw our maker of threshing machines (all warranted to produce a market sample), must adjust their wares accordingly.

It may be broadly stated that with good cultivation and water the soil of Egypt will grow anything. It is the old story: to make a good aeed bed the land must be pulverised to a good depth. With a fine climate and soil a crop may be got, as in Peru, by one man seratching a furrow, another following dropping in the seed and stamping the earth over with his foot, but only inferio
crops are obtained in this way under the most favourable Whats.
What can be done by properly pulverising and deep stirring the soil in Egypt has been shown by the use of Highness the Viceroy and His Highness Halim Pasha fetching far higher prices in the market than any other. It is worts mentioning that in April last, within sight and at a short distance of the Pyramids, there was a peaceful contest between Howard's and Fowler's steam ploughs, very near the spot where t:ok place the battle Napoleon, known as the Battle of the Pyramids.

With regard to the saltness of the subsoil the fo!low. ing is interesting:-A gentleman of standing at suez, fiuding when the French company made the cutting for the SuEZ Water-canal (the supplement of the grest top of the lund, clay was the subsoil, conceived the idea of bringing the clay to the surfice by deep ploughing, thus rendering it fit for cultivation, and converting the arid, barren port of sut\% into a flourishing arricul-
tural district. When the Nile water was let into the tural district. When the Nile water was let into the
canal all Suez rejoiced and glorified the French who bad made it. They sent their horses and asses to drink and congratulatel themselves that for the future instead of buying water ly the skinful from Moses Well, nine miles away, they would have it at their doors, gratis. S. on, however, it began to be brarkish, day as the water evaporated, the Nile running low ceasing to feed the canal, thick incrustations of salt sold. It is still however an open guestion whether some salt-absorbing plants might not be found which, being constantly grown and ploughed in, would after a time produce $a$ soil fit for cultivation.
2. Produce.- The agricultural produce of Egypt is illimitably varied, as of old. Giourds, succulent roots, For Oranges and Lemons Egypt might rival Seville and the Azores; the large Blood Oranges grown in Shoubra Gardens are particularly delicious, and would fetch a Nectarines, Figs, Bananas, Prickiy Pears, grow in ptofasion, and are placked hot from the tree, owing to the powerful sum. Grapes and Pine Apples do not succeed 80 well, on account of the sudden fall of temperature
during the night, the thermometer frequently sinking $10^{\circ}$ in a very short sp.uee of time : glass houses have been, however, ordered out by some of the princes. Dates are produced in enormous quantities, and whetl er fresh, dried, or mashed, form a large part of the native Palin ptis a tar of $3!$ ! a verr to the Gisvernment they are frequently 70 teet high, the Dates growing in clusters under the tuft of leaves; the natives casily
climb uo with their lare hands and feet to gather climb un with their bare hands and feet to gather it bas little root, and is frequently blown down; its wood is tonyh, and makes cipital crates. Syeanore Figs are sold in large quantitis. An alley of these trees forms a complete arcalle and yichls a good revenue; it looks 200 years old, though it was only planted 40 jears ago by Meliemet Ali.
Corn, or Doura (of which the native loaves or flatian are made, one or $t w o$ of a man's wives grinding sufficent meal every day before the inul-hovel door), Burseen or Egsptian Clover, Flax, Sugar-cane, chiefly mighty Cutton cuerywhere-ali these crops are urown on ridyes, so that they can be easily irrimate.l. For Cotton centre to centre; the seed is dibbled in at distances of 1 ft . to 1 ft .6 in , apart, the plants being afterwards hoen. The seed is all in by the end of March, the
young plants appearing a few days after warls; the young plants appearing a few days afterwards; the being irrinated every 10 or 12 diys, though at grenter intervais when the plant is high. The fellaheen are are too smalit tor a water-wheel they will irrigate by skins or buling. In Suptember the Cotton-plant is
9 feet high, full of pods and beautiful vellow flowers, between which time and the end of inerember four
 villages turn in to pick. The harvest is ginned as soon as possille at the numerons Einglish, Fiench, German,
Italian, Maltese, Greek, Syrian, Irmenian, Alluanian, Native, aud even American gimning factories, where the Coiton is ginmed fur the seed and a small sumpur cantar or cwt--in times of comretition for the secd only. The ciean Cuiton t! en goes to Monet-el-Bussal, now fetches from 91. to 12\%. per cat. The produce of an acre of Cottur may be valued at 502 . on an average, so that supposing the rent of the land, seed, cultiva16 s. per anere, to come to 151 ., a very high estimate, the clear profit per acre is $30 /$ - - presuming there invitation s to take shares in Een voluces, or vicerecal is not jet quite safe to ignore. Many of the gianing hydraulic presses fur baling the Cotton, oil presses for
extracting oil from the seed, and producing the now well-known Cutton-sced cake. The greatest difficulty the proprietors have is the cost of labour, which is
nearly as high as in England. Cotton-seed oil is now nearly as high as in England. Cotton-seed oil is now
largely used in the soap trade, and its refined estracts for lubritication.
The Cotton shrub will bear for three years, but as the roots are very strong, deep searching and exhausting for the soil, they are generally pulled up by the tough, is sold for fuel, the leaves for fuel and manure; the land is then rapidly worked over for Indian Corn, which is sown and larvested within 90 days, or with which is sown and harvested within 90 days, or with
Flax or Eyyptian Clover. This Clover or Burseem is one of the fellah's best helps, and when properly irrigated it may be cut 15 times before the great heats come on-it grows as high as Flax.
The camels, horses, oxen, and donkeys, goats, and sheep, are all put on Burseem in the spring; its rich juices fortify and fatten them wonderfully, their nature beoones renovaterd, and they are enabled to withstand been sent to England at various times-it would be advantageous to know how it has succeeded. It is rossible with irrigation to obtain four crops a year on the banks of
and Melons.
On the varieties of Sugar Cane, the yellow and the purple and white, as well as Rice, space will not permit to treat, but should the present prices for Cotton abate, the European capital in the country may be then attracted by these important staples.
Weeds growing on a fallow fied perish completely in the summer from the heat. Hashcesh, "the weed," is well known; when dry it looks like a bunch of Thyme. The natives smoke a few of the leaves on their pipes and after a few whiffs becone affected and start for
pleasant dreamland. The weed when green is pressed, pleasant dreamland. The weed when green is pressed,
and its inspissated juice made up into little sticks and and its inspissated juice made up into little sticks and ffect buts. it is best never to touch it. Flowers are little grown and cared for, the practical fellah seeing no utility in what cannot be eaten or sold.
3. Animals.-The chief anmal of modern as of ancient Egypt is the camel; far from being the affectionatc creature represented, it is exceedingly morose and dangerous, biting viciusly, and kicking when provnked in every posstible direction, which, from its peculiar conformation,
it is cnabled to do. An enraged camel tearing about is ly no means rare in the strcets of Cairo. In their excesses of passion they frequently dangerously wound and sometines kill people. As a carrying animal in the desert its utility is uubounded, but its merits in roads when loaded, breakirc sts back. Transport moreover by camel in towns is not so cheap as cartage, though the loads they will carry are tremendous; four bales of cotton, weighing 300 lbs . to 330 lbs , each,
being frequently seen. The camel is a very shy animal, only frily understood by the Bedouins; it does not hreed in town?. The price of a camel averages from with a little Burseem hay. The dromedary bears the same rution to the eamel as the race-horse to the cart-horse; they have a very easy eight to ton miles an hour pace, and cost about 202 .
The oxen and buffuins are fine large-s:zed strong little milk. They have the swaying neck, drooping sidelong gait of the camel, and are very docile. They do not dravi from the head but from the neck, the yoke passing in front of a bony hump peculiar lo them. Milk is ehiefly obtained from a hardy little race of goats, whose unnaturally distended uilders are kept in bags by the careful natises, so that no stray kids shouhl milk them.
The
The horses as companions and steeds are adinirable, but of little use comparatively for draught, heing small
and fiery. The Arabs spoil the stride by training thein to stop suldenily when at full gallop, puiling them on their haunches amd checking them with a very crnel
curl). To show their slill they will dash at full speed against a dead wall, reiuing up and turuing suddenly when a few inches from it. The Arab horse's paces are many are train ed to walk in the eamel favhion by with this puce are muth sourthe ufter by effete nd Turks. The price of horses has now gone up considerably, formerly they could be oltained for riding purposes at from 6l. to 10l. The sheikhs and principal people ride mares. The Egyptian donkey reaches a development
both of mind and body unh nowu in less fazoured climes; he can live on less foor, sustain greater and more continunus fatigue thay the horse, and carry almost as heavy a burthen; his only deficiency is wat of speed. He, too, has the camel motion, and his paces we the same as those of the horse. Owing to his nut than use him well. If a European riding a donkey in the intricate streets of Cairo loses his way (one tales a homkey in Cairo as a "Hansom" in Londmn), the best will find the nearest way back to its station. The price of a cood donkey with saddle is now $12 \%$. Some fetch
a h:
ass, riullen by the Sultan in the Garden of Shoubra
during his visit to Egypt, cust $500 \%$. It win te remeen bered that the prize was taken at thie Donkey SLonty
His Highness the Prince of Wales with given by His Highness the Viceroy during the animal visit to Egypt. The sheep are small and poid Last year the English Government sent out 25 picked sheep, of best races, bought for 400 l ., to cross with the native breed, under the superintendence of a merater of one our well-known Norfolk sheep-breedir anilies; but when the Arabs saw the big Lesicester their own diminutive race, "Wullat,", said these" "tlith davice of the Christians to make us eat poik ; the are no sheen, but pigs with wool on them." There
splendid animals. thus despised, cooped up in an od stable, soon began to suffer from too great a groxth hoof for their heavy bolies, which superinducel for rot, so that they gradually drooped and died. This cheme, thatif properiy carried out, would have increacel fie wealth of the country, there being no difficult the climate, was thus rendered abortive
The black pig would flourish, but religious prejadic is opposed but numerous instances of sueaking kindness o these animals on the part of the natives, sho that they possess the haman friencliness for the race, although opposed to their creed. White nipe, quail, their season, though the latter have a sardine. Gevour only to be subdued by abundant sprinklins of lemon juice. The Bedouins also bring desert hares 4. Labourers.-Taking everyth
on, an English farmer with ang into cmisidera make a fortune in Egypt after studying the climate for a time, provided he could indke sure of noffensive race, with plene naturally a mild gay et understanding the general laws of humanits : have been however so ground down by centuries o oppression, that a low cunning has been developed painful to note. Gratitade they are unacquainted with appoints Europeans; they are lazy, except in agricalhare; sensual, dirty, and obstinate; on the other in the fields during the full heat of the sun, oins, and a camel's hair bonnet ; not revengeful, and considering their religious feelings against Christiane, an be got to work pretty well by those who stury fear, beirg at the same time just and truthful. The omen and children work almost as much as the men and bear fatigue wonderfully. It is just to say that the English workmen who have gone out to work stean-plughs, cotton gins, \&c., have generally acted batly, beating the natives, getling dol to 301. a mouth, Christians eat our Dates, and throw the stoues in our faces.

The greatest misance in dealing with the natives is he system of backshish which pervades all classes European intercourse is, however, improving this state of thirigs.
Labour might be obtained from Greeks and Maltese, but they are a treacherous and uusafe peop.e to den with, though they have the advantage of working on think of proceceling to the East, and wish to ask any questions, the writer will be hapay to auswer them to the bist of his ability

## Home Correspondence.

Agricultural Eilucation.-I entirely agree in the
conclusion to which conclusion to which Mr. Edmunds arrives in 1 is
aldecss l, fefore the London Farmers' Chab, printed in last week's Agricultural Gazelters' Club, printedi Agricultural S cicty should est.bisha a college where th to be gathered where it may; and at such a cost as t seheme was urgecl on the no:ice of the Ifighland Societ $a^{2}$ the time the Chater for elucation was obtaine $\mathrm{A}_{\mathbf{s}}$ yet however there is no symptom barried out interest being awalened in the minds of those mose interestel to obtan it. Until it is sonyhbt, indee demanded, it is not likely that either of the Nationa Societies will go so far out of their usual course as provide such institutions. If, however, they were their surcess would besecurcd. By "establishing" colleges I mean ther actually doing so, not merely aiding existing institutions. These colleges, if set agoing would requre to provide lecturers to teach chemistry as applicil to agriculture, animal and vegetable
physiolozy, and a knowledge of the diseases of plants showing in what way the pactice of agriculture can be better understood when a knowledge these various branches of lnowle.lge has been with say five lecturers delivering perhaps five lectures

The Committee recommended that the Secretary send the usual circular to members who have not paid their subscriptions for the current year.

Journal.-Mr. Thompson, M.P., Chairman, reported the following arrangements for discussions at the Weekly Councl Meetings:-Wednesday, March 15 Mr. Ellman will read a paper on the management of a Breeding Flock of Sheep; Wednesday, March 29 Professor Voelcker on Natural Deposits of Potash in Germany. The new number of the Journal, including a full report of the discussion on Sewage the week befora last, will be in the
Chemical.-Mr. Wren Hoskyns reported that the sccund lecture to be delivered by Professor Voelcker would be at the end of May, on the irrigation of Meadows by Kiver Wacer. The field experiment carrited on by the Professor during the last seazou did not produce a :atisfactory result owing to the drought He therefore propuses to repeat them. The usual grant of 200 l , had been a warded to Proftsser Voelcker for the following pateres :-

1. On the Absorption of Potashand its Salts by soils of known composition.
2. On Mangel Experiments. These two papera have already heen published.
3. On some Causes of Sterility and Unproductivences of Soils.
4. On the Comparative Feeding Value of Palm-nat Meal and Cake for the forthcoming Journal.
The report was adopted.
Plymouth Meeting.-Lord Feversham, Chairman of the Committee, reported their recommendation that Ex'ibitors' and Agents' tickets be signed on the back as well as in the gate book. That a sum of $20 \%$. be granted to the Lncal Committee for advertising in the district with a view to attract Exhibitors. Twat the Dining Pavilion and First.class refreshments be placed near the Horse-ring, and that there be a temporary fence and special entrance for the use of the contractor, the position of the same to be left to the Honorary Director. This report was adopted.
Education.-The report of the Committee, which had circalated among the Members of Council, was taken as read, when a discussion ensucd, in which Mr. Thompson, M.P.; Col. Challoner, Mr. Holland, M.P.; Mr. Dent, M.P.; Mr. Lawrence, Mr. Bowly, Lord Berners, Mr. Cantrell, Lord Feversham, Mr. Wells, Major-Gen. the Hon. A. N. Hood, Mr. Wren Hoskyns, Mr. Torr, Mr. Randell, Lord Walsingham, Mr. Dyke Acland, and the President took part, and the report was referred back to the Committee. Letters on the subject from Earl Fortescue, Prof. Liveing, Cambridge; and Mr. Robson, B.A., Secretary to the Cullege of Preceptors, were read. It was moved by Colonel Challoner, and seconded by Mr. Randell, that it should be an instruction to the Cummittee to consider whether it would not be expedient to establish an examination of caudidates as to their practical knowledge of Stock and Agricultural Machinery. The motion was negatived on division by 16 Noes to 5 Ayes.
Show Yard Contracts.-Earl Catheart reported the recommendation of the Committee, that it is desirable the extra work to be done by the Contractor at Flymouth should be subject to measure and value, and paid for accordingly; and that with a view to ulterior arrangements it may be desirable that some competent Clerts of the Works or other officer be appointed for this purpose, whose special knowledge gained at Plymouth may possibly render his future services of value to the Society. The Report was adopted, and the name of Mr. Brandreth Gibbs added to the Committee.
railwat arrangements.-Mr. Thompson, M.P. stated that the rates charged for ecnveyance of Stock and Inplements to and from the Society's Shows had been considered by the Committee, who recommended that a circular letter be addressed by the Secretary to the principal Railway Companies, calling their attention to the prejndicial effect prodnced on the Society's Country Meeting;, and consequently on the Railway Company's receipts, by the great trouble and expense iucurred by exhibitors, and requesting that the charges incuy in fure be in scordance with the tariff adopted by the great majority of the Railway Companies by the great 1862 . This Report was adopted.

Lord Berisers having moved that a Committee be appointed to consider the propriety of providing more commodious house accommodation for the use of the Society, and whether the present house can advantageously be disposed of, the motion was reconded by Major-Gen. the Hon. A. N. Hood, and the Hoase and Finance Committees were requested to report to the Council thereon.
The motion of which the Earl of Powis had given notice, viz, that it be an instruction to the Railway Arrangements Committee to seek an interview with the Chairman of the Great Western Company as to the places at which the transfer of Soock from the narrow to the broad gauge will be made for the Plymouth Meeting, was referred to the Railway Arrangements Committee.

Letters iuviting the authorities of the cities and towns in the district comprising the counties of Cam. bridge, Essex, Hertford, Huntingdun, Norfolk, aud Sulfolk, to offer sites for holding the meeting of 1866 in that district, were directed to be sent.
The Council then adjourned to its Weekly Meeting on the 8th inst.

## 

Sermons on what ISuw in Syria, Palestine, and Greece, reached in my Parish Church. By S. Sinith, M.A. Vicar of Lois Weedon and Rural Dean, Author of "The Revelation : with a short, plain, and continuous Exposition." Printed for the Author by Spottiswoode \& Co., New Street Square, E.C. 1864.
We have long had a copy of this work upon our table, and ought before this to have called the attention of our readers to the beautiful simplicity and forcible expresmess of its English, which are here directed to the highest ends.
The simple, pure, and lucid style of which it is so the simple, pure, and lacia been known to agricultural readers, who have benefited by some of the humbler uses to which the author has for many years been content to put it And it is because the Rev. Samuel Sinith, of Lois Weedon, has so long and gratefully been known to thousands tbrough our columns, that we call their attention to works of another and a higher order from his pen. The other book which is mentioned on the title-page of these Sermons was reviewed in the Gardeners' Chronicle at the time of its
publication. The present volume, so clearly described a book of travels in the Holy Land, in Syria, and Greece. Its readers are conducted through the most interesting scenes of Christian and Ancient History by one whose sympathies, experience, and erudition are the best security that all the impressions which these scenes are fitted to produce will be most effectively urged upon their attertion. The following is the Preface:-

The object of the Sermons on what I saw in Syria, Palestine, and Greece, is briefly stated.

On our return home*-for I was accompanied by my wife-a pretty general wish appeared to prevail on the part of my parishioners to know all the details of our pilgrimage in lands so endeared to their thoughts from childhood. A very simple occurrence decided what might otherwise have been doubtful ; and I met their wishes at once by preaching on the subject, for several successive Sundays, in my Parish churcl. I trusted that the teudency of what I said might be to enable hem, as a congregation, to realise more sensibly the scenes and characters of the Bible; to feel as the poor
woman felt wher we spoke to her of Nazareth, and Sychar, and Bethany, and Jerusalem: 'Why, then, I suppose it's all true.' Because we had seen, she
"This, in reality, is our pressing want. The world is too much with us. We lay waste our powers on outward and visible things which pass away, to the endareth for ever. So that something is needed to break the spell which so binds us to earth; and the only effectual thing is a real, heartfelt belief in that gracious Being, who, for our happiness nlways, would draw our affections to Himself, where He is; in Him, whose footsieps we followed on that far-off sacred land; the scenes of whore Parsion were so vividly impressed upon us on the spot, that we saw him, so to speak, evidently before us, crucified

- My desire is to convey those impressions, if possible, to the minds of others; and it wonld indeed be a suhject of rejoicing if He, who puts into the mind good desires, would bring this same to good effect, and so confirm, even in a single instance that faith, which is o the not seen."

Tho Gentleman's House, or How to Plan English Residences, from the Parsonage to the Palace; with Tuble of Accommodation and Cost, and a Series of
Selected Plans. By Robert Kerr, F.R.L.B.I., Architect, Professor of the Arts of Construation in King's College. London: John Murray.
Professor Kerr has produced an exhaustive book on a most interesting subject, one whose history is, indeed,
in great measure the history of Engli-h civilization. And it is not only the present.style of domesticarchitecture that he desnribes, but that of every precerling nge in Englisi history. The first part of the book is descriptive in as many chapters of the dwelling places of every century since the tenth. The second part discusses in general in particular every kind of accommodation which its best solution offers-and what with day rooms, bed rooms, nurseries, eupplementaries and thoroughfares, state rooms, domestic offices, stabling and farm offices, there are nearly 120 separate subjects, and as many chapters in which they are severally discussed. Parts 3 and 4th relate to notes on site and the arrangement of grounds, and notes on architectural style. The question of accommodation and cost occupies the concluding section. The whole is elaborateiy illustrated with plans and elevations of existing mansions. It is a most complete and exhaustive work on a subject which commands the interest of a large number of readers.

## Farm Memoranda.

Lammermuir Sheep Farm: Feb. 22. -Since the comnencement of the year the weather has been stormy throughout, with heavy falls of snow, establishing about a mouth ago a regular blockade, since
which date the hill flocks have been hand-fell. About which date the hill flocks have been hand-fed. About sheep, and this is generally given at twice-morning expense of mantaining a flock is very considerablemore especially if hay has to be bought at the time, as prices run up very fast during a snow storm. On this farm the Mlackfaced division have been kept on Clover and Rye-grass hav ; but having a good crop of Turnips, and fearing to draw too heavily on the reserve of hay, we have put all the Cheviots on to Turnips. They get foar or five hours feeding on the Turnip break each day, and are afterwards turned to the hill to scrape up what Heather they can from amongst the snow, and seem to be doing well. Such weather as this proves the value of a command of rough pasture upon which to turn the sheep, as where there is nothing but field Grass or bare pasture, and that covered with snow, the allow. ance of Turnips must be greatly increased. From the covering of snow, Turnips in the field appear to have been well protected from the frost; but now that the sheep are put upon the break, a great amount of labour is entailed in picking up the Turnips from under the
pavement of snow which is speedily formed by the
treading of the sheep; and the supply requires to be daily provided, as the frost transforms any that are left overnight into lumps of ice before morning. We stored a few Turnips this year in the following way, (Paviour fashion) on the surface of the ground and close together, one Turnip deep, the straw forming a pretty close covering and protection from the frost, and
from such stores, covered as they have been with snow, the Turnips have been taken out very fresh. How they may keep in dry spring weather remains to be proved, but where field workers are searce it has the recommendation of being easily and speedily done The Cheviot ewe hoggs are wintered on Turnips, and having been early put upon them in autumn we find that a considerable number of them have shed their teeth. Finding it not very practicable to put them on cut Turnips in the regular way with cutter, boxes, \&c., we had a Turnip slicer made with three blades, shank, and cross handle, with which the shepherd slices and chops the Turnips where they grow. The young sheep soon learned to follow the cutter closely, the firm snow providing a clean table from which they picked up the chips. The lnives are formed to cat the Tarnip into slices and chips, and not into angular lumps.
Whether our Turnips will stand the somewhat early demand made upon them this spring, we can scarcely yet say; but experience leads us to believe that the true way to economise Turnips in bringing ewes into good lambing condition, is to begin early and with small quantities, and so prevent them even getting down in condition rather than reserve the Turnips for a fow weeks full allowance immediately before lambing.
This spring must now necessarily be a buzy one in regard to farm labour, considerable portions of lea being gtill to plough for Oats, and all the Turnip break for corn also. To-night blows fresh, however, the
snow is rapidly disappearing, zud we hope we have already seen the worst of the winter. J. S. B.

## Miscellaneous.

Short-horn Register. - It is but little moke than four months since the project of establishing a Short-horn buyers and sellers of Short-horns might be secured, wrs formally suggested; and yet, under the management of Captain Spencer, whom men of all parties and shades of opinion selected as a thoronghly fit person to conduct it, the design has becone fashioned into wor ing order, and been followed by complete success. well met; the movement seemed natural ; and the breeders of England may be said to have given their suffrages in favour of the modertaking. Captuin Spencer has already bought and sold several hundred pounds' worth of Shorthorns of both sexes ; and, in every instance, we believe, to the entire satisfation of his employers. We have seen letters to this effect from
many of the parties, and may therefore speak in ro undecisive tone. The "Register," printed (and very badly printed we must 0 wn ) lies before us. It contains the names of 36 bulls, and of 13 cows and heifers, of various ages. Some of these animale are magnificently bred, and display pedigrees which comprise the whole length and breadth of the most distinguished Short horn history. Captain Spencer, we presume, as the character of his "Register" alters, in consequence of sales and additional entries, will print and publish successive editions, so that the public may have continual opportunities of learning the state of the market. Bell's Messenger.

The Labourer.-Who among us can place himself in imagination exactly in the position occupied by the man whom he employs? Where will you find the employer who naturally and cordially accepts exactly the point of view from which any right-minded labourer of course must contemplate his prospects? It is easier to look down with gond-will on those of lower station from your own high place, than to stand as one of them on their platform and thence look up, desirously for them, like the thoughtful ones among themselves, at their reach. And so it is rare to find a benevolence in this particnlar department which does not think of agricultural laboarers as a body needing to be managed, directed, and provided for as such-rather than $\frac{\text { as }}{}$ neighbours in whose personal and family interests warm regard is felt, altogether independently of their relationship as servants.

## Calendar of Operations.

March. - We are now in the midst of the general seed time of the farm, Oats and Barley, Spring Wheat Clover, \&c., being all to put in this month. Potato planting, too, may be done.
Oats. - In reply to the question of a correspondent put a fortnight ago, we shall next week give the illusFrations of worts commonly cultivated, from Morton's

Calondar:-
ravely rartarian White Oat in a coaree thin grain bulky crop of both straw and grain. It is grown

Coud deal in the sowtherna counties, and in the districtso It is very late of ripening, and therefore
fitted for late clinates and poor soils. The Tartarian is shorter-strawed than the The phis much earlier in ripening, and fitted therefore for districts and poorer soils.

The Naked Oat is a very prolific sort, mow li however, to loss by wind at harveat time than lise
kinds; and therefore not coming into has long been known to English agriculture,

The Hopetoun Oat is one of man plants which are due to the energy and arrieoiton verance of Mr. Patrick Shirreff, of East Lothan a tolerably early Oat, with a large panicle, and therefore properly represented in our drawind hand therefore properly represented in our drawing (D). yields a heavy grain and very long straw- - to seeds
distinguished by a small suddy mark on its is straw acquires a reddish hue as it ripens, It in adapted to lately reclaimed land and the lighter of soils, and has come largely into cultiration.
"The Sandy Oat (E), of Aberdeenshire been in cultivation for the last, 25 or 30 yeam a smaller grain than some other kinds, but jield and possessing a remarkably stiff mbraw is uedit adapted to soft and peaty soils.

The Poland Oat is a very shortsstrawed and why early variety, and as such better sble than othorm to meet the difficulties of late diatricts and ridemit The black variety of this Oat is represented at P

The Potato Oat has long been in cultivation rather a short-strawed sort, and yields the verg bes quality known to English agriculture. Its grain s short, and round, and white; the ear is sonnewhat cor-
pact. It is less adanted than some other sorts to tion more clayey soils, and it is more liable on such salto 5 a disease called the Tulip root, which is sufficimith described by it name. Potato Oats are liablotoch at harvest time, and should be cat before the strax has entirely lost its green colour.

The Barbachlaw Oat is a hardy and prolife mat adapted for late climates and moorishic soils. It jidth coarse thin grain, but is very productive both of men and seed.

Besides the Oats thus named and illustratei, man others are known to Scotel and English furmers Amones them we may enumerate--the Angns 0 its, the common Dun Oat, the Berlie and the Canadien ont The last-named is being largely cultivated in nowo tire southern counties, having acquired a high repth tion in 1860 for the quality and quantity of its jith notwithstanding the difficulties of an unuwally season and harvest time. Forty-six pounds ppr nubir [It is however a coarse and thick-skinned veriety.
"White Oats should be sown now, in preferene any other season; and, in the general conduct of them the farmer should, as a general rute, avoid enwing thens after other corn crops, by which they exhanst the la They should receive the same preparation as Barley. Oats on land in such bad order that Barley is not to $\%$. venturcd in, I know not. The common argurani their hardiness, which will give a middling proim about sufficient to pay expenses, and lea profit, when no other crop will do the like.
"The question between Rurley and Oats depods first, on the relative price. Oats may be yield two quarters or more per acre more than Bule it is theretore easy to calculate, at given priceb, tobe grain will pay the farmer hest; but it is nit in mues torgnitten, that Barley generally leaves the being a more better heart than Oats leave it, the lat hausting crop. "Oats on Lays.-It is very common husbandry put in Oats on one ploughing of old Grass, plousb layers of shorter duration. The method is, the land as early as possible, drill-press, it
gow Oats broadcast, and harrow them under. Scotland the almost miversal practice is the Oats after Grass or Clover. In England Whea more common succession. But in very Beans on better to put Peas in on light lant,
soils, and to follow these with Oats or to circumstances. I have known Oata produced inferine crops, followed by Oate next year, and produce largely, which pro exhanst tand Peas or in thus on layers; crops of Oats will scourge the land too mach

Let it, however, be well remember Grass) on the supposition that the farmer wi not allowed, to pare and burn, a method mile practicable.
"As to the quantity of seed required, 2 busher acre of the better kinds, as Yotato and will be as large a meeding as 4 bushels or the lighter

SATURDAY, MARCII 11, 1865.

meetinge fur the exiting week.

It must have been very gratifying to those who have at heart the adrancement of Gardening interests, to have witnessed at Suth Tensington, on Tuesday last, the resival of a series of Houticeltural Mretings similar to thoso which the Horticultural Society used furmerly to hold with so much éclat in Regent Street; to have listened to the explanatious of the Chairman, Mr. Wilson Sadoners, in respect to these and t'e other agencies through which the governing body there has detrmined to aid in the advaneement of legitimate horiculture; and to have suen the display which a proper sympathy with an oriject like this was the means of bringing cut. We are glad to have so unmistakeable a cause of gratulation, and we trust that such sights and such feelings may be encouraged to the uttermust on all sides, so that amity may once more prevail, for verily we have had enough and more than enough of contention and discord. Indeed, we but give expression to a very general opinion when we say that it is of vital importance to the Society itself, that harmony should be speedily re-established.
These scientitic meetings - for this is to be their distinctive title-are to take place on alternate Tuesdays throughout the year, with some few omissions, as when there days happen to fall inconveniently, and during the vacation months of August, Beptember, and Oetober. The new plants, Hnwers and fruits submitted for the judgrment of the Floral and Fruit Committees will form the basis of the exhibition, the metings of these Committees being moreuver continued on the Tueslays throughout the vacation mouths just mentioned. Papers are to be read, short lectures given, and our worthy coadjator, the Rev. M.J. Berkaley
who has been appointed Botanical Referee to the Society, will give a brief account
We would urge upon the raisers, introducers, and exhibitors of new plants, flowers, and fruits, that they should heartily support this movement, which is entirely in the right direction; and we hope that exhibitors generally may also lend their aid by bringing forward from time to
of their ohoice specimen plants. Indeed, if they would but be guided by our advice, the authorities themselves would take some direct steps towards fecuring the presence of a proportion of these latter. Were they only to place a fow small
medals at the disposal of the working Committees medals at the disposal of the working Committee object would be realised.

We received a short time since some plants of Verbena which had suffered from a mysterions disease, but which arrived in such a dry state that we could say very little that was satisfactory about them. It has, however, from local circumstances, the plants while growing, and we found that it was not only Verbenas which suffered, but Petunias, Fuchsias, Deutzias, and, we believe, in other establishments Lobelias, from a similar affection.
The roots were perfectly healthy, and so were the plants apparently in the first instance, though a few had been spotted by thrips, but the appearance was totally different where the insects had been at work. In process of time, however, little dark purple or blackish specks are formed at the tips of the shoots, extending more or less down the stem. The young leaves become thickened and deformed, the parenchym is developed in unusual abundance, the leafstalk becomes brittle, the affected parts wither, and either the whole plant becomes unhealthy or perishes altogether. In some cases the specks first occur on the stem, and occasionally the leaves thioken without much discoloration. There was no mould whatever abont the plants, and no fungous matter in the soil, though the leaf-mould which formed vart of the onmpost was scarcely so much decomposed as might be wished.
The loss of plants last year was considerable, and malters at present do not look very promising.
The point of course is to suggest, if possible, some practical remedy.

Now, it has been ascertained beyond the possibility of doubt that disease is either induoed, or thefe is a predisposition for pernicious affections, where great and sudden changes of temperature and atmosphere take place in the course of growth, or where foroing is carried beyond due bounds. It is believed that one or more forms of Orchid disease* arise or at least are encouraged by similar treatment, and it is pretty well ascertained that rust in Grapes and some other affections arise from sudden draughts of cold air in highly heated houses.

Now, in the garden in question the outtings were struck in a far warmer house than they occupied when established, and we are inclined to affection is due. A quantity of Verbens cuttings Which had been struck with nothing more than the shelter of a common conservatory, seemed everything that could be wished, in the same house where the disease was prevalent. We have suggested therefore that a careful comparison should we are sanguine as to the results. It is we believe no unoommon affection, though we have had no opportunity of studying it before, except in so much depends in every garden now upon raising multitndes of bedding-plants, the subject is one of general importance.

While on the subject of disease, we cannot help again cantioning gardeners against the introduction
of artifioial manures with whose composition they of artifioial manures with whose composition they
are wholly unaequainted. We have, for example, heard of one which consists in very great measure of sulphate of iron, a substance which, though possibly useful in minute doses in chlorotic affections or to vegetation in general, is extremely
prejudicial to plants when in excess, but has the prejudicial to plants when in excess, but has the giving oolour when exposed to the air, and weight, where the eye of the bayer is to be captivated Where the eye of the bayer is to be captivated;
and it is necessary, to avoid the expense of carriage,
to hold out great to hold out great concentration as an inducoment
*. We take this opprtanity! of stating that in our Leading
Article, March
com. Mr Wamer's case of spot should have bsen
Articla, March 4, Mr. Wamer's case of spot should have been
to the purchaser. Now buch a manure would, we conceive, be injurious in many cases; and the same might be said perhaps of some other compositions for which the public pays a great price in proportion to their real produotive vare. purposes, may be had for a small sum; and it artificial manure is to be used on a arge scale, the guines or two guineas which some cases the real value of the manure is scarcely a sixth of the market price. It is perhaps worth inquiring whether in some cases mischief is no done by some of the remedies against thrips and mildew, which, though quite innocent so long as they are confined to the leaves, may not be the absorbed by the roots from the aol on whioh they
have fallen. Sulphur is perhaps the least likely to be injurious, as it is insoluble in water. There is so much empiricism in the application of some of the vaunted remedies, even those which enjoy deservedly a high reputation when employed
judicionsly, that we oan well oonceive permanent injury occasionally to be caused, where the souree is not at all suspected. M.J.B.

We invite attention to the Floral Decoration Show which is to take place in the Gardens of the
Royal Horticultural Society, on the 24th of JuneRoyal Horticultural Society, on the 24th of June-
the day on which the Prizes for Ladies' Indoor the day on which the Prizes for Ladios Speia Prizes, of the value of 10,7 , and 3 guineas respec tively, the gift of Sir Wentworte Dilke, Bart., will be awarded for the most tastefully Droorated Dinner Tablea. Beautiful arrangement of the fruit, flowers, and china will be the test of merit, so that valuable fruit or flowers or china will not be required neither is it necessary that the flowers or fruit should
be grown by the exhibitor. Ladies are invited to join in the competition. Each exhibition is to be shown on a separate table, laid as if for a dinner "a la Russe" of 10 persons. The competitors may use such china glass, metal, or other ornaments as they please; may or may not combine fruit and flowers together; may use Sèvres, Chelsea, Worceeter, Dresden, Staffordshire, or white glasser, or both; may use coloured or plain damask : may, in short, study their own tastes. The prizes are to be awarded by a jury of ladies, assisted by members of the Royal Academy.

## KITCHEN GARDEN PLANTS.-No. I.

## The Pea.

In commencing a series of papers on the esculents which find a place in the kitchen garden, I cannot do better than begin with the Pea, which is the most popular vegetable grown. From the garden of the ducal mansion down to that of the humblest cottage Peas find a place everywhere; they are always welcome at the dinner table, and rarely are they left untouched by any that surround it.
At the outset, I confess to having experienced some difficulty in getting reliable information concerning many of the professedly new kinds. Conditions of soil and climate, together with differences of stock (to use a business designation), have such an important bearing on the trials that have been made of them, that from different localities the reports appear to be conflicting. I intend to give, primarily, the results of my own observation, and to fall back occasionally on the most trustworthy auxiliary information I have been able to obtain.
A slight introductory notice of the new first early Peas of the present season's sending ont, may not be out of place. The First Crop of Messrs. Carter \& Co. Holborn, London; the Ringleader of Messrs. Sutton \& Sons, of Reading; the First and Best Early of Messrs. F. \& A. Dickson \& Sons, of Chester (already well-known early Pea); the Express of Mr. E. Carpenter, of Brighton; and the Rssex Rival of Mr. T. Eley, of Halstead, Essex, form a batch of five new early varieties claiming public patronage. For the last-named, however, unusual earliness is not claimed-as in the cass of the others-as it comes into bearing about the same time as Daniel O'Rourke. All are backed up by
testimonials, and the three great desiderata in early Peas, viz., hardiness, productiveness, and earliness, are claimed for each of them. I imagine they will be found to bear more or less of the characters of Dillistone's Early Prolific, or Sangster's No. 1, and if only one of them should be found to combine the vigour and prodnctiveness of the last with the earliness of the first, it will be a welcome addition to the early Peas. It will be an interesting study to test them, though an
inevitable resemblance there must be between inevitable resemblance there must be between them. yet what this season establishes the next may nudo They will no doubt be tried in several localities ; indeed, thus alone can their merits be satisfactorily deter mined; and it is to be hoped that the utmost publicity
had one anespectable dealer in artifcial manures has told us he ralue was 3ss. a ton, whan the and it was found that the reat

## trials that may be made

- coults of ay to be the "earliest Pea in cultivation" By admithe. said to be from two to four, by others eight to ten it earlier than Sungster's No. 1, or Daniel O'Rourlie grows about two feet in height, pods only at the. the haulm, and yields but one gathering the topo under the most favourable circumatances that It is on gathering can be taken from it. In cold and aspon gituations, and on cold clayey soils, it is very proh Sangster's No. 1 would come into bearing befor This variety, and its synonym Daniel 0'Rourbe is but a selection from it, are the most generally grown first early Peas. The acreage of land devoted to duction of this well-known kind for the marke peak of them as being identical), is something al fabulous. It is invariably grown by contract, and argest houses send down persons to "rogue" them it is termed, previous to harvesting the crop. As they also supply, generally, their own "stocks" for soming the most careful selections are annually or biennith) made, but when subjected to field culture the pient requently develop a rapid tendency to deteriont Light sandy soils in eligible situations, where it possible to obtain them, are generally employed for th Pea harvest.
In raising early Peas for kitchen garden parpeom it has been recommended to sow in long narrow bores,
or half circular drain tiles, about the middle of March, the Peas being raised in heat and allowed to remin till they attain the height of about six incles. The boxes should then be placed in a cold frame, or on i sheltered spot, round which could be placed some mate or hurdles lined with straw, exposing the plank gradually as much as may be possible; and when hardend sufficiently transplanting them to the open grow and planting them thinly. These successive romonl check luxuriauce of growth; thin planting a/ho
increases the vigour of the plants, and under favoundb conditions Peas have been gathered on the let of Jem and even earlier.
Sangster's No. 1, has ${ }^{5}$ by a process of solection when many of the leading kinds of Peas have to anderge, appeared under the synonyms of Sebastopol, Carter Earliest, Veitch's First Early, Sutton's Champion, dc. Early Waterloo, Charlton, Hotspur, Prince Albert Early Kent, or May, and others, are only varions designations given to an old single-blossomed Pea that
is now scarcely to be met with in its original form. \& it only produced one pod on a stalk it soon gave mas the Old Double-blossomed Frame or Early Warnick, variety that ranks next in earlivess to Sangeter's Na. though I have known instances of the true type of the Old Ringwood Marrow, now somewhat ditificalt to be obtained, having preceded it in bearing. The Early Wart in generally recognised as raning Early Emperor, Morning Star, or Conqueror, is two of three days later than the Double-blossomed Frame, has smaller pods. The twain have become amod identical, and can rarely be met with purely dishiucw An old and very dwarf Pea known as Bect's Ent Gem, Tom Thumb, Pois Nain Hâtif, cc., gronde f turning in, and has also long been used for forting purposes. Thanks, however, to the indefatigable exertimes of Dr. Maclean, of Colchester, this Pea is now snpenown by a very prolific and dwarf early wrinkled Marvory named Little Gem, sent out a year or dwarfer then Beck's Gem ; the pods are well filled and bang ver thickly on the haulm; the flayour is far in adyance anything bearing before it, and it is said remarkably well. I hope it has correspendin hood in conjunction with its other good qualin When I saw it growing by the side of Becksition. The summer it was in a very sheltered
latter seems very difficult to keep true, a strong tendency to "sport" into taller gro Little Gem is quite "constant," as the fion point if favour. Quo.

## THE SMALL BIRD QUESTION

Some time in 1863 (see p. 1061) you inserted sin remarks of mine on the habits an plate amall birds, and I then proposed to nities offered, my he pirds which frequent land. I was glad at that time to be able to in praise of that very handsome and useful starling. I should be equally glad to bo in to offer favourable testimony as to tas busy and well-known bird, the House a conscientious witness I am unable sparrow has so closely associated itsel man that it can ecarcely be regarded Any one travelling through wild fuc land, heath, or plain may find some robin welcome, or an inquivitive little wren note of alarm and surprise; but the sparrow no sign. The sparrow is the
man whenever he tills the land and grows corn, and moon as the land is broken up and a farmarmy mil a company of the great aparrow forme farme
almost certain to be quartered upon then

In a state of Nature, and feeding upon the seeds of mild plants, which we mare man came upon the scene, choied the must have been a respectable and useful bind. I grieve when I contemplate his present habits to tee how much he has fallen from that state of innocence. His tastos are now for luxuries; he takes tithe from raste. As soon as the grain is formed in the ear he les his companions to feed on the tender corn. He attends the harvesting of the corn with uncakes up his quarters in the straw, nibbling at every parroms numbering several hundreds may be found spout most farmsteads, and the subsistence of the birds mposing it is grain or seed filched from the farmer, whose stock of poultry for the deficiency by feeding the fowls with marketable corn. Having followed the sparrow through the farm, where examples of his soe nre, I will next accompany him to the garden for the products of which he has also a penchant.
During the winter season, when the titmouse is busy in tho pursuit of insects, and the thrush is hunting out on the ground in pursuit of grubs, the sparrow remasy on the ground farm-yards and stables, but as soon as the earliest somn Peas appear above ground the sparrow commences his course of destructiveness by devouring the tender are often deprived of the luxury of green Peas by the mischievous sparrow. From the time of the first appearance of the Peas until their full development in the garden in my charge, the sparrow is an occasiona the sparrow remains with me, and no opportunity is loot of feeding on the coveted food; and as the young airds sppear they are conducted to the Pea quarte
From this sketch of the present habits of the sparrow it will be seen that it has given up its wild wass, and attached itself to the fortunes of man, and that the adrocatas for the preservation of amall hirds should except the sparrow from their list of pets, and allow its destruction. I do not mean exterminationaion but as we have disturbed thept in due propornature, it devolves upon us to devise means of mainthining a just balance, with a view of securing the
happiness of birds as well as our own convenience. the rule has been that all birds which interfere with the pursuits of the sportsman-the hawk, the owl, the raven, the magpie-should be shot without mercy.
 preserve indiscriminately the small feathered pests absence of their natural enemies. In summing up the charactews destroy caterpillars. sorry I cannot give it much credit in that respect. parrows' tastes may vary; it is very possible that Feroort occasionall to towns, and eating seasoned food, ophisticated but to the hedges for that which is less refers the food hit the sparrow of my acquaintance best deal with, and caterpillars suffer but slightitly from Whack. Willam Ingram, Belvoir.

## Fome Correspondence.

## this disease, both in Orchids and in other plants. About chester, where I was in the neighbourhood of Man- <br> Some time after being there, I had a cutting depenthes sent me. I struck it under a bell-glasg mas grown until it had become established. It aucThen, after a very hot day or two, the plant began to uite on the surface, which on young leaves appeared cood health, while in the case of more matured foling in Coloured ring, however formed round than a little diso ery hometer under the bell-glass, and found the excited on Lealthy development. I kept the thermometer ander The glise, and toots care to give air loured rings saon to give air when required. is grandiflora, one of which the good plants of different timas. As soon as two leaves were odacel, the young plants were taken off and placed mo way ase; these also threw out granules in the atery and tre Nepenthes, but they were rather more throughthe'cuticle, and where ost of them worked out our weare amistod to do so until no spote were left. here I afterwards called pats a large establishment $t$ ose end the general appearance of and I was East Indinn house of the collection.

was a valuable plant of amabilis and among them that it had been sulphored, I asked what it was for, as the plant appeared in excellent health. My informant did not know what disease it was affected with, but thought that it was damp in a certain stage. Some time after I saw the plant again; in spite of all that In the year 1863 I called at the game establishment again, and all was well then; in 1864 another plant of P. amabilis was seized in the same way, in this instance the affection being confined to one of the under leaves. The spot was large and quite putrid. I looked well into it, and I perceived that it consisted of two spots, one much more putrid than the other. In the latter I observed a small discoloured granule, which I set down work of a Fungus; sulphur was preely applied and the wond dried ap. In the autumn I bought several Orchids. Among them were two of Phalænopsis grandigranules in one of amabilis; the latter soon showed out as they appeared and the lant looked all right
December 24, when I had to leave home for a leaf so badly affected that I pulled it the young centre leaf had a large putrid spot in it, which I cut out. Another leaf fell off, and my plant is now a stump. I the Phalænopsis amabilis which was affected with spot last summer, and had been cured by the application of sulphur. The spot had not increased, and the other leaves on the plant looked to be as healthy as any one could wish. I brought the plant away with me; I have watched it daily, and the leaf has shown no further symptoms of decay. This morning I inspected it again, and I remarked a small black spot on a newly made might perhaps be rubbed off. On passing my nail might perhaps be rubbed off. On passing my nail puffy, and that there was a dent in the leaf. I there fore cut out the piece affected, and removed the Thaf whose wound had been dried up with sulphur. in a pot of good open material, into which the roots had freely entered. On examining the wood I found Fungus on it, which had attacked the roots. I should have said that my plant which is now a stump, was also on a block when I bought it. I find that its roots have the same sort of Fungus on them as the others, although the plant has been in a pot since I have had 1 , without
the block. I am of opinion that the first cause of spot the block. I am of opinion that the first cause of spot
is a low temperature, too suddenly increased, thereby producing eruptions, together with a sudden rush cold air when the plants are over excited, thus checking the rapid circulation of 'sap ;' small granules are then formed, making way for any "Fungus" that might be partial to such a spot. W. Craggs. [Your Phalænopsis amabilis has either a very exaggerated form of the second variety of spot alluded to in Mr. Anderson's
paper, or a distinct and more virulent disease. We can paper, or a distinct and more virulent disease. We can
see no Fungus, bat there are some curious brown bodies in the leaf which require further examination. The black speck is no form of it, but probably a condition of Aaderson's third variety. The affection of the roota is very curious, but not produced by a Fungus. M. J. B.] tates that I seem not to be aequainted with the history of this Grape, yet he confirms everything I have stated respecting it. In your Paper for the year 1862, p. 1197, I mentioned that it was identical with the Black Morocco: a statement which "T. R." confirms. I also
stated that it first received the name of Kempsey Alicante at one of the meetings of the Pomological Society-this too "T. R." confirms ; and I moreover remarked that it was a very old variety-this your Correspondent likewise confirms; and more than that; I saw the Grapes growing on the Vines previons to Having seen the Alicante growing at Kempsey, under the skilfal management of Mr . Cor, and being personally acquainted with Mr. C., I here take the liberty of quoting his own words respecting the setting of this Grape. "The right way is," he said, "to keep a dry warm atmosphere, with a free circulation of air, while setting is going on; and to gently shake the Vines, or what is still better, to draw the hand lightly down the bunches two or three times a day daring the time they are in bloom. By this means I have grown," set bunches of this truly useful Grape." Mr. Cox mad no use of pollen from other varievies. I believe tha by grafting it on the Black Hamburgh it sets much
more freely than on its own roots. Mr. Thomson' remarks are correct respecting new varieties of Grapes, and other things, that are constantly being brought under our notice. To avoid old friends with new faces, we have a right to demand every particular respecting them. Sldowd Boswotf, Osverion Hall, Worlsop Imp.
Impressions of Plants.- In answer to the inquiry school begs to inform him that the mode of taking these impressions is thas:-Stretch a piece of white jenn or silk on a cashion, and fix the Ferns or other eaves thereon firmly with mall pins at every point Prepare some Indian ink or green or blue paint witle a
(a tooth-brush is the most suitable), and brush it lightly Ferns so fised a fine dressing-comb over aud about the Ferns so fixed. Let them remain till the ink is quite imp, and then remove the pins with care. The impression will be found quite white. The veins should colour. Lovisa Jessie Brown B hue pen ia the same Having employed some of my leisure time in taking impressions of Fern leaves, \&c., with successful resalte I offer the gubjoined for the information of your corre spondent of last week, the which I have gleaned from prised under three mazine. The process may be comprinting it, and fixing it namely, excitiug the papar, nitrate of silver, hyposulphite of materials used are brush, printing frame, one or two porcelain dishes, and paper, all of which may ve obtained of any photographer. First, as regards exciting. Dissolve one drachm of nitrate of silver in two ounces of rain water. When of paner on a board lution into a saucer. Pin a piece caunel's-hair brush carefully brualh this solution on till the paper will imbibe no more; then hang up to dry it a dark room. This process had better be performed by
candlelight, as if the paper is exposed to the sumlight or to daylight it will turn black. It will be as well also when the paper is being prepared to mark it in the corner on the prepared side, that it may be better distinguished in the after process. Printing : supposing there is good diffused sunlight, and the glassof the printing frame is cleaned well on both sides, place the object to be copied on the glass face upwards, the excited paper on this face downwards, then the backboard, which must be screwed down tight. The frame may be now light; care must be taken placed facing the foll sunlight; care must be taken that no shadow falls on the
frame, otherwise it will present streaks. The time of exposure will be about five minutes. As to fixing, when the printing has gone deep enough, take the paper out of the frame, and immerse it in the fixing solution, made by dissolving 3 ounces of hyposulphite of soda in 1 pint of rain water; let it be immersed for aboat five minutes, then place it in a pail of water for about six hours, changing the water twice or three times, s as completely wash away every trace of the soda, to fade completely away. After which, hane impression as before. When dry, if the natural tint is required colour the picture like the original. R. G. D. Fry, Jun., School" will find that impressions of Ferns or any other leat may be taken thus: fastan with small pins a previously pressed leaf on white satin jean, so that it lies quite flat; then fill a small brush (tooth-brush) with Indian ink, and with a second brush or comb entire surface until it becomes of a dark gray colour Then take off the leaf, and the part it has protected from the ink will remain white. Groups of leaves can be pinned according to taste. $H$. S.
Hardy Flower-garden Plants.-Would Mr. Robinson oblige by naming and telling us something about the best of the hardy and half-hardy plants which would afford graceful and other very desirable effects in our often uninteresting though gaudy flower-gardens A. Keen.

Restiaceory Plants. - Now-a-days, when " senta tionalism" reigns in gardens nearly to the same extent as on the stage, it may seem a needless task to occupy cultivation in this country of any species of Restiace in Sedge-like plants for the most part of little beauty, having their head-quarters at the Cape of Good Hope, tinent, the southern portions of the Australian Con Lechler in Chili. Some among these plants are gracespecies of Thamuochortus, Calopsis, \&cc., which would species of Thamuochortus, Calopsis, \&c., which would
vie, except in size, with the most ornamental of our Grasses. Two different plants, under the same erro neous name of Willdenovia teres, are to be met with Neither of them have any real claim to the name assigned to them in gardens, and published catalogues. The one which, in a recent Number of the Journal of the is a tall-growing plant with a cylindrical stem, bearing at intervals on its surface large sheaths of a bright thesh colour, which contrasts numerous hair-like, often drooping branchlets studded with minute needle-like leaves, and bearing sometimes spikelets like the catkins of the Birch in miniature, in terminal panicles. The female plants are not so graceful as the male; the spikeleta are not so numerous, seen at Kew and Osford, and I am indebted to the carator of the Botanic Gardens in the latter place for sending me a fragment of the same species from the garden at Birmingham. The female plant was grown
many years ago in the Botanic Garden at Liver pool, as shown by specimens now before me. The other species to which I have alluded is R. ferruginosus and pk, a far less ornamental plant, of straggling habit, nd probably valueless to the horticulturist. It is, or Ber Kew, and I have seen it in the Botanic Garden Should anere it was received originally from England

3pecies of this fanill, I should esteem it a favour it
they would kindly forward me fragments of them suffi cient for ident:fication. The true Willdenovis teres is a very different plant from the two grown in this country under that name, and is, Maxoell T. Masters.

## Foreign Correspondence.

Eftpoarom Girbulint. - Koch in his Synopsis indicates he wide distribation through Germany, of Epipogiamplant which, when the excellent Genera and Species of Orchidaceous Plants was written, was only known to you from Austria and Siberia. I have it from the Tente burger Wald, that historically classical spot; and I have it also from various places in Switzerland. I send
you the only specimen I ever found in Holstein, where it is exceedingly rare. F. Mueller, Melbowrne.

## Societics.

Royar Horticultural: March 4 to 6 (Weekly Show).-Messrs. E. G. Hendirson sion some interesting varieties of Cyclamen, among Greaves, Bayswater, came bouquets and one or two baskets of Tulips and other spring flowering plants. Mr. Bull had Dracæns ferrea variegata, two plants Cypiipedium villosum, and the showy Imantophyllum miniatum. Mr. Harding contributed various plants guitable for table decoration, among which were the white-blossomed Cytisus filipes, Azaleas, and the pretty little white-blossomed Andromeda philyremfolia, Mr Valley, Fuiry Roses, Tulips, Hyacinths, and half-a-dozen bouquets. From Mr. Ingram, Royal Gardens, Frog Ansellia africana, Amaryllis, and Apples, smong which Ansellia africana, Amarylis, and Apples, among which Scarlet Russet, Court Pendu Plat, Scarlet Nonpareil, and Gipsy King, all in a state of excellent preservation,
Mr. Beech sent a spike of Schizostylis cocciuea ; and Mr. Marcham, gr. to E. Oates, Esq., three seedling Cinerarias, named Favourite, Gem, and Duke of Buc cleuch. Messrs. Lee furnished cut Camellias, several arieties of Epacris, and other early-flowering plants. From Mr. Meredith, of Garston, near Liverpool, came black as sloes, and still covered with a beuntiful b.oom, than eight months. They were the produce of Vines
in pots ripened early in January 1864. Mr. Tillyard contributed three bunches of excellent Muscat of Alexandria Grapes, and one of new Black Hamburgh From Mr. Bullen, gr. to E. Budd, Esq., came two Quakale.

March 7 (Floral and Fruit Committees).-Of this highly interesting meeting a separate notice will be found in another column. From Mr. Yeitch came an ex various fine varieties of Lycaste Skinneri ; beautiful Phalænopsis Schilleriana; Cologyne cristat one of the most useful of winter-flowering Orchids Cattleya Pilcheri, an interesting variety, the result
 Lorplish lilac. For this a First-class Certificate was purplish lilac. For this a First-class Certificate wa coloured Angræcuin from Madagascar; the deep purple blossomed Barkeria Skinneri superba; the fine variet of Odontoglossum Pescatorei called eplendens, to whic
First-class Certificate was awarded; Cattley Warscewiczii ; and Cypripedium lævigatum, a beautifu species from the Philippine Islands, to which was also justly awarded a First-class Certificate. In the same collection were the wax like white Rhododendro Princess Alexandra, a hybrid between R. jasminiflorun and an unnamed species, to which a First-class Certificats was awarded; also Rhododendron Princess Helena, a
charming pirk-flowered kind, in the way of but chifferent from R. Princess Royal; Magnolia pumila Cytisus filipes, the crimson Camellia named Roi Leopold Hyacinths, Tulips, and Narcissi. From Messrs. Low cane the rare Dendrobium luteolum noticed by us at p. 269, 186 L. To Mr. Sherratt, gr. to J. Bateman, Esq. glorious spike of Phalænopsis Schilleriana, with no fewer than 35 large-sized and beantifully coloured fowers on it. From spike covered with coral-coloured fruit of Cotoneaste Simondsii ; and an example of the Mouluein Dendro bium hedyosmum, a white-llowered species with an orange-coloured lip. Mr. 'Todman, of Clapham, La wome promiaing Seealing Azaleas, the best of whic bright rosy flowers, and the former especiall promising. The creamy white-blossomed Nicotian wigandioides came from Mr. Gibson. Sonchas, with glacefally pendent handsome foliage i Wilson of that of S. laciniatus, was exhibited by Mr resembling B. nodosa. From Mr. Standish cam Corylopsis spicata, described the other day at p. 172 and Camellia Reine des Beautéa, a delicate pink sort fine form and substance, and the double varicty
of these Can ellias, First-class Certificates were awarded. F. J. Grahann, Esqo. showed again his vigorous growing
geedling Russian Violet, named the Czar; and Mr. Buld seedling Russian Violet, named the Czar; and Mr. Bul sent a very interesting group of Aucubas, eight of them which, named macrophylla, fomina latifolia, mascul elegans, and mascula elegantissima, First-class Certifi cates were awarded.
Subjects submitted to the inspection of the Frui Committee were confined to some Apples and Pear from Yorkshire, chiefly for the purpose of being named

United Hortioultural: March 7.-W. Marshall Esq, in the chair. A meeting of this new Society wa last in Arandel street, strand, on The inportanc of forming a Gardeners' Benefit Club in connection with the Society was discussed at some length by Mr. Deal and others, when it was ultimately decided tha at present the Society alone should receive attention The proposed rules for its guidance previously sub mitted to the members for inspection, were confirmed, then took place to arrange preliminaries for futur operations.

Botantal of Edinburgie : Peb. 9.-Prof. Balfour V.P., in the chair. The following communications were read :-1. Contributions to the Flora of Otago New Zealand. By Dr. Lauder Lindsay. The author gave an account of the collections of plants made by
him in the settled districts between Danedin, the capital of the province of Otago, and the Clutha river. These present a parallelogram of country about 60 mile long by 20 broad. It may be characterised as the lowlands, or district of the plains, in contradistinction to the west coast region, which is that essentially of deep fiords with lofty mountain walls. It consists of a succession of plains and gentle uplands, with few hills of an eleration of more than 1500 feet. Its flora may be said to represent the eastern seaboard, the eastern plains, and, generally, the settled districts of Otago $t$ differs materially from that of the Western A!ps (which rise to 9000 feet) of the central great Lake basins and of the western fiords, whose flora has, generally speaking, an alpine or sub-alpine character. Among he more characteristic herbaceous plants of the dis rict are species of Olearia, Celmisia, Senecio, Cor yline, \&c. The author includes 58 natural orders 47 genera, and 235 species in his enumeration. He Lindsayi, Pua Lindsayi, Aciphylla Culensoi, and Crepis hover-zelandica, and ${ }^{i}$ exhibited drawings of them. Chere were also five species which had not been previously found in Otago; 30 were rare in Otago or New Zealand, or exhibited other interesting peculi arities of geographical distribution; 25 species were common to New Zealand and Britain; and 27 were British plants naturalised. Hardy immigrant plants are gradually displacing the more delicate and rare herbaceous natives of Otago and of New Zealand. In the majority of cases it is to the detriment of the colonist, whoze fields or pastures are destroyed by the luxuriaat intruders, though in certain exceptiona cases, for iastance in the pasture Grasses and Clovers, he is decidedly and largely benefited.-2. Remarks on some Seeadling Coniferce raised from Seeds Ripened in Britain. By Mr. McNab. For some years past, said Mr. McNab, my attention has been directed to Coniferm raised from seeds ripened in Britain, and I have now the honour to lay before the Society some observations relative to the few species which have come under my notice, accompanied with a series of living speci mens of each variety, showing the various stages of degeneracy, as well as the diversity of forms, which some of them assume. Beginning first with the Abies Douglasii, some of the specimens are taken from the trees originally introduced by the late Mr. David Douglas, the botanical collector : some from seedlings introduced directly from North.West America during the last ten years; and some from plants ( 18 in number) raised from seed ripened in different districts of Scotland, and now growing in the Botanic Garden. The original trees in the Botanic Garden (introduced by Dunglas), as well as those recently raised from seed direct from the American continent, are of a rich dark green colour, having straight clean stems, while the majority of those raised from British ripened seeds have their leaves somewhat shortened, and of a yellowish green tint, with bar undulated stems, and branches more or less covered with resinous warts. Many of the plants raised from home-ripened seeds have a sickly look and a stunted appearance, notwithstanding that many of them had reached the age of from 14 to 15 years. The soil of the Botanic Garden is naturally of a light sandy description," and it may seem curious that the trees of the Douglas Pine of foreign introduction should do so well while the British seedlings should in so many instance dwindle away

In several counties in Scotland we are
intormed that fine trees of Douglas Pine are to be seen reated from home-saved seed. Soil, in connection with a more vigornus state of health of the seed-producing trees, may account for the presentjapparent luxurianc of the offspring. In several instances it has been found that specimen trees (not the original ones introduced by Douglas) are set down as British seedlings, and said to
seeds. Those who state this
that, previous to British seedlings beinably no Douglas Pine was extensively and cuttings, and these layers and cuttings by lay be noble trees: After British seedlingas must in produced freely, no more plants from cutting to ever heard of. If a degeneracy exists, as In believe it does, it would be well for calt return to the original method of propagation and cuttings, instead of trusting so mach to layen saved seed. Several of those trees which to home cones freely are frequently stunted, and at a prodoce tively early age yield abundance
universally acknowledged that in the case of the Fir and Larch, the healthiest seedlings are thoe duced by large vigorous trees; and that stunted which often produce cones in great profusion, give nin to an unhealthy offspring. Snch must also have the case with some of the origiral Douglas Pinea whi had been placed in situations not altogether enithbl them, and at an early age became weak. The rew that cones are freely produced; but the eresur: any, cannot be relied upon. Plants, three or foar yein old, raised from home-saved seeds of the Douglas Pin as well as those of the Seotch Fir and Larcb, look healtiy as those young plants of the same sge mi from imported seeds. The constitational wearnem the plants raised from British-saved seeds does ma show at once, but at various periods between thwo ifteen years after germination. Seeds of the Dugh Pine are now being sent home freely, and ought to aagerly sought after by cuitivators. It does not alman happen that foreign seeds will produce healthy viguous
trees. Some of those originally sent home by Donde trees. Some of those originaly sent home by Dough produced trees which do not assume the gigantic grom One yet have the fine green tints of vigoroar tam tasifolia, is of a yellowish green colour, with brachee somewhat pendulous, having the stem and bruoker hick with resinous warts. Althongh thi tree is diminutive when compared with most of tho introduced by Douglas, still it has an amount of rigor very ditferent from seedings raised from Britishisarel pendulous trees reared from a cutting, standing side side with the green upright form, proving, instance, that soil has not so much to do with the chaog? as original constitutional weakness. I alsolay before the meeting specimens taken from 12 seedling plants Abies Menziesii, being part of the offspring of the Pinetum, Perthshire, the property of William Thomson Esq., of Balgowan, and which is without excophion the healthiest and finest trees of the kind Europe. It was planted by the late Mr. 2homen Bishop, forester, Methven, about the year 1831. Tio tree grows in a deep, spongy peat soil, where tillers freely, and cuttings stuck into the paat 8000 take root. The plants produced as seen by the specimens now lings were raised from seed from the first cones produced by the tree, may have happened that the male flowers were perfected simultaneously with the female oues exi neighbourhood various species of the the $d b$ exist in A. arge quantities, particulary, A. rubra, and A. excelsa. of them stand within 50 yards of the Abies Menzien udging from the diversity of seedlings, I clined to think that some of the young fems must have been fertilised with the pollen
the above-mentioned trees, particularly wit the Abies nigra; as it is a remarkable fact nearer the seedlings approach to the Abies more healthy and compact they become. I layb you some specimens of Abies Menziesii, raised fro yom from Balgom Notwithstanding that the seedlings were pros a subsequent date, they exhibit much the sal appearance as those raised in the Botan
Although healthy, none of them possess of one specimen which accompanies them, sa taken from a young tree struck from a caltia years ago. I have also to lay before the meeting mens of Picea nobilis, raised from British-sa The seedlings vary much, but none of them vigour of the large tree growing in the Botanic Garden, raised from originally sent home by Mr. Duuglas, or en the reared from layers and cuttings taken frell about 1 he brisish seed.ing a yellowish tint, and finally decay. Man ling a beight of 3 feet These circumstances decay is not altogether dependent on so cuttings from the original imp healthy as the original trees. monticoln-all to the British seed

The Bibliographer's Manual of the rare, curious, and usoful books published in Great Britain and Ireland from the iavention of prin ing, was compiled by Mr. Lowndes, who died in 1843 Mr. Bohn revised and enlarged the work, and publighe in ten parts.
To render it complete he has compiled an appendix, containing an account of books issued by literary and scientific societies and printing clubs, books printed at private presses, books privately printed, and the nd the publication of the of which Sir Walter Scott was President. It instituted at Edinburgh in 1823 , and was limited to 100 members. The Surtees Society, the Camden Society, the Parker Society, and many more which are not so well known, are found here.
Mr. Pohn has with great labour compiled a Mr. Bohn has with great labour compiled
cataioguo which will be extremely useful to litoran men, and to many persons indispensable. An alph betical index of eight double columned pages of th various Societies, Clubs, Institutes, sce., whose publice tions are given, affords some slight notion of th service which Mr. Bohn has rendered to the student o English Literature.

Messrs. Longman announce a new edition of Brande' Dictionary of Science, Literature, and Art, re-con
structed and greatly extended, to appear in 12 monthly Parts, commencing on March 31. Considerable addition have been made in many branches of science, especially

The Report of the Manchester Field-Naturalist Society indicates a flourishing condition of that very useful institution-an institution of a kind we could wish to see multiplied in all the great centres of popu lation, or indeed wherever a sufficient number of persons could be got together. The membere appear to work in good earnest: as indications of which we find
scattered through the report many scraps like the following: - Mr. G. E. Hunt adds to the list of Manchester Mosses Physcomitrium sphæricum, found sparingly in three places on the borders of Mere Mere, this being only the second occasion on which it has been gathered in Britain. The first was 30 years ago when it was detected in the same place by Mr. Wilson Mr. Holland finds Geum rivale and intermedium in considerable plenty close at hand at Mobberley, th held of one of the summer excursions, and draw attention to the curious physiological peculiarity of the
former, in elevating the fruit far above the withered calyx and stamens, considering that this indicates tendency towards the diclinous structure familiar in some other Rosaceas. On the occasion of anothe singular to Norcife Hall, Mr. Grindon exbibits anited so as to convert it into a tubalar cap resom bling the pitchers of Sarracenia, and which, taken in connection with Cabbage leaves that are occasionally found in the same condition, he regards as throwing light on the real nature of these organs.

Catalogurs Recerved. - Thibant \& Keteleer' (Paris) Catalogue Gernéral des Plantes indicates a very extensive collection of choice plants of all kinds, from Orchids and stove plants to Phloxes, Pelargoniums, General Cerns.$T$ vees is an extensive, well got up list; also Catalogue of Vegetable and Flower Seeds.-Fovoler \& Son's (tulas gow) Catalogue of Seeds.-William Paul's New Koses fre., has for its most prominent features the new Rose of the season, of which there are five to be let out from Waltham; and Beaton's hybrid bedding Pelargoniums, of which some 16 will be ready for distribution Waltham. Among the five new Roses occur Giory of Princess Liclitenstein, a hardy white, with large ful globular flowers: both of the H. P. class.-Carstairs Sons' Descriptive Catalogue of Florists' Flowers com prises most of the leading flowers, including a goodly ist of Fancy Pansies.-Maurice Young's Catalogue of New and Rare Plants, Conifera, \&c., is well prepared and comprehensive; the collections of hardy trees, American plants and Conifers being of considerable exmont of Pelargoniums, Fuchsias, and Verbenas, for which the Toilington Nursery is always famous.

## Garden Memoranda.

Thi Karl of Derba'g, Krowslity Park. -Turning that there are several ranges of houses, which have been builtat different times. The oldest range consists of houses, which must have been unique in their day, for they have not only length but breadth to give them a character Few lean-to-houses for Vine-cultivation, even now, are
erected 24 feet wide with a 5 -feet stone pathway; and
few practical men will deny the advantages, in a cultural point of view, of having scope for "length of canes to obtain quantity and qual:ty of fruit. This very range is said to be the oldest in Lancashire; and as to the Lord Derby's statement, that he sees very little dif. ference ia their general appearance since he was a boy Curiously enough, all the old Vines that one meets with, if in a healthy condition, produce more highty. coloure 1, and some say better-flavoureal fruit than younger samples subjected to the same treatment Especially is this the case with Mascats. Some line of
demarcation must, however, be drawn as to age, elee it demarcation must, however, be drawn as to age, elve it
must be at the expense, at ail events, of flavour. One can quite well concelve the green changing into an amber culour more rapidly in the case of an old Muscat Vine, which seldom if ever produces bunches or berrien so large as those from younger plants; lout as yet it is same lypothesis as to superiority of flavour. good with the colour and age of Vines doee not hold the problem The lom visers, be looked for
Vines above referp, which contains some of the old years had an accession of young planta, and a late two variety of ants has been introduced, which Mr. Freeman intends to prove thoroughly, growing those only which he inds to serve his purpose best. The old Vines, and will be cut out as the others incrense in practical test house, feet wide is between 60 and 70 feet long, and 24 Hamburgh, Lady Downes', and Black, Alicante Foster's Seedling is rather a handsome looking bunch with asmall white, or yellowish. white, round berry having a sort of Frontignan flavour. Chavoush is much after the same style, with the berries a little larger, but scarceiy are rementapoured sort. Werther of them, however, are remarkable, and they are decidedly inforior to any Black Alicante were growing side by side the and laving more oblong and larger berries and bunchesapon the whole pretty evenly matched. As to appear ance I should prefer the latter, and decidedly so as to flavour. If there is a point of superiority for angthing being rather more free and vigorons. Since the advent of the Black Alicante, there is a disposition to plant it largely as a highoclass late-kcening black Grape, and even to graft it on Lady Downes', of which there ar now numerous houses planted in the comutry. Museat Hamburgh in another honse was in excellent condition as to colour, growing on its own roots. Another house of the same size was chiefly a Muscat house, the was nal part of the crop being cut; what remained in colour. There or bunch and berry, but excellen Downes', which had made excellent canes, as brown and hard as a piece of half-dried wood, which is anre to be a great success this season. The carliest house had been started some months, with the view of cropping out the old Vines, and getting a few bunches in the eariy months of the year. This mode of treatment seems to be woll enough as an experiment, bnt a few years practice prove conclasively that you wonld wear out every Vine operated upon in this way, as the plants refuse to rest ia the height of the growing season; 80 advance of our forefathers, who used to bezin to force permanent Vines early in October. In all the six in this range devoted Mr. Freeman is going cautiously to work, introducing as many young plants and rooting out, as many old as will lay a good foundation for future years, and not limit too seriously the supply which such a family as he serves, with the means placed at his command, has a ouses expect. There are aiso iwo span-roored low op and the calurm a capital anviliary to the range of main houses, and can be forced for early purposes without having recourse to extreme measures with the permanent Vines
A range of Peach-houses, 90 feet long, contains a collection of trees in fine bearing order, and keeps up he supply until those out of doors are fit for use. Besides these there are succession Pine atoves, full of cliriving plants, to supplement the fine large fruiting house, a woodcut of which has been given at p. 125, (and which it may be mentioned, as well as the Conservatory, and other recent erections, was designed and Mr. McGerrow). Correepond ull of Figs and Oranges in pots, in good order, with ruit-shelves filled with French Beans for forcing pur poses; the one mostly grown here is Newington Wonder Then there are Cucumber, Melon, and other serviceable pits for growing and forcing vegetables to a large extent some of the older ones being heated with flues, and al those recently erected with hot-water pipes.

The plant-houses are not numerous, but they are very serviceable, and contain a collection of plants for and all, and such-like purposes, such as I have never see acelled. There are two span roofed houses, the on 0 feet long, and the other about 50 feet, full of nice igorous plants, which are only grown for a year or two and then thrown aside, others being propagated to take their places. Such plants as these are more
than nuaally interesting, be ing serviceable nrt only in extensive places like Knowsley, but just the sort of thing Which ladies who have only a thouse or proninent of those therefore give the names of the more prominenta, a very
used for winter decoration:--Plumbago rosea, used for winter decoration:-Plumbazo sikea, of rosehandsome subject, throwing up long spikes of rose-
coloured flowers fronn plants one year old; ; Vinca rosea coloured flowers froni plants one year olt, blue plant of the Gentian order; Clerodendrons different sorts Justicia speciosa, than which there is mothing shore graceful or more easily managed; solanum Hapsicas rum roseum, much-neglectel Melastomad, and rum wety one; Poinsettia pulcherrima, very dward very pretty one; Poinsettia prichon ha, very dwarnl grown, and showing large crimson heads; Euphorbi acquinifora, dwarfer than I have seen it before Gesnera ciunabarina, in hundreds-and nothing can be fiver from Neiv Year's llay up to April than this magnificent-leavel and brilliant-flowered Gesnerwort; several dozens of donlle Primulas, growing Wuculia gratissima, showwing large cluaters of flowers The way the latter is managed is this: a plant is Allowed to grow vigorously, and every shoot is layered into a pot durting, and flower all the winter fll thece plants have a little bottom heat and the linnse or surface heat is at no suason kept much alhove what is called an intermediate temperature plants that we have deserihed are moatly yearlinuss, nud the results slinv how advisable it is for such soft-wooded tender plants to manare then in this way
The greenhionse plants are of a like character and cqually seleet, but they require more se, Aato the , nd
them to a flowering state. Geraniums, Azalco them to a flowering state, Geraniums, Azatens, and
Epacris, with a few winterffowering Heathe, such as hiemalis, predominate here. There were one or two plants of Clianthins Dampieri in flower, not a whit too highly spoken of as a deecrative plant. There was also a number of very nice Diantims hyhridus multiflorus, whieh is avillently as free llonining ns its nume inplias; and a few bneketofal of Tropmolum Eclipse, which lonked graceful as a hanging plant. Then in another place was Azalea amuena, grandly managed, every point showing a hlomm bud, and many dezens of plants of
thenn; mot to speak of the more common deeidnous thenn; mot to speak of the more common deecidnous
Azaleas, :Hhoiodendrons, \&c., which are kept in a reserve ground for foreing to furnish cut flowers.
The fruit romm is a large commodious building, from 80 to 100 feet long, with numerous tiers of shelves all round, and a table running all the way up the centre, with three tiers of drawers chiefy hiled specimens of all the Apples and Pears that are gathered and stowed away, so that the family may easily examine them. 'The sorts of Pears that were particularly fine among a numernus collectinu, are well known as a rule, to succeed best all over the country. wero:- Jatie Loulise in extra fine condition, being both larre and well coloured; Beurré d'Amanlis; Grosse Cale ${ }^{\text {basse }}$ from dwarf espaliers, very fine good, some of the samples cracking, as this sort very generally does durin. berg; Demré Din; King Edwart, of enormons size;
Louise Romne of Jersey; a very beautiful looking sort named Hep $:$ orth, but tough and coarse grained in the Hesh; Plarish l Beauty; Beurré Langelier, a nice Vicar of Winkfeld, also fine, but tender. The Apples vere quite as remarkable for size and paradice and Newton' Pippins from a south wall were extraordinary fine samples, Prominent among their fellows stoodRose of Sharon, New England Pippin, Court Pendu Plat, Kerry and Ribston Pippins, Reinette du Canada, and Alfriston. The house, which has been recently built, is well finisherl, and what is often neglecter in houses of this description containing ar interesting collection of fruit, is here specially provided, viz., ample wirking space and means to provide abunhouses keep best in almost total darkness, and here, thongh there are numerous windows for use when required, they are kupt at other times closed with
shutters. Ventilation and artificial heating, 献hongh only sparingly used, are also well providod for,

The garilens at Knowsley, under the carefnl and suc cessful superintendence of Mr. Freeman, are exceedingly well appointed, horticulture being fully represented in all its branches, and likely to be better and better represented every year. The only things that we have now to notice are a Mushroom-honse, 60 feet long, with the usual double-tiered beds, part of which was howing a dense crop; and the head gardener's Cottage. The latter is of recent erection, and is a large commodious building, bandsomely finished both outside and in, and is situated at one end of a neatly designed flower garden. What a pleasure it is to see the chief of this garden entablishment provided with house accommodation of such a character, showing how much his services are appreciated by a nobleman so distin guished and practical as the Earl of Derby. J. 4 ,

## Miscellaneous.

Soil for Tines.- Porous land, particularls when
and light. The more calcareous the soil, the drier and mnre friable it is, the better for the Vine; the water which falls at intervals permeates freely to the roots, the surplus is carried off by the pervious nature of and generous. Granitic soils, or those mingled with dec.mm. pused particles of that rock, also yield good wines. Sirong argillachous loam is very prejudicial to the Vine, it not only restrains the free expansion of the nots but often imparts an earthy taste to the produce In central France it thrives in argillacenus state; in the nortl, fat saud, with a mixture of calcareous loam, is preferred. Almost every free combination of earth moist a site, or too rich an animal manure, are well known; as are the exhaustion and deterioration soils, which, though formerly the homes of generoua quality In Italy sicily the choicest plants grow quarith Three-fourthe of all Vines are planted on hilly ground, and wines of the hichest class are made from such as are reared among stone and loose pieces of rock, with little attention avi highly-dressed land has never produced wine of preferable quality. In districts where the summer is sufficiently long and warm, and the tomperature thronghout the year nevir ainks brlow a minimum of $50^{\circ}$ of Fahrenhoit, the Vine matures unthing but ripe and well-flavoured fruit; and when the hearing exnherunt, the quantity as well as quality is dependent entirely upon the climate. The Grape that furnishes the most siccharine mattor makes the best wine. Denmanis Vine and its Fruit.

## Calendar of Operations.

(For the ensuing wreek.)
Atthotar the weather is still somewhat cold and wintry, a collection of the best hardy annuals may now be sown ; they are of most service before Verbenas, Pelargoniums, and other beldding planta, conne to ner-
 at liberty we would reponmend their being sown in small pots in loamy soil, and not turned out until they are slightly pot-bound; the flower then gains the predominance, and the great proportion of this above the leaf constitutes the chief beauty of most annua's.

FLOWER GARDEN AND PLANT HOUSES.
Crocuses in pots have blossomed beautifully this year, and out of doors there is also a fine display. Among yellows, lilacs, and whites are some very large and showy kinds, which when planted in parallel rows close together, have a striking effect, a point that slomld not be formotten at next planting season.

F'cheras. - Where fine specimens of these are required, a moist atmosphere, with a slight amonnt of shading, will cause the siny sorts to make wood by retarding the flowering principle. Those wintered in onthouses or cellars, if not already done, should now be brought forth and potted, if possible, to give them a start for the decoration of lawns or the fower-garden.
Hyacin'tis. - These should not have too much heat they lose much of their effect when the bells are too far asunder through too much excitement in proportion to light.

New Holland Prants. - Now is a good time to slift such as require more pot room

Orcards.-These will be pushing vigorously, and many on blocks and baskets will require careful attention in the way of watering, which should be done on sunny mornings early, and air given freely for a comple of hours, in order to prevent moisture from lodging amongst the burls and tender ehoots.

## ORCING GARDEN

Cvotmariss - Make it a point to tmpn one an more of the linings frequently until May. See that they are in good condition as regards moisture, and take care that no burning extends into the bed

Pigs.-Provide against red spider by copions syring inge.

Kidney Beans.- Secure abundance of atmosplieric moisture to these, and water them continually with clear weak manure water.
Psaches. - Trees on which fruit is swelling will now begin to enjoy a little liquid manure; guano water, clear and weak, will be found of great service. Gross shoots need scarcely be fearad with this applipation, provided all luyumiant wood is stopped as soon as it is 5 or 6 inches long.

Prarss, - It shonld be at all timen underataod that a sudden check of any kind whatever in at variance with the whole cconomy of Pine growing. In shifting in spring this frequently happens if the plants are pllowed to stand unplunged in a temperature of $50^{\circ}$, Whilst the tar bed from which they were taken has probubly been 85. Such a grant dimerepancy is found to bo followed by pernicions effects. Attend well to atmospheric moisture ; rest assured that as far as the Pine alone is concerned, it is not easy to orerdo it at this period. Vinks. in heat whenever it can be done
Vines.-Look well to the bottom-heat outside. Endeavour to keep your fermenting material to $80^{\circ}$ or even $90^{\circ}$ if possible. When material of this kind in suffered to become inactive at this period, it is worse than useless, Early Grapes now stoning should be rut aver mirpes now stoning should be rut
on all ordinary $85^{\circ}$ or $90^{\circ}$ early insthe allow the heat to rive we may now expect soon to get, siukiug to $65^{\circ}$ at wint.

HARDY FRUIT AND EITCHEN GARDEY.
Protect fruit; blossom when it appears by all pras means. Straw-ropes, mats, canvas, bunting, n+s, F
boughs, and fronds of Fern, should all, or any of them be in requisition

Broccole-As soon as the ground is in a pros Sprouting sort.
Speed, sow a little of the Parim HERBS.-S

## sown in heat.

Tomatos.-These may now be sown, and raised in
Turnips. - If not yet done, lose no time in rettir in a little seed of the White Dutch on a warm berme.

 Mean temperature of the wock, $\frac{12}{2}$ der. br low the arerige STATE OF THE WEATHER AT CHLSHENK,

## The $\mathfrak{F g r i}$ ultural Gatette <br> SATURDAY, MAR('H 11, 1865.

THe report of the Bath and Went of England Society in another column, calls attention to a matter which is exciting much attention in the North of England. It is declared that in the present state of the latw there is no protection fur the property of the farmer so far as sheep and cattle are concerped; that we cannot compel a vicious dog to be kept under proper surveillance unless it gan be proved he has already worried sheep, and that his owner kpows it. A Bill placing the responsibility of misehief done upon the owners of suoh animals has been introduced into the House of Commons, and a petition in its fayour has been widely circulated by the Durham County Agricultural Society.

The propeedings of the Weat Riding megistrates, owing to which Sir Grorges Gbey issued the order forbidding the travelling in daylight of locomotive engires on highways in the district of Lower Agbrigg, have had this further result, that the Steam-pough Company of Wakefield have withdrawn their apparatus from the district in question, and suspended so many of their machines as were enploged in it. This is the natural consequence whigh must follow the Hoyr Secbetary's order whepever it is enforced. There is no reason why the order if needed anywhere is not necessary everywhere; and the ulfimate consequence of it thus must be the entire distruction of the business of hiring out steamoultivators, on which so many clay-land districts are already dependent.

The Royal Society for the Prevention of Cruelty to Animals have widely published the history of a recent case before Mr, D'Eyncoubt, the Clerkenwell magistrate, by which the praotice of exposing shorn sheep for sale in frosty weather wes shown to be illegal, and in contravention of
the statute $12 \& 13$ Vict., cap. 92. They declare it to bo their intention diligently to proceed against offenders in future seasons, regardless of tho results which may follow on convietion.

Barom Liebia has addressed another long report on Metropolitan Sewage to the Lozd Mayor. He is this time anzions in the interests of the public to expose the fallacy of the NapibrHope plan for turning it to agoount. These gentlemen, according to him, propose to take the drainage of North London along a oulvert, failing 9 inohes per mile, from the Abbey Mills to Maplin - there to pour it over some 20 square miles of surface whioh are at present under high w.ter-thus converting that which at low water is a mere slope of sheer mand, some 2 or 3 miles wide, into dairy farms, viclding 40 or 50 tons of Grass per acre, as at Craigentinnr. But such a project is altogether baseless-all the caloulations as to orops, returns, se., are absolutely fabnlous. The soheme is "like a soap bubblo, glistening with"hright colours, but inside hollow and empty; thero is not the slightest doubt that everr peany exanh in in that. frivolous pndertaking will irretrievably be lost." For-and this is all the argument-thire is sand and sand. The sands at Craigentinny do indeed Ficld Grass worth 20\%. and 30\%. per acre; but then, what are the sands at Craigentinny? "Ar exact emparative investigation" of these and those at Maplin "seems not to have been thought necessary." And therefore the probability that the experience of sewage on the ope will be paralleled by the experience of sewage on the other is altogether without foundation.
It appears to us that Baron Litebia is at the least as unphilosophical in denving the asserted parallel without the necessary examination, as others may be in deolaring it. More so, for the latter do proceed upon experience, whereas Lifibri's conolusions are mere speculations. His reports, throughout, are in the very teeth of the Baconian rule which requires you to guide your reasoning by faots, not to ascertain your facts by mere reasoning. In his valuation of sewrege he is guided not by the oonolusions to whioh the actual analysis of it leads, but by the eonclusions to which a reasoning process leads him, applied to various assumption a regarding fool, digestion, and smit iry arrangements, The enormqus sums which he declares that Loadon is at present warting at Barking are ascertained, not by an actual examination of tio material as it is, but by an enumeration of its contents after he has determined by his unrivalled reasoning faculty what it ought to be. And in his present letter also there is an orror of very much the same kind. There was no aclual examination in the first instance of the liquid to be used, and there is no actual examination in the second of the land pn whioh it is to bo meed. But the Loohond and Craigentinny experience is deolare 1 to be the result of Lidinburgh sewage upon land of various quality, "loam," "sand, with trap rook beneath it," and extn "strong olay," there words being utterly indefinite, and conveying no certain meaning. Morenver, Edinburgh sewagr, it is argued, mist contiva areat deal of strect-swcepinc asd other material, the result of disintegrated trap rock, and "must carry in the form of mud towards the meadows the detrituy or mechanically ahriled matlers of the strepts." What it does pontain and what it does parry we are not informed. Libbia, moreover, makes a good doal of the assertion that at Loohend this mud is colleoted by deposit in a pond, and thence oonveyed an a top dressing over the poorer parts of the land
The conclusion to which he leads his readers is that the poor sands are inevitably the poorest in thi ir prudace, that the richer loams which were riginally the best are always the best, that "the higher sitnated meadows, the character of wioh is most remote from sand, must produce higher crops than the lower plots, whioh originally were nothing but fine sand." We are also told that "sand middling tine when comuletely saturated with water, takes up in its power onc-filth of its volume $;$ and a bod of sand could not consequently absorb per aere more than 100 tons of sewage. The largest quantity of sewage brought on $t$, such a sand would percolate through without enriching it."
Unfortunately the whole statement is writton in ignorance of the facts. The low-lying loams and clays are the poorest parts of the Lachend and Craigentinny sewage farms. The poorest :ands through which the gewage "percolates without enriohment of the land," yield 20$)$. worth of (irass per aote ampually. The sowage pouzed over all
brings all to pretty nearly one standard of produce. Church, Wesleyan, Baptist, Independent, and other The merest barren sand, known as such-not indeed by the tests of the chemist, but by those of the great laboratory of Nature-by the condition as to vegetation in which they were before
the sewage was applied, yield now 40 tons of Grass per acre. The portion next the shore has indeed a thin skin of black soil, the result, we presume, partly of mineral and partly of regetable deposit, during its 40 years or more of sewage application, but this appears to be little more than
a colouring of the original sand; and dig 2 or 3 inches down, and you come upon that, of the original colour.

In truth the whole affair is a hand to mouth feeding of the plants direct from the liquid manure. The sewage is used over and over again in order to exhaust the food for plants which it contains. Excepting by its mere mechanical offices and structure, the soil has very little indeed to do with the result. It affords a standing ground for the crop, and it affords a sufficiently open texture for the trausmission of the liquid: and this liquid feeds the crop. Where it is a good loam, and also free in its texture, with a sufficiently rapid slope of surface, the crop is best-most valuable rather perhaps because earliest than because it produces more from month to month than where the soil, a poor sand, is equally open, and as favourably conditioned regarding slope and aspect. It is the stronger clays and the Hatter surfaces, neither of which permit a rapid flow over and through the soil, that are inferior. And the best land of all, worth $5 l$. an acre without sewage, to which Mr. Miller, of Craigentinny, conducted the stuff by steam power, has proved a failure, and has been at length abandoned as a sewage experiment.
The broad and obrious facts to be read at purposes the and elsewhere are that for sewage yield a profitable result-that it is rather by a direct feeding of the plant than by enrichment the soil that we must expect to succeed-that the again-and that any other method of distribution than that of ordinary water meadows, by mere gravitation from surface channels, will exhaust the profits of the undertaking.

## AGRICULTURAL EDUCATION.

IN answer to some of the many questions upon agricultural education which are now discussed, I will give you some outlines of my remembrance of our It lis a large agricultural parish, and 50 years since contained above 3000 inhabitants-now nearly 5000 . Such was the advanced state of education at that time, but few of its inhabitants were capable of intelligently manas thrown upon the hands of the matter of course two or three influential farmers. The farmers soon had everything their own way. The Charitable Trusts were also in their hands, and the lands were let to their dependants, realising some 3000 . per year. Now (and would include mole catching, sparrow catching, and other like et ceteras, and the accounts would run on for many years without passing. The "charity made out the rate-books, in fact was "the factotum" as vestry clerk. Many of the farmors could not write their own names, or at most imperfectly. The state of scholar who could write a good hand and cast up common accounts, beyond which it was superfluous to go. He was then fit for business, and was soon found school was a monstrous innovation, and would bring down upon the hapless father's head all manner of petty sneers at his presumption and aiming
greaness; and as for the daughtors, poor things! "what do they want to know?"-a little reading and sewing is plenty for them. Yes, this in my young days. The young farmers would only "talk of quoits, and cricket, \&c. - the young "'ladies" of poultry and butter, goslings and ducklings, \&c. Now or she was looked upon as a prodigy. The theneral cast of society partook of gross ignorance and much Tanity, which led to much petty jealousy and strife. for its unhappiness and irreligion. Gradually know ledge became valuable, and was sought after by all aggregate and at the present time, taking them in the conducted population. We have courageously and most learn, i.e, established many means by which all may learn, i.e., reading and other Societies of all kinds, whools, Tracts without end
congregations We have Educational, Agricultural,
Horticultural, Floricultural, and Poultry Societies and Horticultural, Floricultural, and Poultry Societies and appears to open before us in the broad road to knowledge. Why ! no abuses or matters exceptional could stand before all this. So now we have everything fair and above board. Churchmen and Dissenters and politicians of all grades cheerfully unite in promoting and neighbourhood.

I often look back upon my own doings and participation in promoting these improvements. I have endeavoured to take my slare therein. I well re
member the old dame and her school where I first attended; next I went to a common day school, and to" "top up "I was sent to a large charity school, where the master was privileged to take a "few boarders" (we had 46 or 47, besides 200 charity boys); I con-
tinued there one year and a half, leaving at midsummer, when I was 12 and a half years old-not 17 as is now When I was 12 and a half years old - not 17 as is now
the case. My first corn stack I built the following harvest, and until I was 24 took my regular part as workman on the farm which I still occupy, where was born, and where my forefathers dwelt and farmed before me.

At the age of 18 a neighbour permitted me to read his newspaper-"Evans' and Ruffy's Farmers' Journal." I soon perceived that wondrously clever farmers as we were, we did not know everything. We could grow our Oats, Wheat, and fallow crops successively. Who could beat that? We could make our Long-
wools fat at three and four years old, and heary sheep; many could not do that, could not make them fat We brought into use the "two-haled" plough, and threw out the one-haled Dutch plough; was not that a feat? In short we knew how to farm; if we did not. who did? I read of the introduction of bones as a manure-how ridiculous ! I read of the Suffilk drill What! put the Wheat in all in rows-how foolish! It ought to be scattered equally over the land. Give me the "seed-hopper ;" I can beat all your drills. I read of the threshing machine in Scotland; very com-
plicated and inexplicable. Then I read of Swedish Turnips; hardy enough to stand any winter-very likely-wish they may. I kept reading on, i. e., of Holkham sheep-shearing, Wuburn gatherings, Southdown sheep, new Leicesters, improved Short-horns, horses; and then, again, of Bakewell, Ellman Yosdale and men of that day; till I began to think I knew very little about it al!, and if they were right, we after all knew very little about our real business, and had very much to learn. We have much to learn;
we have been learning ever since, and wonderful advancements in the science and practice of agriculture we have seen, but I verily believe that at 60 years hence some sexagenarian will look back, as I am doing, and with much pity will deplore the ignorance of these present times. It savours highly of the pedant and the presumptuous to imagine that we have attained in our time nearly to the topmost stave in the ladder of perfection. Why, the scientific department of agriculture is scarcely known, much less practised, and nowhere to perfection. So far as regards field culture, no one can set bounds to the beneficial application of scientific aids, and if here and there a mind strikes out from the common ruck, and achieves success, it is but one instance. We want an educated body of farmers educated in the best sense, educated far in general knowledge, educated highly into the mysteries of
nature, educated in that precise knowledge necessary to enable them to extract the most profitable produce from the soil, educated fully into the geological, chemical, and practical requirements of soils, and the true management thereof, an $d$ their crops. At prosent much of it is conjecture. We follow a known practice somewhere. It fails with us. Why? Because of our ignorance the aid was not adapted either for the soil We climate, or crop. Then comes in the animal economy We want our young farmers to be educated in all
matters relative to the true business management farm stock. Their breeding habits, unanagement, food, propensities or peculiarities, diseases. Their Breeding i.e., the best principles and practice ; Habits : provisions and appliances for their rest and comfort; Management: attention, feeding, cleaning, lairage; Food : an Grasses, roots, bulbs, and tubers, all the tribicial Turnips and Cabbages, all the varieties of corn-cake and cattle foods, how to make them, and how most profitably to apply them in feeding stock; Peculiarities: reedom, confinement, warmth, air, dic.; Diseases : a life-long study of itself. There is no fear of our next race of farmers being too highly taught. Just look at what we have passed through the past 60 years. The race must most in fact turned upside down. Our nex race must keep it righted. O. F.

## THE AGRICULTURAL LABOURER.

The following admirable speech on this subjoct was delivered by Mr. John Grey, of Dilston, at the first meeting of the
Rnyal Agricultural Siciety at Noweastle. Lord Portman was
chairman claseses, and of the influentace illustration of the oo-relations of
Mr. Gerry, of Dilston, said:-Notwithstanding th
very kind encouragement which certain friends are
inclined to bestow upon me, I cannot but feed it
nervous thing for a bumble individual like
be thus called upon to nervous thing for a bumble individual like mysel
be thus called upon to occupy the situation in
now stand. It has been my now stand. It has been my lot, at some times
distant intervals, to speak to sime fellow-countrymen on suljects conneections common interests-the agricultural interests land; but I have not anticipated being cilled of address a meeting so distinguished for rank, so it in numbers, and so important in claracter, ${ }^{2} 3$
which I now have the honour to survey The toast which has been unhappily convenitter hands, is that of the labouring classes; a sulbjen which none could feel indifferent, whether reajacle!
involving the welfare of so lare fellow-subjects, or exercising, as it do portion of influence on the general well-being of society, and of whole moral atmosphere in which we live ind have satisfied myself with making these remath announcing the toast which has been ent to my care, had not that toast been committel:
with a request, that as 1 am considered more conversant with the circumstances of ing classes than some other gentlemen, accompany it with a few remark, which I sionlid pre made, had $I$ consulted my own feelings on present occasion. Those whose lot in life compelat management and good conduct they may do m . to increase their comfort and respectability, $m$ mon greally aiter their condition or improve their cirent on which their individual exertions. The e.uplognem and their families must come from sources ow wher they can exercise no control. We must then low others than the peasantry themselvez for any mater improvement in their condition. The tenant farmen are the parties generally by whom the pensantry employed, and much might be done by their cousifon tion and kindliness. But then, again, the m
which the farmer employs and the spirit with whin
cultivates, depand greatly on the tering on whi holds and the encourageinent which he recives his landlord, and thus the various classes of scietr 10 dependent one upon another, and a direct chain of cor munication is established between the owner end tiller of the soil. It was admitted on all hands the duty of the landlord to supply suitable dwelinen well lavourers on his estates, and it is his dne well as his interest to let his land to such tennts, on such terms as are likely to ensure its gond and liberal treatment; and just in proportion as a liber system of cultivation prevails will the wellare of thi labourers be.
No one can have travelled through the different pro. vinces of this land with much obsergation, withny having discovered that the condition of the persuutry is generally a sure index of clothed, and of cheerful aspect, theu be assure! are well employed and well paid; but, on the contr if we see them with comfortless and ill-furoisho
dwellings, themselves ill-clothed and their childrea ill-educated and of squalid appearance, then surely shall we find that district ill-cultiratel they aved; so certainly and so sympather they act and react the one
of the land in England, still lield by tenants-at-will-or regret and and no system I believe is more calculated thr his to put a check upon extensive and improvement.

Two things are indispensable to the good cultirnser of the soil. The one is, adequate capital in the hard of the occupier, and the other, the knowl necessary to apply that capital to prontial and the consequent absence of good cultivation, the occupier of the means of obtaining cappital, san the inducement to acquire knowledge in a state of comparative sterility, and the in ate stationary ignorance. I know it is allem in favour of this system that such a good under prevails between landlords and tenants, of tenancy rarely occur, and that so engendered makes up for the want of security, and amilline to admit, extent the existence of kindness on the landlord and of gratitude on that of the tenant. Is willing to recognise the feeling of matual reciprocal obligation and attachment, one of the sweetest ingredients and course ; but is that feeling of necessit and more genuine in the case of tenants-a $-\ldots .1$..... that of the more independent and more rudgring tenants, who hold upon lease and grudge the improvements they make that they have landlords capable of appreciu value of good tenants, and willing to give preference at another letting. time to particularise, of farins which years, and which have advanced under rental of $200 \%$. or 300 l . a year to on and ten hundred, without outlay beyond the erection of needful buikigs,

shout harvests that robe our fertile plains, be gathered by them in peace and in plenty-and very long may all classes in this favoured land, combining their efforts tacle of a powerful and prosperous-a happy and a loyal people

## Home Correspondence

Middle-Class Edwcation.-At a time when the Albert Middlo-class College is creating much disan Institution soon to be opened, which it is hoped will go far towards supplying the great want felt in the Albert Middle-class Collere in Suffolk, incorpo the Albert Middle-class College in Suffolk, incorpo-two-fold "purpose of a County Memorial to the late lamented Prince Consort, and au establishment in middle classes can be practically and efficiently carried out. Viewed in the first aspect it is by no means insignificant. It has been erected from the designs of the most approved among a number of competitive architects, at a cost which, together with the furniture and fittinga, will amount to at least 25.0001 . Its situation in the immediate neighbourhood of the old town of Framlinghan is healthful, pleasant, and picturesque, and invested with great historic interest.
Its grounds are 15 acres in extent; and every precaution that science can suggest has been takon to render the building, if possible, fireproof, or in case of such a calamity as fire, to furnish the means of speedily extinguishing it. For the rest it will be seen that the College is named after his late Royal Highness, whilst on the principal terrace will stand his statue, moulded by the eminent hand of 1 bronze by Messrs. Elkington. This work of art, which during its progress has been inspected and approved by her Majesty the Queen, together with the pedestal on which it will be placed, is the magnificent gift of Mr. Thomas Lucas, of the Belvidere Road, Lrmbeth. The undertaking originated with, and has been nobly supported by most of the aristocracy and upper middle-class of the county, whilst many non-residents connected with the locality by birth, business, or otherwise, have also liberally contributed towards it, otherwise, have also liberally contributed towards it,
there being no less than 16 donors of $500 l$. each and there being no less than 16 donors of 5
upwards to be laid out on the building
ships and prizes. Among the foremost are the Earl of Stradbroke (Lord Lientenant of the county), President; and the 24 Governors, who have been unremitting in their attention and efforts as regard the scheme, and to whose zeal it is unquestionably due that the institution is now un fait accompli. To give an instance of the noble-spirited way in which the undertaking is fostered. At the January meeting of the Governors, Sir Edward Kerrison announced his intention of lending 2000l. free of interest towards the completion of the building, \&cc. At the very next meeting, held a few days since, the noble baronet informed his coadjutors that he had decided to give instead of lend that additional sum towards clearing the way, in order that the establishment should not, if it could possibly be avoided, open in debt. As regards the second purpose for which all these traits of lofty and gentlemanly character have been manifested, permit me, sir, to may a few words as to the kind. education which is here offered to the sons of farmers and business men at the moderate cost of 25l. per annum ( $30 l$. in the case of boys non-resident in the county, their admission being always subject to preference being given to Suttor boys), which aun ordinary medical attendance. The prospectus is tho roughly practical, and the course is intended to prepare the pupils for the active duties of agricultural, manu facturing, and commercial life. The scheme of in struction (as settled provisionally) comprises :-Rel gious Instruction, Reading, Writing, Arithmetic Spelling, English Grammar, Geography, and History Latin, French, German, Mathematics (especially Sur veying and Book-keeping). The elements of the Natural Sciences, Agricultural Chemistry, Geometrical Engineering, Model and Architectural Drawing, and Voca Music. To superintend the carrying out of this scheme the Rev. Albert C. Daymond has been chosen as Head Master, from a list of upwards of 160 candidates, and his staff at present numbers ten Assistant Masters, carefully selected for their character, ability, and teaching power -the French, German, and Practical Drawing Masters being in constant attendance at the College. Great care and circumspection are also used in filling up the domestic staff, and nearly the full number of pupilsthree hundred-are already waiting for admission in April. I have enumerated the above subjects in order that you may be able to judge how fully and faithfully it is the purpose of the Governors to give effect to the views of the great man to whom th's Institution is dedicated, and I may here be allowed to express a hope that if the movement is found to achieve that success which is anticipated, other comnties will not be slow to follow the example so worthily set them, and secure for the middle classes throughout the kingiom such an
them on a level with the upper and lower clansea Suffolk, Feb. 27
Calves killed by ealing. Sewaged Italian Ryo-grass. -I related this circumstance some time since, and subsequently conversed with Prof. Simonds on the subject He assured me that the only cuus? Was the excessive richness of the food which they were allowed to eat ad libitum. He said that he knew of mayy such cases occurring with young animals, and thes lambs perish by consuming Clover, the first growth of which had been fed off by older sheep eating cake, \&o The same Italiau Kye.grass when broaght home, cat up, and given in moderate quantities, never injured the calves. This was the first and will be the last fime I ever permit them to help themselves to such stimu.
Feio.-Much discuasion having appeared in the Gardeners' Clunniols as to whether or not the Yew tree is poisonous to cattle, will you allow mo to suggert tut the only method of arriving at a satisfactory con clusion on the subject would he by sulamitting the leaves to a careful analysis at difforent seasman of the year. Some years since, two of my cows diced suddenl from having caten some clippings of Yew in a half-dried state. My impression at the time was, that death Was caused by inflammation proluced by the point hard and sharp at a certain stage of desiccation.

Malt Tax.-I venture to look at the proposed repea the malt tax in a light by which few care to examine the question. I have been a practical farme and feculer of stock for some 30 years or more, and remember reading as to experiments with malt and with Barley, in which, as a feeding material, the forme had no advantage over the latter worth mentioning. It surprises me to observe so much weight laid on th benefit that would arise from the supposed ch eapenin of beer. S me one has calculated that the reduction would amount to a penuy per quart. Now even if it would reduce the price of the quart to a peany chemistry and physiology assure us this would be s misfortune, and not a blessing. Unless all chemist are mere impostors, almost the whole of the nourishing principles in the Barley are utterly destroyed by furmentation. We are assured by the very highest authority in chemistry that 580 quarts best
Bavarian beer, which is very similar to Allopp? Bavarian beer, which is very similar to Allsopp's, forming matter as 11 lb . of bread, or 9 oz . of beef, and 350 lbs . of Barley have been nsed-of sound nourishing Barley food, all now reduced to 1 lb ! ! But what has become of these 350 lbs., says the beer lover? Chemistry says, they were malted in order to produce eugar, from which the alcohol in the beer was formed, and without which beer would never be asked for. So that we are brought down to balance 1 lb . of bread and some alcohol against 350 lbs . of wholesome Barley food; and comparing the price of the 350 lbs . With the brewer charge for the 580 quarts of beer, even adding a trifle for hops, trouble, \&ce, it is easy to understand why Gilead Inoud declare bor to be the true Balm of chemist and physiologist admits that alcohol does not contain a vestige of nourishment, but destroys digestion, and devitalises the blood; and I will conclude by asking those who clamour for free trade in malt, that more beer may be used, to consider what Solomon would have said on this mabject. He desires the people to curse those who only dely supplying them with corn, probably till the price rose to an unreason-
able height. What would he have said had the corn been all but utterly destroyed, worse than being burnt, since it is the fertile source of most of our pauperism and crime? J. Mackemrie, M,D.
Sewaged Italian Rye grass makes the very best hay, which surpasses in feeding properties, as rell as in attening, the best meadow or Clover hay. My horse keepers and stock-feeders now admit this, much to thei into chaff. This statement is consistent with chemica analyses. Care should be taken to get it up green. I should be cut when about flowering, but not allowed to run to seed. As a rule, Italian Rye-grass is over-made. It should heat nicely in the stack. J. J. Mecki.

## Focietís.

Bate and West of Engeand, March 4.-At the sual monthly meeting of Council, the Secretary read the following letter and form of petition fro $n$ the Durham County Agricultural Society:-

Deraam County Agricultural Socteity
"Sir,-I beg to forward you a copy of a Petition which his been adopted oy the Durham County Agricultural Sovicty. attention of all $\mathbf{A g r i c u l t u r a l ~ S o c i e t i e s ~}$ and the Co
"Mr Fenwick, M.P. for Sunderlan 1 , has undertaken to bring in a Bill during the present session, ani your support is most
law mas bo effected.

To the Honourable the Houge of
The Humble Petition of the Members of the Durham County That in the opinion of your petitioners the English law That in the opinion of your petitioners the English law Worrying is defective, and rime large numbers of dogs are kept, and the owners of sheep, especially in the donsels populated
mining districts, are constantly incurring great losses io conmining districts, are constantly incurring great losses in conThe present luw practically affiords no protection to persons a dog can be rendered liable for any damages the animal may have committed, it must be proved that the dog has previously
worried slieep, and that his owner has had due notice of his Worried sheep, and
vicious propensities.

in Scotland and strictness witu which dogs are watchned by their owners, shoeepdoes in England. House to takto into, therofore, humbly pray your Honourable House to take into Jour serious consideration the expediency
of asimilating the law of England, in this respect, with that
of Scotland and Ireland. And your petitioners will ever pray, \&o.
In the course of a long and interesting discussion it Was stated that the evil complained of in the North of
England, is also severely felt in many parts of the Western countie3, and it was ultimately resolved that the Council, fully appreciating the importance of the subject, thank the Durham Society for their communipractice and, although it is not in accordand Society to petition Parliament as a Society, they hope that the attention of individuals in this district will be called to the state of the law with a view to any improvements which may be practicable.

## SMITHFIELD CLUB.

At the last Meeting of the Council at the Agricul tural Hall, Islington: present-The Right Hon. Lord Tredegar, V.P., in the chair; the Right Hon. Lord Feversham, Messrs. Buckley, B. E. Bennett, Beasley, Clayden, Farthing, Greetham, Giblett, Brandreth Gibbs (Hon, Sec.), Keary, Ladas, Leeds, Moore, Nobert Thompson, and Owen Wallis.

The Minutes of the last Cuuncii Meeting were read and coufirmed.
2. It was resolved that in future the Stewards be paid 10l. each.
3. Messrs. Owen Wallis and Edward Pope were elected as the new Stewards of Live Stock, to succeed the two who retire by rotation.
4. Messrs. Sauday and Iiobert Overman were elected Stewards of Implements.
5. The Reports of the Stewards on protests at the last show were received and adopted.
6. It was resolved that the death of the antmal shall be the only remission in the fines due for non-exhibition of animals not exhibited, without 14 days notice 7. That the Silve stock to the greatent amount the buther purchasing late Show be awarded to Mr. Waghorn, of Cheltenham.

The prize sheet for next show was revised. The different suggestions made at the general ineeting, or following alterations, \&e, were made :-
In Cross hror Cuttle. - That an incrense of $5 \%$. be made to the In Sho fit, That the hectish have a distinct chass.
That a new class be added for long-woriled sheep Leicesters, Cutswulds, Lincolns, or Kentish.
$15 l$. . That the prizes for Shropshire sheep, 1 - year-old, be $-1 \mathrm{st}, 20 \%$. That the Class for ${ }^{2}$-year-old Shropshire Sheep be done away
with. That the prizes for $0 \times \mathrm{xfordshire}$ Sheep, 1 -year-old, bo :-
$1 \mathrm{st}, 2 \mathrm{el}$. ; $2 \mathrm{l}, 15 l$; $3 \mathrm{~d}, 5 \mathrm{l}$.
 That a silver Cup, Falne $2 n$, , be given for the best Pen of
Pigs in lien of the Gold Medal.
That Gol Medal be given in place of the Silver Medal to.
the breeder of the animal wiuning the Silver Cun 1. For the best Steer or ox in any of the Classes.
2. For the bat Cour or Heffer in any of the Classes.

 The Hou. Secretary proper certificate be lodged.
9. The Hou. Secretary was requested to communicate with aumuls to thie Slow in Horse Boxes,
quick trains at ordinary
0. 1The Implement Committee was re-appointed with the same power as heretofore.
11. The "following were elected Members of the Club :-Owen Phillips, of Treriffith, Cardigan ; Thos. Parker, of Black Lion, Cardigan; John Lynn, of
Church Farm, Stroxton, Grantham; P. H. Frere, of Cambridge
12. The thanks of the Meeting were voted to the Chairman.

## Farmers' Clubs.

Lompon: Pig Breeding and Feeding.-The following paper was read last Monday by Mr. Strarn, of Sur.
Mr. STEARs said: Mr. Chairman and gentlemen, in bringing upon the card, viz, "The Breeding and Management of Pigs,"
I will; expiain, as far as I Iocan, the importance of this much neglected and almost despised subject, I consider it one of at large, as all classes, from Royalty to the peasaut, are a great measure to the asricultural shows have no doivt, in breeders a chance of seeing what a pig ought to be. still pig class as there is to all other classes. For instance, Newaastle and Lynn gave away in local prizes last summer severa omitted the pigs ; from what cause I never could make out, unless it was that they thought a pig beneath their notice.
The pig is an anical of great importance in an economical The pig is an animal of great importanco in an economica
point of view, if we take into consideration with what extra ordinary quickness the supply can be replenished; for the
fecundity of the sow is astonishing, and the early maturity of her prigeny is almost unezampled in animal creation, The of the pig: and no other animal produces such a variety of
dishes. I consider that pork must be the most proftable article to the butcher as well as to the farmer, the offal being so small compared with either cattle or sheep. In fact there
is scarcely any part of the pig but what can be used for food, and the flesh, in the form of fresh or pickled pork, hams, bacon, sausages, pork-pies, and innumerable other dizhes, con-
stitutes tha princip.1 food of thousands all over the world. It
is my firm belief that the keeping of swine is fast becoming is my firm belief that the keeping of swine is fast becoming
something more than an mere means of disposing of the refuse of the furm, which would otherwise be wasted. Formerly
large breedess and graziers thought the pig beneath their
notice, but I fiud the thing is changing tsill often dicgisted as well as surprised to see what a disgraceful
lot of pigs are kept by many of our large agriculturists as well
as by the smakll ones, such as I am sure if kept to any great extent will ruia any one, for they eat an enormous quantit
of food, and will neither grow nor fatten upon it; but larmers generaily would pay proper attention to breeding, rused at litte more than the preasent cost, and ospecially it
they had suitable piggorics, made use of proper feeding-
troughs, and selected a good herdsman. I have studied the mauagement of pigs for the last 30 years, and havc found tha
the better the attention the greater the proft; and if person wishes to make a pig pay, the pig must be kept
well when young, and not allowed to run 12 months in

The first thing which I introduce must be the piggeries.
 ventilated, others low and damp, nine-tenths of them to small, solue too cold, others too nuuch confived, and naving no
means of altering then between summer and winter; and a great many of them lave the cisterns inside thent, to recelve
the wasi, de., from the honse, which is very lad indred
 them. But the worst of all stios are those with wooden floors
 I think again I do not know that I ought to wonder so very much, when I take into consideration the general construction
of the places where the pigs are leept. If there is one corner on the premises worse than another, that is where the pig-sty
is placed, and people almost require margh-boote to get to it There is no question but what it would be a great boon to the tenant farmer it landlords would take more interest in pro-
viding better buildings for the pigs. It is not the most
expensive vapensiverlace that is the best; 1 consider it decidedly other-
epise. But what is required is a simple, economical, wellsitiated, and well-planned piggery. Some build oxpensive
brick or stone building, which I have proved are not so healt hy brick or stone building, which I have proved are not so healthy
as buildings of another kind. I I find a boarded buildin

means, religious, moral, and the study, whether of the languages or of the sciences, so as to ensure the quality - the strength, tenacity, and ductility therefore methl in his hands, and its capabilitie the polish and the usefulness or anment, and the tarnish will probably be avoided. But it is pos sible that by labouring for these, as the aim and end of education, he may turn the not men with the inne strength and goodness of true metal, but mere lacquered shams, Birminghan ware, men with the "garb" indeed and polish of the gentleman, without that essential middle-class or any other education
To return however to the subject of professional training, on the use and need of which we are glad to claim Mr. Constable's valuable judgment, we may mention as a matter belonging to his own county, that on Tuesday last a paper was read before the Kingscote by Mr. Want, the head master of the middle class school at Dursley, on "Education, that of the middle classes gencrally and the farmers in particular." And after an interesting discussion, resolutions somewhat to the following effeet were adopted:-
"That a sound reigighos, nuncul, and general oducation "That a means of instructing jouths aftor they loavo school,
between the ages of 15 and 21 , is groatly noeded. nee of the prac tical expurience obtaiued by them at linme on the farm, it it
vory desirable that they should receive sound scientific instruction. This for tharpose a porson properly quallied should be "And, provided a sulficient number of young men unite and from their funds the sum of 10 l. towards the purchase of chemieal and other apparatus.
About eight names were given in the room, and it was believed that a class of about 20 may be formed.
Mr. Constable says in his lecture that-"If the middle class cry out for teachers, teachers will be forth coming." And no doubt application will be now made to the Agricultural College, in the hope that the instruction on agricultural science needed by the Kingscote Farmers' Club may be provided thence.

## Farm Memoranda

## indian Agriculture and "Reh"

The following notes on the effects of drainage and of evaporation in a country where rain and hent and droughts are excessive, are intoresting to English agricinlturists,
are taken from the Frient of Inutiin of Oct. 13, 1964 ]
In the year 1858 it was found that many of the villages on the banks of the Jumna Canal were suffering extreme poverty in consequence of the fi:lure prehensible. The crops were sown and tended as o old, and there was no change in any respect except in the important one that the land remained barren The destitution of the villagers became at last so it, nud Colonel Bird Sinith made a report on the subject. Ile thought that the mischief was cansed by the percolation of the canal water through the soil in various dircetions. By this means it bronght into action certain soluble salts in the earth and carried them to the surface, thus prodacing a "saline efflorescence destructive to vegetable production." To avoid this it would be necessary to lower the bed of the canal throughout, and the work would cost at least five lalkhs of rupees. So serious was the evil that the Punjab Government expressed its opinion that it might "be quite worth while to incur this expense to save the loss of revenue which will otherwise accrue, and to avert the distress with which so many villages are threatened. On further inquiry it proved that the deterioration in the soil was much greater and extended over a wider district than had been supposed. The agent of all this mischief was "Reh."
Reh is sulphate of soda. Or, according to a careful analysis by Dr. Thomas Anderson, of Glaggow, it is a mixture of common salt, with much sulphate of soda, potash, lime, and a small quantity of alumina. The water of the Jumna Canal did not bring it to the soil, but only developed it. Captain Glover thought that the only way of getting rid of it was to provide a complete system of surface drainage, so that the salt might be thoroughly washed off the land. The Commissioner of the Delhi division, Mr. Brandreth, ascribed the presence of Rel to excessive irrigation. "The soil," he wrote, is damp for several feet below the surface, and its mere dampness is sufficient tos cause the salt to rise to the surface," Lieut.-Col. Turnbull agreed with Col. Smith, that the cause was the canal being higher than the land. In the water itself there was nothing present which could do any harin to the land. About the potency of the salt there could be no donbt. Some lands it turned into what is called in the collection of reports published by (Government, a "dry swamp." Mr. Sherer wrote :"Land sn affected has, at first sight, all the appearance of fon or marsh, and you are surprised when you press it with the foot not to find it oozy." Sometimes a sickly Grass gresv up, and nothing that was sown would benr frait. The seed might as well have been thrown into the Jumna itself. The effect on the inhabitants was necessarily most disastrous. Sir John Lawrence was at this time Commissioner of the Punjab, and thus the people had every security that their troubles would not be lost sight of. In point
of fact, the local goverument took the matter up in a vers earnest spirit, and there was on the let thane to pi an end to the calamity that had fallen on the pople. After Sir John Lawrence's departiaro this vory curions sulyject contimued t) occupy the attention ou the Punjab Governinent. But the diffivulty was considerably increased by the diotovary uplon analysif siderably increased the canal, and also of tho Rave that the tances contained the principal constituents of Reh. Lieutenant-Colonel Strachey, in letter datod October 24, 1862, ackuowleltged that thia was true, but he gave an explanation the circumstances which we must quote:- As to
the analysis of river waters, I can readily understand the analysis of river waters, I can readily understand
they shonkl contain a sensible amount of sulphate of soda (Reh). The great plains of Northern India are obviously the detritus from the mountahs beyond them. The constituents of the soil in the plains are certainly those of the gilt now broumht down out of the mountains by the great rivers Therefore it is exactly what one might expeet to find that the river water contains a very minute portion of sulphate of sola, and of the other soluble nalts commonly found in the soil. The fuct that rain is searce in the Reh districts accounted for the great prevalence of the salt, because the surface was less effectually washed.
Thus, then, ample information was collected as to the ature of the evil, and its cause. It remains to apply a remedy. In Febrnary, 1863, the supreine govern ment ordered a bit of bad laud to be selected, aunt the experiment tried whether deep dranage would cet rid the Reh. Between February and September the au horities in the Punjab were engaged in carrying o. the arcessary investigations, and the chamical examiner, Mr. 'T'. E. Brown, recommended the artificial production ritro of line a a means of fertilising lam coverel by Reb. Dr. Anderson, of Glasgow, think; that drain ge is the only cure. Tise Government had still to carry out some plan, and it is very civident that it must be a expensive one. Further inquiries could scarcely ad any useful information to that alrealy collceted, and the public would be glad to learm that some practicta measure has been adopted to stop the progress of the a We may add that drave the materials for this article, is worth preserving by agricultarists and cientific men, for very little is knowa about Reb, an is not even mentioned in so elaborate a work as Ure' Dictionary

## Calendar of Operations.

Maror.-The engravings of Oats, promised last weels, nust be postponed till our next issue.
The kwe Flock.-The following on this
It is requisite to provide suitable lambing paddo or pens for the lambing season, to which the ewes can be taken every night. In them, and also about the pasture field, or adjoining fields, shelter pens should be emstructed, in which a ewe about to lamb, or immediately after she has lambed, should be put, if the weather is unfavouraile. These pens are made with struwwattled hurdles; five hurdles making a double pen, three being set down parallel with each other and near that the two other hurdles form the back and front. As the season draws nigh every preparation is made, and the allowance of food is increased. The ewe being heavy with lamb, require additioal support When their 'time is ap,' my ewes are constantly watched for a few days upon the pastures where the have been wintered. As soon as the lambs begin to fall, hey are collecter into a roomy fied provided a n the corner of which, adjoining the shepherd's house, are the lambing paddocks, into which they are driven every dark and unfavourable night. In fine open monnlight nights they are sometimes left out, as it is deairable that the paddocks or lambing pens should be reed from trint, a.e., be sweetened occasionally Tainted straw or gangrenous droppings are sometime atal to ewes if the uterus. ('n the large farms upon the Downs and Wolds, and in many other parts of the comntry, ewes are generally, if not universilly, lambed whate on Turnips. In zuch casea lambing yards, or pens of buncient capacity, stomld be phovica, with a temporary house for the shepherd. It is constant and untiring attention that is required. It in only in special cases that the shepherd's skill and experience are brought into requisition.

The ewe about to lamb must be examined by the shepberd to ascertain that all is right. This being found correct (ic. the nowe and fore-feet in front, and ready to come forth), she should be left awhile to he own efforts. Sbould her paingl be protracted, the shepherd must lend assistance, or the lamb will be dead ere it is brought forth. The ewe shonld be gently laid npon her side: the shepherd sbouk then draw one foot torward atier the other, and thee by a steady pull draw the lamb away. If the lamb is wrongly presented, then comes the difficulty and danger: the shepherd has to puah it back most trequent! ${ }^{\text {in }}$ into the lamb-pouch, there turn it, and by the ewe's pains, and his guidance and help, it is often brought away without mueb damage. The ewe, in all cases of severe labour, should have a mail tablespoonint of haudanum administered, to keep her frem painige till the marta bocome onsier, forlowed in a day or two by a small dose of Epsom salts, and
waru cordisl drums or gruel, and suitable food, such as hav, chat, and sheet Tanhips or Curots.

The hat shoud be cleared of all athesion around the nothils as som as it is born, and very somaterwards suckle 1 . The ewe's udder should be cleared o wool, to prevent its being drawn in by the lamb. The castration should take phace about 14 days after hirth on a midd, danp norning. As the ewes lamb they should be drafted olf to other pastures, and the lawbis onght there to have access to a fenced inclosure, whera selves

SATURDAY, MARCH 18, 1865.

$$
\begin{aligned}
& \text { mbetings for the enseing wbek. }
\end{aligned}
$$

We beg to remind our readers that the second of the Scientific Tursday Meetines of the Royal Horticultural Sooiety takes place next Tuesday. We hope to see it well supported by the profession, in respect to the display of New Plants and of specimons of mperior oultivation.

We are now approaching the mid time of the vernal season, and would therefore reveri for a little to the Spring Flower Garden. This department of florioulture has of late years been comparatively neglected; it is confessedly not receiving the attention which is its due. On that account, and even at the risk of some repetition, we would again press it on the attention of our readers. Most people at one time or cther of their lives have experienced what has been called "the vernal joy." There is no denying the exquisite heauty and delightful fragrance of Spring Flowers. All that can be said against them is that they appear when the great world is in Londori. So mach the worse for the great world! But there are other worlds besides that composed of the upper ten thousand. There are many estimable people of refined taste and high appreciation of beauty, who continue in their country residences all the year round. In addressing a few hints to them, we have found an audience which may be called fit, but cannot be said to be few.

It was formerly remarked that the effects in the flower garden are in spring more transient, suc cessional, and diversified, than at any other period of the year. In the autumn flower garden there is ouly one phase, which, when once complete, remains permanent till the frost destroys it ; in the spring flower garden there are three or four flushes of blussoming, which pass inceessively into each other. In the latter case, thisn, the different flowering plants cannot be completely formed into
distinct nasses ; they retuire to be mberwown, us well as harmonised; and a certain intricacs necessarily emerges, which makes it diftieult to furecast the appearance and expression of the rarious groups as they come successively into view. In the ordinary operations of the bed jing-out system in Juae, one can see distinctly the patterns adopted, and a little play of imagination can add the culours they will display when in full bloom. In Norember and Deember, it really needs the prophetie eye of taste - to use once more the iilustrious Chathay's wellworn phrase-to diseern the effeets that will follow the dispositious then made. In a cold and drizzly day of that dark season, with the soil which is operated on approaching the consistence of mud, it demands much fertility of invention and patience in execution to be a suceessful designer. We would therefore oounsel the inexperienoed aspirant at this kind of work to study his future plans on the ground when the plants are in blossom. Let him mark the variuns cffects of the groups and masses of plants before him, and note them in his memoranduma bouk. Suppose, for example, that he is studying the physiugnomy of a bed of T'ulips, such as is often sceu in ornamental grounds. It is abruptly defined on its elge, we shall say, and circular, elliptical, or rectaugular in the form of its outline. Do that edge and outline please him? Are they in harmony with surrounding objects? Orwould it not be better that tha Tulip bod were broken, fringed, and shaded off, hke the irregular groups and masses uf wild Howers which grow spontaneously in woods aud pastures? Whatever conolusion is come to, areoord should be roade of it, and, if any skill in drawing is possessed, a rough sketch may be addul. Uf course there may be some extremely olever people who do not need such aids as these, their invention being infallible and all-suffioient. We may not presume to offer them adviee, bat even they may be reminded that it was parlly by sketching from nature that Salfator Rosi, and Tubable, and Linvell, and many others acquired their power and pre-eminenve as artists. "I also would be a painter, though a humble one!" the flower gardener may say. If that is his ambitio: he should study effects, with the living objeots before him; he should know well the naturs and capabilities of his materials; and he must havo premeditated designs.
There is another matter which requires foresight and preparation. Often, in this depirtment of his work, tbe gardener tiads his materials soanty and insufficient. Bulbs and other spring flowers cannot be multiplied so rapidly as Verbeuas and other "bedding-out stuff." Perhaps an a lequate supply is to be had only by purchase; and that may be impossible or inconvenient on the drizzly November morning when we have supposed him to be at work. Or his bulbs are snugly ensconeed in the ground, and he eannot lay his hands on them. This is probably the reasun why Eranthis hiemalis, Museari botryoides, and numerous other beautiful spring plants, are seldom so largely and effectivaly employed in the flower gardon as they might and ought to be. They should be diligently propagated by division in the reserve ground, or when already possessed in sufficient quautity, they may be taken up before the disappearance of the leaves in summer, and stored in large puts or boxes, sunk in the earth till the roots are required for planting. Many of them are not improved by being dried.
Some of these smaller plants are extremely beautiful, and can hardly be possessed in uverabundance. Nothing is more attractive for example than the species of Erythronium or Dog'stooth Violet, whether in small clumps or in edgings. Quite a fand of beanty is to be found in the single genus Soilla, especially the species S. sibirica, ameera, verna, bifolia, dec., but who except nurserrmen ever has them in sufficient quantity? We strongly recommend that these, and other plants, such as Dodecatheon Meadia and its varieties, Cyclamen Coum and Atkinsii, Primula cortusnides, and its recent varieties from Japan, as well as the Japanese Epimediums, \&c., should be associated with slight reckwork, suitable soil, whether peat earth or light decomposed turf, being provided for the plants, and the stones being laid on the surface r:ther for protection than ornament. Who has not lost numbers of such things rathless! H haried by the spelea of ignorant labourer-: After such in massicre of innocents, one has a lively sympathr with the rage of the antiquary, when he finds his ufficiulus domestios have been scouring his old helmets or rubbiag th sacred patina from his Roman cuius. This is
doubtless one of the reasons that Alpines are so generally grown in pots and frames.

There is another means of ornamentation in spring gardens, which, though adopted by some skilful gardeners, has not been so generally employed as it is desirable it should-that is, the sowing of hardy annuals in the open ground, in September, to survive the winter, and to come into flower in the opening of the season. Many of the Californian annuals, partioularly in the early stages of growth, have considerable powers of
resisting frost. We have seen self-sown plants of Saponaria calabrica, though a southern species, survive the winter with the assistance of a wall, and showing its blooms, of a more than ordinarily intense hue, in May. As a rale, these annuals have deeper colours in spring-a result which has been asoribed to the fainter light at that seasonand that of course is bad philosophy. It is rather due to their slower and stardier growth, and perhaps to the influence of cold. These annuals, embracing a oonsiderable number of species, are beautiful in themselves ; and, as they present a style of growth and efflorescence differing considerably from ordinary spring plants, they are the more valuable. It may be suggested that it is nseful to have a few dozens of pots filled with Nemophila, Collingia, Gilia, \&o., and kept in
winter in cool frames or pits, to supply materials winter in cool frames or pits, to supply materials
for making up failures or furnishing bare spots in spring. It is hardly safe, however, to introduce them into the greenhouse, as they are liable to be retained there if they come early into flower. In Maroh and April there is no gayer inmate of the greenhouse than the common Nemophila insignis.
The management of the Spring Garden during the summer and autumn months is a matter for disoreet consideration. It is obviously inexpedient to leave it blank during all that time. Where bulbs are regularly lifted, as Tulips ought to be, the ordinary bedding-out plants may be substituted for and give place again to the bulbs in the beginning of winter. But this is working double tides : and the consequent exhaustion of the ground must be repaired by an abundant supply of manure, or compost, or even fresh soil. There are some bulbs, how-
ever, suoh as Crocus, Narcissus, and Iris Xiphium and Xiphioides, which improve when allowed to remain in the ground for three or four years continuously; these it is not desirable to weaken by covering them with a matting of Verbenas and Gazanias, though a thin sprinkling of such plants may be ad missible. We formerly suggested that in
this atyle of zarden, Rhododendrons and other finer this style of garden, Rhododendrons and other finer duced. It would be ia harmony with this kind of ornamentation that Soarlet or other Geraniums of some considerahle size, and prepared for the
purpose, should be spaced out somewhat in the purpose, should be spaced out somewhat in the
gardenesque style, as the late Mr. L.oणDon used to call it." In old times, when "the bedding-ont system" was in embryo, or only beginning to shape itself, one used to see examples of Melaleuca, Metrosideros, and other New Holland plants plunged out in warm nooks, and occasionally the stimulated growth produced those curious bottle-brush-like flowers which were not often witnessed on the shelves of the greenhouse. Some of these plants we fear are things of the past, or are only to be found in botanic gardens. Perhaps the modern Cannas, Ricini, and other inmates of the semi-tropical garden, may take their plaoe.
We oan imagine some of our professional readers exclaiming, Is our work never to be done! You bid us in November and December be tasking ourselves with planting a spring garden.
In spring, when we should be oceapied with propagating, Wherbenas, Lobelias, and Pelargoniums, you tell us to be studying the effects of our past labours, and to be forming plans for the future. In summer you suggest an additional sphere of bedding out. Truly our work is never ended! Well, it is said that when the oultivation of Turnips in the fields was first proposed, the indolent slaves of routine inquired: "When is our work to be
done? When are we to have an interval of rest?" In these days of cheap grain, however, Tarnips form the sheet-anohor of the farmer. Redit agricolis Zabor actus in orbem. So to the gardener labour comes round in an unbroken circle. Bat where there is true diligence, that is love of work, there that there is no season withont its interest, no day without its attractive duty.

When we consider how much the enjoyments of the middle and higher classes in this country depend upon the hortioultural knowledge and

Tros of this body of men appears to be a subject quite within the province and well worth the attention of a great Hortionltural Sooiety like that at South Kensington. We are therefore glad to Council to the meeting held on the 14 th alt., that $\because$ arrangements are being made with the Society of Arts for adding an examination in gardening to the examinations which they now conduct throughout the United Kingdom; and the Council intend to offer prizes to successful candidates, and to allow them, in cases of great proficiency, the means of gaining experience at Chiswick.'
We confess, however, to have some doubts as to the success of this scheme, and would much prefer to see the Society in a position to manage its own affairs-to educate gardeners and to examine them itself. The time. Was when the Society gave a soientific and practical education to gardeners in its own garden at Turnham Green, and conferred a real benefit on many of the principal gardens, not only in Great Britain, but also in many other parts of the world. Our older readers may call to mind the names of many first-class men who were eduoated by the Society, or rather who finished their earlier education in the Society's garden, and who afterwards filled, most worthily those situations to which they were recommended A system whioh was followed by such gond results is certainly worthy of our attention, and should not be abandoned without we see our way olearly to a better.

There was one peculiar feature in the Chiswiok garden training which always appeared to us a most important one. It was not considered advisable that young men should come there to learn the rudiments of practical gardening. These were supposed to have been acquired in private gardens in which an apprenticeship had been previously served. Bat after having aoquired the rudiments of praotical gardening in a gentleman's garden, they came to Chiswick, where they had an opportunity of learning the higher branches of their profession. Here they had the means of acquiring a knowledge of the relative value of all the vegetables and fruits in cultivation, as well as the most approved methods of growing the former, and pruning and training the latter. Here, too, they learned the theory of horticulture, and had the means of beooming well grounded in the laws of vegetable physiology. Moreover-and this is a most important point-in the hothouse department, and in the arboretum, they were made acquainted with all the more important herbaceous plants, shrnbs and trees which were of use either for
ornamental purposes, or as produoing valuable timber, \&c.

These were a few of the advantages which young cardeners enjoyed before the evil days fell upon Chiswrok. And in addition to these, there was one thing they acquired likely to prove of considerable importance to them in after life. The circumstances by which they were surrounded had a tendency to make them more cultivated and refined in their habits; the rust was rubbed off by coming in contact with men of the world whose attainments were of a superior order, and they were, in this way, better fitted for the management of those situations which were afterwards committed to their care. How often do we hear complaints from the employers of gardeners, more particularly from ladies, of their being pestered with a pretence of knowledge by men of the Andretw Fatrservice class, whom Sir Walter Scott has so admirably painted in the Waverley Novels-men who have acquired, like a parrot, a string of Latin names, and faney they are learned! Few specimens of this kind were likely to be recommended to situations from Chiswiok.
In so far as the kitohen garden and fruit department are concerned, we are glad to add our testimony to the statements made at the annual meeting to which we have alluded. These departments are in the most efficient condition; they reflect the highest credit on Mr. Eyles and his assistants, and must prove of great value to the joung gardeners who are employed by the Society. It is therefore, we think, a great pity that the other departments are so much neglected. The Arboretum, unrivalled in the kingdom for a collection of trees and shrubs, is in a most pitiable condition. A short time more of suoh neglect and the names of the trees will be lost, and their origin and history unknown. It may be very true, as was indeed stated at the meeting to whioh we
have alluded, that London is rapidly extending have alluded, that London is rapidly extending Turnham Green, but its baneful effects are not yet felt, and many years must elapse before we need

No doubt some of the Conifers present an unhertis appearance, but other influences than Lond smoke are at work upon them-the subsoil an flat land at Chiswick are unsuitable to many the species of this family of trees.
Let us hope, therefore, that the Council of the Society will look into this matter. Mueh movey
need not be expended upon the Arboretne high keeping is not essential, but by all meana us have the trees preserved and correctly named We have no doubt the Council is perfectly ninced in its desire to advance the education of gardenem and we venture to suggest that this is one of the ways, and a very important one, by which th may be accomplished. In these days someth more is expected from a first-class gardener the knowledge of fruits and vegetables. Parku an pleasure grounds are placed under his care, an nothing oan be of more importance to him thas knowledge of the names and habits of indigenous or exotio trees and shrubs, Moreore the Fellows of the Society themselves, and all who are interested in planting, may learn much from the Arboretum at Chiswick, and, on this soconet as well as for the education of young gardeme we pat in our plea for its preservation. $F$.

Chingse Primroses are certainly amonget the most useful of winter-flowering plants for the grom house and conservatory, both on account of the benuty and the variety of aspect which they present. have already ( 1862, p. 356 ) adverted to some vert fin double-flowered sorts brought into notice by Mem F. \&o. A. Smitre, of Dulwich; and we have been hath much gratified by the sight of a box of flowers from Mesirs. Windrbank \& Kingsburt, Nurserymen, a Southampton, who were, we learn, the raisers of the varieties grown by the Messrs. Smitr. Their straind Primula is a remarkably fine one. The flowers an large, full, and frilled, and in colour vary from whit through shades of pale flesh-colour, to blush of deepess hue, and from that again to the carmine-rose tint of $Y$ Beraspres carminata, and on through the ordinery deep rose tints to a very dark purple rose. The paleones especially are also remarkable for a iarge yellow like eye, sometimes measuring fully dive-eightas of a nch across, the flowers themselves belfaked with on a white ground; and both pure white and fless. tinted white as well as rose and rosy-parple full donble flowers were amongst those sent for ingpection,
respect to these double-flowered sorts, which, with thoo respect to these double-flowered sorts
of the Messrs. Smith, are decided
Windebank \& Kingsbery state that, after reveri years careful selection and hybridising, they have ous ceeded in fixing the valuable property of prodacin double flowers from seed, from 10 to 20 per centi, of seedlings coming double. In illuatration of this the further state, that since 1862 they have prodnced wards of 200 double-flowered plants, all from seed.
We are glad to be aole to subjoin the folloning
remarks on Winter Vabiegated Pbiargomion, yy Mr. Prerx, of Castle Bromwich, as supplementary our own observations at p. 74. There can be Do doal that the varieties of this popular flower with gis coloured leaves are extremely valuable for greenloner decoration during the dullseason of the vear, w.
are scarce. There can be as little hesitation are scarce. There can be as
cluding, from all past experience, that attention bana now been more especially directed towards then, having become more and more an object vator to seek for varieties showing an that desirb respect to foliage which is gay in wincer,
changes will be effected. Hence we may 100 additions to, and for not a few improvements varieties already prodnced. Mr. Peber remark

Variegated-foliaged plants have become able of late years for summer and autuan some of the Variegated Pelargoniums, whethe os ornamental plants for the greenhouse, or for mixing with flowers in bouquets
have for some few years past cultivate have for some few years past cultivated harbled Pelar
classes of Zonal, Garland, and Mar both for exhibition and bedding purposes; and some of the variegated sec daring the winter season, the summer, are by no means to lose all their beauty during unless kept in a hothouse; most striking variety in my time is Burning Bush, which I believer mas Mr. Hauly. exceedingly beautiful, every le deep pink circular band, which does not

## New Plants

295. Tribacdia sahcintha. Hookej, Botanical

Magnsine, t. 5450
This very ornamental Vacciniaceous stove plant bears considerable resemblance to the Murleania sperioicnlirs, and obvininaly s', in the 'orm of its green-tipped ped Aners. The biamelaps are degeribed as pendutous the haves flesho coriaceous, oblong-ovate achminatoacute, three to tive veined; and the corvinbs of flower mother lateral in the leaf axils, or collecied together so as to form a compuind drooping cluster at the apex o the branch. Tue flowers are about an inch in length, wuls clubshaped pedicels, artioulated with the bell onased five-touthed green calyx, and an arceolate very teshy subglobose red corollas tube, terminated by

weatricted yellowish-green limb, with five erect short mb.
This Tlibatulia, like the Hacleania already alluded , was flowered Ly Mr. Bateman, and was exhibited by -viery last spring. It is of the Reyal Horticultural Xew Grenadin. Thoula pupposed to be a native ot misis scleruphears inclined to identity it with the $P$ sammisis seleruphylla of Planchon and Linden (Flore des acres, viii. 205, t. 825 ) which, he observes, it very "e cory mbso only droming." The erect habit, pubescent adicels of thate platit, seem, hand more fleshy pubescent ins of Mr. Bateuants, is sufficiently distinct from it.
peir teees in pots
How atmnat abenrd it spelus even now, how absurd rrite on such a bubject: for o:se is so inclined to think to amall stun a subject: fur one is so inclined to think Oing, like siterne's starling, "I can't git out." Thanks ifiodicquirement of kinume, inge under difficulties aun -he into the cuiture of trishen, and those who have Sprised that ithture been truit trees in poots are now
Yeluphent. The present age for ils Tiy the moderne arent source of success is undoubt*hiace dresingens mathod of feeding trees by rime a plant and of sumay watered, but a planer fed, so that at the ngriment, which hald harl ball of earcho way withoui tree co.nt, whenich had all bu ben washed out os at, and the is tiere are no irnit tiens.
io bind for liberal surface feeding as Pewr treas ous

Quince stocks, and none that can be kept more fully in
a state of robust health in pots. Thin is owing to their numerons fibrous roots, which readily come to the surfice with open moutis if rich tood is given to them
Pear trees miy be potted at any time from November till the end of March, and curiously enough, if potted when the blossom buds are bursting, they will often hear a fair crop the sume season. Tire pots best athapted they thin are 13 -inch, and in these, without repotting they will continue to grow and bear fine fruit for 10,15 , or
inore years, the conly culture required being top-dressing and surface dressing. The former should be done 1 November, by taking out the surface soil 4 to 5 iuches deep, and replacing it with some freah compost well rammed down; the latter, in June, by giving some rich surface dr ssing, so as to lie 2 or 3 inches above tho rim of the pot, forming a reservior surface to hold water. Thisdressing alould be repeated in July, and ggain in August; it may he made with horse-droppings from the roads soaked with liquid nanure, and mixed with a smal quantity of loam, or by the beat of all surface feeders - the turmer inaterind and innlt or kiln dust, equal quantities, saturated with liquid manure - this should mit be laid in a heap, or fermentation makes it simell like a den of very dirty wild beasts. The compost for patting an
top-dressing in autumn should bo garden mould of top-dresenge in huthimn shomit be garden momad
With regard to the managenent of the trees after being potted, the pots should at once be plunged in the ground to three-tourths of their depth,* und if i autumn, some lit' er, leaves, or manure should be placed on them to protect their roots from frost. As but few trees will be likely to bear the first season, they may remain olunged thoughont the summer. In the autumn al! will be found studded with blossom buds. In November they may be removed to their winter and spring quarters, which may be (if no glass-roofed sheds are convenient) a lean-to shed of any kind, sloping to the
N.E., and closed there, but open to the S.W. Three or four rows of trees may be placed here in front, the pots partially plunged and protected with manure; and here they may remain till they have blossomed and set their frait; in short, till all danger from spring frosts is over, which here in Hertfordshire is not till the firs week in June. They will require duly watering, per When tho fruit is fully set and safe, the trees may be removed to their summer quarters; the pots plunged, and surfuce dressings given as above directed.
The very finest Pears may be grown by this method of culture, in all climates warm enough to ripen them. In cuol climates the orchard honse must be called into requisition. Mr. Thomson, of Dalkeith, has, I believe, grown Pears on trees in pots under glase much fines in every respect than those from his wail trees.
This is quite enough to decide the question as to the This is quite enough to decide the question as to the
fersibility of growing Pears in pots in a conl climate. Here, where they bear well, and ripen their fruit in the пpen air, they are most interesting, and give but little

## trouble.

With regarl to the quantity of fruit borne by trees in pots as compared with wall trees, I liave frefurntly seen more Pears on a nicely pruned pyramid of 4 or 5 yenrs old than on a straggling wall tree five times that age; for if well fed, and their shoots pinched in in summer, Pear trees in pots become most remarkably prolific, and above all, they are always healthy and free from canker.
If pyramidal Pear trees in pots are attended to in summer by pinching off the ends of all their young shoots as soon as they have made three or four fullcized leaves, they soon become models of perfection both from their culcure is the facility of removing the trees to a pluce where their blossoms can be protected from our rpring frosts-the greatest evil we have to guard hgainst in Pear culture, for it is now well known that Pear treea on Quince stocks always show abundauce ot blossoms, yet tou seldom give a good crop.

Another advantage this mode of culture gives is that of making the culcivator independent as to the nature of his soil. It may be chalk or clay, gravel or sand, yet a few busiels of good loam and manure in which to put his trees make hom free of all anxiety on this heat. There is no fear of the roots of his trees penetrating to an unlavourable substratm, for if surface dressing is treely given in summer, the roots seem almost by inatinct to come up to teed, and scarcely attempt th enter the soil beneath the por. If they ever do this, the annual removal of the pots tos and from their winter and
spring quarters is quite a sufficient root-pruning. Although 1 have mentioned the front of any shed open to the S.W. as being calculated to give sufficient कhelter to the trees during their blussouning period, there is no doubt but that a roomy airy orchard-houst would be far better. I mention a shed to show vers thumble cultivators what may be done if they happen th hare one ready built. It a shed is to be built there is nothing heiter or cheaper than cheap 21 -uz. glassfourths" as it is called in the tracie-to ro, ${ }^{\prime}$ it with. A lean-to shed, 10 feat wide, and 20 or 30 teet tons. nould shetter a gieat number of trees; but instead o is roof sloping to the N.E., as recommended for mon sheils roofed with slates, of thateh, or relt, reingit, and the Irout if leet, the buck (and euds if thr

* If the soil be light aur sudy, the pmts mas be plunged to Thetr rima ; if cold and at lif, uot so dooply.
place is expoeed) close bourded suit the trout open Gurdeners and amuteurs are, as far as I have seen, not at all aware of the usefuhess of these lenu-to giass. roofed sheds open in front they should have thei vafters $2($ inchee asunder, and if glazed with the above mentioned chenp strong ylass their cost is but trithing In climates not sufficiently warm to ripen Pears, the trees misht remain in them the vear throngh; there are also many garden crops that inight be cultivated under them. Intelligent gardeners would make good use of then if once estabhishod as necessury appendnges to a garden. With regard to fruit trees in pots, one can scarcely calculate the advantages to them from being ander a roof during the winter; their roots are aliel tered from the henvy cold storms of winter, and become ripe and hard. I ain at this time building one of these wan-to glass ronfed sheds 200 feet long and 14 feet wide with a very old Yew helye for ita back wall ; it is opeu in front, and intended merely for the shelter of ficuit Erets; its climate will bo dry, the great desideratum in England.
As this shed is built after rather an original method, and not a brick used in its comatruction, alchough its foundations are peshipa nearly as durable as brick, it
Its poats on the top of whichith.
Its po-trs on the tup of which is laid the phate, are of leat, and 5 inches ly 4. These are let into chst-iron ackets 2 feet long, 5 inelies by 4 in diameter outsid mensure, and 4 inches by 3 inside measure ; each socket has a flange at bottom 3t inches wide, which furms a rooting of aboat 1 font in dianeter, and if the soil is well ramoned, this holda the bulding fast. There suckets are let into the earth t, the dephit of 15 iuches, leavine 9 inches of the iron casing above the surlace of the sont Each post is let into the sockpt 1 fout, and rests on houlder, so that when fitted in, the iron sorket and ost it accurately, and hive a very neat apprarance. The advantages of building light plass.rooted slieds after thas method are obwious entugh. 1. If a tenant wishes to remove his glass-rooled ahed, whick may perhaps be a Vinery or a Peachery, he has merely to draw the postz from their sockets, leaving them in the aubroken ground for his landlord. 2. There are no oundations to dig, or bricks and mortar-thoe detestable nuisances-to be carted. 3. They are light and niry, and as useful as if huilt by what the Yankees call a ponderous British builder.
If any of your readrers wonld like to see the commencenent of the building I knve endenvoured to describe, thes will be shown it on calling on Mlessrs. Thos Rivers \& son, Sawbrid seworth. T. R.

## WINTER FLOWERS.

a febreary day among the london nurserigs. One winter day's ramble hus been sketched at p. 197. I have still another to reeord, and cominence witi Mr. John Fraser's Nersrby, Leyton. This and ite winter flowers bave been treated ot so recently (p. 175) that it is not uecessary for me to dwell on it, but good plunts-anlike good advice-may, advautagenusly, be mentioned twice, and Kalmia glauca cannot be too freely employed as a neat and charming plant for early forcing; while second to no other used lor that purpose, I here find Annggdalus sinensis albo-plena, a plant much like a Pranus, forming dwarf neat bushes, having perfectly double flowera of the parest white, and being one of the most beatiful and easily furced of all suning flowers. Here also is Leschenaultia Baxteri maj ir, Spirma prunitolia flore-pleno, Hovea pungens, Exacuen zyy.
lanicum; and lastly, to puss by more frequently grown early-flowering plante, the heantiful Luchenalia tricolor, which blonms naturally in the greeuhmene in February, is as easily grown as a Crocus, and should be -to the extent of at least a dizen 48 -sized putsin every collection where flowers are required at this time of the year. The culture and kecping here are as perfect as I have seen it in either publice or private garden, but then the great mursery which won'd neglect these things now-1-days, would soon fall into the rear rank, and this time 1 a:m not hunting after neculiarities or excellences of culture: so away to the West to leok for more Howers.
Before entering Mr. Verrcris Nobsert, King'a Road, Chelser, I minat cross the road and lon $\hat{t}$ at those noble specimens o. Yuced recirva, now sprinkled 1 ith snow, in the flower garden opposite. 'They arr of great size and beauty-just such plants as, if in pots, out largest fine-leaved plants: only inconvenient to more. I mention this old phant becatise the effect it produces here, finely grown 1' straight lines around the flowergarden, 1 have not seen surpassed in all my ramblinggs. It was particularly striking last auturm when some of the plants were in flwer. What an excellent subject or the-I whs going to say geometrical gardener, but it will look as weil in dell as on platean, and will bo very largoly ased when parple begin to produce "aspects of inixed vegetation" in the open air. How.
ever difficult it muy be to tind grave or ang of its alliea III most floner gardens, it is satinfactory to kinw that chere is no scarcity of it in all our great indour-plant whoen, and here it is in the greatest potuxion, -fforied by Palms, Tree Fema, Cycadk, tender Pines, in frect liy everything of eldegat and graceful nabit that can anywhere be hunteif up. Tue spuce wcoupied a'oug the cornithr and arljicent houses by
hiose is very large, and yet, winter or sumner, the

Bcene is ever grateful to the eye and mind; because
group the plants as you muy, the "lines of beauty" are ever there; arrange them as yon may, the mys. tery and indefaiteness which constitute beauty o vegetation in its highest sense, cannot be extinguished. Such a scene can have no effect on the minil but an elevating one; nobsidy ever was or ever will be repelle by it, It is only by freely interminṣling sucb plants with free-flowering ones, that you can get the supremest beaty of vegetation - not that when please. a clasa, however large or learned, hut all mankind.
This I say advisedly; and I take this opportunity to utterly repuliate the false notion that it is by culon alme we can attract the non-gardening community Therefire, I urye that every conservatory or honse fin exhibiting plants in their best state, should have in it a large proportion of ever-versant and gracefull habited species which are incapable of being trained into molinese. and morenver always rearly to intensify by contrast, the bemty of iree-flowering plants.
A delicious treat is to be had here in the conl Orchid-
bonse, which would be worth visiting were it only fon the protuse masses of Birkeria that are in full bloom, but Lycaste Skinneri is in still greater profusion and very decided variety-an invaluable plant for the present season. Also in flower, and very beautiful indead, are large masses of Ca'ozyne cristata - the most, striking plants in the house, though other "good things" it the Orchid way are here, with Lamlia Lindleyana, and the pure and exquisite Cattleya Warscewiczii
delicata at its hest. But lere is a plant, another of the perenniallv interesting section, which at nuce turns the tide of Orchill adiniration-a mase of Cephalntus follicularis, nerrly a foot in diameter, with a profusion of by far the largest pitchers I have seen, though always particularly observant about this plant, and al
apparently froin one root-stock. And with this, ever interesting suhjects are not exhansted, for here is pro bably a miane collection of Pitcher plants - the rares species and Mr. Dominy's hybrids being all in excellent character and conitition
By-the-hy I wish Mr. Dominy would infuse a little of the blood of Cypripedium spectabile into some of the ualy-lipped species now so common in stoves; he has done more difficult things, surely. He is raising the valushle Pitcier-plants from seed by the thousand. They are in one of the propagating houses, pricked into pots and pans; yoir misht put half-a-dozen tility plants on the thumb-nail, and yet every little leaf is terminight. The Oisvirandra, gratify a visitor as much at Christmas as Midsummer, is now here in a good state. as I am glad to know it is in several other Londou Nurseries. There is a new Cypripedinm Elwering with Cilinthes; a houseful of
Epacrids in full bloon-quite a gay sight; and Rhododendron Princess ['nyal is freely blonning among the best greenhouse suhjects;-but here I minst wind up, having yeu to go further west

Messre. J. \& C. Lee's Royal Vineyard Nurseries, Hammersmith-the oldest battle-field of the trade, Where the very ground must be full of old pruning-swords-I aporoach with feelings analogous to those
which might be supposed to possess a soldier of the new Empire when visiting the fiell of Austerlitz: but with that the comparison ende, for the fray is still going on as active as ever in the Royal Vineyard, and one of the first things the visitor meets is a show honse. which for its excellence as such, and its contents, might be thought more in unison with the latest advance in a first.class nursery dating from our own day. There are many other fine new houses, within hail of veny useful old ones, that have been doing dinty since the earlier days of the good old king. Well, Tremandra hirsuta is very useful here at this season, with Boronia pinnata, Erica gracilis and grandinosa, Correa marnifica and crrdinalis; hat the most telling plant in this bouse of specinens is Genetyllis fuchsioides, very much earlier than $G$. tulinifera, which is now slowly opening its bract, while G. fuchsinidies is covered with gay flower heads thut have been open for two months, others being expected tocontinne to hold on in perfectiontill May. Talk able time" after trint ! Amang store beaty for a considerDendrobiam corrulescens, Coolozyne cristata, the Frasi cieceas, and Monochoftum sericeum maltitorum, are nme of the best in flower. Though Camellias are late this seasnn, there are a good many specinens in flower amougst the excellent collection of these plants in this nursery; and finally Rhipsalis salicornoider, a small yellow-flowered succulent, is in bloom; this, grown Well in dense little hushes, might make a useful winterhave been driven from oultivation by drought and cold ; they would bear the treatment without suddenly perishing-ergo it was good for them. Thus the glisteming health and beanty of flower which they posess with plenty of light and heat were never to be and in franes kept very warm, that could not be surpassed as ornamental plants from the time the corona of crimson buits appearel thrnush the white spines till flowering was over. Here I atop for the present. The sagacions reader will ohserve that I an but describing a hurried and inpromptu look through some of our great London Nurseries; while to do these establishments anything like justice, and glean all the interest
recessitate "camping out" for a few days at Clapton, mith, as the case might be. Wm. Robinson.

## Home Correspondence.

Royal Horticultural Society.-I am very glad to learn by your Leading Article at p. 219, that there are hroas o laving some interesting meetinrs at the Rnyal H met nultural Gardens. I well rememher the Tueslay meet
ings we former'y had in Regent S:reet, and which wer ontinued for many years with unprearionable succebs Very instructive they were too. I exhibiterl at them for nany years, and looked forward to the day with plea greater or lesser number of neir plants to beseen. If round London there were any gon 1 specimens hloom, they were nearly always proiuced at thma meetings; and it was the sane with fruit. The reann was, that every encourcgement was given to thoze who
supported the Show-medals and cartifiajes were at he command of the officers to award to sulyjects deemed worthy of them. And unt the least interesting part of the meeting was the lecture by Dr. Liudley, in which all available information respecting the merits of tire plants and fruits was given. I have seen many plants brought from a lung distance to thes neetinga, and I have no doubt the Tuesday meet mige now projected will meet with the arane
succeas, provided enoonragement is given to thosp who have plaits to bring.
to support the Society, if they will only make the neetinys as interesting as possible. There are man others besides who are willing to lem a helping hand. I should advise that prize's should he offered or good old things as well as new. New planco are not always ready on the day fixed, , but mens may always be expected, and many olid faces that one seldom sees in our days will undoubtedi appear. It is quite as interesting to see a good oh phant well-grown as muny of tie new ones; ant thourli I ain a lover of new plats, I would mot forget the old kinds, as is too often the case. I gather from your eport that there were some fine Orehids exhilite on the occasion referred to. This chass of plants was
always well represented at the Regent Street meeting and many fine specimens both of old and ne:s lsind have been showa there. I well remember it wa there the first plants of Vanda suavis and of V. coernle were seen. What a sensation these two plants caused at that time!-and indeed I often now hear them spoken of as having been first shown there. It must do good to any Society to have such plants spoken of in such a
way. In the days to which 1 allude, if one wauted to way. In the days to which 1 allude, if one wanted to
see everything new and good during the autumas and puring months, 21, Regent Street, was the place to $b$ visited. I never pass the old place but I think of those meetings with a great amount pleasure. Many exhibitors like myself, supporters of the great shows of 15 or 20 years ago, and many spiritad these Tuesday meetings such that the Fellows myy have some inducements to continue paying their sub. seriptions, for they must have something to see in the shape of flowers and fruit besides what the Garden itself can produce. I hope these remarks from a fourguinea Fellow will not be out of place, for I wish the ociety every success. B. W
Royal Albert and Barbarossa Grapes.-In speaking of the Royal albert in a late Nuinber I stated that it
very mucla resembled the Barb irossa. Mr. Cox, who is acquainted with both varieties, confirms my ouinion. I may here state that the Barbarossa was introduceid from the Continent by T. C. Ward, Esq., and that it was not raised from seed in this country. It was first shown, I believe, at one of the Horticultural Society's meetings, held January 16, 1849, by Mr. Bevingto', gr. to Mark Phillips, Esq., of Stratford-on-Avon, and if I remember rightly there was a white variety, also
naned Barbarossa, exhibited along with it. It w is first offered for sale in the spring of 1850 by Mr . Butcher, of the same place. There can be no misLake respecting the Royal Albert, known to Mr. Cox and myself, ns both bear the same name of Prune d'Hiver, or Winter Plum. The writer of the letter I published in your columns (p.193) also statel that it Prune d'Hiver many years ago. Fidooard Bennett, Osberton Gardens, Worksop, Notts.
Small Birds.-My experience of the housesparsow leads me to give hin a much worse character for depredation in the gardon than your correspondent, Mr. Iagram, gives him. We find here about this time, when the Gooseberry and Currant buda are begiminn to open, that these audacious little gentlomen literally strip the bushes. This is a fact about which there can bo no doubt; for if oue is taken at night and has his corop opened, the latter will be fonta to be crate crammed with buils. The sparrow is besides a b. Nth, cumning fellow; if moved from the bushes, he perches roturning to the stripping process even before you leave the spot. I bave witclued him clusely, but I never could detect him attacking any trees, such ns Ciserries, or Plums, apou which the bulltiuch generally feerls. The lattor is very different in its labits from the sparrow ; it is easily scarod away, and seldom returns the

## 20tices of 3600ks．

Then wpon the Errors of Geology，illustrated by refer－ ace to facts observed in Ireland．By John Kelly，
Fice－President of the Royal Geological Society of ireland．8vo，London，1864．Pp．xvi．\＆ 300. The very first glance at the title of this curious book Geritubly raises a spirit of opposition．The Editor appare as above，the book is labelled Notes on Errors of Geology，which，if not adopted from mere economy ci surme，certainly piace
The main object is doubtless to reconcile the Mosaic momnt of the Creation with geological teachings，and nates the matter more obscure．It is strange when every one is contented to receive without the slightest mingring，the account in Scripture of many matters of 1 encmate character in astronomy and patural history， lent at the time when the bonks with the notions preva tnuy should stagger at similar discrepancies between ihe ac ount of the Creation and what has been as：er－ Taned in modern times of the structure of the earth．
The great olject was to show that the Eurth and all that is in it proceeded from the hand of God，and we mpon well content to receive this，without insisting mpon its being a scientific revelation．
Momic acconnt antagonistic to those not to make the Te have here another attempt to reconcile apparent dincrepancies，and we mast say that it is not a very
happy one，thougls we are far from thinking that the happy one，though we are far from thinking
volume does not contain some valuable matter．

Tho anthor＇s thenyy is that the six days or periods of ereation correspond with the six great systems of rocks， there is not a shadow of proof except in the writer＇s confusion of language which is quite inexplicable in a If the days are to be interpreted as accentific research． as mell comprise 960 millions of years as 960 may ation which confusion letween the creation of the vege Lor the woal beds，tron many ages，supplied the materials Leat,$f$ the ererth，trom the combined action of the innate other parts of the disjointed gerated by the grinding of andusel in the firmament before the sun was formed， 2hom the fresent surface of the gamous plants which bave existed at the same time with the giobe whit ficts relative the coal measures，together with similar subversive of branches of natural history，is at ce of the formation of the six theory of the accord Mintnman thesy to see how the overthrow of the Warip arisen from the existing state of the earth suthor＇s notion that the serlmmentary rocks have been the ejection of comminuted mater been when he asserts earth，really helps his isen from matter ejected not sandy former case into the sea，but into the open air，he We mecomes absurd．
When pasily，if this were the proper place to do ortier to call attention to this arguments，but it is The chapter on def book which eks in Ireland is well worth perasal ；and in out azainst our best geolocical ary now and then casts ropth cousideration in the formation of some strata are n artist was travelling with Donovau the and another scientific friend，in Wales，and a zealous Vulcanian and the other geology．The one aparated and lefr．the artist between the two that they phasibiy the case may be and fartly wrong，and so outh sides，＂and he reprobates．There may be truth on
be the very first to give fair consideration to any theory properly brought before them，convinced as they may be of the justice of their own views，which have been estimation of moltitudes of facts．No one will deny that there are many difficulties in the notion of large systems of rocks arising from mere external abrasion of pre－existent continents；but the difficulties in Mr Kelly＇s theory are at least as numerous，and after all the merest sciolist in geological lore could not help recognising the fact，that many fossil beds must hav recent beds are now in the act of formation．

## Garden Memoranda．

Robert Warner＇s，Esq．，Broompield，ngab Cerlmsford，Essex．－Lovers of Orchids will find Mr． Warner＇s establishment at present well worth inspec tion，there being few places in which that gorgeous family，in which Nature seems to have concentrated the gems of her handy work，is better represented than at Broomfield．Go there when you will，there is Mr．Warner has display of magrificent blooms．
Mr．Warner has been successful enough not only to hit upon the best plan of growing his plants，bat also of flowering them in perfection．For the growth of these and other plants，we find here all sorts and siz＂s of houses，－ther old＂lean－to，＂and more modern ＇spantroofed，＂some facing south and some north；but Mr． Warner is of opinion that the most suitable form of house is the＂span－rooferl，＂and as to aspect，that which has the fullest possible benefit of the sun，with a slight shading when it is too powerful．This is undoubtedly the secret of his success in producing such a large amount of bloom． He never allows the temperature to get so high as most growers，do，a circumstance which，besides being an advantage to the plants，permits the lovers of them to spend more time among them，with a greater amount of pleasure than when they are grown in warmer houses－ this may be said especially of the houses for Cattleyas， Lælias，\＆c．，the doors of which are open every fine day． There is therefore a free circulation of air always passing among them．The plants are also kept as near the glass as possible，in order that they may have the full benefit of light in which to ripen their bulbs． Another point in his practice which deserves notice is， that he never gives his plants so much water that the soil or potting material becomes soddened，a great fault with many growers．Experience has proved that too much water is injurious to Orchids，causing them to make growths or bulbs of such a succulent nature，that it is impossible to get them sufficiently ripened to stand the winter；whereas if less water is given during their period of growth，and they are afterwards care－ tully ripened，their bulbs and leaves become firm enough to withstand the dull weather during that period of the year．
Before entering the first house，we come into a sort of porch，the sides and roof of which are tastefully covered with climbers；out of this the Orchid house door opens，and the possibility of a draught of cold air entering is thus prevented．The honse itself is span－ ronfed，abont 40 feet long and 20 feet wide，and it is used for East Ind＇a＇s species．On entering will be found a grand display，in fact a bank of bloom of Phalænopsids，reaching the entire length of the house． The beauty of their lovely drooping spikes，many of which had from 20 to 40 blooms on them，is still further enhanced by the charm of variety here and there imparted to them by intermixture with plants of，＇the mauvecoloured Schilleriata．
Amongst the different species are many varieties， both as regards colour and eize，as well as with respect to shape of flowers；one variety of grandiflora has the blooms very thickly set on the spikes，aud the lip of a much deeper orange than usual．Here may also be seen the rare and beautiful P．intermedia var．Porteana with a fine spike of flowers；it has been in bloom for several months，and is likely to hast for a few more． roseum，which is not，however，so showy as the other kinds，but it is well worth growing on accourt of the ong time it remains in bloom，which the same spike will do for 12 months at a time．
This bank of Phalænopsids is backed up with such plants as Aerides，Cypripediums，Saccolabiums，Vandas \＆c．，the fine green foliage of which forms a good back ground to the flowers，setting them off to excellent nivantage．Some of the plants of Cypripedium fillyum are very tine，having as many as two dozen fily expanda $C$ ，and we also saw beatike mun are likewise now in perfection．Saccolabium violaceum，with fine arching spikes，one of which is 14 inches long，covered with beautiful white flowers spotted with mauve，is a magnificent plant，which keeps in bloom for many months．
The centre of the house is filled with Vandas，among which V．Lowii 7 feet high bloomed splendidly last year Of V．buavis there are more than 20 plants some of them 6 feet high，and showing fine spikes for flowering in summer；$V$ ．tricolor and insignis are equally fine，
and many of them are in bloom．There are，moreover， and many of them are in bloom．There are，moreover
several fine plants of Aerides Larpentæ， 4 feet high large masses of A．virens superbum，A．quinquevalne rum，A．odoratum purpurascens，A．affine，des

Mr．Warner has inported several fine plants of the long－leaved Sophronitis grandidora，which is now in bloom，and far surpasses，both in colour and size，any of the other varieties；it was hanging along with the
Phalsenopsids，and induced an earnest desire for such a colour in that fine famil
We neat entered a＂lean－to＂house，about 100 feet in length，down one side of which is a row of Coelogyne cristata，just going out of bloom，with which they have been covered．Of this there are two varieties，one with bright lemon colour in the centre of the lip，and baving the additional advautage of coming into bloom just as the other goes out，thereby considerably prolonging
their season．In front of these are many fine Orchids their season．In front of these are many fine Orehids
in bloom，and among them Cypripedium biflorum，with in bloom，and among them Cypripedium biflorum，with two flowers on each spike，a good variety as to colour， \＆c．；also C．venustum，C．javanicum，and Lrelia Liad－ leyana，useful on account of its lasting so long in bloom； together with Aerides cylindricum，a vary rare plant， with large white and pink flowers
On the other side，the whole length of the house， are two rows of specimens of Cattleyas，Læ⿰亻⿱丶⿻工二十⿴⿱冂一⿰丨丨丁口𧘇，\＆cc，in the same beautiful condition：
＂Cattleava House，＂which is spun－roofed，and filled with what might alone be termed a good collection of Cattleyas，Lælias，\＆cc．，in such a state of health and vigour as it really does one gond to witness．One plant of Lælia purpurata promises to produce 50 flowers， and when in full bloom will be a sight well calculated Mr．Warner lasessor for the tronble of cultivating it． 20 varieties of Cutleya Mossim Mr．Warner has about 20 varieties of Cattleya Mossiz，
which bloom every year in great perfection．Here is the fine specimen of Laelia superbiens that，was nuce the pride of the Horticultural Society＇s Gardens at Chiswick． This fine plant was sold some years ago to A．Fairrie， Lsq．，of Liverpool，and on the breaking up of his collec－ tion，Mr．Warieer purchased it；it is still in the best of health，and has just gone out of bl wan．In this house are some large specimens of Letia eleqans，L．War neri，and la anceps，just going ont of Hower；thes must have been splendid，havisg，as they had，some humirels of blooms on them．Un one side of the house are sone fine plants of Dendrob：um nobile，with as many as 200 blooms on a plant，together with 1） Wallichii，well flowered；Collogvne erstata， 3 feet across，loaded with its delicate blossoms；the lovely sweet－scented Odontoglossum pulchellum，with 20 spikes， and another plant the same size just going out of bloow．In this collection were moreover Lalia Bar kerii，with richly－coloured flowers；also four well－bloomed plants of Cattleya Warscewiczii delicata，and a fine specimen of Cologyne flaccida，with 12 gracefully droop－ ing spikes of beautiful creamy－white，yellow，and brown flowers．In this house，tastefully arranged，are several fine specimens of Tree Ferns，the most con－ spicuous among which is Cibotium princeps，which is ne of the mosic ornamental of Ferns？
These intermix well with Orchids，as the effect pro－ duced by them，when judiciously arranged，is reall pleasing，and the little shade they impart is not injuriou to the Orchids．Mr．Warner observed that this house was well adapted for specimen plants，pointing out a the same time that it had five doors，all leading into other houses，and consequently，that a good circulation of heated air could always be kept upamong them．He added，however，that small plants do not succeed wel in it，as they require a closer house till they have become well established．
The wext house is that in which Lycastes，Odonto glossums，and cther Orchids requiring comparatively cool treatment are grown，a system which Mr．Warner adopted many years ago．His plants of Lycaste Skiu－ neri are not flowering well this season．Mr．Blake，the gardener，stated that they had been divided and repotte last year，which was the cause of their not producing such a profusion of bloom as they have for several years past．They are now，however，making strong growths， which promise to furnish a much hetter display next season．This house is planted with Vines，the l Paves of which make a capital shading in summer for Orchids， as well as afford a supply of Grapes，an advantage of great importance in a gentleman＇z place，where fruit as well as flowers is required．Some plants of the Odon－ toglossum grande here are very fine，and judging from the number and strength of the old flower spikes they must have been grand indeed when in bloom last
autumn．Odontoglossum nævium majus，membrana autumn．Odontoglossum nævium majus，membrana－
ceum，Warneri，and many others are also growing very luxuriantly，together with severdl large specimens of Arpophyllum giganteum．The latter are not however showing so well for bloom as they ought to do，owing to the too great distance at which they are placed from the light．If Mr．Warner would remove them to the Cattleya house，and place them as near the glass as possible，the would doubtleas fiud the change beneficial to them．
At the end of this house is a span－roofed one for Ferns and fiae－foliaged plants，in the centre of which is a large tank for gold fish and aquatic plants． Suspended from the roof are some fine specimens of such Ferns as are adapted for basket culture．Amongst them we noticed Adiantum setulosum，A．assimile Davallis ballata，and Pteris scaberula，all of which ar useful for that purpose．In summer Achimenes and Gloxinias are grown in baskets，and when in bloom， mixed with the Ferns，they have a very pretty effect Plants of Eschynanthus are aleo grown in the same
way. Is the centre of the tank stands a large plant of Dicksonia antarctica in a pot-raised, of course, out of the water ; about hat-way down the of of Lycop is a projecting rum, capable of homs to grow luxuriantly in stuch a position, and looks very pretty. At the end of this house, overlanging the water, is Cibotium Schiedei, with fronds 6 feet long, the plant being 12 feet across, its beautiful feathery fronds having a good effect, as they droop townrds the water. There are many other Ferns planted out, in the selection and arranging of which, so as to contrast well with each other, a great deal of taste has been displayed, as well as in the general arrangement of the house. Along the sides are some fine speeimens of Adiantum cuneatum, some of them 3 feet across, together with A. cardiochlecna, variegated Megonias, Marantas, \&c. Into this house Mr. Warner moves many of his Orehids when in bloom, a practice which imparts a very pleasing variety to it, and prolongs the season of the Orchids; as many as 100 blooins of Lycaste Skimeri may sometimes be found here at ouce, and the elfect produced by their mingling with the graceful fronds of the Ferns is very gratifying.

Passing from this house we enter a small one, filled chiefly with Miltonias, Oncidiums, Sobralias, \&ce.; amongst the former are some fine specimens of M. Moreliana and spectabilis; and among Oncidiums Phelpsianmm very finely in bloom. It is one of the best yellow kinds, with a richly culcuredlin. Winter-flowering Oncids are very useful, as they last long in flower, and are well adapted for cutting, either for vases or bouquets. Keturning from this house we come again to thie ciattleya huse, from which we pass to a range of three lean-to houses, facing south, which are planted with Vanes, trained up the root in the ordimary way. The two first euntain many fine Orchids, but they are used ehietly for the commoner kinds, such as Lycaster, Zygopetalums, Plajus Wallichii, of which there ate some very large specimens now showing
flower: Dendrobinm moniliforme, I). densillorum, and many of our stronz-growing but less rare kinds, that any very considerably to the general dis. that ant very considerably last house in this range is a sort of greenhouse for the hardier kinds of Ferns and flowering plants, and is now very gay, especially with Azaleas. Ainong these is a fine specimen of amoenaan indispensable plant where fowers are This house cannot be left without the visitor noticing seven large apecimens of Dendrobium nobile, placed here to retard their bloom; judging from the number of buds with which they are furnished, they will, when in flower, form a comilete floral mass. vate, with only a few bloons scattered over a large plant whereas if it received only ordinary "stove" treat ment when forming its bulbs, and after it had done so had water gradually withheld till they were wel ipened, it would be sure to furnish plenty of flower.
anses described are so situated ony doors pass rom one to the open air, an arrangement which " growers" will at once see the advantage of, as it prevents the possibility of cold draughts, so injurious at all seusons, but more especially when the plante are making their young growths.

There is another "span-roofed" house, about 100 ft long, which contains some of the choicest Orchids, but it is used more for plants in a small state than for specimens. Here are, however, some magnificent plants of Aeriies Schröderi, which, as well as being extremely rare, is one of the finest in cultivation. Besides these there are here some fine Saccolabiums, Dendrobium macrophyllum giganteum, well set with bloom; and D. lituiflorum, a very lundme and rare kiud
Some distance from this is another span-roofed house, which Mr. Warner has had built to receive the plants when any of his other houses require painting or cleaning, he being of opinion that this is matter which should be very carefully attended to. To have the painting regularly done when required is one of the best means of preventing "drip" from the in dull weather. It is also necessary to keep the glass clean, so that the water may pass freely off. W. B.

## Miscellaneons.

Walnut Grafting. -The multiplication of Walnute by grafting is attended by some dificulty, a circumstance the more to be regretted, as there are some superior varieries which it is desirable to propagate on a large seale, and wheh will not be reproduced with any certainty from seed. M. Leroy, of Angens, has atterded much to the subject, and finds that he succeelds best with wo ;d of two or three years, when the tree is in full sup, and the bud is beginning to pluali. One year's wood is too soft for the woody part to offer sumicient surface for junction, while in the oldes branches, the pith occupying only a comparatively sinall space. the graft is more readily applied to the stcek. He found also that grafts made on a level w:th mode of grafting which answers best is what is called Greffe anglsise, which appears to be what is known in

England as shoulder grafting, a method which requires 1861.

## Calendar of Operations.

(For the ensuing week.)
Authough the weather is still comparatively sunless nd cold, and vegetation generally lackwari, beds an borders are beginning to get gay with Crocuses and other spring bulbs. beds should therefore be clean and neatly raked; edges trimmed, and the surrounding lawn wel! swept and rolled. Grass cutting must soon be commenced; see therefore that scythes and mowing machines are in proper order for that purpose.

FLOWER GARDEN AND PLANT HOUSES.
Climbers in Conservatories and other show houses vill now want frequent attention. Prune off superfluous shoots, stop or pinch the points of over luxuriant leaders to induce a thowering habit iu such kinds as produce blossons from the axis of he As regards the keep them neatly tied and trained. As regards the out-door department, sae that everything is neat, clean and orderly. Let all fresh turfing be coll coarse cvercreens or shrubs before the bud becomes too much evergreen.

Anneals.-Make a sowing of tender sorts if not already dune. Pot off Balsams, Cockscombs, \&c.; such things succeed best in a frame placed on gently fermenting materials, close to the glass, and well matted up at night.
Bedding Plants.-Continue pooting off stock for out-duor decoration ; also making cuttings of Verbenas, Fuchsias, Petunias, Calceolurias, Pelargoniums, \&c.; they will all be wanted. Shade newly-potted plants, and remember that in making enttings the leaf should not remember forst allowed to flag, and then an attempt made to restore it by abundance of water, but the foliage should never be allowe 1 to droop.
Dablias.-Repot the most forward cuttings ; and put in others. It is very desirable to have extra trong plants for mixed borders and hotting the oli hese can be obtained by divic have been takenl fron roots,

Orchids.-Those growing in stoves must soon rece:v a slight shade for two or three hours"on bright days more especially those which have been disturbed at the root ; these if convenient, should be removed to a house or pit by themselves, as established plants which laave remained undisturbed will enjoy more whichine.

Tourss.-Keep the foliage dry so long as we are in danger of spring frosts. If a watering is necessary ather from a continuance of dry weather, or from the soil being light, it call be done between the rows, without watering the plants over head. Protect from hail on all occasions, and rain also while the weather is cold.

## FORCING GARDEN

Cherries. - These should have free syringings, with bundane of the syringing however must cease the moment any change of colour in the frait is perceived.

Fras.-Follow up stopping ; give manure water very freely.
Peaches.-Persist in stopping at all times every ross shoot on all the upper parts of the treeallowing such, however, to ramble when they grow towards the extremities of the lower parts; this is the best way of equalising the sap. Syringe freelyespeecially in the afternoon-and at that period endearour to create atmospheric moisture for the ni hit, by prinkling all available surfaces, except flues or pipes. Trees of these and of Nectarines in pots now in full bloom most have as much air as the state of the wenther will permit.

Pinfs-Little new can be added at present. Give air freely to growing successions in dung-pits them to grow more in bulk than in length.

Strawberries. - Keep ap succemions ; do not suffer StBawberkis.-Kit is swelling to get dry; use plenty of liquid manure necording to former directions, viz., constantly clear and weak.

Vines.--Endeavour to avoid the consequences of indulging in ton much atmospheric moisture in the daytime. Mnny berries are doubtless scalded, as well as lowes injured, by a surplus of atmospheric moistore in the merning, or too early in the afternoois, in an endeavenr to accelerate furcing by shatting up unreasomably early.

HARDY FRUTT AND KITOHEN GARDEN.
Have everything in readiness to protect blossoms, the opening of which appears to be late this season, and endervur to wradicate insects by all possible means. See that all winter and early spring work amongst fruit trees is brought to a close forthwith. The period has now arrived for committing to the
Cabragrs.- Earth up plantations of the largest plants, and keep them free from weeds. Sow also seeds of twe or more worta which will succeed each other.
Carrors - Loot sharply after crope of Early Horn
to prevent slugs from eating them. Nothiug in b-Her, perhaps, than cinder-ashes riddled extremely fi:k, and the mere dust takeu out; these sown thickly over th ground peresent such a rough surface, that bua"is and slugs dislike to venture on them.

 MR. C. F. Hrainage of Land. Whatity H. W.S. of Thatord, Herts,

E1OO( UPON the WUOISTON TACKLE aganst

 Royal Agricultural Societv of England.

Che Agxicultural Gatett.<br>SATURDAY, MARCII 18, 1865.

We understand that the Vducation Committee of the Royal Agriculiural Society of Eagland have finally reaolved to report to the Council their recommondation that a sum of $300 l$. be set apart annua!ly for prizes to be awarded by those who conduct the local examinations, superintended by the Cambridge and Oxford Universities.

What has been the history of this affair hitherto :-At the December General Meting of the Suciety in 1863, the Council were startled into the consciousness of an unfulfilled duty by the ansouncement of their entire neglect of the severth object specified in the Charter of the Society, as being among those for which they were incorporated, It is there declared, among a number of other agricultural particularissuch as the promotion of Cattle breeding and of good cultivation, of Agricultural Chemistry and Eutomulogy, of Cottage bulding, \&e. - that the Society are to promute "the education of thonse who are dependent upon the cultivation of the land for their support." The Society had, indeed, by the ir Journals and their Shows, and to sum: extent by their discussions, been promoting agricultural education during the whole course of their career. This was pointed out and admitted by the mover in this matter; but all this they could not help doing; all this was incidentally and iuevitauly the conscquence of their merc existence and activity. Many others of the objects specitied would in like ruanner have bcen promoted br any such combination of the leading agriculturists of the country for the gentral purpose of agricultural improvement. The Suciety, however, had not been satistied with this general tendency and result of their proceedings in the case of the other objects to which their attention is directed. They had nut merely excited a gevera! interest in agricultural pursuits among the large body of their members, und left it to find its own direction and expression; but they hat labourcd specifically and particularly by the offer of prizes, and by the eastly commission of scientitic and intelligent men, at creat expense of labour, time, and roney, and with sprecial direction and intention, to promote a more accurate inquiry into the entomology and chemistry and mechauics of agriculture, and a more general, and, as it has proved, most fruitful interest in the improvement of the cultivation of the syil, and of the usoful
qualities of our various breeds of horses, cattle, Theep, and nigs.
Fhil all the
Whil: all the other objects of the Charter had been thas the sulject of airect laborious and successful cffri, nunu of them being left to a merely natual share in the bencfit accruing from the general inturfst and excitement consequent upon the proce edings of a large Agricultual Suciety, hut each of them being the subject of that special, costly, and cuntinued effort which the Suciety are directed by their Charter to make in the case of each-the seventh-that which specities the promotion of the education of those who are dependent on the cultivation of the land-had been left altogether in neglect. The Journal did indeed promote this education; but the Journal was itself specified as one of the purposes for which the Society was incorporated. The annual shows promoted it; but these, tou, were directly named among the objects contemplated by the Charter. Over and above these the Charter specifies the education of the anriculturist; but over and above these the Suciets had done nothing for the education of the agriculturist.

Now, as ever, the roung man who is io he a furmer, leaves the smali sillage school, or the local boarding commercial school, or the bett.re e unty general or public school, where the general training of schorl life and particular instrnction in the elemeats of knowledge lave been suffered, expsienced, or cnjuyed, anl goes on to a farm, generally under his tather, more rarely under a good practical man elsewhere, aud ther works like a labourtr, or hunts and shoots ant smokes like a man of leisure ; and so, incidentai!y as one may say, and without any systematio instruetion, picks up whatever good or had of conntry hfe and field managem:nt, and market skill he comes across. There is certainly a need of some special direction and incentive, some guidance, some urgency, applitd to just this point iu the agricultural sch. me which has nut hitherto been thourht u!?

Fire, then, is a great national abricultural society whose busiatess it is to adopt measures for the increase of the results and the profits, and for the improvement of the machinery and methods of practical agriculture; ard this is just a task for them. The whole antogy of al! their past proceedings shuws that they may interfere in such a work as this in perfent consistency witio all they have done for agricultural improvement in other points. This is a thing on the same rank with those-having as direct and practieal a ommetion with that immediate increase of farm proluce towards which, as an Agrieultural Society, their efforts have hitherto, and properly, been directed. And it thus may claisn both rein and spur from those in the saddle here, as much as any nther towards which the good horse "R. A. S." has hitherto been directed. Nay! the "rin and spur" applied to professional agricultural education, which on general grounds we thus see are proper for the efforts of the Royal Agricultural Society, but which they have hitherto neglected to apply, are plainly indicated in those words from their Cha:ter which we have already quoted, as part of the very business for which they are incorporated. -This was the case stated at the General Meeting 15 months aryo.

Very shortly after this, Mri. Holland, M.P., moved for a Coramittee of Couucil to inquire into the instructions of the Charter in this matter, and to consider how they could be ubuyed. This Committee has met at intervals ever strice, and appears at length to have brought its deliberations ts an issue by a clear line of demarcation between the two parties in it who have been conducting the discussion. And it appears that those who originally moved the action of the Societr in this matter are in a small minority. Instead of reading the instructions of the Charter in the light of all the other particulars which it specifies, and seeing in this reference to agricaltural education a direction to promote that professional trainiug and instruction with which the ends of arriculture are as directly combected as ther are with all the other objects named; the majority elevate this serentil object for which the Society is incorporated, on to the level of a higher and altogether different class of subjects, with which as a professional body, with strictly defined purposes and objects, the Sueiety has hardly anything to do. They recomenen the Council not to reward professional attaionsent or, as in all the other examples of its rewards, professional skill, but to reward mere quality of mind. They are to give their prizes for attainments in that general middle-clasa education which the Universities by
their examination and degrees promote; and strictly agricultural field to which they are confined by their Charter

Of course the subject cannot be allowed to remain in its present position. We can hardly suppose that the Council will sanction a departure so egregious from the whole scheme and tendency of their proceedings hitherto. But if they should, we cannot doubt that a full general meeting of the Society would be clearly on the side of the minority who protest against the present resolution of their Committee, on the ground both of misrection and of waste
The lecture on Agricultural Education whioh we publish in this Number of our Journal gives the opinions of one who may be considered fairly representative of the agricultural judgment on this subject. With ample experience of business and of life he has been and is a good tenantfarmer, who has long achieved the position of success, goodwill, and general esteem in which he now stands. And notwithstanding the excessive expressions* which he sometimes uses in order to urge his convictions of the need of practical knowledge and of habits of patient industry as alone the true basis of success, we have long known him as one of the most intelligent of the correspondents of this Paper; in full sympathy with all that has been done of fessional advancement of every class connected with the land. His remarks, written some years ago for a village audience, in a style adapted for the amusement as well as the instruction of his neighbours, are nevertheless full of practical wisdom, and deserve the study of those of our readers who are especially interested in the suhject which is now engaging the attention of the Royal Agricultural Society.
We do not, however, rest on a single protest of this kind against the extreme views of those doctrinaires in educational matters into whose hands the Agricultural Society seem about to place themselves. Almost the universal testimony, so far as we have gathered it, of the best farmers in the country unquestionably declares the nead of improved professional training, and the desirableness of the Sooiety directing its efforts for agricultaral education there. And this we undertake next week to show.

Mr. Batley Denton has drawn up a personal petition, which was presented on the 6 th of this month to the Honse of Commons, of the Water Economy of Great Britain. His object is that an inquiry may be instituted into the water economy of the country, and the effect of the drainage of lands, and the sewerage of towns upon the river systems. And he rests his ease on the following grounds :-
(1). That in consequance of growing population-of improved lund culture-of manuractures spreading in all parts of
tbe king dom-of sanitary regulations extending into the king dom-of sanitary regulations extending into
all towns, and of the droughts experienced in rural dittricts, it it of the highestimportanco that the supply
of water for social, agricultural and commercial purposes, be made forthwith the subject of proper conserThation.
(2). That within the last quarter of a aentury numerous Acts
of Parliament (irstly) for the drainage of privato of Parliamont (irstly) for the drainge of private
estater, (secondly) for the drainage of districts, and
(thirdly) for the sewerage of towns, thava come into (thirdly) Sor the sewerage of towns, thava come into
operation, all of which, in difforont ways, affect the
water supply and alter the condition of the rivera Water supply and alter the condition of the rivers.
(3). That the effect discharge a larger quantity of water than had previously
heen discharged in portion of the wator diacharged by drainate was
formerly evaporated from the surface, and therefore Thever found its way into the erivers.
(4). That the maneer aud time in whichich this increased disnecessarily depends, in a great measure, upon carried out. the opations under "The Land Drainage Act, $1861, "$ heing limited to districts, which are generally
portions of catchment basins, mulut bo detrimental til the main river-courses, bec.use while better outfalls quantities of water are suddenly cischarged upon the having been made for receiving it
(6). That the object of all towne in which sanitary regulations and systematic sewerage have been adopted is to
acquire from rivers and from springs fowing into

* Of course this general acquioseence in the argument of

We must add that wo abould find no difficulty whatever in good readera and writers, and fir aritheurers, who are also
serving the inhabitants, in returnod to the rivers pol-
luted in character and diminished in quantity. . That this supply bas in certain instances boen already none of them ever became gentlemen, and I never hearl of any one of them becoming a pauper.

Now just look at my education. You will probel farmers' sons in the present day carried to the eation extreme? Reading, writing, and arithmetic oppoit that was thought necessary for farmers in those were an am not sure that it is not all that a farmer days-1 am not sure that it is not all that a farmer require
to learn at school iu the present day. I from fashion education is become essential to mow the a certain position in society, but I have not meen necessity yet of farmers' sons being kept at school ti they are 16 or 17 to make them good practical farme I have rever been able, in all my experience discover that a farmer's crops grow the better, that $h$ cattle, sheep, or pigs fatten the quicker, that his bome do more work or that his labourers are more attention or industrious because their master is a claseical cechole or because he learnt music, dancing, Greek, and latin when at school. But I promised not to touch on at sulyject that I had not some practical experience o therefore, laive the school training of farmen than I have, by again stating that reading, writing, arithmetic are in my opinion all the school trining absolutely necessary to make a good farmer, belifriu that the youth who can read well is in posseasion of : key that will unlock the storehouse of know!eldge, an that it is his own fault if he does not use it.
believe, and my expersence confrims my apinition f farmi 16 or 17 before they leave school. These boys ( ) their pardon if there are any here, for are usually all young gentlemen in; the pres. day)-these young gentlemen, then, cannot b
made at that age to begin at the beginnins made at that age to begin at the beginning
they cannot be brought to see the necessity there is learn to do anything menial tue necessify hereis work on the farm; they little think the adrantage it will be to them in after life to be enabled not only to say to a man or a boy, go and do such and such thanga but to be able to go and teach them how to do it There is the rent difference it is said between the word "go" and "come." There is a greatdifficulty in learninf and recollecting even the names of our different imple ments and things belonging to them, if nor learnt in early life-our poor old despised Kent plough lias 60 different things belonging to it, such numes as probably some of you never heard before, and if 1 were to tell them to-night you would not recollect them in the morning, nor perhaps wish to do it. There is the sheath, the buck, the cock, the scrode, the spindle, the condum, the bolster, and many others that some of you would have no idea ever belonged to a plongh if yo were only to hear their names, and I frequently meest with persons calling themselves farmers, that ini know the names of all these things, by sight, aud b
boys know thein all well ennugh by name, and look with pity on their master who dhee not and think what a pretty fellow he is for a farmer.

I have been asked by persons often, who are mot farmers, who bave educated their sons till they hase become above their own business, that could not bar the idea of standing behind a counter to weigh pian or measure calico:- perhaps they are not rich enough it send their sons to the university aud make parsons n them, or they have no church patronage if the they therefore think they will make a farmer of nim. I have been asked my opinion as to the best place send these youths to, whether to Norfolis or or to an Aricultury Cullege such as Cirencest others. I invariably answer, send the lad as near ${ }^{2}$ you can to the place you think he is likely to settle in as a farmer, select the man who has the character being the best farmer in his locality, and if you ca find such a thing as a money-making farmer in 4 present day (there are some), and get him to take and treat him as one of his family, send him and I shall be much surprised if he does not learn there from example more industry, perseveranicing economy than will compensate tor any def theoretical or even scientific knowledge that have learnt at Cirencester or any olner places has
Scotland, Norfolk, and sone other distant the merit of being the best farmed of any po the United Kingdon, but the person wecomes farming in these places will, when he become Kentish farmer, have to unlearn a great bent, kuil has previonsly learnt, and you, Mr. President to laar well as any one that nothing is more dificurnt anm than how to unlearn what we have alrendy generilly find these young men, aud farmers sons ge under the have been kept at school till they are 10, wery easy thinf impression that practical farming to learn-that nothing else is required walk aboot look and see what is going on,
their hands in their pockets, with their hands in their pockets, with heels. on their arm and adog at their heeld willing to admit that en is years, and hours every day to learn to make knowledge and practice of furming naturally and with as little effort young piga. But I think differently, a young piga. But I think dieerenty,

He filled every The parish (except the parson's and clerk's), c.msiderable amonnt of property, was retted by all who kim But I say on impossibility to go back to such a state, "Ie are not ruming to the oppasite arion with me re not giending to much time, to acquire theoretical nitnotry, energy, and losing a great deal of that aref'hers possessed. I hope you will not think I am an er opponed to education, but let me give my Tetannapul lof word - a good education to me Q be neglected for acquiring it. Youthaty ought ever ens time to learn, but something ought to be learnt Wing but experience will teach.

But we will now start the young farmer into business ann matin account. He has lony been very wise in his thought himself compen 22, and has for some time isent; has often been finding fault with of any onetior, and caling him mean and stingy (of course erm think vack) for not starting him in business, not ather, hail to depend entirely on his awn calls his apads he went, into business, But as we camuot put old tif mat not shoulders, so we must take him as he is; amselt, he never him up yet, for, clever as he thinks if hear now; and hortunate is the young man who has Ehus or a iniend who is kind enough to give it, whe
The tirsthing I wouhl aitise hiun is what I thin bith yom, sir, woul. wobld advise too, and I don' time a courting, let hime has been alrearly a cousiderabl and of a wife inore a there of requires the helping or cetel in the in tie house, they may as well be $\therefore$ whe will emable a farmer to be ahe to take care of th Wiure liun to kerk and has crops all the day, and will disoong it becumume all the night
inere ath a farm, it is known that our young frien Ghe has who are wanting to assist how thany person tint he hothsing just then to sell. One has a horse - jout the hes but not one he would recome has a duzen $\because$ ing fiend has acuried horemust sumt him. Now my : ra, olmkenk round and observing than most thinge at hif is 10 oftey hairs, and long teeih, suy, "h inat ; just itt his prime, a good seasonel horse, he is mand, wiad mather blind, lame nor lazy, perfectly
gall, $s$ davin a blemish about him : lie ha
as a kitten and as quiet as a lamb: there was never such another horse, and he must certaiuly
give satisfaction, go wherever he miy; - woul. not sell him to any one else." For that reason alone our young friend, if he is sharp, won't buy him Another has the best cow to sell, at least as good as ev a yail was set under; a third has the best breed of pigs ... the king dom, in fact if it is known that he lias rood property, his very house will be beset with calls cards and circulars, each and all expecting to floece him out of something. He must have more than a comm share of shrewiluess if he is not taken in by some o them; but if I an his adviser, there is one thing more than all others that I would caution him against, and that is, those advertising lumbucs that are duil puffing their artificial manues, their prepared catti food, and their agricultural implementg. l'ime wil not admit of giving my reasons for this advice affice it to gay that I hive myself suffered enoug from these things in furmer times, and I should just a oon expect my good friend Mr. W. - to recommen Morrison's pills to all his patients, and persuade al Cothers to soothe their infants to sleep with $G$ drey $s$ for an experienced famer to recommend all the things and implements to a young beginner, and persuade him to use them. I don't think if he winhed to uin him in two years he could find a more effectual way f doing it. No, no, my young friend, don't you be le to believe that you cannot do without, all these things. It is those who sell them who make the money not those who use them; never be tempted to ba re cheap; shun them as you would a draper's sho selling off 50 per cent. below prime cost. Brat now, having trained our young friend and started hitin is basiness, we will leave him to take care of humself, aut just turn our thoughts and attention to onr latourer as much interested in the labourer as in the furmer nay, more, for you may have good labourers withont having gool farmers, but you cannot have good farmers without you have good labourers; therefure it is very essential that our labourers should be properly reared truined, and educated.

It is probable that the mental capacities of our labourers wore too much neglected in the time of my youth, and it is a question with me now, if we are not now going to the opposite extreme. When I was young, sir, almost the only thing then thonght of with resject to the labourers' children, was to practise, to exercise and to increase their plysical piwers, to develope their muscles, to give strength to their bodies and lunds,
and to prepare and fit them for the laborious duties that would be required of them in after life. They were taught "To leara and labour truly to get their own living, and to do their duty in that state of life to to which it had pleased God to call them." Athletic sports and gymnistic exercises were encouraged ; they were allowed to walk as they liked, to run, to tumble to jump, or to wallow, when they pleased-in fact to
live and act much in accordance to Nature, and not in the artificial state they are brought up in in the present day. Each boy then tried to excel in some feat of strength, or agility; their ambition was to be thought and to become a man. With what delight the little urchins would tell each other what great things they were going to do when they got bigger. Just fancy such a make your heart therll again, to hear one of these little rascals say, "Shan"t I be just gla! when I get as bing as our Jack, I shall leave off going to school then, and go keeping crows ; I shall have 3s. a week, gad our mother says she will put 6d. every Saturday night into m money box, to lielo buy me a brall-new jacket, and know our master will give me $6 d$. for myself to spend at the fair if I scare all the crows awey, for he did give our Jack one last year
All they thouglit of, all they talked about, was their work; no crime was in their opinion equal in enormity to illeness; they were taught to bulieve that that was be parent of every vice. Tho height of their anab appear at church in on Sunday, and to have a goni dumer when they got back! aind I don't know thit haiss was not true philosoplyy, for wise men have said "Man only requireth food and raiment-all else giveth trouble." Rural sports were more encouraged then unning matches, cricket matches, wresting matches, and occasionally boxing matches. These sometines rousht black eyes and bluoly noses, but no bones wer roken; the bnys were thought none the worse of by any except the mother, and she was more please. 1 than crossed when her boy was champion. I expect to hea some of you say, "What a shocking thing to be in such a state of ignorance!" but I never knew any of those boys to do wrong because they did not know any better. But this state was too barbarous to be ailowed to last oreat change came mong us. Religion becam ashionable, or, at least, the profersion of it; the die enters wire oprning their Sinday sehools in ald direc cions. The rival systens of Bell and Laneaster sprang an, and prople became so sympathetic, sentimutal, ant dilanthropic, that these poor b.yys could no longer be eft to Nature and their parents to rear: thev must b ellucated, and their mental powors must no longe remain dormant.

I caught this eifucational fever, and inust evere:y guine , no young person of 17 was ever more san trom eduoring those Tuis fever of mine neare brought a rupture between my gnod old father and myselt than any other thing that ever occurred I well recsllect his saying "lis thought Master Wil would go mad on learning. Why," вaid he, "he can" eat his supper now without a book on the table, and I really believe, if he could have his way, he woul make all the penple scholars; and I shunht like to know who is to do the work then?" I told him thousht they would do their work the better for He said, "I tell you they won't, sir; and when you have bad as much experience as I have had, you will find that a mal who cin read, write, and cypher will never thresh for a living; I tell you be can't On: how I pitied my poor lather's ignorance and not dare tell him so. I thought then what a sad thing it was to be s) benigited us he was; I have had 49 years experience since then, but it al goes to confirm that he was right ant that I was wrong, for I have never known an ellucatel person get his living as an agricultaral lab urer yet. I do not mean a person that has bad a college education that has learnt the dend languages, metapliysies, and the arts and sciences; no, but I mean a person that can read and write, and do the first four rules in arithmetic well.
I have known such persons to become pupers; I hnv: known them to become drunkards; I bave known them t.) become thieves; lhave known them to go to gatol, and I have heard of their gaing to the gallows, ut I never knew one $t$ ) becsme a rood acricultural abomer yet. I cansay, ani do say, that in lothing that I ever set my heat up n was I ever so grievously disappointed as in the high hopes I entertainsel of edacation. I thoug!t when our parish schonls became ceneral; when tho mass of the people had been instructed there, that they must becoine batter, that they would be more honest, more temperate, more indus rious; better sons, better husbands, better fathers, better servants, better masters, and better labourers -how, have they become so? I should like to have thet question faithfully and fearlessly answered by every tarmer, and by every labourer, too, that has lived as long and watcied the result as narrowly as I have. I have heari many of my brother furmers express their regret that education-that is, such an education as our lubourers boys get in our parish schools-does them no good. I have often wondered to see out school walls covered with muns; to see how readily the boys point ont to you a city in China, or a rive in the centre of Anrica, and yet not know the names half the towns in our own country : and yet when they leave ach nol, and are emploved in agriculture, the
never the knowledge of Chins or Africa the leas advantage to then ; but it would be very useful to them to know the names and distances of our county towns, and to have a better knowledge of common things. I dare say it will be thought very presumptuou for me to find fault with the system pursued in ou schools, but we farmers are very apt to judge of things by the result; and if the seed sown does no produce a good crop, we think the seed defective or the caltivation bad. And now, after having pursued this educational scheme for more than 30 years with no better results to ourselves, we begin to think there must be something wrong in the system
