is margined back and front with *Flower of Spring* variegated *Pelargonium* instead of *Cerastium*. In this border Mr. Welsh, feeling the necessity for relief to the eye from the vast mass of colouring, has planted entire beds with *Centaurea*, *Cerastium*, and silver variegated *Pelargoniums*. The east border at the top of the garden is about 30 yards long, and is continued with bedding of the same class here *Indian Yellow Pelargonium*, planted in a very dry soil, comes out very well, as also a bed next it of the golden variegated *Sophie Dumaresque*, which for strong growth and bright colouring is much before *Lady Cullum* in effect. To the left of the border are two square grass plots with circular and oval beds planted with the choicest of zonal and variegated *Pelargoniums* and *Verbenas*. Particularly noticeable are grand beds of *Amy Hogg*, *Waltham Seedling*, *Rabens Improved*, and *Violet Hill Nosegay*, *Waltham Lass*, *Mechanic Rudersdorf*, and *Rose Rudersdorf*, these are all that can be desired for grand masses of bloom and habit. *Duchess of Sutherland* and *Lady Constance Grosvenor* are both good, but the former is not so fine as *Amy Hogg*, neither does the latter surpass *Cybister*, except in the dwarf habit, which is an improvement. The two centre beds in these plots are filled, the one with *Lady Cullum* (60 plants), the other with *Sunset*. *Lady Cullum* is disappointing at present, the habit is free and strong, but there is a dulness in the colouring, it wants more yellow and less black in the leaf. In comparison *Sophie Dumaresque* is much more effective. *Sunset* is a failure for bedding, the foliage being too crumpled out-of-doors. The oval beds are filled with *Verbenas*, of which *Firefly* (scarlet) and *No Plus Ultra* (pink) are much the best bedders. Passing down from this bright spot, which is divided from the under portion by a thick Beech hedge, we come to an intermediate piece of grass, in the centre of which stand two splendid *Mulberry* trees, with seats underneath. Under these trees are three large beds filled with *Centaurea candidissima* lit up with *Christine* and *Dr. Hogg Pelargoniums* planted through them sparingly, and at the opposite side by the wall (which divides this portion from the kitchen garden) runs a line of *Viola cornuta* in full bloom. Taking a seat under the *Mulberry* trees, we enjoy a view of Mr. Welsh's grand effort, and which alone would make him famous as a colourist in bedding out. No art could paint the lines of colour so effectively as it is portrayed in these perfect ribbon borders, which are about 70 yards long, by 12 feet broad, bordered with eight lines of bedding plants, viz., the back row of silver and green colours (variegated *Acer* and *Hollyhocks*), 2, scarlet (*Excellent*, zonal *Pelargonium*), 3, silver grey (*Centaurea*), 4, magenta-rose (*Amy Hogg*), 5, Purple King *Verbena*, 6, silver variegated *Pelargonium*, *Flower of Spring*, 7, crimson (*Iresine*), 8, gold and red (*Mrs. Pollock*). At the end of these ribbon borders, three beds come in with very good effect, a centre square bed of *Pelargonium* *Cirelet*, and the two side beds alike of *Perilla* and *Centaurea*. The perfection of this piece of bedding may be estimated by the fact that every plant in it is so well grown as to be fit to put on an exhibition table. Turning to the right we come to an enclosure near the greenhouses, the circular beds in which are filled with a mixture of plants such as *Arundo variegata*, *Cannas*, *Aloes*, *Bambusa variegata*, *Brugmansias*, variegated *Pampas Grass*, *Echeveria metalica* and *glauca*, &c.; an edging of *Polemonium variegatum* is very good in the centre beds. In front of these a bed of *Pelargonium*, *Beauty of Calderdale*, is perhaps the most recherche in the whole place. There is also a bed filled with the new variegated zonal *Pelargoniums*, and another with the new bicolors, far more effective for bedding purposes than the tricolors, the latter being wanting in the distinctness of colouring which marks the former.

Amongst the new tricolors were noticeable, *Louisa Smith* (very fine), *Mrs. Dix*, *Countess of Craven*, *Mrs. Watson*, *Queen Victoria*, *Princess Silverwings* (very crumpled), and *Glen Eyre Beauty*, whilst in the new bicolors we noticed the *Queen* (with white flowers and fine foliage), *Egyptian Queen*, *Artemus Ward* (very distinct), *Earl of Dublin*, and *Model* (very neat foliage). *Perilla* is very coarse, though effective, but of all, *Beauty of Calderdale* comes out here far ahead, the colour is grand and well defined, and the foliage of the largest size and smooth. Among other plants, the *Golden Feather Pyrethrum* (seedling) was very good, but we cannot say as much of *Fuchsia Golden Fleece*, which seemed a complete failure.

When it is considered that this bedding ground is surrounded by a wall 8 feet high, it will be understood at once that there is great difficulty in making a successful bedding display, far more than when there are shrubberies and lawns as adjuncts.

In the square of grass behind the two ribbon borders are some fine plants of various choice *Conifers*, about 10 or 12 feet high, such as *Araucaria*, *Cedrus*, *Cupressus*, *Pinus*, &c., which serve greatly to improve the appearance of this portion of the grounds.

Mr. Welsh must feel well repaid by the large amount of success which has attended his labours since undertaking the management of this property, and also by the pleasure which his grand display affords to numerous visitors through the season, and the emulation which he excites in the gardening community to imitate or approach him in success. *Alexander Campbell, Jun., Dublin.*

Obituary.

In the death of Dr. MACLEAN, of Colchester, horticulture loses one of that small band of practical experimentalists whose labours are so valuable. For many years Dr. MACLEAN practised as a physician in Colchester; but his leisure hours were devoted to

Look to your Grass Lands.

JAMES CARTER AND CO.'S RENOVATING MIXTURE OF GRASSES and CLOVERS SHOULD NOW BE SOWN. This Mixture is specially prepared to suit the various soils, and consists of the most desirable kinds to produce a Permanent Pasture of first-class quality on old decayed Pastures and other lands that have suffered through the extreme dryness of the past season.

CARTER'S "PRIZE MEDAL" PASTURE GRASSES for FORMING NEW MEADOWS, mixed to suit all Soils, from 21s. to 35s. per acre. Special low quotations for quantities on application to JAMES CARTER AND CO., Seed Farmers, 237 and 238, High Holborn, London, W.C.

GREEN FOOD SEEDS.—1869. Welsh Winter Vetches Winter Rye Trifolium incarnatum Winter Oats Italian Rye-grass Winter Rape

To BE SOLD, on Commission, 200 bushels of GREY STONE TURNIP, 50 bushels of SKIRVING'S SWEDE, 50 bushels of GREEN ROUND, 13 bushels of SIX-WEEK WHITE STONE, 1 cwt. of HOLLOW CROWN PARSNIP, 30 bushels of GREEN TOP SCOTCH, 1 cwt. of EAST HAM CABBAGE, 4 tons of YELLOW GLOBE WURZEL, and 23 bushels of WHITE SPANISH ONION SEED, also about 8 quarters of DICKSON'S FAVOURITE PEA; all the growth of 1869.

Special Offer of New Potatoes. THOMAS PIERPOINT, Warrington, begs to offer the POTATOS introduced by him in 1869-70 at prices one-third below the fixed quotations for 1870. The Harry, a very early variety, is thus reported in the "Gardeners' Magazine," Feb. 6, 1869, p. 53:—"Harry, Kidney, combines in an exceptionally perfect manner the finest quality with elegance of appearance and great productiveness."

THOMAS PIERPOINT, Seedsman and Seed Grower, 123, Bridge Street, Warrington.—[Please to note address, as there is another of the same Name and Trade in town.]

H A L L E T T S PEDIGREE HUNTER'S WHITE WHEAT, ALSO THE ORIGINAL RED.

Price, including bags, Five Guineas per Quarter, by the Quarter or Half quarter; One Guinea per Bushel for less than a Half quarter, delivered at the Brighton Station, in bags sewed up, sealed, and containing printed directions for planting, upon receipt of Cheque or Post Office Order, without which it will not be sent to unknown correspondents. Less than a bushel not supplied.

Apply to Captain HALLETT, F.R.S., The Manor House, Brighton

Wheat Sowing. DOWN'S FARMER'S FRIEND for Preventing the Rust in Wheat, and the Ravages of the Slug, Grub, and Wireworm. A 9d. packet is sufficient for Six Bushels of Seed Wheat, which can be dressed and sown in a quarter of an hour.

THE LONDON MANURE COMPANY (Established 1840) Have now ready for delivery, in fine condition, CORN MANURE, for Spring Use

LAWES' WHEAT MANURE, for AUTUMN SOWING, now ready for delivery. All other Manures and Cakes as per Price List, supplied on the lowest terms. Apply for prices, &c., to JOHN BENNETT LAWES, 52, Mark Lane, London, E.C.; Dublin, and Shrewsbury.

REES AND CO.'S BIPHOSPHATED PERUVIAN GUANO (Registered Trade Mark, Flying Albatross), is now ready for delivery in quantity and in fine condition. It is believed to be the best Artificial Manure yet produced.

Autumn Sowing. ODAM'S NITRO-PHOSPHATE or BLOOD MANURE for WHEAT.—This Manure, specially prepared for Autumn Sowing, is rich in Ammonia, Phosphates, and other ingredients required for the healthy growth of Grain Crops.

Particulars will be forwarded upon application to the Secretary, or may be had of the Local Agents. C. T. MACADAM, Sec. Chief Office, 109, Fenchurch Street, London, E.C.; Western Counties Branch, County Chambers, Exeter; Irish Branch, 40, Westmoreland Street, Dublin.

THE BIRMINGHAM CATTLE and POULTRY SHOW.

The TWENTY-FIRST GREAT ANNUAL EXHIBITION of FAT CATTLE, SHEEP, PIGS, DOMESTIC POULTRY, CORN, ROOTS, and IMPLEMENTS, will be held in BINGLEY HALL, on SATURDAY, MONDAY, TUESDAY, WEDNESDAY, and THURSDAY, November 27, 28, and 30, and December 1 and 2, 1869, when PRIZES to the amount of nearly £2100 will be awarded in the following Divisions, viz.:

FAT CATTLE 2507 10 0 BREEDING PIGS 277 2 0 FAT SHEEP 313 8 0 ROOTS and CORN 70 10 0 FAT PIGS 69 11 0 POULTRY and PIGEONS 747 14 0

Prize Lists, Certificates of Entry, and every information may be obtained from the Secretary The ENTRIES CLOSE on MONDAY, November 1 JOHN B. LYTHALL, Secretary. Office, 30, New Street, Birmingham.

SMITHFIELD CLUB FAT CATTLE SHOW.

The ANNUAL SHOW of FAT CATTLE, SHEEP, and PIGS, will be held at the AGRICULTURAL HALL, ISLINGTON, on MONDAY afternoon, December 6, and Four following Days. Intending Exhibitors are requested to apply for Certificate Forms by the reference letters as under.

CATTLE.—Form A. For an OX or STEER (in any Class). " B. For a COW or HEIFER (in any Class). " C. For a BEAST in Extra Stock. SHEEP. " D. For a PEN of three WETHERS (in any Class). " E. For a SINGLE SHEEP in Extra Stock. PIGS. " F. For a PEN of three PIGS (in any Class). " G. For a SINGLE PIG in Extra Stock.

ENTRIES for LIVE STOCK CLOSE NOVEMBER 1. Prize Lists, Forms of Certificates, and all information may be obtained on application to Mr. DAVID PULLEN, Assistant Secretary, at the Office of the Honorary Secretary, corner of Half-Moon Street, Piccadilly, London, W.

MEETINGS FOR THE ENSUING WEEK. October 19, 20—Herefordshire Agricultural, at Hereford. 21—Ayrshire, at Kilmarnock.

The Agricultural Gazette.

SATURDAY, OCTOBER 16, 1869.

THIS, upon the whole, has been a pretty fair season for green crops. Turnips, Mangels, Swedes, as a rule, look well; most of them are uncommonly late; nearly all have more top than usual. Many green crops also manifest an unusual tendency to run to seed; this has been especially the case with Sugar-Beet.

The middle of April is time enough to sow the crop. Every day the seed is put in before the 16th increases the risk of runaways. The Lavenham crops this year have been sown from the end of March to the end of April, and with the exception of one crop, which we believe was put in in May, they are all run more or less, and most of them in almost equal proportion.

Deep culture, by providing a well-filled cellar all around and beneath the roots for them to draw upon during drought, must likewise prove useful as a means of preventing "bolting." The irregular feeding of plants—gorging to-day, and starving to-morrow—is one of the surest means of sending them into seed, and such irregularities are much more common on shallow than on deep tilths.

But probably the surest remedy against bolting consists in a careful selection and storage of the seed sown. It is, however, a singular fact, that the seed of last year and of this is the same; it is a year older, and that is all! We can hardly suppose that another 12 months having passed over the seed, could develop the greater energy seedward.

We have often heard aged gardeners say that the older the Cucumber and Melon seed the more freely the plants would bear fruit. If so, old seed of other plants, such as Beet, might readily manifest the same peculiarity. Have our readers observed any unusual tendency to run away in old Mangel seed? We hope some of them may record their experience on this head, as the point is important.

Sugar-Beet from forming a larger top than most of the Mangels, might possibly manifest this seedward tendency, if such exists in plants raised from old seed, in an exaggerated form. Another season or two's experience will set this matter at rest. Most of the growers are saving next year's seed from a careful selection of their best roots; and next year's produce will be the offspring, not only of new seed, but of that grown under their own eyes and garnered by their own hands. It cannot be denied that, although this season common Mangels and early Swedes and Turnips manifest

an unusual elongation of top and tendency to bolt, yet the Sugar-Beet has done so much more than others. The fault, therefore, must either be in the seed, the skies, or the constitution of the plant. It would be folly, as well as directly opposed to many years' experience, to look for it in any constitutional bias, while either the changeable weather or the age or quality of the seed might account for it. The weather alone has been enough to make any susceptible crop take a wrong turn. Biting frosts and burning heats, delugings of cold rain succeeded by the most withering droughts, have succeeded each other in rapid succession, like the combinations in a kaleidoscope. Hence, possibly, the large percentage of runaways. They are probably merely the abnormal products of an exceptional season. Next to the runaways the wireworm and grub have been the greatest foes to the crops. A great many fields are blank; in fact there is scarcely one with a full regular crop. We were told that the seed came up well, but the plants in a young state were attacked by wireworm and ruthlessly destroyed thereby. The best remedy for this scourge was found to be a roll, to crush down the plants, and compress the earth so firmly together as to present a mechanical barrier to the devastations of these pests. It seems doubtful whether the rolling killed the worms or merely shut them in; the point of most moment is, that it is asserted to have saved the crop. In fact, amongst the best growers strong opinions were held in favour of a solid seed-bed and a firm surface for the young plants. A deep, well-worked, richly-manured tilth, and then solid rolling before sowing and after the plants appeared, was the panacea advanced against blanks; and those who had practised it had the most regular plant.

But it must not be inferred that these drawbacks have spoiled the crops. A sweepstakes had been entered upon by the growers for the best crop of three acres, to be judged by Sept. 20, and on that day the crops were examined. Several of the gentlemen, from irregularity of plant, &c., withdrew from the competition; but the crops of most of them were looked at, and five of the best were judged and weighed. It should be noted that the plants are still in full growth, making rapid progress in size and weight. In fact, with fine weather, there is every prospect of another fourth being added to the gross yield within the next month.

Yet on September 20 this year the maximum weight is greater than that reached a month later last year, that is, over 21 tons per acre. Another grower has reached 19 tons, a third 15, a fourth 14½, and a fifth 13½. Had there been a regular plant, the average would have been about 18 or 20 tons per acre.

The common Mangel crop will not greatly exceed this average this season. As a means of comparing the respective weights of the two crops, a portion of one of the best fields of Mangel in the whole district was examined and weighed. It was a model crop of a choice variety of Tankards. The soil was naturally good, and it had had a heavy dressing of farmyard manure. The crop had been skilfully cultivated and scrupulously cleaned. The plant was regular, at distances of 32 inches between the rows, and about 18 inches asunder in the rows. This gave 7 rows to 6 yards in width. The yield was 30 tons gross weight—that is, 24 tons of roots and 6 tons of tops per acre. The following tabular statement will exhibit at a glance the respective weights of each grower, and the difference between the Sugar-Beet and the best crop of Mangel:—

Table with 4 columns: Grower, Gross Weight, Roots Weight, Leaves Weight, Roots per Rod. Rows include Common Mangel-Grown by Mr. Allen, Lavenham; Sugar-Beet-Grown by Mr. Hitchcock, Lavenham; Mr. Robert Edgar, Cuckfield; Mr. G. S. Mumford, Lavenham; Mr. Robert Hawkins, Milden—first field; Ditto—second field; Mr. William Biddell, Lavenham.

Stones per Rod, or Tons per Acre.

The results are given in tons per acre, as a stone per rod may be so stated. By multiplying the number of roots per rod by 160, the number per acre is found. This tabular statement conclusively shows that as much gross weight of Sugar-Beet may be

grown as of Mangel. An excess of top will, however, be noticed. This will probably be corrected to a great extent by a careful selection of seed. It is, however, a lesser evil than may be imagined, as sheep, cows, and bullocks are passionately fond of the tops, and they form a sweet succulent article of food, either neat or cut up with dry chaff. It has been proposed by some to consume the tops with sheep before the roots are harvested, in order that they may be consumed in a clean state. This would, of course, make the harvesting more difficult, though it could hardly injure roots for sugar-making, as it will be remembered that, for this purpose, the crown is dispensed with. Attention will doubtless, however, be directed to the growth of heavier roots and less tops. It will be observed, that the best grower this season has reduced the percentage of top to root considerably below all the others.

Another fact rendered patent by this tabular statement of results, is the light average weight of the roots—the prize Beet only exceeded by a fraction $1\frac{1}{2}$ lb. a-piece; while the others descend gradually down to a pound per root. There is no reason, in the nature of the Sugar-Beet, why 2 or even 3 lb. per root should not be reached. It is in this direction that a maximum weight must be looked for. Mr. ALLEN's weight of Tankards has only to be given to the Sugar-Beet, and his number of roots doubled, and then no crop could for a moment compete for profit with Beet-sugar. Such results seem quite within the range of possibility, for we observed little difference in the size of the Sugar-Beet when, either from accident or design, the roots were placed wide asunder. Most of the growers, for convenience of cleaning, had five rows on the three yards stretch, one or two had six, and one had less than five. The roots in the six rows were equal in size to the five, and the thinner plants were among the lightest seen. Two hundred plants to the rod should be about the average, and these, developed pretty well, would give a splendid return. It is astonishing how irregularity of size and a loss of a few ounces on each root brings down the gross yield. Blanks, again, play havoc with final results. There was not a single field with a uniformly perfect plant. Wireworm and grub must be vigorously fought against and extirpated to enable farmers to make a full return from this new money-maker. These pests seem to enjoy the sweets as much as ourselves, but, of course, what they win we lose, and unfortunately their pound of sweet food may deprive us of tons of roots.

By growing a full plant, economising the leaves, and making beef out of the pulp, there is no doubt but that Sugar-Beet growing will prove profitable to the British farmer and useful to the nation. It puts money into the farmer's pocket, and finds employment for his workmen at a season when both are likely to be scarce.

A SUBJECT of especial agricultural interest at this season of the year, and well worth examination at any time, has been mooted in a recent communication from Mr. C. PAGET, of Ruddington Grange, near Nottingham. The proper depth of drains, more especially in the case of pasture land, has long been a question on which great difference of opinion has existed; and the discussion is one which may be usefully revived just before the winter's drainage works begin. Mr. PAGET on page 1024, and Mr. WILLOUGHBY Wood on page 878, have contended for 3 feet, as being generally a sufficient depth for the drainage of grass-lands; and in both cases instances are described in which this opinion had been amply confirmed by experience. On the other hand, one does not see why, if the use and fertilisation of an additional foot of subsoil by the deeper drain is good for the crops proper to plough-land, it should not be equally serviceable for many of the Grass plants and the Clovers of green fields. In the former case, indeed, we can by deep and thorough tillage let down the surface water almost half way to the deeper drain at once. but, in the long run, old grass-lands whose subsoil it is not possible to stir, will let the rain-water percolate throughout their subsoil to a pipe laid 4 feet deep, and, that being proved by the activity of 4-foot draining soon after rainfall, it is hard to doubt that the crops of Grass sown on land thus fertilised must be better than those which are fed from a shallower, and therefore less abundant, store of food. We

have also the experience of many drainage engineers, which can be quoted to the effect that whatever may be the immediate result upon grass-lands, the deeper draining ultimately tells to the advantage of the crops they yield, just as it does upon the produce of the Wheat and roots and Clover crops of arable farming. On the whole, therefore, we believe it is a fortunate thing that the Enclosure Commissioners stand committed to the general adoption of the deeper drain, alike on grass-lands and on plough-lands. We shall be glad, however, to hear from any correspondent on this subject any statement of experience on which his own opinion may be founded.

— THE price of Wheat lowered from 1s. to 2s. a quarter at Mark Lane on Monday, and trade has been dull throughout the country at that decline. Other grain and feeding stuff have been without much alteration.—The live stock and meat trades have again been in an active state for fine qualities, 5s. 6d. being the highest quotation for beef, and 5s. 11d. for mutton.—The agricultural seed trade is still nominal in amount.—English wool is in better demand, but dearer.

— At the Educational Congress held during the past week at Birmingham, Mr. PAGET, of Ruddington Grange, Nottingham, thus referred to his experience on half-time labour for boys upon the farm:—"He had been alluded to as an employer of agricultural labour who had for many years insisted upon the education of his farm boys, that they should spend some days in the schools as well as at work, and what was the result of that system? In the first place it had been in operation 16 years; and, although the experience of one farmer could not cover a great extent of ground, the results had been so uniformly alike, and so successful, that he had no hesitation in saying the system was a decided success. Upon his farm he had 34 boys employed, upon the condition that they spent the alternate days of the week in school. He had done this without any sacrifice on his own part, because he felt at the outset that it must be a business success; and it had proved, commercially speaking, successful. He had, too, been better served under the system than before its introduction. His system was this:—He received the boys at nine years of age, on condition that they were able to read decently, and at the annual examination of his school it was proved that his boys fully maintained their own with the boys of those persons who sent their children to school in the regular way. At 13 they were examined, and those who could write accurately from dictation, read correctly, and do the first four rules in arithmetic received from him a prize. He had written to the employers of some of the children who had been taught under his system, and the uniform reply of the masters was that they were perfectly satisfied with their servants, and the servants themselves had written to him letters of the most creditable kind. That was a proof that after leaving his farm they continued their education. After they left his farm they had no difficulty whatever in obtaining situations, because they were better servants than the majority of their class. To obtain admission to his farm, the children of the locality attended the village school to learn to read, a proof that in education they saw promotion in the distance. As to the general question of how far education should be compulsory, he had contended for many years, while member for Nottingham, that as society was bound to provide for the poor and criminal classes it was bound to see that the poor were brought up in such a manner that there should be the least probability of their becoming paupers or criminals."

— A very important and urgent question is mooted by an "Inquirer" in the following note—Being resident in a neighbourhood where straw costs 70s. per ton, I desire to elicit from any of your readers a method whereby one can obtain a substitute for straw, either by the use of boarded floors, sawdust, or any other means to save expense. I have heard that in the large cowhouses in London, coir-mats are sometimes used—are they efficient? Would they answer for horses as well as cows? Any information would be thankfully received. I remember reading of a farm where sand was used for animals to lie on—has experience shown that system to answer? To all which questions we direct the attention of our correspondents.

— A police report of Tuesday last throws some light on the London milk manufacture. A dairyman and cowkeeper, of Green Lanes, Stoke Newington, employed a cowman and his wife, who resided in a cottage near the sheds, where he keeps about 60 cows. These people have been charged before the Clerkenwell magistrates with stealing milk. At their cottage the prosecutor retains milk, which it was the prisoner's duty to sell, receive the money, and hand it over to the prosecutor's clerk. The male prisoner had left for a week's holiday, and the prosecutor having made certain discoveries, went to the cottage, and, on measuring the milk for sale, found 12 quarts, being 5 quarts more than had been supplied that day from the house. In the 12 quarts that he took there were only 7 quarts of milk, the rest had been made up with water. On cross-examination he declared that he never added cochineal, salt, or other deleterious matter to the milk he sold. He never adulterated his milk. The male prisoner held up a large bottle containing a nasty-looking brownish liquid, and said that was what was put into the milk to make it look rich. Ultimately Mr. BARKER committed the prisoners to the Middlesex Sessions for trial, when possibly further details may be forthcoming.

— At the Great Braxted meeting, last week, Rev. J. BRANSTON, vicar of Witham, called attention of the employers of agricultural labour to the need of conciliating and retaining the labouring men on their farms. Employed during the sunny days of the year, they are not certain of employment the whole year round, and so they look for other employment. They go to a town or turing district, or to some railway, and find employment where they shall be sure of work the whole of the winter; and in consequence they are lost to the farming interest, as it having once tasted the sweets of higher wages they received at home, they never return to employment. This is one cause why labour is becoming more and more scarce, and will prove a detriment to the employers, unless they look to it well, and see to their young men a remedy suggested by Mr. BRANSTON—the maintenance of friendly personal relations with the lads of the farm—will no doubt exert some influence of the kind he anticipates; but the idea that they are to be thus kept in ignorance of the higher wages is ludicrous. The competition for employments for the services of the labourer is not to be deprecated as unwholesome or unbecoming by any class of employers. Let every master, according to work, and boys and young men have no ground for dissatisfaction. Provisions would do more than all the petting world to satisfy young men. (This, with that personal consideration which is always due to "bours," whether they be masters or men, and they be young or old, would go farther to retaining lads upon the farm than any special course a particular end in view.

— The reviewer of the new number of the Agricultural Society's Journal in our columns some weeks ago, to its statement that the award of the Society of Arts' prize to Mr GIBBS, for his drying damp agricultural produce, implied that the judges, who had been unanimous in their verdict, thereby necessarily sanctioned and affirmed the principle of Mr. GIBBS' invention. Mr. DENTON has taken exception to this statement, (p. 1048) that the decision must be considered an award, as he had stated it to be, not indeed a machine described in the essay, but for the purpose on which it was founded. The terms in which the offer of the prize was announced should terminate discussion. The gold medal of the Society and a sum of 50 guineas were offered "for the best essay on harvesting of corn in wet seasons."

The first part of such an essay—after noticing the systems at present adopted in damp climates for counteracting the effects of moisture upon corn in the field, and avoiding such exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytical exposition of the best available means.

- "1. Whereby cut corn may be protected from rain in the field.
- "2. Whereby standing corn may be dried in wet seasons, and thereby be fit for use by actual process.
- "3. Whereby cut corn may be dried, or may be ventilated, but air, or other methods, with a view to its being fit for the store, both in the ear and after threshing.
- "4. Whereby cut, sprouted, or otherwise injured corn, wet, may be best treated for grinding or for other purposes.

The whole to be supplemented by a statement of the results, and actual cost of each system described, authenticated estimates of any process proposed for adoption based upon existing but incomplete experiments. The above requisitions are given suggestively; and the writer to the editor or to the treatment of the subject, provided it be kept within the scope of the rules, and within the limits of the prize, may be as liberal as he thinks fit. It is probable, as a matter of fact, that the gentlemen who undertook the award of the prize "the best essay" as aforesaid, may have seen approved of the principle involved in Mr. GIBBS' invention, and even of the actual machine which he described in his essay, but we have the best reason for believing that neither the principle involved nor the machine described was made the subject of discussion by them. They probably concluded that their duty was performed when they had carefully considered the relative merits of the essays before them, and certify that the one which they had selected "furnish a practical and analytical exposition of the best available means, &c." And we do not think the award need have been dissented from by any even though the machine, one of many means described, had not commended itself to their judgment as upon a good or satisfactory principle. In any case, if the judges, if they had been canvassed on the machine was sound, but the Society of Arts' award, we think, committed by their judges to that assertion.

— The Rev. F. O. MORRIS writes to the editor of the Agricultural Labourer in regard to a remark of Mr. WARD at the Berkshire agricultural meeting—"All I can say is that a labouring man with tolerable prudence enjoys good health, may enjoy life a good deal more than the hard-working mechanics in our towns." He says—
"I was sitting yesterday in one of our cottages when I saw the wife of our largest farmer, who lives a mile and a half from here, at the top of our hill, the highest ground, I believe, in the East Riding of Yorkshire. He farms about 200 acres of land, which is not large compared with some of the West farms. I went out to speak to her for a moment, but it ended in a talk, chiefly about a late farm servant of theirs, who had buried about ten days before, and whom I had attended for the last seven days of his illness, which only a fortnight from the day he was first taken ill, and a day of his funeral. I had some further conversation afterwards, when she came down to decorate the coffin."

The Yorkshire agricultural labourer is no doubt better off than the labourer in Devonshire, and that is the very fact on which, no doubt, Canon GIRDLESTONE relies as the explanation and justification of his efforts. In two instances lately tenant-farmers have been punished—the sentence on one, a man of wealth and position, near Trug, Hertfordshire, having been three months' imprisonment with hard labour—for cruelty to their cattle. The prosecution in the latter case was instituted by the Society for Preventing Cruelty to Animals. Horses on the farm of Mr. GINGER, of Boxted, Hemel Hempstead, having long been in a state of great suffering and utterly unfit for work, and the evidence proving that Mr. GINGER knew of their state, and that they were worked by his authority, he was sentenced to be imprisoned for three months, with hard labour, in the House of Correction at Hertford. In passing this sentence the Chairman remarked that it would be a farce to impose a fine in such a case upon a man who farmed 500 acres of land, and had private property besides. ROBERT SHARPE, Mr. GINGER's foreman, was sentenced to be imprisoned for six weeks, and the ploughmen who were with the horses were fined 11s. each, including costs. It should be stated that Mr. GINGER and his foreman had been previously convicted, and fined for a similar offence.

Leases, and their advantages to both landlords and tenants, were recently treated of in the following conclusive and encouraging manner by Lord PORTSMOUTH:— "Since 1822 the experiment of 31 years' leases, with free liberty to the tenant, and practically vesting all buildings in the tenant, has been tried on my estates in the county of Wexford, and has proved highly successful. Badly cultivated patches of land, with wretched houses on them, have been changed into well-cultivated farms, with first-rate homesteads. The rental has been more than doubled, is punctually paid instead of irregularly paid. Discontent and misery exist no longer. With such results, are not landlords blind to their own interests who refuse to their tenants the common justice of leases with equitable conditions? By what law of right can buildings which a tenant built and paid for belong to his landlord? If it be decided on a final day, simple justice—which as the rule in the land law for English tenant-farmers have received from the Statute of 1831—will work a vast and beneficial revolution in the rural districts of Ireland."

OUR LIVE STOCK.

WE beg to remind our readers of Mr. Fowler's sale next Tuesday. The Prebendal Farms are within a very short distance of the Great Western and London and North-Western railway stations at Aylesbury. A review of the catalogue of this herd will be found in our issue of last week.

Mr. Duckham's first periodical sale of pure-bred Hereford cattle will take place next Thursday, when 100 head of first-class stock from the herds of many of the best known breeders will be offered. The sale will be held in the showyard at Hereford, the day after the county Agricultural Meeting.

Mr. Thornton will sell the entire herd of Short-horn belonging to Henry Emson, Esq., of West Ravendale, near Grimsby, on Wednesday, 20th inst. We are informed in the preface of the catalogue that "this is one of those old-fashioned herds for which the county of Lincoln has long been celebrated." Sires from Messrs. Torr, Dudding, Lawrie, and Cartwright having been used, which is a good guarantee of purity of blood. The pedigrees, however, are very short, usually registering two or three crosses of pure blood only. We do not include *Fannal* in this statement, a well-bred young bull (lot 73), from Aylesbury, by Lord BULLOCK (22126), and of the *Flower* tribe. Mr. Thornton speaks of the cattle as very uniform in character, and recommends them as "admirably adapted for the foundation of a future herd."

The Aylmham Hall sale came off on Tuesday, the 5th inst. The respectable average of 301 15s. 3d. was realised over the whole of the 27 animals offered, while the cows and heifers brought 32l. 1s. 5d. each. The highest prices were given for the four females of the *Cressida* tribe, a most excellent strain, as we pointed out last week. The first of these, *Andromache*, became the property of Mr. J. P. Foster, at 60 gs.;

Cressida 6th was bought for 62 gs. by Mr. Jefferson; *Maece*, by PARIS (20,409), and a daughter of *Andromache*, was sold to Mr. W. Ashbourne for 28 gs.; while *Maria*, by GRAND DUKE 10TH, and also a daughter of *Andromache*, became the property of Mr. Foster at 40 gs., and goes with her mother to Kalthow. The highest figure for bulls, 37 gs., was given by Mr. Carard, for *MACAR*, also of the *Cressida* tribe. *Lalida*, by CAMBRIDGE BARRINGTON 1ST, proved the ancestress of some of the highest priced stock, her daughters *Leona* and *Leda* making respectively 32 and 38 gs., and her grand-daughters, *Godtha* and *Libya*, 39 gs. each. *Irz*, by CERDIC, and of the *Winifred* family, was sold for 39 gs., and *Juanta*, a six-months-old calf of the same strain, was bought for 21 gs. by Mr. J. Bowness. The remainder of the herd brought little over ordinary prices for cattle of similar age.

A month ago we gave some account of the late Mr. Benjamin Wilson's stock at Brawith, near Thirsk, in Yorkshire. The herd consisted of four families, two of which, the *Vesta* and *Certainty* strains, were long bred at Brawith. *Miss Milward* is of a good sort, bred by Earl Cathcart, and several animals are descended from the stock of Sir R. Crompton, Wood End. The sale of this herd took place on Friday, the 5th inst., the Messrs. Wetherell, of Richmond, acting as auctioneers. A large local company assembled, and although no extraordinary prices were given, the good average of 23l. 6s. 9d. was obtained over 24 animals disposed of. The three heifers of the *Certainty* tribe brought an average of 38l. 6s. 8d. each. The first of these, *Beauty of Brawith*, by YOUNG EMPEROR, was bought by Mr. Atkinson for 28 gs. *Certainty 12th*, by EARL OF BRAWITH, of the same strain, and out of *Beauty of Brawith*, became Mr. Metcalfe's property for 56 gs.; and *Certainty 13th*, full sister to the last-named lot, was secured by Mr. David Neasham for 25 gs. Among other fair prices may be mentioned 33 gs. for *Vesta 2d*, a 9-year-old cow, the oldest representative of the *Vesta* tribe, and now the property of Mr. Mason, of Skelton. *Venus*, by EARL OF BRAWITH, was purchased by Mr. Swaine for 34 gs.; and *Vesta 5th*, by the same sire, was knocked down to Mr. Barby for 35 gs.

One of the largest and most important Short-horn sales of the present season took place at Shouldham Thorpe, Downham Market, on Wednesday, the 6th inst., when the Messrs. Wetherell, of Richmond, disposed of 14 cows and heifers and 6 bulls, bred by and the property of Mr. Gamble. On the 18th ult. we gave some account of the origin of this herd, and mentioned particularly several members of the Brawith *Certainty* tribe, and of the famous *Telluria* sorts. Mr. Gamble may be congratulated upon the result of his sale, as the 50 animals offered brought the famous average of 19l. 2s. 4d. each: the female portion, comprising 14 head, averaged 47l. 11s. 7d., and the 6 bulls brought 17l. 19s. 6d. each. Mr. Aylmer secured the 11-year-old cow *Charme*, by GOLDFINDER, bred by Mr. Benjamin Wilson, for 25 gs., and this was looked upon as a good beginning. Lot 1, *Fairwater*, by PLATO (18,552), was bought by Mr. Micklethwaite for 70 gs.; and Mr. John Aylmer took the next lot, *Fame*, by 3D DUKE OF THORNDALE, and of the *Telluria* family, at 60 gs. Next came a daughter of *Fairwater* (lot 4), a nice roan heifer, which was purchased by Mr. Durrant for 73 gs. *Friendly* (lot 7), half-sister of lot 4, was bought by Mr. Micklethwaite for 60 gs. Mr. Barclay, who could not leave *Pearl*, by THE SKIFFER, finally bought her for 90 gs., and the same spirited breeder bought *Charafel*, by FELIX, of the *Certainty* tribe, for 100 gs. Another *Certainty* heifer, *Conquest*, by ZEALOT, was purchased by Mr. Micklethwaite for 56 gs., and the same gentleman secured *Flawless*, a daughter of ZEALOT and *Fairwater*, for 60 gs., and ZEALOT (20,480), the sire already mentioned, for 53 gs. We have not space to give a full list of the prices obtained at this remarkable sale; but we may mention that the eight numbers of the *Certainty* family brought on an average 47l. 12s. 9d. each, that the 18 representatives of the *Zinc* and *Zeal* tribes made 42l. 17s.; and that the 17 descendants of *Fuchsia*, by THE CAPTAIN, made 43l. 12s. each.

The prize list of the Staffordshire Agricultural Society, at their recent meeting at Burton-on-Trent, as published in p. 1049, contains an error, which, though not likely to mislead, ought to be corrected. The "William Wood" to whom the 1st prizes in the classes for yearling bulls and bull calves, and the 2d prize for yearling heifers, were awarded, is, of course, Mr. Willoughby Wood, of Holly Bank, Burton-on-Trent.

SMITHFIELD CLUB FAT CATTLE SHOW.

I BELIEVE no one can fail of seeing that the rules and regulations as respects exhibitors at the Smithfield Club Cattle Show at Islington are increasing in number and complexity year after year. In fact, in a short time the committee will require a pamphlet to embody their endless regulations; however, if it pleases these gentlemen, perhaps the exhibitors have no particular objection as long as the regulations (however numerous) are of an innocent character, but this year the committee have introduced what I am sure will be considered a very whimsical idea, I should almost be tempted to believe it is a little bit of fun on their part, did I not feel assured that such steady men as the committee of the Smithfield Club never could condescend to be playful.

In the printed document that is forwarded to intending exhibitors with the form of application for space, I find in the second column the following queer announcement:—"It is contemplated that in the year 1870 all the signboards shall be uniform in size, colour, and lettering;" and they kindly add, "This notice is given for the information of exhibitors, so as to prevent their unnecessarily ordering new signs, which may not come within the regulation." Good gracious, sir! are

all our present signboards to be thrown overboard? Is this levelling up or levelling down? The latter it must surely be, for how could A, B, with a 4-foot frontage have a signboard as long as C, D with his 20 yards of space? Let us put it clearer. We know that Messrs. Gibbs and some of the other large seed growers have a space of about 50 or 60 feet frontage. Now, I want to know how their signboard can be reduced, or whether they will be willing to have a signboard of the same size, for example, of that of Mr. Free, the cattle quage man, whose stand is about 4 or 5 feet frontage. You see the less must govern the greater, for how could a 4 or 5-foot space man contrive to put up a signboard of the length of Messrs. Gibbs' 60-foot signboard? You well know the signboards generally run the whole length of the space each exhibitor occupies, the 60-foot space man, or even a 20-foot exhibitor, would be compelled to have a zigzag, roundabout, up-and-down or spiral line, if his avocation is to be compressed into a board 4 or 6 feet long only.

But leaving the size of the signboards, let us speak of the insisting on all the signs being the same colour. What tint it is to be they do not say (rose-pink I stick to); and all the same lettering—Old English, German text, Roman, Italic—none is named; this is left, I suppose, for another committee meeting. That which they have already announced may be considered sufficient information for our little minds to take in for a time; we shall be enlightened further in the course. Only imagine the state of anxiety Mr. Thorley would have been in had such an idea occurred in his day! I recollect at Battersen he had a splendid signboard, the king of placards it might have been called. It was about the size of the side of a small house (though it did not exceed the space he paid for). This board, if I recollect rightly, had a bull or two in one corner, a lot of sheep in another, a true Suffolk Punch and colt in the third, and some beautiful fat pigs and poultry in the fourth corner; the whole board was emblazoned with splendid gold letters. Why, sir, that signboard alone drew a crowd of people round it, the country fellows and town folk stood gazing at it all day long. The very look at it, even without swallowing any of the celebrated spice, made the sightseers sleek upon the spot.

It is really melancholy to think that in 1870 all our present signboards will be disestablished, and woe to the painters and writers of that period—all private judgment and taste will be obliterated from the Agricultural Hall. If the regulation should be carried out, what a miserably dull place the Hall would be. Variety is pleasing—it matters not what colour the committee adopt—pea-green, drab, sky-blue, yellow, black and tan, mauve, or brickdust. If all the boards are to be the same, our eyes will sicken at the sight, ladies and gentlemen of the slightest artistic taste will flee from us. Surely some deep plot must underlie this contemplated regulation. Some poor painter—perhaps a relative has to be provided for, he is to be the appointed agent to whom we are all to go, when we ask the momentous questions—What size? What colour? What lettering is our signboard to be? In fact, there is really no time to be lost; two or three hundred new signboards cannot be manufactured in a day.

Now, if this new regulation is really to come into operation in 1870, the committee will be bound not to stop at mere signboards. The next order will be, that all the exhibitors are to dress alike, and all the men to be of the same size. A quage will have to be put up; we shall have to be weighed, perhaps. If 5 feet 10 inches is to be the height, I am a doomed man, and even though height be not insisted on, yet I never look well in green. And should there be no restrictions about the cattle? Should not they also be the same size, colour, &c.? though for the matter of tint, the bullocks could easily be painted. If white is the order of the day, what a commotion would be raised should it be discovered that the prize pig had some black on his ear or tail! Now, though some of your readers may say this is all a joke, yet, believe me, it really is no fun, when the order, or rule, or regulation is there to be seen in black and white. Pray think over the matter, and favour the numerous exhibitors with your views on this subject. True Blue.

RECENT ANALYSES.

THE sample sent herewith, marked No. 5, is a German phosphate, with an appearance remarkably like solidified guano. Dr. Benjamin H. Paul's report upon it is follows:—"I have examined the sample of guano, or mineral phosphate, sent to me by Mr. E. O. Greening, and find that it contains 69 per cent of insoluble phosphate of lime, but neither ammonia nor organic substance."

In North Germany and France these phosphates are generally applied as manure after simple crushing, without manufacture into superphosphate. The French and German farmers have great faith in this plan, and a member of our governing Council who has tried the experiment upon a small farm this year reports satisfactory results. I ought, however, to add that Professor Voelcker, in one of his reports, does not express approval of the plan, but otherwise; and it is for English agriculturists to decide how far the common practice of France and Germany renders the experiment worth further trial in this country in the face of this adverse scientific opinion. As compared with English coprolites, the German phosphate I send you is very cheap. I am told it can be extracted, washed, and crushed at a cost, including royalty and all expenses, of 30s. per ton, and that the selling price in Prussia is about as follows:—

- 45 per cent. of soluble, 20s. per ton.
- 50 per cent. of soluble, 25s. per ton.
- 55 per cent. of soluble, 30s. per ton.
- 60 per cent. of soluble, 40s. per ton.
- 65 per cent. of soluble, 45s. per ton.

There are, it is said, millions of tons awaiting extra-

tion, and one enterprising English firm has already established works upon the spot, utilising the cheap labour of the country and sending superphosphates to England at a good profit to themselves. For purposes of comparison I quote the present prices of English coprolites. Whole Cambridge coprolites, as raised, containing 57 to 60 per cent. phosphate, are worth about 52s. 6d. to 55s. per ton, and if ground, about 65s. per ton. Brown Cambridge coprolites, containing 47 to 50 per cent. of phosphate, are worth about 35s. per ton, and if ground, about 45s. to 47s. 6d. Suffolk coprolites, containing 53 to 55 per cent. of phosphates, are worth 45s. whole, and about 52s. 6d. ground, per ton. It is very evident from these figures that the German agriculturists have a considerable advantage over British farmers in the cost of phosphatic manures.

Sample No. 6 is the celebrated Driffield Company's pure cake. Dr. Paul's recent analysis of it is as follows:—

Oil	9.95
*Albuminous compounds	32.63
Mucilage, &c.	33.18
<hr/>	
Total of feeding parts	75.77
Moisture	10.32
Woody fibre	7.77
Ash	6.14

100.00
*Nitrogen, per cent. 5.02

The company are now charging 11l. 10s. per ton for their cake at the works, making a small allowance to the trade and to co-operative associations like our own.

Sample No. 7 is "pure" English linseed-cake, made for us under contract at a present cost of 10l. 10s. per ton. Its analysis by Dr. Paul is as follows:—

Oil	10.82
*Albuminous compounds	31.46
Mucilage, &c.	36.64
<hr/>	
Total of feeding parts	78.92
Moisture	19.19
Woody fibre	4.11
Ash	6.78

100.00
*Nitrogen, per cent. 4.84

We sell this cake to our members at 11l. 5s. per ton present price, and as our working expenses absorb about one-half the gross profits, there is the return of the other half to be reckoned as a deduction from the cost.

Sample No. 8 is a Liverpool-made pure cake, standing very high in the locality, and well spoken of by practical farmers.

As will be seen by Dr. Paul's analysis, it does not compare in percentage of nitrogen with the "Driffield," or the Association's oilcake, and is somewhat high in woody fibre and mineral matter. This illustrates the necessity of testing by analysis even the best oilcakes, to know their comparative money value in purchasing:

ANALYSIS OF LIVERPOOL PURE CAKE.

Oil	10.04
*Albuminous compounds	24.25
Mucilage, &c.	35.75
<hr/>	
Total of feeding parts	70.04
Moisture	16.45
Woody fibre	5.77
Ash	7.70

100.00
*Nitrogen per cent. 3.73

Edward Owen Greening, Managing Director, Agricultural and Horticultural Co-operative Association, 29, Parliament Street, Westminster.—P.S. Since the above letter was written there has been an advance in the price of English cakes of 5s. to 10s. per ton, and in American cakes of about 7s. 6d. I may add, for the information of your readers, that the Peruvian Government have just advanced the price of guano another 10s. per ton. As the higher the value, the greater the temptation to adulterate, farmers cannot now be too careful in giving their orders for guano.

THE PLACE OF PEDIGREE IN AN ESTIMATE OF LIVE STOCK.

On the Necessity of Furnishing Judges at Shows with Pedigrees.—It is sometimes asked what is the value of pedigree if it does not produce animals probably superior to those which are less well bred? In answer to this it may be replied that, as a rule, the most highly bred animals are intrinsically the best. But the tokens of this superiority are sometimes so minute as to escape the notice of all except the most practical and accurate of observers. Two yearling heifers, for example, may resemble each other so closely in form and size that it would be difficult to give precedence to either, unless the hand, coming to the assistance of the eye, was able to detect a softness of touch (certain indication of high breeding) in the one which was wanting in the other. Or, if there is a difference of form, it may be in some part which may appear insignificant to those who are solely guided by considerations of marketable value; as, for example, a well-shaped head, with tapering muzzle, and a mild prominent eye. And yet so important were the indications of the head held by no less a judge than Mr. Bates, that he was accustomed to say (with exaggeration of course) that he would buy a bull by seeing his head looking out of a window. It is probable that some persons may regard these minutiae of touch, shape of the head, &c., as mere matters of fancy, devoid of practical importance. I warn any breeder who buys a bull whose touch is deficient in mellowness, whose head is coarse, and whose eyes are small and sunken, that he will have to exercise abundant patience before the stock of that animal are ready for market. Surely the time which bullocks take to feed, and the amount they consume before they become fat, are no matters of fancy, but of

pounds, shillings, and pence, of profit or of loss. It is fortunate that observations have been made which place the effects of even a remote cross beyond dispute. "The most remarkable statement which I have met with," says Mr. Darwin, "of the persistent endurance of a single cross is given by Fleischman, who, in reference to German sheep, says that the original coarse sheep have 5500 fibres of wool on a square inch; grades of the third or fourth Merino cross produced about 8000, the twentieth cross 27,000, the perfect pure Merino blood 40,000 to 48,000. So that in this case common German sheep crossed 20 times successively with Merinos, have not by any means acquired wool as fine as that of the pure breed." Admitting with Mr. Darwin that the above is an extreme instance, and to be accounted for by peculiar circumstances, we have here positive proof of the necessity for pedigree in forming a correct conclusion of the value of breeding stock. We can well imagine, supposing the cross-bred and pure Merino sheep in question had been exhibited, that if an ordinary farmer had been the judge, he would have given the prize to the sheep with the 20 Merino descents, instead of to the pure Merino, in case the former had been larger or fatter than the latter. But a reference to their respective pedigrees would have reversed the decision, as far as their value for breeding was concerned.

To apply the foregoing reasoning to Shorthorns, I can conceive it quite possible to produce a bull with only three or four descents of pure blood, and whose g.g.g. dam was either a cross-bred cow or a Highlander, should be equal in outward appearance to one of the largest and purest Herd Book descent. To withhold from the judges their respective pedigrees, would in this case be to incur the risk of placing the g.g.g. son of a mongrel before the descendants of Bates' Duchess or Booth's Bracelet family. At county shows especially, it is a matter of everyday occurrence for animals of inferior pedigree to win prizes over the heads of those better bred than themselves. I would expressly guard against its being supposed that I advocate giving a prize to an intrinsically inferior animal on account of his pedigree. All I desire is that this should be taken into account, in weighing his claims to that distinction. And I believe that the admission of the evidence of descent would not unfrequently (especially at provincial shows) have the effect of calling the attention of the judges to the merits of animals which they might otherwise have overlooked.

It is difficult to overrate the importance of sound decisions at our agricultural meetings. When a prize is given to an underbred animal, simply because his condition has been made up regardless of expense, it is equivalent to giving a fictitious value to his blood, while better bred animals are placed below their rightful position. Whenever showy mediocrity is thus held up to public admiration, while the claims of pure blood are ignored, the effect is to put those who desire to improve their stock upon a false scent, and to convert what ought to be a valuable lesson into a delusion all the more mischievous because it is backed by authority. But, until authentic evidence of pedigree is placed before the judges, it is difficult for them always to do strict justice. *Willoughby Wood, Holly Bank, Burton-on-Trent.*

Home Correspondence.

The Potato Disease has come at last, with more than its usual virulence. About five weeks ago black specks fell down upon the haulm; they looked like round blemishes that might have been made by hailstones. These round dots gradually expanded into black rings of rotteness, giving forth the unmistakable smell of the Potato plague. The gangrene then run down the stems, and now almost every tuber is unsound. My practice for years has been to grow chiefly early Potatoes, and take them all up and store them in earth before or immediately after a speck of disease appears. The Potatoes will thus keep sound, but once the virus has gangrened the stems many of the tubers will rot though taken up apparently sound. The seeds of the malady has reached them, and it bears fruit into rotteness afterwards. Till the middle of September I do not think there was one unsound tuber to be found. But one short month, and there is scarcely a sound one. Potatoes do not keep well if taken up green and stored in the usual manner, but stored in earth, they keep sweet and sound, tasting, when used, like fresh-raised Potatoes. But it is difficult to impress the importance of early harvesting of Potatoes on farmers and labourers generally. It seems they would rather lose the crop than lift them before Michaelmas; and I am sorry to say that many of them will lose almost the entire bulk this season. It will be a sad loss to the poor, and it is all the worse to bear from the fact that it might have been prevented. I have no panacea to offer against the disease; but by early planting and early harvesting we may have our crops safely stored before it comes. By having the crops in the ground we only invite the disease down the useless stems to the sound tubers; and the result is rotteness and destruction of thousands of tons of the best Potatoes. *D. T. Fish, Bury St. Edmund's.*

The Potato Crop of 1869.—I cannot allow the letter of your correspondent (Mr. Paterson, of Dundee), in regard to this crop, to pass unchallenged. He says, in your last week's issue, that "It is the opinion of practical men that the crop of 1869 will be the heaviest crop, and the best quality, that we have had for years." Now, with all deference to his opinion, I must, as a practical man and a grower of Potatoes, take exception to this statement, for unfortunately, in this neighbourhood, where there are many thousands of acres grown

this year, the crop is, to say the least, anything but heavy one; and, as for the quality, all the farmers in the district complain that they have many—some say, that others a third, and some unhappy few on doing it, already diseased, and probably many more will be so for market if kept any length of time in the ground. Doubtless your correspondent has reliable information with regard to the district from which he writes for me. I must protest against his *ipse dixit* being taken as conclusive evidence of the state of the entire potato crop of the present year. *A Subscriber, Bury St. Edmund's, October 11.*

Steam Cultivation; the Peterborough trials in connection with this subject there appeared in the last impression a lengthy exposition of the only patent Mr. Toepffer, of the North Lincolnshire Ploughing Co., and we commend the temperance and fairness in which he treats the subject; but we feel that it ought not to allow some of his statements to go unchallenged. Your readers will remember that we have on several occasions, and no one can have forgotten our thorough belief he has in the superiority of the economy as the only profitable and practicable method of cultivating land by steam power; but nearly at the close of his lengthy letter is devoted to the disparaging of the "roundabout" system as originated by the late Mr. Woolston, and to Mr. Campaign's new system in particular. We feel bound, therefore, as the author of that patent, to offer some remarks in its defence. Mr. Toepffer candidly admits that the anchors used well at the trials, and that the two men who were saved were not required and were actually saved with; and this establishes all that the patentee claims. And yet while thus acknowledging that two men are positively saved by their use, he goes on to state that the "roundabout" system is still in vogue in the state, and that most attempts to improve it have failed to its complication, without any real advantage. "Also, that while the anchors are well on the Peterborough soil, they would prove on very light sand or upon rocky soils," and these are conditions so strange and so exceptional, that no practical farmer will heed them for a moment. Facts are stubborn things, and we are prepared to state that Mr. Campaign has, during 1868 and 1869, saved over 500 acres with the aid of his patent anchors upon his own premises, with a working staff of three men and two boys, and without any other machinery; the anchors have never once failed to hold, upon land varying from light fen to strong clay. Again, Mr. Toepffer suggests that in fields with irregular boundaries the anchors may be used to require help to move them on; but here he is wrong as upon one of Mr. Campaign's farms there is a straight headland, and yet the difficulty he invented never occurred. We hope to convince Mr. Toepffer that his theory is beaten by practical results; and that there are other points in his arguments that may readily be dispersed if he will pay Mr. Campaign a friendly visit, and see the tackle working upon his own farm. *Bayer's letter now has run to a considerable length, and would only further remark that we appreciate the advantages of the double engine system, than ourselves, and it is clearly the only one that will develop the letting-out system which Mr. Toepffer so ably advocates; but he is, in our opinion, decidedly wrong in supposing that it will meet the wants of thousands of British farmers, who (in the great majority especially) want their work done at the same time and it is well known that there are many who have the ability, the means, and the desire too, to do their work within themselves, and thus utilise the steam power already in their possession. And there is abundant proof that this is being accomplished at a small cost, and both profitably and well. *Amies, Barford, Peterborough, Oct. 14.**

Cost of Steam Cultivation.—So Mr. Toepffer's article turned up from the Peterborough trials, and after a friendly talk, and then some running down of the roundabout tackle, as well as puffing up the double engine sets upon the contract plan, he winds up with some advice to the agriculturists desiring to obtain correct information as to their farms cheap steam cultivation is this:—"If you have three, or four neighbours, according to the size of his farms, should join and buy a steam-cultivator, or a number of at least 20-horse power with double engine (the more the better), or to encourage some industrious working man in the neighbourhood to assist you in purchasing one, or to encourage some one of the most powerful descriptions, to let it out to you in their locality." Now, this is blind advice, and a farmer who is to use this tackle is not to be told that he is to pay per acre for its use, neither does Mr. Toepffer tell these men who are to find the money, that they are to get as well as pay for its use, yet he leads to the conclusion that an industrious working man may be found in their parish who has a knowledge of the machinery. Let him do as I do—give quantities of manure, and particulars—and we shall be getting on very well in the matter, without which his statement is of no value. His costs (this year) per acre stand thus:—Manure, 10s. 6d.; men, coal, water, and oil, 3s. 2d.; interest on machinery and tear, 1s. 6d.; total, 1s. 8d.; then add 1s. for scuffling with horses, this brings my total cost of the bed for Wheat up to 6s. 8d. Ridging and sowing—a man, coal, water, and oil, 5s. 1d.; interest on machinery, 1s. 6d.; total, 6s. 7d.—the actual cost of a set for roots or Beans. That is the stuff that Mr. Toepffer should get to guide the more ignorant farmer. Yes; and it is stuff that will make the horse farmer look hard at, and say, "I may, for it is a fact that I can stand by." I occupy my 109 acres of work just done to be looked upon by the horse farmer cannot equal at any cost, and Mr. Toepffer can do with his latest improved double engine set. The last evidence that we have of this point is from Mr. Charles Bates. He told

* Variation of Animals and Plants, Vol. II., p. 88.

all the farmers... that he paid 15s an acre for the engines; that they used four horses to fetch water at a cost of 40s. With such figures as these before us it is no wonder that Mr. Toepffer to talk of "economy," and now he is taking upon that point he does not talk for he must have two engine-men to a set of his machinery, and the wide cultivator that he talks of is a thoroughbred Smith, the one I found and used at Leicester Show, without which he cannot do his wide work at all. Let him give over talking of what he can do, and instead tell us what he does do. He ought to be in a position, as the manager of a large agricultural company, to give us the work done with a set of implements, with all the particulars. That is the only way to get a fair estimate. We do not want his empty statements. In doing my 100 acres we consumed 8 tons of coal, or an average of 1 cwt. 2 qrs. 17 lb per acre. That tells you that we did not need four horses to fetch water as well as men to go with them. The "economy" is all on my side, let him say what he may; let him bring his data to prove it. He can talk of doing as much work as four sets of roundabout machinery. Yes, anybody can talk; let him do his 30 acres a day if he can, and tell us all about it. He can run two engines, one at work and the other at rest, that we know all about; but whether he can do his work with 1 cwt. 2 qrs. 17 lb. per acre, we know nothing about, yet we want to know all about it. Mr. Toepffer has told us a bit; if Mr. Toepffer can do better than I do, let us have the particulars. *William Smith, Woolston, Bletchley Station, Bucks, Oct. 11.*

The Crops of 1869.—If I have misrepresented Mr. Anderson, I am quite ready to apologise; but really many exaggerated statements he makes are so prejudicial to the agriculturist, that I trust he will be careful for the future. His sayings may be read with interest by his employers, but they are of no practical value, for it is impossible for him to arrive at an accurate idea of the crops while rushing through rural counties in a day, quietly sitting in a railway carriage. With respect to Mr. Lawes, I must say at once, I have no doubt he fully believes in his experiments, and in the result of them. Now, I candidly place no reliance upon them whatever, any more than I did in the experiment he conducted some years ago of feeding animals on malt. Surely there was a more one-sided affair than that! What is the value of Mr. Lawes' experiments of growing Wheat on artificial manure? My theory is this—that the soil upon which Wheat is planted or sown should be in a proper condition for growing a crop without the aid of any artificial manure at all; that it is wrong in principle to make any such application, and certainly not to be done with no profitable results. In an experience of more than 20 years I have only twice tried the effect of artificial manures for Wheat, and each time with an unsatisfactory result. I have often seen my neighbours try the same thing, but without any benefit whatever. I would, therefore, urge others to be careful in their application of artificial manures for the Wheat crop. Mr. Lawes, in your impression of the crop of 1869, says—"The Wheat crop of 1869 is slightly below the average in quantity, and that it will be also deficient in quality, as estimated by the weight per bushel. An average crop is represented by a proper bushel of 2½ bushels, weighing 61 lb. per bushel, I am disposed to fix the present crop as equal to 27 bushels of the same weight." Does the experience of the threshing machine verify Mr. Lawes' conclusions derived from the results of his experiments? I say it does not. On every side one hears of the disastrous yield of the year. In some cases so low as 12 bushels per acre, and in others 16, but the generality 23 or 24 bushels. What is the price of Wheat at the present time certainly no indication of any such deficient yield? Mr. Toepffer's arithmetic is very ingenious and clever, but "artificial." He assumes the crop of 1868 at 27 bushels per acre, which I question. He deducts 10 bushels per acre as my alleged deficiency, which is correct, and he arrives at the wonderful conclusion that "we have only 18 bushels as the average for 1869." He evidently seems surprised at the result of his own calculations, and well he may be when he tells us, "I have probably 60 acres on my farm which will yield an average of six quarters per acre. Can the farmers of England be doing so? Surely they must be asleep." I will now give Mr. Lawes my own of the Harvests of 1868 and 1869. The yield of 1868 was very abundant, being one of the best I have ever known. I estimate the average at 27 bushels per acre. That of 1869 I believe will be very deficient both in quantity and quality. I estimate the yield at 24 bushels per acre, or 12 bushels per quarter. Mr. Lawes estimates the deficiency at 10 bushels per acre. I will leave your readers to judge which opinion is the most correct. *John Ford, Hall, Warwick, October 12.*

Farmers' Present Prospects.—There is something very discouraging in the farmers' present prospects. Their corn crops are bad. The Wheat crop in particular yields badly, and the quality is light and inferior. Moreover the price has fallen some 20 per cent. since the commencement of harvest. This is an extremely light crop and defective yield used to command high prices. Imports have been liberal, but not in accordance with our requirements, and by no means commensurate with the nation's ultimate wants. Barley is all probability the only remunerative crop, and is only cultivated in Barley districts. In many parts of the country it is not grown. The Beans and Peas, which have been very extensively planted, and which have been harvested, are proving one of the worst crops ever grown. The disease on all strong lands has destroyed the crop, and on mild soils they are

very bad. To add to the farmer's catalogue of discouragements, the foot-and-mouth disease amongst farm stock is very prevalent, cattle, sheep, and pigs alike being affected seriously by it. Verily, we say, the farmer's prospects are very discouraging. Well, it may be said, surely his sales of fat stock are satisfactory—the price of meat is exorbitantly dear. So it is; and the very cause of that is, that the farmer has so little to sell. The summer of 1868 proved disastrous in so many ways. A vast percentage of stock was necessarily slaughtered because in consequence of the drought they had nothing to eat. These animals, for the most part being in little better than store condition, did not greatly enhance the market supplies. Pigs being so cheap, owing to the cost of food, were so neglected that piglings were not deemed worth the raising. The drought and heat also influenced the generative power of breeding sows, so that at the present time the stock of pigs is unusually small, and the price of pork unusually dear. The farmer then is no great gainer by the high price of meat. The only satisfactory and encouraging thing is the beautiful season through which he is passing, and the kindly growth of his green food and winter crops. Mangels, Turnips, Coleseed, are all progressing admirably, and his grazing fields present a luxuriant pasture for the stock upon which he depends. This is some consolation, but how is the farmer to work through these discouragements? Well, advice is easily offered, but not often of great worth, nor can it always be taken. My first point is to thresh as sparingly as possible. The present supplies will speedily be dispersed. Imports will fall off as winter approaches. Seeding is at hand, and less corn will be shown in the market. This will cause a reaction in price, and as the fact of deficient produce will soon be universally acknowledged, the price will in all probability be increased, and grain become dearer throughout the year. My next point is the adoption and practice of every economy in farm practice consistent with good management both indoors and out. I would next say that the chief hope of recouping this state of things during the winter must be in attention to the farm stock. The fattening of the stock of the farm will be of immense importance to every farmer in the ensuing winter. The price of meat must be high, and stock will no doubt well repay any reasonable outlay to promote their progress. Every attention then must be given, nor must the farmer object to fatten animals he would at other times class as stores. These, in times of high prices, will generally prove profitable graziers. Pigs are remarkably dear, but in the Potato districts, where "blights" are so sadly plentiful, they will best pay as consumers, and these "blights," aided by Indian corn at present prices, will speedily fatten them and prove an advantageous investment. Indian corn, either steeped or ground, has in the past year proved a very serviceable and adventitious aid in the fattening of all kinds of stock, and, if the price is satisfactory during the forthcoming winter, it may and will be the great resort of graziers. Cakes are so abominably adulterated as to become unpopular as feeding stuff, hence resort is more had to meal and corn. Mangels and Swedes, if liberally supplied to cattle in cold weather, should be supplemented by cotton-cake or Indian corn. It prevents scouring or looseness of body in a great measure, in fact it permits the free use of such watery roots, and aids in the more profitable wintering of cattle by acting as a "corrective" against a too abundant ration. *A. J.*

Thin Seeding.—The evidence upon the seedling point is conclusive that the farmer must judge for himself as to the best quantity of seed needed, according to the quality and condition of the soil on which he works, and that seasons may upset the best judgment. See Mr. Mechi upon this point:—"Each farmer should judge for himself by comparative trials, for soils and climates vary, the crop is also influenced by season, and especially by high or low farming." I am glad to find that Mr. Mechi has yielded to reason. Mr. Mechi has made an extract from his book, and it reads thus—"Tiptree Hall Farm (with chapel land) 178 acres." In the *Times* he quoted thus from his book: "Tiptree Hall Farm (with chapel land), 170 acres," and now I will quote from his balance-sheet: "Tiptree Hall Farm, Total landlord's measure, 177 acres," (see *Agricultural Gazette*, January 23, 1869). This proves that his statements are not to be relied upon, and the "doubts" about his 6 quarters of Wheat per acre on 78 acres in 1868, his 63s. 9d. per quarter for Wheat sold in 1868, with his valuation for corn, hay, &c., 379l. on Jan. 1, 1869, are not "dispelled," not even by his statement about "hard cash available." He must dispel them by positive proof, or they will hang on for ever. *William Smith, Woolston, Bletchley Station, Bucks, Oct. 11.*

Mr. Mechi's Balance-Sheet.—I fear Mr. Smith, as also myself, must be satisfied with our own opinions regarding Mr. Mechi's balance-sheet. He asserts that I have "shoved in figures as a mere makeshift to confound the whole thing;" at the same time informs us that corn, hay, &c., unsold, means corn, hay, cake, bran, and all feeding stuff on the farm. I am not aware that farmers purchase cake, bran, and feeding stuff to sell again. What quantity of Wheat was included in the 558l. 6s. on Jan. 1, 1868, we have no means of knowing; but looking at the amounts received in 1867 and 1868 for Barley, Peas, and Beans sold at market, hay sold, corn and hay sold to live stock, Oats, Beans, and hay sold to horses, and bearing in mind the land on which these items were grown, there could not be any large quantity included in the valuation of 1867 or 1868. He is in error in his assumed remnant of 237l. 12s. when he says, "Then look at his Wheat: it shows at 63s. 9d. for 1868, and, when asked, he would not tell me how much of it was grown in 1867; the remnant of 237l. 12s. proves that there could not have been much." This sum he gets by subtracting 84l., the value of 30 quarters, at 56s., sold on Feb. 12, 1869, from valuation of corn and hay unsold on Jan. 1, 1869, viz., 379l., forgetting that the higher-priced Wheat, to which he says I am

"looking for help," was in valuation of 1867, which amounted to 558l. 6s., not 379l. The Rivetts must, on the whole, have sold for a higher price than 47s.; for Mr. Mechi says (February 20, 1869), "My 78 acres of Wheat have thus yielded an average of over 6 quarters per acre—20 acres, which were of Rivett Wheat after white Wheat, did not yield so well as the white Wheat, nor did the red Wheat," the white yielding 72 quarters and 8 quarters, as mentioned (at least off two fields); the 20 acres of Rivetts could not have produced 133 quarters—a trifle over 6½ quarters per acre, but if we assume some Rivetts were included in valuation of 1867, and selling for a higher price, a difference of at least 10s. per quarter, we can at once account for the 310l. 2s. 6d. amount of Rivetts sold in 1868. The red Wheat could not have been grown largely, as quantity sold in 1868 realised but 157l. 8s. 6d. thus we might infer that 45 acres were in white Wheats, the higher priced corn: still, as the valuation does not specify each kind of corn, we must take the accounts as correct, and I see no reason to doubt them; and until a better and more systematic form of farm accounts be introduced, much must be left to conjecture. *Another Farmer.*

Societies.

GREAT BRITAIN.

"Prosperity to Agriculture"—At the late annual meeting of this Society, Colonel Brise proposed, and Mr. Mechi acknowledged this toast.

Colonel Brise said—He hardly knew what the position of this country was at the present moment so far as the late harvest was concerned. They had hardly yet had sufficient information to enable them to form any decided opinion upon the yield of the harvest, but as far as they had been able to gather they found that the Wheat crop was a deficiency. With that exception he believed agriculturists had not very much to complain of. He must say, however, that they had had cause for complaint and alarm at the virulent epidemics that had lately overtaken their herds in this country. Very few farms in their own and other counties had escaped—the foot-and-mouth disease had been prevalent in almost every hole and corner of the county; he had been visited by it himself, and although he did not look upon it as a very serious epidemic, or as anything like the cattle plague they had in the country a year or two ago, yet it was very disagreeable and inconvenient, and, moreover, was attended with loss to those engaged in farming. It was unfortunate that this epidemic should have come upon them at the present time, for an Act of Parliament was passed during last session which some people thought would have had a very great effect in stopping the spread of this disorder, but that Act did not come into force quite soon enough to test its effect. He believed that the disease was in a great measure atmospheric, and that it had been here for some years, although no doubt it originally came from abroad. He could only tell them that in his own case he had a considerable herd of Shorthorns; no animals being affected with the complaint had been within some miles of them, and yet it broke out among them, thus showing that if the Act had been put in force it would not altogether have remedied the evil. They had this year, however, passed a Contagious Diseases (Animals) Act, which appeared to give great satisfaction to a great many of their fellow countrymen, but he confessed he was not satisfied with it, and never had been. He contended against the principle of the measure in the House of Commons and elsewhere on every occasion on which he had the opportunity. However, he thought every credit was due to Mr. Forster, the Vice-President of the Privy Council, for no man could have given more diligent attention to the subject than he had, and he believed that he really and earnestly had the desire to satisfy the agricultural community as far as he could, but circumstances were against him, other pressure was put upon him from different quarters, and among others from the commercial interest—those men who were so blinded that they would not see that the interests of the consumer and the producer were identical on this subject. But he must say that he did not consider it right that a matter of such serious importance as the health of their cattle should be left to the will of any single individual, whoever he might be, or of any Privy Council. There was one other subject connected with their interest as agriculturists to which some attention had been given in the last session, and that was the adulteration of seeds. When the Bill on that subject was first introduced into the House of Commons he did not think it would be of any value to the agricultural community—he thought it would be very difficult to find out whether the seed had been heated in the rick, in the hold of a ship, or in the factory; and he thought it was one of those things in which the intelligence of the agriculturists and the good feeling of the seedsmen would find out in the end that honesty was the best policy. However, he was glad the Bill went on, for they had a select committee upon it, and the evidence that came out was most valuable to all connected with the agricultural interest. It came out before the committee that out of every 100 lb. of Turnip seed that the agriculturists had been sowing on their farms, 25 lb. of it was dead or crushed seed. It was extraordinary that the wholesale seedsmen, high-minded and honourable as men in other businesses, had not thought it wrong, or they had seen no harm, in selling this adulterated seed to the retail seedsmen, the latter having a thorough knowledge of the fact, but the poor farmer knowing nothing whatever about it. This had not been the case with the Turnip seed only, for other seeds had been similarly adulterated; and it had had this bad effect, that when a seedsmen had had any really first-

rate seed to sell in the market he had been obliged to compete with this adulterated seed of which he was altogether ignorant. The gallant colonel remarked that the wholesale seedsmen had been conscience-stricken at the imposition they had practised upon the farmer, and they had come forward in the most honourable way and given evidence before the committee. The toast he had to propose was "Prosperity to Agriculture." He would rather not give them any advice upon agricultural matters, as they understood them better than he did, but if he must do so it would be this, to continue and progress in the old beaten track, at the same time taking advantage of all the modern appliances and improvements of the day, cultivating deeply and manuring highly—[Mr. MECHI. Hear, hear—at the same time not to be led away by any ideas of the very large fortune and successful issue of those who experimentalised, but to examine carefully all those experiments and to form their own opinions upon them. This was one way of farming. Another way was to farm very highly, to experimentalise, to write letters to the *Times*, to tell everybody how much they grew and how much they ought to grow. He thought some of his friends would agree with him that it was a capital plan to farm like that if they had any other business to depend upon; but at any rate they were under deep obligations to those gentlemen who did experimentalise and gave them the benefit of their experience. He did not know one subject on which those gentlemen had advised them, and on which they had profited more than thin seeding. This had been a capital year for those who had adopted thin seeding. He did not imagine that any season had been more suitable for it; and having himself experimented in some measure, he must fairly and honestly state that, although this year it had been successful, he had lost more money by thin seeding than he ever did by thick. He believed that for thin sowing they must adhere to conditions—deep cultivation, well manuring, &c., and they must be free from insects, slugs, wireworms, rooks, and rabbits—(applause, and a Voice, "Game")—and they were ever dependent upon atmospheric influences. If they steered clear of all this he believed thin sowing would be successful. Many people formed their ideas of the value of land from large crops that were grown upon it, and they heard a good deal about this in certain localities. Now he thought those who formed their opinion in this way were very often misled. He wanted to know whether they were to form their idea of the value of land from the extent of the crops grown upon it, or whether—which he contended was the right way—from the rent the farmer or occupier could afford to pay for it to get a fair living out of it. If a farmer wanted to hire a farm he calculated what the land would produce. If he found that by the ordinary way of farming it would produce 4 quarters per acre he made his offer for the land on that basis, and that, he maintained, was the value of the land. If the farmer chose to invest another 1000*l.* of his capital on that land he might grow 5 or 6 quarters per acre, but that was merely a speculative business—it was lucrative sometimes, but it was speculative, and did not increase the value of the land—it was merely a matter for the farmer and his own business—he risked his money, improved the land, and produced a greater crop. He did not think but there was plenty of intelligence, ability, and enterprise among the farmers of this country, and he did not think there was any deficiency of capital where the farmers thought that capital could be employed with any certainty—but a man was not always inclined to speculate and risk his capital. Farming differed very much from other businesses, for if a trader went into the market he could obtain any money he might require, on certain securities, to enable him to carry on his business; but if a farmer went into the money market the capitalist looked askew at him—he did not consider his security of tenure good enough, and he was too dependent on the seasons—he was not therefore inclined to advance his money on speculative and high farming. He did not think it was to the interest of the landlord to throw two or three holdings into one, to square all his fields, pull down his trees and fences, and to build factories and cottages here and there over his estate; and if he wanted any evidence to still further confirm him in this opinion which he had always held, he had only to turn to a recent letter in the *Times* from a commissioner in Ireland. That gentleman told them that a certain Mr. Allen Pollock purchased an enormous estate in Ireland, got rid of the fences, squared the fields, built immense factories on the estate, drained the land, reclaimed all the uneven land, and did everything that an improver could do. Why, what was the result? The Marquis of Clanricarde's estate, which runs into the estate of Mr. Pollock, had been carried on under the old system for many years, and his tenants could afford to give nearly as much rent as could the tenants of Mr. Pollock, although the latter had spent on the land more than the fee simple of the estate. In connection with the toast he had been asked to propose, he should couple the name of his old friend Mr. Mechi, assuring him that in any remarks he had made in the course of his speech he did not mean anything personal—[Mr. MECHI. Hear, hear.—and that he always entertained a hearty cordial feeling towards him, and hoped that for many years to come he would give them his advice and be their agricultural Mentor.

Mr. MECHI rose amidst plaudits, and said he thanked Colonel Brise and the company for wishing him good health. He believed they and many of the farmers of England wished him good health, but he could not conceal from himself that there were a few, and he hoped only a misled few, who would wish to see Mr. Mechi swept from the face of the agricultural world. [Laughter, and "No, no."] They were there that evening to speak the truth, and he assured them that he could forgive those who happened to have such a feeling towards him. He congratulated the company

present and the district generally on the success of the gathering that day and on the general growth of the Society. Most of them recollected that this Society had grown out of and was founded upon the ashes of a once excellent institution at Waltham, and he felt sure that the good sense and greater intelligence of modern times would prevent the good ship from being wrecked, like its predecessor, by reason of the personal attacks and abuse of a few ill regulated persons who were the means of its destruction. However, that had all passed away, and he rejoiced in the regeneration of the Society. He believed that they were one and all—landlords, tenants, and the public at large—agreed in wishing prosperity to agriculture, and they asked, as a natural consequence, how that prosperity was to come. It was quite clear that it had not always prospered to the full extent of their wishes, for while his friend Colonel Brise had been censuring the squaring of fields, cutting down of fences, and doing away with small farms, &c., he had told them that the poor little farmer was working as hard as two labourers, and yet only living as well as one. He could not see the consistency of those two remarks. He would tell them where the small farmer was suffering—it was from being shut up by trees and hedgerows, small, bad, muddy roads, &c., and having to compete with men who were working on an improved and more intelligent principle. The little farmer naturally gave way in the unequal contest. Were they, then, satisfied with agriculture as it was? Then they agreed with him that they ought to do all they could to progress. He did not consider that progression was to be the mere act of the tenant: he believed that agricultural progress, to be complete, must be by joint action of landlord and tenant. Steam power was multiplying, and, as the population also increased, the demand for food was greater, and the manufacturing people, who were their customers, demanded that they (the agriculturists) should no longer muddle along in the old track, which Colonel Brise so strongly recommended, but that they should get out of that deep and uncomfortable rut by improved education, enlarged views on the subject of landlord and tenant, and, by the use of steam and other machinery, go on progressing. Colonel Brise told them that the banker would not advance money to the farmer in consequence of the insecurity of his tenure and the uncertainty of the seasons, but he omitted to tell them that if the farmer had a 21 years' lease, and if he had the power to transfer that lease, the banker would take a very different view of his customer; but so long as the agriculturist remained in the uncertain position of annual tenure, he was placed in a disadvantageous position compared with traders in towns. Did they suppose that a trader should invest large amounts on premises which belonged to another man, and of which he had only an annual tenure, without any security that those expenses would be returned to him? Certainly not—and therefore he said agriculture was in an anomalous position, a position which should not exist in these days of improvement. While he said this he did not believe that the landlords had not the welfare of their tenants deeply at heart. He believed that the landlords of this country were desirous that agriculture should prosper, and he thought it only required a little thought and consideration of what was now going on in the country to cause a great change in their opinions. There had already been a great change in their opinions as to trees and fences, and he believed the time was approaching that while the tenant would be bound, as every tenant ought to be, on a fair and just condition, he would be no longer restricted by those antiquated practices suited to another period—instead of keeping in the old and uncomfortable rut, they would adapt themselves to the greater intelligence and necessities of the age they lived in. He daily received communications from agriculturists from all parts of the world, and probably, therefore, no man had a better opportunity than he had of judging what was going on, not only in British, but also in foreign agriculture, and to what conclusion did it lead him? First, on the subject of education. The very style of the writing in the letters he received from different counties, and in his visitors' book, was almost an indication of the style of education in the different parts of the country; and he could not agree with his friend Mr. Carter, that the education of Essex was satisfactory. Why, without blaming any one, the best man he had at work for him, and who had been on his farm 25 years, could neither read nor write.

Mr. CARTER—I referred to the young people—to the children.

Mr. MECHI agreed that there had been an improvement in the education of the children, and there was plenty of room for it. He was of opinion that they were backward in the education of their labouring people, and although he did not go so far as to advocate compulsory education—he would have a compulsory education rate. [Cries of "No, no" and "Yes, yes." Did they approve of a compulsory rate for mending the roads? ["No."] Well, what sort of roads would they have if they had not a compulsory rate? A Voice, "As good as now," and "No, no." Why, 20 years ago Arthur Young told them they could not drive a coach through the country, but Macadam and compulsory rates had enabled them to improve their roads; and he asserted without fear of just contradiction, that leaving the education of the people to mere benevolence was an injustice and imperfect mode of action. In the parish of Tollesbury, with 5000 acres there was at one time only a small dame school with 12 children stifled together in a room. This state of things had been partially altered by the benevolence of friends like Mr. Du Cane, but at the same time he had known men, with 700 or 800 acres of land, who considered that education spoiled their best labourers, and would not, therefore, contribute a shilling. He maintained that such people ought to be compelled by a rate to do that which

was admitted as a necessity by the Government for the public at large. He knew this was a matter they were here to speak the truth.

He would now change the subject, and a matter mentioned in the afternoon by the Chairman, namely, the housing of the agricultural labourer. Could they wonder at Ireland being mentioned when recent statistics showed that there were one-roomed cottages, each occupied by a family who huddled and slept together? It was a condition that this should be so. Now, the condition of their own labourers, the Chairman that, taking the agricultural counties of Essex and many other counties, the condition of the labourer was quite equal to that of the mechanic, the carpenter, the magistrate of the city of London, he told him all the circumstances and conditions of the working classes in times of distress and dearth—he knew that where an agricultural labourer had a decent cottage with two or three rooms, a garden for 1*s.* 6*d.* or 2*s.* a week, the town was packed in two rooms at 1*s.* 6*d.* and very often in one room at 1*s.* [Hear, hear, and a Voice: "This is a fair comparison with farming."] Yes, it had to do with the labourer, and they ought rather to be satisfied with his remarks than otherwise, because it was the farmers were grinding their own necks, whereas he did not admit anything of the kind of a labourer who earned on an average 1*s.* 6*d.* a week, whole year round—was quite as well off as the labourer in the town who had 1*s.* or 1*s.* 6*d.* per week.

Now they came to the question of poultry, and gentlemen laughed at Mr. Watson's remarks on poultry keeping, but he was inclined to think that many of them knew very little about it. He had a flock of 400 fowls, which he sold at 2*d.* a pound, while he sold his bullocks and sheep at 1*s.* 6*d.* The poultry sold for double the price of the meat without costing a penny extra, but he was less per pound than the meat. If he had not been considered anything, he did not project the show, and he urged upon the farmers not to be especially of partridges, and remarked that he went about the farm just as they liked, within 30 feet of the hen-house always, and his largest crops of straw and corn from 100 to 150 per acre. And this result was obtained by giving that the fowls had free access to the land within a week of sowing. If they were to have plenty of insects to eat, they would have plenty of eggs. Alluding to the progress being made in the present day, Mr. Mechi mentioned that he had been expending 10,000*l.* on machinery for the purpose of converting Beet into sugar; and he then advocated the use of machinery of recent now implements, including the drying apparatus, and expressed his intention of giving a prize to the labourer who best carried out an earth closet system in his cottages.

Mr. HERBERT LEIGH proposed the "Judges" coupling with the toast the name of C. Hall.

Mr. HALL, in responding, referred to the fact that he had given the labourers upon the way to their work, as previously alluded to, and he noticed great improvements in the work in that neighbourhood since the formation of the society. He had been a practical farmer for 40 years, and he noticed that the soil was growing one-third more corn upon the same land than they were formerly.

Reviews.

Practice with Science: a Series of Agricultural Papers. Vol. II. Longman, Green & Co. Farming professors and lecturers of the Royal Agricultural College is here presented to the reader in a series of papers on Real Property, Reports of Experiments on Barley, Cattle Grazing, Farm Accounts, Stock Feeding, Rural Education, &c. These papers, in Ireland, and other topics of agricultural interest, have been very ably discussed, and the public will be the means of making generally known the and substantial character of the teaching at Cirencester College. We extract from Mr. Edwards' capital paper on Stock Feeding, proper to the time of year.—

"What should guide our choice of Stock for feeding?—I would first of all select those which are the most profitable, and which they are either profitable, and which are not do justice to the food they eat, or which, in case of sheep, they have received a large amount of food, so surely as they begin to thrive, instance that I am not alone in this, I have known the case of an eminent grazier, who, chasing his different lots of graziers, and looking over them, and picked out those considered as not likely to fatten well, and sold them to a dealer at the best price. It may be asked who is to fatten the animals? I will answer that the farmer will discount, the more careful will be to improve their stock; and so on, until they find which graziers dislike to buy, and points to guide a grazier in the purchase of a well-formed head, with a large eye, and a good ear. We generally find in all animals if we

 ...Calendar of Operations.

...straw and any Potatoes turned up gathered. If...
 ...for winter Wheat, the land may be scarified...
 ...the Wheat drilled in. If for spring Barley...
 ...it should be ploughed, and a well...
 ...put a layer after each plough to break up any Potatoes, or...
 ...the Potatoes that left may be given to some of the...
 ...who have sown for the gathering. In...
 ...Land, where the Potatoes are grown in lazy-beds, the...
 ...tops are pulled by the hand and removed, the Wheat...
 ...is then sown, and covered by the operation of digging...
 ...The straw generally comes up well, but there is a...
 ...considerable sacrifice of seed, so that for the small...
 ...holdings dibbling in the Wheat after the digging...
 ...would be preferable.

Carrots are dug with a spade, two roots at a time, if...
 ...the soil has been properly put in at the side. The...
 ...spade should not touch the Carrot. If the roots are...
 ...very long it may be necessary to lay hold on the top...
 ...with one hand while the other presses down the...
 ...handle of the spade. But it does not take much to...
 ...loosen a Carrot in the soil in which they are grown, and...
 ...an active man will loosen as fast as a boy or woman...
 ...can top the roots into a basket, the tops being left on...
 ...the ground. The basket is then carried into a cart...
 ...Carrots are stored in a shed or barn, and are...
 ...used as a substitute for...
 ...Carrots, and they are the best way of...
 ...before they are roasted, the other...
 ...The crop, however, may, in the first place, be stored in...
 ...sand, like Carrots, and the scraping, washing, spitting, and...
 ...drying deferred until the time of sale. But the...
 ...sooner the kind-drying takes place after the crop is...
 ...lifted the better, and there is some art in kind-drying...
 ...so as to retain the bitter and aromatic properties of the...
 ...root. Hence some manufacturers prefer buying the...
 ...fresh roots when dry.

Chicory is also grown as a forage plant for soil...
 ...and it yields four or five cuttings, the last about...
 ...time. It is best adapted for mixing with other...
 ...forage plants as hay, given to stock when on Vetches...
 ...and Globe Turnips, both fattening sheep and neat...
 ...cattle, and also for young stock of every kind, at this...
 ...peculiar season of the year, when the heath is...
 ...able to get into an abnormal state. When milk cows are...
 ...exclusively fed upon Chicory it affects the milk, but a...
 ...small quantity mixed with sowage Grass, Vetches, or...
 ...Globe Turnips, will improve both the health of the...
 ...cows and the quality of their milk.

Steam Culture—Large areas of land are cultivated...
 ...by steam during this month, and those who have to...
 ...be employed will prefer to do so for, although...
 ...the land becomes...
 ...is...
 ...when dry...
 ...the wet...
 ...is to cultivate...
 ...and this applies...
 ...not only to stubble, but also to lea. True, so long as...
 ...cattle are out at grass on farms where there is no...
 ...natural meadow and pastures, lea cannot be ploughed...
 ...until the water are finally housed for the winter. But...
 ...the months the arable pastures are cleared of stock, these...
 ...who have to fire to burn should embrace the first...
 ...opportunity, a very great advantage of dry weather...
 ...is possible. Those who have taken of their own...
 ...experience go on with the keeping pace with the...
 ...season, but those who have to hire must wait their turn.

Spring Beans, winter late, are frequently abroad in...
 ...the north at the middle of the month, and, when this...
 ...is the case, the crop is sometimes sown on the...
 ...pastures and oat stubble, so as to get the land...
 ...ploughed and sown with Wheat. Steam is of inestimable...
 ...value in such cases, as the land may be ploughed...
 ...and sown as fast as it is cleared of the bean crop.

Winter Beans—Sowing continues to be success-...
 ...fully applied during this month, not only to Italian...
 ...Rye-grass, for sowing, but also to land from which corn...
 ...and root crops have been removed, and Cabbages...
 ...planted. A fresh break of Italian Rye-grass may yet...
 ...be laid down, and the old broken up.

Water Meadows should now be ready, as the first...
 ...floods are the richest.

Sundries.—Paint and put past implements as they...
 ...are done with for the season. Keep the stackyard...
 ...clean and neat. Finish cutting and plashing fences. Clean...
 ...ditches, catch in. Lame roads repair, so that...
 ...no water shall stand in pools during winter. "October...
 ...ale," brew from the best quality of malt only.

Live Stock.—Horses require particular attention, both...
 ...as to feed and grooming, when mending their...
 ...summer coats and putting on their winter clothing; they...
 ...also experience the change from green to dry food; the...
 ...work is likewise heavy. And thus they have to...
 ...endure at a period when their physical energies are...
 ...naturally in a lax state. The change from green to dry...
 ...food should be by degrees, but hardly any rule can be...
 ...laid down to meet all the exigencies of the stable in...
 ...different localities at this season. The grand relief is...
 ...the extension of steam tillage and steam power to do...
 ...all the heavy work of the farm in cultivating and...
 ...threshing. Other stock also require peculiar attention...
 ...at this season, for many of the maladies experienced by...
 ...lambs, calves, yearlings, and other stock, are less or...
 ...more due to an oversight of their natural requirements...
 ...at this season. It should always be borne in mind...
 ...that the farther and faster we advance in improved...
 ...agriculture, the more artificial is the state of live stock, and...
 ...the greater the care they consequently require...
 ...artificially. W. B.

New Hardy Trees
PAUL AND SON will be pleased to receive Orders, which will be executed to the best advantage for the following NEW HARDY TREES and SHRUBS:
 (1) **PAULSONIANA** (A NEW SPECIES)
 (2) **WATERBURY** (A NEW SPECIES)
 (3) **WATERBURY** (A NEW SPECIES)

Large Evergreens and Forest Trees
MESSRS. PAM. LAIN AND SON have a large quantity of the following trees and shrubs, part of which are for sale at the following prices:
 Cedar, 1 to 2 feet, 10 to 15 feet
 Cedrus Libani, 6 to 15 feet
 Aconitum, 2 to 6 feet
 Portugal Laurus, 2 to 6 feet
 Chinese Arbor Vitae, 5 to 12 feet
 American, 5 to 10 feet
 Thuja aurea, 1 to 4 feet
 Green Box, 1 to 6 feet
 Sarcocolla, 2 to 4 feet
 Box, 1 to 2 feet
 Yew, 1 to 2 feet
 Yew, 2 to 3 feet
 Yew, 3 to 4 feet
 Yew, 4 to 5 feet
 Yew, 5 to 6 feet
 Yew, 6 to 7 feet
 Yew, 7 to 8 feet
 Yew, 8 to 9 feet
 Yew, 9 to 10 feet
 Yew, 10 to 11 feet
 Yew, 11 to 12 feet
 Yew, 12 to 13 feet
 Yew, 13 to 14 feet
 Yew, 14 to 15 feet
 Yew, 15 to 16 feet
 Yew, 16 to 17 feet
 Yew, 17 to 18 feet
 Yew, 18 to 19 feet
 Yew, 19 to 20 feet
 Yew, 20 to 21 feet
 Yew, 21 to 22 feet
 Yew, 22 to 23 feet
 Yew, 23 to 24 feet

Finsbury Steam Joinery Works, 121, Bunhill Row, E.C.

Heating by Hot-water.

SHANKS' IMPROVED WROUGHT-IRON BOILER.
This Boiler is made on the principle of the Saddle and Tubular combined. The Tubes, Fire-box, and Shell-plates are all of Wrought-iron, and consequently are not liable to break from expansion and contraction of the metal, as Cast-iron Boilers are. The Tubes are placed in the Fire-box, and so arranged as to expose a very large effective heating surface to the direct action of the fire, the advantage of which is obvious.

A. S. and SON will be glad to furnish their IMPROVED BOILERS separately, or to furnish Plans and Estimates for Erecting Hot-water Apparatus complete in any part of the country.

HORTICULTURAL BUILDINGS in IRON or WOOD.
Catalogues, containing Designs of Houses, &c., will be forwarded on application. Special Plans and Estimates for Ranges of Houses to be erected in any part of the country will also be furnished.

A. SHANKS and SON, Deas Iron Works, Arbroath, N.B.; and 27, Leadenhall Street, London, E.C.

IRON GREENHOUSES CHEAPER THAN WOOD.
Beard's Patent Non-conducting and Ventilating Metallic Glass Houses.
Victoria Works, Bury St. Edmund's.

MANUFACTURED BY
CHARLES BEARD,
Senior Partner in the late Firm of Sanders, Frewer & Co., which Firm was dissolved by mutual consent.
The Patentee wishes to observe his Patent Houses obtained the First and only Prize at the Royal Horticultural Congress, South Kensington, 1865;
The First-class Certificate at the Grand Manchester Horticultural Show, 1867;
The Three First-class Certificates at the Royal Horticultural Show, at Bury St. Edmund's, 1867, viz.:—One Prize for Patent Glazing without Putty; One Prize for Best System of Patent Ventilation; One Prize for S. F. & Co.'s Improved Flower Standa.
These much-approved Patent Systems of Glazing and Ventilation are also extensively adapted for all Agricultural Buildings, Public Halls, Churches, Factories, Railway Stations, &c. &c.
Full particulars and Prices of the Patent Houses, glazed with 28 oz. Sheet Glass from 1s 6d per foot super and upwards. As also Illustrated Catalogues for 12 postage stamps, may be obtained on application to CHARLES BEARD, Victoria Horticultural Works, Bury St. Edmund's.
PATENT GLAZING BARS, to screw on wood, may be had separately. Full particulars for stamped envelope.

T. G. MESSENGER,
MIDLAND STEAM POWER HORTICULTURAL WORKS,
HOT-WATER APPARATUS, VALVE MANUFACTURER,
LOUGHBOROUGH.

Honourable Mention awarded at the International Exhibition, 1862, and at the Dublin Exhibition, 1865; also a First-class Certificate by the Royal Horticultural Society.

T. G. Messengers, Patentee of many important improvements in Buildings and Implements connected with Horticulture, and which meet with unqualified approbation, is prepared to give reference to hundreds of works entrusted to him and pre-eminently answering the purpose for which they were constructed.

Any House Glazed, single or double, with or without putty. The mode adopted by T. G. Messengers for Heating and Ventilating Forcing Houses is particularly successful, drip being entirely prevented.

Houses can be constructed on his Patent Ventilating principle to open the whole of roof and sides as though the glass were entirely removed, at once placing the plants in the external atmosphere.

T. G. Messengers's Boiler possesses all the advantages of the Tubular and Saddle combined, has hollow furnace bars, requires but a shallow stokehole, exposes as much surface to the direct action of the fire as can possibly be obtained, the whole of which can be easily cleaned, and it is an important fact, that out of upwards of 600 now at work made upon the improved principle not one has cracked.

T. G. Messengers's Valve (single or double) is effective, simple, easy to work, and as durable as the pipe to which it is attached.

Designs and estimates supplied for all kinds of Horticultural Work, and guaranteed to answer the purpose for which they may be intended. A richly Illustrated Catalogue, with descriptions, forwarded post free on receipt of 33 stamps.

CRANSTON'S PATENT GLASS BUILDINGS for HORTICULTURE. Plans and Estimates free.

It is with great gratification that we announce our permission to refer upon any occasion to the various

HEATING APPARATUSES at the above, where our "ONE BOILER SYSTEM"

HAS FOR YEARS BEEN SUBJECTED TO THE MOST CRITICAL TESTS WITH EVERY SATISFACTORY RESULT. IT IS MATCHLESS FOR EFFICIENCY, AND IS WORKING THE LARGEST APPARATUS ON RECORD.

These are no theoretical statements, but positive facts, and it is not too much to add, that no boiler can boast a parallel.

For List of Details, see "ILLUSTRATED BOOK of DESIGNS" (12th Edition), which can be obtained by addressing a note to

THOMAS GREEN AND COMPANY, HORTICULTURAL ENGINEERS, &c., KING'S ROAD, CHELSEA, S.W.

GREEN'S PATENT IMPROVED TUBULAR HOT-WATER BOILERS.

OBLONG BOILER.

SQUARE BOILER.

THE ABOVE BOILERS ARE

THE MOST EFFECTIVE AND DURABLE EVER INVENTED.

can be set to work at a nominal cost, inasmuch as no brickwork is required; as will be seen from the above drawing, they are placed upon a Cast-Iron Sole-plate, which serves the purpose of Foundation and Ashpit.

In the peculiar and substantial manner in which these Boilers are made, they are warranted to last for years without getting out of order; in fact, we guarantee them for years, but feel convinced that they will serve all the purposes for which they are intended for a much longer period.

They are specially adapted for Heating Greenhouses, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c.

THE FOLLOWING ARE THE ADVANTAGES OF THESE BOILERS:—

- 1st, They require no setting in brickwork.
- 2nd, They are complete in themselves, having perfect means of regulation.
- 3rd, They take up little room, and can be put in places inaccessible to other Boilers.
- 4th, They are economisers of fuel, owing to the great amount of heating surface upon which the fire acts in a direct manner, and the consumption of smoke.

- 5th, The fire can be made to last from 12 to 24 hours without attention.
- 6th, Any number of Flows and Returns can be annexed to the Boilers by means of T-pipes.
- 7th, By means of mud doors, they can be readily cleaned out when required.
- 8th, The Chimney is made of cast-iron, which can either be taken through a roof or turned into a flue, to meet the convenience of the situation that it may be fixed in.

PRICE LISTS ON APPLICATION.

Vases and Fountains, for the Garden and Conservatory.

ANDREW HANDYSIDE AND CO., Britannia Foundry, Derby. 33, Walbrook, London. The Britannia Iron Works have for the last 40 years been well known for the production of Fine Iron Castings. The use of Cast-iron permits a delicacy of outline, and smoothness of surface, impossible in cheap Stone or Terra-cotta. Cast-iron Vases, if occasionally painted, will not crack when exposed to wet or frost.

Five large Sheets of Designs and Price Lists post free for 6 stamps. A. H. & Co. make the better kind of IRON and GLASS CONSERVATORIES, and have constructed some of the largest and finest in the Kingdom.

Rosher's Garden Edging Tiles.
The above and many other PATTERNS are made in Terra-Metallic Ware, Terra-Cotta, Stoneware, and Bedware, and of great durability. The planer series are especially suited for KITCHEN GARDENS, as they harbour no Slugs and Insects, take up little room, and once put down incur no further labour and expense, as do "grown" Edgings, consequently being much cheaper.
GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, of great durability and superior finish, and in much variety of design.
F & G ROSHER, Manufacturers, Upper Ground Street, Blackfriars, S.E. Queen's Road West, Chelsea, S.W.; Kingsland Road, Hoxton, N.E. Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES for Conservatories, Halls, Corridors, Balconies, &c., as cheap and durable as Stone, in blue, red, and buff colours, and capable of forming a variety of designs. Likewise more elaborate designs. Pattern Sheets of Pavements, with prices, forwarded for selection.
WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Slabs Paving Bricks of great durability, Dutch and Adamantine Clinkers, Wall Copings, Red and Stoneware Drain Pipes, Slates, Cements, &c.
To be obtained of F. & G. ROSHER, at their premises as above.

SILVER SAND (REIGATE), at the above addresses— 14s. per Ton, 1s. 2d. per Bushel; 2s. per Ton extra for delivery within three miles, and to any London Railway or Wharf. Quantities of 4 Tons, 1s. per Ton less. A coarser grained Sand 4s. per ton more. Samples of Sand by post on receipt of stamp.
FLINTS and BRICK BURS for Roadways or Ferneries. KENT PEAT and LOAM supplied at lowest rates.
F. & G. ROSHER.—Addresses see above
N.B. Orders promptly executed by Railway or Vessel. A liberal discount to the Trade.

"Every Cottage should be provided with a Water Tank." *Disraeli.*
Iron Cisterns.

F. BRABY AND CO. having laid down more extensive and Improved Machinery on their Deptford premises (17th Wharf), are prepared to supply WROUGHT-IRON TANKS, GALVANISED or PAINTED, of superior quality, at reduced prices, and at very short notice.

An Illustrated Price List of Galvanised Iron, and other of BRABY'S special Manufactures, sent on application. F. BRABY AND CO., Limited, Fitzroy Works, Euston Road, London; or through all respectable Ironmongers. N.B. Open Tanks of different sizes packed one in another to save carriage

GREEN'S PATENT SILENS MESSORS, for NOISELESS LAWN MOWING, ROLLING, and COLLECTING MACHINES for 1890.

Every Machine is warranted to give entire satisfaction, and if not approved of, can be returned at once and a full refund given.
PRIZE MEDALS AWARDED TO GREEN'S PATENT LAWN MOWERS.
First Prize Medal at the International Exhibition, London, 1862
First Prize Medal at the International Exhibition, Dublin, 1865
First Prize Medal at the Namur Exhibition.
First Prize Medal at the Gand Exhibition.
First Prize Medal at the Leeken Exhibition.
First Prize Medal at the Lieneas Exhibition.
First Prize Medal at the Brussels Exhibition, on two occasions.
First Prize Medal at the London Exhibition, 1873.

Green's Patent Lawn Mowers have proved to be the best, and have carried off every Prize that has been given, in all cases of competition.
The extraordinary success of Green's Patent Lawn Mowers is an established fact. During the last ten years the demand has been unrecanted, and one is a proof of their superiority over all others. The following are their characteristic features—1st. Simplicity of construction, every part being free of excess. 2d. They are worked with far greater ease than any other Lawn Mower. 3d. They are the least liable to get out of order.
Green's Patent Lawn Mowers combine all the advantages of self-sharpening, and when the cutters become blunt by running one way round, they can be reversed again and again, bringing the sharp edge of the cutters against the bottom blade, which operation can be done by any inexperienced person, owing to the peculiar adaptation of the Machine, which is possessed by no other. Illustrated Price Lists free on application.
THOMAS GREEN AND SON, Smithfield Iron Works, Leeds; and 64 and 65, Blackfriars Road, London, S.
N.B. All orders are executed on the day they are received.

SHANKS'S PATENT LAWN MOWER
The Patentee's agents recently introduced SHANKS'S MACHINES

Several important advantages possessed by the PATENT DOUBLE-EDGED SOLE-PLATE, which The unprecedented Sale for 1888, notwithstanding the Season, forms the best testimony that the advantages have been appreciated.
ALEXANDER SHANKS & SON beg to intimate to Exhibitors of Lawn Mowers at the Paris Exhibition that their Firm's Mowers were the only ones which the Jury awarded a Medal, and which also had the highest Prize ever given to Lawn Mowers.

ALEXANDER SHANKS & SON have for some time the Revolving Cutter of their Machines set with Steel on both Sides of each Blade, so that becomes blunt by running one way, it can be turned the opposite or sharp edge of the Cutter to the Plate. In addition to this, A. S. & Son use a better Blade than any other, with Two Edges, and can be reversed at the back, when worn down, the plates may be unscrewed and brought to the front. It will be seen as a glance in the accompanying illustration that the arrangement enables the cutting parts to last twice as long as in ordinary machines, where the unimproved Sole-plate is renewed when the edge is worn down.
A Wind-Guard has also been introduced to prevent Grass being blown past the Box during the process. There is no ribbing with these Machines. The Machine has a most beautiful appearance, being smooth and Every Machine is warranted to give entire satisfaction, and if not approved of, can be returned at once and a full refund given.
Illustrated Price Lists, with full particulars, sent free on application.
ALEXANDER SHANKS & SON, 27, Lendenhall Street, London, E.C.

SUTTONS' SUPERB DUTCH HYACINTHS FOR CULTIVATION IN POTS OR GLASSES.

The best 12 HYACINTHS for 12s. Messrs. SUTTONS' COLLECTION of HYACINTHS consists of more than 200 varieties, a PRICED and DESCRIPTIVE LIST of which may be had on application. Suttons' Collections of Named Hyacinths. 100 HYACINTHS in 100 very choice sorts £4 4 0 100 " 50 very choice sorts 3 10 0 50 " 50 very choice sorts 2 2 0 50 " 25 very choice sorts 1 15 0 25 " 25 very choice sorts 1 1 0 12 " 12 extra fine sorts 0 12 0 12 " 12 choice sorts 0 9 0 12 " 12 good sorts 0 6 0

The order should specify whether they are intended to be grown in water or earth, as all kinds are not equally suited to be in water. It should also be stated whether single or double blossomed kinds are preferred; otherwise we usually supply about two thirds double and one third single. The single varieties generally thrive best in water, but their merits are never apparent until the flowers are fully expanded. SUTTONS' MIXED HYACINTHS for Beds or Open Borders.—Double, Single, and various colours, 2s. 6d. per doz., 17s. 6d. per 100. SUTTONS' HYACINTHS in DISTINCT COLOURS for Massing. Bedding, Ribbon Gardening, &c.—Double and Single, various shades, separate, 4s. per dozen, 30s. per 100.

Suttons' Complete £1 ls. Collection For OPEN GROUND CULTIVATION, Carriage Free. 12 fine mixed Border Hyacinths 6 Polyanthus Narcissus 12 Phœnix Eye Narcissus 12 Double White Narcissus 25 Double Daffodils 6 large Camerelle Jonquils 50 fine mixed Double Ranunculus 50 scarlet Turban Ranunculus 12 fine mixed Double Anemones 12 Single Anemones 50 Crocus, 3 sorts 50 Snowdrops 25 Winter Aconites 6 fine mixed Gta Botus 12 Duc Van Thol Tulips 6 mixed Single Early Tulips 6 fine mixed Double Tulips 6 " Parrot Tulips 6 Genesiana Tulips 25 fine mixed Tulips 6 " English Iris 6 " Spanish Iris 3 Lilies, of sorts 3 Ferraria pavonia 6 Dog's-Tooth Violets 3 Crown Imperials

For further particulars and Prices of GLADIOLUS, RANUNCULUS, ANEMONES, &c., see SUTTONS' AUTUMN CATALOGUE, gratis and post free on application. SUTTON AND SONS, SEEDSMEN TO THE QUEEN, READING, BERKS.

ECONOMY IN THE GARDEN.

James Carter & Co. Seed Growers AND NURSERYMEN, 237 AND 238, HIGH HOLBORN, LONDON, W.C.

CARTER'S COLLECTIONS OF HYACINTHS, CROCUS, TULIPS, &c., TO PRODUCE A PRETTY AND PERMANENT DISPLAY DURING WINTER AND SPRING.

JAMES CARTER AND CO. strongly recommend the following COLLECTIONS, assorted from the most popular varieties—

Carter's Collection for Window or Conservatory Decoration, £1 ls.

CONTAINING 12 fine named Hyacinths 12 Jonquils, sweet-scented 50 named Crocus, finest 1 Creman persicum 1 Lilium speciosum 35 extra selected Snowdrops 3 La Candeur Tulips 3 Royal Standard Tulips 9 fine named Poly Narcissus 1 Deyra spectabilis 9 Scilla bulbifera 3 Tozmos Tulips 3 Rex Rubrum Tulips 3 Yellow Los Tulips 6 Red and Yellow Van Thol Tulips 3 Rose Van Thol Tulips

Subject to variation as the season advances. CARTER'S COLLECTIONS, with increased quantities of the above varieties, 4s., 6s., and 8s., packing included in all cases.

McLAREN'S PROLIFIC RASPBERRY. SPECIAL NOTICE.

AWARDED A FIRST-CLASS CERTIFICATE. JAMES CARTER AND CO. beg to state that in consequence of the rapid demand for this valuable novelty their stock of strong Canes is now exhausted.

The entire stock will be held next season by J. C. & Co., and Orders are now booked to be supplied in rotation next autumn at the following Prices:—

As the supply next year will be limited, early Orders are recommended. 6 Strong Canes, 7s. 6d. 25 Strong Canes, 20s. 12 Strong Canes, 12s. 100 Strong Canes, 60s.

Carter's Collection of Bulbs for Conservatory and Outdoor Planting, price 15s.

CONTAINING: 6 Hyacinths, extra fine named 12 Narcissus, double White 6 fine hedding 12 Peasant's Eye 3 Tulips, Tournefort 3 Tulips, Yellow Prince 3 Tulips, Rex Rubrum 3 Tulips, White Pottobakker 12 Tulips, extra fine mixed 60 Crocus, fine Blue 50 Crocus, fine White 50 Crocus, fine Yellow 18 Anemones, extra fine mixed 4 Gladiolus Branchleyensis 6 Iris, choice English 14 Iris, choice Spanish 9 Jonquils, Campenel 18 Ranunculus, extra fine 24 fine selected Snowdrops

Subject to variation as the season advances. CARTER'S COLLECTIONS, with increased quantities of the above varieties, 30s., 4s., and 8s. No charge for packing.

Decoration of the Drawing-room.

JAMES CARTER AND CO. offer for this purpose their choice Selections of HYACINTHS in Pots, GLASSES, &c. 12 choice Hyacinths in new-shaped Glasses 1s. 12 good " " and 12 new-shaped Glasses 18s. 6d.

Carter's Collection of Bulbs, for Outdoor Planting only, price 21s.

CONTAINING: 18 Hyacinths, choice in Scissors 6 Gladiolus, Branchleyensis 12 Narcissus, double white 12 Iris, extra choice mixed, English 12 Peasant's Eye 12 Double Daffodils 12 Iris, extra fine mixed, Spanish 36 Tulips, extra fine mixed 3 Lilium candidum 60 Crocus, blue 3 " striped 60 " large yellow 3 " tigrinum 50 " white 100 Snowdrops, selected 24 Anemones, extra fine mixed 24 Winter Aconites

Subject to variation as the season advances. CARTER'S COLLECTIONS, with increased quantities of the above varieties, 4s., 6s., and 8s. No charge for packing.

For full instructions for cultivation, and particulars of the above Assortments, see

CARTER'S ILLUSTRATED BULB CATALOGUE For 1889, Gratis and Post Free.

JAMES CARTER AND CO., THE ROYAL SEEDSMAN, 237 AND 238, HIGH HOLBORN, LONDON, W.C.

British Fern Catalogue. ROBERT SIM will send, post free for six postage stamps, Part I. (British Ferns and their varieties, 36 pages, including prices of Hardy Exotic Ferns) of his PRICED DESCRIPTIVE CATALOGUE OF BRITISH and EXOTIC FERNS, No. 7. Foot's Cray Nursery, Bidecup Hill, Kent

Carnations and Picotees (in Choice Show Varieties). JOHN J. HASLAM, Bradshaw Gardens, Chadderton, Manchester, again calls the attention of the Trade, &c., to the unrivalled Collection of the above. He can also supply APPLE and GOLDEN HERRY TREES in Lancaster fresh sorts with AURICULAE, POLYANTHUS, PANSIES, FANSIES, PINKS, &c. Prices Lists on application.

VARIEGATED ARABIS, for Edging.—Good strong Cuttings, 4s. per 100, or 600 for £1, cash. MADRESFIELD COURT VINE.—Strong Canes, 10s. 6d. and 15s. each. Eyes or Grafts, 6d. each. MRS. PINCE'S BLACK MUSCAT.—Strong Canes, 5s. 7s. 6d., and 10s. 6d. each. Eyes or Grafts, 3d. each. J. HOUSE, Eastgate Nursery, Peterborough.

NEW CATALOGUE of choice AZALEAS (Indian and Hardy), CAMELLIAS, RHODODENDRONS, ORCHIDS, LILiums, &c., offered by LOUIS VAN HOUTE Copies of the above may be had direct from Ghent, or from L. V. H's Agents, R. SILBERRAD AND SON, 6, Harp Lane, Great Tower Street, London, E.C. Royal Nursery, Ghent, Belgium

Gladiolus.—ROSES. M. CH. VERDIER fils (late Firm of Victor Verdier, Paris, and Ch. Verdier, fils, Nurseryman, 12, Rue Dumeril, Paris, has just published his new CATALOGUE OF GLADIOLUS, containing the names of the varieties of the season, which may be had free on application to his London Agents, Messrs. SILBERRAD AND SON, 6, Harp Lane, Great Tower Street, E.C. N.B.—A CATALOGUE OF NEW ROSES (which will be sent out next season) is also ready, and can be had on application to the above.

SPRING BEDDING PLANTS.—Large Surplus Stock, consisting of the most approved varieties for Ribbons, Beds, &c., as DAISIES (White, Red, Pink); PANSIES, perpetual blooming for both seasons, as Blue and Yellow of various shades, Purple, Black, White—very few of the new bred, with other popular Spring Bedding Plants. Lists of application to JOHN FLEMING, Chesham, Maidenhead.

Polyanthus. STEPHEN BROWN offers splendid Mixed POLYANTHUS, beautiful variety, grown from seed saved from his first-class Salisbury Collection. First quality, 3s. per doz., 2s. per 100, 160s. per 1000. Second quality, 2s. per doz., 15s. per 100, 120s. per 1000. 1s. each, discount to the Trade. STEPHEN BROWN, Seedsman and Florist, Weston-super-Mare, Somerset.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION. Notice is hereby given that an ADDITION to the LIST of PENSIONERS will be made in January next. All Persons a series of beneficial CANDIDATES are required to send in their Papers and Testimonies to the Committee on or before MONDAY, November 5 next, after which day they will not be received. Preference will be given to those Persons who may have been subscribers for 15 Years and upwards. Should there not be a sufficient number of that class, then the names of those who have not subscribed so long, or not at all, will be considered. October 14, 1889. EDWARD B. UTTLER, Secretary, 14, Coventry Row, Covent Garden, W.C. P.S.—Printed Forms may be had of the Secretary on application to the Secretary.

The Gardeners' Chronicle. SATURDAY, OCTOBER 23, 1889.

AMONG the many HORTICULTURAL EXHIBITIONS that have taken place during the past summer, that held at LISBON seems worthy of special remark, from the rarity of such events in the South of Europe, and in the Iberian peninsula in particular.

From a report lying before us, signed by BERNARDINO ANTONIO GOMEZ, it appears that the exhibition originated under the auspices of the Real Associação Central da Agricultura Portuguesa, and was mainly supported by private persons, though the Municipal Council of Lisbon contributed largely to its enrichment by sending their large collections. The Duke of CADAVAL's park was the site selected, and in it a glass house was specially erected for the reception of the more tender subjects. This structure was designed and executed by M. STREET DE ARRIAGA E CUNHA, and for elegance and judicious arrangement was well adapted for the purpose in view. From the enumeration of the plants—which, however, is chiefly restricted to generic names—it would appear that the same preference for ornamental foliage plants, so prevalent in North and Central Europe, has at length manifested itself in the South. A magnificent group of Cactuses and Begonia, belonging to José MARQUÊS FERREIRA DE LUENA, remarkable alike for variety and luxuriance of growth, formed the chief point of attraction in the exhibition. The numerous ornamental forms of Eranthemum, Alocasia, Ecbites, Coleus, Achyranthus, and others, were likewise conspicuous, associated with Pelargoniums, Fuchsias, Potunias, Rhododendrons and Azaleas, together with Dracenas, Gloxinias, Cinerarias, and Bonapartes. Two splendid specimens of Latania Commersoni excited universal admiration, as also did fine examples of Clerodendron Thomsonae, Theophrasta imperialis, Pandanus javanicus, and various species of Magnolia, Erythrina, Metrosideros, Aucuba, &c. The exhibition was further enriched by several species of well-cultivated Cycads and Palms, and the Tree Ferns were particularly attractive. A numerous and well-grown collection of Coniferae excited equal interest, notably some fine specimens of Thuja Loblii, Thuja sp. dolabrata, and Scindapsus verticillata. Forming a surprising contrast with the foregoing were some good

of all commercial men Cotton, wool, grain have their prices and demands according to demand or supply, and so do various other species of plants. The Orchid market, although the articles to be disposed of are purely luxuries to the eye, fluctuates about as much as any of the markets where the necessities of life are to be disposed of.

The Orchid family at the outset was limited, in these days it appears to have multiplied far beyond anticipation and the cry is "still they come." Many are the acquisitions from an eye-sweet point of view, that have been obtained time after time, but nothing more lovely than the white Moth Orchids—nothing so exquisitely beautiful, not a single individual that can lay claim to the same pure chasteness of colour, and to a form that can leave nothing to be desired. The date of their introduction to the plant-houses of our country is coincident with the beginning of Orchid cultivation, and their career, under the care of our cultivators, is somewhat uneventful. At times they are seen in great beauty, both of foliage and inflorescence—not a speck to mar the fine circling flower panicles, nor a blotch of disease upon their broadly ovate succulent leaves. At other times their foliage is seen loathsome with disease, their very substance being extracted, leaving wrinkles and blotches, thickly set together, even apparently having a decided centre, but all ultimately broken together, and betokening eventual decay and death. Following the inevitable natural law of the family, the greater the signs of debility shown the greater the disposition to get into a state of inflorescence, and, although the gardener in charge may pinch the coming flower stem as a corrective measure, with the view of saving his plant, it either in course of time breaks away again from the top eye remaining, or starts afresh from the base of the foliage. The flowers, if allowed to form, often prove equally beautiful with those on unexceptionably healthy plants, and contrast ill with the diseased foliage, looking as if they ought to be in better company. Some, by careful watching and under the influence of remedial treatment, do survive and start away on their own accord from the fleshy-looking crown—indeed, the tendency is to reproduction by lateral extension, but it is the reproduction of deterioration induced by an unimpeded obstruction; and although we have experienced it going on, two and three times removed, it eventually ends in death.

But the wearing-out process asserts its prerogative even among healthy plants—plants that have been so long-lived that have lived a life where admiration was never once withdrawn. There has been abundant evidence to collocate, showing that the *Phalaenopsis* *amabilis* and *grandiflora*—species which have been nearly 30 years under cultivation in this country—can be grown a certain time, say for a dozen years, with uninterrupted success, and then the deteriorating tendency of the nature of the plants themselves, clearly shows itself. Many orchid-lovers who dispute the validity of this theory, but let them study the history of the genus, and then report. The strongest argument I have heard in defence, is to this effect—that granted *P. amabilis* or *P. grandiflora* will lose their vigour in course of time, and as a consequence lose the principal leaves, and probably their whole foliage, yet they easily break away again, and the living plant only requires to be sustained, and nursed and treated properly, to keep up unimpaired interest in the beauty of its foliage, and the plenteousness of its flowers. All I have to say is, follow out the life history of the plant, and the grower or owner will see that by no process can the same vigour be infused, nor the same dimensions attained, proving conclusively that dissolution is only a matter of time. In good hands, the lives of plants can be prolonged like the lives of individuals, if not subjected either to fast living, to injudicious checks in the shape of food or water supply, to improper aeration, or to extremes of heat or cold. Many growers can rear first-rate specimens of the plants in question, by refusing to allow them to flower, and by so doing add to the years of their life. But what is gained by this is lost in the want of the same quantity of flowers during the lifetime of the plant. It may be good enough practice for a great spurt to astonish and electrify the sightseer by the hugeness of the specimen (comparatively speaking) and the quantity of flowers produced, but to the real Orchid lover this is but a questionable return. Moreover, plants grown in this plethoric condition—for the predisposition is in that direction, if you stay the process which Nature assigns—are apt to become diseased. The least injudicious management will induce that dire plague—rust spot, and once into the system of a *Phalaenopsis*, it is not up to the present time, has been found able to resist for its eradication. It is so thoroughly mixed up with the system, that the usual recipes which may stay its inroads, are futile to coax away or dispel it. Indeed, this part of vegetable pathology is but imperfectly understood, as a variety of causes may operate to produce the same disease.

But the plant is popular. It must be grown, can be grown, for years, but what about the supply? It is one of the most difficult of plants to import. The two most common, *P. amabilis* and *P. grandiflora*, notwithstanding the attractions of other-known to science or cultivation, are the most beautiful, and therefore the best. In recent years we have had new fields to replenish our stores. In addition to the old district, we have Borneo and Pulo Penang, which have supplied quantities of the *P. amabilis* variety, and many excellent forms have been a ready proof. The constitution and the appearance of the plants from the three different districts vary so much that a skilful grower, or a careful observer, will be able to separate them all. Looking, however, to the increased demand, which is steadily going on, increasing still, notwithstanding the fluctuations and depression of trade, we apprehend there will be some difficulty in maintaining an adequate supply. At the

present time the two species named above cost as much gold to secure in this country as ever they did, and the market is rising. All those who hold stock have nothing to fear so long as they keep them free from spot, in fair healthy condition. As an instance of how importers of the greatest experience in the country are affected by circumstances over which they have no control, I append a passage from a letter of Mr Stuart Low, received in August last, which I trust he will excuse my publishing, in support of the plea I have propounded as to difficulty in importation and consequent losses incurred—"We have recently had one or two hard hits on theory of importation. Just recently we have had what, when packed, was perhaps the most valuable lot ever sent us—a grand lot of *A. l.* species, and bulk was great also, but losses about total—so much so that out of this, and previous lots, we have not offered a single plant to any one, only a few odds and ends being saved from the wreck. Add to these two lots a third of *Phalaenopsis*, of which out of 480 we saved one, and you will agree with me that results are not brilliant." Here is an instance of the enterprise of that firm, with returns absolutely nil. Had these 480 *Phalaenopsis* come to this country alive, they were worth, in round numbers, 1000*l.*, and would have exercised very little effect upon the market so far there are to offer at anything like tempting prices. Native localities got cleared out of such valuable marketable commodities, and unless the collectors stumble upon new districts we have need to be watchful over the stock now in the country. Reproduction by seed is a slow process, taking years to make plants fit to send home. Then all our efforts at rearing the genus from seed have failed. There is no difficulty in hybridising the species and getting seed capsules, and quite as little difficulty in crossing varieties—the great matter is to get the seed to germinate. I effected an excellent cross between *P. amabilis* and *P. Schilleriana*, and was all excitement for years, hoping against hope that the seed would germinate; but, like many others in rearing *Phalaenopsis*, I was doomed to disappointment. J. Anderson.

(To be Continued.)

THE CLOCHE AND THE CORDON.

We are enabled, with Mr. Robinson's permission, to avail ourselves of two cuts from his "Parks, Promenades, and Gardens of Paris," illustrating these two

subjects, concerning which not a little has been already said in our columns. No one will deny the handiness of the cloche for winter salad growing, raising seedlings, striking cuttings, protecting winter

flowers, and the like. In France the cost of these cloches is about a franc a-piece, and they may now be obtained in this country at as cheap a rate.

Our second cut shows the way in which the cordon may be advantageously used to fill vacancies at the bottom of walls, the front of pits or plant-houses, or any low naked wall with a warm exposure. In small establishments, or in the hands of amateurs, this method of fruit growing has its advantages.

Home Correspondence.

Acalypha tricolor—It appears singular to me that this plant has not been exhibited worthily of special comment at any of the principal exhibitions this season. I cannot account for it, as it is one of the finest variegated foliage plants I am acquainted with. The specimen which I exhibited at Worksop on Sept. 2 was the most admired plant in my group, and for contrast of colour in a collection of variegated foliage plants it has no equal, the colour being so varied; indeed, it may be termed a plant of many colours. I have one specimen that measures more than 6 feet by 6 feet, which is truly fine, and pronounced by competent judges and visitors to be the finest plant in England. I had the same in grand condition last season, but for want of room in the winter I cut it down close, just as I would a *Pelargonium*. I shall be compelled to do the same thing again this winter, otherwise I shall not be able to remove it out of the house, in consequence of the enormous size it will attain. This I much regret, as I find the plant improves in size of foliage and colour with age. Would Mr Veitch kindly inform your readers what size it attains in its native country (Fiji Islands), its height, size of foliage, and appearance? I should imagine it to be one of the most beautiful foliage plants imaginable in its wild state. I find no difficulty

in its culture, plenty of water being the only secret. I have sent some of the foliage for your inspection. Edward Bennett, Gr to G. S. Foljomb, Esq., Osberton, B'k'ng'p. Very large and extremely handsome. The plant is described and figured in Dr Seemann's "Viti Flora," from which we will shortly extract an account. Eds.

International Fruit Show, Edinburgh.—My attention has been called to a letter in the *Gardeners' Chronicle* of the 9th inst, signed "Observer," and headed "The Troubles of the English Exhibitor," reflecting on my conduct, as secretary of the Royal Caledonian Horticultural Society, at the International Fruit and Flower Show held here last month, in regard to two Pines which were sent by Mr Ward for competition in class 3, and I shall be obliged by your inserting the following statement in answer. On September 7 a box was delivered at the Music Hall, and opened by Mr. Young, assistant secretary, who found it contained two Pines, the one a Charlotte Rothschild, the other a Blood, but no card was inclosed stating from whom they came, nor was there any marking on the address to lead to it. The box was therefore laid aside, and in the course of the day Mr. John Methven, gardener, Blythwood, applied to Mr Young to know if a box with two Pines had arrived, and he produced a letter from Mr Miles, instructing him to get the Pines staged and disposed of after the show. Mr Young accordingly delivered the box to Mr Methven, who took charge of staging the fruit and disposing of it afterwards. The letter, which is said to have been addressed to me by Mr. Ward, when the box was sent away, was never received; and I did not see Mr. Carmichael, the Royal gardener alluded to, till the morning of the 8th, when he came to act as a judge. In the course of the forenoon, Mr. Carmichael asked me if I had received a box with two Pines and a letter regarding them, when I informed him I had not, and in the evening he again asked if the box had cast up, and showed me Mr. Ward's letter to himself of the 6th, wherein he asked Mr. Carmichael to desire me to have the Pines returned to Mr. W. after the show, which I agreed to do if the box came; but as I did not know the address, I asked him to give me the letter, which he did, and the same is now in my possession. On Saturday the 11th I left town, and did not return till Monday the 20th, when I found a letter had been delivered at my house that morning from Mr. Ward, addressed thus: "Mr John Stewart, St. George's Hall, Edinburgh," being the letter of the 18th referred to, and the only one I have received from him, his two former letters never having reached me, and no wonder, if they were addressed the same as his letter of the 18th. How that one should have been delivered at my house I cannot understand. As I saw from that letter that the box had never cast up, I called on Mr. Young to know if he had heard anything of it, and shown me the letter, which explained to him the mystery about these Pines, and he then informed me for the first time that the box had been delivered to Mr. John Methven (as detailed above), that the Pines having gained the 1st prize, Mr. M. had written Mr. Miles, informing him of his success, and that he had sold the Rothschild, but could not get a purchaser for the other, that Mr. Miles had written to Mr. Methven in answer that there must be some mistake, as after having written to him to take charge of the Pines, he had changed his mind, and not sent any, and on this being communicated to him (Mr. Young), he had written Mr. Ward, who had entered for the same class, to know if the Pines were his, but had not received an answer, which he supposed was owing to his letter being addressed to Stortford in place of Bishop Stortford. He, therefore, agreed that he would write him again, explaining everything, which he did, and I afterwards understood that Mr. Ward had expressed himself as satisfied with the explanation he had received. In the prize list, published in the "Gardener," the error was corrected, and an advertisement was sent by Mr. Young to the "Journal of Horticulture" and the *Gardeners' Chronicle*, correcting the same. [Not received.] The above are the exact circumstances connected with the mistake about Mr. Ward's Pines, and I must express my surprise that, after the explanation given to him by Mr. Young, he should either have written the letter signed "Observer," or given the information to enable another to write it. The mistake did not occur through any of the officials of the Society, it was caused solely by Mr. Ward himself,—first, by his not putting a card into his box stating from whom the fruit came, and, secondly, by his putting a wrong address on his letter of advice to me, in consequence of which it has never reached me. John Stewart, Secy, G. A. S. Hort. Exhib., Oct. 13.

Victory of Bath Melon—I think it would be a great boon to the gardening public to be in possession of a really first-rate Melon. According to my judgment no Melon comes up to Victory of Bath, considering all its merits. The plant is very hardy, that is, will bear treatment that would kill such sorts as Golden Perfection, and sets abundantly without artificial impregnation: in fact, I have this season gathered three crops from the same plants, and was obliged to pull them up to make room for winter Cucumbers, or I believe they would have ripened a few more. The fruit is beautifully netted, of a fine golden yellow colour; the flesh, which is green, may be eaten to the rind. It is of most exquisite flavour, and may be eaten like a Jargonelle Pear. An average fruit weighs about 3 lb., quite large enough for a gentleman's table. I have not seen any other sort this season, hence I may presume my stock pure. I shall feel pleasure in giving a few seeds for trial upon receipt of a stamped directed envelope. A. S. Kemp, Haxthorn, Sharncliffe, S't'p.

Special Pelargonium Show—If the question were asked as to which is the most popular plant at the present time, the Rose or the Pelargonium, it would, I think, be a somewhat difficult matter with many to

decide, and there would be found numbers who would say the Pelargonium; and certainly, whether we glance at the garden of the cottager or the peer, we shall find them both very extensively cultivated, and perhaps the latter will be found in more places than the former. This being the case I, with many others, think that if the Rose is of sufficient importance to have a special day set apart for a show, the Pelargonium is equally entitled to the same honour; and as during the last three seasons it has been thus favoured, it is highly desirable, considering the prominent part it plays in the decoration of our flower gardens and conservatories—and in view, too, of the improvements continually being effected in the various sections of this popular plant—that a special show should still be held, either apart from or in conjunction with one of the other shows. Your correspondent Mr. Cannell, a few weeks back, touched upon one or two points, about which I think there would be found some difference of opinion, but if the former subscribers to this special show were to meet, I think it probable that some alterations might with advantage be made in the schedule; but, as you remarked then, there is no time to lose. I hope that those principally interested will take the matter up, and if so, from the amount of interest displayed in the past, I feel sure that the movement would be attended with the same success which rewarded those who organised the show of the past season, there being numbers of amateurs and others who attend these shows, for whom the large shows possess little or no attraction *Philos.*

Cantharellus carbonarius.—Will you allow me to correct an error in your leading article at p. 1061. The *Cantharellus carbonarius* found by me about a fortnight ago was not found on charcoal heaps in the woods around the Wrekin, but in the Duke of Sutherland's wood at Lilleshall. I have carefully examined several charcoal heaps in the Wrekin woods, but hitherto have failed to detect a single specimen of this Fungus. Yesterday I went again to the Lilleshall woods, and examined some eight or ten charcoal heaps of different ages; but, with the exception of one heap, where I found three specimens, I could discover no additional heaps that afforded the *Cantharellus*. From the heap where I had previously found this Fungus I gathered about 40 specimens, most of which I have this day forwarded to Mr. Broome. Should I discover more in the course of a week or ten days, I shall be happy to send specimens to mycologists who wish to make drawings of the *Charcoal Chanterelle*. *W. Houghton, Preston Rectory, Wellington, Salop, October 15.*

Shanking of Grapes.—"Twenty sovereigns would I give, if I had as much," said a veteran horticulturist the other day, "if I could only find out to my satisfaction the real cause of that evil. Thrips, red spider, and mildew I can form some conception of, but this shanking beats me." There is much truth in this; it beats a good many besides my friend. I have seen more of it this year than I ever remember before, and all who have to contend with it assign some reason of their own for its presence. Bad borders and overcropping are frequently mentioned, and, no doubt, are likely to bring it about. Spider and thrip attacking the foliage may be added. I venture to suggest another cause, which I have never seen hinted at before: it is this—an excessive reduction of the amount of atmospheric moisture at the time the Grapes begin to colour. This, I should say, hastens the maturing of the wood before the Grapes are supplied with the necessary amount of organisable matter to perfect themselves. To give any more physiological reasons in support of this hypothesis I will not attempt; but I should like the contrary to be proved, *i.e.*, that the proper balancing of atmospheric moisture has not much to do with shanking and deficiency of colour in Grapes. We have here a viney which three years ago was infested with all the known diseases and pests. Last year we reduced them to three, *viz.*, shanking, spider, and thrip; this year to two—shanking with slight appearance of the return of mildew. The latter we mastered in three weeks; this I think is the worst of all—it spreads so rapidly, and leaves traces of its stealthy steps on the berries to the last. To inquire the cause of shanking in such a case as that would be absurd. There is enough visible at once, without having to pry into the earth beneath. The fact of the Vines having been infested with spider for a dozen years would be sufficient in itself; but when it occurs on apparently clean healthy young Vines, growing in borders of modern construction, and managed by man whose skill one can scarcely doubt, one cannot help being possessed of the feelings of my friend with his 20l. *W. P. R., Oct. 12.*

Destroying Wasps' Nests.—The public is indebted to Mr. Squire for his information on destroying hornets' nests with chloroform, but that portion relating to wasps must be received with caution. For instance, wasps are always found at night guarding the entrance to their nests, and a very slight disturbance will put them on the *qui vive*, even a light thrown on them from a lantern will often do it, so that to put a stick or one's finger into the hole to ascertain its direction, would be to destroy all chances of killing the whole of the wasps. I have destroyed in one season upwards of 100 nests, and without being once stung (using the old-fashioned squib), my first care always being not to disturb the doorkeepers. I never felt the slightest fear, but was never courageous enough to put my finger into the hole. There are many queer places I would put my finger into rather than into a wasps' nest. Nor do I think we must take it as a general rule that wasps use rats' holes, or even a bank. I have found more nests on an average in flat ground, and with one small entrance hole made by the wasps themselves. But this, I think, depends in a great measure on the locality and the season, for when dry they prefer the flat ground. When living in Scotland, on the banks of the Clyde, a proverbially wet part, I destroyed in one season 14 nests, all of them hanging to branches

of trees. This I attributed to the dampness. On closely watching a wasp's nest, it will be observed that they come out as well as go in loaded, the load out being the earth they remove in making room for their nest and its passages, which load they drop soon after taking wing. *A. M., High Trees, Red Hill.*

The Veitch Memorial.—Though believing firmly that the genius, enterprise, and unconquerable energy of the late Mr. James Veitch will ever remain his most fitting memorial, it is yet natural and proper that his contemporaries should do something worthy of themselves, and, if possible, of him, in testimony of their esteem and regard for his memory. I wish to share, however humbly, in this good work, and to join with you in urging that what is done may be done, not only thoroughly, but promptly and spontaneously. Respect for the dead, and a sensitive regard for the deepest feelings of the living, suggest the propriety of pushing the good work through to completion with the least possible delay. While the matter is undecided, permit me to offer the following suggestions as aids to determining the character and form of the testimonial. It must, as you observe, be agreeable to the family, and it ought to be appropriate to the man and his works. Now, whatever else Mr. James Veitch was, he was pre-eminently a horticulturist. He had a large hand in making horticulture what it is to-day; and that work, steady, progressing, absorbing, largely moulded, may we not almost say, made the man. Would he have cared for a monument? I think not. Mr. Thomson's suggestion of a Veitch Prize or Medal is much more appropriate, and would be serviceable to horticulture for all time coming. If it were practicable, a Veitch Club in London, forming a rendezvous for gardeners in the capital, for social recreation, the reuniting of old ties and the formation of new, a bond of union among gardeners, and a centre of intellectual culture and professional instruction, would be a grand memento of the dead, and might become a tower of strength and a source of blessing to the living. Such an institution is one of the horticultural wants of the age. A Veitch Horticultural Library, on the circulating plan, open to all gardeners on paying a nominal subscription, could be easily established, and would bind up the name of our lamented friend with the sweets of knowledge and the pleasures of our higher literature. There is another thing which ought certainly to be done, that is, to have a portrait painted by a good artist and placed in the council chamber of the Royal Horticultural Society at South Kensington. This, with either the Veitch Library, Club, or special prize projects, would make the name of the deceased still a quickening power in horticulture. A word upon the last point, and I have done. The memorial should be a measure, as far as such things can be made so, of the width and depth of our esteem and regard. All that can should have a hand in it. Money will be needed, but money is not the chief thing. As much love and sympathy can be given with a shilling as with a guinea, and there is no fear of our esteem being measured out by such base standards. By all means let the men with guineas to spare place them at the disposal of the committee; but let not these guineas stay the flow of shillings and pence in the same direction, if these are the promptings of a true regard. Let every gardener but determine to have a hand in the Veitch Memorial, and the work is done, and what we do, let us do quickly. *D. T. Fish.*

The Royal Horticultural Society.—I naturally expected to get some hard hits in answer to what I wrote about the Royal Horticultural Society. It is always so easy to "abuse the opposite counsel," and I was, of course, so executed by "malice, hatred, envy, and all uncharitableness," that to hear only of mortified pride, disappointed ambition, and interested motives, is quite a relief. If my friends had said I wanted to get on to the committee to "rob the till," that would have been something. But I did not expect that any one who took the trouble to read my note could have taken the view that Messrs. Cannell and "Veritas" have done. If I had been excluded from the committee for non-attendance, I should have said nothing, but at the meeting to which I alluded the three names had already been struck out, and not only was mine not among them, but I believe I had attended much oftener than many of the others who were left on. No; my name was struck out by the Council in direct opposition to the rule they profess to be guided by, and so far from attending only when certain flowers were before the committee, I tried to attend whenever I could. Did I say a word against the Floral Committee, as Mr. Cannell seems to infer I did? Where? let me ask. I should be, indeed, ungrateful to do so, for I have ever experienced from its members, with but one or two exceptions, the utmost kindness; and I admire them for their patient endurance of much which nothing but their love of floriculture would lead them to submit to. The fruit is higher up, and until we see an infusion of fresh blood into the Council—not gentlemen of fortune or chief gardeners—I fear much we shall see no improvement. Let Mr. Cannell agitate for this, and he will do good service. I have too great a love for flowers to wish ill to any institution connected with gardening. I have written what I know are the opinions of a large number of persons in every branch of horticulture. *D. Deal.*—As political chiefs have brought peace to their bosoms, and benefits to the State, by inviting into office representative men, and have found in fierce and restless adversaries their wise and steadfast friends, so I believe would the Council of the Royal Horticultural Society do well at this time to recognise a feeling prevalent among its fellows, that the legislature might be enlarged to the advantage of the Society. There are many of us who, highly esteeming the active members of the Council,

would like to see their number increased by admission of practical horticulturists, forming a communicating link between the wealthier and poorer members of our gardeners' guild, between employers and the employed, as well as between the city and country contingents, mixing freely with each other and visitors, hearing and reporting any just criticism or any sagacious hint. We would have the expenses of travelling and attendance paid, and there might be no jealousies, a fresh election at intervals. We want these men to bring us into closer harmony and union, by bridging over the gulf separates at present two sections of the Royal Horticultural Society. Why should not the names of men as Veitch and Turner, Lee, Henderson, Williams, and 50 others in their turn, be found on the Council list? There need be no alterations, but merely additions. We all of us esteem gratefully our officials, and we only ask the Council to increase their popularity by increasing a power, which comes in at this crisis most precious—the power to add to numbers. *S. R. H.*

Potato Grafting.—Mr. Simpson states, at p. 1061, that I do not recognise that the stock has any influence on the scion. I did not assert this, but I assert that the stock has no influence in changing colour from white to red, &c. It is a well-known fact that the Potato is self-supporting, and in this respect not to be distinguished from the stock and scion of the tree. I have any influence on each other, and even if the produce would most likely be deformed and less. In September, 1853, Dr. Maclean, of Chester, whose death has lately been recorded, a young plant of the white Silesian Beet was grafted of Red Beet, and *vice versa*—see *Gardener's Chronicle*, 1855, p. 29. At the time of the experiment the plants were each about as thick as a straw. A junction was effected, and when in 1854 the plants were grafted on Red was taken out of the ground there was seen a slight contraction at the junction, much like that formed by "choke" in a rocket case. Above the line of contraction the stock was absolutely white, below it was absolutely red, not a trace of blending the two colours could be observed. By similar experiments on other vegetables and plants Dr. Maclean had so far assured himself of the perfect independence of scion and stock, and he acquires the belief that neither the colouring matter of the specific characters of the one or the other could be altered by the union. The results of the trial wholly confirmed that view, and demonstrated that the White Beet adhered to the Red Beet by a junction of cellular matter, and also that the Red Beet stock thus held together in the first instance, and afterwards produced its own colouring matter in its own new cells as they formed superaciously, the red adhering to the white cells while in the nascent state, but retaining each the peculiarity belonging to it, without any interchange of contents through the junction of the cells in contact. This is entirely consistent with all that has been discovered by modern physiology, and who have applied themselves to a study of the principles of the individual cells of which plants consist. In the cells of the Red Beet resides a power of forming colouring matter, and in those of the White Silesian Beet a power of forming yellow, and this peculiarity is not altered by the one growing into the other; red-forming cells produce their like, and yellow-forming cells produce their like, and the limit between the scion and its stock is unmistakably traceable, and notwithstanding the combination of the two sorts in one, each preserves that which is natural to it. What is true of the Beet is quite true of other plants, and, as I have stated, I am not able to comprehend the change of colour that has been stated to have been effected through grafting. Nothing can possibly be gained by grafting Artichokes into Potatoes, unless it is to have both. That Artichokes grafted into Potatoes will, I have no doubt, but I am not prepared to acknowledge that they will cross; but "nothing venture, nothing win," seems to be Mr. Simpson's motto, and I would advise him to follow, as he is very intelligent and persevering. He, however, says that after years' trial he cannot truthfully state that he effected the slightest improvement by the practice; on the contrary, the produce has been invariably been most ugly. This one point he has not to me, which is one of the points in my communication, my statement being, "Potato grafting, I fear, will be worth the trouble and time bestowed upon it only in experience with regard to procuring new varieties." I decidedly against the practice. I trust we shall satisfactorily settle this question ere we see the *Osberton Hall, Worksop.*—Since writing the above communication on the 11th inst., I see your correspondent, Mr. Fenn, has replied to my letter, and concludes his remarks by stating that he cannot quite understand the two last paragraphs of my former letter, therefore I will quote a portion of my remarks again, and endeavor to be more explicit. "That Potatoes grow worth grafting sets I fully acknowledge, but the change from white to kidneys, and *vice versa*, and from modern white, I am at present not able to comprehend. I quite understand that a red Potato grafted into a white one will produce red Potatoes, and a white grafted into a red will produce white Potatoes, that is, if all the eyes are destroyed (not otherwise), or there will be a mixture of colours—that is to say, both the stock and the scion will produce Potatoes of their respective colours and shapes." Grafting, as stated in the above communication, will not alter the colour, and I do not see the possibility of its altering the shape; indeed, to produce true hybrids by grafting appears to me to be a very able, and I believe Mr. Fenn's success in obtaining two new varieties may be accounted for in some way than by grafting, although I am quite convinced

Mr Fenn believes they were obtained by that process, and he certainly ought to know more about them than any other person. We all know that in digging up a crop of Potatoes the tubers are found to vary. The other day I was at Handsworth Nursery, where they were engaged in digging Paterson's Zebra Potato. Here were to be seen purple, white, striped and mottled, all from one variety. Thus we see the peculiarities of the class, and also the difficulties of coming to a just conclusion with regard to the grafting process, which may prove in the end a delusion, although it may appear at the time quite conclusive. In the second paragraph alluded to, I stated "it may not be generally known that Potatoes will even grow without eyes—one square inch of the substance of the inside of a tuber will grow." This appears incredible to Mr. Fenn, who states it is something beyond his experience, the mere mention of which will send him on another track. I hope he will give us the benefit, should any occur, in his next experiments. I again assert such will grow, make naulm, and form tubers, without a fang or symptom of an eye in its composition. The young tubers will vary in shape and be small. I do not assert every piece will grow; probably some may rot, while others will grow. Even a much smaller piece than what I have stated will grow. Indeed I assert the Potato is vital to the core, in this lies the difficulty of experimental grafting, for if all the eyes were removed from the stock it would not prevent it (at times) from throwing up haulm and forming tubers. I state "at times," because every tuber may not start into growth. *Edward Bennett, Osherton Hall, Worksop.*

Is not the tuber-grafting of Potatoes sheer humbug? and are not the so-called results mere accidents? I knew a gardener who took the 1st prize for round and kidney Potatoes for years from the self-same stock of Ashleaf Kidneys. *Paddy.*—[From an article in a *Forbes* paper we learn that Dr Innes, of that town, has been experimenting on the subject of Potato grafting. "The Doctor, last spring, took black kidney Potatoes and cut out the eyes by a wedge-like notch. Into the cavity thus made, in one set, he inserted the eye of a Regent Potato, and into the cavity of another the eye of a Fortyfold. The sets, it will be observed, were black kidneys, and the inserted eyes were (white) Regents and Fortyfolds. The product is a mongrel group of large, pink, round-shaped Potatoes, intermixed with white, round, and pink and black kidney-shaped ones. It is clear that the graft between the black kidney and the white round Regents and Fortyfolds produced a hybrid of a round kind modified in colour. Potatoes, white and round, were also got from the same stem, as well as pink and black kidneys."]

Radiation.—Here is a question for the wise men of the *Gardeners' Chronicle*—What is the difference in instance, the amount of heat lost by radiation through glass of different thickness or weight per foot, such as 16-oz., 26-oz., &c. *Enquirer.*

Boilers.—I would like to know how much good is to result from the projected trial of boilers. It seems to me almost an infatuation which the trade in hot-house boilers is drifting to, and only to be productive of uncertain good to the buying community. Upon the principle of "little good little harm," it may be tolerated; but what about the economy of the boiler itself, even supposing makers and patent holders were to have trials to their hearts' satisfaction? Heating is a simple question of calculation, and gives forth no uncertain sound to those who care to investigate properly, and take action accordingly. It is not a matter of heavy or lighter draught, requiring the dynamometer to test, as in the various implements used in field operations, or in having furrows set up with the nicest cut and the greatest mathematical precision; it is simply a question of what kind of fuel is to be consumed, and what amount of work is expected to be done with the selected article. There is an idea abroad, that the more turnings and windings you have in a boiler, so that the flame can play hide-and-seek in various storeys of metal, the more powerful it is, and the more eligible for general work. False impression indeed! The supporters of this theory forget that a portion of their vaunted boiler is nothing else than a smoke flue, which the tongues of flame possibly never touch, and the coating of soot that gathers on the metal is about the best non-conductor known. One might ply the office of chimney sweep every day to a boiler of this description, and the amount of heat utilised in the passage through it is inappreciable. What should be studied, therefore, is how shall we present a surface that radiant heat shall most efficiently impinge upon? If it be in a locality where dress or small coal is cheap, I should say that some form or another of the saddle is decidedly the most economical, as it is most durable. If it be wanted transversely to catch the action of the flame in its passage over the boiler sides, so much the better. The best coats that have ever been quarried will not give out beyond a limited number of yards of flame, and therefore some limit to multitudinous passages is desirable, for it is perfectly clear that what the smoke disperses in heat it nullifies with its gathering sooty covering; and for people to propound that they can utilise all the caloric in their favourite boilers, and ultimately send forth the smoke cool from the top of the chimney, is simply an impossibility. I opine, that in all the modern and ancient systems the water in the bothy kettle must yet be boiled at the top of the respective chimneys, serving to show that under the best system so much heat is bound to be lost. Given a cold frosty night and several thousand feet of piping to heat properly, and I would like to see the nurseryman or gardener, or anybody else, who would tell his stoker to be cautious, in order to economise the heat in the desired quarter, and if you fire vigorously a certain quantity will vault up the chimney and disperse in pe; indeed, smoke. If coke be about as cheap as coal, as it generally is at certain distances outside of the coal

country, I have no objection to some or other of the forms of tubular boilers, with their network of piping, which carry heat more generally and more expeditiously than any of the forms of saddle; but to attempt to use common coal with such a boiler, would be futile and uneconomical. But withal, I have a decided partiality for the horizontal form of boiler, which lies better to the fire. If proof were wanted, from a scientific point of view, we need only point to the Cornish boiler, as used and recommended by the foremost engineers of the age as the one best suited for purpose and economy, and bear in mind that the Cornish boiler presents the saddle outline to the fire when the bars are placed in position. In point of durability, even makers themselves are bound to admit that a properly made saddle has no equal. We have four of them occasionally at work at Meadow Bank, two kept as emergency boilers, which enables one to sleep quietly at all times. In times of a spurt—as witness 1860-61, the thermometer being 13° below zero—we can keep out the enemy without hard working, which is more due, however, to the arrangement and sufficiency of the pipes placed, than probably to boiler power; but we have both as vouchers. I was going to say, however, that I have wrought one of these cast-iron saddles 15 years, and it is as efficient now as ever it was, and likely from the uniformity of the play of the fire, to last quite as many years more. I would not vouch so much for the best made of the tubulars, from the different junctions of metal, and from the partial action of the fire. The proper arrangement of the pipes, so as to present a minimum friction to the circulation of the water, is of first import, meriting far more attention than it receives. Let the water have an unimpeded passage, and it will flow upwards, and onwards, and backwards, in such a style, that it must be a very badly set boiler, and a very bad boiler to boot, that will not do its duty. I like, amongst the many forms I have seen, that of the "concentric saddle boiler," advertised in your columns, as likely to be powerful, economical, and good. If it had a transverse wing at the back end of the fire, it would, in my opinion, be about the best form practicable for utilising heat, and sending the water forth in rapid and constant circulation. *James Anderson* [Such a boiler has lately been fixed to heat the herbarium and library at Kew. We may hereafter be able to report on its performance. Eds.]

The Royal Vineyard and other Vines.—My experience with this Grape is that it does best grafted or inarched on some other variety; I have not yet seen it do well on its own roots. It is planted in a house at this place, on its own roots, with Lady Downe's, Trentham Black, and Black Hamburgh. Compared with the others it is the weakest grower; the berries are not large, and they are unequal on the bunches, which are also small; none of them ever weighed over 1 lb, while Black Hamburghs, in the same house, have had bunches weighing over 6 lb, Trentham Black and Lady Downe's from 2 to 3 lb. In other gardens where I have seen Royal Vineyard growing on its own roots the results have been similar. At one place celebrated for good gardening the gardener told me he did not thin-out the berries at all, and yet the Vine was making strong shoots. I fancy the bunches which were exhibited of it before the Vine was sent out were from inarched or grafted Vines. I have seen it growing in a Muscat-house, inarched on another variety, with bunches of from 3 to 4 lb, the berries large and equal in size, but the gardener told me it did not keep well; it hangs late here, up to February, with care. Is it possible that grafting, so as to increase the size of bunch and berry, deteriorates the quality of the fruit? Be that as it may, in the case of the variety in question the results which have been arrived at by grafting one variety of Grape Vine upon another are most remarkable. Graftings such weak-growing and difficult-to-manage varieties as Grizzly Frontignan and Chasselas Musqué on the Black Hamburgh is said to improve those sorts, and yet I have seen both sorts grafted on the Hamburgh without any improvement. On the other hand, a house of Black Hamburghs with which I am acquainted, in a retrograding condition, was resuscitated by being grafted with Canon Hall Muscat, and produces far superior Grapes as Muscats, to the Hamburghs. Again, the Muscat Hamburgh, on its own roots, is seldom seen with well-set bunches, but grafted on the Hamburgh the bunches are large, and well set with berries equal in size. That new variety, Mrs. Pince's Black Muscat, I have not yet found to be improved by grafting. It has succeeded best on its own roots, both in regard to colour and flavour, grafted on Lady Downe's the berries are larger, but colour and flavour are very much deficient. Royal Ascutt is a very inferior Grape grafted on the Black Hamburgh, the bunches are meagre-sized, the flavour and texture of the flesh not unlike that of Gros Guillaume. They both fruited in the same house, and some persons thought the Gros Guillaume the better flavoured of the two. Muscat Champion and Buckland Sweetwater are improved by being grafted on Black Hamburgh. The first named is a new Grape, with a decided Muscat flavour, and that is more than I can say of Mrs. Pince's as yet. It is always deficient in colour, and is not a free bearing variety, but is one of the finest flavoured of Grapes, new or old. Buckland Sweetwater is perhaps not improved in flavour by being grafted, but the berries are firmer in the flesh, and consequently keep better. Much more may be written on this subject, but these few notes may be useful to some of your readers, and may perhaps be the means of inducing others who have had more experience than I have, to state their views on the subject. While writing about Grapes, I observe the account of the awards at the meeting of the Fruit Committee of October 5. In class 2 there was no competition, and in the others but little. If, instead of the best three bunches of Chasselas Musqué, it had been for three bunches of white Grapes, any variety

except White Muscat of Alexandria, there might have been a good competition. There might have been a class of the same sort among the black Grapes—three bunches of any variety of black Grapes exclusive of Black Hamburgh. I make these suggestions because I think there would be a better competition, and a more interesting one. *J. Douglas Esq., Loxford Hall, Ipsford.*

Orchid Culture.—Mr Gammie's letter at p 991 of your *Journal* appeared while I was having a holiday in Switzerland, or I should have noticed it and thanked him for his observations, before Mr. Anderson seemed to think I had no proper right to question the treatment he advised for *Dendrobium Falconeri*, but that I have been the means of drawing out such a letter from Mr. Gammie—which, I hope, is only one of a series—abundantly satisfies me of the advantage of ventilating in your pages questions upon which information is wanted. At that time I had just purchased a plant of *Falconeri*; previously I had only had three very small plants; but since then I have also bought some of the newly-imported pieces, and I now feel, from closely observing them all, more at my ease in the matter. I shall not try the cool treatment to my Orchids yet, and particularly to this one; for I find what upon a Vine would be called air-roots upon most of these newly imported pieces. This tendency in *Dendrobiums* I hold to be the best proof that they are doing well,—during their season of growth, I mean, though they should not lose them when resting. I want Mr. Gammie, if he will be so kind, to tell me if he has seen *Falconeri* growing what is called *in situ*; and can he confirm my opinion, from its drooping habit, and tendency to root and propagate from its bulbs, if it is, so to speak, the Ivy among Orchids? Mr. Gammie is fortunate in his position among the Himalayas, and we must picture him rich indeed in Orchids; but I am yet of the opinion, judging from the imported pieces, that our well-grown plants far surpass anything that is purely wild there; but if he has any under his own cultivation and care, I should like to know the size of the bulbs. Mr. Anderson took offence at this question—why, I do not know, but I trust Mr. Gammie will not, for what other test have we? Do we not read that So-and-so showed bunches of Grapes, or a Pine, of such-and-such a weight? or Mr. So-and-so sent *Palargoniums* a mass of bloom, the plants being of such a diameter? the canes in such a vinery were a model of growth, being the extraordinary thickness of blank, though they have only been planted two years, &c. &c. Therefore, I entirely disclaim want of courtesy in such questions. *Dendrobiums* are, I think, the most valuable class of Orchids, and the most easily grown and propagated; with this valuable merit, that you can, I believe, force or retard them all, and the flowers of nearly all stand, when cut, to perfection. I sent last winter to a lady five flowers of *D. heterocarpum* and four of *D. moniliforme*, and she told me they served her three successive nights. She added no forcing, and had the pleasure of being envied by all the ladies who saw them. I have a *D. nobile* now in flower, and shall try to keep going as nearly as I can till next June; and live in hope that when I have more plants of what I should call the noble section, that we may have some of them every week the year through. I will, therefore, put it to all gardeners who have to supply their employers with flowers, are they not worthy of more attention than any other class of plants they can grow? I have read Mr. Gammie's advice as to temperature and light, and quite agree with him, as also upon watering. Nature has provided two distinct seasons, the growing season and the resting season, and we must provide two distinct treatments. As to atmospheric moisture, and the mode of feeding and stimulating them during growth by that means, I have already said what I can. During the resting season, the temperature being lower, makes the air dryer, and diminishing the watering does all the rest. As regards shading, my gardener says that our nobles flowered much better when they were not shaded, and, he thinks, made better bulbs, and he is anxious to try all strong-growing sorts so again; we are therefore going to feel our way in this matter next summer. The shading we have used has been the thinnest tiffany, which lets the house feel the sun, though it prevents burning. I find I have omitted to ask, Is not *Falconeri* one of the deciduous class? We grow all *Dendrobiums* we have room for in baskets suspended from the roof; they are "potted," if I may use the term, in crocks and Moss; but the whole class prefer to have their roots outside, and as soon as time becomes an object, the syringe is found to be the best watering-pot. *G. H.*

A Monster Potato.—I believe the monster Potato (p 1088) that Mr. Grieve saw at Daneker, in Fife-shire, is a variety which I have grown for the last nine or ten years. I had it under the name of Mallet's Manifold, and it came, I believe, originally from Ireland. It is an enormously strong grower, the stems as thick as a good sized walking-stick, and nearly as hard in texture. The tubers are kidney-shaped, and some merely oblong, of a large size, with deep eyes, and the skin of a leathery deep red, almost like red Beet when rubbed off. In the years when the Potato disease was very virulent it never attacked this variety, either in the stems or tubers; and when all other varieties were leafless, this kept quite green till the frosts blackened it. I grow them in rows, 4 feet wide, from their length of stem, and I have no doubt if grown in rich soil, and trained upwards, they would form monster specimens as at Daneker. It is only a field or cattle Potato, but in June or July it is not bad for eating when boiled or roasted. A few years ago I gave some to a friend to set, and he took the 1st prize for kidney field Potatoes with them, at the Birmingham great root show that year, exhibiting them, however, under a new name, namely, *Tillery's Goldfinders*. *William Tillery.*

Sambucus racemosa (pp. 1016, 1035) —By way of encouraging your correspondent "E. S. D." to renew

at length supplant the original form; so that we now find in *Geonoma* an effete ovary in the male flowers, a castrated stamen-tube in the female flowers—neither of the two of any actual use, but remnants of a structure which combined active organs of both sexes in the same flower. Some eastern Palms, especially among the *Spathelliflorae*, are said to have at this day truly hermaphrodite flowers. Among American Palms one finds in some species an occasional bi-sexual flower with all the organs perfect, but it is a case of extreme rarity. Even in Mauritia, where stamens are certainly present in the female flower, they have always seemed to me emasculated. *Journal of the Linnean Society.*

Cocoa-nut.—The cultivation of the Cocoa-nut is limited to the regions bordering the Atlantic and Pacific Oceans. As we ascend the Amazon it gradually becomes sterile. At Manaos, 800 miles up, the fruits appear fully formed externally, but are invariably empty. At San Carlos del Rio Negro, almost exactly midway between the two oceans, there were, in 1854, two well grown Coco Palms which had never even flowered. *Journal of the Linnean Society.*

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

GREENHOUSE or tuberous-rooted *Tropaeolums* will have generally commenced growing freely by this time, and will therefore need particular attention. Where any have not yet received the necessary shift into the blooming pots, they should be attended to forthwith. For the rest, as soon as the young rambling shoots have become sufficiently long to require support, this must be afforded them. The full-sized trellis or other support intended to be covered should be placed in the pots at once, and a judicious and artistic system of training be entered upon. The first or primary shoots generally grow pretty freely before there are any symptoms of lateral shoots being likely to follow. If the former are trained in the best manner possible across the whole support, it must follow that the minor shoots which will follow will better aid in filling in all immediate spaces. Where this is not studied, the whole growth will quickly establish itself at the apex, leaving the lower space more or less unoccupied. They like abundance of fresh air and light, and are not fond of too damp an atmosphere. *Blandfordias* may now be shifted into fresh soil. Equal parts of loam, sand, and peat, will suit them well, with a good sprinkling of silver sand. Great care should be taken not to make them too wet at the root during the incoming winter months. They will then make fresh roots early in the spring, and push up robust flower spikes, which are very telling in comparison with their narrow grass-like foliage. Afford the early or winter blooming strain of *Pelargoniums*, such as *Rubens*, *Gauntlet*, &c., a nice warm, light, and airy situation, with a moderate supply of root moisture, and give them an occasional damping overhead. These, as I have before intimated, should now be shifted finally into their blooming pots, which it is essential should be small in size compared with the extent of the plants themselves. Those plants which are now about to show flower, such as the many beautiful varieties of *Epiphyllum truncatum*, *Gesnera Cooperi*—an old but very beautiful species, various *Orchids*, such as certain *Cattleyas* and *Dendrobiums*, and the beautiful and free-flowering *Calanthe vestita*, with its three or more varieties, should be all brought to the fore, and receive that amount of attention which they deserve. In instances where it is not advisable to afford water to the roots of any, no little aid may be afforded them by simply sponging over the leaves with fresh tepid water, as by simply increasing the surface-absorbing capacity, increased aid is insured, to compensate for the strain placed upon plants in the act of blooming.

FORCING HOUSES.

I can add little this week to my reiterated advice regarding *Vinerias*, which at this season require but little direct attention, though thoughtfulness should always be observed until the last bunch of Grapes has been cut. The chief point to be attended to in reference to late Grapes arises from the necessity of keeping them back as much as possible as soon as they are sufficiently ripened. The weather we have experienced has assisted us in that respect, when a moderate dry atmosphere prevailed. The *Pines* in various stages of growth should now, as I have more than once suggested, be all nicely housed for the early winter campaign. Plants on which are ripe fruits not required for a few days, may be taken, pot and all, into the snugest corner of the latestinery. Here the fruits will keep longer than when severed from the parent plant, and be fresher when required than when hung up under the roof of a fruit room or other similar situation. Those which are swelling freely in a primary stage, immediately succeeding the blooming period, may be excited advantageously by affording a stimulant to the roots in the form of manure water. Keep up a moderate amount of atmospheric moisture constantly, especially in fine bright weather. This should at all times be diminished or increased in conjunction with the external atmosphere. Considering that young *Cucumber plants* have now made a fair start in those houses intended to furnish the mid-winter supply, and that the roots of such plants have begun to extend and ramify throughout the soil, it will be advisable to choose a bright warm sunny day upon which to give them a slight root-watering. First afford an increase of bottom-heat, and having soft tepid water to hand, when it may be freely applied. As they continue to grow, do not omit to pinch out all such tendrils as may form as soon as they appear, as they rob the plants of what they require for ulterior uses. A successional sowing of *French Beans* (dwarf) should also be made, to

succeed those already placed in the fruiting pots. Prepare the necessary fermenting materials for the early beds of the necessary *Asparagus*, and if not previously attended to, see that the surface growth has been removed from such as is intended to be forced, that at least a little rest may be afforded it.

HARDY FRUIT GARDEN.

Persist in brushing the leaves off wall-fruit trees, for the sooner those upon *Peaches* and *Neectarines* are removed the better. These cling very tenaciously to the parent stems this season, and should a sharp frost occur before the wood has had an opportunity of becoming somewhat hardened by exposure to the air, after the leaves have fallen, no little risk of injury will be encountered. The sooner we can get them off without undue violence the better. Give to the *Fruit Room* abundance of fresh air until after the primary sweating of the fruit is completed.

HARDY FLOWER GARDEN.

Those who value present appearances more than the absolute security of many scarce plants, or their gardener's peace of mind, and have still all their bedding stuff fully exposed and not potted up, should at least have all the more important things taken up, and laid in a closed shed, or so, until it is possible to finish all, immediately succeeding the first frost we may experience; for the season wears, and it may not be wise to run any risk beyond what is unavoidable. Plants taken up late should have many of the grosser, more sappy leaves removed; and should dull, November-like fogs prevail, a little fire should be kept slightly going in connection with all structures containing such plants. Give a surface dressing of finely sifted leaf mould or other rich material to beds containing old plants of *Polyanthuses*, and to all plantations of *Pansies*, double *Violets*, &c. This will not only tend to ward off frosts, but will materially assist the roots.

KITCHEN GARDEN.

The old, and now decaying, stems of *Asparagus* should be at once cut off at the ground line and cleared away, and along with them any weeds which may be on the ground. At the earliest opportunity afterwards 2 or 3 inches of well decomposed manure should be spread all over the beds and alleys, if any. It is customary to advise digging the beds over; this I object to, as the *Asparagus* is a surface-rooting plant. The abundant supply of manure we so constantly afford will keep the ground well open, however tenacious the soil may be originally; besides, the roots delight in firmness. This more immediately in relation to large flat beds, not constructed with mid-alleys. The latter will require some of the soil out of the alleys to be placed upon them, in thickness according to the shallowness of the soil, or upon or over the surface of the crowns, for, under any circumstances, the frost must be kept from these latter. Where beds are formed separately, as intimated, a neat workman-like finish should be given to the whole by running a line along the edges, and packing them up straight and neatly therewith. Remove all the lower leaves which part readily from *Brussels Sprouts*, and clear them off. This will admit the air more freely into and around them, and, irrespective of a neat and tidy appearance, will tend to harden them more fully, preparatory to the severe period we may anticipate. *W. E.*

TOWN GARDENING.

Chrysanthemums, both large-flowered and *Pompons*, are fast coming into flower. They should be housed, and allowed all the air possible consistent with avoidance of wind, rain, and frost. They should be watered as they may require, with soft water. Waterings of liquid manure should now be discontinued altogether. Where there is not the convenience of a house, a canvas tent will do equally well. This should be so made that the sides can be drawn up during fine weather. Look to the *Hyacinths* that were put aside in glasses in the dark last month. Some of the earliest may be brought to the light; if any of the roots are diseased at the base, and not started, take them out, well wipe them, and replace them in soft water with a small lump of charcoal. By this means I have seen roots recover and flower well, but late. More bulbs should be put in pots and glasses as directed last month, to follow in succession. The beds and borders intended for bulbs should be at once forked over and levelled, and the roots planted. *Tulips* should now be planted about 6 inches apart, and the same distance from row to row diagonally, and about 3 inches deep from the upper side of the root. Each hole should be made with a trowel, and a little silver sand put in; the bulb should be placed in the hole and covered with a little more sand, the earth should be then levelled over and gently patted down with the spade. The following varieties are very distinct, and flower well in town:—Double *Tournesol*, yellow and red; double *Yellow Rose*, and double *Rex Rubrorum*, scarlet; single *Prince*, white; *Hyacinths* should now be planted in the same manner as the *Tulips*, and when the planting is complete, the beds should be hooped over so as to protect them from excessive rains and severe frost. The following varieties are all single, but they are the choicest, and the best adapted for bedding:—*Amy*, bright crimson; *Robert Steiger*, crimson; *Grand Vaicqueur*, pure white; *Voltaire*, waxy white; *Charles Dickens*, pale blue; *William I.*, purple. The following varieties of *Crocus* are all fine flowers and free bloomers, and make a nice edging round the margins of the beds, planted 2 inches deep, and 2 inches apart, or in patches of five, 2 inches apart, in separate colours:—*Queen Victoria*, pure white; *Sir Walter Scott*, lilac purple; *David Rizzio*, deep purple; *Ne Plus Ultra*, light blue, tipped with white; *Proserpine*, fine lilac; and *Large Yellow*, *J. D.*

STATE OF THE WEATHER AT CHISWICK, NEAR LONDON.

For the Week ending Oct. 20, 1859, as observed at the Horticultural Gardens, Chiswick.

October	Moon & Age	BAROMETER.		TEMPERATURE				
		Max	Min	Of the Air.		Of the Earth.	1 foot 2 feet deep.	
Thurs. 14	9	30.056	30.005	57	43	50.0	55	54
Friday 15	10	29.783	29.518	59	50	54.5	53	51
Satur. 16	11	29.831	29.248	68	39	44.0	55	51
Sunday 17	12	29.821	29.641	60	30	41.0	53	42
Mon. 18	13	29.498	29.289	49	32	39.5	50	52
Tuesd. 19	14	29.862	29.482	47	26	36.5	50	51
Wed. 20	0	30.121	30.028	51	36	43.5	47	50
Average		29.785	29.611	53.0	35.0	44.0	52.1	51.5

Oct. 14—Very fine, clear, sun, dense overcast.
 15—Dense, overcast, overcast and cold, cloudy.
 16—Bright rain, showery, clear and very boisterous.
 17—Very fine, clear and fine, overcast.
 18—Heavy rain, heavy showers, clear and fine.
 19—Overcast, dense overcast, clear and fine.
 20—Fine and frosty, very fine, overcast and cold.
 Mean temperature of the week, 59.16 deg below the zero.

STATE OF THE WEATHER AT CHISWICK.

During the last 43 years, for the ensuing Week, ending Oct. 20, 1859.

October	Average Highest Temp.	Average Lowest Temp.	Mean Temp.	No of Years in which it Rained.	Greatest Quantity of Rain.	Prevailing Wind.
Sunday	58.3	30.6	47.9	20	0.89 [in.]	1
Mon	55.9	33.5	47.2	21	0.80	1
Tues.	55.6	38.4	46.1	18	0.72	1
Wed.	55.1	38.4	46.7	27	0.82	1
Thurs.	54.5	35.9	45.1	27	1.03	1
Friday	54.0	35.7	44.8	20	0.63	1
Satur.	51.9	36.3	46.6	22	0.68	1

The highest temperature during the above period occurred on the 25th, 1837, and 30th, 1833, 26th, 1853—therm. 67 deg., and the lowest on the 29th, 1836—therm. 22 deg.

Notices to Correspondents.

CONSERVATORY PLANTS. P. M. The plants in a conservatory with the glass left "muffled" through the winter, we presume, constantly covered up, would be in a sorry condition by the return of spring. As a rule, the exceptions are very limited, they require all that our climate affords at that season. In any severe weather covering might be retained for a few days without damage, but the sooner it is removed the better. The ingress of frost must be prevented by artificial means.

DISEASED CUCUMBERS. J. L. C. Your Cucumbers are diseased with that disease which is peculiar to them, and which is inexplicable in its causes and remedies as that of the We think chills, cold water at the root, or unwarmed temperature may have something to do with its cure, have, however, never practically had to contend against it, although frequently it has come under our observation.

EXAMINATIONS. G. asks if an examination will be made of it were self examination and the examiner were present of common sense.

FERNS. *Constant Reader.* *Lomaria gibbata* is described by Martens who have seen it in its native habitat to be an annual fern species, with a stem from 2 to 3 feet high. It is, therefore, quite permissible to class it as a Tree fern.

FOREIGN FRUIT. R. J. Yours is a knotty point, the determination of which will turn on the wording of the Act. Taking the broad view of the question, fruit from the Channel Islands ought not to be shown at an English exhibition as English produce, or put on equal terms with the grown in the climate of England. The reason is obvious—the more favored climate of the islands in question. As yet, the Channel Islands are not included in a English county of Hauts, it is difficult to find any legal ground of exclusion.

FUNGUS. G. R. *Reverend.* Your large Fungus is *Agaricus pustulosus*, an uncommon species, the smaller one *Agaricus sonatus*; both are edible, but the latter is not held in esteem, and but little is known of the former from its comparative rarity neither are in any way related to the *Cantharellus*—*Mushrooms*, *Gloster*. Your Fungus is the *Cantharellus*, *Fairy ring*, *Champignon*, &c. Cook it as you do the *Mushroom*—G. M. The Pear leaf Fungus, *Restelia cancellata*, has been reported at the Horticultural Gardens.

HEATING CONSERVATORY. A. Rost. Trotman's hot-water stove proves, we believe, very efficient for heating conservatories such as yours. We cannot recommend ordinary stoves for the purpose.

NAMES OF FRUITS. T. S. M. Pears: 1, *Fandante d'Inde*; 2, *Passe O'Imar*; 3, *Barré Bosc*;—G. N. Pears: 1, *Bosc*; 2, *Comte de Luny*; 3, *Cham Montel*; 4, *Figuette*; 5, *Naples*; 6, *Verulam*; 7, *Cham Montel*; 8, *rotten*; 9, *Barré d'Amans*; 11, *Eastern Pear*; 13, *Doyenne gris*, others unknown.—*Rev. W. M.* *Apple*: 1, *Christien*; 2, *Louise Bonne of Jersey*; 3, *Flemish*; 4, unknown; 5, *Glen Moreau*; 6, *Barré Del*; 7, *Dict. 10*, *Shroton Court*; 11, *Vicar of Winkfield*; 12, *Morcan*; 13, *Williams Bon Christien*, others unknown.

NAMES OF PLANTS. *Strelitzia*: 1, *Pyris pinnatifida*; 2, *Strelitzia pinnata*; 3, *Berberis* (*Mahonia Aquifolium*);—A. D. R. *Lupinus arboreus*, a very old kind, not seen for 20 years, and not worth reintroducing.—*R. G. L.* *Calceolaria parviflora*, introduced from Mexico some years ago, and now spreading widely in market gardens in the London.

NOT: W. J. Epps. *Corylus Colurna*, the Constantinople Walnut, for Hot Water Pipes. A. D. Use the black coats of manganese.

SUMMER VINE BODDING: Will "J. S." oblige us with his address, and further state where and when he commenced summer Vine budding for seven years?

THE EARLY SANDRINGHAM KIDNEY POTATO: D. W. asks if the Potato advertised under this name was raised at Sandringham, and whether it is really good for anything. It is very satisfactory to our correspondent and others that this Potato may be tempted to purchase the vegetable raised at Sandringham, believing that it would not detract its being introduced into the public unless it were really good. We learn from Carmichael that the Potato was not raised at Sandringham, and that he did not know anything about it until he saw it advertised.

TEMPERATURE. *Essex Gardener* will find the culture of plants fully explained in our last year's volume, p. 100. The soil should be a very rich loam.

T. P. T. H. C. This tree ripens its seed occasionally in England, and generally in France. It is, however, that these seeds do not germinate so freely as those imported from America.

ERRATA.—In Mr. Bennett's remarks on the ribbon border, Rufford, at p. 1088 col. 4, read 12 yards instead of 10. P. 1089, in Mr. Sage's letter, for 15 feet read 160 feet.

COMMUNICATIONS RECEIVED.—Vilmorin & Co.—J. J.—W. C. (thanks).—T. J.—D. M.—J. Y.—W. W.—H. E.—J. M.—M. A.—A. S.—F. W. B.

THE LANDS IMPROVEMENT COMPANY.
(Incorporated by Special Acts of Parliament.)
Directors
Messrs. Chapman, Esq., Whitehall Place, S.W.
Messrs. Farnham, Esq., Messrs. Herries, Farquhar & Co., 16, St. James Street, S.W.
Messrs. M.P., Eaton Square, S.W., and Galloway House, Whitehall Place, S.W.
Messrs. King, Esq., 1, King's Bench Walk, Temple, E.C.
Messrs. Roper, Esq. (Managing Director), 2, Princes Terrace, Hyde Park, S.W.
Messrs. R.H. Smeiser, Esq., Q.C., 8, Park Street, Westminster, S.W.
Messrs. West, Esq., & C., M.P., 1, King's Bench Walk, Temple, E.C.
Messrs. W. Williams Wynne, Esq., M.P. (Chairman), 2, Lower Berkeley Street, Portman Square, W., and Coedy Maen, Berkeleyside, W.
The Company advance money, unlimited in amount, for all purposes of Agricultural Improvement, including the erection of Cottages and Farm Buildings, to the Owners of settled and other lands, and to the Clergy in respect of their glebe lands. The same money and expenses are liquidated by a rent-charge on the land, reducing principal and interest, over 25 years. The lowest rates of 4% to 5% is required.
Forms and further information apply to GRANVILLE H. DEER, Esq., Managing Director, No. 1, Great George Street, Westminister, S.W.

THE GENERAL LAND DRAINAGE and IMPROVEMENT COMPANY.
Directors
Messrs. Chapman, Esq., F.R.S. The Right Hon. Viscount Combermere.
Messrs. Thomas Clark, Esq. Edward John Hutchings, Esq.
Messrs. C. Colclough, Esq. William Tate, Esq., M.P.
Messrs. W. Carr, Esq.
J. LALY LENTON, Principal Engineer.
The Company advance money, unlimited in amount, for all purposes of Agricultural Improvement, including the erection of Cottages and Farm Buildings, to the Owners of settled and other lands, and to the Clergy in respect of their glebe lands. The same money and expenses are liquidated by a rent-charge on the land, reducing principal and interest, over 25 years. The lowest rates of 4% to 5% is required.
Forms and further information apply to GRANVILLE H. DEER, Esq., Managing Director, No. 1, Great George Street, Westminister, S.W.

LAYBIRD, CALDECOTT, BAWTREE, DOWLING, and COMPANY (Limited).
CORN, SEED, MANURE, and OILCAKE MERCHANTS.
Address: 19, Seed Market, Milk Lane, E.C.; or Basingstoke.
Copies and prices sent free on application. Prizes Medal, 1851 Wheat, 1852, for "Excellent Seed Corn and Seeds."

CAMPAS GRASS—Extra fine plants, 4 feet high, only one year from roots, and full of roots, will flower abundantly in any soil, and also younger plants in any quantity. Prices according to quantity required.
SUTTON AND SONS, Reading Nurseries.

Look to your Grass Lands.
MES. CARTER AND CO'S RENOVATING MIXTURE of GRASSES and CLOVERS SHOULD NOW BE USED. This Mixture is specially prepared to suit the various soils, and is the most desirable kind to produce a Permanent and first-class quality on old decayed Pastures and other lands that have suffered through the extreme dryness of the past season.
4d per lb., or 5s. per cwt.
MES. CARTER'S "PRIZE MEDAL" PASTURE GRASSES for MIXING NEW MEADOWS, mixed to suit all soils, from 2s. to 4s. per acre. Special low quotations for quantities on application to MES. CARTER AND CO., Seed Farmers, 237 and 238, High Street, London, W.C.

A L L E T T S
HUNTER'S WHITE WHEAT,
ALSO THE
ORIGINAL RED.

Including bags, Five Guineas per Quarter, by the Quarter or by the bushel, One Guinea per Bushel for less than a Half-quarter, and at the Brighton Station, in bags sewed up, sealed, and containing printed directions for planting, upon receipt of Cheque or Office Order, without which it will not be sent to unknown correspondents. Less than a bushel not supplied.
Apply to Captain HALLETT, F.L.S., The Manor House, Brighton.

LAWES' WHEAT MANURE for AUTUMN SOWING, now ready for delivery.
Other Manures and Cakes as per Price List, supplied on the same terms. Apply for prices, &c. to JOHN BENNETT LAWES, Mark Lane, London, E.C.; Dublin, and Shrewsbury.

MES. CARTER AND CO'S BIPHOSPHATED PERUVIAN GUANO (Registered Trade Mark, Flying Albatross), is now the best Artificial Manure yet produced. Its base is pure Peruvian Guano, it contains 21 per cent of Soluble Phosphates, and 10 per cent of Ammonia with Salts of Potash. See the analysis of the same, by Professor Way Mr. Weston, &c. in the 2cwt. bags, each of which is sealed with the Company's Trade Mark. The analysis of the same is in the hands of the Secretary, Messrs. K. & Co., 102, Whitehall Street, London, E.C.

Autumn Sowing.
DAMSS NIRO-PHOSPHATE or BLOOD MANURE for WHEAT—This Manure, specially prepared for autumn sowing, is rich in Ammonia, Phosphates, and other elements necessary for the healthy growth of Grain Crops. It is a guarantee of the value of Blood as an ingredient in the manure, and the rate of from 3 to 4 cwt. per acre, either drilled or sown broadcast, should be well harrowed in. The Patent Nitro Phosphate or Tenant Farmers' Manure, which has been for years under management of the best cultivators of the country, consequently the best guarantee for the genuineness and efficacy of the Manure, will be forwarded upon application to the Secretary, Messrs. K. & Co., 102, Whitehall Street, London, E.C.; Western Branch, County Chambers, Exeter; Irish Branch, 102, Whitehall Street, Dublin.

THE LONDON MANURE COMPANY
(ESTABLISHED 1840)
Have now ready for delivery, in fine condition,
CORN MANURE for sowing, in fine condition,
SUPERPHOSPHATES of LIME
PREPARED GUANO
MANGEL and POTATO MANURES.
A 60 Genuine PERUVIAN GUANO, and NITRATE of SODA
EX-LOCK Warehouse, SULPHATE of AMMONIA, FISHERY SALT, &c.
E. P. ROSE, Secretary.
Offices, 110, Fenchurch Street, E.C.

"Every Cottage should be provided with a Water Tank." *Disraeli.*
Iron Cisterns.
F. BRABY AND CO. having laid down more extensive and improved Machinery on their Deptford premises (Isa Wharf), are prepared to supply WROUGHT-IRON TANKS, GALVANISED or PAINTED, of superior quality, at reduced prices, and at very short notice.

LISTS ON APPLICATION.
An Illustrated Price List of Galvanised Iron, and other of BRABY'S special Manufactures, sent on application to F. BRABY AND CO., Limited, Ferry Works, Easton Road, London, E., or through any respectable Iron Merchants.
N.B. Open Tanks of different sizes packed one in another to save carriage.

Cottam's Iron Hurdles, Fencing, and Gates.
COTTAM'S HURDLES are made in the best manner, of superior Wrought Iron, by an improved method. Illustrated Price Lists on application to COTTAM AND CO., Iron Works, 2, Winslow Street, Oxford Street, London, W.

COTTAM'S PATENT PORTABLE UNITED COW FITTINGS.

Their advantages are—Portability, not Fixtures, removable at pleasure, no Woodwork or Partition to impede Ventilation or breed Vermin, Hay Rick & stored with as much necessary, increased width and depth of Feeding Troughs, Water Cistern, and Patent Drop Cover to prevent water-gorging. Cleanly, durable, and impervious to infection, being all of Iron. Prices of Fittings per Cow, 5s. Prospectuses free of COTTAM AND CO., Iron Works, 2, Winslow Street (opposite the Pantheon), Oxford Street, London, W., where the above are exhibited, together with several important improvements in Stable Fittings last secured by Patent.

Rosher's Garden Edging Tiles.
THE above and many other PATTERNS are made in Terra-Metallic Ware, Terra-Cotta, Stoneware, and Redware, and of great durability. The plaster sorts are especially suited for KITCHEN GARDENS, as they harbour no Slugs and Insects, take up little room, and once put down incur no further labour and expense, as do "grown" Edgings, consequently being much cheaper.
GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, of great durability and superior finish, and in a new variety of design.
F & G ROSHER, Manufacturers, Upper Ground Street, Blackfriars, S.E. Queen's Road West, Chelsea, S.W., Kingsland Road, Kingsland, N.E. Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES for Conservatories, Halls, Corridors, Balconies, &c., as cheap and durable as Stone, in blue, red, and buff colours, and capable of forming a variety of designs. Likewise more elaborate designs. Pattern Sheets of Pavements, with prices, forwarded for selection.
WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Superior and other Stables Paving Bricks of great durability, 1 Water and Ammonia Cisterns, Wash Copings, and all Stoves are made in plain, painted, or enameled, &c. To be obtained of F & G Rosher, at the premises as above.

SILVER SAND (REIGATE), at the above addresses—14s. per Ton, 1s. 2d. per Bushel, 2s. per Ton extra for delivery within three miles, and to any London Railway or Wharf. Quantities of 4 Tons, 1s. per Ton less. A coarser grained Sand 4s. per ton more. Samples of Sand by post on receipt of stamp.
FLINTS and BRICK BURS for Bookeries or Farmhouses. KENT PEAT and LOAM supplied at lowest rates.
F & G ROSHER.—Addresses see above.
N.B. Orders promptly executed by Railway or Vessel.
A liberal discount to the Trade.

Wheat  **Sowing.**
DOWN'S FARMER'S FRIEND for Preventing the Rust in Wheat, and the Ravages of the Saw, Grub, and Wire worm. A 1/2 packet is sufficient for Six Bushels of Seed Wheat, which can be dressed and sown in the same manner as usual. Testimonials from the latest Wheat Growers in the Kingdom bearing testimony to its great power and efficacy, may be had of Agents, who are appointed for every district.
Full directions for use are given with each packet.
Prepared at the Manufactory, Weymouth, Dorset.
CAUTION—To guard against fraudulent imitation and consequent disappointment, see that the signature of HENRY DOWN is on the label.
Agents in every Town throughout England, Scotland, and Ireland.

MOST UNDOUBTEDLY the LARGEST ROOT SHOW in the Kingdom is held at GLOUCESTER annually on NOVEMBER 9. PRIZE LISTS for the forthcoming Show are now ready. The following PRIZES are offered for—
SWEDGES and TURNIPS £75
MANGELS 25
POTATOS 10
WHEAT and BARLEY 11
APPLES and PEARS 15
CIDER and PEARL 10
..... £127
A comparison of these figures with those of any other Root Show in the Kingdom will show that the Gloucester Root Show is the largest. The number of entries at the last Show exceeded 1000. Forms of entry may be had gratis of Gloucester. A. C. WHELEER, Hon. Sec.

The Largest Root Show in the Kingdom.

THE ROYAL BERKS ROOT SHOW will be held at READING, on SATURDAY, November 27, when PRIZES amounting to more than THIRTY-FIVE POUNDS will be awarded to the best specimens of MANGEL WURZEL, SWEDGES and TURNIPS, KOHL RABI, CARROTS, &c. Latest lists for receiving Goods, November 25. No charge made for entry. For complete Lists of Prizes, apply to SUTTON AND SONS, Reading, Berks.

THE BIRMINGHAM CATTLE and POULTRY SHOW.
—The TWENTY-FIRST GREAT ANNUAL EXHIBITION of FAT CATTLE, SHEEP, PIGS, DOMESTIC POULTRY, CORN, ROOTS, and IMPLEMENTS, will be held in BINGLEY HALL, on SATURDAY, MONDAY, TUESDAY, WEDNESDAY, and THURSDAY, November 27, 28, 29, and 30, and 1st December 1869, when PRIZES to the amount of nearly £1000 will be awarded in the following classes viz—
FAT CATTLE £77 2 0
FAT SHEEP 30 8 0
FAT PIGS 6 11 0
DOMESTIC POULTRY and PIGEONS 74 14 0
Prize Lists, Certificates of Entry, and every information may be obtained from the Secretary.
The ENTRIES CLOSE on MONDAY, November 1.
JOHN B. LETHALL, Secretary.
Offices, 39, New Street, Birmingham.

SMITHFIELD CLUB FAT CATTLE SHOW—The ANNUAL SHOW of FAT CATTLE, SHEEP, and PIGS, will be held at the AGRICULTURAL HALL, ISLINGTON, on MONDAY afternoon, December 6, and Four following Days. Intending Exhibitors are requested to apply for Certificate Forms by the reference letters as under—
CATTLE.—Form A. For an OX or STEER (in any Class).
" B. For a COW or HEIFER (in any Class).
" C. For a BEAST in Extra Stock.
SHEEP. " D. For a PEN of three WETHERS (in any Class).
" E. For a SINGLE SHEEP (in Extra Stock).
PIGS. " F. For a PEN of three PIGS (in any Class).
" G. For a SINGLE PIG (in Extra Stock).
ENTRIES for LIVE STOCK CLOSE NOVEMBER 1.
Prize Lists, Forms of Certificates, and all information may be obtained on application to Mr. DAVID PULLEN, Assistant Secretary, at the Office of the Honorary Secretary, corner of Half Moon Street, Piccadilly, London, W.
N.B. All communications respecting the Show must be addressed to the Assistant Secretary, as above, and should bear outside the words "Smithfield Club Show."

The Agricultural Gazette.
SATURDAY, OCTOBER 23, 1869.

WILLIAM it be the best "steam tackle," or the best invention of any other kind that is desired, there are at least two ways in which the truth upon the subject may be sought for. One very easy method is that the public should simply pin their faith to official judgment. The other is that they should trust themselves; using all the opportunities for self instruction with which the energy of rival salesmen, rival manufacturers, rival advertisers if you will, is certain to supply them. In considering the relative merits of these two methods, we may in the first place readily admit that it is a very fortunate thing for the efficiency of each that the other is in full swing of influence and operation alongside of it. It is well that National Agricultural Societies should organise public trials of competing implements, and issue reports of them drawn up by men specially selected as trustworthy. Their awards cannot fail of being among the most weighty of the particulars by which the private judgment of a purchaser will be influenced. But it is very fortunate for him and for the "public"—which is only another word for him—that such official trials are not satisfactory. Not that that word does not generally apply with a certain degree of fitness; but that, as a matter of fact, such trials do not satisfy. It is only the First Prize man who is satisfied, and he not always. Everybody else, from the *Mark Lane Express* downwards, is "never loath to bring these authorities to book."
We quote our contemporary as thus inevitably agreeing with us that, after all, private judgment is the better and the higher court by which the question of merit has finally to be determined, notwithstanding that the general tone of its remarks upon the recent steam cultivation trials at Peterborough is calculated to discourage any other assistance to private judgment than the official programme offers. The *Mark Lane Express* does not indeed object to the farmers present at these trials having had the opportunity given them of judging for themselves; but understanding beforehand about the proposed meeting that "the proceedings are mainly advertisements," it resolved not to send a reporter. But this seems to us to be abdicating

the position of a journalist altogether. In the first place — Why should a newspaper object to advertisements? And, in the second place, what purpose does an agricultural journal serve if it will not work for the information of those farmers who cannot be present. We do not see that the writer justifies himself by the explanation which he offers: —

“Let us still more thoroughly illustrate this,” he says, “by assuming that we had deputed some one to attend at Peterborough; and gentlemen who occasionally favour us with reports often act as judges themselves. To have made, then, his account worth anything, our representative would have had to speak out, to give a preference to, or to declare against some particular performance, or some particular implement; and so surely as he did so would somebody straightway write to correct any such an impression.”

Well, but surely this is exactly what, in the interests of truth, we all desire! For ourselves, we believe that our columns are the most serviceable, not when the Editors have them nearly all to themselves, but when correspondents, differing possibly as black and white, are in full tide of discussion.

We cordially welcomed Mr. TOEFFER on one view of the Peterborough results, and Mr. SMITH upon the other. Our readers thank us for the picture which has thus been given of both sides of the shield. And so may the readers of the *Mark Lane Express*: for the interest of its article on the Peterborough meeting rests very much upon the extracts which it gives from papers which, it seems, we had unwittingly accepted after it had refused to publish them.

One other extract, however, we must give, which is original. The contrast which our contemporary asserts to exist between the official judgment and that of any independent person, whether its own reporter or not, is very amusingly put. —

“When judges are appointed it is a very different matter; we are then quite willing to give the lucky recipient all the benefit of the decree in his favour, although if the judges should have made a mistake our readers will allow that we have never been loath to bring these authorities to book.”

Of course! Everybody knows the perfect independence and straightforwardness of the *Mark Lane Express*. We say so with the most cordial admiration of it. All we contend for is that our contemporary is not very logical in refusing to give, publish, or promote a private discussion, decision, or award, on account of objections, to which, on its own showing, it appears that the official reports, which it allows, are equally obnoxious.

THAT part of the CONTAGIOUS DISEASES (ANIMALS) ACT, which relates to the management of live stock when attacked by contagious or infectious diseases, has excited a good deal of interest during the past fortnight.

At the Michaelmas Sessions, special, general, or quarterly, which have been held throughout the kingdom, the question—how to carry out the Act—has come under consideration. In most instances the magistrates have delegated their powers to a general committee, who in turn have appointed local committees of magistrates and farmers, whom they have designated as the local authority to put the Act in force.

In most of our cities and boroughs, also, the municipal authorities have nominated committees to carry out the details of the enactment, so that the measure, as it affects our home stock under disease, may be stated to be now in general operation throughout the country.

The first part of it, which has been in operation some time, has been already fully discussed. The regulations affecting the home transit of cattle have not yet, however, been definitely settled; and instead of acting hastily and inefficiently, the Lords of the Privy Council have, as our readers are aware, appointed a special committee to consider the whole subject. And they, with equally commendable prudence, have issued circular letters, asking for information and suggestions for their guidance from various agricultural authorities.

Many of these suggestions have been published. It is for the committee to winnow and sift the several proposals, after which the Privy Council may issue its Orders, so as to complete and perfect this part of the Act.

It is to the third division of the subject—the management of our home-fed stock when affected by contagious or infectious disease—that we refer especially, when we speak of the adoption of the Act by the several Michaelmas Quarter Sessions now being held in England

and by the municipal authorities of our cities and boroughs. And we ask, What is the reason of the extraordinary delay which has taken place in carrying into effect this portion of the Act?

Six weeks ago we wrote, “the question is simply this—unless the powers of the Act are put in force at once in every district where there is a local bench of magistrates, the inquiry will not be, Where is the disease? but, Where is it not? The loss on the live cattle of England, should the disease continue to progress at the rate it is now spreading, will in a month amount to as much as would buy a small principality.”

This was not done; and hence, no doubt, in great part the news of foot-and-mouth disease which we receive from every part of the kingdom. After a delay, during which the disease has had time to spread without hindrance, it will be a much more costly and laborious work to wield the powers of the Act over so wide an area as now requires their operation.

Permissive legislation is at all times unsatisfactory; and to make regulations which have an important influence over our foreign and home trade in live stock, and to leave the agency by which they have to be carried out to be appointed by an authority which is not bound to act for two or three months is a grave mistake, unjust to the measure itself, by not giving it a fair chance, and injurious to the public interest.

The Orders issued by the Privy Council should have been not only imperative, as the term implies, but also immediate in operation. If this had been the case we should not have seen the authorities deliberating in October on the best mode of working an Act and Orders published two months ago. At the West Riding of Yorkshire Sessions, Mr. J. D. DENT, M.P., in introducing the subject alluded to this delay, and said, “It would have been a good thing if the Act had been earlier put in force:” and we are surprised that there has not been more general surprise expressed that a measure which was deemed urgent in July has not been called into operation, in one of its most important sections, till now, three months later.

All the powers of that section of the Act which relates to the foreign trade were put in exercise at once. Another equally important section has been left inoperative for ten weeks, and has passed almost unnoticed. The results are before us in the presence of pleuro-pneumonia, totally in many localities, and in the almost universal spread of foot-and-mouth disease throughout Great Britain. It has entered nearly every feeding house and dairy, destroying tons of beef, and reducing the value of thousands of store stock from 2/ to 5/ each. The capital of the farmer has been wasted, and the food of the consumer has been destroyed. To the working man, who without meat cannot work, and to his children, who ought to have milk, the scarcity which has been thus created is a visitation of consequence, beyond money estimate.

A TURN in the downward prices of Wheat has at length taken place, and throughout the country the rise of 1s to 2s. at Mark Lane has been fully sustained. Oats are 1s., and Maize 6d per quarter dearer. Fine malting Barley is actively inquired after, at extreme rates. —The trade in British animals and meat is good, but an unusually large supply on Thursday caused prices to fall to 5s 6d per 8 lb for beasts. Prices for prime sheep touched 6s. per 8 lb —The seed trade is limited; winter Tares and Rye are both cheaper. —In wool a steady business has been done, but not at higher prices.

We have received just as we are going to press the following letter on the foot-and-mouth disease and on the Act of last session, from Mr. C. RANDALL, of Chadbury:—“While acting under the recent Order in Council in carrying out the provisions of the Cattle Diseases Act, 1869, with the view of checking the spread of foot-and-mouth disease, it has appeared to me most desirable that we should know what we are to do, when, in spite of all precautions, it attacks our flocks and herds. I have asked one of the highest veterinary authorities we have to tell me, for the benefit of others as well as on my own account, what course to pursue, and I feel sure you will willingly make known the advice which he kindly allows me to publish. He says, Simple remedies are much to be preferred, and in very many cases nitrate of potash thrown into the drinking water, at about the rate of half an ounce to a gallon, is all that is required. It is, however, better that nitrate of potash be alternated with the sulphate of soda, given in the same quantity and in the same manner. The feet should be kept as clean as possible, and only the detached horn removed with the knife. I believe also that a solution of the nitrate of potash, 4 ounces to a pint of water, is as good an agent as can be used in the early stages of the disease; diluted carbolic acid on the other hand, may be required later on. Nothing but strict isolation is likely to succeed as a preventative. When the disease exists in a district,

farmers ought to use means equally as adopted for the sequestration of their animals, and time of cattle plague. As a rule, sheep suffer from cattle, excepting in their feet. Local authorities, therefore, all that will be required, is the same as used to the feet of cattle.

We direct attention to the annual show of the Smithfield Club. The special prizes for the year include 100/ for the best beast; 50/ for the best pen of sheep, 10/ for the best sheep, and the above are in addition to the 100/ Plate and 10/ Cup, the money for the 100/ Plate and 10/ Cup, the money for the class, and a Gold Medal to the breeder. The entries will close on Monday, November 1. 0 g

Cattle diseases were reported at DUNNE, chief constable of Cumberland moreland, to the Quarter Sessions, on Wednesday. He gave details of several cases of pneumonia and foot-and-mouth disease which appears to have been introduced into the county by the cattle sold at Appleby on the 24th of August last by Mr. AINSWORTH, of Spittal, Stainmore, accordingly been summoned before the Sessions on Tuesday, a return of animals of the foot-and-mouth disease was presented by the Clerk of the Peace. Since September it first broke out, 2565 cattle have been which 1859 recovered, 60 died, two were 644 remain under treatment. Only two divisions are entirely free from the disease, most prevalent at Coleshill, Atherstone, and worth, Warwick, and Brailes. A committee of each petty sessional division was created to strictly enforce the provisions of the Diseases Act in the county.

The Herefordshire Society held a show at Hereford, on Tuesday last, when 26 classes of sheep, horses, and pigs were exhibited. Mr. A. ROBINSON, of Leominster, was awarded the 1st prize, and Mr. J. HAMPTON, of Leominster, the 2d. Mr. J. JUN., of Swanstone, was 1st in yearling prizes of M. BIDDULPH, Esq., M.P., 100/ for the best lot of beasts, irrespective of age the highest prize was awarded to Mr. JUN., of Dilwyn. For yearling heifers, Mr. M.P., offered prizes, the 1st of which was Mr. HARDING, and the 2d to Mr. FENY, a sub-Sir H. G. COTTRELL, Bart., offered prizes for old heifers, the 1st going to Mr. TUDOR, and Mr. WILLIAMS. J. KING, Esq., offered prizes of young steers, but there were no competitors. CROFT, Bart., M.P., and O. W. ROSS, Esq., offered prizes for pairs of older steers, but were of local importance only. Thus it is conceived that the Herefordshire Society has fortune to find its funds and prize lists augmented by the public spirit of gentlemen of the county. Many of the prizes for other animals are awarded the same way. Mr. TANNER, of Dornicote, was lead in Shropshire sheep, Mr. DAVIS, of Warcolms being a good 2d. The pigs and horses of local interest. With two entries of horses the prize of 10/ was awarded to Mr. J. LULLOW. The cart stallion prize was given to Mr. WRIGHT, Esq. (10/), there were only two entries.

Competition in fertilisers is, it is largely added to the present elements between this country and the Continent. According to the *Economist* —

“The arrangement which the Peruvian Government entered into, with a combination of French houses, for the sale to them of a large quantity of guano, to meet the necessity of dry guano, is a very important one, and will have a great effect on all the guano trade, and the proceeds of it, and also on all the guano in Peru. In return, we suppose for the guano, the Peruvian Government is to receive the guano in return, until the payment of the guano is altogether paid, and it is a very important circumstance that the guano is to be mortgaged, and that the proceeds of the sale of the guano under existing contracts of 1873. The combination will certainly be powerful, though they will not exactly control all the guano world; and though it is also stated as coming into more and more formidable competition with natural guano.”

OUR LIVE STOCK.

THE sale of Mr. Kearney's Shorthorn Kells, Ireland, came off on the 13th of the month, and the animals trace directly back to the great Chilton sale, in the year 1839. Sixteen of the cows and two bulls are descendants of *Britannicus* (lot 8, Chilton sale), and 18 females are the offspring of *Portia*, by CATO (119) (lot 3, Chilton sale). The cattle were poor and low in condition, the heifers, the company was not large, two or three exceptions the prices were high. The 51 cows and heifers averaged 25/ 1s 6d each—the five bulls 25/ 1s 6d each—the 56 animals being 26/ 9s. 10/ d., and the

quality as... sheep... Local... red... cattle... The first four lots sold at prices... Waterloo 23d, one of the... Water to tribe, must have been cheap at 25 gs.,... by REX 16,830, was bought by Mr... by Lady Pizot. When she... a considerable excitement ensued... not cease till she was knocked... to Mr. How, of Broughton... from 20 to 30 gs., until... was put up, and sold at 41 gs. to... by DR McHALE was bought... for 44 gs., Louise 7th foaled... to King's Fort, and Louise Belle, by... to Mr. G. Atkinson, of Sea-... for 50 gs. The bulls brought a higher average... PRINCE BERTRAM, by PRINCE... of the well-known Bonnet and Bliss... purchased by Mr Garnett for 50 gs.; and... a son of Belligerent (23,491) and... (lot 9), became the property of Mr... Woodroffe for 40 gs. The remaining bulls were... and brought respectively 7, 8, and 17 gs.

Mr Horton announces a sale of pure-bred... the property of... at... near Bamford. The sale will take... November 9, and will afford an... opportunity for obtaining animals which will... for dairy purposes. The cattle are... thoroughly accustomed, of dark fawn... of large size, and accustomed... all the winter.

Fifteen cows and heifers and five bulls, all pure-bred... are to be offered for sale, near the... station at Kendal, on Monday, November 1. These cattle are the property of the Rev. Thos. Stanforth, and will be sold by Mr. Wm. Kirby, of Windermere, auctioneer. Five of the lots are served by the well-known PEER OF THE REALM, one is served by HANDA (23,877), a Crossbred bull bred by A. ROBERTSON, of Ulverston, and another is in calf to Mr. GRENADIER (21,576), bred by Mr. Stanforth, and the 2d horse of the *Favourite* by MARLBORO' (11,811). The females, writes a contemporary, "which will commend themselves most directly to the Shorthorn public, are probably *Minstrel 3d*, *Georgie*, *Grace*, *Red-and-White*, and a 3-year-old heifer of the same name. The first of these, *Minstrel 3d*, by 10TH DUKE (17,739), from the Holkar sale of 1861, is a breeder when bought, she has produced five calves since then, and is now in calf to PEER OF THE REALM (21,576). *Georgie* is of the same family as *Grenadier*, and is by Mr. Richard Booth's ELFIN KING. *Grace* springs from *Medora* by AMBO, with subsequent crosses of Farnley and Springfield bulls; and the two lots named *Red-and-White* are both of the *Togas* and *Foggathorpe* line—the latter (lot 10) doubly so, *GRENADIER* being her sire.

The seventh volume of the Hereford Herd Book appeared at the commencement of the present year. The list of bulls ends with No. 2636, and the volume is pretty equally divided between bulls and cows. Mr. De laune, in his preface, speaks of the increasing number of his supporters in carrying on this important work, but expresses his regret that owing to the difficulty of obtaining the necessary information from breeders, the publication of the present volume has been delayed for some months. Excellent photographs of no fewer than 12 famous Herefords have been given the pages of the volume. At the conclusion of the long list of cows and the usual index of names of breeders and animals, is the appendix promised in the sixth volume, showing the prizes won at agricultural shows by animals entered in the preceding pages. It is to be regretted that in this valuable addition the indexing should be so imperfect. In attempting to look up the pedigree of prize animals mentioned in this list, we were frequently unable to find it on the page to which we were referred. Thus, the pedigree of *Duchess of Gloucester*, first at Birmingham and Smithfield in 1864, is said in the appendix to be on p. 3, the portion devoted to bulls, and he who seeks for the pedigree of *Ostrich*, first at Manchester last summer, is referred to p. 328, devoted to cows. We should not have mentioned this had not similar errors occurred throughout the appendix. The able lecture read by Mr. Duckham before the Breconshire Chamber of Agriculture, upon Hereford cattle, last January, forms a very readable and instructive termination to this volume.

representative one: it is not large numerically, but for quality, size, wool, and character, the sheep composing it will give place to few. There are 93 ewes, and these last season produced 154 lambs, counting all dead and alive. This is only additional evidence as to the unwonted largeness of the fall of lambs last spring. The rams let and sold remarkably well, several lots going into France, in some cases accompanied by ewes, others went to Denmark, and the general demand was above the average. Mr. Crosswell has somewhat reluctantly shipped some of the present year's lambs into France. The flock has not been so fortunate as usual in taking showyard honours, but in spite of this drawback the demand for rams has been larger than in any past year.

THE AGRICULTURAL LABOURER.

[The following letter on this subject appeared in yesterday's *Times*.]

IN the *Times* of Friday, Oct. 15, there appeared a letter from the Rev. F. O. Morris, which gave an account of the condition and prospects of the agricultural labourer on the Yorkshire Wolds, and which showed that with care and prudence, and if blessed by health, he is by no means so destitute of present comfort, or so unable to make provision for the future, as some of our agricultural friends and others holding similar opinions represent him to be.

I believe that in the agricultural districts of the West Riding of York our labourers are quite as well off as in the East Riding. Wages range from 13s. to 15s. per week, and at the harvest time, when men are engaged by the day, they receive from 18s. to 20s. per week for four or five weeks, as well as their meat. At the same time many married men take harvest work by piece, and with their wives and children follow the reaper, taking up, binding, and setting up the corn, and the wages which they earn are certainly equal to those of the single men. As an instance of what may be done at these times, I can mention a boy of 12 years of age, who earned, in 1868, 20s. and his meat, and in 1869, 25s. and his meat at harvest work during his Midsummer holidays, 17 17s. 6d. of which I am happy to say he has invested in the savings' bank.

In this neighbourhood a portion of land sufficient to keep a cow is attached to many cottages, and if no garden be contiguous to the house, there is generally an allotment of a rood of land in the garden field. A cottage with a rood of land lets for 3l. to 4l. a year. The parish in which I reside contains about 600 inhabitants, and is purely agricultural. We have in it 25 holdings, containing from 3 to 8 acres of Grass each, which, together with the cottage, cow-house, &c., are let at rents varying from 10l. to 20l. per annum. Of these 20 are occupied by men who are either at present agricultural labourers or have been so for the greater portion of their lives; and who have made what money they possess by one industry, and good management as agricultural labourers. Several own a couple of cows, and probably winter three or four ewes. One of these small takes I saw 12 ewes this autumn, the property of a man working as an agricultural labourer, but whose wife and daughters make something by taking in washing. In several of these cases the occupiers would gladly take more land; indeed, one of them has recently taken 16 acres of arable land in addition to his Grass, but I am rather afraid he may have undertaken more than he can manage.

The Claro Savings Bank, which has branches at Knaresborough, Wetherby, and Pateley Bridge, numbers among its depositors a very large proportion of agricultural labourers of both sexes. Our single men and women are usually hired for farm service from year to year at the statutes at Martinmas. For many years I attended as one of the managers of the savings' bank on the market-day in November after the yearly wages are paid, and I can, therefore, speak from personal experience of the number of male and female agricultural servants who came at that time to deposit a portion of their wages in the bank. They often commence as mere boys and girls with a sovereign, and increase the deposit each year, until by the time they are one or two and twenty young men will have sums varying from 30l. to 40l., and women from 20l. to 30l. Some, indeed, who are careful, industrious, and have got situations as foremen or shepherds, will have very much larger sums; and, with reasonable care and health, no young couple in this neighbourhood who wait to marry until 25 should have less than 50l. to 60l. with which to start in the world. Unfortunately very many, probably the greater number of them, do not save. Dress with the girls, drink and careless love of pleasure and company with the lads, sometimes the want of prudent parents, take away their earnings, and if they marry at one or two and twenty they have to take any not a few they can get, and are hardly tried to bring up in decency the large families which usually follow such early marriages.

Much may be done by the clergyman or schoolmaster in the way of inculcating the habit of saving. At the last Martinmas my brother, who has charge of this parish, received for investment in the savings' bank 102l. from 14 young men and women, all in agricultural service, who had been educated at the National School, and several others invested their wages themselves.

I can also corroborate Mr. Morris's statements as to the kindness and sympathy generally shown by farmers to their servants and daughters. There is among some of them a carelessness with their huts in their houses, and a want of kindly superintention, which I fear is not peculiar to them, but is shared by many in higher ranks. But to the old and sick poor their ready help and sympathy are seldom wanting, and many are the regular dinners sent from the farmhouse, together with other comforts, if there be sickness or distress in the labourer's cottage.

At the same time I must confess that there are

many cottages here and in this neighbourhood which are deficient in sleeping accommodation and in sanitary arrangements. Very much wants doing, and the difficulty is to find the means to do it, and to secure a fair return for the money laid out. Many landowners have this will but not the means to put their cottages into thorough order, for there is not merely the outlay upon new cottages to be considered, but also the loss of rent, on those which ought to be pulled down. If the Government would advance money for cottage building, as was formerly done for draining, I believe many landowners would welcome it as a great boon.

There is another point, too, in which I think we have, perhaps, gone too far, viz. in throwing together farms and doing away with small occupations. We have been trying to get men of larger capital, with improved implements, and a wider field for agricultural science, and have overlooked the incentive to industry which the hope of a small farm held out to many a provident labourer. Too often a small man of that class has embarked in an undertaking beyond his means, and has failed; but to compensate for this there are many who have started as agricultural labourers, and by their own industry alone have raised themselves to the class of comfortable farmers. I must apologise for the length of the letter, but I believe it is a fair statement of the condition of many of our labourers. John Dent Dent, Ribston Hall, Wetherby, October 18.

THE STEAM CULTIVATION CONTROVERSY.

THE steam-ploughing and steam-cultivating controversy does not appear to be in a happy state, viewing it sentimentally, nor in a satisfactory condition, if we apply to it either a logical or commercial test. The points in dispute are those which belong to the less expensive roundabout system and the details of the direct method of draught. The one need not be described, but the other is composed of its two traction engines of 10 to 20, 30, or 50-horse power, with weight and first cost in proportion—the former (weight) varying from 15 to 40 tons per engine, and the latter (cost) from 1500l. to 4000l. at one blow.

Each of these two systems has its vigorous champion. On the one side we have our old friend Mr. Smith, of Woolston, and on the other Mr. Toepffer, of the North Lincolnshire Steam Ploughing Company. Into the merits of steam-power for cultivating the land we need not now enter, for cultivators are like reaping and mowing machines—there is no difficulty about getting a variety to do the work equally well, and therefore the whole matter resolves itself into a question of wear and tear, and the surrounding costs which form items in the balance-sheet.

Mr. Smith adheres to the outlay of 450l., and the performance of work at the rate of 6 to 10 acres per day, the cost being only 4s. 8d. to 6s. per acre, according to the depth and character and condition of the soil. Mr. Toepffer, on the other hand, attempts to reduce the roundabout system, and all other light forms of engines, tackle, or general first cost. Mr. Toepffer, however, studiously avoids any statement in regard to the actual cost per acre at which land can be cultivated by the expensive appliances which he advocates. He does not, indeed, tell us what he, as the representative of a company for letting out tackle, charges per acre for the work he does for the Lincolnshire farmers. As matters now stand, therefore, we cannot do less than admit that Mr. Smith has the best of it, both logically and practically. In regard to the latter, Mr. Smith has far the best of the argument. Mr. Toepffer, and the other advocates of the heavy and expensive system, make it a part of the conditions of their ultimate success that small farms must be absorbed into large occupations, and occupied by men of capital, while the "useless fences" of small fields must be so levelled as to be more profitable in themselves, at the same time that an open farm is created for the application of the ponderous engines and tackle which Mr. Toepffer says constitute the only correct and profitable method.

Thus, it will be perceived, while Mr. Smith takes all things in connection with farms and farmers as they are, calculating on the small fields and abrupt undulating valleys as they exist in many parts of this country, and the limited amount of capital which farmers can command to invest in auxiliary machinery, Mr. Toepffer dwells on the condition in which Nature ought to have constructed, and our forefathers to have mapped out and fenced, the land.

By this line of argument Mr. Toepffer raises all the questions which are now being so anxiously discussed in regard to small farms and large farms, or a mixture of both, and the advisability or not of dividing some of our present large occupations into small holdings, so that men with small capital, and good judgment and moral character, may have a chance of rising from their humble position as peasants or 2-horse farmers. Into these questions of social and political economy, it is not our purpose or duty on this occasion to enter at length. But Mr. Toepffer inadvertently raises these questions, although his "arguments" mainly consist of bare statements. Is Mr. Toepffer prepared to prove the following points—That it is necessary for a small farmer to have the portion of his land to be fallowed ploughed at the rate of 30 or 36 acres a day? That the wholesale work he advocates is better adapted for small undulating valleys, with their small fields and tortuous water-courses, than is a lighter, albeit a slower, system of work? To it the saving of labour, as he puts it, is good either for the farmer or the country, thickly populated as it is? That it is a mistake for each small farmer to have a set of the low-priced tackle, or for three or four small farmers to join and have one of them, drawing lots for the first turn? That it is more economical in the present embarrassed state of the labour market for large numbers

of men to be engaged for a few weeks in wholesale cultivation after harvest, with the certainty of being left to their own resources, or having to flee to towns for employment during the winter? There are many other questions which suggest themselves in this place, but is Mr. Toepffer prepared to answer these and work them out, with their usual surroundings, to their logical conclusion?

Without desiring to complicate this subject further, we should like to know whether the farm labour question has not been reduced to this condition—that farmers now have to look upon their men, not only as to how much they are worth per week during spring hoeing, hay time, and harvest, but how much they can afford to pay them per annum so as to be able to keep them all the year round. It is rapidly coming to this position. If, therefore, farmers would have the services of their men in the busy season, they must find employment for them in October, November, December, January, and February. If this view be not taken and acted upon, there are many agricultural districts in this country where there will be no skilled labourers at busy seasons of the year to work the few machines we already have. Horses, too, must be kept to the extent of a certain number. On both the grounds, therefore, of horse labour and manual labour, it is a serious question whether more than half the land of this country could not be more economically cultivated with a small portable engine, and the roundabout tackle and cultivators, than it could with traction engines and tackle which could do from 20 to 36 acres per day. What farmer of 100, 200, 300, or 400 acres wants his work done at the latter rate?

In conclusion, we may give this illustration:—If there had never been any coasting vessels, there would never have been any three-masted ships for crossing the seas; and if there had never been any river steamers, there never would have been the magnificent Cunard and Peninsular and Oriental lines of steam packets. Mr. Toepffer, in those interests which he professes to advocate, may take a lesson from these data. If steam cultivation be economical and profitable, and at the same time farmers are timid in investing their money in the system, the very best thing Mr. Toepffer and his friends can do is to promote as far as possible the small and inexpensive system of doing the work; for what they want is, for the farmers of every corner of this country to be shown the effect of steam cultivation. Thus, the smaller and cheaper sets will be a "roundabout" system of advertisement for the larger or the "Great Eastern" character of performance. This is not a matter of feeling or sentiment, or friendship, or anything of that sort; but it is a question of expenditure and return of money on the outlay. If, therefore, Mr. Toepffer and his friends would cultivate the large open fields of this country, as the wolds of Lincolnshire and Yorkshire, and the heavy clays of other counties, they will do well not to divide the manufacturing interest, but to look upon the roundabout system as a pilot which, if steam cultivation be right, cannot fail to lead the way to the direct, and, as it is characterised, more perfect and expeditious method. W. W. G.

TRANSIT OF ANIMALS.

The committee of the Scottish Chamber of Agriculture having considered the communication from the Privy Council on this subject, have agreed, for the approval of the directors, to report, in answer to the question—

I. How a Sufficient Supply of Food and Water may be Provided for Animals brought by Sea to British Ports.

1. In voyages not exceeding five days and five nights, a supply of food, equal to 1 lb. per day, of good wholesome Oatmeal, draked in water, seems sufficient, and very suitable for horned cattle; a less supply—say 1 lb. per day—would suffice for sheep. In voyages exceeding five days, cut hay, in addition, seems requisite,—the all wance not being less than 1 stone hay and 4 lb. meal per 24 hours. Where Hay is given, it might be moistened with molasses and water, to sweeten it; and even when the water may be had through keeping, the molasses will remove the bad smell, and sweeten it to the taste, and cattle will eat it readily. Each large animal should have two gallons of water each 12 hours, and smaller animals in proportion.

2. It should be compulsory on all owners of animal carrying vessels to have on board, and to supply to each animal daily, a sufficient all wance of food and water, as above specified. Oatmeal could be carried in no great bulk, and with no risk from fire, and cut hay, closely pressed, could be put up in convenient parcels for using, and could be stored apart from risk of danger by fire, while fresh water might be carried in tanks down the ship's sides, without interfering materially with cargo room. A vessel constructed in every way suitable for cattle traffic has yet to be built.

II. How a Sufficient Supply of Food and Water may be provided for all Animals carried by Railway in Great Britain.

1. It should be made compulsory on every railway company to provide ample drinking-troughs, abundantly supplied with pure water, at all the principal loading and unloading stations in Great Britain.

2. It should be compulsory on railway companies to expedite the speed of animal trains. In case should they be permitted to run animal trains slower than 18 miles an hour, stoppages should be limited.

3. When Nos. 1 and 2 enforced, very little food or water would be required for animals in transit in Great Britain, but if the time of transit exceeds 12 hours, it should be compulsory on all railway companies to supply water at the end of the first 12 hours after receiving them at the station of loading, and food and water on the elapse of every 12 hours thereafter they are in charge of the railway company.

4. The best and most convenient food for both railway companies, and cattle owners, and stock, seems to be Oatmeal draked with pure water when in drink. The all wance should be not less than 1 lb. per head of horned cattle, 1 lb. per head of sheep, each feeding time. Such food is easily carried—not bulky, nor liable to accident by fire, and is more suitable for animals in transit than hard hay or softer food.

5. The only means of supplying animals with food and water on transit in the present truck is by pails and men, or by troughs in the trucks. Water could be run into the trough by means of the water-nozzle shown by Mr. Reid, without causing disturbance to the animals, or much delay at the drinking stations; and Mr. Reid's truck, which the com-

mittee understand has been under the notice of the Privy Council officials, might suggest a mode of watering and feeding animals on long journeys.

III. How Animals may be Protected from Unnecessary Suffering by Overcrowding or other Causes during—(1) Sea Passage, (2) from Foreign to Home Ports, (3) from Ports in United Kingdom to Ports in Great Britain; (4) on Landing, and during Inland Transit.

1. DEPARTURE FROM SEA PORTS.

1. All vessels carrying animals should, on inspection, be licensed to carry only a given number of stock, regulated by the size of the animal and the vessel's cubic space.

2. The present system of packing animals in vessels as deck load causes them much suffering by exposure to weather, and want of means of supplying them with food and water. To prevent, so far, diseases, the animals when so carried should be so arranged on deck as that their heads are to the centre of the vessel, and their bodies protected from spray and seas that may be shipped during the voyage. A protection on deck, formed of galvanised sheet iron, sprung from the bulwarks of the ship on either side, extending towards the centre of the deck, leaving sufficient room for supplying food and water, and behind each row for cleaning, would be no appreciable hindrance to sailing and working, and would protect deck animals from starvation, spray and seas often shipped, and the injuries they sustain by sliding on their own damp and dung. When carried as below, vessels might be ventilated by removing a plank on each side of the upper deck above where animals are. The open space might be protected by louvre boarding to keep out the sea, and upright iron ventilators, fore and aft, to create a current when the hatches are down, and ample room should be given for supplying food and water. Such changes, made under practical builders, in the construction of cattle-carrying vessels, would remove the cause of most of the unnecessary sufferings animals endure in transit by vessel.

3. The committee are of opinion—

(a) Passages from Foreign to Home Ports.

(1) That all foreign going vessels should be subjected to the closest inspection, and thoroughly cleansed and disinfected, before being permitted to take animals on board. (2) That animals only should be taken on board after a strict veterinary inspection, and none but sound animals, which had not come into contact with animals labouring under contagious disease, be permitted to be taken on board or carried. (3) That a log of animal health and casualties during the voyage be kept by the captain, in which every illness and death experienced shall be entered, along with the times at which they are fed and watered, and mucked during the voyage. (4) That such log should be exhibited to the inspector at the port of landing, and similar inspection should be made by him at that port, and in animals labouring, or which had laboured, under contagious or infectious disease, or which had come in contact with such diseased animals, be permitted to be landed in life. (5) Vessels only should be permitted to carry animals which had been specially fitted for the purpose, with sufficient standing and breathing room, properly ventilated, and having the means of supplying the animals carried regularly with food and water.

(b) Passages from ports in the United Kingdom.

As the committee believe that much of the pleuro experienced in Great Britain is brought by animals from Ireland, the same rules as to cleansing and disinfecting and ventilating vessels is necessary, so is a similar inspection at the port of embarkation and debarkation, and the same consequences for disregard thereof ought to ensue. They also believe that other lung diseases may be induced or hastened by overcrowding and exposure to weather, and, in consequence, the same rules as to the construction of vessel, mode of placing and protecting the animals in it, and supplying them with food and water, as suggested in foreign-going vessels, should be observed and strictly enforced.

2. WAGGON TRAFFIC.

1. Waggon carrying animals should all have sprung buffers, and be built same as passenger trains, and should be constructed so as to form a protection against weather and shut out draughts, and at the same time leave abundance of air. The trucks should in every case be roofed, and should be thoroughly cleansed and disinfected, and none but healthy animals permitted to be trucked.

2. Animal traffic ought to take precedence of all other save passenger, and if cattle cannot be sent by special train, they should, if possible, be sent by fast goods train, and in animal traffic, all railways should be viewed and treated as one company, and engine drivers ought to be put under the same regulations as to stopping, starting, and shunting animal trains as in passenger trains; and a way bill ought to be kept of every lot, containing the time and every incident of the journey.

3. All animals should be watered at the end of the first 12 hours from the time of loading, and fed and watered every 12 hours thereafter; and they should have water offered to them before being allowed to quit the station of their destination.

N.B.—During the years 1868-69 the directors made an investigation into the diseases which are believed to be imported into Great Britain, or to be induced in animals through sufferings endured during transit by sea and land, and more especially in reference to the disease of pleuropneumonia, and they take the liberty of annexing their report, and the veterinary opinions on which it was in part founded.

The report is to be submitted to a general meeting of the Chamber on November 9.

Home Correspondence.

Mr. Patrick Shirreff, of East Lothian.—I would ask the attention of your readers, in the words of the North British Agriculturist, to the claims of Mr. Patrick Shirreff for a substantial token of their appreciation of his great merits as a propagator of several distinct varieties of Wheat and Oats. Some months ago the idea of presenting him with a testimonial was taken up, but the sum hitherto subscribed does not exceed 200l., notwithstanding that in the list of subscribers there are the names of several eminent agriculturists connected with the Lothians and Berwickshire. Few persons resident in other districts of the United Kingdom have contributed; and it is intended to close the subscription in a short time. Landed proprietors and farmers should therefore hasten to subscribe, and thereby bear their testimony to the meritorious efforts of so devoted a labourer in the field of improving the cultivated cereals. Some of your readers may not know the services which have been rendered by this gentleman in the prosecution of agricultural progress. Mr. Patrick Shirreff has spent the greatest portion of a long life in the endeavour to promote the interests of agriculture by raising new and superior kinds of Wheat and Oats. One who has laboured so assiduously and devotedly in the behalf

of those directly dependent upon the sale of the farm, should be acknowledged as a J. C. M.

Last Words on the Tiptree Balance.—I have just received from Mr. Mechi kept "cake, bran, and feeding" sale. Mr. Mechi has frequently told us about his feeding stuff, therefore whatever there was of that kind of stuff upon the farm on January 1, 1868, should have been included in the valuation of 373l. 10s. 6d. of hay, &c.; and there must have been some 300 quarters of Act ought to have been brought to bear upon the balance for starting his cattle. We have nothing to do with the will hereafter show) with the balance of 373l. 10s. 6d. on January 1, 1868, for the balance on January 1, 1868, ought to have been big enough to have made a balance of 73 acres of 18/8 Wheat, at 6 quarters per acre, an average standing at 63s. 9d.; but to make the balance clear to "Another Farmer" I will go over the balance again.—The total of 1235l. 5s. 9d. for Wheat in 1868 represents 387½ quarters at 63s. 9d. per quarter. Now we must make the 73 acres up to 100 acres, and the 387½ quarters represented by the 1235l. 5s. 9d. The value of these 50½ quarters stands at 3240l. 15s. 6d. Mr. Mechi's sale of 30 quarters of it at 56s. 6d. per quarter. Now we must look to the Rivetts. The Rivetts' 310l. 2s. 6d. and Mr. Mechi tells us that he has 100 quarters of them. Therefore I fix the price at 31s. 6d. it is of no use "Another Farmer" quibbling about a trifle about that point—a penny or so per quarter is Mr. Mechi alone who can put us right on that point. This 310l. 2s. 6d. represents 132 quarters of wheat per quarter, and we must fetch them up to 100 quarters. To do this 132, at 16s. 9d. are needed, gives a total of 110l. 11s.; to do this we need a lot of 1867 Wheat, and as I fixed the price at 78s. per quarter, I shall take 132 quarters of 78s. per quarter is 11s. 3d. over the average, therefore we must divide the 110l. 11s. by 11s. 3d. which shows that 155 quarters of 1867 Wheat are needed to make the Rivetts' area up to 100 quarters. The total value of the 155 quarters is 12075l. 7s. 6d. Now, let me look at the white Wheat Rivetts have 767l. 11s. 9d., and Mr. Mechi tells us that he has 100 quarters from 56s. to 62s. per quarter of it. I shall take an average here as I did in my last letter, and set the price at 59s per quarter. The 767l. 11s. 9d. represents 260 quarters; this needs 100 quarters to make it up from 59s. to 63s. 9d. per quarter, the total of which is 617l. 15s. Now, we must set a lot of 1867 Wickets to make this up, and as I set the price at 78s. per quarter, to do this, 86 quarters are needed; adding this to the 100 quarters of 1867 Wheat, which is 335l. 8s.—Now I will fix a price upon the Red Wheat by striking an average between the Rivetts' at 47s., and the White Wheat, at 59s. The average is 53s. per quarter. The 157l. 8s. 6d. and 100 quarters they stand represents, at 53s. per quarter, 59 quarters to make them up to 63s. 9d. per quarter, 59 quarters are needed. The total of this is 3137l. 15s. 6d. I will fix a price on the hay, straw, bran, &c., other than Wheat, &c., on the farm on January 1, 1868. I will fix it at 100l. Mr. Mechi can correct me if I am wrong; "Another Farmer" cannot. Mr. Mechi will go in and strike the balance:—

Table with columns for Valuation Jan. 1, 1868, Corn and hay, &c. (unsold), Balance—"over the left", and a list of quantities of wheat and other crops with their respective prices and values.

"Another Farmer's" balance of 558l. 6s., 1868, is of no use against this balance of 373l. 10s. 6d. The balance of 1032l. 8s. to loss will show to "Another Farmer" that Mr. Mechi's balance-sheet was a most seasoned dish, spiced well up with 1867 Wheat to the average up to 63s. 9d. You tell us that you said at Great Braxted—"He believed they would convince the farmers of England wished him good, but he could not conceal from himself that they would see Mr. Mechi swept from the face of the agricultural world." Now I take it that this might apply to your case, for I will not be "misled" by it, and I do not think I can prevent others. Yet I have no doubt that "Mr. Mechi swept off the face of the agricultural world," but I do hope that his balance-sheet will stand upon every point (if questioned) by some better proof. If they cannot stand that, I will not better never publish another. William Smith, Agricultural Editor, Bletchley Station, Bucks, Oct. 18.

Steam Cultivation.—In your impression of this subject, you kindly granted me space to make a few lines on this subject. I then alluded to a correspondence in Bell's Weekly Messenger, signing himself "the boy," having closed his correspondence on steam cultivation, expressing a hope that he would be filled up the space kindly offered by the editor of Bell's Weekly Messenger, in these words—"I will send us the history of a steam cultivation where the cost of cultivation is as low as that of Mr. Smith's, we will gladly give it a place in our columns." I also wished to know if the article quoted by Mr. Smith, of Woolston, taken from the Agricultural Gazette, January 20, 1866, was correct. His reply to me was unsatisfactory (see Agricultural Gazette, January 30, 1869), and as I then remarked

yet remains to be accomplished. In fruits and vegetables, including field root crops, the display was really magnificent, and in some respects, particularly in fruits, actually surpassed any previous occasion. I doubt whether this department of the show has ever been exceeded, as a whole, on this continent. The extensive display of Apples, Pears, Peaches, &c., would have astonished a stranger accustomed to associate only frost and snow with the climate of Canada. Outdoor Grapes, which are now cultivated extensively in some places, will not generally ripen well this season, but those of indoor growth on exhibition were not only numerous, but of great size and of superior quality.

During the two principal days of the show week, upwards of 70,000 people entered the grounds, which, with the extensive buildings they contain, were densely and inconveniently crowded. The presence of his Royal Highness Prince Arthur, and his Excellency Sir John Young, Governor-General of the Dominion of Canada, and our Lieutenant-Governor, tended, no doubt, to increase the number of visitors, for Canadians are proud of British connection, and are always ready to show their attachment to their sovereign by a hearty and loyal welcome to any of her representatives that may come among them. The wise liberality of the Legislature, seconded by the voluntary aid of the people, enables the directors of the Association to offer prizes, both in value and number, that will always command an extensive competition—the whole list amounting to 12,000 or 14,000 dollars, or nearly 30,000 sterling; and while of late years the progress of the Society may be said to have been rapid, its growth has been healthy and enduring. To old-country people, who have had no personal experience or observation of the rapid development of new settlements, it would appear marvellous, bordering on the incredulous, to be told that the pretty and thriving city of our London, surrounded by a rich and extensive farming country, was 40 years ago an unbroken wilderness, and that there were several persons at the recent exhibition held in the "Forest City," who assisted in making the first clearances! Truly this is an age, in more senses than one, of transformation and rapid progress, of which this new world on the western side of the Atlantic affords very many striking exemplifications. *Geo. Buckland, Bureau of Agriculture, Toronto, October 2.*

of all descriptions so plentifully and well for 6d. per week, as the cottager in our rural districts can from his own garden, and this, added to the above 6d. worth of firing, and to the 12s. 1d. will make 13s. 1d. per week. Then there is the difference in the rental of the cottages in town and country to be compared, and here we shall find an important difference in favour of our rural and agricultural men, in our country parishes they vary from 1s. to 1s. 6d. per week, or from 2l. 12s. to 4l. per annum, whilst those of the urban class will range from 1s. 11d. to 2s. 7d. per week, or from 5l. to 6l. 15s. per year, which in the agricultural class will give an average of 3l. 5s. and of 5l. 17s. 6d. for the town classes, or an advantage of 1s. per week in favour of our country friends, which will raise the 13s. 1d. to 14s. 1d. per week. Now, in striking a balance between the two sides of the question, the calculations as above will stand thus:—

Country Class.		£	s.	d.	
Forty-eight weeks at 10s. per week	..	24	0	0	
Four ditto, harvest	..	6	10	0	
Gleaning, 3 bushels, at 48s. per quarter	..	0	18	0	
Rough fuel, wood, roots, &c., worth 6d. per week	..	1	6	0	
Vegetables, worth 9d. to 1s. per week, say 6d.	..	1	6	0	
1s. per week less rent	..	2	12	0	
		£	5	12	0

Town Class.		£	s.	d.
Fifty-two weeks, at 14s. per week	..	36	8	0
Balance in favour of country class	..	20	4	0

But, to make it quite clear, I will take the above in another way. The farm labourer will get nearly all the wood fuel he requires, and he will only spend 6d. per week for coals against the town labourer who will have to buy all his fuel, which cannot cost less than 1s. per week for kindling, coals, and so forth. The difference between the two classes will then stand thus:—

Country Class.		£	s.	d.	
Agricultural labourer, 48 weeks at 10s. per week	..	24	0	0	
Harvest, &c., 4 weeks	..	6	10	0	
Gleaning corn, 3 bushels, at 48s. per quarter	..	0	18	0	
Deduct—					
Fifty-two weeks' fuel at 6d.	..	1	6	0	
Rent	..	3	5	0	
		4	11	0	
		£	26	17	0

Town Class.		£	s.	d.	
Fifty-two weeks at 14s. per week	..	36	8	0	
Deduct—					
Fifty-two weeks' fuel at 1s. per week	..	22	12	0	
Vegetables, 6d. per week	..	1	6	0	
Rent	..	5	17	6	
		9	15	6	
		£	26	12	6
Balance in favour of the country labourer	..	0	4	6	
		£	26	17	0

Now, thus far, it is quite obvious, comparing the two classes side by side, that our agricultural labouring friends need not feel at all humiliated in comparison with their town compatriots, for the purchasing power of our country class, even taking them at the average wage of 10s. per week, is quite equal, if not superior to that of their competitors. But if we take our horse-men, who, as many well know, earn from 1s. to 1s. 6d. and 2s. per week above the other men, the comparison is even yet more on the side of the rural class. Besides, many of the men spend more time in the year at piece-work than by the day, and many thus, with threshing, draining, and haysel taken into account, earn from 2l. 10s. to 4l. in addition to what I have calculated, and which would increase the balance in favour of our country friends by that amount.

We will just look at the physical and moral condition of the two classes, which may be very well taken into account; and I do not think our agricultural labourers ought to be stigmatised as a helpless race, when we can see with regret that their fellow labouring classes, and the poor in the large towns, are, in too many cases, in a dreadful state of poverty, squalor, and wretchedness. By their overcrowding they become a debilitated and degenerated race, a state of things which happily amongst the rural classes has no parallel. From what is stated by an able writer, Dr. Stallard, while writing of pauperism and the poor and labouring classes in London—which town he looks upon as "a magnified representation of all large towns,"—it would seem that the helpless dependence of these classes is so great that one-sixth of the population in the first half of 1863 received parochial relief. Speaking of the Holborn Union, Dr. Stallard says the physical condition of the labouring classes has undoubtedly degenerated; of Bethnal Green he says the same. "I venture to assert," he says, "without fear of contradiction, that there is scarcely a native male adult in Bethnal Green who is fit for military service; nowhere is the standard of comfort so low." A very large proportion of the "debility, deformity, disease, and premature deaths" amongst the London poor, as well as the want of stamina in after life, is owing to insufficient, irregular, and unwholesome feeding during the period of growth. The late Mr. Bryson, the town surveyor of Newcastle, strongly laments the want of good accommodation for the working classes. Mr. Errington, the registrar, writes that many of the houses in the overcrowded parts of Newcastle are wholly unfit for human beings. This is a representation of the state of our large urban labouring classes, who are often huddled together as closely as pigs, without any regard to sex. With reference to education, the rural labouring classes in some of our most purely agricultural counties are proved, by the Registrar-General's report, not at all behind some of the great manufacturing and mining centres; for instance, in Westmoreland, out of those married, the men signed their names in the proportion of 84.1, and the women 85.2 per 100. The proportion in Rutland was 79.0 and 87.4 per 100 respectively; while in manufacturing Lancashire the proportion was

Foreign Correspondence.

ONTARIO (UPPER CANADA): The Provincial Exhibition.—From the returns made to this department the average of farm crops in this province appears to be considerably greater than for some years past. There are a few sections of the country, not of the Rindge area, in which the midge (Wheat-fly) and rust quarters have been very destructive, and in other places their Wheat. Insects have been felt, but in a much inferior degree. I shall state, and in large districts it may now be regarded as almost entirely gone. The yield of Wheat, in the 11s. 9d. unaffected districts, will vary from 18 to 30 bushels per acre, the latter being occasionally exceeded in cases of superior cultivation. Oats in general are a heavy crop, say from 40 to 60 or 70 bushels an acre. Barley has been given. The culture of the latter is this season increasing, a large portion of the crop being a market in the States. Notwithstanding the fact that a price duty of the American tariff, Canadian Wheat, from its good malting quality, is regarded by the Americans as a necessity, and the same remark applies to the finer varieties of Peas, which are a heavy crop this year, and in general of excellent quality. Indian Corn is in most places very inferior, the summer temperature having fallen below requirements of that crop, and the unusual character of the season has also, to some extent, been prejudicial, as likewise in the case of Melons, Tomatoes, &c., grown in the open air. Pastures have maintained a beautiful green through summer, a phenomenon quite rare in this climate. Keep for stock has consequently been abundant, and hay has yielded from 1s. to 3 tons per acre; the quality in some instances is more or less inferior in the making. Haymaking with us is generally very simple and rapid process, and when a rainy season comes on our farmers, from inexperience, work to advantage or rather don't work enough, and the hay frequently unnecessarily suffers. Potatoes are a heavy crop, but some varieties on wet land are suffering badly in the rot. Root crops of all kinds will be generally abundant. The cultivation of Turnips, Carrots, and Mangels is, in the better favoured districts of the province, steadily, if not rapidly, increasing; and I have seen as heavy crops, and of equal quality, grown in Canada, as are usually to be met with under a thorough and expensive cultivation in England. Although the average of our cereal and root crops per acre must be regarded as comparatively low, owing to the rough state of newly but imperfectly cleared land, and often very superficial preparation, I am convinced that a large portion of the arable soils of the province would produce even less, certainly no more, if subjected to similar treatment. On the whole, Canadian farmers have every reason to feel satisfied and thankful for a bountiful harvest; and, although prices may look a little lower than what we have been accustomed to of late, the greatly increased growth of the present year will more than compensate for any diminution of prices we are likely to experience.

The 24th annual exhibition of the Agricultural and Horticultural Association of Ontario was held last week at London, and proved a great success. The entries in various departments, comprising live stock, agricultural and horticultural products, implements and machines, manufactures and fine arts, amounted to upwards of 7000, being equal to, if not greater than, previous occasions. The horses and finer breeds of cattle and sheep were not in number, and in some instances, perhaps in quality, quite equal to what I have seen on similar occasions in older and more advanced parts of the province; but the display of pure-bred stock of the principal breeds that are to be found in the mother country, from which we are frequently having importations, are certainly highly creditable. The skin and energy of our farmers. The display of grain and dairy products was remarkably good; and the various implements, machines, carriages, &c., the skill of our mechanics in adapting his productions specially to the wants was strikingly manifest. In a country where labour is scarce and consequently dear, we have seen to agricultural mechanics mainly for improving and cheapening cultivation, and in this respect much

Farmers' Clubs.

LAVENHAM.
The Agricultural and Town Labourer.—At the last meeting of this club Mr. BAKER read the following paper:—I think I may say this subject would not have been thought of had not a stigma been cast upon the agricultural labourers, by some members of a conference held in London, at Willis's Rooms, to consider their position. It is not to be wondered at that the town labourer should be considered the better off when many talk, as though the country labourer belonged to a race of some inferior beings, when at a conference they were spoken of as "helpless and down-trodden and depressed," and as much too "helpless" to help themselves, or possess any independence, on account of the aforesaid ignorance and helplessness. These are some of the epithets indulged in by some of the speakers at the above Willis's Rooms conference, who, if they had taken the trouble to extend their vision, would have found such language not any more deserved by our rural than our urban population.

We will now come to the question of wages at the present time, and in doing so I shall only draw a comparison between the agricultural labourer and the unskilled labouring classes in our towns, and shall deal, as a rule, only in general terms, and approximate as near as I can to a fair view of the two sides. I find that in 1837 our country weekly labour wage was 11s. per week; in 1868, 10s., in 1869, 10s. 9d.; so we may fairly, at the least, take the average at 10s. per week for the last three years, and the unskilled labour in our town populations from 12s. 6d. to 15s. per week, or say an average of 14s. per week; and, whether the country wage is 9s. or 11s., and the town labour 13s. or 15s., it will not materially affect their comparative or relative positions to each other. I contend, and I think I shall be able to show, that although our rural classes, as farm labourers, do not receive so much in a weekly money wage as town labourers, yet with their harvest and other advantages, they more than equal those in the town. Amongst these advantages is that of having a cottage garden, in which, as a rule, he can grow all his vegetables for his daily use, in addition, there are great numbers who have allotments likewise, and many get sufficient hedge stuff with wood, roots, &c., as rough firing, to carry them through the year—all of which the town labouring classes have to pay for in hard cash, and to this we may add the little item of gleaning corn to the country labourer's advantage and account. We will not say anything about piece-work, and the additional earnings made thereby, with the exception of harvest, which is a material addition to the weekly income. Take a harvest at 6l. 5s. to 6l. 15s., for four weeks per man, it will add 4l. 10s. to the 10s. per week, or make an addition to the 10s. of 1s. 8½d. per week, or 11s. 8½d. per week through the year. Gleaning, which I have spoken of, and which is not to be picked up in the streets of our towns, is a nice little adjunct in aid of the necessaries and comfort of our rural cottages of homes, and I think, when we have heard of from 2 to 4 bushels per cottage being gleaned, we may fairly assume 8 bushels to be about an average, and, by taking Wheat at 48s. per quarter, this will be 18s., or say about 4½d. per week added to the 11s. 8½d. which will make 12s. 1d. per week; the wood, scrap faggots, and rough stuff that arise through the winter months are frequently enough to be worth in many cases 6d. per week through the year; nor can the urban labourers and cottagers supply themselves with vegetables, &c.,

influence upon agricultural progress it will materially help to maintain. The labours of Mr. W. Smith, of Wotton as the pioneer of steam cultivation, have been the subject of discussion and recognition. The subject was discussed by M. Dumas, the distinguished French chemist, in his country, and notably to the experimental farm of Mr. Lawes, at Rothamsted, and to the sewage farm at Park Farm, which deserves a record for the attention which has been directed by it at once to the long-continued and valuable labours of our great agricultural chemists, Messrs. Lawes and Gilbert, in the domain of agricultural theory, and to the leading question in the domain of agricultural practice, which is receiving so satisfactory a solution in the hands of the Metropolitan Sewage Company."

Handbook of Hereford Cattle. Vol. VII. (Hereford: Messrs. W. & A. G. Walling, Printed at the Times Steam Printing Offices, Maynard Street.)

Thomas Duckham has issued another volume of his Handbook of Hereford Cattle. It contains under the pedigrees of 731 bulls, from No. 2906 to No. 3636, of about the same number of cows; and about 300 of the best herds and breeders are referred to in its pages. The book is illustrated with lithographs of several of the most noteworthy animals, and there is an appendix containing the prize lists since the last issue; and a report on a lecture on the breed, given by Mr. Duckham before the Brecon Agricultural Society.

We may add to our notice of this book some reference to Mr. Duckham's quarterly record of Hereford Cattle—a pamphlet which he circulates among the breeders and sellers of Hereford stock in promotion of his business as an auctioneer in connection with the breed. The present number contains some interesting memoranda as to the fortunes of the breed in other countries, and we quote the following notice of how the Herefords are liked in Michigan. Governor Crapo, of Flint, writes thus of them:—

The Herefords have done extremely well; in fact, they could hardly have done better. They have had no more than ordinary fair keeping, and yet they are in the same condition, and their coats are very fine. I have no doubt that the Herefords will yet be the stock of Michigan. They are docile and hardy, besides being easy keepers; and I have no doubt will stand a severe winter, and come out ahead of the Short-horns in the spring, on two-thirds the cost of keeping. I have raised with them, and shall increase the number of my herd as rapidly as possible, being confident that as soon as their merits are known they will be appreciated. There is now almost a mania through the country in favour of the Shorthorns, which I am to admit are a noble and valuable breed of cattle; they are adapted to the luxuriant pastures and the climate of Kentucky, rather than to Michigan. I have seen my Hereford bull VELVET JACKET, my Shorthorn bull LUCIFER, both about the same age, and I am obliged to feed the Shorthorn on nearly twice the grain, &c., that I do the Hereford, to keep him in equally good condition. Shorthorns are undoubtedly a valuable breed from which to procure grades by crossing with our native or common stock, where meat is the object; but for a rough-bred race of cattle I have no doubt that, in Michigan, the Herefords will prove unrivalled. I intend, however, to give the Herefords, Shorthorns, and Devons a fair trial, both as full-bloods and grades, and my health will permit me to carry out my original intention.

Farm Memoranda.

LANSHIRE, BOYNE DISTRICT: Oct. 18.—A long and tedious harvest is all but completed; a few fields remain out yet, but the crop was generally in about 10 days ago. The harvest in this quarter was cut about September 1, and quick work was made in cutting down of it—cutting with machines being the rule, and the scythe the exception. Every kind of corn is being tried, but the manual delivery by Brigden & Bickerton, Berwick, seems to be most in favour, and some excellent work has been made; I suppose no one could tell how much it has cost them here, but as much as 12 acres a day has been cut by some of them. It was mostly all cut before the weather broke, but very little was carried, so that the corn was stacked in bad condition, and a good deal was sprouted in the stook before it could be put in condition for carrying. Some of the stooks stood more than a month, so that very few fine samples will be found in this quarter, but all acknowledge to being a better crop than last year, although scarcely worth an average, and to go through the country a person could form little estimate of the bulk of the stacks, as the stacks are built in all sizes and shapes, and mostly all have wood in the inside of them. A great deal of it has been heated, and some, we believe, from steam thrashing-machine and threshed out a great deal of it and sent it to the market, which has taken the price down considerably. The rain, which did so much harm to the grain crop, has been very beneficial for the Turnips, and a bad crop of this year is scarcely to be seen. Very few of the Turnip crops are taken up yet, but they appear to be doing well. Our stock in this quarter are all very healthy, and very few cases of foot-and-mouth disease are in the country. However, we are well prepared to deal with it as all the machinery of the Contagious Diseases Act has been set in motion, while stock are mostly all in fat stock. A good few bullocks are being sent to the Christmas shows, and we have no doubt that Banffshire will stand its ground manfully as before. The plough is at work on most farms, turning over

the stubble fields intended for Turnips; the wet weather is keeping back the Wheat sowing; clay-land is very wet. Saturday the 16th was the worst day we have had for many years, and, in consequence, low-lying fields are standing in pools.

When the weather clears up, Potato-lifting and Wheat-sowing will be the pressing operations of the farm here, but until the land is in better condition we must work and wait. W. J.

The Poultry Yard.

We recollect, many years since, when geese were supposed to belong to Lincolnshire, the fenny parts of Cambridgeshire, and places where there were extensive commons, that it was said nothing would eat after a goose. We believe the first who said so was a wag, and belonged to the society where they said that in an adjoining parish only one bell was rung at a wedding, but all were tolled at a funeral (there was but one). That at another place you must be careful not to tie your horse to a tree, because it involves a fine of 100l. (The place is on the seashore, and there is not a tree.) So the goose; it is not that nothing will eat after it, but if it be Grass, the truth is the goose leaves nothing to eat. The sharp sides of their bills cut it off close to the ground. We said a short time since, when speaking of Michaelmas, that geese seemed to be out of season at that time, there being little or no demand. The quarrel is not, however, with the bird, but with the season. Where one goose was eaten at Christmas 40 years ago, 100 are eaten now, and they make good prices, provided they are large. Poultry in general is, however, fast becoming a trade. The geese that used to remain the property of the breeder till the Barley stubbles were ready for them, are now sold when a few weeks old to a travelling collector. Such men go about the country where there are commons; they go to Ireland, France, and Belgium. They collect all the geese they can, and bring them to England. Stratford enjoyed almost a monopoly of goose-feeding for many years. A tale is told that when Oats were very dear, there was a meeting of coach proprietors at Romford to consider the price. When they had hailed all their acquaintances, there still remained a man in the room whom no one knew. They looked at him and at each other, they coughed significantly; at last they begged him to leave. He said he thought it was a meeting to consider the price of Oats. "So it was. Who was he?" "A goose feeder." The announcement was received with shouts of laughter. This soon ceased when he showed he consumed many more Oats than the largest coach proprietor in the room. Those days are gone; the coaches are become things of the past, and the goose-feeders have gone to Lincolnshire and Cambridgeshire. Railways have rendered carriage easy and cheap. Contiguity to London is no longer an essential. When all was brought to London in cart or waggon, every mile was of importance, on account of cost and time. Now the "iron horse" snorts his way, heedless of weight or speed.

We suppose it is natural for men to grumble. It prevents fits of ill temper. There are those who say the milk that travels up 100 miles, and is then dispensed by unquestionable cockneys, clad for the occasion in white smock frocks, is not so good as that which used to be carried by the strapping milkmaids, wearing their shiny leather ankle-boots, and notorious for their gaily-coloured cotton kerchiefs. And Strawberries are now brought to town in long skeleton carts, while many can recollect, during the Strawberry season, a line of fast-walking and gaily-dressed young women, each carrying a large round basket on her head, filled with Strawberries. These came about every two hours, and supplied the principal dealers. People say they were better than now. All this is to end by saying that in our fast-living days a man can hardly allow himself to wait till September to sell the bird he hatched in March or April, he therefore sells his gosling to the "feeder."

Many years ago the distinction was so marked, that in the market they were known as "country" and "feeder's" geese. There is now little need of any distinction—all are "feeder's." But we mourn over the legitimate farmer's goose—the stubble goose. No other bird of the tribe is as good; no other feeding made so good meat. What a depth of breast, of rich, juicy, tender, succulent meat! What flavour! Such an one, eaten with Apple sauce as brown as itself, and leaving the question of stuffing an open one, would go far to make us wish there were at least one Michaelmas Day every week, and that, eschewing the modern style, we had an old-fashioned stubble goose to keep it upon.

Poultry Keeping.—[The following is the advice of the Rev. F. Watson at the late meeting of the Great Braxted Labourers' Friend Society:—The first question was, Does poultry-keeping pay? Perhaps just now, when pigs are selling at very high prices, it may be more profitable to give the dross corn to them; but, generally speaking, he was sure poultry did pay. Mr. Fowler, of Aylesbury, who is celebrated for his poultry, says that his poultry-yard has yielded him a return of 500l. per annum for many years past, and the profit varies from 60l. to 80l. He is very successful in prize taking; he cannot expect every one to be so, but he feels sure a profit of 10l. per 100 acres on all farms ought to be made from poultry alone. In Norfolk there are market people who make a good livelihood by their trade in poultry. Their custom is to purchase the poultry and eggs from the farmers in their neighbourhood, and take them to Norwich market. Every Saturday the large space opposite the Town Hall is filled with them; these are the persons who purchase young turkeys of the farmers every autumn, and fatten them for the London market at Christmas. If poultry-keeping does not pay, it ought to do so, when

the London public are content to pay 7s. and 8s. for a pair of spring chickens about the size of partridges, and 2d. for eggs called English new-laid. The best kinds of Poultry are the Dorkings and the Bramsh Peckers; the largest dead chickens Mr. Watson ever saw were a cross between these breeds. At Cucknashford show last year Mr. Dowsett carried off both prizes for chickens, with two pairs which weighed respectively 16 lb. 14 oz., and 16 lb. 9 oz. But if people were satisfied with plump, rich-flavoured chickens, weighing about 3½ lb. each, they could not do better than keep game fowls. With regard to ducks, the Aylesbury were the best. Mr. Fowler has exhibited some weighing 18 lb. per couple. The best food for fowls is Barley and Wheat, barley-meal and oatmeal; and for ducks the best food is tallow greaves, soaked or boiled in hot water, and then barley-meal and bran mixed with them in the liquor altogether. Grains mixed with barley-meal are very good, all whole corn given to ducks should be thrown into water. Oats thrown into a pan of water whole are the best for geese.

Miscellaneous.

Death of Mr. H. Stratford, Jan.—We very much regret to see the announcement of an inquest at Camboise, Northumberland, before Mr. Lonsdale M. Cokeroff, on the body of a young gentleman named Henry Stratford, of the Civil Service, who died on the preceding Saturday from injuries received in a coal mine. From the evidence it appeared that the deceased, together with his friend, Mr. F. Vine Bainsford, a Swedish engineer, and the chief viewer's son, under the care of four colliery employes, made a descent down the West Sleekburn Pit, when a roof stone, coming away, struck his back, broke his thigh-bone and foot, besides causing other injuries. Mr. Stratford made great progress towards recovery for the first week, but then a change for the worse set in, and the unfortunate gentleman expired on Saturday, October 2, at Camboise Vicarage, where he and his friend were on a visit. Verdict, "Accidental Death." He was the only son of Mr. H. Stratford, of Euston Square, the Shorthorn auctioneer, and was a well known member of the London Athletic Club.

The Earl of Rosslyn and his Tenantry.—On Saturday evening the Earl and Countess of Rosslyn entertained their tenantry at Dysart, on the occasion of the birth of an heir to the estates. The noble earl, in proposing "The Dysart Tenantry," said that they were second to none in Scotland in point of the antiquity of their holdings, as well as second to none in prosperity. That was owing, he would say without hesitation, to a good understanding between the landlord and tenants. It was owing to the fact that the landlord and tenants on the estate, if they had any differences and difficulties, had come together. The landlord had always been accessible to the tenant, and the tenant ready to hear what the landlord had to say, and between them, without any recourse to third parties, they settled matters amicably and pulled together well. They heard in the newspapers of large estates well managed, and yet the tenants were not contented. They heard of the law of hypothec on one side, and the game damages on the other, and 50,000 things rising to distract the amicable relations between landlord and tenant. As to the law of hypothec, it was so simple, and entirely a matter between man and man, that he could not understand any party trying to make it a political question at all. It had nothing to do with politics. It was a law which gave the landlord the first claim on his farm. At this moment the question was complicated with a great cry about tenant-right in Ireland, and the great cry about that at this moment was simply because the Irish had never had leases. They had had holdings of lands without leases, and if a tenant spent any money upon his farm he might be turned off, especially by a capricious landlord, without getting compensation. Nothing could be more unjust or unfair. If it had been carried out in this country we should have had a rebellion long ago. In this country, however, it had always been the custom to have leases, and he hoped it would continue. He did not want the landlord to have an unjust and undue power, but merely that he should have a security for that back rent which it was the custom to have in Scotland, and which enabled men who might not have an accumulation of capital to enter farms which otherwise they would be unable to stock. As to the game question, he was quite satisfied of this, that if there was an undue proportion of game on a farm doing damage to a crop the landlord must be a knave or a fool who did not remedy it. How could a man maintain a farm and be expected to keep a large amount of game? He could not understand that for a moment. He, for one, declared that he would destroy every single head of ground game, if necessary, rather than that his tenants should suffer from their ravages. But he was sure there was not a man present but would be sorry if his landlord wanted a day's shooting and could not get a shot at a rabbit or a hare. Common sense and fair play was what should prevail in a matter of this kind between landlord and tenant. For himself he proposed after this term to give his tenants the right of killing their own rabbits.

Calendar of Operations.

OCTOBER *Manuel harvest* generally takes place about the end of October. The crop should be pulled and stored before frost sets in, otherwise it is liable to rot in the pits or barn. In tailing no more should be removed than the small rootlets and earth, and the tops should be twisted and not cut off the bulb. The roots are generally stored in pits and barns like Potatoes and Carrots, but in some cases in narrow bins between hurdles stuffed with straw. The Mangels in the bins above the hurdles are raised in the form of a roof, and

thickly thatched with straw, and the bins are placed alongside each other sufficiently close to keep out frost, while they let steam out and air in. The tops are generally ploughed in for manure. Dry settled weather should be selected for the work.

Autumn manuring for Spring Beans.—The operation is similar to that for winter Beans. During this month farmyard manure can be carted on to the land without doing comparatively any harm in dry seasons, and in wet ones what little harm is done is greatly rectified by the winter frost. It is otherwise in early spring, and besides the carting, when the manure is applied at this season, the drills are in a better and more forward state to receive the seed in spring by dibbling in on the winter made staple, which forms a fine seed-bed for this crop—much better than when the land is newly cultivated.

Parsnips require to be early sown in spring, by the middle of February, and as the land can be more easily manured at this season, it should be done. But, apart from this, the Parsnip is a plant that requires the manure to be thoroughly incorporated with the land before the seed is sown. The land should be a fine deep, dry, friable or sandy loam, deeply cultivated, and in a high state of fertility. The land requires to be deeply ploughed, then smashed across. It is then drilled and dunged in the usual way, and in covering the manure the drills should be well ridged up to the winter frost; or if the intention is to sow on the flat, which is generally the preferable plan, the manure should be carefully covered 4 to 6 inches deep.

Carrots.—The Belgian and common field Carrot require the land to be cultivated, manured, and prepared for them at this season as above described for Parsnips. The former is grown on a greater variety of soils, and the latter on sandy soils, of a less fertile description naturally; but they both grow more freely on land that has been manured the previous autumn.

Potatoes.—Many manure the land at this season purposely to improve the quality of the crop, likewise for getting the earlier varieties planted in time in spring. Cultivation and manuring similar to that for Carrots.

Mangel Wurzel.—Some apply farmyard manure at this season, either on the flat or in drills, and then artificial manures at the time of sowing. Manuring at this season is a great relief to spring work cultivation.

Steam Ridging and subsoiling. In all the above examples of autumn manuring for Beans, Carrots, Parsnips, Potatoes and Mangels, the ploughing, smashing, ridging and covering the manure is best done by steam, and where land requires it, it may be subsoiled at the same time. After the land has been cultivated for a length of time by steam to the depth of 12 and 14 inches, it may then be turned up to this depth, placing the furrow slice upside down. But at the commencement of steam tillage, when the land previously has only been ploughed to the depth of from 6 to 7 inches by horse teams, subsoiling for a few years is preferable to turning up the land to twice the old depth with the plough. It may be smashed up to twice the depth without danger, but it is seldom advisable to plough deeper than the old furrow. But after the subsoil has been thoroughly loosened and aerated, and noxious salts either oxidised or washed into the subsoil or through drains, the land may then be ploughed to the proper depth at this season. Over a large area of Scotland and the north of England all the stubble lands for the ensuing green crops are ploughed to the depth of 12 or 14 inches at this season by four-horse teams, and we have followed the same practice in Huntingdonshire with equal success. But, at the commencement, the land must either be subsoiled for a few years, or the work of deepening done by degrees, not more than 2 inches of the subsoil being brought to the surface at a time. By steam, however, the work of deepening may be done much more advantageously by a subsoiler below the common plough or ridge plough. Thus, in opening the ridge furrows for the manure, the ground on which the manure is to fall is subsoiled; and, in covering the manure by splitting the ridges, the open furrows are subsoiled, leaving it in the best possible condition for the successful winter drainage of the land.

Live Stock.—Brood mares require double attention at this season, for independently of their physical condition naturally, the foetus now begins to draw heavily upon the daily sustenance of the body, more especially if only recently separated from their foals. The diet should be nourishing, cooling, and slightly laxative. Foals, whether newly or recently weaned, also require special care, otherwise their growth will be checked, and their symmetry, beauty, and usefulness impaired. The old saying, "Starve a foal at this season, and twice the food saved will not recover the loss sustained," is a true one. After this season, what they gather in the pastures is unfit to support them. Outdoor exercise is needed, but the essentials of the dietary must now be supplied indoors; and whatever the dietary is, they should have been taught to eat it before they were weaned.

Milch cows should now have plenty of green food indoors, as sewage Grasses, where they can be got, and Vetches, Cabbages, and Turnips. In our southern counties they may gather something daily in rich pastures—in the north, very little; and with such soft food hay, chaff, and meal mixed should be given. In short, milch cows are now gradually put upon their winter keep. The old practice of not housing at night before November, when the fires are lighted, is out of date; for although the nights during October are often free from frost in our southern districts, the ground is wet, and nothing is more injurious to a milch cow than a wet, cold bed.

The Dairy during October can seldom be kept sufficiently dry, and at the proper temperature, without artificial heat, and no greater mistake can be made

than to allow the milk room and other departments to become damp and mouldy at this season. Always kindle the fires in time, for "it is easier to keep out than to put out." If this is done, very fine butter and cheese may be made throughout the month, for the milk, although less in quantity, is rich in quality when the cows are properly fed, groomed, and attended to. When fed on Turnips the tops should be given to store cattle. Many farmers prefer ploughing down the green-tops for manure, estimating them at more value for this purpose than for feeding material, owing to the large percentage of the tops being in a rotten and unwholesome state. But, even when all green and fresh, the tops should not be given to milch cows, as they disagreeably flavour the milk. W. B.

Notices to Correspondents.

AGRICULTURAL IMPORTS DURING 8 MONTHS, 1868 AND 1869: R.

Table with columns: Articles, 1868, 1869. Rows include Oxen, Bulls, and Cows; Sheep; Corn—Wheat, from Russia; Barley; Oats; Beans; Indian Corn, or Maize; Wheatmeal and Flour; Hops; Oil Seed Cakes; Potatoes; Provisions—Butter; Cheese; Eggs; Fish, cured or salted; Lard; Meat, fresh or slightly salted; Meat, salted—Bacon and Hams; Seeds—Clover; Flaxseed and Linseed; Rape; Wool, Sheep and Lambs; Yeast, dried.

BLACK LEG H. H. When young animals are progressing too rapidly upon rich food, a condition of things which commonly precedes "black leg," astons may help to lower the plethora of the system, and thus do some little good: but they certainly have no specific influence, and in practice they constantly fail to prevent the disease.

Books: There is no manual of agriculture of much service at "about 2s 6d to 5s in value." You had better apply to Mr Allnut, at the Agricultural Library, No. 200, Fleet Street, for his list and advice.

CLOVER DODDER H. A. Your plant is Clover Dodder. Clover is to be threshed out of the rick, and if not by a special Clover seed machine, it must be passed through the threshing machine two or three times. It is cleaned by fan and "resing" sieve.

THE PRIZE PLOUGH: H. Naim. It is a two-horse iron-framed plough, for horse-work, made by Fowler & Co., Steam Plough Works, Leeds.

W.M. WOOD AND SON have to offer... STOCK of the following: Sycamores, 7 to 8 feet; variegated, 5 to 6 feet; Horse Chestnuts, 8 to 10 feet; Catalpa syriaca, 7 to 8 feet; Laburnums, 4 to 6 feet; Weeping Ash, ex fine, 7 to 8 feet; Ash-leaved Maple, 7 to 8 feet.

Messrs. PAMPIN AND SON have a large stock of the following, and offer them at low prices: Cedar of Lebanon, 10 to 12 feet; Cedrus Deodara, 6 to 15 feet; Aucuba japonica, 2 to 6 feet; Portugal Laurels, 2 to 6 feet; Chinese Arbor-vitae, 5 to 12 feet; American Arbor-vitae, 5 to 10 feet; Thuja aurea, 1 to 4 feet; Green Box, 1 to 6 feet; Striped ditto, 2 to 4 feet; Evergreen Oak, 7 to 10 feet; Yew, Common, 4 to 10 feet; Irish Yew, 3 to 5 feet; Laurel, 2 to 6 feet; Araucaria imbricata, 10 feet; Green Hollies, 1 to 12 feet; Weymouth Fir, 3 to 6 feet; Spruce ditto, 2 to 4 feet; Birch, 14 feet.

Special Offer of New Potatoes. THOMAS PIERPOINT, Warrington. POTATOS introduced by him in 1863... Harry, Kidney, combines in an exceptionally fine quality with elegance of appearance and heavy yield.

LEAF MOULD WANTED.—Any person who has an article to dispose of may apply to J. KENNARD, Swan Place, Old Kent Road, E.

SILVER SAND and PEAT, from Bedfordshire. Quantity. This Sand is acknowledged by Florists as the best yet obtained. Price lists on application to J. ARNOLD, Builder, 29, Clarendon Square, St. Pancras, W.

GENUINE TOBACCO PAPER, of the finest quality, 100s. per lb., or 5s. per cwt. WILLIAM RUSHFORTH, Nurseryman and Seed Merchant.

APPLEBY'S GENUINE TOBACCO PAPER, 4 and 4lb. packets. Testimonials too numerous to insert. Price on application to HENRY APPLEBY (Patentee) Ivory & Son, Nurserymen, D. King, Surrey.

The Cheapest and Best Insecticide. DUTY-FREE. By Her Majesty's ROYAL LETTERS PATENT, and by Appointment to THE ROY. BOARD OF CUSTOMS.

POOLEY'S TOBACCO POWDER, for the prevention and destruction of Blight and other Diseases in Potatoes, and in all the various kinds of Garden and Field Plants.

POOLEY'S TOBACCO POWDER, for the prevention and destruction of Blight and other Diseases in Potatoes, and in all the various kinds of Garden and Field Plants. Sole Manufacturer, T. A. POOLEY, Bonded Wharf, Wapping, E.

LOOKER'S PATENT BARKING PROPAGATING BOXES.—The most simple and by far the cheapest arrangement for raising Cuttings, and other Horticultural purposes. BENJAMIN LOOKER, Inventor and Manufacturer, Kingston-on-Thames.

SHAW'S PATENT FRIGIDOMO. For Samples and Prices apply to J. SHAW AND CO., 29, Oxford Street, Manchester.

E. T. ARCHER'S FRIGIDOMO. Patronised by Her Majesty the Queen for the Devonshire Gardens, the Duke of North Devon's Devonshire, late Sir J. Paxton for the Crystal Palace, Kew; Professor Lindley for the Horticultural Society. The best shading is "Frigidomo" white or brown, made of prepared hair and wool, conductor of heat or cold, keeping a fixed temperature applied. It is adapted for all Horticultural purposes.

ECONOMY IN THE GARDEN.

James Carter & Co. Seed Growers

AND NURSERYMEN,

237 AND 238, HIGH HOLBORN, LONDON, W.C.

CARTER'S

COLLECTIONS OF HYACINTHS, CROCUS, TULIPS, &c.

JAMES CARTER AND CO. strongly recommend the following COLLECTIONS, assorted from the most popular varieties:—

Carter's Collection for Window or Conservatory Decoration, £1 1s.

CONTAINING:

- List of plants including Hyacinths, Narcissus, Tulips, etc.

Subject to variation as the season advances.

McLAREN'S PROLIFIC RASPBERRY. SPECIAL NOTICE.

For full description, see page 989, ii.

Gardeners' Chronicle, Sept. 18.

JAMES CARTER AND CO. beg to state that in consequence of the rapid demand for this valuable novelty...

The entire stock will be held next season by J. C. & Co., and orders are now booked to be supplied in rotation...

As the supply next year will be limited, early orders are recommended.

6 Strong Canes, 7s. 6d. | 25 Strong Canes, 20s. | 12 Strong Canes, 12s. | 100 Strong Canes, 60s.

PARISIAN MUSHROOM SPAWN.

J. C. AND CO. are prepared to supply French Spawn, which is said to be a great improvement upon the ordinary Spawn...

Price 6s. 6d. per Box (sufficient to spawn a moderate sized Bed); Half Boxes, 4s.

Decoration of the Drawing-room.

JAMES CARTER AND CO. offer for this purpose their choice Selections of HYACINTHS as below, including Glasses.

12 choice Hyacinths and 12 new-shaped Glasses .. 21s. 6d. | 12 fine " and 12 new-shaped Glasses .. 19s. 6d. | 12 good " and 12 new-shaped Glasses .. 18s. 6d.

Carter's Collection of Bulbs, for Outdoor Planting only, price 21s.

- List of bulbs including Hyacinths, Narcissus, Tulips, etc.

For full instructions for cultivation, and particulars of the above Assortments, see

CARTER'S

ILLUSTRATED BULB CATALOGUE

For 1869, Gratis and Post Free.

SUTTON AND SONS, SEEDSMEN TO THE QUEEN, READING, BERKS.

VEITCH MEMORIAL.

At a MEETING held in the Council Room of the ROYAL HORTICULTURAL SOCIETY, on WEDNESDAY, October 27, in furtherance of the Proposal to establish a MEMORIAL of the late Mr. JAMES VEITCH, James Bateman, Esq., F.R.S., in the Chair, the following RESOLUTIONS were adopted:—

Proposed by G. F. Wilson, Esq., F.R.S., seconded by Mr. Gibson:— 1. "That, as a desire has been expressed by many gardeners, both in private letters and through the public journals, that the memory of the late Mr. James Veitch, and of the many benefits conferred by him on gardeners and gardening, by the impulse given to horticultural pursuits through his enterprise, influence and example, should be perpetuated by some fitting Memorial, this meeting, fully appreciating Mr. Veitch's claims on the grateful remembrance of horticulturists and the loss which his family and horticulturists generally have sustained by his early demise, determines that effect shall be given to the desire thus expressed."

Proposed by Dr. Masters, seconded by Mr. Standish:— 2. "That a General Committee, consisting of the following gentlemen, who have signified their approval of a 'Veitch Memorial,' is hereby constituted for the purpose of carrying out the foregoing Resolution—

- GENERAL COMMITTEE. Mr. J. Anderson, Mead-walk Bank; Mr. James Barnes, Exmouth; Mr. W. Barnes, Camberwell; Mr. A. F. Barron, Chislewick; Mr. R. Bebble, Bleton; Mr. T. Blair, Shrubland; Mr. J. H. Brookes, Carsbalton; Mr. E. Hudd, late of Cobham Hall; Mr. R. Bullen, Glasgow Botanic Garden; Mr. W. Carmichael, Sandringham; Mr. W. Coleman, Eastnor Castle; Mr. T. R. Cox, Clonville, East, Worcester; Mr. J. Cox, Kettle; Mr. A. Cross, Tortworth; Mr. J. Cross, Rendcomb; Mr. W. C. Verwall, Thorpe Parrow; Mr. F. R. Cutler, London; Mr. T. Davis, Bures, Colchester; Mr. W. Dean, London; Mr. W. Dodds, Bower Ashton; Mr. J. Douglas, Loxford Hill; Mr. J. Douglas, K. K. K.; Mr. Downie, Edinburgh; Mr. Drummond, Edinburgh; Mr. M. Dunn, Powerscourt; Mr. W. Earley, Digswell; Mr. G. Kyles, South Kensington; Mr. D. T. Fish, Hurdwicke; Mr. J. Fleming, Clivedon; Mr. W. G. Gaiger, Burton Close, Bakewell; Mr. W. Gardner, Weston; Mr. J. Gibson, Battersea Park; Mr. A. Graham, Tedworth; Mr. H. Hepburn, Searesbrick; Dr. Hogg, London; Mr. A. Ingram, Alnwick; Mr. D. James, Carton Park; Mr. Johnston, Glamis Castle; Mr. T. Jones, Petworth; Mr. J. Knight, Floors Castle; Mr. Lamb, Colston Bassett; Mr. W. B. Latham, Birmingham; Botan. Gardens; Mr. T. Lees, Tynningham; Dr. Masters, London; Mr. D. Matheson, Tulichallan Castle; Mr. C. McDonald, Woodstock Park; Mr. J. McPherson, Osborne; Mr. A. McKensie, Alexandra Park; Mr. J. McNab, Edinburgh; Mr. T. Methven, Edinburgh; Mr. M. Methven, Blythwood; Mr. D. Methven, Edinburgh; Mr. W. Miller, Combe Abbey; Mr. J. Moore, Potter's Bar; Dr. Moore, Glasgow; Mr. J. Moore, Chelsea (Hall); Mr. C. W. Monro, Morston; Mr. J. Pearson, Rangemore; Mr. J. R. Petch, Masley Hall; Mr. T. Rabona, Alton Towers; Mr. A. J. Ramsay, Castleboro'; Mr. T. Record, Lillesden; Mr. J. Robertson, Dublin; Mr. W. Robinson, London; Mr. J. Rust, Bridge Castle; Mr. J. Rutherford, Dublin; Mr. T. Rutland, Benthley Priory; Mr. W. Smythe, Emsley Hall; Mr. Z. Stevens, Trenham; Mr. J. G. Temple, Packington; Mr. W. Thomson, Dalkeith; Mr. D. Thomson, Drumlanrig; Mr. G. B. Tillyard, Brooklesby Park; Mr. A. Toward, Osborne; Mr. E. Welsh, Armagh Palace; Mr. C. West, Carton; Mr. E. Westcott, Raby; Mr. G. Westland, Witley Court; Mr. W. Wright, Plas Newydd; Mr. J. Young, Wentworth.

And that the following Members of this Society—namely, Messrs. Gibson, Eyles, Fleming, Hogg, Masters, McKensie, Moore, W. Dean, and Penny, form a Central London Committee; the following—namely, Messrs. W. Thomson, Anderson, Downie, Drummond, Johnston, Knight, Lee, Matheson, McNab, Methven, Methven (Blythwood), Mitchell, Syme, Bullen, and D. Thomson, act as a Committee for Scotland; and the following—namely, Messrs. McDonald, Dr. Moore, Douglas, Dunn, Robertson, Welsh, West, and Rutherford, act as a Committee for Ireland, with power to add to their numbers."

Proposed by Mr. W. Dean, seconded by Mr. Rus:— "That the various Members of the Committee be authorised to obtain subscriptions in aid of the Veitch Memorial, in their several districts, and that Mr. W. F. Wilson be appointed Treasurer to the Fund thus obtained."

Proposed by Mr. Standish, seconded by Mr. Gibson:— 3. "That Mr. Moore be requested to act as Secretary." 4. "That the Subscription List be closed at Lady Day." 5. "That these Resolutions be advertised in the Gardening Periodicals."

Subscriptions may be sent to G. F. WILSON, Esq., Treasurer of "Veitch Memorial Fund," care of Mr. RICHARDS, Royal Horticultural Society, South Kensington, London, W.

Post Office Orders to be made payable at Kensington High Street. Cheques crossed London and County Bank.

The Gardeners' Chronicle.

SATURDAY, OCTOBER 30, 1869.

MEETING FOR THE ENSUING WEEK. THURSDAY, NOV. 4, LINCOLN 6 P.M.

In a recent number of the "Bulletin of the Botanical Society of France," M. ALPHONSE DE CANDOLLE replies to much of the criticism evoked by the publication of his LAWS OF BOTANICAL NOMENCLATURE, and by the discussion on them at the Paris Congress. We need not enter into the strictly botanical part of the subject, but we may set before our readers the gist of M. DE CANDOLLE's remarks on the nomenclature of cultivated plants. The laws laid down by the learned Professor, and recommended for adoption by the Congress, were given in our columns, 1868, p. 405. M. DE CANDOLLE gathers from what has been said in this and other journals, that horticulturists are not altogether satisfied with the regulations sought to be established. The dissatisfaction arises, in M. DE CANDOLLE's opinion, not so much from any absolute defect in the code, as it does from the want of sufficient knowledge on the part of those who have to apply it. In many cases the necessary data for the application of an exact name are not forthcoming, a state of things unhappily too common, but one not fairly chargeable to any defect in nomenclature. To make his meaning more clear, M. DE CANDOLLE gives by way of illustration the case of a person entering a crowded drawing-room. It may happen that he does not know the name of anybody in the room, or he may mistake one person for another. This is sufficiently annoying, but it furnishes no reasonable ground of complaint against the laws or customs of the country, because every individual in the room has his family and baptismal

names duly registered somewhere or other. The essential thing is to know the persons, or, failing such knowledge, to be able to acquire the desired information. But some persons may have changed their name. True; nevertheless the change is not effected without public notice being in some way or another given of the fact. So in the case of plants; it is not the nomenclature which is at fault. The inconvenience arises from the difficulty which the gardener experiences in carrying out his researches among the botanical records. Ordinary gardeners are not sufficiently instructed to make use of botanical treatises, while more highly educated horticulturists often experience a difficulty from the absence of libraries or herbaria. There are many cities of horticultural note wherein, from the reasons just cited, it would be next to impossible for the inquirer to determine the name of a plant with certainty.

M. DE CANDOLLE then proceeds to express himself in favourable terms as to the establishment of the Scientific Committee, which he calls *parfaitement composé*, and urges the adoption in catalogues of certain signs to indicate seedlings or sports (see p. 492, 1868). These signs are only to be used in cases where the origin of the plant is known with certainty, and where there can therefore be no hesitation as to the proper use of the symbol.

M. DE CANDOLLE, as it appears to us, has omitted one great source of inconvenience in plant nomenclature, and that is the use, or rather misuse, by gardeners and others not acquainted with the laws of botanical terminology, of scientific expressions and denominations. We, of course, acknowledge the right of any gardener or raiser to give names to those productions in whose origination he has had so great a share: what we object to is the application, to such hybrids or sports, of names which in form are identical with those applied by botanists to species. If, for instance, a new seedling Phlox be christened Phlox Fraseri, any botanical reader would infer that a new species was intended; but if it were named Phlox John Fraser, no mistake could possibly occur. The botanist would know that he had to deal with a garden variety, and the horticulturist would in his turn be the gainer, because he would know immediately that he was not talking of a newly-imported or little-known species. The signs proposed by M. DE CANDOLLE for garden varieties might still be attached in catalogues, though they could not be made use of colloquially. This last circumstance affords additional reason for preferring vernacular designations for the quasi-artificial productions generally classed under the head of "garden varieties." Another difficulty in nomenclature arises from the practice some nurserymen have, though we are glad to say this is much on the decline, of naming their newly-imported plants at once on their own authority, without waiting to ascertain from some competent botanist whether the name be properly applicable or not. This of course arises from the necessity, for commercial purposes, of attaching some name to the plant. In catalogues such appellations should be distinctly given as provisional only, and have the word *Hort.* after them. But even in such cases it would be desirable that, pending the registration of the plant in due form, some appellation different in construction from the recognised scientific epithets should be applied, so as to avoid all risk of error, and obviate the dreadful incubus of synonym on synonym.

THE VEITCH MEMORIAL scheme is now fairly launched, and we wish it God-speed. The meeting on Wednesday, over which Mr. BATEMAN presided, was unanimous in its favour, and since some 80 committeemen have signified their intention to work heartily to give it effect, there need now be no fear that it will not be brought to a speedy and successful issue.

The fact that the movement is a spontaneous outpouring of the feelings of gardeners towards one who ever befriended their class, is extremely gratifying, and the sympathy which finds its expression in this graceful public act will no doubt be fully appreciated by Mr. VEITCH's family. To some extent, doubtless, the moving cause is that of gratitude to a benefactor for personal favours, or of affectionate remembrance of a valued friend, but now that a commencement has been made, the sympathies of a more numerous class may be enlisted in giving effect to the scheme, as a mark of sympathy with

a bereaved family sorrowing for the loss of its head.

The many suggestions which have been made as to the form which the memorial should take—all good in their way, but not all equally practicable—and which were brought under the notice of the meeting in the various letters of those who had signified their approval of the movement, naturally elicited some discussion, but it was agreed that nothing definite could as yet be determined, since the result must be governed by the amount subscribed. Instead, therefore, of attempting to solve this point, the meeting was content to affirm generally its preference for a portrait rather than a monument, supplementing this by one or more Veitch Prizes—annual, biennial, or triennial, according to the means at the disposal of the committee—a conclusion which we are able to state will be acceptable to Mr. VEITCH's family, by whom a preference has been expressed for a monument or a portrait, either with or without the suggested prizes or medals as might be found practicable.

The sense of the meeting was taken as to some other subsidiary points, in order to facilitate the working out of the scheme. Thus, though it was felt that the action should be prompt, and the decision as speedy as possible, it was not considered wise to close the subscription list before next Lady-day. The opinion of those who were present was in favour of limiting gardener's subscriptions generally to a guinea, not of course to the exclusion of smaller offerings—the shillings and pence, as Mr. FISH puts it—of under-gardeners and others, while of course the larger offerings of the wealthy will be made at the option of the donors. As regards the prizes, should it be found practicable to establish them, the meeting unanimously decided against adopting the form of a medal, and in favour of a Veitch Prize, to be awarded in money or otherwise, as may hereafter be decided. The prizes, it was understood, should be offered for competition amongst gardeners only; and, whatever number might be forthcoming, it was considered that they should be given to reward the meritorious cultivation of plants and fruits alternately, rather than for novelties, and that they should be distributed in rotation at one or other of the principal exhibitions in London, Edinburgh, or Dublin respectively. The difficulties likely to arise in carrying out the otherwise unobjectionable proposals of a club and a library, were considered fatal to the adoption of these proposals, and much the same difficulty would attend that of the education of orphan children of gardeners, or that of Dr. MOORE's, read to the meeting, to establish a fund for supporting disabled collectors, or their too-often bereaved survivors. The suggestion to add a Veitch Pensioner to the roll of the Royal Gardeners' Benevolent Institution met with greater favour, though, judging from the opinions expressed, the Prize and the Portrait seem to be the forms most likely to be eventually adopted.

We understand that the mode of working out the scheme will be, to consider the members of the General Committee, scattered as they are throughout the United Kingdom, as Local Secretaries and Collectors in their respective neighbourhoods. In this way many hands will make light labour; while as all these gentlemen have come forward spontaneously, we can but conclude that such duties will be to them a labour of love.

— WE extract the following remarks on the management of LAKES and PONDS from the pages of the *Medical Times*:—"Common water exposed to the atmosphere soon becomes mixed with organic matter, from the droppings of birds and beasts and the decayed leaves and other vegetable matter washed into it. What next happens depends on the fact whether the water is in motion or at rest. If in motion, as in a rapid river or a lake, the bottom may be swept clean, for a lake, be it observed, is a body of living moving water—an expansion in the course of a river, not a mere motionless pond. If at rest, the organic matter sinks and accumulates, and undergoes changes when may be detrimental to the health of the neighbourhood. Then the question comes—What is the scientific mode of treatment?—bearing in mind that some ponds, like the London Serpentine, require not only to be made free from noxious emanations, but to be safe means for bathing and skating. One summary mode was adopted with the ornamental water in St. James's Park. It was made universally shallow, with an impervious bottom, so that it may be at times emptied and cleansed. The results are not good. The colour is frightful, the water offensive, and the bottom becomes covered with black mud. The eye gets none of the natural gratification and repose which it expects, the water is shallow and therefore heated, and the accumulation of organic debris considerable. In the Serpentine the colour was

better, the water full of minute green confervæ. On keeping a jar of water from the Serpentine, and one from St. James's Park, in the shade for many months, the former yielded abundant oxygen in the sunshine, and no unpleasant odour; the fact remains that, in this and all other cases, no outlet, organic matter accumulates, and the successive crop of organisms falls to the bottom, dies, and forms mud; for the true mud of ponds is clay or common m.c., but the accumulation of vegetable matter. Even when the Serpentine is remodelled, this will require some provision to prevent its accumulation. Our plan would encourage the growth in it of plants which, by their "previous sewage contamination," and which all the microscopic confervæ, can be themselves removed. Such a plant is the *Anacharis*, which grows greedily using up all impurity, and converts it into oxygen-breathing vegetable tissue, and of being fished out easily once a year, thus leaving a certain quantity of organic impurity from the water. The edges of the Serpentine in Kensington Gardens—should be fringed with those most beautiful of English plants which grow on our rivers—the showy *Caltha palustris*, the trifoliate, *Butomus umbellatus*, the *Epilobium*, *Salicaria*, the *Sagittaria*, *Nymphaea*, *Najas*, like—so that the crowds who hunt the banks for a glimpse of Nature, however slight."

— In a recent article in the "Revue de M. DUBREUIL, speaking of the one of the UNILATERAL CORDON (one-sided) for the Apple, commends an edging for fruit gardens, on the ground that it serves to fill a space which it would be difficult to occupy advantageously. At this M. DUBREUIL cautions growers against two errors in this mode of culture, and which are serviceable to our readers to point out. The first consists in attaching to the wire support the bud which is to prolong the cordon. The error is that the current of sap is impeded, so that the buds receive an undue quantity, and hence the shoots instead of fruit-spurs. To correct this M. DUBREUIL recommends that the terminal bud be allowed to take its natural upward direction, and develop itself freely during the period of growth. The time of winter pruning the branch is to be towards an inclined horizontal to the wire, except 6 or 8 inches at the extremity, which may be to ascend obliquely, so as to favour the development of the new bud which is to prolong the branch. Through the lengthening of the cordons, the buds of adjacent trees join, the ordinary practice being to inarch the extremity of one cordon into the branch of its neighbour at the point where it branches. A continuous current is established between all the branches forming the cordon. This process, says M. DUBREUIL, entails the serious objection that it deprives of their vigorous terminal bud, the development of which induces the formation of new vessels in the cordon of the sap, and favours the development of new roots, which may seek nutriment in so much more rapidly by the growth of preceding years. Moreover, the lateral buds, from the "pinching" of the roots, hence M. DUBREUIL recommends that the terminal process to be discontinued, and that the terminal bud of each cordon be allowed to develop itself freely into a branch. When pruned, the bud may be cut away near its base, above a vigorous bud destined to form a new and vigorous shoot. The consequence of these repeated pruning operations effected nearly at the same point, a gony shoot is formed, hindering the proper flow of the sap to the bud, it is advisable to preserve another bud, and to cut down, so as to secure the formation of a shoot next season. The extremity of the old branch may be cut away immediately above the point of attachment of the new shoot, which latter at the winter pruning should be shortened to 3 or 4 inches. Successive shoots should be pruned, and so on year after year, the main object being attended to being the prevention of the consequences of any swelling that may be formed, and securing every year a vigorous bud at the extremity of the branch, to promote the flow of the sap.

POTATOS.

I AM grieved to hear on all sides of the account of Potatos. Here they are excellent, and from disease. They were dug up by August and not one has decayed in store. Mr. Knox, Leach, the gardeners respectively, of Mr. Fox and Lord Portman, called here this week. Mr. Knox stated that he had 20 sacks (!) of diseased Potatos from his garden. On this occasion Mr. Leach, according to his usual habit, brought me some noble tubers—I never saw any so uniform in shape, well formed, clean in the eye, and perfectly level on the surface. He raised them last year, but never "sent it out." I have not time to report on it, if permitted, next year. The shape of shape is desirable; but, from unprudent selection or grafting, we have got into kidney-shaped Potatos. The Potato is round at one end and kidney-shaped at the other. Rounds should be crossed with kidney-shaped Potatos with kidneys. Strawberry raisers must not be mistaken. Thus we see on the same plant round, conical, and round berries. M. de Jonghe, and M. de Jonghe, late of Frogmore, understand formation of berries. The berries of La Constante, Lucas, and B. Fenby by M. De Jonghe, and of Frogmore Pine by Mr. Powell, raised by Mr. Ingram, both first-class, are my assertion. Be it however observed, that the Potatos and Strawberries, too, are much affected

Very strong rich soil will often force a Strawberry into a cockscomb, and a level Potato into a deep-eyed coarse one. Miss Burt, of Clendon, won the 1st prizes at Blandford with the Silver-skin and Early Blues. I never saw more beautiful Potatoes. Here the Silver-skins were so scurfy, and the Early Blues so deep-eyed and coarse, that I lotted them to the pigs. I sent to the same show a Lapstone, given to me by Mr. Turner, and Cobbler's Lapstone, given to me by Mr. Fenn, and they won some high honours. They were very good indeed. Not thinking of exhibiting, I gave away to a poor man, Bere Regis, from six to twelve each of the best, and what of all my Potatoes. As I was driving along he ran across the field and 'fed my vanity!' saying, 'I read your noble articles on 'taters.' Could you give me

know it to be a very good early sort. As Hero and Taylor's Hybrid are much alike in appearance and identical in flavour and quality, observe the former has short haulm and a white flower, and the latter rather longer and stronger haulm and a pale blue flower. Both are said to have been raised by grafting, the former by Mr. Almond, of Little Fencote, Bedale, Yorkshire, and the latter by Mr. Taylor, of Great Fencote. I know nothing of grafting myself, but I never read greater marvels than were in Mr. Taylor's grafting notes, written five years before he sent them to me, and which, on permission, I forwarded to Mr. Fenn, who has them still. 'Natur,' said Squeers, 'is a rum 'un,' so we must not decide too quickly. Mr. Fenn will do all that can be done in the matter. I think if a weak-growing kidney was inserted into a strong-constitutioned one, constitution might be imparted. At present I must rest here. We want to know, as Mr. Dean says, when the new roots become independent of the tuber. I imagine they draw from it a very long time, because, if you cut a piece off a tuber it will rot, and the crop will ripen some days before it will ripen from an uncut tuber. So say the shrewd Yorkshiremen. Mind the words—'Early ripeners and late keepers.' I am safe till next June. It is fair to say the Cobbler's Lapstone and Pebble White do not ripen quite so early as the above; and when supertuberation sets in early, none will grow out more quickly than the Cobbler's Lapstone. It is the King! W. F. Radcliffe.

NEW STRAWBERRIES.

WE are indebted to Messrs. Vilmorin-Andrieux & Co., for the following descriptions and engravings of eight new varieties of Strawberries raised by the late Dr. Nicaise, whose fame as a successful raiser and grower has long been favourably known.

Perfection (fig. 1).—Fruit large, conical, and pretty regularly formed; seeds prominent and regularly disposed, of a lively reddish colour, contrasting with that of the skin, which is of a dark red, merging into a deeper tint; flesh dark red, juicy, sweet, and fine flavoured. The aroma somewhat resembles that of Brune de Gilbert. The plant is a strong grower and hardy, resembling Marguerite (Lebreton) in the disposition of the foliage and in the form of the fruit. It is very prolific, and appears to be exceptional in quality.

Passe-Partout (fig. 5).—Fruit very large, the first crop producing broad and flat specimens, after which they come of a more elongated form; seeds almost black, slightly prominent, and widely separate; skin of a deep

FIG. 1.

FIG. 6.

FIG. 2.

FIG. 4.

FIG. 7.

FIG. 3.

FIG. 5.

glossy red colour; flesh red, streaked with white, sweet, slightly acidulated, and aromatic. The plant is of medium height, with very dark green leaves and hairy leaflets; it is a vigorous grower, and late.

Abd-el-Kader (fig. 6).—Fruit very large, sometimes enormous, usually elongated, but often roundish; seeds prominent; skin of a bright vermilion-red colour; flesh dark salmon-coloured; sweet, slightly acidulous, aromatic, and highly flavoured. The plant is dwarf, but vigorous, in growth, having small leaves, with elongated leaflets supported on smooth slender stalks. A pretty variety, of a peculiar structure, which would make a fine contrast in a collection.

Gabrielle (fig. 7).—Fruit medium-sized, round; seeds not very prominent; skin of a rather dark shining red, flesh red, firm, very juicy, sweet, and exquisitely flavoured. The leaves of the plant are strong and straight, with nearly round leaflets on long smooth and very stiff stalks. It is a hardy, prolific, and very late variety, of great merit.

François Joseph II. (fig. 8).—A fine large fruit, of a

Yorkshire Hero?" I sent him, with others, 12 such potatoes as I never saw before. Another year Miss Burt must take extra care. I am, however, always glad when the ladies win. She exhibited the best specimens of "taters" I ever saw at an exhibition. The destruction of Potatoes is not only a national but a national discomfort, I venture to press on the necessity of planting "early ripeners and late keepers." Yorkshire Hero and Taylor's Hybrid are the sorts to have, they come out of the ground by August 7, and keep good till June. I dug my Potatoes in the 4, but so good were the Heroes that my servants preferred them to the new Royal Ashleafs. —Round Potatoes: Gryffe Castle Seedling and Royal Early Emperor Kidneys, Royal Ashleaf, Yorkshire Hero, Taylor's Yorkshire Hybrid, Cobbler's Lapstone, and Pebble White, sent here by Mr. Fenn. As far as I have tasted my Potatoes of the year, the last has been the best: it is a species of Lapstone. I have not got Mr. Myatt's Kidney, but I

Alexandra (fig. 1).—Fruit very large, roundish, and flattened, sometimes assuming the shape of a horse-shoe, in which case the fruit is sometimes larger than the variety called Dr. Nicaise; colour, deep orange-red; seeds close, not very prominent, of a yellowish colour; flesh rosy, and highly flavoured. A very good and distinct variety.

Penelope (fig. 2).—Fruit very large, round, sometimes flattened, of a pale red colour; seeds small, distant and rather prominent, flesh salmon-coloured, sweet, juicy, slightly acidulous, and strongly flavoured. The plant is dwarf in growth, and produces few leaves, with hairy leaflets. It is hardy, and very prolific.

Amazona (fig. 3).—Fruit large, of an elongated conical form, which is almost always regular in outline; seeds not deeply embedded; skin of a light reddish colour, with a tinge of vermilion on the top; flesh white, inclining to rosy, sweet, and very aromatic. The plant is vigorous in growth, of a medium height, hardy, and prolific.

beautiful roundish heart-shaped form; seeds yellowish and prominent; skin of a brilliant rose colour; flesh rosy, and of a most agreeable flavour. The foliage of this variety is of a bright shining green colour. A vigorous-growing, hardy, and prolific variety.

REVIEW OF THE GENUS NARCISSUS.—V.

Group III. (Continued).—PARVICORONATE; crown less than half as long as the divisions of the perianth.

In this paper we propose to treat of the four remaining vernal species of the Parvicoronate group, which taken together may be known from all other Narcissi by their saucer-shaped crowns, from a line to one-eighth of an inch in depth. Of the four, three are quite common in cultivation.

14. N. pachybulbos (Durieu, Revus Bot. 2, p. 425).—Bulb ovoid, 2 inches or more thick. Leaves 4-5 to a scape, flat, caescent, about a quarter of an inch broad, flattish, with a blunt keel. Scape under a foot high, compressed and acuticulate, 5-9 flowered. Longer pedicels about equalling the spathe. Tube pure white, half an inch long above the ovary. Expanded flower 6-7 lines across, pure white, the segments of the limb not more than a quarter of an inch long, and consequently only half as long as the tube, roundish, much imbricated, cuspidate. Crown not more than a line deep, subentire, pure white. Anthers biserial, subsessile. Walpers' Annales, 1, p. 838; Durieu, Expl. Alger. t. 47, fig. 1.

A native of Algeria, not yet, so far as we are aware, in cultivation in England. It comes very near to some of the small varieties of Tazetta; even if it were introduced, the flowers are too small for it to be likely to be a popular species. It is said to be slightly scented.

15. N. juncifolius (Linn Sp. Plant. p. 417).—Bulb ovoid, under an inch in thickness. Leaves 1-2 to a scape, deep glossy green, 8-12 inches long, semi-linear, channelled down the face, about a line in thickness. Scape equalling or shorter than the leaves, slender, subterete, bearing 2-6 fragrant flowers in the latter part of April. Spathe 18-21 lines long, the longer pedicels about the same. Tube 10-11 lines long, exclusive of the ovary. Divisions of the limb a bright full yellow, spreading horizontally when fully expanded, 3-4 inch long, slightly imbricated, oblanceolate or obovate cuspidate. Crown saucer-shaped, not more than a line deep, about the same colour as the limb, the edge faintly crenulate, about 3/4 inch across. Anthers sessile, biserial, the three upper ones protruded into the crown. Curt. Bot. Mag. t. 15. Redouté Lal. t. 159, Reich. Ic. t. 811; Queltia Jonquilla, Herbert and Kunth; Juncifolia, minor, media, and parvicorona, Haworth, Mon. p. 7.

This, the well-known Jonquil of the gardens, extends in a wild state from Spain, through the south of France and Italy, to Dalmatia. It has often been confounded, both in books and gardens, with N. juncifolius, but is much more robust in general habit, with larger and more numerous flowers, and a crown considerably shorter in proportion to the divisions of the limb. We have never seen any variation of the colour, which is a beautiful bright yellow. It is, perhaps, the most fragrant of all the species, and is often seen with double flowers in gardens.

16. N. biflorus (Curt. Bot. Mag. t. 197).—Bulb ovoid, more than an inch in thickness. Leaves about four to a scape, 3-4 inch broad, slightly glaucous, flatish bluntly keeled, often more than a foot long, compressed, with two salient edges, bearing typical flowers at the beginning of May near London. Spathe about 2 inches long, usually exceeding the pedicels. Tube about an inch long, exclusive of the ovary; expanded flower 15-18 lines across, the divisions milk-white (not so pure a white as in the next), spreading horizontally when fully expanded, 3-4 inch long, 3-4 inch broad, obovate, much imbricated, blunt or cuspidate; crown 1-1 1/2 line deep, less spreading than in poeticus, yellow, about a quarter of an inch across, the edge conspicuously crispo-crenulate. Anthers sessile, uniserial at the throat of the tube. Eng. Bot. t. 276, Red. Lal. t. 405, Kunth, Enum. 5, p. 73, Reich. Ic. t. 810. N. poeticus, Hudson; N. cathartica, Salisb. Prodr. p. 225. N. triflorus and dianthus, Haworth, Mon. p. 14.

Though this is said never to perfect its ovules and pollen, it is very common as a wild plant, has become naturalised in abundance in many counties of Britain, and is distributed on the Continent, through France to Switzerland, Italy, and the Tyrol. Grenier and Godron (Fl. Franc. 3, p. 257) describe an intermediate between this and Tazetta, under the name of Tazetta poeticus, with smaller and more numerous flowers than in biflorus, and a longer, deeper-coloured crown, which is the N. biflorus, var. hybridus, of De Candolle's "Flore Française;" and Dr. Henon, who made during many years a special study of the French Narcissi, writes as follows—"The station of Lattes, near Montpellier, is remarkable in that it offers many species mixed in the same meadow (poeticus, angustifolius, biflorus, Tazetta), as well as a considerable quantity of intermediate forms, varieties, or hybrids. In 1810, along with MM. Dunal, Delille, and Bouchet, I asserted that at this station might be seen all the passages from poeticus to Tazetta passing through biflorus without any appreciable line of demarcation. This assertion was strongly criticised; but verification being made on the spot with M. Delille, it was established that the fact was beyond doubt."

17. N. radiiflorus (Linn Sp. Plant. p. 414).—Bulb ovoid, about an inch in thickness. Leaves 3-4 to a scape, flat, with a blunt keel, glaucous, often a foot or more long in cultivation, 3-4 inch broad. Scape a foot or more high, compressed and two-edged in the typical plant, producing near London one or very rarely two flowers in the latter part of April. Pedicel generally much shorter than the spathe, which is 1 1/2-2 inches long; tube white, 12-14 lines long above the ovary, and about a line in thickness; expanded flower 21-24 lines across when expanded, with a distinct and agreeable odour, the divisions a pure snow-white, obovate, blunt or cuspidate, slightly imbricated, 6-9, or sometimes in cultivation even 12 lines broad; crown 1-1 1/2 line deep, saucer-shaped, very much crisped, with a bright scarlet edge, the mouth 4-4 1/2 lines across; anthers sessile, subuniserial at the throat of the tube. Eng. Bot. t. 275, Red. Lal. t. 160, Reich. Ic. t. 808.

Very common in cultivation, and extending as a wild plant all through the south of Europe, from France to Greece. The principal varieties are as follows:—

Var. 1, radiiflorus.—A more slender plant than the type, with narrower leaves, and obovate divisions of the limb of the

flower so much narrowed downwards that they are not at all imbricated in the expanded flower, and also more narrowed at the point. Crown rather narrower, and consequently more erect. Flowers at least a fortnight earlier than the type, generally in the first week in April near London, or even the last in March. N. radiiflorus, Salisb. Prodr. p. 225, Reich. Icones, t. 809; N. angustifolius, Ait. Kew, edit. 2, vol. 2, p. 241, and figured by Curtis in the "Botanical Magazine" under the name of N. maialis, which is afterwards corrected to angustifolius. A very handsome plant, truly wild in the Alps of Central Europe, and admitted both by Koch and Reichenbach as a distinct species.

Var. 2, stellatus (N. stellaris, Haw. Mon. p. 15, Sweet, Brit. Flow. Gard. ser. 2, t. 132).—A late-flowering form, with the divisions of the limb, as in the last, narrowed at the base, and not imbricated.

Var. 3, recurvus (N. recurvus, Haw. Mon. p. 15, Sweet, Brit. Flow. Gard. ser. 2, t. 188).—A late-flowering form, with weak recurved leaves, and the divisions of the limb reflexed and crisped towards the edge.

Var. 4, poetarum (N. poetarum, Haworth, Mon. p. 14, N. poeticus, var. grandiflorus, Herbert and Kunth).—An early form, with the expanded flower 2 1/2 or even 3 inches across, and much imbricated divisions.

Var. 5, verbenensis (Herb. Amaryl. t. 37, fig. 2; N. verbenensis, Room. Amaryl. 240).—A very slender late variety, with the divisions of the limb reflexed, 8-9 lines long, which are yellowish at the base.

This concludes the series of the species, with the exception of some little-known narrow-petaled autumn-flowering species, and the very abnormal N. Broussonetii, to which my next paper shall be devoted. J. G. Baker.

Home Correspondence.

The Royal Vineyard Grape.—Having had great experience in Grape growing, including the Royal Vineyard, I will here explain my mode of setting its fruit. The Royal Vineyard is one of those kinds that produce a quantity of little water-like beads on the pistil of each flower as soon as it opens, and which, in my opinion, is the cause of its bad setting, and, to further the process, I gently draw my hand down the bunches about twice during the few days they are in bloom, taking care to keep my hands dry; and I have no hesitation in saying they will then set as freely as any Hamburg or Sweetwater. Like some other kinds, they will crack a little at times, but I have not found much of this with Vines planted inside, and where the borders are kept moderately dry when the fruit is beginning to ripen. Unlike the Barbarossa, and some other late-keeping varieties, that crack across the centre and point of the berry, the Royal Vineyard cracks just round the footstalk. In point of flavour, for a late-keeping white Grape, I consider the Royal Vineyard next to the Muscat of Alexandria. A. S.

Yellow Bedding Plants.—Some few weeks ago I was travelling from Chelmsford to Ipswich by railway, when I was very much struck with some remarkably long rows of a beautiful yellow flower (not unlike a Tropaeolum), in what seemed to me to be nursery ground, not far from the Ardleigh station. I am unable to say whether it was a Tropaeolum or not, as our speed was too great to define it. I have just been informed that the above grounds belong to Messrs. Carter & Co. If such is the case, and these gentlemen would kindly state what the plant in question was, they might possibly be doing a service to the gardening world. Judging from what I saw of the Viola lutea at Battersea and other places this summer, I should be indeed chary about doing away with the Calceolaria and substituting it; after all, the Calceolarias are not to be despised, for with a little system and forethought we may have them in bloom from June till the end of the season—I allude to Gaines' seedling and aurea floribunda. The Tagetes signata pumila, though considered rather dinky, is nevertheless very effective for autumn work. Thomas Simpson, Broomfield, Chelmsford [Messrs. Carter & Co. inform us that the part of their seed farm which borders the Great Eastern Railway near Manningtree Station was set out with annuals as follows, arranged in long rows the entire length of the field: Mignonette, Virginian Stock (white), Candytuft (Dunnett's extra crimson), Nasturtium Tom Thumb (yellow), Collinsia atrorubens (purple and white), Nasturtium Tom Thumb (scarlet), Virginian Stock (rose), Chrysanthemum (new golden), Candytuft (purple), Candytuft (white), Collinsia multicolor marmorata (pink and white); and they further say, "We arranged them to contrast colours, as we thought they would be admired by the railway passengers as they passed down the line; and we are very pleased to learn, from your correspondent's inquiry, that they have produced the desired effect."—In your impression of October 16, Mr. Bennett, of Osberton, in again advertising to the Calceolaria having proved uncertain in many places, asks "Where shall we get a substitute?" That has yet to be found, but not in yellow Pansies, although they are very good in their way. I see no difficulty, however, in growing the yellow Calceolaria. All the plant wants is a deep soil with a cool bottom. The largest Calceolaria plants I ever saw were grown in a farm garden where the soil was undrained, and consequently very damp. A little dung from the farmyard was dug in before winter into the strong clay border. Small plants planted out in May became large shrubby specimens by October. In light soils, dig the soil out of the beds you mean to plant; put a good layer of rotten cow-dung in the bottom; fill in the soil again, and plant. All the Calceolaria plants that I have treated in the above way have done admirably. They were watered when planted out, and only once after (in 1868), and they bloomed up to Christmas. W. Hutchinson, Llwyndu House, Abergavenny.

Passiflora macrocarpa.—Yesterday I cut one of these fruits, which in colour and shape resembled very much a rather unhandsome Vegetable Marrow. It weighed 4 lb. 13 oz., girthed lengthwise 27 inches, and round the middle 19 1/2 inches. Its smell was rich, and I should be rather inclined to say heavy—certainly not so tempting

as the smell either of a Pine-apple or a Melon. The fruit is the first ripened from a small plant which I had spring was planted in a brick box in a French nursery, and I have sent the fruit to the family, and I have not had time to have a description of its eating qualities. I will forward to you if you wish it. It is made into a compôte. E.D.s. At the same time the same box was planted a Stephanotis floribunda, which grew amazingly, and flowered freely on the Pine stove, also in the same box was planted a P. edulis, which, however, grew so freely that to be cut away to make room for the P. macrocarpa, but in a tub at the other end of the Pine stove. The P. edulis, which fruited freely, setting its fruit with the assistance of the P. macrocarpa, which requires to be fertilised. I cannot say that the P. edulis is disagreeable, but my taste has not got sufficiently educated to like it, though I am told that when eaten with a little sherry it is excellent. Wm. Miller, Combe Abbey, October 26.

Judging Melons at Edinburgh.—The Melons which the Melons at the late International Exhibition in Edinburgh, were judged, has, both among the exhibitors and onlookers, excited much inquiry. It was that there was something new in the means of the censors in finding out the merits of the Melons. A reporter remarks that old Melons were taken by surprise; I may add that many were equally astonished at the fruit, but neither did the largest or handsomest Melon. Some suppose that the smell would be the by which the judges were guided. The Melons who were taken by surprise know well that of Melons often have very little perfume, past use, and some of the worst smell on pleasantly. There were two classes at the exhibition, scarlet-fleshed and green ditto. We saw how the one colour can be known from the other without cutting. It often occurs, when a cross between two kinds, that the fruit has the outward appearance of one parent, and the flesh of the other. When cutting is not practised, coloured flesh could easily be exhibited in Melons. I merely write for information. Being a grower of Melons, I am eager to learn the means of proving their quality, as it has sometimes been that I have sent to table what I considered a Melon, which after it had been cut was found to be for use. So much for appearance and smell, when suspicious of bad quality, tasted Melons by the same method that vendors try cheese, ripened without deforming the fruit. I think it would be also applied at exhibitions, and then the appearance arising from cutting the fruit would be avoided. J. O.

Wasp's Nests.—I have had a good deal of experience in taking wasp's nests in various ways. The best, but not the best, is that practised by boys, where one digs out the nest in the middle of the day, whilst two or three others stand round with a stick to knock down the wasps as they come out. Half the wasps belonging to the nest are killed about, to do more mischief, I believe, than they had the nest to work at. Then there is the plan of putting a squib into the nest, and digging out the nest whilst the wasps are busy with the smoke. I used squib cases made of tubing. Some skill is required in making the hole so that it should always be effectual. Sometimes 2 or 3 feet from the entrance, but we have sometimes 2 or 3 feet from the entrance, and the passage may run horizontally close under the ground, and in such cases it requires a well made hole to reach them. But I have given up this plan, and a simpler one of pouring about half a pint of kerosene into the nest at night. This also will reach the nest. The wasps will then be killed, and make a fresh entrance nearer to the nest. A dose of gas-tar be repeated, it will almost certainly reach them. I generally dig the nests out about the end of the day, and give the larvae to the chickens, and fond of them. I have occasionally known this to be that the eggs have tasted of kerosene, doubt chloroform would do instead of kerosene; but I have never tried it. It would be expensive if there were many nests to take, and a most curious way of destroying wasps, if a piece of sponge or rag dipped in cyanide of potassium placed just at the entrance of the nest, and that comes near it drops down dead. In a few days no more wasps come out of the nest, and which come back to it die—so poisonous is the gas which it gives off. When nests are taken there will still always be a few wasps taken at home. Every one of these may be placed a bottle upright in the ground, and the entrance to the nest was buried up to its neck in the bottle. They never come out, and I have sometimes had a common quart bottle full, and sometimes there will be not a dozen or two of stray wasps. C. W. Strickland.

The Troubles of Exhibitors.—As Mr. Bennett's letter confirms mine in every particular, I will reply from me; but as he wins up by putting the sole blame upon Mr. Ward, perhaps I am fairly entitled to a line or two in extenuation, would, however, be a good rule for all exhibitors to write their name and address in large characters on the inside of their box lids, as an instruction to the unpackers, and as an address for their return journey. Doubtless Mr. Bennett's all other exhibitors will do this for him. And his not doing so was the fault, and he took that he committed. In every case he took special care to be right. Mr. Ward seems surprised that Mr. Ward moved in the matter. What! sit down

adopt, as the flowers are only exceptionally circinate; Muller gave the name *A. Wilkesiana*. The synonymy of the plant would therefore be, *Acalypha Wilkesiana*, Müll. Arg. (*A. circinata*, A. Gray, MSS. in Herb. Kew; *A. tricolor*, Seem. MSS.). *Berthold Seemann*.

Viola Blue Perfection.—Mr. Bennett's remarks about yellow bedding Pansies (p. 1033), in which he has so ably championed their adaptability for the summer decoration of the flower garden, has induced me to say what I know about the good qualities of this *Viola* for a like purpose. I had the pleasure of first making its acquaintance at Wilton Park last August, and if I did not hit my hat to it on so doing, I at least paid the homage of declaring it to be the gem of the flower garden there. It was used as a belting for a round bed, with, I think, a centre of white variegated *Pelargonium*, and the effect it produced was so good, and its character, whether in habit or colour, so striking, that I vainly tried to ascertain what it was, but no one could tell me. Mr. Challis, the gardener to Earl Penbrooke, was unfortunately not to be met with, so that I could get no information from that source; however, I at last met with Mr. Waring, of Salisbury, and he informed me that, though growing it himself, he was ignorant of its correct designation, and it was not common in the locality, but he would vouch for it that it was a most continuous bloomer from early spring to late autumn. Fortunately Mr. Jobson, of Rotherfield Park, Hants, sent a plant of it to South Kensington, and got for it a First-class Certificate under the above name, and so cleared up that mystery; but how it originated seems to be yet unknown. Gardeners will find this *Viola* to be a great acquisition as a blue bedding plant, as it is an immense improvement on *cornuta*. *Alex. Dean*.

Potting Lilliums.—Allow me to thank "W. E." for the very practical hints which he gives us week after week. It will be admitted on all hands that the *Calendar* has never been filled with better instruction. I have been a reader of the *Gardeners' Chronicle* for at least 20 years, and have never seen the "*Calendar of Operations*" so well filled with useful matter as now. But does "authority" exclusively belong to that page? or is it ground whereon those only who will sing "*Quantum libet*" may tread? What means "W. E.'s" phrase, "authoritative tone of denial?" I stated my experience; what better authority is there than that? I grew up amongst Lilliums, and have had the advantage of seeing them potted under many circumstances, and have potted them myself times enough to enable me to condemn the practice of storing away the bulbs until spring. I can scarcely understand "W. E." No one will blame him for acting as a *chaperone* to "J. D." who possibly may be of the fair sex. But "W. E." says he can emphatically endorse the advice given by "J. D.," i.e., pot your Lilliums in the spring; and afterwards he says, the best time would be somewhere in January. This is said in a tone not "authoritative" enough to please me. "J. D." will have something to do to make even town folks believe January to be spring. I say you cannot state within a week when to pot all Lilliums at every place. My advice was, to do so when the stem is dead, and I still uphold it. The stem is kept alive sometimes by roots emitted from itself, independent of the bulb. These roots sustain it after the bulb has stopped its supply, consequently the bulb is at rest previously, and the stem becoming dead—and when that is dead, "the advent of the resting period" is long passed. Leaving the bulbs until they have begun to make roots is the cause of more failures than "W. E.'s" *argumentum ad ignorantiam*. "W. E." advises those who "value their bulbs" to follow the advice of Mr. Smith. I have no doubt Mr. Smith can give sound advice, but your readers will be discouraged to find that Mr. Smith has said absolutely nothing about the time of "potting" Lilliums! Who will set us right? and "authoritatively" tell us which is wrong? *M., Oct. 18.*

Duke of Cornwall Melon.—I can endorse all that Mr. Simpson has said in favour of this valuable, but little known variety. It is to be had in perfection to the end of December or middle of January, and is particularly well adapted for pot culture in Pine stoves, as it delights in a strong heat. Poor soil increases its fertility and diminishes its size. It has filled up a blank long felt, viz., a first-class late Melon. *James O. Smythe*.

Coloration of Leaves.—The case you give at p. 1033 of the change of the colour of the leaves of *Pelargonium l'Elegante*, by simply twisting the leaf-stalks, is one of considerable interest, and opens up a wide field for experiment. There can be no doubt of the fact, that in many cases the first result of a check to the sap, or a bruise on the tissue of leaf, flower, or stem, is a change of colour. In the latter case, the change may simply be the result of a disarrangement of cellular structure. The normal organisation is broken up, the cells are pressed higgledy-piggledy into each other, and consequently the light is reflected or absorbed in a different manner to a different extent; and at a change of angle, the light medium being changed, a change of colour would necessarily follow. But it is not quite so easy to see why a change in the quantity or quality of the sap should result in a change of colour, and yet such changes may also be simply mechanical. Vessels fully distended with fluid will present somewhat different angles to such as are partially collapsed, and the light falling upon the latter would be reflected differently. But it is not simply that the amount of sap would be lessened by the twistings adverted to, but its quality would be altered. The mere hindrance at the injured portion would affect the sap that had to wait at the barrier. The interruption would gorge the sap vessels underneath to repletion. This would force the fluids below the barrier into closer contact with the light, and thus bring a maximum amount of inspissatory force to bear

upon it at that particular point. The result would be, that the sap that passed through the barrier would be thicker beyond it than if it had not been stopped; and this difference of quality, combined with the contracted state of the half-filled upper cells, would produce the change of colour. The quantity and quality of the sap being thus changed, such changes necessarily affect the structural arrangement of the leaf. The latter being altered, ever so slightly, would necessarily affect the number, rate, and direction of the rays of light reflected from or absorbed by it. This change of quality and position of the leaves is probably the chief reason of all the varied tints they manifest throughout the season. The bright greens of the opening spring, the sober and staid colours of the summer, and the glowing tints of autumn, what are these but the reflexes of altered structure and the sure indexes of changed position? The sun impinges upon them at different angles all through the season, and very largely according to the transparency, or opaqueness of the reflector, the leaf or flower, will be the colour. Of course I am not advancing this as a satisfactory theory of colour, but simply as a reasonable explanation of the changes in the same plants throughout the season, and of others that may be artificially induced. Change of front, or of cheek to the colouring medium alone, has a wonderful effect upon colour. For example, take this very plant, *Pelargonium l'Elegante*, train it up to a stake—that is, connect it with a pillar or a pyramid—and the leaves will begin to glow into a pink at once, without any artificial tinting or bending. This is a fact that I have proved for myself, and therefore there is no uncertainty about it. Many of your readers cannot have failed to notice the two very fine pillars of this plant shown at the Royal Horticultural Show at Manchester. They were exquisite examples of cultivation, and their leaves glowed almost into scarlet from top to bottom. But none of the leaf-stalks seemed to have been twisted. If they were, of course we shall hear about it from the exhibitor whose name I regret to have forgotten. But assuming that they were not bent, whence the colouring? Why, they bent themselves. There may be exceptions, but as a rule this variety does not colour much, if at all, when running on the ground. It has shown no pink whatever with me in the flower garden. It is naturally a true ivy-leaf, keeping close to the ground; and with leaves, hugging it pretty closely, offering up the whole surface to the sun, at nearly a right angle. Train it up to a stake or over a pyramidal trellis, and this position is much changed. The fact is, the leaf of this *Pelargonium* has this peculiarity—it is dense and weighty for its size and the strength of its footstalk. Hence, no sooner is an attempt made to make it grow upright, than down go the leaves to an unnatural position; and this, I believe, is the chief secret of the excess of, or the change of, colour. Mere intensity of light will produce the same effects in a modified manner. Some plants of *l'Elegante* grown on brackets in the spring were suffused slightly with pink. But here again the natural position of the leaves was affected by hanging down, so that it is impossible to say how much of the colour was owing to the closeness to the glass, and how much to the weeping position. Scarcely any plant seems more susceptible to this pinking than the *Panicum imbecille variegatum*. Its beautifully green and white variegation may be made almost red by growing it in a strong light. I have seen a basket plant of this, with the very stems changed into the brightest colour, and both the white and red portions of the leaves crimsoned over with glowing brightness. The colouring of this *Panicum* is likewise much affected by the temperature in which it is grown. In the stove it dresses itself in its gayest colours, and is a charming addition as a basket plant among roof climbers on brackets, or covering a trellis. It is also good for running among ferneries, &c. Permit me to conclude with the following question: How is it that so many of our tricolor *Pelargoniums* are so much more perfectly coloured in the autumn than at any other season? That they are so, few flower-gardeners will deny. At the present moment such varieties as *Lady Cullum*, *Lucy Grieve*, *Miss Watson*, *Mrs. Pollock*, *Sunset*, glow their brightest just before the frost chases them away from our sight. Is it the hectic flush of coming death? But how, then, is it displayed? Is it the dying sun painting his loveliest before he sinks into winter somnolency? or is the long night of darkness preparing for him a better canvas for the fixing of its tints? or what is it? The fact of the beauty of such plants growing with the declining year must be acknowledged by all careful observers. How comes it, and by what ministry? *D. T. Fish*.

Tropaeolum Bothwellianum.—One of the most effective wall plants that has ever come under my observation is the *Tropaeolum* named above. It covered 100 yards of a wall 7 feet high that separates the quaint and beautiful flower garden at Bothwell Castle from the pleasure grounds; but it not only covered it in the ordinary way that *Tropaeolums* do, but with a sheet of the most brilliant orange-scarlet that ever eyes beheld; and as it is probably the most valuable acquisition of its kind, and has been distributed by Mr. Turnbull to many of his noble employer's friends, I proceed to give some description of it in the interests of gardening. It is one of the *Lobbianum* section, and may be considered as a selected seedling several times removed off *Brilliant*, having much of the characteristics of that flower, with the additional decided advantages of being of denser habit and infinitely more prolific in bloom. The fine purple or claret-coloured stems, and the entire almost orbicular leaves, of an olive colour, render it very marked. To that must be added the short footstalks which carry them, and the shortness of the intervals which enable the flowers in the one case to throw themselves clearly in advance when fully expanded, and in the other to

increase the yield of bloom in any given distance. The flowers themselves are of a brilliant orange-scarlet with the two top petals adorned with black radiating lines. On the southern exposure of this garden these flowers were literally studded along the wall, so dazzling that none of the tribe referred to could compare with it, and with the additional advantage, on inspection, of beautiful foliage set behind them to garnish them. I saw this on October 1, when I was gardening generally in the more inhospitable part of the North showed most things flat and dead. I have not exaggerated the picture. Even at the low part of the garden was "over" in my interest, but this and the 8-foot border adjacent which may be represented as an instance of a "border improved, and keeping pace with the improvement" of the times, was as showy and generally vating a piece of flower gardening as could anywhere be seen—thanks to the *Tropaeolum* referred to, and parti-coloured hues of thousands of *Dahlias* blooming in grand style. All hail to the *Dahlia* yet as an ever bedder, and never too fiery in effect from its clothing of leaves. *Delphiniums*, *Stocks*, and the blue, and orange of *Alyssum*, *Lobelia*, and *Geranium* made up, with some other mixtures, a gorgeous *ensemble* that might feast the eyes of flower-lovers days and days. One other word by way of comment to Mr. Turnbull's seedling, and that is, that of it was associated with the common *China* in the fine soft pinky blooms peeped out with advantage at intervals, and so would fallow some of the selected hybrid perpetuals, only the chance of association. *A.*

Foreign Correspondence

CENTRAL PARK, NEW YORK.—The general idea of this park having been described (p. 1017), I now advert to a few particulars respecting its arboriculture.

One department worthy of special attention is the Arboretum, which occupies about 40 acres, and is selected so as to interfere as little as possible with the more special requirements of the park. It is a collection of American and other trees, and one who wishes to become acquainted with the arborescent vegetation that will flourish in the north and middle sections of America, should visit this Arboretum. It is not arranged in a regular manner, but is so planned that all the most beautiful features of lawn and woodland landscape are preserved intact, so far as is possible, the natural relationship existing among trees and shrubs, which he may search of, without difficulty.

As regards plantations in the park generally, there have been made about 11 years, and the growth of trees and shrubs is highly satisfactory. The planting for the most part is in groups or masses, and of a kind similar to the way in which plantations are carried out in the public gardens of Milan, and in other public parks in Italy and France, the object being an improvement as regards picturesque effect of our parks at home, where the dotting and massing of trees and shrubs is followed, without regard to kind, character, colour, or foliage. As regards trees and shrubs of a deciduous character, the Americans have a much richer field in which to work than we have; and the pictorial effects which they produce, especially in public parks, are, for the most part, that can be desired.

Flower gardening seems to occupy but little attention, even in places where one might expect to find it as in public parks and open town spaces, and the flower is to be met with. It is intended, however, believe, some day to have a flower garden in Central Park. Among the most noteworthy trees in the park, of course, the "big tree" of California, and a variety of *Conifers* in general, various *Blechna*, including the pretty little hairy-leaved species of the Alps; nearly a dozen different kinds of *Strawberries*, which, when in bloom, have a rich and striking appearance; various other flowering trees and shrubs, and good sprinkling of weeping trees.

An essential feature of most metropolitan parks is an avenue or grand promenade, level, open, and shady; and this has not been overlooked in Central Park, in which there is a short but fine avenue of American *Birs*. This is appropriately named "Vine" in this instance being *Wistaria*, and is led over a flat top, supported by massive pillars placed 9 feet apart, and set in stone plant-boxes. Of the latter there are 70, and each contains one plant of *Wistaria*, which is trained to cover both top and pillars. When I saw it in full bloom, which was about the 20th of May, I saw, either indoors or out, I never witnessed a walk. An amazing amount of surface is covered when in blossom, and of all the floral displays in the world, I never witnessed a more beautiful and adequate idea of its great beauty.

Of water there is plenty, and it forms a conspicuous object in the landscape. True, the great reservoirs which supply the town are placed a little too high to be seen from points from which it might be desirable to see them; but besides these there are other ornamental water-works which have received skilful treatment, and which are most effective. These cover an area of nearly 40 acres, a portion of which is in the form of lakes, and in other shapes. At one part a ravine has been opened, and a small stream of water is here and there carried down from miniature cascades as it falls over boulders. Numerous rustic rock fountains for supplying pedestrians with drinking water have been provided in different localities, fountains of this simple, natural character have the merit of being less expensive and more pleasing and satisfactory than any other for park purposes. There are also large ornamental drinking fountains for horses, with tazzas in their centres, furnished with cups for birds. It is also proposed to have an establishment in the park where springs and wells of artificial mineral waters may be dispensed to convalescents and invalids, as well as to the public generally, and a firm, eminent in the preparation of such waters, has, I believe, been appointed to erect an establishment of the kind. Boating on the lake is a favourite amusement, and is every year on the increase. In this way the visitor can pass an hour very pleasantly, and derive new impressions of portions of the park from the water, while the Park Commissioners get a considerable rental from the boat-contractioners, all of which helps towards the better maintenance of the park. These lakes, with their boats and water-fowl, have a truly picturesque appearance. Road and other watering in the park is an operation requiring great attention. There are several elevations to which water will not rise, and these have to be kept in order either by means of engines or water carts. The water distributed over the park by means of carts amounts annually to many thousands of gallons, costing in its distribution many thousand dollars. Some more economical plan of watering is, however, I believe under consideration.

That portion of the park which is termed the terrace, is extremely effective. In the valley sleeps a placid lake, while a little higher up is a noble stone basin, about 90 feet in diameter, and fountain, overlooked by a terrace set on arches, and flanked on either side by flights of steps, the whole being backed up by a fine plantation of thriving trees on grassy slopes.

Skating is a favourite pastime with the Americans in winter, and for this ample accommodation has been secured. Ice disasters are also provided against, but in a different way from that in which we manage the matter in this country. There, by a well-ordered provision, water can be withdrawn at any time from the height in which it is kept in the reservoirs and lakes in summer, to a lower level, thus leaving only a safe depth below the skaters. The ice, at a large annual expense, is kept constantly clear of snow, which sometimes falls to a depth of six inches during the year. It will then be seen that between boating in summer and skating in winter, the Americans manage to get the maximum amount of enjoyment out of their ornamental waters. What, therefore, need hinder us at home from doing the same? Now that the Serpentine is about to be cleaned out, the American plan as regards skating facilities might be readily applied to it. The water could easily be withdrawn to a safe depth, while, from the fountains near the Bayswater road the ice could be fresh supplied as often as might be required.

The comfort and convenience of pedestrians in American parks are better cared for than with us about London, for under all crossings of drives and rides subways for pedestrians are provided. These subways are not damp or uninviting; on the contrary, they are light, attractive, and ornamental, the principal one among them being used as a refreshment department. They are faced with stone beautifully dressed, and furnished and ornamented with 'stars and stripes' in different colours. Cannot we introduce some improvement of this kind into our London parks, in which, as at Hyde Park Corner, for instance, people on foot have to stand waiting for lengthened periods before even the police can conduct them across in safety. In such cases elegant subways would surely be acquisitions. The principal subway in the Central Park cost a million of dollars.

As regards material for walks, which are generally about 15 feet in width, experiments have been made for several years with cement, asphalt, concrete, and pavement of various sorts, none of which have proved entirely satisfactory, though some have developed valuable qualities. Several pieces of walk have been laid down with a composition of tar, gravel, and cement, coal tar having been first used, and subsequently the ordinary tar of commerce. The appearance when the materials are properly mixed and laid down, is, as far as it has been tested, the most satisfactory of anything that has yet been tried; and it has the advantage of being dry and free from dust, while heat or cold does not diminish its practical utility.

The rust-work employed in American decoration is of a more substantial character than with us. The seats and arbours are ample also; most of the former are furnished with canopies, the brightness of the transatlantic sun rendering shade more necessary than in England. Other buildings in this park are also of a highly decorative character, the band-house, or orchestra, having very much the appearance of those at South Kensington, while the casino, both internally and externally, is very ornamental. In front of the last-named building are a fine drive and grass terrace, with the vine-covered walk already alluded to, the whole being finished off by means of a dwarf wall. The approaches from the lower ground to the walk are furnished with flights of 20 steps.

The entrances to the park are not yet complete, but judging from what I saw of them they will be in keep-

ing with the surrounding objects. The names to be attached to them sound singularly to European ears. Among them are the Scholars' Gate, Artists' Gate, Artisans' Gate, Merchants' Gate, Women's Gate, Hunters' Gate, Mariners' Gate, Gate of All Saints, Boys' Gate, Children's Gate, Minors' Gate, Engineers' Gate, Workmen's Gate, Clergymen's Gate, Pioneers' Gate, Farmers' Gate, Warriors' Gate, and Strangers' Gate. These names have a certain significance attached to them as regards the objects to which they lead. Few glass-houses are as yet erected, but one not unlike the Palm-house at Kew with its lake in front is, I believe, in contemplation.

I may add that rock-work, in connection with water, is extensively introduced into several parts of the park, and is generally so constructed as to be of a bold, natural character. Ferns are used for the decoration of the rocks, but not in sufficient abundance. Intermixed with rock creepers, as they are here, their elegant fronds have, I need not say, a charming appearance. A rock garden forms an interesting screen to the zoological department, which is as yet badly furnished with both beasts and birds. I may note here that, with the view of gathering information on the subject of the insects of the park, a collection of caterpillars has been made, and a proper record taken of the trees which they seem to frequent. This, if well carried out, may afford some useful entomological information. Near a gymnasium is one of the largest and finest trees of Quercus pedunculata I ever saw; it is one of the trees saved from the natural forest, and is one of the largest in the park. A little further on, the visitor gets a glimpse of the highest ground in the neighbourhood, and here it is intended to build an observatory 140 feet high, which, together with the natural elevation of the ground, will be some 300 feet above the datum line of the river. This will form a conspicuous object, seen either from the casino, refreshment pavilion, mall, or terrace.

Before leaving this Central Park I may add that flowering shrubs, especially *Cornus florida* and *Magnolia*, bloom beautifully in it; its water, islands, bridges, which are mostly of a rustic character, its rides, drives, terraces, and avenues are all on a grand and effective scale, and when the band plays on a fine summer evening, one feels that it is what it should be, truly a place for recreation and enjoyment. *Joseph Newton, Oxford Terrace, Hyde Park*

Notices of Books.

Transactions of the Woolhope Naturalists Field Club for 1868 (Hereford) 8vo, pp. 277, cuts and photographs.

A day with a field club in fine weather is almost as enjoyable as a day with the hounds, far more so to some people. In most cases, on such occasions, a great deal is said which, however valuable it may be at the time, is hardly worth recording, unless in the columns of the local journals. The managers of some of these bodies, however, think differently, and the result is that their "Transactions" too often contain a vast amount of twaddle, a large proportion of crude compilation, and a minimum of honest observation. Let us hasten to say that these remarks do not apply, except to a very limited extent, to the volume before us. There is in it, indeed, a slight infusion of what is very pleasant to read of in the county paper a few days after the event, but which is apt, when reproduced in the "Transactions" after a year's interval, to lose its interest. But in the case of the Woolhope Club the proportion of chaff to grain is really very slight, and the papers on local geology and natural history are admirably adapted to convey sound and accurate information, and to excite an interest among the residents in the natural features of their district. The Woolhope Club is fortunate in possessing among its members several accomplished naturalists, who appear thoroughly to understand what are the legitimate objects of such a club, and what are the best means of carrying them out. Two special subjects of investigation, in addition to the general natural history of the county, engage the attention of the club, viz. the remarkable trees of the district, of many of which, in this as in former volumes, small but characteristic photographs are given, and the edible Fungi, of which, also, some excellent coloured figures are supplied. By way of illustration we may cite a passage from a paper of Dr. Bull's, on the Elm—

"The English Elm, in ordinary Herefordshire soil, will grow more rapidly than that most vigorous growing of all the varieties of the Wych Elm, the Chichester Elm, a tree that in suitable soil will often make shoots of from 6 to 10 feet long in a single year. The actual experiment has been made. Planted side by side the English Elm grows more quickly, and general observation here seems to confirm it. I wish to lay stress on this point, because it seems to explain the complaint that has met me from several quarters, that the English Elms you buy now are 'such poor Elms that they won't grow well, and no dependence is to be placed upon them.' The fact is, the English Elms are now sent out grafted on the Mountain, or Wych Elm; they make wood much more rapidly, and have not the disadvantage of sending up suckers from the roots. 'I think I may say, sir, that grafted English is universal in the trade' was the result of my inquiries of a nurseryman. So long as the tree is planted in the rich, heavy soil, so prevalent in nurseries, the advantage is undeniable, a larger tree is grown in a shorter time, and equally good, but removed to the ordinary stiff clay loam of the county (Hereford), and the roots of the Wych Elm root. The tree may grow, but will not thrive. The conclusion is evident. If you wish to plant English Elms in the common soil, you must get them on their own roots, not on the Mountain, and this you must take care to do, or you will grow them from suckers yourself."

A little more editorial care in revising the proof-sheets would be advisable in future years, not only as to the correct rendering of scientific names, but also as to the list of honorary members, among whom we find the names of some, such as Professor John Lindley, who have paid the debt of Nature; Professor John Phillips, too, is still stated to reside at St. Mary's

Lodge, York, though it must be some 14 years since he migrated from the northern city to Oxford. But these are minor blemishes, not seriously impairing the value of a very interesting volume.

Garden Memoranda.

MEADOWBANK, the residence of Thomas Dawson, Esq., is situate seven miles south of Glasgow, in a very quiet part of the country, and is of easy access by railway from the Southside station. This spot cannot fail to attract the notice of travellers by the Caledonian Railway, after crossing the Clyde near Uddingston station, from the extensive ranges of glass-houses, and neatly kept grounds, which at once suggest the idea of a village of glass, surrounded by a miniature park, and reminding one of old stories of moats and fortifications; being skirted on the west by the river Clyde, on the north by the embankment of the Caledonian Railway, on the east by the Uddingston turnpike-road, bounded by a substantial stone wall, on the south by the kitchen garden wall, gardener's house, &c.—access to this garden of treasures being by a small door in the boundary wall.

The first thing to attract the notice of the visitor is the enchanting but unpretending appearance of this garden and chateau of modern times,—

"Where Scottish scene does sit serene,
And Flora's beauties reign supreme."

—the residence and the grounds being alike free from any attempt at architectural grandeur, while Mr. Anderson has made the most of the ground by a series of successful and happy combinations of hardy and half-hardy plants, which are at the same time both pleasing and picturesque. In the more exposed parts of the grounds many half-hardy plants had suffered much from the frost at the end of August. The glass erections are 16 in number, and appear to have been built at different times, according to the requirements of an ever increasing collection; but, from their neat and clean appearance, bear ample evidence of being well cared for.

The collection of Orchids, for which this place is justly celebrated, is in itself unique; and, doubtless, a list of some of the best specimens will be very acceptable to many of your readers, particularly the long list of species in flower on the occasion of my visit on September 17. Having recently visited some of the leading London and other gardens, I was frequently asked what was to be seen at Meadowbank, and some little surprise was expressed by some, and a little disappointment by others, on learning that my visits were few and far between. I trust this short, but very incomplete list, may be the means of satisfying their wants to some extent, while to others it will be a means of extending their knowledge of species which may be had in flower at this season. To attempt anything like a detailed account of this wonderful collection would occupy too much space in your pages. I shall, therefore, confine myself to some of the most remarkable specimens, and to the general species in cultivation in most collections, more as a means of showing the various subjects cultivated together in the same house at this season, than to enter into a description of the numerous varieties with which the collection abounds, not only of those which are described, but those also which are undescribed. Of the latter I had the good fortune to find three in flower.

House No. 1 contained, amongst many others, in flower, the following, which create at this season a magnificent display—*Miltonia Regnelli* full of flower, five spikes; *Zygopetalum rostratum*, fine; *Aerides quinquevenerum*, several fine specimens in flower, one of the finest I ever saw producing six unusually strong spikes on a single stem; several varieties of *Vanda tricolor*, one very scarce, i.e., *Vanda tricolor meleagris*; *Cypripedium Stonei*, one stem with three fine flowers; *Miltonia virginialis*, associated with *M. Morelana*, a specimen 2 feet across, full of flower, the striking contrast of colour producing a grand effect; *Epidendrum cochleatum major*, fine; the Java variety of *Aerides suavisimum*, with four fine spikes; *Dendrobium formosum*, with one lead and two flowers; *Vanda cœrules*, with one strong spike; *Oncidium barbatum*, several plants of this lovely species making a grand display; *Lælia elegans*, in several varieties, one in particular far surpassing anything I ever saw before, both for size and depth of colour, being much darker than any of the varieties called *Turneri*, of which there is a fine example in flower in the same house. *Cymbidium Masterii*, good; also the old *Cattleya guttata*, two plants of *Miltonia Clowesiaana*, with 13 spikes each; *Aerides Thibautianum*, with five noble spikes; two plants of *Eriopsis rutidobulba*, with two and three fine spikes respectively. *Cattleya Leopoldii*, a glorious lot of plants, mostly getting past flower, a hybrid *Cattleya*, between *guttata* and *Loddigesii*, partaking in a marked degree of the characters of both parents, the growth being not quite so strong as is usually seen in *C. guttata*, while the sepals and petals, flushed with a delicate shining rose, are of the same size as and spotted like *guttata*, with a labelum indicative of its close affinity with *Loddigesii*.

altogether a lovely plant, with an apparently strong constitution; *Miltonia Clowesiana* superba, with extra large flowers; *Miltonia virginalis*, also fine; *Zygopetalum Mackayi*; *Cattleya speciosissima*, one of the most showy species at this season; *Miltonia Moreliana*, with 23 flowers; *Saccolabium Blumei* majus, *Calanthe veratrifolia*, *Vanda suavis*, *Oncidium Batemanni*, *Oncidium Papilio*, *Cypripedium Hookeræ*, *Cattleya Aclandiae*, the good old *Coclogyne speciosa*, a grand plant, near 3 feet across, full of bloom; one of the finest of all the *Miltonias*, candida *Jenischiana*, four fine spikes, with flowers of unusual size and colour, in both respects reminding one of *Odontoglossum Inseayi*, with the lip of *Miltonia candida grandiflora*, only brighter in colour and double the size. *Cattleya Trianae* and its varieties will shortly make a fine display in this house, there being many specimens with from five to ten sheaths each in luxuriant health. From the roof are suspended grand specimens of *Dendrobium Cambridgeanum*, *D. cumulatum*, *Limnates rosea*, *Calanthes* in varieties, &c.

House No. 2.—One of the grandest features which meet the eye on entering this house is the unique specimen of *Cattleya exoniensis*, Mr. Dominy's greatest achievement, and certainly one of the most beautiful *Cattleyas* in cultivation. This specimen has 13 growths or leads, which will convey some idea of the size of the specimen; it was just beginning to unfold its flowers, which at a hasty glance would remind one of the most brilliant variety of *C. labiata*: the specimen in question would doubtless be undervalued at 150 guineas. There were also grand examples of the following in this house:—*Cattleya Mossiae*, the Syon House variety, with several leads; also *Cattleya quadricolor*, *C. Dawsoni*, *C. maxima*, *C. Mossiae*, *C. marginata*, *C. Aclandiae*; *Dendrobium thyrsoflorum*, with growths 2 feet 6 inches in length; *Oncidium nebulosum*, showing for flower; *Oncidium Kramerianum*, *O. sessile*, *Burlingtonia fragrans*, and many other grand specimens.

House No. 3 is rather a span-roofed pit, but of large proportions, having no path inside; the cool end of this is devoted to the cultivation of *Odontoglossums*, and a few other plants requiring similar treatment, and the warmer end to a collection of seedling *Amaryllis*, and, judging from the exuberant growth of many of the *Odontoglossums* contained in this pit, it answers the purpose admirably. A long stage, covered with gravel, occupies the centre of the pit, and is of such a thickness as to exclude any direct circulation of air or heat from the pipes below; while the heat rising from the sides disperses itself more evenly, and is a check against a sudden current of cold air from without, the lights having to be tilted in front in the usual way. To enumerate the species of *Odontoglossum* contained in this pit would alone make a long list, and many of the species are represented by the score, some of the following being unusually fine:—*Odontoglossum nebulosum*, *O. Alexandræ*, *O. Pescatorei*, *O. luteo-purpureum*, *O. latro*, &c.; *Oncidium caudatum*, the rare *Masdevallias*, quite at home, as well as many other gems. *Robert Bullen, Curator, Botanic Garden, Glasgow.*
(To be Continued.)

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

VERY careful management will now be required in *Heath-houses* as regards their requirements, under the varying fluctuations of the external temperature, &c. In regard to the inmates, greater attention will be requisite in respect to those varieties, whether of the true *Ericas* or their near allies the *Epacrises*, which are cultivated amidst the various drawbacks always associated with houses in which mixed collections are kept, such, for instance, as many of our greenhouses and semi-conservatories. In either case, a cool temperature, free from any form of draught, is of the first importance. Too dry an atmosphere, or one too densely charged with moisture, are alike objectionable. Then, again, a sour stagnant soil, whether caused by imperfect drainage or a too retentive compost, through an insufficiency of sandy matter, or from the pots becoming dirty on the outside, tends to cause unhealthiness at the root. However trivial the original causes may be, ill health quickly increases in intensity, and hence the need of carefully guarding against these and all similar apparently trifling circumstances. Dispense with artificial heat as much as possible to the last. Covering the exterior of low-roofed houses or roomy pits with mats, as a protection against frosts of moderate intensity, is much better than a resort to fire-heat, however little. In connection with the above, I may refer to another lovely genus, namely, *Leschenaultia*; similar treatment to that which is given to *Heaths* will suit them well, the same attention to trifles being also equally necessary in this case. They thrive best when placed near to the glass, and seldom do better than when elevated to within a few inches of it. Both are very liable to the attacks of mildew, which can only be prevented by keeping the atmosphere moderately dry and fresh. The only safe cure is to apply a good dusting of finely-powdered flowers of sulphur all over. There is also another family of Australasian plants, to which the above remarks may be applied with much force. I refer to the fragrant and beautiful *Boronia*, and especially to *B. serrulata*. These are equally impatient of heat, draught, or damp, and especially dislike being kept over-moist at the roots. Added to which I may draw attention to a fact of no little importance, which is too frequently overlooked in regard to these latter. As is well known, the native habitat of *Boronia serrulata* is a somewhat protected locality upon the coast of New Holland, where it is enabled to fully develop and to ripen well the wood it annually makes. Now we too frequently overlook this fact. With a little extra

heat we may somewhat hurry the growth onward, and then by placing the plants in a moderately exposed, dry, and sunny aspect, we may ripen the artificially formed wood in like manner. Hence, much of the ill-success will be done away with, as the want of a better developed wood-formation is often the cause of the ill-health of this particular species. Let the temperature in all stoves be gradually reduced to an average of 60° by night for the next few weeks, bearing in mind the fact that to start any hard-wooded plants into growth which should now be resting, will be to irretrievably spoil them for a good summer display.

FORCING HOUSES.

All that is required in *Late Vineries* having fruit still hanging, is a minimum temperature of about 40°. This should be constantly maintained by the aid of very slight fires on frosty nights. During fine bright warm days persist in keeping the house as cool and airy as possible, so as to keep the berries from any material change. Remove every symptom of decayed or decaying leaves, and so keep all sweet and wholesome. In regard to *Pines* there may be instances where, for want of more room, the sucker-cuttings have been potted, and placed on a temporary hot-bed composed of fermenting materials alone. Here, in an atmosphere best suited to them, they root and grow freely; but they must not be permitted to remain in such a place one day longer than is necessary at this time, otherwise they will become drawn and weakly, and will not prove so stocky as they should be to form a basis for producing good fruit. A drier atmosphere, with a gradually reduced temperature, must, therefore, be sought for them. Be careful in regard to watering all young successions, those near to flues or other heating mediums will require more frequent supervision in this wise. Get the lights ready for placing upon *Peach* and *Nectarine* houses without further delay, and let them now be put on at the earliest opportunity.

HARDY FRUIT GARDEN.

Persist in wiping off the ripening leaves upon *Peach* and *Nectarine* trees. Already these are very late before they part, and I fear the wood will not be fully ripened, causing the many evils attending such a state to follow, such as gumming, &c. The removal of all leaves at the earliest moment, therefore, becomes a matter of importance. In view of the above facts, I do not advise that the wood should be loosened from the walls quite so soon this season, but rather to keep it attached a week or two longer than the sun may act more powerfully thereon. Do not longer delay the necessary plunging to the pot-rim of all *Strawberry* plants intended for forcing, or others potted up for transplanting out in the early spring, as a protection against frost.

HARDY FLOWER GARDEN.

Those who do not make a display with spring blooming plants, by means of planting those that will flower early into the beds immediately the bedding stuff has been removed, should, now that the frost has destroyed the beauty of the summer plants, have all vacant borders immediately forked or dug up and finished off neatly without delay. It will be advisable at the same time to give the borders or beds a moderate dressing with manure, which, if forked in thus early, will become thoroughly incorporated with the soil, and lose much of that crude strength which is apt to cause strong sappy growth, and comparatively little flower. Where spring bedding is adopted no further delay should now take place in regard to getting all the necessary subjects planted in their permanent blooming quarters. As regards height I may say that the pink *Silene pendula* may be planted in the centre of beds containing either the blue or white *Forget-me-Not*. The thicker these latter are planted now, so much the more densely will the bloom be at flowering time. The stronger the plants of any of the above are now, the sooner by a week or two will they bloom in the spring. This is a matter of some importance, to which I believe I before referred, at the time of sowing. As edgings to the *Forget-me-Nots*, either the lovely little *Saponaria calabrica*, var. *rubra*, the yellow bedding *Pansy* or *dwarf Tulips*, &c., will match well. Whilst the white variety of *Saponaria*, the *Clarkias*, *Collinsias*, *Limnanthes*, *Nemophilas*, &c., would do well to edge the *Silene* or others to which their flowers afford a proper contrast. *Wallflowers* will transplant well at this time, if proper care be taken not to injure the roots, and a good soaking be given to them immediately after being planted. I would advise that all grass plots which did not happen to be mown last week, be mown during the incoming one, commencing with the 1st of October; that is, if sharp frosts, and such as are likely to stop such work, do not prevail.

KITCHEN GARDEN.

Do not delay any longer the necessary taking up and housing of all root crops, such as *Carrots*, *Beet*, *Salsafy*, *Scorzoneræ*, &c., which have been left out so long to insure a more perfect growth. It would not be safe to risk them longer after this date. I suggested a week or two since that the main crops of *Beet-root* should be stored away out in the open borders, and clamped precisely in the same way as *Potatoes* habitually are. The same remarks apply with equal force to the keeping of *Carrots*, as the crop lasts far better so treated, than when the roots are packed in dry sand or in underground cellar-like places, where the air can penetrate to them pretty freely, and where dry-rot and other similar evils are known to exist and to multiply greatly. Remove as much of the surface growths as will part freely both from *Rhubarb* and *Seakale*. Give the former a sound dressing with good rotten manure, and keep the latter free of weeds or other litter likely to keep the sun and air therefrom, each of which should now have uninterrupted play, duly to ripen off the crowns, preparatory to the process of early forcing. *W. E.*

TOWN GARDENING.

The Golden Rod, Double Sunflower, and Milk Daisy, particularly the latter, of which there are many varieties, are very showy plants for towns. These, and all other plants, are improved by cultivation, and unfortunately they seldom receive, for a number of instances, when once planted they are allowed for years undisturbed. One would suppose that their rubbishy appearance that they were only a harbour insects. If these are divided into shoots, and planted three in a patch, and nearly as they progress in growth during summer, they produce a gay appearance, and well deserve the trouble bestowed on them. The *Frazinella* (*manica*) is a plant that will do well in any town garden, throwing up pyramids of flowers 2 feet 6 inches high, and emitting an odour like that of lemon. For its beauty and fine scent it should be introduced into every town garden; and now is the season to propagate it, by dividing the root. The *Widow herb*, is valuable in shrubberies under the drip of trees, and succeeding everywhere grows about 3 feet high; the roots should be cut in patches about 4 inches deep. This is the best season for dividing and transplanting the *manica*, an excellent plant for town gardens, as the *Dahlias* and *Marvel of Peru* with the first they should be cut down 3 inches of the ground, taken up and placed a few days, when they should be put away in winter, either in a cellar, or in a pit dug in the garden, covered with straw, and banked over with a few inches of soil. By this method the plump and fresh, and start freely in spring.

STATE OF THE WEATHER AT CHISWICK, BRISTOL.

For the Week ending Oct. 27, 1884, as observed at the Horticultural Society's Garden, Chiswick, Middlesex.

October	Moon's Age	BAROMETER.		TEMPERATURE.			Price, per bush.

Oct. 21—Densely overcast, cloudy but fine clear at night.
 22—Frosty, foggy, drusey, overcast, overcast and drusey.
 23—Densely overcast throughout, rain at night.
 24—Cloudy, very damp, fine, but cloudy, clear at night.
 25—Densely overcast, foggy, very fine, clear at night.
 26—Very fine and clear, cloudy, cold wind, clear at night.
 27—Very fine, frosty air, clear and fine, fine and clear.
 Mean temperature of the week, 41 deg. below the average height.

STATE OF THE WEATHER AT CHISWICK.

During the last 43 years, for the ensuing Week, ending Oct. 27, 1884.

October and November	Average Highest Temp.	Average Lowest Temp.	Mean Temp.	No. of Years in which it Rained	Greatest Quantity of Rain in 24 Hours	Frequency of Rain
1841-84	51.0	34.0	42.0	21	4.5	1.1
1841-4	51.1	34.1	42.1	25	0.5	1.1
1845-8	50.4	33.3	41.8	9	0.1	1.1
1849-52	53.5	35.9	44.7	9	0.5	1.1
1853-6	52.1	35.6	43.8	23	0.4	1.1
1867-70	52.9	37.8	45.0	20	0.8	1.1
1871-4	52.8	36.3	44.7	19	0.7	1.1

The highest temperature during the above period occurred on the 31st, 1864—therm. 67 deg., and the lowest on the 30th of Dec. 1841—therm. 20 deg.

Notices to Correspondents.

BARNES TESTIMONIAL. Mr. Pottle, Gardener, Little Woodbridge, 5s.
CLOCHES J. C. and others. Messrs. Hooper & Co., Avenue, Covent Garden Market, W.C., have these cloches for sale.
CORRESPONDENCE. J. S. Nankin. The publication of a letter would injure the cause you have at heart.
FERNS. *W. T. Lastrea rigida*, *Adiantum Capillus-veneris*, *Notholaena lanuginosa* and *Muranta*, *Ceterach nigricans*, *Cheilanthes fragrans*, *Cystopteris fragilis* and *Pendulum vulgare*.
FUNGUS. *Sigma*. Your Fungus is *Clavaria pistillata*. The fructification is totally different from that of *M. J. B.*
GROWING GRAPES FOR PROFIT. A. B. It is rather a province to advise you as to how you can best succeed by your Grapes, money making in whatever way, being rather a difficult matter now-a-days, success in any undertaking requires a practical knowledge of the subject; and much depends upon surrounding circumstances. There is firstly the production, secondly the marketing of the same, which is the most important part, and many at one place, for example, dispose of fruit at just double what another may get for the same. When can you most readily dispose of your fruit? Where is the market? Late Grapes will sell better than early forced fruit. If you force your Grapes, they will more readily bear forcing the next year. It is quite a mistaken notion of yours that you should have a rest every third or fourth year. Culture of Grapes is a perpetual, and every year they will repay your outlay by a satisfactory crop.
LATE FRANKFORD. *CAULIFLOWER.* *W. Drummond* writes: "heads" sent were large, compact, and very well cooked they were not particularly good; but the late in coming into use, it may be considered a good variety.
NAMES OF FRUITS. *AG Paris* 1, *Beurre Clairgeon*, *Chrétien d'Hiver*; 4, *Duchesse d'Angoulême*; 5, *Rance*; 23, *Gansell's Bergamot*; 25, *Gloire de France*; 26, *Crassane*; 15, *Figue de Naples*; 16, *Beurre de France*; 13, *Belle et Bonne*; 14, *Autumn Colmar*; 5, *Champion*; 3, 7, 9, 11, 17, quite rotten *Apples* 1, *Perle*; 2, probably *Lemon Pippin*; 6, *Boston Russett*; 5, *Essex*; 10, a small *Alfreton*; 11, *Winter Coaln*; 9, *Essex*; 13, *Hawthorn*; 21, *Royal Winter Nonpareil*.
Turner Pear. *Hacon's* incomparable.
POTATOS. *R. Heady*. Your seedling *Potatoes* were of a rate; white, mealy, and excellent in flavour.
ERRATA. At p. 1114, col. c, 5 lines from the bottom, Mr. W. Lee instead of Mr. Moor.

RAYNBIRD, CALDECOTT, BAWTREE, DOWLING, AND COMPANY (Limited),
 COALS, SEEDS, MANURE, and OILSEED MERCHANTS.
 Address: Seed Market, Mark Lane, E.C.; or Basingstoke
 Prices post free on application. Prize Medals, 1851
 for "Excellent Seed Corn and Seeds"

Seed Potatoes.
AND P. SHARPE'S WHOLESALE LIST of all
 the new and best varieties of Early and Late POTATOS is
 ready and may be had on application. The quality is very fine,
 and the price is low.
 Seed Growing Establishment, Wisbech.

IMMEDIATE SALE, about 2 tons of MONA'S
 PRIDE POTATOS, at 1s 6d. per stone; also a quantity of
 ROBUS DOMESTICA TREE SEED (the true Service), at 2s. 6d.
 per lb., new seed.
 Apply to the Proprietors of the Onehan Nursery, Isle of Man.

RICHARD WALKER has the following to offer for
 sale:—
 1. SEAKALE, for forcing, extra fine, 10s. per
 cask; 2. ASPARAGUS for forcing, at 2l per 1000, or
 10s. per cask; 3. CHAMPION DRUMHEAD CABBAGE
 per cask; 4. CHAMPION DRUMHEAD CABBAGE
 per cask.
 RICHARD WALKER, Market Gardens, Biggleswade, Beds.

Prize Pedigree Wheat.
JAMES CARTER AND CO. offer the following choice
 samples of SEED WHEAT, grown from Prize Stocks, with the
 greatest care in Selection, &c.—
 TALAVERA WHITE WHEAT.
 SHIRREFF'S BEARDED WHITE WHEAT.
 ROUGH CHAFF WHITE WHEAT.
 FENTON WHITE WHEAT.

Price—bushel, 11s. per quarter. Stock limited.
 WHEAT—leading varieties, for Seed.
 BARLEY, leading varieties, choice samples, for Feed.
 OATS, leading varieties, choice samples, for Seed.
 Lowest prices on application.
JAMES CARTER AND CO., the Royal Seedsmen, 237 and 238,
 Holborn, London, W.C.

H A L L E T T S
 PEDIGREE HUNTER'S WHITE WHEAT,
 ALSO THE
 ORIGINAL RED.

Price, including bags, Five Guineas per Quarter, by the Quarter or
 Half-quarter, One Guinea per Bushel for less than a Half-quarter,
 delivered at the Brighton Station, in bags sewed up, sealed, and
 containing Printed Directions for Planting, upon receipt of
 cheque or Post Office Order, without which it will not be sent to
 any of our
 known Correspondents. Less than a Bushel not supplied.
 Apply to Captain HALLETT, F.L.S., The Manor House,
 Brighton.

**LAWES' WHEAT MANURE, for AUTUMN
 SOWING**, now ready for delivery.
 All other Manures and Cakes as per Price List, supplied on the
 usual terms. Apply for prices, &c., to JOHN BENNETT LAWES,
 Mark Lane, London, & G.; Dublin, and Shrewsbury.

THE LONDON MANURE COMPANY
 (ESTABLISHED 1840)
 Have now ready for delivery, in fine condition,
 CORN MANURE, for Spring Use
 DISSOLVED BONES, for Dressing Pasture Lands
 SUPERPHOSPHATES of LIME
 PREPARED GUANO
 MANGEL and POTATO MANURES.
 Genuine PERUVIAN GUANO, and NITRATE of SODA
 Dock Warehouse; SULPHATE of AMMONIA, FISHERY
 L., &c.
 Offices, 114, Fenchurch Street, E.C.

**DEES AND CO'S BIPHOSPHATED PERUVIAN
 GUANO** (Registered Trade Mark, Flying Albatross), is now
 ready for delivery in quantity and in fine condition. It is believed
 to be the best Artificial Manure yet produced. Its base is
 the best Artificial Guano; it contains 21 per cent. of Soluble
 Phosphates, 8 to 7 per cent. of Ammonia with Salts of Potash. See
 reports of Dr. Voelcker, Dr. Anderson, Professor Way, Mr. Ogston,
 Mr. Sibson. Delivered in 2 cwt. bags, each of which is secured
 with a leaden seal, bearing the Company's Trade Mark. The analysis
 is guaranteed so long as the seals remain unbroken.
 Agents for the North of England—Messrs. Keighley, Maxstead
 & Co., Hull.
 Agents for Scotland—Messrs. Richard Connor & Co., Glasgow and
 agents for Ireland—Messrs. R. F. Gladstone & Co., Dublin
 DEES AND CO'S Biphosphated Peruvian Guano Company
 (Limited), 32, King William Street, London, E.C.

Autumn Sowing.
**WAMS' NITRO-PHOSPHATE or BLOOD
 MANURE for WHEAT**—This Manure, specially prepared for
 Autumn Sowing, is rich in Ammonia, Phosphates, and other
 elements required for the healthy growth of Grain Crops.
 Analyses of Blood and the grain of Wheat show that they are nearly
 identical in composition, hence the value of Blood as an ingredient
 in manure. It may be applied at the rate of from 3 to 4 cwt. per acre,
 according to the condition of the soil, either drilled with the seed
 broadcast, or if the latter, it should be well harrowed in.
 WAMS' NITRO-PHOSPHATE, whose Members are Cultivators of upwards of
 1,000,000 acres, which has been for years under management
 by the same firm, and consequently the genuineness and efficacy of the
 Manure is guaranteed.
 For further particulars apply to the Secretary,
 Messrs. WAMS, 113, Fenchurch Street, London, E.C.; Western
 Branch, County Chambers, Exeter; Irish Branch,
 Westmoreland Street, Dublin.

ASPIC L'HOMME LEFORT (the new French Cold
 Cream Wax), indispensable for Budding, Grafting, Healing,
 and all other purposes. In tins, 6d., 1s., 2s., 4s., and 6s., of all
 sizes.
 HOOPER AND CO., Covent Garden Market, London, W.C.

Wheat Sowing.
OWN'S FARMER'S FRIEND for Preventing the
 Smut of Wheat, and the Ravages of the Hessian Fly, and Wire-
 worm, &c. A few packets is sufficient for Six Bushels of Seed Wheat,
 and will keep it safe and fit to sow in a quarter of an hour.
 It is the largest Wheat Growers in the Kingdom,
 and its great power and efficacy, may be had of
 any of our Agents for every district.
 Full particulars for use are given with each packet.
 Prepared at the Manufactory, Woburn, Beds.
 To guard against fraudulent imitation and consequent
 loss, see that the signature of HENRY DOWN is on
 every packet.
 Agents in every Town throughout England, Scotland, and Ireland.

THE BIRMINGHAM CATTLE and POULTRY SHOW.
 —The TWENTY-FIRST GREAT ANNUAL EXHIBITION of
 FAT CATTLE, SHEEP, PIGS, DOMESTIC POULTRY, CORN,
 ROOTS, and IMPLEMENTS, will be held in HINGLEY HALL, on
 SATURDAY, MONDAY, TUESDAY, WEDNESDAY, and
 THURSDAY, November 27, 29, 30, and December 1 and 2, 1869,
 when PRIZES to the amount of nearly £2100 will be awarded in
 the following Divisions, viz.—
 FAT CATTLE £207 1s. 0d. BREEDING PIGS .. 277 2 0
 FAT SHEEP .. 210 8 0 ROOTS and CORN .. 76 10 0
 FAT PIGS .. 69 11 0 POULTRY and PIGEONS 74 14 0
 Prize Lists, Certificates of Entry, and every information may be
 obtained from the Secretary.
 The ENTRIES CLOSE on MONDAY, November 1.
 JOHN B. LYTHERALL, Secretary
 Offices, 33, New Street, Birmingham

SMITHFIELD CLUB FAT CATTLE SHOW.
 —The ANNUAL SHOW of FAT CATTLE, SHEEP, and
 PIGS, will be held at the AGRICULTURAL HALL, ISLINGTON, on
 MONDAY afternoon, December 6, and Four following Days.
 Intending Exhibitors are requested to apply for Certificate Forms
 by the reference letters as under.
 CATTLE.—Form A. For an OX or STEER (in any Class).
 " B. For a COW or HEIFER (in any Class).
 " C. For a BEAST in Extra Stock.
 SHEEP. " D. For a PEN of three WETHERS (in any Class).
 " E. For a SINGLE SHEEP in Extra Stock.
 PIGS. " F. For a PEN of three PIGS (in any Class).
 " G. For a SINGLE PIG in Extra Stock.
 ENTRIES for LIVE STOCK CLOSE NOVEMBER 1.
 Prize Lists, Forms of Certificates, and all information may be
 obtained on application to Mr. DAVID PULLEN, Assistant Secretary,
 at the Office of the Honorary Secretary, corner of Half-Moon
 Street, Piccadilly, London, W.
 N.B. All communications respecting the Show must be addressed
 to the Assistant Secretary, as above, and should bear outside the
 words "Smithfield Cattle Show."

The Agricultural Gazette.
 SATURDAY, OCTOBER 30, 1869.

MEETINGS FOR THE ENSUING WEEK.
 Nov. 2 } London Farmers' Club (Mr J. Howard, M.P., on Conti-
 } nental Farms), at Salisbury Hotel—5 p.m.
 3 } Central Chamber of Agriculture (Present unsatisfactory
 } Method of Taking the Corn Averages, and the Need of a
 } Uniform System of Weights and Measures), at Salisbury
 } Hotel—11 a.m.

"AGRICULTURE is too big to be moved much
 by any number of steam-tugs." The writer of
 this sentence could hardly have remembered the
 enormous power of the steam engines which are
 now being brought to bear on the work of steam
 tillage! He had not thought of the Buscott
 30-horse power engines which "get over" more
 than 30 acres daily of stiff clay ground! He did
 not know that Mr. CAMPBELL is contemplating
 the use of 100-horse power in a single field!
 Surely a steam-tug of these dimensions must
 move English agriculture, however "big" she
 be! But, indeed, we need not imagine from the
 quoted sentence anything more than that the
 writer was urging the undoubted truth that
 agriculture needs much that is beyond steam-
 power, whatever quantity of it be brought to
 bear—much to which directly it cannot be
 applied. He did not mean to disparage steam-
 power. He only desired to point out that Life
 and the Individuality of plant and animal, and
 the chemical tendencies and character of atoms,
 limit the power of the farmer, whatever may be
 the aid derived from steam. Steam-power cannot
 force the circumstances proper for the Turnip upon
 the acceptance of the Wheat-plant—it cannot
 of itself enrich soil which is barren by reason of
 the absence of fertilising matter—it cannot main-
 tain the life and vigour of a biennial plant after
 it has matured its seed. There is much beyond
 its power, and agriculture, which includes the
 whole, is "too big" to be moved by it alone.

There is much, however, undoubtedly that it
 does move most effectually. Indeed so great a
 part of agriculture consists of the proper tillage
 of the soil, so much of all depends on this
 one item, that we may say not only that the
 agriculture of particular localities and farms,
 but that the agriculture of whole districts—that
 English agriculture generally in fact, is being
 benefited by steam-power. Messrs. FOWLER
 & Co.—one likes to feel a continued indebted-
 ness to the name—are as a matter of fact pulling
 the agriculture of all England along. So is
 Mr. SMITH, of Woolston. The steam plough
 works at Leeds are virtually in themselves a
 spoke in the great wheel of English agricultural
 progress. On a recent visit we were glad to
 hear of the great demand for engines of great
 power which now exists. The essential point to
 be desired is that the clay lands of the country be
 deeply broken up and tilled. Whether that is
 done by engines let out on hire or by engines
 owned by the tenants of the land, matters
 nothing to an outsider interested only in the
 due tillage of the land. But the facts before
 us prove unquestionably that the contract
 system is extending, that an increasing number
 of engines of great power are being issued to
 companies and firms who undertake the cultiva-
 tion of the land at so much per acre; and that
 farmers of plough land, without any need of in-
 creased capital—with, indeed, a diminished need
 of capital (for they can dispense with horses in

the neighbourhood of a good steam plough)—are
 getting all the advantages of steam cultivation.
 Agriculture includes the cultivation of animals
 and plants as well as soil; and steam-power has
 hitherto had comparatively little influence upon
 these other departments of its field. A good herds-
 man has been hitherto supposed to be a man of
 quiet, easy, kindly temperament, dealing gently
 and leisurely with the living creatures he has
 charge of—a man as far removed as may be, in
 idea, from that of the snorting, reckless,
 irresistible steam-horse. But even he (with
 the living creatures which he tends) is dependant
 on the fertility of the farm, and that again
 hinges very much—not exclusively, indeed, but
 still materially—upon a well-tilled soil. The
 writer of our text was right in his assertion that
 fertility depends on other things as well as on
 that process of aeration and pulverisation which
 we call tillage—he was right in pointing out that
 fertilising matter from without needs to be
 actually added to the soil from the manure heap
 or the factory, as well as in admitting that
 fertilising matter from within needs to be made
 accessible by tillage, in order to the best result.
 But most people will, we think, pronounce him
 wrong if, without the qualifications we have
 pointed out, he should persist in saying that
 "Agriculture is too big to be moved much by
 any number of steam-tugs."

THE relative positions of the agricultural and
 town labourer is a very good subject for the
 labourer himself to discuss; but we doubt
 whether much service is done by bringing it
 under the notice of a Farmers' Club. The jury,
 whose verdict alone is material to the issue,
 generally arrive at their decision without much
 consultation with members of Agricultural
 Societies and Chambers: and there can be no
 doubt as to which way their award is tending.
 Our increase of population takes place mainly
 through our towns; and the class calling them-
 selves agricultural labourers have with each
 decennial census been for many years decreasing.
 No doubt a young man, whether in this class or
 any other, is often incompetent to judge what is
 for his true interest, but it is not always till he
 comes of age that the decision in his case is
 delayed. If he has entered young enough as
 ploughboy, he will rarely change his lot, unless,
 indeed, unfortunately, he should be caught up
 by the recruiting sergeant. It is thus with the
 father that the determination of his future
 generally rests. And a jury of labourers, partly
 fathers and partly grown-up sons, are likely to
 give as true a verdict as a jury of their employers,
 in Farmers' Clubs assembled, upon what is for
 their benefit.

We notice that at Lavenham the other day
 Mr. BAKER, a member of the local Farmers'
 Club, proved to his hearers, as he has since
 proved probably also to most of his readers, that
 the ordinary agricultural labourer of Suffolk is
 upon the whole at least as well paid as the
 ordinary unskilled labourer of the town.
 Assuming fairly enough the wages in the two
 cases to be 10s. and 14s. a week respectively, and
 valuing to the former his harvest money and his
 gleaning, his garden and his cheaper cottage,
 it is found that they are nearly paid alike—
 the whole of these advantages covering the
 difference in the actual money payment, amount-
 ing in fact to 4s. a week and 4s. over—thus
 making him 4s. per annum better than the other
 on the whole as regards mere power of pur-
 chasing. But when the physical and moral
 condition of the two are contrasted, Mr. BAKER
 says that, what with overcrowding and all its
 evils, sanitary and social, in town, there is no
 possibility of resisting his conclusion, that the
 country man is by far the more fortunate of the
 two. Many instances moreover can be named,
 he says, of men in good social position, substan-
 tial occupiers of land around Lavenham, who
 have risen from the ranks of the common agricul-
 tural labourer, showing that such men are not the
 downtrodden, helpless class which it suits the
 purpose of some people to call them.

The discussion which followed Mr. BAKER's
 paper (p. 1122) is well worth reading. The
 meeting was fortunately presided over by an
 outspoken chairman, who began apparently with
 a little bit of sarcasm:—"There is one item
 which Mr. BAKER does not include in his calcu-
 lation, viz., the allotment ground—acres of
 which are let to cottagers at a rent of 1s. per
 rod." To this, however, Mr. BIDDELL replied—
 "Mine pay only 6d.;" and Mr. ORPEN—"I
 know some places where they get 10 rods for

8s."—Newcastle had been referred to by Mr. BAKER as exhibiting many of the worst features of town life; and certainly if any one desires to see his ideal of black dirt realised, he should visit the mass of houses clustered in the valley on both sides of the river Tyne. The Chairman fortunately knew Newcastle-upon-Tyne, and this is what he said of town labourers there:—

"Newcastle-upon-Tyne had been mentioned, and he could state, from experience of three years' residence in that town, that they would find nowhere stronger men, women, boys, and girls. They would find houses there, too, as neat and as clean as he could wish to see. The people there, instead of living upon potatoes, as they did in this part of Suffolk, lived upon oatmeal, broth, and peas, and their arms were twice as large as the country labourer's. In proof of this, he might mention that a gentleman who had an estate in the North took some men there from Kent, but he found that they could not do anything like the day's work that the North countrymen could. The badness of the town houses had been mentioned, but perhaps it would have been better if that subject had not been mentioned at all, as he could find places in that very town (Lavenham) which were not fit for a pig to live in. Then, again, he did not think it was fair to compare the rates of mortality in towns with those in the country, for wherever large manufactories were carried on, people would be sure to go in search of employment; sometimes they would get work, sometimes not, and many of them were really starved to death. He thought the country places were as bad as the towns as regarded overcrowding. A great deal was said about drainage, but he was persuaded one of the great causes of illness among the country people was overcrowding. He had been into houses where the father and mother, four or five grown-up boys and girls, and three or four children, all slept in one room."

Mr. RINDER did not much help the case of the agricultural labourer when he offered an explanation:—

"He was sure the Chairman would bear him out when he said that half the workmen did not deserve nice respectable cottages; they tore down the staircases and broke up the shutters to use for firewood. There really was no encouragement for any gentleman to build nice respectable cottages."

It is plain then that, whether the question be one on which a discussion before agricultural employers can bear useful fruit or not, there is a good deal to be said on both sides of it. "Town labourers are huddled together in miserable lodgings unfit for human beings." "Country labourers live in places unfit for pigstyes." "There is scarcely a native male adult in Bethnal Green who is fit for military service." "Nowhere will you find stronger men, women, boys, and girls, than in Newcastle-upon-Tyne." "No man is in so comfortable a position as the provident man in a rural district, who may earn year in and year out 15s. a week."

Probably the safest conclusions at which an outsider, patiently considering the various allegations and opinions, can arrive, may be stated thus:—Both in country and in town great poverty and great misery exist; both in country and in town the provident and well-conducted man is able to rise in his position; whether in country or in town, there is no help, even for the "helpless" classes, that can approach self-help for its power and efficiency. In the worst paid agricultural districts the young unmarried agricultural labourer has plenty of pocket-money. He can squander it and acquire habits which will render comfort in after life impossible, whatever be his earnings; or he can save it and begin life with a good character, a houseful of furniture of his own, and the best girl in the parish for his wife.

The possibilities of the agricultural labourer, whether for decent comfort or for utter misery, are at least equal to those of the corresponding class in town. And we feel sure that any considerate master, who by the interest which he takes in the lads and young men upon his farm, shall retain them in his service, and thus keep them from the chances of town life, will at least have done them no harm. Paying them as much as possible according to their work, i. e. "by the piece," and interfering successfully by friendly advice in the alternative before them of saving or of wasting wages in their youth, he will have secured for them a place in the higher division of a class which contains a large proportion of individuals living in comfort and respectability.

— THE corn trade on Monday relapsed into the inactivity and low prices of the week before last. New English Wheat is quoted at 40s. per qr. at Mark Lane, and the highest figure named for White is 41s. per qr. Fine samples of Barley are in demand, at full rates. Inferior Barley, however, and other spring grain and pulse, have followed the decline in the price of Wheat. — Beasts and sheep, and beef and mutton have also declined considerably in the metropolitan markets, the supply having been in excess of the demand.—The

seed trade has no prominent feature.—English wool, although steady in demand, does not increase in value.

— The following question deserves a prominent place. If any of our readers can help our correspondent, he and others will be very much obliged. "A Constant Reader" writes as follows:—"Will any of your able correspondents be so kind as to favour me with their opinions as to the best mode of reclaiming a large tract near to the sea, which, by neglect, and the annual cutting of Bent, has been reduced from a flourishing rabbit warren to a blank waste of shifting sand. My object is to get it coated over, if possible, with a herbage suitable to rabbits and sheep. Bent, if left undisturbed, will, in the course of time, spread over the ground, but it is not a Grass on which animals can thrive. It has been stated that extensive sand-wastes in Russia have been restored and made firm by the use of a Lupine, which has spread over their surface a coat of verdure. Could you inform me which Lupine this may be, and whether it is wholesome provender for sheep and rabbits?"

— A large public meeting of Cheshire farmers and landowners, led by Mr. G. JACKSON, of Tattenhall, Mr. BARBOUR, of Bolesworth Castle, and others, has resolved —

"That looking at the fearful loss Cheshire has sustained by the unrestricted spread of pleuro-pneumonia, and the lessons taught at Aberdeen and throughout England by the cattle plague restrictions, which stopped the progress of pleuro pneumonia for the time, this meeting strongly favours the opinion that slaughter should follow in all cases certified by the Chief Constable to be pleuro-pneumonia."

And — "That the Cheshire cattle owners, relying on their own independence, approve of the formation of a county association, to provide compensation for all animals slaughtered under the certificate of our Chief Constable, that have been slaughtered in consequence of having pleuro pneumonia, and that the Cheshire Chamber of Agriculture be invited to patronise such a county cattle insurance association."

The last resolution was not carried without opposition, and a declaration of that failure which had overtaken many similar associations; but Mr. HARBOP, of Frodsham, said for the last 17 or 18 years he had been connected with a society which had not come to grief, and which had paid some thousands of pounds compensation. It went through the cattle plague, and he could see many to whom he had paid money—one to whom he had paid 300l.; and every shilling was paid that that association had agreed to pay. He believed that a Mutual Cattle Insurance Society was practicable, and it was the thing he had been agitating for the last 10 years, as agent for the Norfolk Farmers' Insurance Company. The opinion of their manager was that 1s. per head, or at most 1s. 6d., would insure compensation to the extent of 10l. or 12l. That would not quite compensate for three-fourths or more of the loss. As to the working part, don't be afraid of that. He was sure they had intelligent men in every village, who, with the assistance of a veterinary surgeon, could distinguish between pleuro and other complaints; and supposing they did make a mistake, it was better to slaughter one in error than to leave it to spread disease throughout the neighbourhood. The resolution was put and carried.

— The prospectus of a Farmer's Supply Association has been issued, which proposes to bridge the interval between the purchaser and the producer, much after the fashion of co-operative agencies. The following extracts explain the principle on which the Association is to act; and it is, we think, so far sound, inasmuch as, by the addition of another active firm to the many rival agencies at work, it contributes to increase the intensity of that competition on which we all depend for cheapness. Among the names on the council are those of the Hon. H. W. PETRE, of Essex; Mr. F. S. CHAMPION, of Sussex; Mr. G. B. SOLLY, of Kent; and Mr. TRASK, of Hampshire; and other gentlemen. The prospectus says—"The consumer is at present separated from the manufacturer and producer, and large commissions and profits are made by intermediate agents, the burden of which falls upon the purchaser. This can only be met by farmers combining their purchases, and thereby obtaining farming requisites at a considerable reduction in cost. This combination will give farmers the control of the agency through which they purchase, and enable them to obtain genuine and first-class manufactured foods and manures, which it is now almost out of the power of a single purchaser to secure, for adulterations are now systematically practised, and the markets are full of inferior articles. It will be the object of the Association to obtain genuine articles of every kind, by purchasing only under formal contracts, guarantees by analyses, and direct of the manufacturer and merchant, so that fraud can be immediately exposed and dealt with."

— Among the subjects to come under the attention of the Central Chamber of Agriculture next Tuesday, is the variety of weights and measures still in use in corn and other markets. Mr. E. SMITH, of Amotherly, Malton, read a paper on this subject the other day before the Malton Farmers' Club, in which a number of instances of this variety are given. For example, an imperial bushel of good Wheat will weigh 63 lb., Barley, 56 lb. At Malton, however, part of the Wheat is sold at 70 lb. to the bushel, and part at 63 lb. The factors, in making their returns to the excise, estimate Wheat at 63 lb. and Barley at 56 lb. The excise, whose duty it is to give the averages, calculate Wheat at 60 lb. the bushel, Barley at 47 lb., and Oats at 38 lb. Beans and Peas are returned by the factors at 63 lb.; the excise give Beans at 63 lb., but Peas at 64 lb. These divergencies are therefore misleading in the settlement of way-going crops, where the price is fixed by the Malton averages. If we go northward we find Wheat sold by the "boll" of two bushels, Barley and Oats by the quarter, though this is not universal

The report of Carlisle market quotes down "Carlisle bushel," leaving us to infer it is 220 lb and "pack" prevail as measures. In Lancashire the Hull farmers sell Wheat at 63 lb to the bushel, factors at 60 lb. In Wakefield, Doncaster, and other places, farmers sell Wheat by the load of 14 sacks, Barley at 56 lb per bushel. In the north, Wheat is sold by the 'cental' of 108 lb. Wheat by the bushel of 70 lb., Irish Wheat the comb (4 bushels) in use, and in Hampshire market runs thus:—"White Wheat, 7s. 6d. to 7s. 7 1/2 lb.; Barley, from 6s. to 6s. 3d. per imperial sack for malting qualities, and at from 22s. 6d. to 23s. 6d. per sack of 13 score 10 lb. for grinding. Oats 23s. 6d. per sack of 14 score 10 lb., and 22s. 6d. to 23s. 6d. per 12-score sack." The county contributes its quota to the general market prevailing. Of meat, in some places 14 lb. to the stone, in others 16 lb., and in others 18 lb. In some places it is sold by the score. There is at butter, we have 16 oz., 18 oz., 20 oz., and 22 oz. the lb. We have "long roll," "short roll," and "without end."—It will be a useful service if the Chamber shall, through their affiliated societies, come to an agreement upon a point which would give much variety and difference.

— Mr. BAILEY DENTON calls attention to the need of draining the streets of towns as well as of merely sewerage its streets for house drainage. The combination of both systems of pipes results in an interchange of air and surrounding earth of their respective sides, and in dry weather, when the natural surface becomes low, the earth becomes charged with sewage imperfectly conveyed in leaking drains, the fouling of a town's site in this way with excrement is inevitably followed by disease. The remedy would be to have tight sewers for house drainage, and ordinary drains for street drainage. In this way the town site would be dry, without any chances of becoming flooded. HAWKESLEY does indeed declare that dry sewers to economise all the animal excreta of a town, we imagine that few will conclude with him that Mr. BAILEY DENTON's difficulty would be even if dry earth conservancy were a practical operation.

— Mr. GOODWIN, the Secretary and Treasurer of the Bath and West of England and Southern Agricultural Society, has issued the first volume of that Society's Journal. It is chiefly for Professor BROWN's exhaustive treatise on the foot-and-mouth disease, which will be more generally read and studied just at the present time than is generally, we fear, the case with other articles. There are also good reports on the Southampton meeting, and on local breeds of sheep. The appended Note-book is a collection of selected paragraphs from contemporary journals.

— We regret our inability to give a full week of the very interesting agricultural discussion held the other day at Lavenham, under the auspices of the local Farmers' Club. Mr. BIDDLE's very energetic promotion of the Sugar-Beet in that neighbourhood has given a good deal of interest to the agricultural proceedings of the week, and we shall next week report some of the topics of current importance, delivered by Mr. BIDDLE, and other members of the club. We understand that Mr. DUNCAN's sugar factory is working day and night, dealing with several hundred tons of roots per week; and there is every prospect of proving a permanent addition to the general supply, and to the agricultural profits of the neighbourhood.

OUR LIVE STOCK.

MR. DUCKHAM's first periodical sale of Herefords was held on the 21st inst. at the ground at Hereford, the day after the agricultural meeting. The result was satisfactory, animals being sold at fair prices. STANWORTH's ably fine bull, bred at Adforton, and the son of Mr. Tudge's prize stock, brought the highest price of 190 gs. Mr. H. R. EVANS' PRINCE OF WALES, for 105 gs., and WELLINGTON, the property of the same gentleman, went for 60 gs.: Mr. COBURN'S 2-year-old bull, made by FENN & HARDING'S NOBLE made 60 gs. Other bulls fetched from 40 to 50 gs. Mr. B. ROGERS' MESS STANTON, which was three months' old bull-calf was sold for 50 gs. for cow and offspring. The GROVE stock, to Mr. T. JEFFRIES, realised an average of 50 gs. Nearly all of them had calved recently, and the Hereford Times says, the prices added to those of their dams, there is satisfaction of the increasing demand for good Hereford last summer's bull-calves brought from 160 to 180 and averaged more than 25l. 5s., and the calves averaged more than 20l. These prices, especially to the Grove stock, but good pedigree to quality, were given for other animals.

— On Tuesday, the 19th inst., Mr. STRAFFORD's sale took place at the Prebendal Farm, and was for the most part satisfactory, as a reference to the accompanying list will show. 1811l. was realised, which represents an average of 46l. 8s. 10d. upon the 39 animals disposed of. 30 cows and heifers averaged 51l. 11s. 9d.

Two of the cows and a calf were bought for the Queen:-

Table with columns: Name of Animal, When calved, Price, Purchaser. Lists various animals and their sale details.

We are constantly reminded, by the results of the importance attached to pedigree by breeders of cattle. The sale of Mr. Empson's most excellent stock at West Ravendale on the 20th inst. was only a new proof of this fact. Only seven out of the females offered for sale brought above 30 gs., and the top price given was 37 gs. The average over the animals disposed of was 22l. 14s. 9d., and the sum total realised, 1796l. 3s. 6d. The exception to the above statement was FAUNIST, by LORD BLITHE...

THE IRISH LAND QUESTION. The following is a speech by Mr. C. R. Read, M.P., at the recent meeting of the Belfast Agricultural Society. I was at a little local show three weeks ago in the county of Roscommon, where there were 500 entries...

very well here, I can assure you that in many societies in Ireland they do it a great deal better. Now, I have a few words to say about the Irish land question. You naturally suppose that I, as a tenant-farmer, had all my sympathies with the farmers of Ireland, and I was distressed beyond measure when I found that their demands and desires were such as I think no Government, no Parliament, and no country will ever gratify. In the first place they are all unanimous on one point—they demand fixity of tenure. What does this mean, but that every man who is now occupying an acre of land in Ireland should occupy it as long as ever he likes, at the present rent; that as long as he pays the landlord his present rent the power of eviction shall be removed from the landlord, the landlord shall become a sort of lord of the manor,—but he will hardly be this, because the lord of a manor inflicts a fine whenever he has a new tenant. He will not be so well off as this, but he something like a receiver of title rent-charge, the only alteration is to be in case of a depression or advance of prices. I would ask if it is good for the country— independent of its being a flagrant assault on the rights of property—is it good for agriculture, and is it good for the nation at large, that anything so preposterous should be granted? There is another thing brought forward—namely, that the landlords in Ireland do nothing. I can assure you that is the greatest exaggeration. There is no doubt that in buildings there is a difference between us in England and the landlords of Ireland. If a landlord here has a farm of 500 acres he erects the farm buildings and farmer's house, and perhaps some half-dozen cottages; but if he had it in Ireland he would have to erect 50 cottages, 50 pig-styes, 30 cow-houses, and is there anybody, unless he is a millionaire, who could afford to do that over a large estate? On a good and well-managed estate there is a considerable assistance given to a tenant. If he wants to build a house he generally gets the slates and timber, which constitute the chief part of the expense, from the landlord. I have had shown me the result of an immense amount of money expended by landlords, which they borrowed from Government, in draining and improving estates, and not a single sixpence has been charged against the tenant. Then, again, there is a great rage against the absentee landlords. Many hard things are said about them, but I find, for the most part, that these landlords are the most generous; that their rents are cheaper; and that their agreements, when there are any (agreements in Ireland being the exception and not the rule), are more liberal, and their estates are better cultivated than those of the smaller resident proprietors. Then you have read, and you have heard a great deal said, about the cruel evictions in Ireland. I believe that the landlords in Ireland change their tenants so very seldom that they would do anything rather than turn a man out of it is possible for him to pay his rent. So much is this so, that instead of considering an improving some of their properties, as I think they ought to do, they allow them to be subdivided in a most injudicious manner. I believe that since the Potato famine there have been few evictions in Ireland; and when they tell me of the wholesale confiscation of the tenant's property by the landlord, I am sure of this, that the rabbit confiscates more of the property of the tenant in Great Britain in twelve months than the whole of the Irish landlords have confiscated in the last 12 years. But you will tell me very truly that two wrongs do not make a right, and that if anything exists which causes even exceptional injustice, that is no reason why the law should legalise that injustice. If a landlord will not grant a good tenant a lease, if he evicts him, or unfairly raises his rent when that tenant has spent a large sum of money in improving his estate before he has had a fair opportunity of reimbursing himself, I say there ought to be some cheap, competent, and ready tribunal to which that tenant could appeal to decide what compensation he is entitled to. It may be asked, what sort of court would you have? Well, there are throughout Ireland certain courts held by assistant barristers (who are something like our county court judges), and it is my opinion if you had four commissioners appointed in each county, two appointed by the landlords and two appointed by the tenants, with this legal gentleman to preside over them and only to give his vote in case they could not agree, such a tribunal would command the confidence of the tenants and would be accepted by the landlords. There is only one thing I have altered my opinion about since I have been in Ireland, and that is the buildings. I was bold enough to say in the House of Commons that I thought the present law sufficient—that if the tenant built upon the land, and the incoming tenant or landlord would not buy these buildings, he could sell them or remove them as he pleased. I thought that would be enough; but having been in Ireland for five weeks, I do not now believe it. If a landlord lets a lot of land in small patches to people, and knows they are going to build upon them,—if he winks at their putting up their cabins, or pig-styes, or whatever they be, and then evicts them, it is his bounden duty to pay the full value of those buildings, though they may be to him a source of nuisance rather than profit. Then with regard to leases in Ireland, it is said there are no leases. There are more leases in Ireland than in this part of Norfolk: there are leases for lives, for 90 years, for 60 years, for 30 years, for 20 years, and I have seen piles and piles of leases which the tenants have declined to sign, but to which I should have cheerfully put my signature, and have considered the rents to be very liberal. I am in favour of every good tenant having a lease, but sometimes you cannot make them take these leases. We were told at the North Walsham dinner the other day that the cure for Ireland was to make everyone take a 30 years' lease,

and then at the expiration of this 30 years' lease the landlord should pay for every single improvement during that time. How could you possibly have that doctrine in Ireland and not have a similar one in England and Scotland? In Scotland they have leases for 19 or 21 years, and I am sure a Scotch tenant, as a rule, expends ten times more in the improvement of the land than an Irish tenant. Then you see what happens at the end of the lease. If you take up any newspaper you see that the Duke of Argyll, for instance, has a whole list of farms to be let by tender, and the out-going tenant is no more regarded than you or I should be. Thank God, that is not extended to Norfolk, and I hope it never will be. One other remedy put forth is, that the Ulster tenant-right in the North of Ireland should be extended to the whole country. I don't think you are aware what this is. If this tenant-right was for the payment of unexhausted improvements no one would give it more hearty support than I would do, but it is paying for the goodwill of the farm—nothing more nor less than this; and depends, not on the condition of the farm, nor on the improvements that the tenant has made, but it depends for its value on the rent that the tenant has paid, and on the good-nature of the landlord who allows it to be sold. I speak to you as practical men. Suppose that Ulster tenant-right was to become law in Norfolk to-day, and suppose we who happen to take a new farm have to pay 10l. an acre down for the goodwill of the farm, why, it would ruin every one of us at this table. Instead of having 10l. an acre to lay out on our land, as we have now, we should have 20l. to lay out, and we should not receive one penny more interest for our 20l. than for 10l. at present. I ask you to raise your voices against this, and I ask you, as practical men, to say that such an extension of that tenant-right would be the most damaging thing that could happen to agriculture. One other little matter is, that there should be written agreements. Well, that may sound, and doubtless is, a very good policy; but when you have agreements in Ireland—and I have seen them—Paddy particularly objects to put his name to the agreement; he is allowed, perhaps a fortnight to think it over, and then, when asked what he thinks of it, says "Think of it! faith, your honour, I am sure you would not put in anything against me, I have not looked at it." Then he signs the agreement, and also invariably breaks it. I have heard of another thing in the House of Commons, and that is the tyranny of landlords in seizing a man's crop upon the land, and not paying him for what we call covenants and tillages. I asked a very respectable man, "Would you not think it a better custom than you have now, that when you left a farm you should have your straw, your hay, your Turnips taken at the consuming value?" "Consuming value," he said, "what would that be?" "Why," I said, "two-thirds of the market value." He said, "Your honour, I would rather sell it as I do." What is the case? When a tenant goes he sells off the manure, the hay, the straw, the Turnips, and the man who pays his tenant-right for the goodwill of the farm comes in and finds nothing upon it whatever. There is a little improvement which I think might be made, and that is with regard to a six months' notice to quit. I say there ought to be a 12 months' notice to quit farms, not in Ireland only, but in England and Scotland. But I found out that in Ireland the tenancies there are so long and so uncertain as to when they began,—as to the time of year,—that it is the invariable custom to give 12 months' notice, and, therefore, what I thought would have done them a great deal of good would be nothing more than carrying out what they practise now. Then I tried to find out a practical grievance, and I discovered what I think a little one. In Ireland the poor's rates are half paid by the landlord, and half by the tenants. This seemed a good arrangement, but the poor's rates in Ireland are so small, sometimes being only 6d. in the pound for the year, that the tenant does not get a great pull out of it, but you come to the county rate, which they call cess, and which includes the roads, and this is frequently 2s. to 2s. 6d. in the pound. This is all paid by the tenant, and I say if the policy is as good in the one case it would be still more so in the other, because those gentlemen who levy the cess very often make new roads and bridges which are permanent improvements, and sometimes the drainage of a river is done by the Board of Works, and the whole of this expense is put on the county cess, whereas I think it should be equally divided between the landlord and the tenant. I believe honestly and truthfully what I have shadowed out would meet the approval of all right-minded men concerned in the management of the land in Ireland.

MUSTARD.

Among the few monopolies which are now in existence in this country, perhaps the most exclusive is that of the Mustard trade, which is entirely in the hands of some half-dozen manufacturers. Such a state of affairs is highly detrimental to the growers of the seed, who form a large class of agriculturists. Red or Black Mustard seed (Sinapis nigra), is almost exclusively grown in the southern division of Lincolnshire, the Isle of Wight, and some part of Norfolk; there is, however, only one market for it, and all the growers must come to Wisbeach to sell their produce. This fact in itself seems contrary to present customs; besides which, only on about four Saturdays in the year can it be sold at all. This year the crop has been unusually large, the yield being far in excess of that of late years; but owing to the showery weather prevailing at the time when it was being harvested, a great deal of the seed was secured in a damp condition. Last Saturday was the chief market day for Mustard,

the town of Wisbeach being almost full of growers, the offices of the buyers were crowded from an early hour, and in the Corn Exchange all other trade was nearly at a standstill.

The manufacturers, as usual, were very independent, and the farmers, not being able to make the rates they wished, had to be contented, or the reverse, with the highest price the buyers would give. Several of the manufacturers refused to bid for grey samples, and the few who were not particular as to the colour of the seed showed a remarkable determination to give very little for it.

Although a large quantity of the seed shown was much discoloured, yet there were many samples of very fine seed, and these made fair prices: one gentleman from Gosbison, in Lincolnshire, sold a parcel of 2000 bushels—of his own growth—for 14s. 3d. per bushel; this, however, was an exceptionally fine sample. The average price for this year's seed will not exceed 10s. 6d. per bushel, and the yield will perhaps reach 24 bushels per acre; but on some of the newly broken up pasture-land the crop has been very heavy, more than 30 bushels being obtained.

Loud and long were the complaints to be heard from those who had been holders of grey seed, and some irascible individuals consigned the whole of the buyers, Mustard, and all connected therewith, to a place where, according to report, Mustard and all other calefacients will be superfluous. That the manufacturers are able to lay their heads together, and thus compel the growers to take their price, is undoubtedly unjust to the farmer; but so long as the whole trade of the article is in the hands of a few large firms, the poor producer must grin and bear it, or grow something else. Messrs. Royle and Headland state in their "Materia Medica" that commercial flour of Mustard consists of—Red Mustard, 98 parts; White Mustard, 147 parts; Wheat flour, 56 parts; Capsicums, 1; Ginger, 1/2; and Turmeric, 2 1/2 parts. Such being the case, it appears that Mustard really is not Mustard, but a compound in which the genuine seed plays only a part.

Possibly, but not probably, the Mustard-seed crushers are going to give the great British public the benefit of this cheapness of the seed, and lower the price of the manufactured article. If they do so, they may perhaps lose the bad reputation they have acquired, for it is a common complaint that good Mustard is about double the price it ought to be; consequently the temptation to small dealers to sell an adulterated article, either of their own or a manufacturer's mixing, is hard to withstand. The result is that, oftener than not, the article put on the table for Mustard is what appears to be a base compound of pea or bean meal, or bakehouse sweepings, disguised with a little oil, common Ginger, Pepper, or Chili-pods. If it be thought that bakehouse refuse is too foul a compound to use for this purpose, we would ask—how often has the reader seen a coarse dusty-looking compound on the table, in a high state of fermentation? This is German yeast, or barm, which has been introduced in some nefarious manner. No matter whether we go into hotels or private houses, one of the most unusual things we meet with on the table, is a pot of decently pure Mustard. Where this is found, however, there is no condiment like it, and with the price of raw Mustard what it now is when it leaves the grower's hands, this pure article ought to be general. At any rate, there ought not to be that monopoly which makes the pure article so dear that a great inducement is held out to unprincipled manufacturers and dealers to sell a spurious compound.

Mustard makers will do well to beware in time, for as matters now stand, with the calculation which may be made that raw seed may be always obtained at a reasonable price, a great inducement is held out to the many capitalists who now want profitable employment for their money; and if these Mustard monopolists do not reform themselves, competition will be sure to do its proper work—indeed, the very best opening, we believe, which could suggest itself now in the whole business of the country, is the manufacture of Mustard, with the view of selling a pure article at such a fair price as would stop adulteration, and thereby enable travellers and housekeepers to be sure of a good condiment when they "dine out" or send to the family grocer. *Nemesis.*

LARGE AND SMALL FARMS.

[At the late quarterly meeting of the Dalrymple Farmers Club, Mr. Smith, the President of the Society, read the following paper.]

In considering this subject I refer, of course, to the advantages accruing to the farmer, but a very slight examination will show that any advantages which we would derive would be shared in by the people at large; and for this reason, that by whatever process—whether by obtaining the same crop at a smaller outlay, or a larger crop at the same outlay, the result is in either case cheapening the products of the earth to the consumer, along with an increased profit to the cultivator. Whether this end can be best attained by large or small holdings is an undecided point, and involves the question—Which offers the best opportunity for exhaustive cultivation? Now, it must be borne in mind that the words large and small are in this case only relative—what is large in one county or district, or on one class of land, being small in another. For example, a small sheep or hill farm might be a large agricultural one. A great part of the first might not pay to be ever otherwise than in pasture, and the rent of the one might be two or three times, per acre, the rent of the other. It follows, of course, that the exhaustive cultivation of the one is impossible in the other, and the labour and superintendence required in the one case might be two or three times more than is necessary for the same extent of land in the other.

I am disposed to think, for the reasons now to be

mentioned, that a medium-sized farm is the best, and a medium-sized farm I would define as one which the lessee can fairly and carefully superintend himself, neither more nor less. There are, of course, exceptions to every rule—this as well as others—but the exception proves the rule. The disadvantages of a large farm against which there is no set-off are numerous and very evident. In the first place, and chiefly, there is scarcely any trade or profession in which a man has to trust so implicitly to servants, and in large farms this, of course, becomes more and more the case; while only faithful service can ensure satisfactory results. Practical men like yourselves can readily appreciate the difference between saying to your servant come to your work, and having to say to him go to your work. It may, quite possibly, be the difference between profit and no profit. This is a matter of much greater importance than in manufactures, because in a factory the workpeople are concentrated in one building, and constantly under the eye of the managers and foremen. To effect so complete a supervision in agricultural operations you would require a foreman for every man: it would, at least, be quite impossible for any one man to overlook the working of other men employed, perhaps two or three miles from each other. I have heard manufacturers remark (and I find the same holds good in agriculture) that the larger the concern is the greater is the danger, and, indeed, the certainty of waste and extravagance creeping into its operations. For instance, a plough may want some trifling repairs, or a horse-shoe want nails, or any one of the hundred wants continually cropping up, may be supposed to require attention, and man, horse, and implement may go off to the smithy, the wright's shop, or saddler's, perhaps two or three miles off, and at a loss of half a day. One half of these journeys, I am satisfied, would be found unnecessary were the farmer in a position always to examine the grounds of the necessity himself. On moderate-sized farms it is quite possible to find useful employment for the field hands detained indoors in winter by stress of weather; but where the servants are very numerous this is much more difficult, and involves an expenditure of wages without return. In large farms there may be some saving to the landlord, and consequently in rent to the tenant, by the concentration of buildings in one place, but I question whether this is not more than counterbalanced by the loss of time involved in men, horses, and implements having to travel long distances to and from their work. In any size of farm the extent of crop primarily depends on the amount of seed sown, but the value of the profit depends on the economical working, which in its turn depends upon personal and careful supervision. I am therefore disposed to think, for the reasons I have indicated, that medium farms may be worked most economically, and that farmers will find that after they have passed some such limit as I have laid down their profits are in an inverse ratio to the extent of their holdings. As their holdings increase, their profits get less in proportion. Of course, I do not mean that this would go on till there was nothing left, but after a certain point I believe that the farmer does not earn the proportion of profit which a large outlay and constant labour deserves, and a considerable part of his capital would probably realise as much for him if invested at fair mercantile interest, without any of the risk or toil and anxiety attendant upon money outland on a business. Every man in any business of an honest kind is fairly entitled to be recompensed for his anxiety and trouble and risk, and if the returns on his capital do not sufficiently reward him for these, his business cannot be said to be a paying one; and in this sense, to which I do not see how any objection can be taken, I question whether large farms can be said to pay. One advantage which a large farm undoubtedly possesses over a small one is the power which the holder has, on account of his extensive holding and his larger capital, to employ machinery in his agricultural operations with economy. The use of machinery involves at first a very large outlay, which, however cheap in the long run, is too expensive for a small holder. The interest, even if he could command the capital, forms a serious addition to his rent, while in the opposite case the interest will be but a small item in the whole expenditure. The possession of it gives the owner, among many obvious advantages, the power of getting his work done with the greatest possible expedition, in suitable weather, with an important saving of wages; the speedy and economical ingathering of his crops, and with the power to be early in the market, and to sell at once, should prices rule high. The last is a matter of great importance, and would weigh materially against any argument, but that I hold that machinery may be as cheaply applied on medium as on large farms.

There are two points to be considered in this connection: first, the suitability of machinery to the extent of the farm; and secondly, its suitability to the means of the farmer. As to the first, I speak from experience, because my own farm is a medium-sized one, and I find that, taking everything into account, the interest on field machinery during the time it is idle, the expense of working, &c., I saved considerably by its possession. In proportion, I am convinced, is the saving effected on larger farms, because my first outlay is proportionately less. I have a machine just now, for instance, which in three or four seasons will pay itself in wages saved, and I shall have it for nothing during the rest of its existence, which will be a very long period. I speak generally of the machinery in use in our neighbourhood, and I except steam ploughs, which, while very costly, we need not here take into account, as they are not adapted to the formation of the land around us. As to the second point, I am bound to say that those farmers who cannot or will not spare sufficient capital to provide themselves with scientific appliances for the

cultivation of their farms, are placed at a great advantage; and in the existing race of competition are easily distanced. I do not for a moment mean to have exhausted this subject in this brief time. I can only hint to you the reasons which are established in my mind the truth of the statement, that, while large farms are good, moderate-sized farms are better. Small holdings I do not think advantage. I do not here speak of small or peasant property. Were that question imported into the discussion, argument might have to be revised. Now, I would generally, and without regard to the argument, to add a few words more. The progress of science and its application to agriculture is rapid, and the farmer who neglects its teaching will speedily be stranded on the shore, while his neighbours are carried on by the tide, and if there is one thing which science, as a matter of common sense, teaches more clearly than any other, it is that if you are ungenerous and unkind to your servant when well treated, and generosity is thrown away. Bear in mind that, whatever the treatment you must always incur the bulk of the expense of generous treatment, and it is the extra which you make the profit. You have, say, a field of 100 acres, you must plough it, but it may be that it only requires a little extra labour to make it bear a good crop. Should you put in inferior seed, a great part of the labour may be lost, which would have been saved by the use of good seed, only a little dearer; or, at that a critical time in the growth of the crop, extra manure for forcing will make the difference between only a moderate and an excellent crop. Should you like to see everybody thoroughly supplied in order that the most may be made of the soil, you have none too much of it for our population, and I hope to see the time when all the soil shall be available for the wants of the people, and the land shall flourish like a well-trimmed garden.

Home Correspondence.

Depth of Drains. — I observe at p. 1094 an article on the subject of drainage, recommending the pipes to be laid from 3 feet to 4 feet below the surface, and that drainage engineers seem to be of the opinion that the deeper drainage is best. Now it has appeared to me that the depth of the drains depends mainly on the nature of the soil. I conclude from the address of this letter that for some miles around this neighbourhood the soil is clay, admirably suited for brick-making, and from 5 feet to 10 feet deep. A neighbour of mine bought an estate a few years ago, and laid out a considerable sum in draining his fields for several years, and, according to advice, laid his pipes 4 feet 2 feet below the clay. He found, however, that the water did not run off, and his fields were not better. On the cause being explained to him, he was persuaded to take up his drains, and lay them above the clay, instead of below it, where they never reached. I found this to be the case on a meadow of my own, and have been obliged to relay my pipes about 17 inches deep from the resting upon, instead of lying under, the clay. The depth of the drains must depend on the nature of the soil. *Experientia docet, Clayton, Sussex.* Your article (p. 1094) you say, "Mr. Paget recommends for 3 feet as generally a sufficient depth for pasture land." I have not therefore made myself understood. I think that 4 feet drains will be as efficient as any other, if placed sufficiently deep each other; but that when an impervious stratum requires frequent drains, and there is no bottom at the depth of 6 feet, a drain of 8 feet is much more and equally effective. I also know that when a measure is found at a greater depth, say 6 feet, drains of that depth suffice at much wider intervals, and that the saving made by using them in my case, at the least 20 per cent. On these points I think the Enclosure Commissioners would vary the depth of these drains according to the circumstances of the case. *Charles Paget, Ruddington, Nottingham.*

Woolston against Tiptree. — Mr. Smith is a man for smashing, and no doubt thinks he has done so. Mr. Mechi in his farm accounts, although I have not seen any knowledge of accounts can easily see that Mr. Smith is not an "accountant," either by nature or by teaching. In your number for October 16 he has done of another opponent, and talks very glibly of doing things in the way of steam ploughing. He states 3s. 2d. for man, coal, water, and oil, for 100 acres, and 1s. 6d. for interest and wear and tear per acre, that the whole work done was 109 acres, and this represents interest and wear and tear of ploughing apparatus. Mr. Smith's engine is a locomotive, and therefore can do no other work than the farm except threshing, chaff cutting, &c., and such like. We may, then, safely assume that the cost of the engine, or, say, 125l. out of 1000l., be put down to the ploughing tackle. Then the ploughing tackle itself, with windlass, wire rope, &c., implements, cost 250l., so that we have 125l. on which to charge interest, wear and tear, &c., what Mr. Smith has forgotten altogether. It is customary to reckon 5 per cent. interest, and 10 per cent. for wear and tear, and 5 per cent. for depreciation and repairs account for wear and tear. We have Mr. Smith's "repairs account," so I will take the usual way of 15 per cent. to cover all three. 15 per cent. on 375l. amounts to 56l. 5s., instead of 37l. 3s. 6d., which Mr. Smith allows! I believe, however, that 109 acres is not the whole quantity under plough each year at Woolston, but I think it is under-estimate it if I reckon it to be 120 acres.

actually ploughed each year. But 562.5s. spread over 25 acres would amount to 5s. per acre for interest, wear and tear, and depreciation, instead of the simple 6d., which Mr. Smith puts down. Can Mr. Smith clear himself of this alleged miscalculation as easily as Mr. Meets? Mr. Meets shook off the Woolston sophisms? G. A. H. Mr. Smith's 1s. 6d. per acre means so many shillings a day; and that, over the number of days in the year on which Mr. Smith's farm were large enough, the engine would be at work, is, we presume, his justification of the argument. One shilling and sixpence an acre is 12s. a day, and a use of the engine during 100 days per annum would, at this rate, involve a charge of 60l. for interest.]

Cost of Steam Cultivation on the Woolston System.
 "Agricola" p. 1120 shall have the particulars for Mr. Bates' letter was in the Times of August 1, 1869, "Agricola" had better get a copy of that paper, and also a copy of your paper of January 1, 1869, and see to the "correctness" of them himself; and he will do so, for it is not gentlemanly to openly doubt statements when a sufficient reference is given. Now for the particulars:—

- 1. Finished harvest.
- 2. Started the smashers by steam-power on part of No. 1 heavy land, 20 acres.
- 3. Worked all day.
- 4. Finished the 20 acres at 10.5 A.M. Then shifted the tackle to No. 2, heavy land, and started.
- 5. Worked all day.
- 6. Finished No. 2, heavy land, at 5.10 P.M., 22½ acres; then shifted to No. 1, heavy land.
- 26. Sunday.
- 27. Worked all day.
- 28. Worked all day.
- 29. Finished No. 1, heavy land, at 8.20 A.M., 16½ acres. The men were at dung cart the rest of the day.
- 30. The men at dung-cart all day.
- Oct. 1. Tackle shifted to, and started on light land, No. 6, working the ridger and subsoiler.
- 2. Worked all day on No. 6.
- 3. Sunday.
- 4. Finished No. 6 (14 acres) at 11.20 A.M., then shifted and started the ridger and subsoiler on No. 1, light land.
- 5. Worked all day on No. 1.
- 6. Finished No. 1 (12 acres) at 8.20 A.M., then shifted the tackle and set the smasher to work on No. 4, light land.
- 7. Finished No. 1 (12 acres) at 11.50 A.M., then shifted the tackle to No. 5, light land, setting the ridger and subsoiler to work.
- 8. Worked all day on No. 5.
- 9. Finished No. 5 (12 acres) at 11.15 A.M., and then packed up the tackle for the year.

The total consumption of coal has been (on the 100 acres) 18 cwt., or an average of 1 cwt. 2 qr. 17 lb. per acre. A boy only 15 years of age worked the implements during the whole period.

I have noticed Sundays and dung-cart to make it quite clear as to the working days. It may be seen that I smashed 71 acres in 8½ days, and that I ridged and subsoiled 38 acres in 6½ days. The former was done at a depth of 6 inches, and the latter from 10 to 12 inches. Now, I must give a day's working expenses when working the ridger and subsoiler.

Engine man	per day	3s. 6d.
Windlass-man	2 6
Two anchor-men	5 0
15-year-old plough-boy	1 6
Plough-boy's assistant	2 6
Two roller-boys	1 6
Water fetchers	2 0
			18 6

The ploughboy's assistant is not needed with the smasher, therefore the cost for men at that work stands at 16s. per day. The average daily consumption of coal was 1½ cwt. and a fraction, 99 cwt. to smashing, and 99 cwt. to ridging and subsoiling. The 71 acres of smashing in eight and a-half days stands thus:—

Men for 8½ days, at 16s. per day	£6 16 0
Coal—4 tons 19 cwt., at 16s. per ton	3 19 2½
Oil, at 9d. per day	0 6 ½
		£11 1 7

—or an average of 3s. 2d. per acre, yet not quite, for I had thrown fractions away. The 38 acres of ridging and subsoiling in six and three-quarter days stands thus:—

Men for 6½ days, at 18s. 6d. per day	£6 4 10½
Coal—3 tons 19 cwt., at 16s. per ton	5 8 2½
Oil, at 9d. per day	0 5 0½
		£11 18 1½

—or an average of 5s. 1d. per acre, and a very little fraction over, and that is all. In my letter of October 11, I stated that the smashing cost 3s. 2d., and the ridging and subsoiling cost 5s. 1d. per acre; therefore "Agricola" may now see the data upon which my statement was founded in both cases: 1s. 6d. per acre must be added for interest of money and wear and tear. Now, let me tell "Agricola" one fact: I am now getting my 6 acres of Mangels, and the last year's ridging and subsoiling for them, at a cost of 7s. 3d. per acre, has left the land in such a beautiful condition that it will need only a cultivating with horses, at a cost of 2s. per acre, for Wheat this autumn. "Agricola" may, if he likes, see this done, and he may also see my Wheat that has already been planted on seed-beds costing only 6s. 3d. per acre, steam and horse-power work included. Yes; and there is my ridged work to see if he likes: I will stand no nonsense about his "doubts." William Smith, Woodstock Station, Bucks, Oct. 25.

Mangel Running to Seed.—Referring to your article on the running to seed of Mangels, I have a small field of 5 acres planted with this root. One half of it was drilled with seed obtained from Sutton's, and on this portion very few indeed have run away. On the other half, from seed purchased of a local dealer, a very large percentage have bolted, and I have from time to time had them topped. I must observe that the seed was cultivated and treated in every respect alike, and only one day intervened in the drilling. This would appear to do away with the theory of the season being the cause, as the weather was the same in

both parts of the field, and in my case it would appear to be caused by the difference of seed. F. W. Bignell, Loughton, Stony Stratford, Oct. 22.

Sand for Bedding.—Sea-sand has been used in my stables, in place of straw, for the last two seasons. Eleven horses, seven of which were hunters, have been free from colds, they have also had cool feet, and there has been no scent of any sort. Hampton-Lewis, Heallys, Beaumans, October 24.

Societies.

BATH AND WEST OF ENGLAND.

Bath: October 26.—At the usual meeting of the Council it was resolved that the Taunton meeting (1870) shall commence on Monday, June 6; and the Council having approved the stock and poultry prize sheets, ordered that they be forthwith printed and circulated. The total amount offered in prizes exceeds 1350l. To encourage proficiency in horse-shoeing Mr. Miles, of Exeter, again offers three prizes; it being stipulated that no man who has won a 1st prize in this competition will be eligible to enter. In the stock classes all entries must be made on or before April 20, in the poultry classes on or before May 1. Among the special conditions affecting the exhibition of stock are (1) the appointment of two inspectors to examine sheep on their admission to the showyard, with instructions to report to the stewards any cases in which sheep have not been really and fairly shorn bare, and (2) that "all cattle will be required to be paraded in the ring at least once a day, at the discretion of the stewards."

The Meeting of 1871.—Mr. Ramsden having presented an invitation to the Council from a public meeting of the inhabitants of Guildford and neighbourhood, for the Society to hold its meeting there in 1871, a deputation was appointed to visit the town, to inspect the ground offered for showyard and fields, and to report to the Council at the next meeting.

Farmers' Clubs.

HENHAM

The Development of the Agricultural Resources of Great Britain.—Mr. J. HOPE, jun, read, on Tuesday week, a paper on the above subject, from which we make the following extracts—When I consider the great importance of British agriculture in its relation to the supply of food to the people of the United Kingdom, I think I have introduced a subject worthy of the attention of all who take an interest in the prosperity of the British isles. I may say, in commencing, that I have no extravagant theory to present to you, or Utopian scheme to enforce, nor even to indulge in flights of imagination, but in a sober, rational, and earnest manner to present to you some considerations of a matter-of-fact character, that may tend in some very humble way to the development of the agricultural resources of this country. I do not expect (in our time, at least) to see Turnips growing on the top of Skiddaw, Potatoes on the crest of Snowdon, white Wheat on the summit of Ben Nevis, nor even Cabbages on the ridge of the Dunkerron Mountains of Kerry. As the quantity of land in these islands cannot be increased as the inhabitants increase, and as we do not possess the resources of Brother Jonathan in being able to go "further west," as found necessary, we must make the best (the very best) use of what resources are at our disposal. In this age of wonderful schemes it is not very likely that any great engineer will be able to shift us from our insular position by drifting us down south, say between Madeira and Morocco, therefore we must be content with our temperate, rather foggy, and uncertain climate. However, it has this important advantage, that it is able to grow the finest beef and mutton in the world.

Population.—According to the census of April, 1861, the number of inhabitants in the United Kingdom, including the Channel Islands, Isle of Man, &c., was 29,334,710, and now in October, 1869, taking into our calculation the annual addition to our population, our numbers will be 31½ millions; and in 50 years more, according to the present ratio of increase, our people will have doubled their numbers. And still further to show the development of the Anglo-Saxon race, we may say that the United States doubles its population in 25 years. "Should the same rate of increase go on (I here quote from C. A. Coke's census) England and Wales (not the United Kingdom) in 1901 may be expected to number 36 millions of the human race, which in the succeeding 50 years, or in 1951, may be increased to 73 millions, nearly four times its present inhabitants. This, however, is a point none can determine. We can but estimate the probabilities of the future by the increase of past years." On an average 373 persons reside on a square mile of surface in England, and, with the exception of Belgium, with 400 persons to a square mile, is one of the most densely populated countries on the face of the earth.

Food.—The supply of food to the nation is one ever increasing in its urgency, and its importance brings us to our subject. It is granted that our population numbers 31½ millions, we may ask the question, how much corn is required annually for our own consumption? Some political economists of eminence calculate that 1 quarter of corn is required on an average to feed every man, woman, and child for one year, and some also, of good authority, calculate 6 bushels per head. As the truth generally lies between extremes, so probably it may do so in this case. In my calculations I will assume the medium quantity to be nearest the truth, and I find we will require about 27 million quarters of corn for the food of the people of the British Isles.

Our Corn Growing Resources.—Taking the Board of Trade returns for 1868, which is the latest and best authority we could get, we find the following results for the United Kingdom:—England: 3,396,890 acres of

Wheat (310,000 acres increase over 1867, partly in consequence of the failure of the Turnip crop); 1,790,210 do. Barley; 1,488,170 do. Oats. Wales 130,552 acres of Wheat, 151,608 do. Barley; 257,153 do. Oats. Scotland—124,893 acres of Wheat, 219,515 do. Barley. 1,011,430 do. Oats. Ireland: 286,790 acres of Wheat, 183,252 do. Barley, 1,699,919 do. Oats.

Wheat Grown.—For the present we will only concern ourselves with Wheat, or human food. We had in the United Kingdom in 1868, 3,951,018 acres of Wheat, or in round numbers 4,000,000 of acres; taking 3¼ quarters (some say more) as an estimate, we find that in 1868 we grow in these isles about 1½ million quarters of corn.

Wheat Imported.—According to the Economist, our importation of Wheat for 1868 was in round numbers rather over 8 millions of quarters, which practical agriculturists say can be grown at home. For a period of years past our average annual importation was 10 millions of quarters of corn. The annual increase of corn required is about 200,000 quarters for the increase of population. And now, taking into account the proportion of Rye, Oats, and Barley consumed for human food, you will find our original estimate of the annual consumption per head to be very near the truth.

Dr and Cr Account.—I look upon every effort that is made for the increased productive power of our isles as being to the credit or profit side of our country, and I also look upon all land that is farmed under its productive power for want of capital, knowledge, industry, energy, or other causes, as being to the debtor or losing side of our country.

Beef and Mutton.—Leaving this corn question for a time I will now turn your attention to the question of beef and mutton, and taking Dr. Wynter's statement of the annual consumption of London as the basis of our calculation, I find it requires (exclusive of fish, fowls, rabbits, hams, bacon, &c.) 1,500,000 sheep, 250,000 oxen, 30,000 calves, and 30,000 pigs, and taking into account the fact that the population of London is 3,000,000, which forms about the tenth part of the population of the United Kingdom—in round numbers 30,000,000 (the Mark Lane Express of the 11th inst., in speaking of the corn question, makes use of the same quantities, and as this was written a week previously, it is a coincidence and also a confirmation)—and I find that we require, as near as I can come, for our annual consumption, 15,000,000 sheep, 2,500,000 oxen, 300,000 calves, and 300,000 pigs.

Cattle Imported.—The cattle imported are as below specified. I arrived at the conclusion by adding one-third to the first eight months made up and published by the Board of Trade so as to bring in the last four months of the year:—Cattle, all kinds, 124,781; sheep and lambs, 386,394; swine and hogs, 29,304. There are also comparatively minor imports of salt beef, pork, bacon, hams, &c., which I do not take into account. It will be observed that in comparison with our own importations, our importation of live cattle is of a very minor character.

Number of Live Stock.—The following figures will show the number of live stock in the United Kingdom in 1868, with the increase and decrease over and under 1867:—

Cows, 3,625,137	Increase, 52,343 over 1867
Other kinds, 5,458,279	299,800 "
Sheep and lambs, 95,607,819	1,789,861 "
Pigs, 3,189,167	Decrease, 1,081,933 under 1867

Effect of High-priced food on Stock.—"The high price of pigs and sheep in 1866 had the effect of increasing the number in 1867, and the very large decrease of pigs in 1868 was caused by the high price of food in that year." We see how wonderfully the law of supply and demand—the only just standard of value—can regulate our supplies of food with a precision that is perfectly astonishing, and with results that are of most reliable data for our information, and help us to understand the science of Political Economy, and to know that the balance can be kept without any paternal Government aid or centralizing influence.

Land and Crops Required.—The total area of the United Kingdom is 77,513,000 acres. Of these, 22,164,584 are under permanent pasture, and 11,659,855 under corn crops—a part of which, Barley, Oats, Beans and Peas, are used for cattle food—and under Turnips, Mangels, &c., 2,782,131. The total acreage under crops is 45,652,545, which leaves a balance of 32,000,000 acres of what is called waste lands, which we will not take upon ourselves to specify, as the Board of Trade say "that land capable of cultivation, but lying waste and untilled is erroneously returned under the heading of 'bare fallow or uncropped arable land.'"

Importations of Feeding Stuff.—We import in vast quantities Oats, Barley, Maize, Peas, Beans, Millet, Lentils, &c., the quantities of which we cannot now go into, and also immense quantities of linseed, cotton, rape and ruben cakes, containing, as our agriculturists have found, the highest and most nutritious and flesh-forming substances, with least waste of ash, moisture, and other useless matter, and also containing, as a matter of necessity, the richest manurial value—in fact, being worth nearly half the cost for that only—and with Peruvian guano advanced 10s. per ton last month, this item forms a very important estimate in the grazier's calculation. Linseed cake is, in its nature, the article that can be quickest manufactured into beef, &c., it is, in fact, concentrated ready for immediate transformation into the living organism. In this wonderful arrangement of indirect manure purchase we see the compensating clause of Nature, and how also "the liberal soul shall be made fat" in increased fertility and larger crops.

Turnip Crop.—We know that Turnips contain an average proportion of 90 per cent. of water, and being now rather an uncertain crop—to a certain extent—and the corn-land being required for food for man, not for cattle (as per statements of foreign corn imported as previously stated), we find we are fairly brought to

the question of "The development of the agricultural resources of the United Kingdom"

Waste Lands.—We have 32,000,000 acres of what are technically called waste lands. Of these there are (published in 1863) 2,000,000 acres occupied with woods and plantations, 7,000,000 acres in Scotland consist of sheep pasture (at a considerable elevation, and little improved), 8,000,000 in Ireland unenclosed (generally quite unimproved), 3,000,000 acres are mountain and bog, 12,000,000 acres consist of unimproved and very unproductive lands of every other kind. While I admit most freely that a large portion of land is farmed in very high, first-class condition, I also am compelled to say, from practical agricultural authority, that a very large proportion is cultivated in such a way as to be very unproductive, and also very unprofitable. In the matter of the reclamation of waste lands much has been done, but more remains to be done, and I look forward to the future of our country with promise, because the spirit of enterprise is abroad, and young England is putting on the armour for the foe. There are now victories, bloodless conquests, to obtain over the vast resources of the forces in Nature, and countless laurels for agricultural heroes to obtain, in which they will receive the blessings of the poor, the hungry, and too often famishing, population of our people, and in which they will know that "Peace hath her victories, not less renowned than war."

Suggestions.—In the few suggestions that I have to make I feel the need of much wisdom in touching on those great questions which lie before us, and wish to speak with perfect kindness and forbearance, and humility, knowing, as I do, that many older and wiser heads than mine have failed to solve or settle the following problems, which bear directly on the solution of our subject. The conveyance of land should be shorn of its cumbersome and expensive character, and be placed on a simple and equitable footing, so that the sale of land may become as simple—though not quite so quick—as a quarter of corn; as it is, the premium charged and the delay attendant is a disgrace to our legislators. The law of landlord and tenant might be so contrived as to be not "one-sided justice" to either, but with such covenants for the mutual protection of the rights and properties of each as to produce a good understanding between them. In homely language, we may say that they sail in the same boat, their interest being incidental; and where this is not the case improvement is stopped, and land deteriorates in value. Good leases, and fair compensation for improvements on both sides, and in cases of dispute a reference to a wise arbitrator, would lead to this desirable consummation, as will also the consideration of the next point. A settlement of the Game Law question, probably by the medium of a mutual compromise between the landlord and tenant, treating rabbits simply as vermin to be quickly destroyed as a nuisance, leaving the landlord the enjoyment of the hares and winged game, as already suggested by a large number of tenant-farmers and landlords, and thus doing away with the prolific source of dispute, the "gamekeeper," the tenant himself seeing that the hares and winged game are looked after for his landlord's shooting. I believe this question will soon be settled by the sheer force of common sense, and I heartily wish it a speedy burial. The waste lands to be improved, so as to develop our resources, and employ our able-bodied paupers who cannot get work. As land is a sound investment, it is to be hoped that there need be no lack of capital after the bursting of the bubble "limited liability," with its extensive depressing results; and after the money lost on foreign loans and Quixotic enterprises, I doubt not that money would be to be had on a safe, though slower, investment in the reclamation and improvement of the land of our own country. No more wilful waste should be countenanced in the matter of sewage, which is nothing else than "national loss," and the utilisation of it will be a source of national gain. The sanitary laws alone (apart from the question of finance) will compel us to take up this question.

More Meat, more Manure.—The manufacture of more meat, more manure, should be encouraged, primarily as a source of profit in the animal; and, secondly, as a fertilising power to aid in developing our resources. It can be proved that the quality of a farm is before its quantity, so that as far as possible every acre of land should be brought up to the highest state of efficiency, so as to double its producing power, and sell off 200*l.* or more instead of 100*l.*, and still under liberal treatment maintain its efficiency.

Rents.—As rents have increased, so have our crops, and power of producing corn and cattle. This shows that it has stimulated enterprise, by introducing improvements on every hand, in the shape of drainage and machinery. Free Trade showed this country the necessity of flinging aside notions of standing still, and induced us to go on with the spirit of progress, so that it has not by any means been an unmixed evil to the agriculturist, but otherwise.

Education.—The lack of good education in an agriculturist is simply undeveloped power, for if in any age the aphorism is true that "knowledge is power" it is so now. The leading general principles of science should be taught, so as to enable the farmer to grasp the leading principles of cause and effect in all their varied relationships with the laws of Nature; character of the soil, with regard to its capacity for bearing certain crops; the nature of the growing plant, its culture, and proper nourishment; the knowledge of the laws of life and health of the living animal, so as to develop this knowledge in a utilitarian way, with a view to increase and profit. This knowledge must go hand in hand with experience, to be of a strictly practical character, it being quite impossible for any man actively engaged in the business of farming to sit in his study all the day long; this can only be done by the literary man. "We must have men of thought," and we must also have "men of action."

The Peasant.—Better dwellings are in many places required by our peasantry. Better houses often mean better morality. The better education of the working power of the farm would enable the labourer to take a keener interest in his work, and an intelligent pride in the working of the same. A well-educated peasantry would also prove the best safeguard of our country's prosperity, and would help to solve the puzzling social questions awaiting solution, to wit—pauperism, crime and other kindred questions. I most cordially sympathise with all men who are labouring in an earnest and thorough way for the amelioration and solid instruction of our working people, for I believe the training and development of a noble race of men and women to be of vital importance to our nation.

Reviews.

Horses and Stables. By Colonel Fitzwygram, 15th (the King's) Hussars. (Longmans, Green, Reader & Dyer.)

A title-page with not a wasted word, a list of plates, a table of contents; and then Chapter I. on Ventilation, beginning "Pure air is as important to the integrity of the blood as wholesome food to the maintenance of the body;" no "Introduction," no "Preface"—the character of the whole work is illustrated by this directness and simplicity of its commencement. "Horses and Stables" is a very good and useful book, containing a fund of serviceable information in a succession of well-arranged short paragraphs. In section 10 of Chapter I., which relates to the ventilation and construction of stables, we read the cubical dimensions per horse in a number of public and private stables. They vary from 300 cubic feet in many of the inferior cab stables, up to 2500 cubic feet in the Royal Mews. A common dimension is 700 cubic feet; all the barrack stables quoted being, however, more. This and the other chapters of the book are illustrated. We have, for example, plans and elevations of good and faulty stables, the former yielding light, fresh air, and ample room to every horse, the latter imperfect in all these particulars. The first part of the volume relates to stables and stable management; the other parts more directly to the horse and to its treatment under disease. We shall bring the work under the notice of our readers by occasional extracts.

The Poultry Yard.

EACH season brings its duty, and to those who love order, even in their hobbies, the preparation for winter comes as naturally to them when thinking of their poultry, as it does when the first chill suggests the wisdom of making some difference in costume.

With the recollection of the unusual heat of last week fresh in our minds, we thought a friend was mistaken when, while looking with us at some stock, he said, "You must now look for daily decreasing light and increasing darkness, for cold nights and mornings." Impossible, thought we, the change would be too great, but it came.

Many do not sufficiently calculate the great change that takes place while the days shorten and the nights lengthen. The sun loses power, the earth becomes chilly; no growth of Grass, no animal life, nothing for poultry to eat but that which is given by hand. In many places, till this time, the chickens, now nearly as large as their parents, have roosted out and about. They have squeezed themselves still into the rip, in which they roosted when they were first deserted by their mother. They have perched on low rails and in hedges, but that must now be put an end to. During the long nights between this and Christmas they want more shelter than Nature has given to them. It is perfectly true that all her works are perfect, and that all are fitted for the weather they have to encounter, but anyone who has had the opportunity of watching birds will soon know the difference. Instinct teaches a bird at roost in wet weather to form a slope of its body to shoot off the rain. With the head tucked into the feathers, the legs drawn up and the body drooping from the shoulders, the rain runs off. We have seen it run a stream from the tail of a pheasant; but we have brought up our birds artificially, and they cannot bear the same hardships that one can which has never been sheltered. We have often wondered that in a wet time partridges should find the places they do. On the shelves of beetling banks, in the mouths of rabbits' burrows, under the roots of large trees—they choose fit shelter with admirable instinct. They are equally clever at sheltering themselves from cold winds. Our fowls, however, look for shelter to the places and contrivances they have always known, and it is for that reason we must, now the weather is changed, make fresh arrangements for them.

Where there is plenty of room there is no difficulty. All that has to be done is to bring the chickens into the fowlhouse to roost. This is sometimes troublesome, because after the hen has left the chickens they still roost in the rip, and when they are too large to do so, they roost, some in, some outside. We find the easiest way is to move the rips away. Nothing else is of any use; fowls firmly believe there is no place like home. Where twelve little chickens roosted for warmth after their mother had left them, 12 nearly full-grown fowls persist in lodging. It is a squabble towards roosting time, squeezing and screaming, the strong ones making good their entry, the weaker edging about till they get opposite the door, when they are out in a minute. This goes on till it is quite dark, when they settle down as they can. Some, however, roost on the top of the rip. It may be suffered while the nights are warm and comparatively short, but as soon as the weather breaks, and the nights lengthen, they must be brought to warmer and more secure roosting. The rips must be taken away, and the birds

driven into the house where they are intended to roost. After this has been done for a few nights the chickens take to it regularly. It may be that young chickens are almost too many for the place. If they are allowed to live in it, disease would be the consequence. If you have no other space to give them, do at once kill the faulty birds; care and food are not to be thrown away upon them, and the older they grow less they are worth. The perfect birds increase in value as they get older, till they attain maturity. Those that, from defects or absence of certain qualities, are destined for the table, become less valuable because they get older and more unprofitable, from each increasing their cost. Nothing destroys more pleasure so much as overstocking, and looking the fact that the little chickens of Manx are large fowls now. If you mean to do well, they now come to kill or sell.

The Birmingham entries close on November 1st. There is no accepted definition of the word used in an exhibition sense. When Birmingham first each percentage a cock and three hens or pullets it was altered to two, then, in the case of game, to one. The cocks and pullets are shown separately, and a definition of an exhibition pen, we say a cock and two hens. We advocate moderate feeding, with the best we give all the help we can, but as we like to know we are giving, we avoid prepared foods.

Farm Memoranda.

WESTER ROSS: Oct. 20.—A more bountiful and tantalising harvest we have not had in the West of Scotland for a very long period, and much more has been sustained. In the later districts a great deal of the crop remains out, and much of it must be all but spoiled from the length of time it has lain in a soaked condition. On August 19 we commenced harvest with six scythes, a smaller number than we used as the crops did not ripen simultaneously. We commenced on September 9, and on the evening of September 10 we left in the fields as much of the crop as we occupy three days in carting home. The rain, however, on the 12th, and no less than four days elapsed ere we got the three days' leading crop gathered together the remainder of the crop. The last of the crop brought home, it is superfluous to say, in anything but a good condition, on the evening of October 9. We cut 150 acres of Wheat, Oats, and Barley. The number of stacks was about 80. The whole of the cutting, gathering, binning, stooking, and carting, that being 26*l.*, or a little under 3*l.* per acre. Scythemen had 3*l.* 6*d.*, binders, 2*l.* 6*d.*, and gathering, 1*l.* 6*d.*, and rakers, 1*l.* 2*d.* per day. The rations. All the half-year servants were engaged in the harvest work, and their wages included in the harvest expenses, consequently the outlay is very much lessened. We employed a man for several days in cutting the crops on the farm adapted for it. The work was admirably done, every ear being in its right place, but the expense was certainly not less than with the scythe. The same result followed the machine as at other times were obtained with the scythe, and it was found that, although the machine seemed to have quite encircled the sheaves out of the way, yet, when the sheaves were scarcely so much ground gone over as the scythe. We did not anticipate that the expense of harvesting would be lessened by the use of a reaper, and consequently felt no disappointment in the result, and neither do we anticipate that there will be any material lessening of the expense in the future, as long as labourers are so abundant and wages so low, but the advantages resulting from having a reaper incomparably better than the scythe, especially when the crops are not their universal use, especially when the crops are not their universal use, especially when the crops are not their universal use. Notwithstanding the beneficial changes that have been made on the reaper, there is still a great deal for improvement. There is a liability to break down, interruptions which are not convenient on a large farm, besides numerous evils resulting therefrom, which one never bargained for. A servant, a few days ago, reached a neighbouring farm breathless, and that she had been sent to ask what the cause of the calamity had befallen them, as they had seen her there, their servants pass on horseback at a life-gone rate. She was informed that the servant had not gone to the stably with a broken harness, but a reaper. Our grain this year is of very various kinds, all that was secured before the rain is very much what was overtaken by it is greatly discoloured, and much of it sprouted, and must be in an unfit condition for months to come. The weather, however, is now to have settled, and the remainder of the crop is being gathered in. Potato lifting, which has been hindered by the weather, is now being prosecuted. Few fields of Wheat have as yet been sown, and with a view to the possibility of settled weather, a large breadth would be sown. We in the North are taking very little thin-seeding, but the tendency is fairly in that direction. With good soil, in fine condition, a very large quantity of seed is sufficient. Cattle are selling well, while sheep have greatly advanced in price, and there is, no doubt, by the disease among cattle.

ABBERTON, WORCESTERSHIRE: The allotment system.—We have much pleasure in calling attention to the result of a trial of the allotment system on the estate of William Laslett, Esq., at Abberton. It is a benevolence, and always a friend of the labourer, ready to express his friendship in a substantial manner, determined upon making an experiment with a few small allotments, so that he might be able to do as a means by which the hard-working

New Bedding Plant, Veronica Blue Gem.
THOMAS CRIPPS AND SON have great pleasure in announcing that they have purchased from Mr H. Warren, of Salisbury, the entire STOCK of this very distinct and useful plant, which excited so much admiration at South Kensington on the 21st ult. Unlike other shrubby Veronicas, it is of a neat, dwarf habit, the parent plant being only 9 inches high; the foliage is small and box-like, the axils of nearly every leaf producing large spikes of mauve flowers, making the plants appear literally clothed with bloom. It commences flowering when only 2 inches high, and continues in bloom throughout the season. Awarded first-class Certificates this year at Salisbury, Sherborne, Shirley, Bath, and South Kensington, and described by the *Gardener's Chronicle* as "a fine acquisition," and by the *Cottage Gardener* as "one of the prettiest plants that have been exhibited this year; its dwarf, neat habit will make it very useful for bedding and decorative purposes." Plants ready in May next, at 5s. each, with the usual discount to the Trade on six plants.
 The Nurseries, Tunbridge Wells, Kent.

Camellias, Azaleas, and Epacris.
HENRY WALTON, having a large stock of the above, finest plants possible, well set with bud, being all home worked, can with confidence recommend them.
AZALEAS, 24s. to 63s. per doz. | **CAMELLIAS**, 24s. to 63s. per doz.
EPACRIS, 15s. to 24s. per dozen.
 Having several hundreds of beautiful trained Azaleas, from 2 to 4 feet, fine for exhibition purposes, 10s. 6d. to 63s. each; also fine Half and Specimen Camellias, 10s. 6d. to 100s. each—this is a favourable opportunity for parties furnishing new houses or improving their present collections. Trade liberally dealt with. CATALOGUES on application.
 Edge End, Marsden, near Barnley, Lancashire.

Laurus latifolia
(CERASUS LAUROCERASUS, var. LATIFOLIA).
L. PAILLET, NURSERYMAN, Chateaux les Sceaux, near Paris, France, offers to the Trade for the first time his splendid new LAURUS, obtained from seed, between a seedling of *Laurus colchica* and *caucasica*. The immense size of its beautiful deep green foliage, its great hardness and rusticity, combine to make this novelty the most valuable of ornamental Evergreen Shrubs for Parks and Gardens. After having been planted in the open air for two years, the leaves of this variety attain a length of from 11 to 12 inches, and a width of from 4 to 5 inches. Price 12s. 18s., 20s., and 25s. per pair according to size. One plant over, set gratis, which are more. An illustration and further particulars will be sent on application by registered letter.
 All kinds of new and other Roses, disposable in large quantities, at low prices.
 Special culture of FRUIT TREE STOCKS, Young SHRUBS, and FOREST TREES, disposable in immense quantities at very low prices.
 All orders must be sent to Mr. L. PAILLET as above; or to his Agents, Messrs. R. SILBERRAD and SON, 5, Harp Lane, Great Tower Street, London, E.C.

British Fern Catalogue.
ROBERT SIM will send, post free for six postage stamps, Part I. (British Ferns and their varieties, 36 pages, including prices of Hardy Exotic Ferns) of his PRICED DESCRIPTIVE CATALOGUE of BRITISH and EXOTIC FERNS, No. 7. Foot's Cray Nursery, Sidcup Hill, Kent.

Special Offer to the Trade.
JOHN J. HASLAM calls the attention of his numerous trade customers to the Collection of choice named **CARNATIONS** and **PICOTEES** (true to name), which he can supply in good strong plants at a reduction of 15 per cent. Bradshaw Gardens, Chadderton, Manchester.

Gladioli—New Roses.
FUGÈNE VERDIER Fils Aîné, **NUSSERYMAN**, 3, Rue Danols, Paris, publishes in August and September of each year complete and descriptive CATALOGUES, with prices. They comprise all the finest and newest varieties of Gladioli, Paeonies, and New Roses. Gratis and post free on application.

WEBB'S NEW GIANT POLYANTHUS, Florist Flower, and **GIANT COWSLIP SEEDS**; also Plants of all the varieties, with double **PRIMROSES** of different colours; **AURICULAS**, both Single and Double, with every sort of Early Spring Flowers. LIST on application.—Mr WEBB, Clifton, Reading.

Everlasting and Dried Natural Flowers.
JAMES CARRIER, DUNNEIT, and BEALE'S WHOLESALE LIST of the above is now ready, and will be forwarded immediately on application. 237 and 238, High Holborn, London, W.C.

RAYNBIRD, CALDECOTT, BAWTREE, DOWLING, and COMPANY (Limited), Seed, Manure, and Oilcake Merchants. Address: 25, Seed Market, Mark Lane, E.C.; or Bas ngatoko. Send for an illustrated list post free on application. Prize Medal, 1861, for Wheat, 1862, for "Excellent Seeds Corn and Seeds."

The Gardeners' Chronicle.
 SATURDAY, NOVEMBER 6, 1869.

We have recently received from our excellent friend Mr. THWAITES a specimen of a minute FUNGUS which has caused some consternation amongst the coffee planters in Ceylon, in consequence of the rapid progress it seems to be making amongst the COFFEE PLANTS. A few trees were noticed to be infected in May last, and at the time of Mr. THWAITES' communi-

cation (July 24) two or three acres were showing the Fungus upon the leaves. These latter fall off before their proper time, and fears are entertained as to the effect on the amount of the crop.

The most curious circumstance is, that amongst more than a thousand species of Fungi received from Ceylon this does not occur; and that it is not only quite new, but with difficulty referable to any recognised section of Fungi. Indeed it seems just intermediate between true moulds and Uredos, allied on the one hand to Trichobasis and on the other to Rhinotrichum. Though the Fungus is developed from the parenchyma of the leaf there is not any covering to the little heaps such as is so obvious in Uredo and its immediate allies, while the mode of attachment reminds one of Rhinotrichum. We are obliged, therefore, to propose a new genus for its reception.*

As the Fungus is confined to the under surface of the leaves, and the mycelium is not superficial, it may be difficult to apply a remedy; but we should be inclined to try sulphur by means of one of the instruments which are used in the Hop grounds in Kent, or syringing with

* *Hemiteles*, Berk and Broome sori somewhat circinate, hyaline, naked; flocci distinct, inarticulate, flexuous, spores somewhat kidney-shaped, at first smooth, then granulate-verrucose on one side, attached obliquely at the base to a little papilliform point. *Hemiteles*, Berk and Br., forming little white circular patches on the under side of the leaves, consisting of minute filaments of flexuous threads surmounted by a single spherical spore attached obliquely at the base, rough externally, with wart like papilla, quite smooth on the side nearest the sori. The upper portion of the leaf above the patches looks as if it were burnt. Figure represents a group of threads with young immature spores highly magnified, together with one of the tufts as seen from above, and spores in different positions.

one of the sulphurous solutions which have been recommended for the extirpation of the Hop mildew. M. J. B.

ESSENTIAL to the tree when living, serviceable to it when dead, beautiful in all stages, from that of the tender bud to that of the "sere and yellow" fall, it is no wonder that the leaves attract universal attention. Age does but lend them additional charms. Constant to their purpose throughout, in death they are well nigh as important to the tree as when living. Thus AUTUMN LEAVES appeal to the most varied sympathies. Every one admires their rich hues. Poets and painters naturally revel in such things of beauty, moralists find in them most appropriate illustrations to give point to their teachings, and more practical gardeners utilise them by collecting them for their compost heaps!

While still green they are the agents by means of which the plant breathes, absorbs, and exhales. They serve to build up and consolidate its tissues; they are all-important agents in the formation of the starch, the sugar, the gum, the resin, the oil, the scores of ingredients elaborated in the plant. Without their aid the plant cannot, in most cases, avail itself of the supplies of nutriment stored up in its own tissues, still less can it draw from earth or air the food necessary for its support. No sooner do they lose their healthy green colour in autumn than they cease to be directly useful to the tree, though still, as we have seen, doing excellent service in the compost-heap. All this is so well known that it may seem trite to refer to it. The cause of all these changes, however, is by no means so generally understood, and as some valuable practical hints may be derived from the investigation of these matters, we need offer no apology for stating in general terms what is known of those changes in the leaf which precede its fall. The colouring matter of the healthy leaf consists of small granules of waxy or fatty matter, often encrusting a central nucleus of starch. These green granules constitute the chlorophyll of the botanist, and they are the very life-blood of the plant. If they are healthy the plant is vigorous, if they are diseased or deficient the plant is sickly. Hence the autumnal change of colour in the leaves is due in great measure, but not entirely, to the alteration in this "leaf-green." Its granules acquire a yellow or orange tint, gradually disintegrate, lose their kernel of starch, and ultimately disappear completely, leaving in their stead a few very small orange-coloured granules, and often a few drops of some oily substance. In this manner the leaf becomes, before its fall, emptied of all its active ingredients, such of them as are fluid or soluble are transferred to the stem or branch, there to aid in the consolidation of the tissues, the ripening of the wood, and the formation of the various secretions. The conduits and pipes passing from leaf to stem, the cells and vessels, are at this time filled with starch, the organising layer between the bark and the wood is gorged with nutritive material, in part transferred from the foliage. What remains behind in the leaf is either effete matter, no longer serviceable to the plant, or insoluble mineral substance, useless at this stage of the plant's existence, but returned to Mother Earth to be again utilised, perhaps by the same plant, in some other way at some other time.

While all this is going on slowly and surely, provision is being made for the severance of the useless and exhausted leaf from the stem. A thin layer of mealy cells gradually insinuates itself across the leaf-stalk at right angles to the other tissues, and by this living knife-edge or wedge the dead is separated from the living, as when a surgeon removes the gangrened extremity of a limb. The practical significance of all this lies in the word "rest," the discoloured leaf in autumn indicates the necessity for repose. If the "wood be well ripened" the rest after all is more apparent than real—in other words it is a change, or at most a slackening of work rather than absolute inactivity. With the returning warmth of spring a new set of actions begin, whose vigour is proportionate not only to the favourable or unfavourable conditions at the time, but also, and this markedly, to the perfection with which leaf action, and consequent ripening of the wood, have been carried on in the preceding autumn.

These facts offer a rational explanation of the practice recommended by "W. E." at pp. 1092, 1140, and approved of by most gardeners, of removing at this season, with a broom or other-

wise, the leaves of Nectarine or Peach trees grown against walls. As many of these leaves, perhaps the majority, are still green, and their removal is not easy, so forcible a mode of detachment looks at first sight like a barbarous process, antagonistic to the natural state of things, as above explained. But when we remember that, owing to the deficiency of light and heat at this season, leaf action and its consequences can hardly be carried on effectively or profitably, and that such unseasonable activity may even induce disastrous effects, it becomes easy to see the propriety of what at first seems questionable practice. The truth seems to be, that such plants as the Peach have not adapted themselves thoroughly to our climate; they require a certain aggregate amount of heat, and a certain intensity of light. In the East, where these trees are nearly wild, these requirements are fulfilled in the course of a comparatively short time; here, if they do get a sufficiency of light and heat, a much longer period is occupied in the process, and the trees are often surprised by autumn frosts before they have received their proper share—before, therefore, their work is complete. It is better, nevertheless, to allow the tree to rest, even if the work be not fully accomplished, rather than to incur the risk of exhausting or destroying the tree by allowing it to continue its operations under unfavourable conditions.

WE extract from the columns of the *Devon Weekly Times* the following particulars relating to the TESTIMONIAL to Mr. BARNES, late of Bicton:—"The retirement of Mr. JAMES BARNES, for nearly 30 years director and manager of the Bicton Gardens, Arboretum, Home Farm, &c., and the eminent services he has rendered to practical gardening and horticulture for a period of 50 years, induced some friends to co-operate, with the view of marking their sense of his services by some visible token of their warm appreciation and esteem. Only such as were personally acquainted with Mr. BARNES, or were familiar with and had received benefit from his labours, were invited to contribute; and the testimonial, simple as it is, and as it was wished to be, may be regarded as the spontaneous expression of friendship and admiration for a venerable, skilful, and excellent man. The presentation was made on Friday afternoon, at the Bude Haven Hotel. Mr. LANG (manager of Lord POLTIMORE'S gardens, &c.) presided, and Mr. FOSTER, Esq., Exmouth, occupied the vice-chair. The testimonial consisted of a very handsome silver tea service, on which was the following inscription:—"Presented to Mr. JAMES BARNES, for 30 years director and manager of the Bicton Gardens, &c., by attached friends, in recognition of his manly sincerity, integrity of character, and benevolence and geniality of disposition, and in appreciation of the valuable services he has rendered, through a long and useful life, to horticultural science, practical gardening, and agriculture." Mr. BARNES returned thanks for the testimonial in a few appropriate words."

M. DEHÉRAIN has recently addressed to the French Academy of Sciences, a note on the DECOMPOSITION of carbonic acid by the LEAVES of PLANTS, under the influence of light. M. PRILLEUX, he observed, had attributed the same decomposing faculty to all the luminous rays of equal intensity, while M. DECAISNE had affirmed that in plunging equal weights of marsh-plants into vessels filled with carbonic acid surrounded by liquids of divers colours and of equal transparency, he has constantly found that more oxygen was disengaged from plants lighted by the yellow and red rays, than by those which were lighted by the blue or green. In former researches M. DEHÉRAIN had demonstrated that evaporation is more active in plants exposed to yellow and red lights than in those exposed to green and blue. This coincidence he regarded as establishing a connection between the two vital functions of the leaves—the evaporation of water and the decomposition of carbonic acid by the disengagement of oxygen.

A PRESENTATION of a gold watch and an address was made at Altrincham, on the 27th ult., to Mr. THOMAS BAINES, gardener to HORATIO MICHOLLS, Esq., of Summerfield, Bowdon, on the occasion of his removal to the vicinity of London, with his employer. The address, illuminated on vellum, and mounted in a handsome gilt frame, was as follows:—"Presented, with a gold watch, to Mr. THOMAS BAINES, by the gardeners and friends of Altrincham, Bowdon, &c., on his leaving the neighbourhood, as a mark of their esteem and regard, October 27, 1869." The watch, a very handsome and massive one, bore an inscription in nearly similar terms. Mr. BAINES' high position as a cultivator is well known, and this mark of appreciation from those amongst whom he has long sojourned must be particularly grateful to his feelings. May he long live to take a prominent place in metropolitan horticulture!

A copy of the OBITUARY record of FELLOWS of the LINNEAN SOCIETY deceased during the year ending May 24, 1869, has just reached us. It has a special interest for us in many ways, amongst others in containing the names of such men as WALKER ARNOTT, WARD, DILKE, VON MARTIUS, and others connected with Botany and Horticulture. As in former years, the Society has done us the honour in many instances of extracting and adopting the biographical notices that have appeared in our own pages, a compliment that we may well be proud of. A remarkable feature in the list in question is the great age attained by so many Fellows of the Society. This is illustrated by the fact

that of 14 deceased Fellows whose age is mentioned in the above list (comprising 17 in all), the youngest was 51, the oldest 94; the numbers run thus—51, 54, 58, 59, 70, 75, 76, 80, 82 (two), 86, 88, 92, and 94. It is curious to observe that not one of the 14 died within the sixth decade. Dividing the number of years (1647) spent by the deceased Fellows on this earth by the number of individuals, we get as a result that the average longevity of a Fellow of the Society is 75 years, a circumstance that ought to induce our young naturalists to join the Society, and might be pleaded as a valid reason why insurance offices should reduce the amount of their premiums on the production of evidence that the insurer had joined the Society. Fellows have the option of compounding for all future payments by paying a sum equal to ten years' annual subscription at the time of their election, or at any subsequent period. Clearly the Society is in most cases a loser by this compounding process, a circumstance which perhaps induced the venerable Dean of Winchester, a year or two back, while in his eighth decade, to cease paying the annual subscription, as he had done for half a century or more, and compound for all future payments by tendering the usual composition fee. Reverting to the 14 gentlemen whose ages we have recorded above, it is satisfactory to find that addition to natural history assuredly does not tend to shorten life. Moreover, it is noteworthy that in most cases the naturalists mentioned above were not stay-at-home philosophers. Many had been travellers in extreme or unhealthy climates, several had served in the navy, several had passed great part of their lives in the incessant labour and harass of medical practice; almost all were, as the brief history of their lives shows, men of active habits.

— What does the reader think a PAPASICULTIVATOR (*papasiculteur*) is?—a grower of Papaws, or a trainer of papas? No; only a Potato grower. "Papas" is good Peruvian for Potato, so says the "Revue Horticole."

— In a recent issue, Mr. BENNETT, of Osberton, called attention to the beauty as a foliage plant of the plant known in gardens by the name of *Acalypha tricolor*. Having seen Mr. BENNETT'S plant, we can endorse all that he says as to its striking and novel appearance. It is not only beautiful in itself, but it affords variety, a quality that is very often charming, and certainly is so in this case. The proper name of this plant is *ACALYPHA WILKESIANA*, and it is thus spoken of by Dr SEEMANN in his "Flora Vitiensis:— "This shrub attains about 10 feet in height, and its foliage has generally the colour of our Copper Beeches; but very often the leaves assume a great variety of tints—pink, yellow, and brown, and then the plant is highly ornamental. It is often cultivated by the natives (of the Fiji Islands), together with other fine foliage plants, such as *Dracena ferrea*, *Codisum variegatum*, *Nothopanax fruticosum*, &c." The flowers are small, whitish, and borne on long, slender, feather-like spikes. What little elegance the flower-spikes may possess is quite eclipsed by the splendour of the leaves. Dr. SEEMANN'S communication on the subject will be found at p 1137.

— In the volume of "Transactions of the Woolhope Naturalists' Field Club for 1868" (noticed at p. 1139), there is amongst other interesting papers to which we may hereafter refer, a note of Mr. EDWIN LEES on the formation of FAIRY RINGS, and on the Fungi that inhabit them. Mr. LEES includes among fairy rings a variety of appearances which we have not been accustomed to consider as fairy rings. Our notion of a true fairy ring has always been associated with a circular outline, and with the presence of Fungi; but Mr. LEES includes rings (?) on which, owing to the irregular form, not even fairies could trip a round dance, and in which Fungi may or may not be present. Mr. LEES, however, includes them all under one head, and attributes them all to one cause—the subterranean gyrations of the mole. "In making his runs he disturbs the roots of the Grass, and the Grass itself withers and dies in the round that he has made. This offers a pabulum to the wandering sporules of Fungi not to be neglected. * * * For an uncertain time their occupation increases the size of the ring, but they do not originally form it."

— The fine specimen of the Ginkgo or Maidenhair tree, *SALISBURIA ADIANTIFOLIA*, at Panshanger, described by Mr. W. PAUL at p. 1067, in our volume for 1884, is nearly equalled by one at Whitfield, the residence of the Rev. ARCHER OLIVE, in Herefordshire. According to the account in the "Transactions of the Woolhope Naturalists' Club," this tree is the largest specimen of its kind in England, except that at Panshanger. The Woolhope tree now measures 7 feet 2 inches in girth, at 5 feet from the ground, is 50 feet 6 inches in height, and has a diametric spread of foliage of 40 feet. It is graceful in form, resembling a Beech in outline, and is supposed to have been planted about 1776, and therefore may be about 96 or 97 years old.

New Plants.

— *ONCIDIUM EUXANTHINUM*, sp. n.
Tetrapetala micropetala: "habitu Oncidii bifolii, Sims." Panicula ampla; sepalis oblongis obtuse acutis, lateralibus tertio infima connatis; labello basi humerato, lacinialis posticis cordato-retundatis hinc dentatis, isthmo subnullo, lacinia antica reniformi bulbo; callo ante basin laminaeformi transversa plurilobo, callo papuliformi supposito progre diente verrucis multis utrinque soritatis oppositis; tabula infrastigmatica porrecta; alis rotundatis lobulatis.
A very pretty Oncid, with the habit of *Oncidium bifolium*. The flowers have greenish sepals and petals, with transverse brownish bars, and a lip of the most beautiful yellow, having numerous brown blotches between the basilar side lobes. The flowers are as large as those of the old *Oncidium reflexum*. It was imported from Brazil by Messrs. Veitch, *H. G. Rehb. fl.*

— *LÆLIA ELEGANS* var. *LOBATA*.
Petalis angustis utrinque medio rotundo unilobatis, labelli lacinialis lateralibus prope rectangularis.
A curious variety of the old *Lælia elegans*, having the petals very narrow, and bearing one obtuse lobe in the midst on either side, and having also rectangular side laciniae of the lip as in *L. elegans* Houtteana. We have to thank J. Day, Esq., for it. *H. G. Rehb. fl.*

— *PASSIFLORA ORGANENSIS*. *Garda*.
Glabra, foliis basi rotundatis eglandulosis subpeltatis 3-nerviis divaricatis sub 3-lobis, lobis lateralibus ovatis obtusis, medio lato obtusissimo; petiolis eglandulosis, pedicellis geminis petiolo longioribus (nonnunquam brevioribus); calycis segmentis oblongis obtusis, petalis longioribus, coronae filamentis serie interioris complanato-petaloidis, petalis brevioribus, serie interioris connatis. *Gardner in Hook. Lond. Jour. Bot. iv. p. 104, Walp. Rep. v. 772*—Crescit in Brasilia montibus Organensis. *Gardner, n. 425* et ab aliis fore omnibus collectoribus allata. *V. sp. sic*
Var. *marmorata*. Foliis superne albidis maculatis. Prope urbem Rio. Miera! Bowman! *V. sp. sic et cult.*

This, though apparently a common species, does not appear to have been introduced into cultivation till recently. It is a stove climber, with much of the appearance of *P. punctata*, but has more pointed leaf-lobes, and only a single row of threads in the mouth of the flower tube. The under surface of the leaves is sometimes of a rich claret colour. The flowers are small, greenish white, the coronal threads violet, and tipped with white.

In the variety *marmorata*, now for the first time described, the upper surface of the leaves is prettily mottled with whitish or yellowish blotches. This form was introduced into Messrs. Veitch's establishment by the late Mr. Bowman. For specimens of the flowers we are indebted to Messrs. Veitch. As an ornamental foliage plant it will not take first rank, as it is perhaps inferior in that respect to *P. Maximiliana* (= *P. discolor*, Link and Ott, et Hort. Angl. plurim; *P. vesper-tilio*, Lemaire nec Linn.). On the other hand it is superior to *P. punctata*, which is occasionally met with in our gardens. *M. T. M.*

CYPRIPEDIUM PARISHII, *Rehb. fl.* (See p. 811)
We have quite forgotten to state that the first introduction of this most extraordinary plant to Europe is due to Mr. Stuart Low. It appears that the firm of Low & Co. have a special title for *Cyripedium*, having introduced no less than eight new species, probably even more, viz., *Lowi*, *Lindl.*; *Stonoi*, *Low*; *Dayanum*, *Rehb. fl.*; *virens*, *Rehb. fl.*; *Hookera*, *Rehb. fl.*; *Bullenianum*, *Rehb. fl.*; *concolor*, *Parish*; *Parishii*, *Rehb. fl.* *H. G. Rehb. fl.*

PLANT PORTRAITS.

ACER RUPINERVA ALBO-LIMBATUM.—*Bot. Mag. t. 5798*.
Aceraceae. This noble Japanese Maple is of about vigorous growth, and bears broad palmately 3-5 lobed leaves which are of a deep green colour, margined with white, while the petioles, peduncles, and underside of the midrib is of a pale red. It is a native of Japan and has been shown by Messrs. Standish & Co. under the personal name of *Acer japonicum*.
ANACTERIS DAWSONIANA.—*Flora des Serres, t. 185*.
Orchidaceae. One of the finest of our variegated-leaved Orchids, its tints and markings being of exquisite beauty. The leaves are ovate-lanceolate, dark velvety rich olive green, traversed by about seven longitudinal copper-coloured veins, the space on each side of the midrib being filled with fine reticulations of the same colour. It comes from the Malay Archipelago, and was introduced by Messrs. Low & Co.

AERIDES LOBBI.—*L'Éclair. Hort. t. 579*.
Orchidaceae. A beautiful stove epiphyte, with distichous linear leaves, obliquely lobed at the apex, and long dense cylindrical pendant spikes of flowers, which are white in the centre, slightly tinted with blue rose towards the outside, somewhat spotted with violet, the lip marked with a whitish central bar, and stained with deep violet on either side. Native of Montmeun, introduced by Messrs. Veitch & Sons.

CATLEYA FIDORATA.—*Flora des Serres, t. 1826*.
Orchidaceae. This remarkably showy species has short clavate stems, which terminate in an oblong ligulate leaf. The flowers are about the size of those of *C. Trianae*, and have whitish sepals and petals, while the lip is strongly tipped with rich amaranth, and its disc conspicuously marked with a broad stain of bright orange. It was introduced by M. Linden from Central America.

CHAMEPYRIS SPHEROPIA ANDELYENSIS.—*Rev. Hort. 1869, 31, fig. 8*.
Coniferae. A compact growing hardy evergreen shrub, of conical outline, and which is sometimes erroneously named in gardens *Rotinospora leptocoma*. The cones resemble those of *Bista* in form, but are described and represented as being much smaller, glaucous, with imbricated scales, bearing a mucronate protuberance. "The fructification," observes M. Carrière, "shows clearly its relationship to *C. sphaerocoma*." It was raised at Andelys, a French town, in the department of the Eure.

CLEMATIS FIBRIFOLIA.—*Rev. Hort. 1869, 10, fig. 1*.
Ranunculaceae. This distinct-looking species is described as a hardy sub-shrubby climber, growing to a height of 7 feet or upwards, producing three-parted leaves having lobulate segments, and numerous pretty, bell-shaped, nodding, yellowish white flowers, having rather long narrow tubes, and forming, as it were, axillary panicles, more or less branched. It was introduced to the French gardens from the Botanic Garden of Naples.

COMMELYNA DEFICIENS VARIETATA.—*Flora des Serres, t. 1824*.
Commelynaceae. This is a diff. low growing, stove perennial, and seems to be well adapted for summer gardening. It has terete branching stems, clothed with ovate lanceolate leaves, which are freely and elegantly striped with longitudinal bands of white, the small blue flowers being produced at the ends of the branches. A native of Brazil, and cultivated by M. Van Houtte.

COMMELYNA PROSTRATA.—*Gartenora, t. 692, fig. 1*.
A stove perennial of prostrate habit, resembling in growth the well known *Cyanotis vittata* (*Tradescantia zebrina* of gardens). It has succulent rooting stems, oval green leaves, and small blue flowers. A variegated variety is sometimes met with. It is a native of Peru.

DRIMYS COOPERI.—*Refug. Bot. t. 19*.
Liliaceae. One of a curious and rather pretty group of dwarf greenhouse bulbous plants, the present species having rather large bulbs, from which issue the broad, oblong lanceolate, green, unspotted leaves, and several dense racemes, usually 30-40 flowered, of nodding green and purple flowers on short scapes. It comes from the Cape of Good Hope, and has been introduced to the unique collection of W. Wilson Saunders, Esq.

ERYTHROXYLON MEXICANUM.—*Gartenora, t. 615*.
Erythroxyloideae. This is described as a slender branching shrub, with obovate oblong obtuse leaves, and small solitary greenish flowers growing in the leaf-axils. The plant is cultivated

under the name of *Erythroxylon Coca*, and is a native of Mexico.
GRONOMA GHIESBREGHTIANA.—*Bot. Mag. t. 5774*.
macoae. A dwarf almost stemless Palm, requiring moderate temperature. Its fronds are pinnately compound, which are much broader. The spathe are simple, linear, on tall erect peduncles, which overtop the introduced to the Continental gardens from China, by M. Ghibbri brought. Flowered at Kew.

GRIFFINIA DRYADES.—*Bot. Mag. t. 5786*.
Amaryllidaceae. A remarkable in the genus for its tall flower and its large flowers. It produces spreading, stamens foot long, and stout scapes as thick as the finger, from 10 to 13 large blue-lilac flowers, which are from the centre of the segments towards their base. Introduced from Brazil, and cultivated by W. Wilson Saunders, Esq. Lemaire says the name should be rendered *Dryades*.

GYMNOSTRIK LATIFOLIA.—*Rev. Hort. 1869, 31*.
Graminaceae. A remarkably ornamental perennial, a robust-growing cane-like stem, attaining a height of 10 feet, and furnished with broad lanceolate spreading leaves which have a short hairy ligule, and are of a bright colour, with the broad medium vein whitish. The inflorescence consists of amentiform nodding spikes. It is a growing Grass, forming handsome tufts, and a noble *Arundo Donax*. The roots may be taken up and placed under cover, as in the case of *Canina*, for protection may be afforded to them in the open ground has been sent from Monte Video, by M. Lemaire, to the *Muséum*, at Paris.

IRIS STYLOSA.—*Bot. Mag. t. 5773*.
Iridaceae. A spring-flowering perennial, of slender erect habit, to a moderate height, furnished with narrow ensiform leaves, sweet-scented pale violet-coloured flowers, the petals of which are mottled with yellow, and marked with curved transverse bands. It is a native of Africa, and was sent to Kew by Mrs. Bodichon. It had been introduced to the genus *Neubeckia* by Alefeld, on account of its perianth.

MACKAYA BELLA.—*Bot. Mag. t. 5797*.
Acanthaceae. A growing and remarkably beautiful greenhouse plant, of slender growth, nearly glabrous, with virgate lanceolate oblong sinuately-toothed leaves, and terminal racemes, 4-6 inches long, bearing numerous large erect flowers, having a slender tube campanulate spreading 5 lobed nearly equal limb, the throat of the limb pencilled with transverse concentric white lines. It is dedicated to the late Dr. Mackay, of Natal, who was sent from Natal to the Kew Gardens, and is now in the D Urban Botanic Gardens.

SEWAGE.

YOUR leader upon sewage and nursery carried my thoughts back more than 20 years time when I had charge for a short time young *Camellia* stock at the Royal Exotic Garden, Chelsea, then under the management of Messrs. Knight & Perry. At that period the late Mr. Joseph was a firm believer in the value of liquid sewage fertiliser. He had a pump put down for the liquid excrements from the stables, privies, &c. I remember well being somewhat shocked when watering the pits, then stocked with *Camellias*, to be accosted by Mr. Knight and to bring a watering-pot that way. He pointed to the pump, and I was requested to fill the pot. The stuff looked and smelt vilely. Mr. Knight's disgust and indignation in my face, and his manner assumed their gentlest, and said, "Now, Mr. Fish," said he, "I am going to give you a valuable lesson, and show you how to make plants grow like weeds. Every day when you water plants, come to this pump, and put a pint of it into each pot of water, and take notice of the result will have." Annoyed as I was at first, I obeyed the instructions to the letter, and soon became convinced my instructor was right. The *Camellias* grew well under my care, and Mr. Knight often when he saw me at the pump, or smelt the compound as he passed by.

That possibly has been the most fruitful lesson of my life. I have never forgotten it. It set me to thinking the place of waste in the economy of production has borne fruit in helping to solve one of the most difficult, and certainly the dirtiest, questions of the day. Dirt, however, is necessarily one of the facts of a working world, and it cannot be rendered innocuous by being ignored. It has drawn our attention on all hands, and even the most engulfed life in its horrible vortex, or engulfed wretchedness in its slimy embrace. For what is suffering, and much of the death that we see, but simply dirt in the wrong place. Like common ingrit between debauched machinery, dirt and prematurely extinguishes it.

As I showed in my paper read at Manchester, we can only escape from its enervating force and its stultifying power by enlisting it into our service. There is one outlet for the world's filth, and that is the vegetable life. The refuse that fills the air and pollutes the earth and poisons the water may be built up into Apple, Pear, Cherry, Peach, &c. Apricot trees, or into such or other fruit, or be worked up into a juicy Cabbage or a succulent sweet Lettuce, or crisp Cucumber, or a luscious apple or Melon. It may be transformed into the clusters in our finest Grapes, or made to give the sweetest Rose-bud, or be blanched into cauliflower spot or wrinkle or any such thing.

These views are neither new nor novel, but transforming of the waste of the world into a major portion of the work goes on to produce it. Our dead bodies and the products of combustion and decay are mostly distributed into the air or dissolved in the water without hindrance from us. Every day, possibly, the weight of every human being is thus distributed, etherealised, then transported, and finally ascends from all the smoking chimneys and reeking dunghill? All this is removed and

away without our ministry. It is only the more gross enormities and their appropriation, that have been deputed to us. Their offensiveness is the voice of love and mercy urging us to remove them from our sight, and place them on one side, so that they may be absorbed. These offensive matters are but the necessary food, the daily bread of plants. Set bread and butter, bread, sugar, or tea before living plants, they can make nothing of these in a sweet and perfect state. Give them a feed of offal, the offscourings of the earth, in a liquid or semi-gaseous form, and they will lap up that as a thirsty dog laps up water.

Such views are not more sound in theory than fruitful in practice. They have been amply confirmed by 20 years' experience. For that period I have applied liquid and solid sewage or excrement to almost every garden plant, with manifest advantage—excepting to Heaths, and a few other hard-wooded plants. It has mostly been applied in a liquid state. The best portions of such matters are easily soluble, but such liquids have been absorbed by ashes, dry, common, and burnt earth, sawdust, Cocoa-nut refuse, leaves, straw, dung, short grass, and almost every conceivable absorbent that could be converted into solid manure or compost. I, however, do not approve of burning weeds; there seems a loss of manure in doing so. These are treated thus, when any are about. But no well-kept garden should ever have a weed large enough to be carried out of it; they ought never to get beyond the seed-leaf, for they rob the proper crops, and impoverish the soil in growing more than their remains, however carefully treasured, can possibly enrich it. But occasionally weeds are to be found, especially in large nurseries, and the best place for them is either the livings, which not only destroys them but kills the seeds, if any; or they may be disposed of in layers with short grass edgings of walks, lawns, &c., and frequently soaked with sewage. Towards autumn, if enough hot dung can be added to the mass to generate a gentle fermentation, a heap of manure will be formed that will grow anything in the garden in a most satisfactory manner.

The solid deposits of sewage I consider of less value than the liquid, and by having a second well to pump from, and a deeper cesspool for the reception of the solid, and by keeping the pump in constant use, and if possible occasionally flushing out the solid by a strong rush of water, it is surprising how slowly the sediment accumulates.

However, Mr. Masters had to do with a large amount of solid, and his mode of managing it seems alike economical and successful. With the exception of charring the weeds, the refuse could not be turned to better account. There seems no part of his practice that could be improved upon. And even the burning forms ash, as you point out, which may be most useful as a deodoriser. But dry and burnt earth are powerful deodorisers, and living plants beat all dead substances whatever in extracting offensiveness out of the world's waste. Some of these may neutralise or bind up dead matters for a time, but plants extinguish them; they do more and better—they transform them into sweetness. The sewage of to-day becomes the perfume of the Violet and the sweetness of the valley Lily, as it rings its tiny bells in its silvery steeple above its broad church of ample, cool, rich, and fresh leaves, to a feast of pleasure, not many months hence. *D. F. Fish, F.R.H.S.*

LARGE MELONS.

SEVERAL letters appeared in the *Gardeners' Chronicle* of last year from correspondents who had evidently been successful Melon growers, and at p. 1040, 1869, I see one is mentioned that weighed 24 lb. Very good work indeed, but four Melons of 6 lb. each would be more useful for the dessert table. Nine years ago, when examining the market gardens about Lyons and the South of France, I found a very vigorous, strong-growing kind of Cantaloupe, which had a very thick rind, and was not very good in flavour. I had at the same time growing here a small American kind, that I got from New Orleans, which only grows about the size of an Orange, is very thin rinded, of an exquisite Muscat flavour, and is a very free setter.

By crossing these two, I have got a first-class hybrid, with the fine flavour, thin skin, and free-setting properties of the small American, and the strong, hardy constitution of the Lyons Cantaloupe. I now grow no other kind, and so keep the stock pure. Two years ago I cut three from one plant, the weights of which were 23 lb. 15 oz., 17 lb. 12 oz., and 16 lb. 1 oz.—making a total of 57 lb. 12 oz. from the one plant. We cut many more very heavy fruit, but I kept no record of the weight. I was rather surprised to find the flavour quite as good as those of the smaller size. The flesh is pink in colour.

The mode of culture is very simple. Our Melon ground was, till this year, on the south slope of an old gravel pit. In November the ground is thrown up in ridges to sweeten, and remains thus till spring, when the spaces between the ridges are filled with hot manure, and all levelled neatly down. The seeds are sown in 3-inch pots, one seed in a pot, and placed in a cool frame, for if raised in heat they are often too delicate for outdoor culture. By about May 15 a fine stock of plants ought to be ready for planting out. Choose a fine day, and arrange your cloches about 3 feet apart. Under each cloche plant a Melon; water and shade for a few days. When the plant has filled the cloche with foliage, it (the cloche) must be lifted and supported on three forked sticks about 6 inches above the collar of the plant. If the cloches are not wanted for other purposes they may be left in this position till the end of the season, to keep the collar of the plant dry.

The Melon, if the collar be kept dry, is a hardier plant than most of us think it is. In the autumn I put a handful of dry powdered charcoal round the neck of each plant, which I find very good for the prevention of

canker. I cover the ground all over with clean straw, which prevents evaporation in hot weather, and keeps both fruit and foliage clean during rainy weather. For the latest crops, we sow the seeds under the cloches where they are to remain. I have this day (October 19) cut 22 fine Melons from plants the seeds of which were sown on the 21st of last May, and the flavour of one cut is nearly as good as those I cut in July and August. *John A. Watson, Campagne Lammemoor, Geneva, Switzerland.*

HOW I GOT OVER MY "DISENDOWMENT."

ABOUT two years ago, owing to a change in the government of this place, I was "disendowed" from having my usual supply of manure from the farmyard, and was told that if I must have manure I must buy it. These were hard lines; and to send "to Coventry" for manure would take more of our time and our money than my estimate would permit. There was, however, no getting away from the fact that I was disendowed of my chief staple, "manure," that which gardeners so much depend upon for the production of good vegetables, and which are required at this place in no very moderate quantities. The problem generally held before the gardener to solve is this,—Given a piece of land, on which during all your life and the lives of as many as may live and die in the culture of that piece of land, from one to some hundreds of years: how to grow a good and plentiful supply of vegetables, rich and crisp, and in every way equal to vegetables seen at anyone else's table. In my case, the supply of vegetables was to be nothing short of that produced previous to the disendowment of manure, and I had to set about the manufacture of manure as best I could.

Having a large tract of pleasure-ground kept under the mowing machine, it occurred to me that this short Grass, which hitherto had been a nuisance, might in some way be utilized. I could not give it away, and when it was thrown into heaps it stunk intolerably. I resolved, therefore, to try how cattle could be fed upon it. On the strength of this idea I immediately set to work, and in the rubbish yard made a cattle-shed and fold-yard, sufficiently large for the accommodation of four animals. The yard littered down, and the water laid on, I was prepared for the cattle. A farmer close by let me have four yearling heifers, for which he allowed me so much per week for their keep. This was about Christmas, and until Grass came these animals were fed with hay, which I had saved from parts of the pleasure-ground which it is not so necessary to keep mown. When, however, grass-mowing with the machine commenced, it was carted into the fold-yard, and readily eaten up by the cattle, and any excess of what they required to eat was trodden under foot and speedily made into manure. All refuse from the garden was thrown into this place, and was either eaten or trodden into manure. In the course of the summer the cattle thrive amazingly, and it was now evident that the scheme was a good one, as I could manufacture manure as fast as it could be dug in, and not in very moderate quantities either.

Having thus given a brief statement of how, in the manufacture of manure, I got over my "disendowment," I may be allowed also to state in what other respects the fold-yard proved useful. Every one knows what luxury there is in the keep of a cow for a family, and on the strength of what I knew the cattle-yard could do, I bought a milch cow, for which I paid 15l. 10s., and during the first year, besides supplying my house with what milk and butter we wanted, we sold, including the price of the calf, milk and butter, as much as exactly realized the purchase-money of the cow. The cow is this year free to begin with, and I am pleased to say in better condition; and so far as the season has gone, yields more and of even better quality than her yield of last year, which is proof sufficient that her keep and habitation in the rubbish yard is as nearly as possible that which she likes. In addition to the animals mentioned I have also some pigs, which thrive amazingly on short Grass, Cabbage leaves, run Cauliflower, &c., and which add much to the richness of the manure. In the same yard I have also some fowls, so that this yard not only produces a plentiful supply of manure for the garden, but supplies my house as plentifully with good milk, butter, bacon, and fresh-laid eggs,—things not much to be despised either in town or country.

In this case of "disendowment" it happened to prove better for me in the end than if my supply from the "state farmyard" had been continued. I should only have got my supply in dribbles, now I have it in abundance, either well made or under-made, and at any time I want it. Let it be considered that I was eagerly selfish in establishing a cow for my own use, I should say, in justice to myself, that eight years ago this formed part of my agreement, but during that period circumstances in my house did not particularly require a cow, and not until I really wanted it did I make use of my privilege.

If a man has for his motto "Live and let live," and this coupled with a fair share of well-directed energy, depend upon it, it matters little whether or not that man be "disendowed;" even if "disestablished," he will right himself again. I have no doubt there are many large gardens similarly circumstanced to those of which I have now charge, where the short Grass might be utilized something after the manner above described. *Wm. Miller, Combe Abbey Gardens, in "Florist and Pomologist."*

HEATING VINE BORDERS

SOON after the late Mr. Thompson's (of Welbeck) experiments on the flow of sap in trees were published in the volume of "London's Gardeners' Magazine" for 1829 (p. 253), and it became known that means were taken at that place not only to protect the external borders of the early forcing-houses from the inclemency

of the weather, but that heat was also applied in order to stimulate a healthy action between the roots and branches of the growing plants, public attention became directed to the great revolution taking place in the practice of early forcing. In the same season a new forcing-house was erected in the gardens of the Earl Fitzwilliam, at Wentworth, in the external borders of which hot-water pipes were laid, but with what amount of success I never could ascertain. At Syon, about the same period, Mr. Forrest planted Vines on a bed of fermenting material in some of the forcing-pits, and they did admirably for a time, until the material of which the beds were composed became effete.

At Canon Hall, in Yorkshire, from whence the grand Muscat of that name was sent to the Horticultural Society nearly half a century since, and which Grape has so signally failed in the hands of most cultivators, experiments were instituted by Mr. Alexander Wilson, and are described by him at p. 26, vol. iii of the "Transactions of the Royal Horticultural Society." The most successful was from a "Vine grown in a pit on a bed of rotten leaves, which might be described as neither hot nor cold," until the Vine began to grow, and the heat in the pit increased, when a little heat could be perceived at the time the Vines were in blossom, not one of which failed to set, nor was there one bad berry when ripe; it was, therefore, inferred that if the "border of a viney can be heated a little, success will be sure." The discussion which has recently taken place in the *Gardeners' Chronicle* on this subject shows that a system of chambering, aerating and border heating is practised by many of our best producers of early fruit, and that others are still content to call in the aid of well protected fermenting matter to guarantee the latent heat of the previous season stored up in the border, in order that a healthy co-operation may be carried on between the roots and branches of the Vine.

At p. 260 of the same volume of the "Transactions" of the Society, there is a plan and description of an early viney erected at Trentham by Mr. Fleming, and which I had an opportunity of seeing some time since; the borders of which are chambered, and from which drains are laid into the house at intervals, and the whole is heated by fermenting dung closely covered in—the ammonia penetrating into the border, and also through the drains into the house when required. Wide cement troughs are fixed under the border into which manure water is placed when it is required to give an extra stimulus. Mr. Fleming also states that the "bunches and berries attain a very large size," but is of opinion "that moderate sized bunches, except for the purposes of exhibition, are much more satisfactory than very large ones, since the berries swell and colour better, and the bunches retain their bloom more perfectly, and look better when dished up, keep up a supply longer, and when it is necessary to send the supply to a distance, they travel infinitely better: it will therefore be well to reduce the large bunches to a moderate size."

A very successful mode of producing early Grapes has recently come under my own observation, in the gardens at Bereleigh Lodge, the delightful residence of Mrs. Forbes, near Petersfield, in Hampshire. The viney was erected for the late G. Forbes, Esq., some 13 or 14 years since, for the purpose of growing Vines in pots, in the management of which, however, the gardener did not prove very successful. The whole length of the house is 27 feet 6 inches, and the width 11 feet. A bed 25 feet in length occupies the middle part of the house from the north end, and is surrounded by a path on the sides and southern end. The roof is fixed, and ventilation is effected by 18-inch openings on either side, and also by an opening light at the top of the southern end, which is glazed; the northern end is opaque. The heating, which is very effective, is by hot-water pipes from a conical boiler, and regulated by stop valves.

Eight Vines were planted along the centre of the bed, in a foot of soil, 11 years ago; each presents the general contour of a Currant bush, the branches extending to the pipes on either side of the bed, and reaching almost to the apex of the roof, which is 4 feet 6 inches from the surface of the bed. They consist of the following sorts, viz, Charlesworth Tokay, Dutch Sweetwater, White Muscadine, and the remaining five Vines are Black Hamburgs. The house was begun to be forced the second week in February, and the Sweetwater Grapes were ripe on May 15. The Vines, notwithstanding the limited space in which the roots have to range, are in the most robust health, some of the leaves I put my rule across and found them to be 16 inches in diameter. The bunches were thinned down to an average of 10 on each Vine—and they were admirably finished, some of the Tokays being more than 2 lb. in weight, and of that beautiful amber colour which is often so difficult to obtain. The Hamburgs were from about 1 to 1½ lb., and of excellent colour and quality, nor did I observe a streaked or imperfect berry in the house.

The bed in which they are grown is full of roots to the very surface, and Mr. Adcock, the present excellent and intelligent gardener, told me that he top-dressed early in the spring with good yellow loam, well mixed with pig-dung and superphosphate of lime—simply removing the crust from the surface before applying the mixture. Mulching with sheep droppings is resorted to during the progress of growth, and over this mulching tepid water is plentifully poured when the state of the bed requires it.

I do not by any means wish to assert that the house in question is the best that could have been devised, or even that its arrangement is of the most economical kind, or that the selection of sorts is the best that could have been made; on the contrary, I believe that by restricting the path to the centre of the house, double the amount of equally efficient border and training-space may be obtained, but to show that by

the application of sound principles to everyday practice, very favourable results may be obtained. Thus the apparatus for heating this small unpretending structure is so arranged that the very shallow bed—one foot in thickness—in which the Vines are grown, is sufficiently warmed without the aid of any extra heating or protecting material. Look on this picture and on that—of wide external borders not only heated at a very considerable expense, but over which covering of some kind is also indispensable during the season of forcing, as a shelter alike from the ill effects of frost, rain, and snow, and this has hitherto been effected by masses of fermenting material, or leaves and fern thatched over, or a covering of tarpaulin; temporary roofs of glass, tiles and boards have also been employed, and these in front of grand ranges of ornamentally constructed forcing-houses.

A few such easily heated simple structures as the one I have attempted to describe would prove an admirable supplement to many such ranges, not only in point of economy, which I hold to be very considerable, but these more majestic houses would then at a lessened expense, come later into use, and with a more telling effect in the autumn months, when families are usually residing at their country seats.

In some parts of the country coals are cheap enough. I recollect the late Mr McIntosh, when gardener at Dalkeith, telling me that coals were delivered into the garden at 5s. per ton. To a like question, Mr. Fleming informed me a few years since that the expense of coals at Trentham was about 8s. 6d. per ton, whilst at this place the price is seldom under 28s.; and where forcing is carried on extensively, such a price is, to say the least of it, a very serious drawback. We are told, however, that great results are to be expected from some newly invented boilers, which, if fully realised, will prove a great boon to all engaged in the protection of plants or early forcing, and more especially in districts of the country where fuel is scarce and expensive. S. N.

Home Correspondence.

Potting Lilies.—I was glad to find the remarks of your correspondent "M." at p. 1138, are likely to lead to some expression of opinion as to the correct treatment and period of potting Lilies. Many amateur growers are very anxious to know how and when to perform this operation, as we find from inquiries from customers when ordering bulbs. From close practical observation I have found that Lilies generally, more especially the Japan species, are often greatly mismanaged during growth, and equally abused during dormancy. Now, although I am thoroughly convinced of the necessity of repose to all plants, and advocate its universal observance, it is plain there are limits, "variable, I admit, in their application," beyond which we may not with impunity carry the system, any more than we may its opposite. In this case it is apparent the usual period of rest beneficial to many bulbs is, to members of this genus, by far too lengthened; the vitality of the bulb is very materially weakened, and the utmost its remaining powers can effect is the development of leaves and flowers, bearing little or none of that beauty so characteristic of this tribe. I have no doubt but that the precise period of potting is of more importance than are the general ingredients of the soil. In fact I have long considered it an absurdity to attach an undue consequence to the minutiae of soil, as we find soils of the same kind differ chemically in different localities. In the case of Lilies, fine plants with wonderful blooms have been obtained by different growers, and produced in different soils, of very different composition. The mainspring of success lies in the proper period of potting, and the handling of the bulb at this time. I have found that as soon as the growth matures and the stem changes yellow to the base, the bulbs should be turned out of the pot, and if division is required this operation must be performed with such care as to mutilate as few of the roots attached to each bulb as possible. These appendages are the chief organs which impart vigour to the plant, and should to all intents and purposes be as much, or more, cared for and regarded than the scales of the bulbs. Each of these roots has an important office to perform, and will be found provided with organs which are active all the year round, contributing to and storing up in the reservoir of the bulbs nutriment during dormancy, and aiding the growth during the active stage. If potted at the season abovenamed, say about the middle of November, and stored away in a quiet cool place, in less than a month growth by the root will have commenced. This fact is of itself a sufficient guarantee that the practice of turning out of pots, lacerating and tearing off the so-called old roots, and storing in sand or similar material, is barbarous in the extreme, and is as opposed to Nature as is the practice of storing away as they decline for the season, and repotting in spring at a period when activity by the root is at its maximum height, and a young embryo growth very vigorous. My Japan Lilies are treated all alike, and I have at this moment hanging in my establishment stems of *L. auratum* bearing the pedicels of from 60 to 85 flowers upon each stem, and this season I have had from 25 to 40 flowers upon a single stem in a 32-sized pot. My system of management is based upon the above formula: I repot in November, and if bulbs have been individually grown in small pots for decorative purposes, without disturbing a root or piece of crock I repot into such larger sizes as desired. The same is done with compound specimens; they are simply repotted on with the same care and regard to roots as in the case of an *Erica* or similar plant. If bulbs are wanted for commercial purposes, they are sized out and potted with all the root possible into such sizes as are suitable for sale and transmission. Bulbs kept exposed for sale or other purposes during winter lose at least 50 per cent. of their strength; this great reduction, it must

be admitted, materially deteriorates from their value. As before said, I attach little importance to soil, but rely almost exclusively upon the ammonia extracted from animal manures, and abundantly applied during the process of growing, also during the swelling and opening of the buds. The ammonia facilitates the due maturation of growth, and enhances the colour and odour of the flowers. Without tendering any positive rules as to soils, I have found the staple ingredient a rich fibry loam, as devoid of mineral impurities as possible, a small quantity of peat as rich in humus as can be secured, and sharp river sand; these, well incorporated together, form a compound which will be found exactly what these denizens of the East require. *Ransley Tanton, F.R.H.S., The Nurseries, Epsom, Surrey.*

I am pleased with the compliment "M." a reader of your paper for 20 years, pays myself and my colleague, when he says he has never seen the Calendar so well filled with useful matter. I beg to inform him that "J. D." is not one of the fair sex, but an old practical gardener, requiring no *chaperone*, for he learnt the mode of wintering and potting Lilies from the late Mr. H. Groom, of Walworth, who was one of the best growers of his day, and whose system he ("J. D.") has adopted in town with tolerable success for many years. *J. Dale, F.R.H.S., Gardener to the Hon. Society of the Middle Temple.*—I notice that in your paper there is a discussion going on anent the proper time for potting Lilies. Now, I am only a young learner, but of course that is the more reason why I, like others, should know the why and wherefore of things. Where I work, it is our practice to put by the Lilies when they have finished blooming, and after the lapse of a few weeks to cut down the dried-off stems, and then to store the pots of Lilies under the house stages in a cool but dry corner, where they lie protected from frost until just before Christmas, when they are repotted after a comparatively long season of rest. On the other hand our Gladioli are topped (*i. e.*, the stems are cut) immediately after being taken up from the bed, and put by to dry until again required. Now it seems to me that both Lilies and Gladioli should, after blooming, have time allowed them in which their stems may die away, and then should come a still further period of rest for the bulbs, before being required to start into life again. I should also like to ask another question, and that is—What time for potting the Lily bulb is most advantageous to the wear of the bulb? I suppose bulbs, as well as mankind, have their term of existence, although in this respect they may vary; but what I mean is—would "M.'s" or "W. E.'s" method preserve the bulb the best? *Youngster.*

Yellow Bedding Plants.—At page 1136 Mr. Hutchinson states, in reply to my remarks on the above, that he finds no difficulty in growing the yellow *Calceolaria*. Perhaps not. He also states that all that the plant wants is a deep soil with a cool bottom. This is, no doubt, very suitable to the growth of the *Calceolaria*, but this will not ensure its success in all parts of the country. It may do so at Abergavenny, but not in Notts or Yorkshire, although in some situations in both these counties it succeeds remarkably well, whilst in others it defies the skill of the gardener and chemist. The situation and seasons have more influence on the growth and successful culture of the *Calceolaria* than any soil it can be planted in. I can enumerate several places within ten miles of Osberton where nearly every kind of soil has been tried, both in damp and dry situations, without success; and I am fully convinced, if soil would ensure its success, such practical men as Mr. Miller of the Manor, Holah of Rufford, Henderson of Thoresby, Hall of Sandbeck, and several others who bed out largely in this neighbourhood, would grow it more extensively. Indeed, at some of these establishments there is hardly a *Calceolaria* to be seen. At Osberton they generally do pretty well, only twice during the past ten years have they proved fickle, but this is enough to shake my entire confidence in them. The only sort I can fully rely on is *amplexicaulis*. This never fails. I grow extensively *Tropæolum "luteum" improved*, in the more conspicuous places, but for the future I intend to plant more extensively the yellow bedding Pansies, so charmed was I with their appearance at Sandbeck and Rufford. *Tagetes signata pumila* I believe I had the honour of first recommending as a very useful bedding plant, fine for autumn, and continuing in blossom a very long season. The true dwarf variety is certainly a gem, but I find it very difficult to procure true. I, however, saw a very striking bed of it lately, at J. Garside's, Esq., of Carlton House, Worksop. It was a large circular bed of the best variety, and stood out very conspicuous, being in full beauty, whilst the remainder of the garden occupants were entirely destroyed by frost. Yet notwithstanding the yellow foliage plants that have come to our rescue lately—the *Tagetes*, the yellow *Tropæolums*, Pansies, &c., we cannot dispense with the *Calceolaria* where it will succeed in any moderate degree of certainty; but in places where it will not grow or live a substitute must be found, and I have at present met with nothing more suitable than the Pansy for the purpose, if a true yellow is required. Those I spoke of in my former communication, and *Viola lutea grandiflora* (Tyerman's), are in every way suitable for yellow bedders. *Edwd. Bennett, Osberton.*

Lawn Mower.—The report of the International Exhibition of Horticulture at Hamburg, published in your journal of September 11, I beg leave to state is incomplete, so far as it refers to Williams' American "Archimedean" Lawn Mower. Having officially represented my State at that exhibition, the invention received my particular attention. Your reporter is right in saying, that at the first trial of lawn mowers, in the presence of the judges, no one appeared to show off the "Archimedean," the agent having received no notice that the trial was to take place on that day. My appeal to the committee in charge

induced the judges to grant another trial, which resulted in gaining for our mower the silver medal offered for one of the two best constructed lawn mowers. *H. Glafcke, late Major U.S.A., State Commissioner at the International Horticultural Exhibition of Hamburg, Harfords, Connecticut.*

Golden Champion Grape.—There has of late been considerable doubt thrown upon the character of the fine Grape, as to its strength of constitution, in houses most likely from the fact that to maintain the requisite to the great demand that has been placed upon it the stock has been unduly forced and over-gated, and its constitution consequently injured. I may therefore be of interest to some of your readers to mention that the Golden Champion will make a most did growth when grafted upon the Black Hamburgh. I called recently upon Mr. Jones, gardener to Mill, Mottisfont Abbey, Romsey, and he showed me in one of his vineries, a rod of the Golden Champion the growth of a graft upon the Black Hamburgh in February last, that was as fine and well ripened as rod of any other Vine would have been under the conditions. Perhaps those who have not hitherto been entirely satisfied with the growth of their plants by try grafting, or, if disposed to be even more experimental, may bud it on some well-established variety kind, as Mr. Stevens does at Trentham. I am by what I saw of the way in which Grapes are raised at Mottisfont, it is likely that Mr. Jones will be able to give a good account of the Golden Champion next May. *Alex. Dean.*

Our Fruit Failure and its Lessons.—To guard this evil as far as possible should be our object, and Mr. Fish gives us excellent advice in his article at p. 1038. Mr. T. C. Sage supplements a recommendation that a portable hot-water apparatus should be invented to use with the improved houses recommended by Mr. Fish, and which I endorse, not that I altogether blame the frost of spring for all the damage done. To arrive at the nearest possible conclusion as to the causes of this service if records were given of failures, with noted day and night temperature during the time the trees were in bloom, the state of the atmosphere during time, class of soils, &c. We should then gain a useful information on this point, which would be in guarding against much of the evil in the coming season. My own belief, in regard to the failures of fruit crops of the past season is, that the whole of blame should not be laid to frost alone. We have orchard-houses here with trees trained to wires or back walls. The outside border is 2 feet 6 inches wide, then a path of 3 feet, with a centre border 6 feet, in which are planted bush trees of Peaches, Apricots. The spaces between these are filled up with Peach and Nectarine trees in pots. The two last are which are respectively 25 and 30 feet long each, and nearly 14 feet wide, contain three Peach trees trained to the back walls, one Nectarine, and one Apricot, six trees planted out, and 20 pot trees of Peaches and Nectarines. The whole has now had three seasons work, and produced this year about three parts of fair crop for young trees—one tree of the *Chambour Peach* had only one inferior fruit. This tree has been every season; I do not think this variety is suitable to orchard-house culture. The best and finest fruit was obtained from a variety called *Dymond*, which I bought it from the Messrs. Veitch two years ago. It is really a very fine Peach, quite distinct from any other kind that I have. Altogether these two sorts have produced this season about 580 fruit of Peaches, Nectarines, and Apricots. In the same house I have now from 90 to 100 lb of Grapes nearly ready for use. The soil in one house is a heavy loam, with a liberal mixture of chalk, and in the other it is a natural garden soil, which is a heavy clay, with a sixth part of chalk. The trees do remarkably well in both houses, and are now looking very promising for another season. The weather here during nearly the whole time the trees were in bloom was bright and sunny during the day, with a very keen easterly wind necessary to give a liberal amount of air during the middle of the day, which was an evil, as the cold current of cold wind seemed to congeal the pollen, so hard that it was with difficulty it could be separated with a camel-hair brush. The weather during the nights was generally cold and cloudy, with more or less frost, and one or two storms of sleet and snow, as they were in full bloom; but, notwithstanding all, some Peach and Nectarine trees on the open wall produced a good crop. Taking all the trees together in the air, we had rather more than half a crop. I should state the trees on the open wall were produced by having two 9-inch boards side by side, and leaning on to some stakes leaning from the border to the wall, which formed a broad canopy standing out over the tops of trees about 12 or 15 inches; this, I believe, in ordinary seasons is the best covering for open walls. I have tried a great many things, but cannot find anything to answer the purpose so well as this. They were produced as soon as the blooms began to show colour, and remained on till the leaves were large enough to afford a slight protection to the young fruit. Now, my conclusion is this—if the frost is to be blamed for the loss of the unheated orchard-house fruit here, why should it not destroy the whole crop on the open wall, which was very much more likely to suffer than that in the orchard-house, where care was taken to box up the much of the sun-heat as possible every afternoon, which could be perceptibly felt at midnight, and in the same hour the surface of the walls in the open air would be disagreeably cold to the touch, and in the morning ice would often be seen hanging from the edges of the boards farthest from the wall, while the

The houses the temperature was hardly down to 40° Fahr. The lowest point touched during the blooming season was 2° below freezing, and this only once. I found, as a rule, that the pollen worked best in the morning before the cutting east wind was admitted. I had a hive of bees in the houses during part of the time, but they did not seem to move any better than was done with a camel-hair brush, which was kept going every day, both in the houses and on the open wall. On making inquiries of others, I find one cultivator attributes the loss of his crop to an insufficient supply of water to the roots previous to the blooming period—a point in which I believe there is much truth. Others, who have the assistance of a hot-water pipe, turned a little heat on at daylight in the morning, and gave air almost immediately, have a good crop. To ascertain as far as possible the results from different quarters must be my object for the length of this letter. I desire to see better crops of fruit, to obtain which let us have our houses properly constructed, for the cultivation of the fruit, with just enough piping to keep out frost during the blooming season. The walls can then be devoted to choice Pears, Plums, &c., which will be much improved by being grown against a south wall. *J. May, Hants.*

Vine Roots.—A subject to which for some considerable time I have given particular attention, has been adverted to by two of your correspondents. The first, Mr. Gill (see p. 1061), asks "if Vines make roots without the action of leaves and branches?" the second, Mr. Anderson (see p. 1137), putting the question in rather a different form, asks, "Do Vines make leaves and branches without the aid of new rootlets?" My answer to both of these questions is an emphatic No. It is as absurd to believe that, as it would be to believe a tree to live without roots altogether. These views of the subject are antagonistic to sound reason, and all the laws of the vegetable kingdom bearing hereupon. Mr. Anderson makes reference to opinions given by several gentlemen of very high standing in the horticultural world, and whose opinions are worthy of very respect. These gentlemen appear to have held different views upon the subject, but I am of opinion a little explanation would have shown "that yet, with all their differences, they all agreed." The best way to come to a correct conclusion upon this subject is to examine it physiologically. Now, much attention to not only Vines, but all sorts of trees, shrubs, &c., has brought me to form very different opinions from those which are commonly held upon many of the laws which govern the rise and flow of the sap, the formation of buds, branches, roots, and such like. I am prepared to receive much opposition from those who may have hurriedly examined the question, and who have not given it that attention it so well deserves. Those however who year after year, and at various seasons, will take the trouble to examine the roots of Vines, fruit trees, and any thing else they like, will I think in the end arrive at the same conclusion as I have done. In the first place, I would draw the notice of the reader to the fact, that the roots have absolute and entire control over the whole tree—stem, branches, and leaves—and even being the fact, when a tree becomes unhealthy, do the parts of gardeners at once examine the roots to ascertain the cause? This is proof positive that whatever they have to believe regarding the matter, their practice is substantially antagonistic to the foregoing questions. To come more fully into the subject in hand, let me notice what in autumn—for it is here I must begin to properly handle the subject—in autumn, when the fruit of the tree begins to ripen, then to a certain extent the roots set from rest to act. Gradually and by slow degrees the two motions become less active, until by the time the leaves have fallen the action has entirely ceased. This is the nature of Nature gradually sinking into sleep—or rest if you will, and this is as absolute for the Vine or any other tree, as it is for the animal kingdom. You will notice with all the known laws of Nature. By referring to Lindley's "Theory of Horticulture," you will there see the author's reasons for this. I, however, differ from him in some of the points; although what he says is to a certain extent true, yet, nevertheless, it is not the whole truth. The passages and surface become to a certain extent choked up, but every gardener knows well enough that they do not become entirely incapable of performing their functions, as we are by artificial means prolong the period of their existence. The roots, therefore, must have something to do with the matter. Yes, undoubtedly they have, and by their desire to go to rest refuse to supply the food necessary for keeping the leaves upon the trees. The roots are the mouths—the leaves the mouths—so that it would be as unreasonable to suppose that the leaves and branches of a tree would develop and grow without the action of the roots, as it would be to entertain the idea that the human stomach could be fed without the mouth providing it with food. At the end of the natural period of rest for the Vine, the buds begin to "swell," as it is popularly said; and how and by what means is this swelling process carried on? Not certainly without the action of the roots. Some I know declare that this is accomplished without the aid of the roots—that a store is laid up for this very purpose, and that this process takes place quite independently of root action. How can this possibly be the case? There must be a vacuum left somewhere, equivalent to the increased bulk of every bud upon the tree. Nay more, if, as Mr. Anderson says, the roots were dormant after the buds began to swell, we must expect a very large vacuum to have been made in the roots of the Vine, so much so indeed, that a perceptible difference must have been admitted in their circumference. And, further, it is admitted by most physiologists that the leaf draws the sap to it in much the same way as a valve draws water in a pump. Now, if this be the

case, a great number of the channels must have been entirely dried up in the roots, and as we in Scotland say, must have lost the "faug," that is to say, that these channels would require to be re-filled ere the leaves could perform their pump-like functions. Now as I deny in toto that the roots do not work as early as the leaves I will ask you to prove the matter for yourselves. After the buds have swollen for a short time, and the leaves begin to develop—at which time Mr. Anderson says his roots were still dormant—let a Vine be cut over near the ground, and what is the result? why, bleeding of course. Now what is the cause of this bleeding? Nothing more nor less than the action of the roots gathering food and forcing it up to the leaves or stomach of the tree. If the roots were dormant there would be no bleeding, and if the leaves alone were the cause of circulation of the sap there would be no bleeding, as, these having been removed, if the roots did not act independently, the flow of sap would at once cease when the union had been broken. This is the reason, although perhaps imperfectly understood, why all good gardeners incline to prune their Vines as soon as possible after they lose their leaves, as then and then only there is no danger of bleeding. Now although I have spoken thus, I do not deny that to all appearance the Vines were dormant. But such was not the case. As soon as the buds began to swell so soon did the action of the roots begin. Let us not suppose, however, that the starting into action of the roots as a natural cause should produce young roots or spongioles. Oh no, it is an after consequence. The food taken up by the roots has to be digested in the stomach of the plant—that is, the leaves—and return again ere young rootlets are formed. So that there may be no misconception upon this point, let me say that buds are leaves, flowers, and branches, in embryo, and consequently, act as stomach and lungs, until such time as the leaves begin to develop. The food or sap, therefore, is provided by the roots, and passing up through the tree to the bud, becomes there digested, and afterwards part thereof descends, and forms young spongioles; hence the reason why the action of the roots is not visible till some time after their real work has commenced. If anyone has the least doubt that it is the descending sap which forms the young rootlet, let him have one of the sections magnified, and he will at once perceive that it is done in much the same way that an icicle is formed, viz. by a descending deposit on the outside and point of the old wood. At page 18 of "Lindley's Theory of Horticulture" will be found a cut which will amply illustrate what I mean. I know that what I here advance is antagonistic to the views of many of our leading men; yet, nevertheless, unless they are prepared to give a better, a clearer, and more convincing proof of the correctness of their theory—for it is nothing more—I must abide by my own conclusions. *James M. Millan, Erskine Gardens, Glasgow.* Our correspondent is not quite up to time in his notions of vegetable physiology. *E. S.*

Lilium lancifolium.—Without venturing on a lengthened disquisition as to the general culture of this lovely genus—on which much diversity of opinion exists—I wish merely to state that at the present time we have here several plants of the above growing in only 4-inch pots, varying from 12 inches to 18 inches high in the main stems, each being furnished with five or six fully developed and deliciously scented flowers; hence affording admirable subjects for parlour and sitting-room purposes. The bulbs in question were procured from a London firm early last spring, and arrived here in a somewhat shrivelled dormant state. They were forthwith potted in a mixture of peat, loam, and silver sand, in 4-inch pots, in which they have grown up to the present time, resulting as I have previously detailed. Possibly there may be nothing new in the mode of culture; it is, however, the only instance that has ever come under my cognisance, and I have had considerable experience in the culture of them. Here I may be allowed to remark that some of the finest and best-bloomed specimens I ever saw were grown by me in 12-inch and 16-inch pots—several bulbs in a pot, and they were received and treated under similar conditions, excepting the small pots, to those which form the subject of the foregoing remarks. *William Gardiner, Eaton Park.*

Picea Pinsapo.—It was very interesting to read Mr. Gardiner's paper on *Picea Pinsapo* (see p. 1137), how it was attacked by a Fungus, blown down twice, and twice reared up; how, after all these casualties, it was thrown into a state of fructification—on the principle, I should say, that, finding its constitution gradually becoming weaker, it concentrated its remaining strength, like other races of plants and animals, in an effort, before death, to perpetuate its species. Mr. Gardiner says, that of late years the tree became less healthy, and that he subsequently found that the cause was an attack of Fungus. Now, in my opinion, this is a point which requires some clearing up. Was Fungus the primary cause of the decay, or was it only a consequence of decay arising from a totally different cause? In the "dark-coloured loam" in which the tree was planted might there not be something lurking which eventually proved distasteful to the roots? or did not the roots penetrate deeply (as the roots of Conifers do sometimes), to the formation of has, which abounds in lime, and there sicken and die, and during their decay became attacked by the Fungus? This opinion is strengthened by Mr. Gardiner's description of the state in which he found the roots, "one of the main surface roots was healthy." This is almost of itself evidence enough to prove that the Fungus was not the primary cause of decay; there is, indeed, direct evidence from Mr. Gardiner himself to prove that it was only a consequence of some other decay, as he says, "so far as I can ascertain, the Fungus is now apparently in a state of non-vitality." We may, then,

almost safely infer that decay originated in those roots which penetrated deeply into the subsoil, for, we observe, in its after history, that the tree showed marked evidence of renewed vigour by a formation of new bark at the base, and of terminal growth in the branches. All this to me, seems evidence that Fungus was not the primary cause of the decay. Perhaps Mr. Gardiner could furnish other information respecting the situation where his *Pinsapo* is planted, whether the situation is wet or dry—extremes either way might induce decay. "M. J. B." might be induced to say something in this case, but would that he could shift the primary cause of decay on to the shoulders of anything but this horrid Fungus, which haunts every gardener like a nightmare—lest either his Conifers, Peach trees, or Vines, should become irretrievably afflicted with it. There are three beautiful specimens of the *P. Pinsapo* here, which are respectively 20, 25, and 30 feet high, healthy, and otherwise well developed, but I trust we may be more fortunate than Mr. Gardiner has been with his. I should rather see cones produced upon them through maturity of years than by circumstances such as appear to have brought about the premature coming of Mr. Gardiner's trees. *Wm. Miller, Combe Abbey Gardens.*

The Early Maturation of Potatoes, so as to secure the crop in a healthy condition, is the great desideratum, and, with early sorts, this may generally be safely accomplished, but with late kinds it is occasionally well not to be in too great a hurry. This season we took up our principal crop in the first week in September, which for late sorts, in a general way, I consider too early, excepting in such a season as the present. The rainfall here for the last three years, in the months of June, July, and August, has been as under:—

	1867.	1868.	1869.
June	inches, 0.82	1.40	0.88
July	4.00	6.25	0.45
August	2.34	5.40	0.83
Inches.	8.06	7.14	2.16

This year, owing to the diminished amount of rainfall, especially in August, we have suffered more from drought than we did last season, though later in the season, and in a different manner. The park has in many places showed more brown than I have ever before observed. August-sown seeds, as Cabbage, Spinach, &c., at first came up badly, and many trees, particularly Beech, were prematurely shedding their leaves; but other things that failed last season have done well this, as late Peas, but then in May of this year we had 5.82 inches of rain. Potatoes ripened off early, the haulm being generally withered by the end of August; and fearing a repetition of the superabundance of last year, they were taken up as mentioned above, excepting part of a late kind, called here *Scilly Red*, the tubers of which were found too small to be useful, the tops of these being still somewhat green, though the leaves were mostly gone, they were left in the ground, in the hope they might still improve. Upon taking them up on the 15th October we were not disappointed. This fact proves that though the leaves may be mostly gone, yet, while matured juices are left in the stems, the tubers will grow and increase the value of the crop, other conditions being favourable. Early Potatoes in the garden were all that could be desired, both as to quantity and quality, in the field we had quality, but the quantity below average. *T. C. Elliott, Melbury House Gardens.*

"The Question."—Nothing stimulates a man so much to industry and good conduct as the hope of being, in the end, well rewarded for his pains. The Devil know this when he said, in his malice, "Does Job serve God for nought?" Gardeners are very apt to look upon their remuneration as inadequate, because they do not go into the matter in a business-like way, to see what they really do get. I once tried to convince an old pensioner that he had had about 2s. 6d. per day for all the years he had been a foot soldier, and he smiled at my view of the matter, but when he saw how I accounted for the Government securities for the whole term of his natural life, at even 1s. per day—and that he would have had to save from 300l. to 500l., and let the same out at good interest, to bring in 180l. a year and that this represented a saving of 20l. or 30l. a year for 15 years, he saw clearly that he had had 2s. 6d. a day, and something over. Now the only way to right the matter between the gardener and his employer, is to state clearly, in the first place, what the employer really does pay, for he must not be condemned without a hearing. Some proprietors of farms in Wales once sent a deputation to London, to confer with the Government about abatements and allowances, and when the items of cost were fairly set against the selling price, they were all convinced that they had an excellent paying business, for they had never had their balance-sheet so well audited before. The writer of this letter was duly examined by the Income Tax officials, and had to state the value of his salary in cash, and not only that but the cash value of household fuel, milk, vegetables, and the use of furniture, bed and table linen, carriage and the like, but this is not all, for enquiring into the cost of his life, and charging to the rent the various taxes, and the various rates, highway rates, inhabited houses tax, and the like, and the value of the water, &c., &c., of which the gardener attached to a country mansion or gentleman's seat does not pay, or, in other words, has it saved or added to his wages—and, as there can be no wrangling about figures, it is quite clear that the salaries of some gardeners, like the pay of the soldier above-mentioned, are certainly larger than they usually reckon them to be. But two and two will only make four, and not either three or five to please either party. The gardener who has been honourably dealt with by a generous employer usually becomes grateful, and firmly attached to his patron's interest; and the employers described by the late Dr. Lindley as persons who "should be allowed to serve themselves," who use their position as masters to get their work done for less than its fair and just value, need not be at all surprised at the servant copying so plain an example, and using his abilities, not for his employer's interest, but for his own. In Lancashire and elsewhere, where the effects of trade unions are felt, the wages for skilled labour have lately risen to an enormous extent, and these unions, in some instances, have dragged not only their own members but others out of the low wages formerly paid, into a very different state. As an instance of this I will add, that the papers teem with advertisements for masons and bricklayers at 7d. per hour, which, at 50 hours per week, gives 35s. 4d., or within a fraction of 100l. a year, and this, be it observed, is not for masters but for journeymen. When well

educated boys are leaving school they aspire to learn some business, which encourages them to climb after the coveted prize, and, in the case of the 7s. 6d. per hour, with an assistant, or labourer, to do the drudgery, always looks forward to the end of his bricksetting apprenticeship as to a land of Goshen not very far off. All the interested parties must be convinced that, unless well educated boys, of good character and strong constitution, can be induced to learn gardening, we shall feel the effects of a low status, and the art will assuredly go down to meet the scale. But how have these men got their wages raised? Simply by the clear head and the labouring hand, to combine and persevere, and with the natural imperfections of human nature, all starred ideas have often been entertained to compel numbers to support the union by which their wages had been got up. Still there stands the fact unquestioned, that the whole of the trades have bettered their condition, and it is to the union, with all its faults, that they owe the debt. I will now give one example of the unfairness of prices as affecting gardeners. The tailor, for one of the necessities of life, gets 30 per cent. advance for his skilled labour, whilst the wages of gardeners have been almost a fixture, to my knowledge, for the last 30 years. The science and practice of gardening, like that of railways, is but a thing of yesterday, for it had no literature even in my time. The gathering of Fern seed at stated times, &c., for witchcraft, and the "virtues" ascribed to certain plants, as the Chaste tree, and the superstitious pieces of information to be derived from Herbals and the like, furnish important evidence to show our patrons the "datum peg," or the watermark, from which we started; while the great fruit flower and vegetable shows will mark the progress that gardening and gardeners have made during the lifetime of living men. My namesake, Mr. Forsyth, got a grant from Government for improvements in fruit growing, and I name it here to show that the Government of that day set a good example, and did not let a public servant who had done some service to the community go unrewarded. The jealousy caused by this grant was discredit to the Opposition, and some of us can now look and laugh at their failures. For example, the late Thomas Andrew Knight experimented with Pine-apples mounted on shelves to produce their fruit without bottom heat, to fulfil a theory that the heat should go the other way. One would have thought that the Cucumbers and Melons, and all the host of cuttings from the hot-beds, would have exhorted the President, and warned such a shrewd observer. Mr. Knight's failure to grow Pine-apples without bottom heat has been like a bell on that rock, and has warned all his followers to give it a wide berth, and this gentleman was louder than any one in condemning the grant to the King's gardener. I am not expecting Government aid for gardeners, but I do expect that as they have a multitude of cares, and as their business requires great attention to be paid to it on Sundays, as well as on other days, and by night as well as by day, some adequate consideration for unremitting labour of head as well as of hand should be given. But some one will say, How are we to know who are gardeners and who are not? Easily enough. You do not mistake the hodman of the bricksetter for the craftsman he is writing upon, although he may be the best man in dress as well as in person. You have no difficulty in telling who are tailors, and who are not, although nearly half of all the human family "stitch at times." When learned men want to distinguish the human family from others having a brute resemblance, they say man is a cooking animal (using fire) to which the knight of the thimble might add that he is a dressing animal (using clothes), but he certainly is a gardening animal, a real cultivator, which no brute has ever been. All gardeners ought to be able to show that they are, or have been, recognised by some competent authority as such. An indenture of apprenticeship, on stamped paper, after the Scottish fashion, tells the fee paid, the time served, and the restraints used to learn the business. Moreover, it gives dates, and a clue to the history of the man, and subsequent papers will show the times and places where further proficiency has been acquired, without subjecting the gardener to any more prying or examination than would be required by an insurance office before granting a life policy. If a gardener's club were established in London with branches in the country, it would soon become impossible to palm off inferior men as well educated gardeners, and the headquarters would always be something like a home to fall back upon, and a source from which good gardeners could be drawn. We see the sailors in their "Home" in Liverpool. When we had only the wretched huddle for a house, and the rushes for a floor, the mason of the middle ages came, and was honoured as well as rewarded. He it was that took us out of the hut and the log cabin, and laid the foundations of the church, the castle, and the palace, of which it has been well said, "their very ruins are tremendous." In like manner, the craft confided to old gardeners, or rather to gardeners now living, is so well worthy of being handed down to posterity, that we shall commit a great blunder if we let it slip over one generation. And a society for the preservation of the craft is much wanted. The well educated youth leaving school with a strong constitution should pay some one a fee, and submit to the restraints of an apprenticeship, and thus the relationship of master and apprentice would be of the greatest value in securing the best interests of both, and as this would add to the gardener's income, it would at the same time make a legal demand for a course of instruction which no man could afford altogether to ignore, which is far from being the case now, where money is paid, and the young man is left to his own resources. Too much stress cannot be laid upon the simple fact that the gardener must be born an amateur, with sufficient force of character to grapple with the difficulties attending a thorough knowledge of plants, and their culture. He should have a great love for the other branches of natural history, and, generally speaking, of what may be termed rural life, for it would be perfectly useless to look for high class attainments where those are wanting. I could at any time during the last 20 years point to men who have been pitched into situations of trust as gardeners by patronage, to the great detriment of better men, and to the utter ruin of the gardens entrusted to them. I recollect an instance of one of these would-be gardeners appointed as one of the judges at an exhibition of fruit and flowers, and when his decision was called in question he astonished by exhibiting the other judges' medals, and saying "I have never seen a better specimen of the said gold medal having grown a better of grapes in his life, and I do not see that I patronage can bestow this style of practical information. There has been too much fiddling up in one string in coming out against the low rate of wages for gardeners, without stating honestly both sides of the question; for one gardener of the above named stamp would be found able to weigh down the scale against ten meritorious men. Far be it from me to speak slightly of patronage when it is bestowed on real merit by those who are competent to judge, but few will deny that among the number of young gardeners now learning the business, as well as among the young men with whom the writer of this letter has been associated, a goodly portion never could be good gardeners, for they never took root in their business. I am happy to be able to state, however, that the greater part of those who really loved the craft, and studied hard to master it, among my acquaintances, got well rewarded. The gardener's wages and the comforts of his residence, and the like, can never be of the slightest importance as influencing the fortune of his employer, and therefore it is too often from sheer thoughtlessness that his interest is overlooked. If we could only get young men to

understand the great value of high moral training, which is a cheap commodity, then when high class information has been engrafted upon that stock, the fruit will, generally speaking, be forthcoming in due season. Alex. Forsyth.

Notices of Books.

Field, Forest, and Garden Botany; a Simple Introduction to the Common Plants of the United States East of the Mississippi, both Wild and Cultivated. By Asa Gray. New York: Ivison. 8vo., pp 386.

In our student days, we hardly know why, unless from a supposed difficulty (purely imaginary) in procuring specimens, it was the fashion for students of botany to disregard, or even disparage, the study of any but "wild" plants. The fact that such and such a flower was a garden plant was, with many students, a sufficient reason for casting it aside without more than a passing glance. Of course, we are speaking of those who studied botany because it was part of the curriculum, and who "crammed" as much of the subject as was necessary for a "pass," never cared to digest what they had learnt, and, having obtained their object, straightway forgot all they had learnt. In the case of the few who studied botany for its own sake, and because they liked it, there was still a difficulty about garden plants, because few or none of the ordinary text-books make more than a passing notice of them. This has always seemed to us a great oversight, because garden plants are often more readily and constantly accessible than wild ones; they have as a rule larger and more conspicuous flowers, so that their structure is more readily made out by the inexperienced student, and they present a greater range and diversity of conformation than do wild plants. Again, if the student be desirous of studying the comparative anatomy or morphology of flowers, garden plants and garden varieties, such as double flowers and the like, offer facilities not possessed by our native plants. For physiological purposes, for investigations into the life-history of plants, garden specimens are indispensable. Some such opinion seems to have induced the eminent Professor of Botany in Harvard University to draw up the present volume. "It is very desirable," says he in his preface, "that students should be able to use exotic as well as indigenous plants in analysis; and a scientific acquaintance with the plants and flowers most common around us in garden, field, or greenhouse, and which so largely contribute to our well-being and enjoyment, would seem to be no less important than in the case of our native plants. If it is worth while so largely to assemble around us ornamental and useful trees, plants, and flowers, it is certainly well to know what they are, and what they are like." Hence "one of the main objects of this book is to provide cultivators, gardeners, and amateurs, and all who are fond of plants and flowers, with a simple guide to a knowledge of their botanical names and structure."

Of course, the book will be mainly serviceable to American students, but it will be of use also on this side of the Atlantic, and may serve as a model for some one to draw up a similar work for this country. There are one or two similar works in the French language, but none in English that can boast anything like completeness. The present work consists of a description, in as simple language as possible, of the majority of the more conspicuous and easily studied plants of the United States, east of the Mississippi, and of the principal garden flowers. These are all arranged according to their natural orders. The name of Professor Asa Gray is an ample guarantee for the accuracy of the book, which is intended to be used as a companion volume to the "First Lessons in Botany" by the same author.

It is curious to see how the idiom of the language is changing in America. One would hardly expect to notice this in a technical work written by so accomplished and correct a writer, and yet it seems strange to English eyes to read "for" in cases where we should say "in honour or in commemoration of." Thus "Martynia, named by Linnaeus for Prof. Martyn," meaning, not as might be inferred that Linnaeus had been requested by Martyn to name his plant for him, but simply that he bestowed the name "in honour of" Martyn. And so in the case of "Paulownia, named for a Russian Princess." The same expression is made use of in every case where a genus is named after a person else we might have thought it accidental. As it is, we point it out as an instance of a change in language going on in our own time, pretty much in the same way that species are supposed to be undergoing modification.

Some time since we had occasion to speak in terms of high commendation of the series of elementary Atlases intended for use in village schools and similar institutions, and published by Messrs. W. & A. K. Johnston, of Edinburgh and London. We may now announce the publication, by the same firm, of a similar series of Atlases of Physical Geography, at the extremely low price of 2s. 6d., 1s., and 6d. respectively. The maps are not so clear as was the case in the preceding series, indeed too much seems to have been attempted in a little space, nevertheless they will be of service for giving instruction in the main physical and climate peculiarities of the globe.

Florists' Flowers.

NOT many years since the HERBACEOUS CALCEOLARIA formed an important feature of our large metropolitan exhibitions, and though it is scarcely represented now, there is reason to hope the day is not far distant when it will be once more seen, in all its gay and gorgeous hues of colour. Probably one of the most attractive features of the exhibition held at the Crystal Palace in May last was a group of seedling Calceolarias exhibited

by Messrs. Dobson & Son, Woodlands Nursery, which were worth, for crowds of visitors hung about them, they were something altogether new, and of a type familiar from his childhood. The old type of herbaceous Calceolaria, that used to be bred of a size so large as to resemble in habit Mr. B. S. Williams' splendid Crotons, appeared to be a thing of the past; but with it has gone to some extent that ideal of form that used to be worshipped by florists 20 years ago. It should be smooth and full, like a small bladder, not flattened, nor indented like a bell, perfectly round in the outline whichever way viewed." I have no doubt but that Mr. Glenny wrote this, he had the shrubby Calceolaria in view, for he confessed that a higher type of perfection of form found in the shrubby rather than in the herbaceous Calceolaria. Mr. James, of Isleworth, a strain of herbaceous Calceolarias is now the very finest in cultivation, claims to have obtained dwarf growth by crossing with the shrubby Calceolaria. This was a decided gain, whether obtained in the way as Mr. James states, or whether it was simply a selection. If by the former, then it is worth another effort to bring about what is wanted in all our finest strains of herbaceous Calceolarias—an improved form and, if it can also be an admixture of the rich dark hues found in flowers of the shrubby kinds.

It was my privilege during the past summer to inspect, when at their best, the splendid Calceolarias grown by Mr. James and Messrs. Dobson & Sons. Actually these two strains, so long termed identical without adding to or detracting from the glory of either. I thought Mr. James' Calceolaria greater variety of colours, and of than the other way, and the indication of a near approach to a decided purple spot, while there was the preponderance of dark flowers—rich shades of blue, mauve type was absent from Messrs. Dobson's Calceolaria, but if there was less of variation, it was to some extent compensated for by some brilliant golden yellow of great size, handsomely spotted with dark spots, and here, too, were some grand dark flowers, as good as either of these, except in the matter of variation, was a fine strain in the hands of Mr. Wheeler, Warminster, which I saw at the meeting of the Bath and West of England Agricultural Association during the past summer; but all of these wanting in that which will no doubt soon be a perfected form. Flowers, wonderful in size, have been seen this season, but in many they are long, flat, and indented, and the orifices and upperside wide apart. Then in the matter of variegation, have perhaps branched out widely enough for our present, for "the colours and the markings of Calceolaria are becoming exceedingly numerous, and the last few years they have been diverted from general characteristic in an extraordinary manner from speckles and blotches of all forms and sizes, and have produced blossoms with stripes like a Calceolaria ramifying from the hollow which is at the base of the rays from the centre to the outer edge." Mr. Glenny in 1860, and if to these positions we presently add "the roundness and freedom of form—so large a majority of the present variety deficient in these respects"—then we shall have a comparative perfection with the Calceolaria.

But little propagation of the Calceolaria appears to be attempted now. Growers like Mr. James who exhibit occasionally, grow on a few good plants for the purpose, and name them, and the specimen plants he sometimes produces represent or four years' growth. Sometimes, too, a first year having the quality of form in a high degree, is grafted for the purpose of getting seed to raise a new strain. The Calceolaria is now almost generally raised from seed. The latter part of August or the first of September—if there be ample convenience for wintering the plants, and giving them every attention, or even earlier in cases where the winter is limited, and the plants have to struggle against a severe winter, is a good time at which to sow the seed. It should be sown in pans or large pots about 10 inches in diameter. If pots are used, they should be filled about three-fourths up with crocks, and over this soil, say three or four inches of equal quantities of peat and good garden soil, should be passed through a fine sieve and to which should be added a liberal quantity of silver sand. Sow the seed very thinly, as they are so minute, and afterwards shaking over them a little fine soil, water with a fine rose. Perhaps as a general rule it is better to attempt to cover it. Place the pots or pans in a cool and protect them well from the mid-day sun, by placing a piece of glass over the pots, the soil should be kept regularly moist without too frequent watering, thus the germination of the seed will be greatly promoted. As soon as the plants can be handled, they should be pricked off into larger pots, about an inch square, and a compost containing less of peat and more of garden soil. As soon as the plants thus transplanted are well established, touch each other, plant them out singly into 60-pots, and continue to shut them into larger pots as the fibres touch their sides. During the summer and spring months, they will make fine plants, and bloom early in summer. All plants exhibiting a weakly, and straggling habit should be thrown away as worthless.

I am afraid that the interesting class of Calceolarias is dying out, although it has been respecting these that they "are more hardy than the

Round London they appear to have been entirely passed from sight. Occasionally they can be met with in some remote country show, and are seen to be invariably well grown, and highly productive. It is to be hoped that they will be taken up again, by some one ere long, and presented to the public in some more attractive colours, combined with the fine style of growth that some years ago used to be seen at the Royal Nurseries, Slough. R. D.

The Apiary.

UPPERS—I do not wonder at tradesmen who retail honey being unwilling to heave over a heavy box of combs upwards every time a comb is required. The is probably kept bottom upwards not only during the winter but on the tradesman's counter, to exhibit the honey to his customers; then, if the combs are to be used, they are to be taken out of the bars, which is unquestionably the only way, yet long it is boxes are at present constructed, that the comb has to be turned over, and a risk run of losing a mass by setting honey running, which had dripped down into the top of the box as it lay underneath. The alternative, to break out comb as the box is a clumsy and troublesome business too. Could all this be prevented by a different construction of boxes, according to a plan that Taylor recommends in the case of straw supers? Let the top of the super be formed of two boards, glazed either across the grain, one made to fit the inner diameter of the super, and a quarter of an inch thick, the other made wide enough to cover its outside diameter, and of thicker material. This could be fastened to the super's sides with screws. Now, when it is desired to remove any combs, all that would be necessary to do it with perfect ease would be to unscrew the place the box on its top, turned down, to remain in place, and remove the sides of the box all at once, leaving the combs standing up on a flat board, and thus in the easiest of all positions to cut them from their attachments. Of course it would be necessary to fix the board to the flat board-top and I see different ways of doing this, and at the same time leaving a flat surface for the honey to run from. A glass case, instead of the box, may be used to cover the combs when lying on the tradesman's counter.

Lower square or oblong boxes are still more easily constructed, so that the comb will be available by this method. Large boxes may have two opposite sides made movable by being fastened by screws, and brass hinges, and eyes may be added to come into use when all the screws have been taken out. One movable side would be sufficient for a small box. I have seen such a box as the above with a pane of glass over the mouth, and many they lay on a tradesman's counter, showing the comb beautifully through a couple of windows, while the comb was taken out with the greatest ease, and without the loss of a drop of honey. A. B., North.

OUT A MONTH ago I placed a small super, weighing 6 or 7 lbs, over a hive of bees, as it was wet and they could not get out. I thought they would clear out the combs, so that I should have them and empty for next summer's campaign. Can I tell me whether it is necessary to remove the super, and if so, how soon? It seems a great pity, in cold weather, to subject the poor bees to ejectionment. I have stands in a beehive of which the back is but sheltered by a wall. Will it be necessary to surround with hay-bands, or any other covering? The climate is very damp, and the situation windy, but the front and sides of the hive, and the top, are all in Lancashire.

do not approve of allowing partially filled supers to remain on during the winter. Unless the stock is strong in bees, or only poorly supplied with stores, more than probable that the bees will already have cleared from the super. In that case it would be better to remove it. At any rate, on some cold morning if you lift it up to see whether there are many bees, if so, wait until some very mild day, when, removed the super, place it in a warm room, with a partially open window; the bees will return to their present stock without injury. The cover of the hive, of course, be put on as soon as possible after the removal of the super. We do not, in the south of England, need to wrap up our hives, when protected by a house, with hay bands, cloths, or other material. It is only in your climate a mat made of loosely twisted straw might be of advantage. It should be so managed that it should throw off any rain that may drive in from the roof of the bee-house. The great thing, however, is to keep your stocks very populous, and well provided with stores, when the bees will be able to stand any of our weather without any other protection than what may be afforded by shelter from rain.

Garden Memoranda.

DOWNBANK. THE RESIDENCE OF THOMAS DAWSON. (continued from p 1149).—Proceeding from the house No. 4, we enter No. 4, which is a large spanned structure, erected for the cultivation of the Orchids, of which there is here a fine collection, some in inch-glass, some in pots, and some in the open air. The stage are arranged for effect with flowering plants and foliage plants. Extending the entire length of the stage are a great many fine plants of the genus *Phalaenopsis*, on many of which I counted upwards of 20 spikes of bloom in grand perfection—the number of expanded blooms at the time being upwards of 100. So gorgeous a display may be more easily imagined than described. In front of these was a *Epilendrum vitellinum*, mostly large plants, producing their brilliant orange-scarlet flowers in profusion, and, belted with foliage plants and other plants, it looked as if the idea it was to carry out the style of ribbon borders. The following

Orchids were also noticed, either as fine varieties, or as specimens of gigantic proportions—*Oncidium incurvum*, 4 feet across, but getting past its best, though even then I counted 23 spikes of bloom in fine condition. *Odontoglossum labellatum*, *O. Kramerii*, *O. Lindleyanum*, *O. Uro-Skinneri*, *Trochilium turanense*, with upwards of 100 flowers, *O. Lindleyi* extra, a specimen 2 yards across and having 17 of its large spikes just in perfection, was of itself worth a day's journey to see, *O. serratum*, *O. obryzatum*, *O. incurvum majus*, *Lacoste Schilleriana*, &c., all in flower. I cannot leave this house without alluding to one other specimen, although it was not in flower, this is *Angaria Cowsoni*, which measures about 3 feet across, and invariably produces about 70 flowers. The growth of this fine specimen this season is as good as ever.

House No. 5 is in two divisions—the first being occupied by a collection of *Amaryllis*, in the cultivation of which Mr. Dawson takes great interest, and possesses one of the most complete collections in the country; but being their dormant season, I had no opportunity of making notes on varieties. The second division contains a great number of fine specimens of *Aerides Lobbii* and *Saccolabium curvifolium*; in this house are also several plants of *Saccolabium gattatum*, *A. pumilum*, *Pleurochilus pulchellus*, and others, amongst which was a fine plant of *P. cornu-cervi*, and the curious *Pleurochilus loweri*, besides a quantity of the finest *Cypripediums*.

House No. 6 is chiefly devoted to a collection of *Cattleyas* in magnificent condition, and far too numerous to name and describe here; the collection consists mostly of fine specimens of the leading kinds found in trade catalogues. Conspicuous also in this house were grand examples of *Gomezia planifolia*, *Pogstachya pubescens* in flower, *Oncidium ensiferum*, *Oncidium reflexum* in flower, *Laelia autumnalis*, a great quantity, with scores of flower-spikes, sufficient in themselves to create a grand display during the dull season; *Maxillaria venusta*, *Laelia flava*, *Laelia cinnabarina*, *Trichoplia suavis*, *T. picta*, and *T. crispata*; *Epidendrum lechrosum amabile*, *Zygopetalum maxillare*, *Odontoglossum Insleyi*, *O. hastatum*, *O. nastilabium*, *O. Uro-Skinneri*, *O. cristatum*, *O. pendulum roseum*, and *O. novium*, the two last being enormous specimens; *Epidendrum campylostachy*, *Cattleya citrina*, *Sophranitis grandiflora* and others, were suspended from the roof of this house, and doing admirably.

House No. 7 is certainly the crowning point of the whole; indeed I hesitate to note the gigantic proportions of the specimens contained in this house, more especially considering the extreme rarity of some of them; I shall, therefore, confine myself to the names of a few of the most familiar species, which in most instances may not only be seen in fine specimens, but in great variety and quantity, the following being prominent—*Dendrobium Purshii*, *D. forbesii*, *D. subseriale*, *D. Bensoni*, *D. Farmeri*, *D. aurinum*, *D. Vestrumii*, *D. sessile*, *D. crispatum*, *D. prunellinum*, *D. cumulatum*, *D. macrophyllum giganteum*, *D. Wardianum*, *D. Devonianum*, *D. chrysotoxum*, and *D. crassinode*, with *Dendrobium glumacum*, *D. filiforme*, and *Aerides maculosum*. On the centre stage are some *Vandas* of remarkable size, 5 or 6 feet high from the pot, clothed with foliage to the bottom, many with four growths and upwards, while one specimen has 50 growths of various sizes, *Vanda Bitemini* is 8 feet high, *Vanda Loweri* 4 feet, *Cypripedium villosum*, 3 feet across; *Oncidium lanceatum*, very fine and in great quantities; also *Cattleya Dowiana*, *C. amethystoglossa*, *Oncidium Cavendishianum*, *O. Linnæi*, and great quantities of *Aerides*, such as *A. Larpentæ*, *A. nobis*, *A. "fox-brush"*, and *A. roseum*, *Vanda Bensoni*, and *V. Hookeri*; the old *Anselma africana*, unusually fine; *Angraecum sesquipedale*, *A. eburneum*, *A. caudatum*, *Cyclopis Linnæi*, *Cyclopis pandurata*, *Saccolabium ampullaceum*, *Cattleya superba*, all fine specimens, together with numerous other fine species and varieties of little moment to the general reader, many being comparatively unknown except to those who are continually novelty-hunting.

House No. 8 contains, amongst a general temperate collection, the following, most of which may be counted by the dozen, the plants as a rule being small, but in fine health.—*Cattleya Warneri*, *C. Mossiae*, *C. bicolor*, *C. Trianae*, *C. speciosissima*, *C. Skinneri*, *C. Leopoldi*, *C. Dawsoni*, *C. bulbosa*, &c.; *Laelia anceps*, and its varieties *Dawsoni* and *Barkeri*, *L. purpurata*, *L. gigantea*, *Epidendrum rhizophorum*, very large and in flower, *E. nemorale majus*, one of the finest Orchids, and a noble specimen, *Trichoplia eucnea*, *T. suavis*, *T. crispata*, *Oncidium Forbesii*, *O. Papilio*, with upwards of 30 flowers expanded, quite a feature in themselves. *O. sarcochilus*, grown in small pots suspended from the roof in quantity, and very fine. There are here, also, many *Dendrobies*, amongst which were fine examples of *D. heterocarpum*, and other fine species. One other plant, deserving of special notice, is a magnificent specimen of *Laelia superbissima*, fast rivalling the famous *Broomfield* plant. Adjoining this house is a lean-to frame, in which are some fine examples of the lovely *Disa grandiflora* in flower.

House No. 9 is devoted to a small but choice collection of novelties belonging to the cool Orchid section, amongst which are several gems of sterling merit, either as new and rare species, or older ones seldom seen in such good condition. The following are a few species, which are evidently quite at home in this house, a portion of which is partitioned off, and forms a sort of closed box, having a northern aspect; the plants are close to the glass, and kept very cool, and I never saw *Laelia majalis* anything near so fine as it is here. *Barkeria*, too, are doing well, in the other portion of the house, and occupying one end are several plants of *Flore de San Joseph* (*Epidendrum erubescens*) growing in wild luxuriance on the stage, uncontrolled by pots or

other incumbrances, *Laelia albida*, and its varieties, by dozens, *Laelia furfuracea*, *Oncidium leucochilum*, *O. ornithorhynchum*, *Odontoglossum Phalaenopsis*, some of the *Lycastes*—one new species very fine, and a beautiful *O. longotlet*, which will doubtless be shortly described and named.

There were various other houses, devoted to other objects but it is not my purpose here to enter into any details of the contents of these houses, suffice it to say, that there is here also a good collection of miscellaneous plants, Mr. Dawson having many pet varieties amongst them. Long may he live to enjoy the fruits of his labours, and maintain the proud position he has so deservedly won, and in which he has been so materially aided by Mr. Anderson's skill and sagacity. Robert Bullen, Curator, Royal Botanic Garden, Glasgow.

Miscellaneous.

Gigantic Trees—Passing and stopping for a few hours at Pueblo Nuevo, with its curious Cactus fences, I put up for the night at Nagarote, where I measured a famous Genisaro tree (*Pithecolobium saman*, Benth.), belonging to the Mimosa tribe, of which the villagers are justly proud, and for which 200 dollars have been offered—a high price in a country where timber abounds, and yet they had the public spirit—the rarest of virtues in a Spanish American—to refuse the offer, others say the Government made them refuse. The tree, of which a woodcut is given in Spurr's "Central America," is but 90 feet high; but some of the lower branches, which are quite horizontal, are 92 feet long and 5 feet in diameter. The stem, 4 feet above the base, is 21 feet in circumference, and the crown of the tree describes a circle of 348 feet. A whole regiment of soldiers may seek repose in its shade. If this vegetable monster had been a denizen of any part of the eastern hemisphere, it would have become a fit object of tree-worship, that singular religion which flourished long before temples and churches were thought of, and which enjoyed a more extensive geographical range than any creed has done since. At one time it was diffused over the whole of Europe, Asia, Africa, and Polynesia. Throughout Europe and some islands of Polynesia it has been supplanted by Christianity, in parts of Asia and Africa by Mohammedanism, but nowhere have its rites been entirely suppressed. Deprived of their religious character and import, many of them have survived to this day, everywhere associated with mirth, good feeling and festivity. No trace of tree-worship has been noticed amongst the natives of Australia, nor amongst those of the New World, though it had penetrated to the easternmost islands of Polynesia. The fact is most singular, as no continent boasts of such magnificent and venerable trees as America. In the virgin forests of Brazil there are trunks of such gigantic size that fifteen Indians with outstretched arms could hardly span them; trunks which, by counting the concentric rings of their wood, must have been in existence when Homer wrote his immortal poem. In Upper California and along the whole north-western coast of America the vegetation attains enormous dimensions and age. Three hundred feet is no uncommon height for a tree, and some of the *Wellingtonias* overtop St. Peter's, and almost rival the height of the pinnacle of Cheops, whilst their age is such that they must have been in full growth long before the Saxon invasion of England. Yet these peculiarities do not seem to have made any impression on the mind of the American Indian, evidently proving that size, venerable look, and age of trees are not sufficient to account for their worship by the largest section of the human race. Indeed, tree-worship can scarcely have sprung from simple admiration. We have plenty of people among us with a strong leaning that way, and can pretty well judge of its range and scope. The Rev. Charles Young tells us that from childhood nothing in Nature had a greater attraction for him than trees, and a giant tree, such as that of which the bark existed at the Crystal Palace, had been the height of his ambition among the sights of Nature. To gratify this feeling he made purposely a voyage to the Amazon, of which he has given an interesting account to Galton's "Vacation Tourists," and one might suppose that when at last he found himself among the vegetable giants of Brazil feelings superior to those of gratified curiosity would come to the surface. But there was nothing of the kind; even a botanical interest does not appear to have been roused in him. Mr. Young's predilection is rather prevalent in the United States, where travellers are almost bored to death by being taken to see big trees. Dr. Russell, who went thither for a very different purpose, and during a period of great civil commotion, repeatedly mentions his being forced to visit such objects; and he tries to account for the admiration Americans have for their vegetable monsters by the fact that in the United States few things are old and venerable, and any exception to that rule is carefully noticed. I remember, in passing through Cambridge, Massachusetts, seeing a black board, recording that the mayor and aldermen of that town had been such Vandals as to cut down an old and large tree which stood in the middle of the road, and underneath was written with chalk, "Let this be remembered at the next election!" A ride of three days from Managua, by way of Tipitapa and Juigalpa, brought me to Chontales, the finest and most fertile district of Nicaragua. Approaching it from the west, as I did, you find yourself amongst rich undulating grass-lands, which even at the end of the dry season retain their verdure and afford pasture to thousands of heads of cattle. On nearing Libertad, the ground becomes more elevated, the climate considerably cooler, and you get occasional glimpses of the Lake of Granada, with its islands and majestic volcanoes. Close to Libertad commences a dense virgin forest, which extends to the Atlantic seaboard, and a singular feature of which is, that the stems of

the trees are of a very light grey, as well indicated by Mr. George Chambers in some of his clever sketches; but the correctness of which I was inclined to doubt until I had actually seen it in the landscape itself." Dr. Seemann's "Dotlings in Nicaragua."

A Natural Life-Raft.—"Only a traveller's story!" such used to be the reception of many curious and wonderful "natural history" facts related by travellers before the beginning of the present century. The study of Nature was then in its infancy, or more correctly speaking, illustrations in aid of the study were then few in comparison with those of the present day. The increase of the facilities for travel during the last 50 years has been the means, more than all other items in the progress of civilisation, of making us acquainted with Nature's work, and has also proved, in general "travellers tales" to be true, or at least "founded on fact." It our grandmothers had been told that in "out-landish parts of the world" there grew water-lilies with such big leaves that one of them would support herself and her good man sitting comfortably in their easy chairs,—"Ah! only a traveller's tale" would have been the answer. But in her days there were no such journals as "Land and Water," and natural history was then treated almost as a mystery, and not, as now, a popular study. Although we are all familiar with the wonderful tales told by voyagers on the Amazon of the buoyant power of the leaf of Victoria regia, now a common and well-known water-plant, I have not seen recorded the actual weight supported it may therefore interest your readers to mention an experiment made here last week:—A leaf was selected, the worst but one of eight on the plant, as we did not like to destroy the best; it was, however, pretty perfect, only a few holes within 6 inches of the margin, diameter 5 feet 6 inches. On this leaf I placed a wheel 3 feet 6 inches diameter, with eight spokes made of thin wood, and a small footboard, on which I stood and floated "high and dry;" the wheel was necessary to distribute the pressure over a considerable portion of the surface, the texture of the leaf being exceedingly tender (the footboard did not touch the leaf, but rested on the spokes of the wheel). I have no doubt that if the wheel had been of the same diameter as the leaf it would have served as a life-raft for a small family, as the next experiment will show. The wheel and footboard were removed from the leaf and its surface left quite free; we then gradually spread over the surface shell gravel previously weighed out in lots of half cwt.; basketful after basketful was shovelled on up to 3 cwt., when the gardeners standing by would not believe their own eyes, and began feeling under the leaf thinking there must be some other support than water,—but no, the leaf floated quite free,—another 20 lb., and another, and another, was thrown on, and yet the good ship remained seaworthy and no signs of foundering; 426 lb. called, water began to leak in through the holes; the excitement or, perhaps, the heat of the "stove" in which we worked, made us rather hasty and unsteady in loading cargo, the weight of which was being augmented by the leakage and an unlucky cast tilted the leaf on one side, the water rushed over, it crumpled up like a sheet of paper and sank in deep water, carrying with it a load of 436 lb. (besides water). This is the greatest weight I have yet seen a leaf support, and the eight now on the plant may be considered equal to 1½ tons. William Sowerby, Botanic Gardens, Regent's Park, in "Land and Water."

Coal Plants.—The Lepidodendron was as abundant as the Sigillaria, and though nearly related to it, it had a very different appearance. The stem was covered with beautiful markings, arranged spirally, and was repeatedly branched like our ordinary forest trees. The leaves were short and flat, and the fruit was a cone produced at the end of the branches. Although as large as the cones of many Fir trees, it has all the characteristics of the small cones of the Club Moss. This tree grew to a height of 50 to 70 feet. World of Wonders.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

We are now entering upon the dullest and most unfavourable period of the whole year, so far as the culture of plants under glass is concerned. The artificial heat, which is necessary as a security against frosts, and, in the case of soft-wooded plants, is needed to dispel the excessive dampness so characteristic of our atmosphere, should receive our constant attention. If we are to grow plants to anything like fair specimens, or indeed, if we only wish to keep the general stock in good and thriving health, we must aim at something more than giving waterings at regular intervals, affording air daily, and keeping out the frost. As the days shorten, light decreases, so that everything should be discouraged which tends to keep a plant in active growth, except so much as is needed to insure permanent healthiness. The nearer we approach to the shortest day the more fully should these rules be carried out, by gradually affording less heat and moisture, without, if possible, decreasing the amount of fresh air. Now, in regard to the supply of water during the winter months, it is well known that plants in general thrive better, and imbibe the proffered nutriment with far greater zest, if, as in the case of root waterings, it is afforded somewhat sparingly; or withheld until the ball attains an extent of dryness short of incurring a risk of the plants flagging. When we consider that these rules can be safely acted upon during the dry summer months, with perfect immunity from injury to the plants, it will be readily seen how very essential it is to the well-being of individual specimens—more especially those at rest—

that all root waterings, save those that are absolutely required for their existence, should be withheld at this time, when no great tax, either from direct sun-heat or atmospheric influences is likely to be placed upon them. For this reason, I would not place any specimen which should now be undergoing a season of rest near to any form of artificial heating apparatus, because if the ball is forced into a dry state, a corresponding frequent supply of water must in the course of things be given. This acts as a stimulant to active growth, and a derangement of the system consequently follows. In most structures there are of necessity some certain corners or positions where, during severe frosty periods, the forced heat will make itself felt; here we should place what soft-wooded plants we require in continuous activity, or those of any variety that we value the least. Those specimens of the lovely Hedychium, which have ceased to flower should now be removed to an intermediate house, in a dry warm corner of which they may be permitted to ripen off the old growths, which will then die down and make room for those which will be produced successively in the ensuing spring. Anomatheca cruenta is one of the prettiest little bulbs we know for pot culture. If potted about this time in sandy loam they will make a good growth of bright green foliage during the winter; and commencing to bloom late in May, will produce a succession of brilliant crimson flowers, tinted with scarlet throughout the summer. A juncea is another pretty free-flowering variety, with pink flowers, having a dark blotch at the base. I may state that the former of these makes a very pretty display when planted separately in a bed in the open ground. As natives of the Cape of Good Hope, their general treatment will be understood without further comment being needed.

FORCING HOUSES.

The necessary preparations must now be made preparatory to commencing forcing the earlier Tineries. In cases where the roots are growing in outside borders, the necessary protective substances should be obtained, and a good covering of fermenting materials should be properly prepared and placed thereon. It is a good plan to place a nice layer of well-ripened bracken Fern over the surface of the border, upon which to place the warm material. This, whilst it neutralises the intensity of the heat upon the immediate surface of the border and near to the surface roots, affords them additional encouragement to grow, and aids in retaining the body of heat both latent and artificial. I have recently stated that hot stable litter, if moderately sweet, or, next to this, heated leaves, afford the best possible medium with indoors to aid Vines in breaking, or making their young shoots. In structures of moderate extent advantage should be taken of such assistance. The renewal of the heat in tan beds connected with Pines generally should be seen to in the early part of this month, when the tan beds are finally made up for the mid-winter season. The pots may be eased up to and around the rim where there is any certainty that no further fluctuations of any consequence will occur. Gradually reduce the artificial temperature to 62 or 63° by night, with an increase of 8° to 9° by day, that is, of course, with an additional increase of 7° or 8° by sun-heat. The bottom-heat should not greatly exceed 75° or 77° by the middle of the month. Attend to the necessary shifting of Cherry trees grown in pots for early forcing. The same advice applies to Fig trees under like circumstances. Top-dress such as do not need fresh potting with an admixture of good rotten manure and fibrous loam. Place this upon the surfaces of the old balls, after first removing all unnecessary or loose soil therefrom.

HARDY FLOWER GARDEN.

Auriculas should now be placed in the cold pits or other places where it is intended they should winter. Climbing plants generally attached to walls should be first pruned back somewhat, and then nailed in, preparatory to covering up any of the semi-hardy ones which may need protection, such as the Banksian and other tender Roses, &c. Lose no time in planting-out, or potting for future planting all bulbs intended for blooming in the outer borders. Our best old gardeners used to fix the 9th November as the latest date when all such should be got in, considering that they would then have time to root and establish themselves ere severe weather set in. In the last Calendar, under this heading, for "October," read "November."

KITCHEN GARDEN.

Those who have not attended to the storing away of their Root-crops will have run some risk of getting them frozen, for already we have experienced somewhat severe frosts. Those who have delayed the operation so long should lose no further opportunity. Potatoes, whether with indoors, in sheds, or in clamps, will require constant attention, as indications of disease are exhibiting themselves in cases where few if any of the symptoms were seen at the getting-up time. All diseased tubers should be sorted out and removed at the earliest possible time. Take advantage of each fine day to push forward the final earthing-up of successional or late Celery and Cardoons. The sharp weather we have already had should induce additional activity upon all proper occasions. Bank the main crop up substantially as an additional security against any sort of weather which may ensue. W. E.

TOWN GARDENING.

GRASS-PLOTS and verges should not be mown again this season. They should be well swept and rolled, and, to give the walks a neat appearance, the margins should be cut with the edging iron. Collect together all dead leaves and cuttings off bushes, and prepare them for manure by burning them, and mixing the ashes with rotten grass which has previously been

collected into a heap. This should be well over and mixed thoroughly together; it will make an excellent manure for digging into borders. If a larger stock of Chrysanthemums required, continue to take off suckers from low pot them separately in 60-sized pots, and keep through the winter in a cold frame. Freshly trees and shrubs should be securely staked, to them from being disturbed in the ground by frost. This is of the utmost importance to their health and therefore should not be neglected for a moment. If a covering of leaves or rotten dung be upon ground to cover the roots, it will greatly assist them in making a fresh growth. J. D.

STATE OF THE WEATHER AT CHISWICK, NEAR LONDON. For the Week ending Nov. 3, 1867, as observed at the Observatory.

Table with columns: October and Nov, Moon's Age, BAROMETER (Max, Min), TEMPERATURE (Of the Air: Max, Min, Mean; Of the Soil: 1 foot, 2 feet). Rows for Thurs, Friday, Saturday, Sunday, Monday, Tuesday, Wednesday, and Average.

STATE OF THE WEATHER AT CHISWICK. During the last 43 years, for the ensuing Week, ending Nov. 3, 1867.

Table with columns: November, Average Highest Temp, Average Lowest Temp, Mean Temp, No. of Years in which it Rained, Greatest Quantity of Rain. Rows for Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday.

Notices to Correspondents.

BOILER: Subscriber of 20 Years. The saddle for one of the small ones, is also one of the best boilers. We cannot recommend one that will be better. Of the different saddles, that called saddle is probably the best. CLOTHES: H. D. H. (see p. 111.) We do not know the ball in Dublin. People should advertise the COKE: Subscriber. Coke gives off, weight for sulphurous vapours than coal. COLLETTIA CRUCIATA: We believe this to be a CUCUMBER ROOTS: I O I. Your Cucumber roots by a minute worm of the genus Vibrio. We see the perfect insect, but in small quantities. For the roots, and take care not to use the wheel that you have used. GHERKIN: C. G. Gherkin prophetaurum—Gherkin commonly found in the bottles of pickles. LATE VINERY: J. H. If the wood is not up a little to heat and plenty of air. NAMES OF FRUITS: J. J. Constant Reader. For Winkfield; 2, Winter Crassane, 3, Beurre known; 5, Bishop's Thumb, 6, Flemish Apple Boston Russet—C. D. Apple probably King. Specimen sent very scrubby.—George, 3, Crassane, 54 and 55, Beurre Diep, 12, Knight's Winter Crassane, 13, Dunbar, 4, King of the Pippins, 1, Winter Strawberry, 6, Roston Pippin, 7, Stagg's Nonpareil, 8, Gloria Mundi; 2 and 8, not known.—C. R. 4 O. I. C. and Apples, 1, Dutch Codling, 1, Golden Russet, 11, Winter Mjelling flower, 1, Napoleon Russet, 16, Waltham, 18, Hoysche Golden Russet, 19, Old Golden Cio's Golden Drop. Others unknown. NAMES OF PLANTS: Alpha. We cannot pronounce Phlox, or any other trees, from the leaves. They, orientalis, var. freudenlandi.—J. S. As far as we can tell, in the absence of better not white clover or Lotus corniculatus.—G. G. REMOVAL OF VINE: A Correspondent inquires upon leaving the property, is entitled to take the plants. TESTIMONIALS: G. With many of your remarks certainly not in your special application of the overwhelming majority we against you. You at some points; for instance, Dr. Lanley's position the Council Room of the Royal Horticultural testimonial was presented to him before he instituted in his honor subsequently. The testimonial, though truly it was less than it been. London had a monument erected to his sees it, and substantial relief was afforded to us. We suspect that your name did not appear in the lists, or you would not have fallen into these VETERAN MEMBERS: J. M. We will forward you London Committee. A good suggestion, in small cases. WINTER-TINERIES: T. F. Wellingtonians in pots attacked like yours, probably from the roots in bad condition. The late frost does not seem to the young shoots, and it is probable that the trees may be affected with Fungus. It is to examine the roots of the affected trees, on account of a Pinsky in the last Gardeners' Conference often suffer from this cause. N. J. are now several instances in which this has been the case. Worms: D. H. Lime-water, perfectly clear, for safety for bringing worms out of the pots, case of such plants as leathes, which do not matter. YEW: H. H. Plant at once. H A L L E T T ' S

PEDIGREE HUNTER'S WHITE WHEAT, ALSO THE ORIGINAL RED.

Price, including bags, 1 1/2 Guineas per Quarter, by the Quarter or Half Quarter; One Guinea per Bushel for less than a Half Quarter. Delivered at the Brighton Station, in bags sewed up, sealed, and containing Printed Directions for Planting, upon receipt of Cheque or Post Office Order, without which it will not be sent to unknown Correspondents. Less than a Bushel not supplied. Apply to Captain HALLETT, F.L.S., The Manor House, E.

THE LONDON MANURE COMPANY

(Established 1846) Have now ready for delivery, in fine condition, CORN MANURE, for Spring Use, DISSOLVED BONES, for Dressing Pasture Lands, SUPERPHOSPHATES of LIME, PREPARED GUANO, MANGEL and PLANT MANURES. Also Genuine PERUVIAN GUANO, and NITRATE of SODA, ex Dock Warehouse; SULPHATE of AMMONIA, FISHERY SALT, &c. Offices, 116, Fenchurch Street, E.C.

REES AND CO.'S BIPHOSPHATED PERUVIAN GUANO

(Registered Trade Mark, Flying Albatross), is now ready for delivery in quantity and in fine condition. It is believed to be the best Artificial Manure yet produced. Its base is Peruvian Government Guano, it contains 21 per cent. of Soluble Phosphates, 6 to 7 per cent. of Ammonia with Salts of Potash. See reports of Dr. Voelcker, Dr. Anderson, Professor Way, Mr. Ogston, and Mr. Sibson. Delivered in 2 cwt. bags, each of which is secured by a leaden seal, bearing the Company's Trade Mark. Price £11 per ton. The analysis is guaranteed so long as the seals remain unbroken. Agents for the North of England—Messrs. Keighley, Maxstead & Co., Hull. Agents for Bristol—Wm. Smith & Co. [Aberdeen, Glasgow and Agents for Ireland—Messrs. R. F. Gladstone & Co., Dublin. REES AND CO.'S Biphosphated Peruvian Guano Company (Limited), 33, King William Street, London, E.C.

Autumn Sowing.

DAM'S NITRO-PHOSPHATE or BLOOD MANURE for WHEAT.—This Manure, specially prepared for Autumn Sowing, is rich in Ammonia, Phosphates, and other ingredients required for the healthy growth of Grain Crops. Analysis of Blood and the grain of Wheat show that they are nearly identical in composition, hence the value of Blood as an ingredient in Manure. It may be applied at the rate of from 3 to 4 cwt. per acre, according to the condition of the soil, either drilled with the seed or sown broadcast, if the latter, it should be well harrowed in. Prepared by the Patent Nitro-Phosphate or Tenant Farmer's Manure Company, who are Members are Cultivators. It is a valuable Manure, of their own manufacture, and is guaranteed to be the best Manure for the purpose of sowing Wheat and other Grains. Full particulars will be forwarded upon application to the Secretary, or may be had of the Local Agents, C. T. MACADAM, Sec., Chief Offices, 109, Fenchurch Street, London, E.C.; Western Counties Branch, County Chambers, Exeter; Irish Branch, 40, Westmoreland Street, Dublin.

LAWES' WHEAT MANURE, for AUTUMN SOWING, now ready for delivery.

All other Manures and Cakes as per Price List, supplied on the lowest terms. Apply for prices, &c., to JOHN BENNETT LAWES, 59, Mark Lane, London, E.C.; Dublin, and Salisbury.

Wheat Sowing.

DOWN'S FARMER'S FRIEND for Preventing the Rust in Wheat, and the Ravages of the Stag, Grub, and Wire-worm. A 94 packet is sufficient for Six Bushels of Seed Wheat, and may be dressed up 1 lb. to sow in a quarter of an hour. Testimonials from the largest Wheat Growers in the Kingdom, bearing testimony to its great power and efficacy, may be had of Agents, who are appointed for every district. Full directions for use are given with each packet. Prepared at the Manufactory, Woburn, Beds. CAUTION.—To guard against fraudulent imitation and consequent disappointment, see that the signature of HENRY DOWN is on the label. Agents in every Town throughout England, Scotland, and Ireland.

MOST UNDOUBTEDLY the LARGEST ROOT SHOW in the Kingdom is held at GLOUCESTER annually on NOVEMBER 9. PRIZE LISTS for the forthcoming Show are now ready. The following PRIZES are offered for— SWEDES and TURNIPS .. £57 MANGELS .. 20 POTATOS .. 10 WHEAT and BARLEY .. 11 APPLES and PEARS .. 15 CIDER and PERRY .. 10 £123

A comparison of these figures with those of any other Root Show in the Kingdom will show that the Gloucester Root Show is the largest. The number of Entries at the last Show exceeded 1500. Forms of Entry may be had gratis of Gloucester. A. C. WHEELER, Hon. Sec.

The Agricultural Gazette.

SATURDAY, NOVEMBER 6, 1869.

AN important contribution towards the settlement of the Irish Land Question has appeared during the current week, in a pamphlet from the pen of Mr. CAIRD. Treating the Irish farmers and landowners as belonging to the same species as ourselves—amenable to the same motives—liable to the same influences which some students and speakers on the subject appear to deny—Mr. CAIRD treats the question as anyone interested in the prosperity of an estate might do. The land is half cultivated, the tenantry are purposeless and helpless, the labourers are in miserable plight. But this is no new thing, requiring any special theory for its explanation, or any heroic treatment for its remedy. Such things have happened before. The very counties which now furnish us with examples of the best agriculture, the highest rents and largest produce, were a century ago no better off. In the Lothians, as in the northern counties generally, "leases for lives, no outlay by the landlord, on the contrary, grassums, or fines paid to him for renewal, subletting, and subdivision to crofters, strict entails tying up the land in the hands of needy owners, then kept Scotland in a state of stagnation and chronic poverty."

What is the history of the wonderful improvement which has since then been witnessed? From 1780, owing chiefly to "enabling laws" affecting the condition of strictly entailed estates, the principle has become established, and the practice has become universal, "that the duty of the landlord is to provide his farms with buildings, and other permanent improvements, and that of the tenant to find the capital for cultivation, under the security of a lease for a fixed term of years." And it is to the influences of the lease for a term of years that the whole change is to be attributed.

What, then, is Mr. CAIRD's remedy for the present state of Irish agriculture? Would he yield to any cry for "fixity of tenure?"—that would be both futile and dishonest. No law can ever fix a rent, and circumstances may again arise, as heretofore, to diminish the value of an Irish farm below its present rental. No law, moreover, can interfere between the two parties to a bargain, and alter the terms of it by mere enactment, without a display of dishonesty which one instinctively would call lawless. But does the law never interfere between the landlord and the tenant? Undoubtedly it does. It gives a year's holding to the man who is accepted as tenant for however short a period. In this its practice rests on the very nature of things—on the fact that the land yields its return only once a year.

Why should not the presumption of law, based upon this natural condition of things, which gives 12 months tenancy without consulting the will of the landowner, be extended?—and, on the ground of the equally natural and unquestionable fact that the return to the enterprising farmer is not realised within the year, why should not the tenant, "holding without written lease, be secured in possession by presumption of law (except for failure to pay rent) for an equitable term, say five years, sufficient to recoup the expenditure necessary to a proper system of cultivation?"

It is in this way, and pleading the existing practice and presumption as its precedent, that Mr. CAIRD would, as it were by force, introduce into Ireland generally that wonderfully fertilising and enriching agency which everywhere else the agricultural lease for a term of years has proved to be.

We shall recur to the pages of this publication for the purpose of again discussing some of the points to which Mr. CAIRD refers. Meanwhile

* "The Irish Land Question." By James Caird. Pp. 35. Longmans.

many of our readers will no doubt read and study the pamphlet for themselves.

THE Council of the Royal Agricultural Society unanimously adopted the report of their committee, recommending that their usual annual grant in connection with agricultural education be made for 1870. The expediency and usefulness of their educational examinations have always been consistently maintained in these columns, even upon those practical grounds which in all probability will supply the point of attack upon them. It may, however, be useful to take the opportunity of again stating the reasons why we think the examination system should be maintained.

The Royal Agricultural Society necessarily represents to the outside world the great body of farmers in the country, and its action is to a great extent looked upon as representing the opinion of farmers generally, and the extent to which they are disposed to keep on a level with the ideas of the community at large. The effects of any distinct want of sympathy between the farming and other classes would sooner or later be serious, but in the present position of political parties they would certainly fall most heavily on the farmers. In all reasonable matters, therefore, it is clearly their policy to fall in with the general current of opinion. Now, if there is one question at the present time which has taken a decided hold of the popular mind, it is that of popular education, technical as well as general—nor is this merely a temporary popular whim; it is, on the contrary, the expression of a growing national need. The opinion is gradually gaining ground, though expressed some years ago by men like Dr. PLAYFAIR, that England has been falling behind in manufacturing excellence on account of her incapacity to compete with the intelligence that more highly educated artisans bring to their work in other countries. Quite lately this has supplied the text for articles in the Times. As long as we maintained our superiority in the more substantial manufactures we were indifferent to our known inferiority in matters of taste and art. This was a mistake; the sense of beauty shown in other nations more than amongst ourselves indicated a capacity of culture which only wanted turning into more utilitarian directions to convince even practical men of its value. While the latent power of other nations has been developed, we have been content to rest at the same level. But though technical education has been and still is neglected among us, general education, its necessary forerunner, is every day receiving more attention. The prestige of the Universities could not prevent their funds being looked into and applied to the endowment of new professorships: endowed schools have been dealt with in the same spirit. The turn of the landed interest will come next. It will be required to do something for education, and the demands that will be made from it will depend on the disposition that it shows to act independently of coercion. It is however well to remember that, by a natural process of gravitation burdens thrown on landowners tend to fall on rent. This will be remembered, and an enlightened spirit among farmers themselves will undoubtedly favourably affect their position when national education comes to be dealt with.

The connection between these considerations and the examinations of the Royal Agricultural Society may seem to be slight, but it is far less so than it seems. The matter is in truth a crucial one. If the examinations are discontinued farmers must be held to be guilty of greater indifference to education than any other class in the country whose work deals with matters requiring an equal degree of intelligence. If that should unhappily come to be the case, they will not be credited with much sympathy for national education generally. This simply means that, as less will be expected from them, more will be required.

In the present day no class can afford to stand still. Other countries understand this better than we do, because they see that no class in a community can confine the effects of its deficiencies to itself. The Americans can hardly be called unpractical or unprosperous, yet they are everywhere founding agricultural colleges, and they have the greatest confidence in scientific and technical education as promoters of material prosperity and national progress. This is the root of the matter. Education gives a man

a capacity for adapting himself to altered conditions and turning them to his advantage. The practical man always remains in his groove, and sooner or later falls to the rear; the well educated farmer is armed at all points, he is progressive as well as practical, and on progressive men a country depends for its permanent well-doing.

To abolish these examinations would be reactionary. It would have been far better not to have commenced them than to give them up after only two years' trial. They have not yet attracted a large number of candidates, but they are a means, not an end. The object of all examinations is to direct and give method to professional study; and that so little of it at present exists among agriculturists is the very reason why the examinations are wanted. As soon as it began to be found that it gave a man some stamp to have passed these examinations, as in all other cases of the kind a body of students would be created. It can hardly be contended that this would not be desirable. Some students there would always be, and it would not be very creditable that the Highland Society only should give these their opportunities of distinction.

To conclude, one argument against the scheme will doubtless be the expense. For this there is an easy remedy—give no prizes, but merely certificates, which will cost nothing more than the paper on which they are printed. The highest rewards at Oxford and Cambridge are only the appearance of a list in a newspaper. The prize system is economically absurd. No labourer could be worse paid than the man who looks to a few pounds' worth of books as the only reward of perhaps months of exertion. D.

THE Wheat trade at Mark Lane, and throughout the country, has continued during the week without any alteration in price. The lowest figure now quoted at Mark Lane is 40s. per quarter; but we are informed that in the Isle of Thanet even, a district usually celebrated for its fine quality of Wheat, the price has been as low as 38s. per quarter. Thus it seems inferior Wheat does not come to London. Malting Barley has been inquired after, and fine qualities have advanced 1s. per quarter in value. Oats, beans, peas, and other feeding stuffs, have remained without alteration. The trade at the Metropolitan stock and meat markets has been dull, at previous prices, the best beasts making 5s. 6d., and the best sheep 5s. 8d. per 8 lb. On Monday there was the large supply of 6000 beasts, more than half of which were foreign, and 14,895 sheep, only 1570 of which were imported. The agricultural seed trade continues in a very depressed condition.—English wool is no dearer, but factors are speculating, on the ground that the home-grown wool trade must soon participate in the general improvement in the prices of manufactured cloths.

Mr. HOWARD'S lecture on Continental Farming, before the London Farmers' Club last Monday, which occupies so many columns of our paper to-day, will be read with interest for its picture of both merits and defects. From both sides of the picture English agriculturists may learn. The possibilities of improvement by the more general adoption of irrigation, and by the extension of Beetroot cultivation, are very forcibly put, and attention will no doubt be directed to them. The light thrown by Mr. HOWARD'S pictures on the policy or impolicy of cottier farming and petty landowning is also most serviceable and timely. We may next week refer more in detail to the lesson thus given to us, for the present the lecturer must be left to tell his story without comment.

At a meeting of the Council of the Central Chamber of Agriculture, held on Tuesday, Mr. C. S. READ, M.P., president, in the chair, it was decided that the annual meeting of the Council should be held at 2 o'clock P.M. on the Wednesday in the Smithfield Club show week, and that the question for discussion at the February meeting, 1870, should be the "Best Mode of Providing for the Future Maintenance of Highways and Turnpike Roads." The subject of the day was "The Present Unsatisfactory Method of Taking the Corn Averages." A resolution to the effect "That, in the opinion of this Council, the corn averages as at present taken are fallacious, and that the buyers' returns should be limited to purchases from growers only," was proposed by Mr. GARDNER (East Kent), and seconded by Mr. CLAY (West Yorkshire). An amendment, "that the returns should be made by the growers only," was proposed by Mr. W. SWITHEEN (Worcestershire), and seconded by Mr. VARDEN (Worcestershire). A lively discussion ensued, in the course of which Mr. DUCKHAM said that in Herefordshire they had resolved to recommend the adoption of the standard at which the tithes were commuted, and to drop the averages altogether; but if the present system were to be continued, then he maintained that all buyers should return to the Inland Revenue Office the quantity of corn they had purchased, and the price; and no great difficulty would arise in regard to such a system as that being adopted. Ultimately the amendment was withdrawn, and the original motion carried unanimously. With respect to "The Necessity for a Uniform System of Weights and Measures," the disadvantages of the differing weights of the market bushel were exposed. News-

paper reports of markets were generally unintelligible, except to people expert in local customs. The superiority of weight as a rule of sale over measure was insisted on. Disputes and risks of litigation would then be avoided. Mr. DUCKHAM moved "That, in the opinion of this Council, all agricultural produce should be sold by weight only." The motion was seconded by Mr. WILLSON, and carried unanimously. It was agreed that the resolutions should be forwarded by the secretary to the provincial Chambers, and that a copy of them should be sent to the President of the Board of Trade.

The value of fresh brewers' grains has long been known to cowkeepers. Their serviceableness has, however, hitherto been confined to the neighbourhood of the mash tun, where they are made, for they do not "keep." Messrs. MILBURN have, as our readers know, conceived the idea of drying them, or making them available at a distance. They have hitherto, however useful as cow-food, been supposed comparatively of little value for general purposes, but it is found that they are largely bought, when dried, at a price we should have hardly thought them likely to command. It has been generally alleged that there can be no goodness in the husk of Barley, but grains do not altogether consist of mere husk; and it is urged besides that linseed-cake is only husk, and still realises 12l. a ton. Desiccated grains, they say, are specially good, because the stomach of the animal can so easily extract what nutriment they contain, which arises from the "cooking" they have undergone by both the maltster and the brewer. The chemical view of the desiccated grain is presented in the following analysis from Dr. VOELCKER and from Mr. SIBSON:—

COMPARATIVE ANALYSES.

Table with 7 columns: Grains, Oats, Beans, Linseed cake, Barley, Wheat. Rows include Moisture, Oil, Albuminous compounds, Gum, starch, and digestible fibre, Woody fibre, and Mineral matter. Total values are 100.00 for each column.

These figures are presented to us by Messrs. MILBURN as fairly contrasting the value of their food with that of other well-known substances. They seem, however, to prove, if, indeed, they do prove, too much for the grains. It is difficult to read with intelligence such a classification of ingredients as is here presented. We see, for instance, that brewers' grains contain 24.87 per cent. of albuminous compounds, while Barley contains only 10.84. That certainly needs further explanation. We are quite willing, however, to believe there is more in grains than the cowkeepers' use of them has yet taught us, and the following passage from MURPHY'S "Chemistry" is worth consideration. He says—"The grains left after mulling (with superfluous moisture evaporated) are very beneficial for the use of swine and cattle, as they contain gum and some of the nitrogenous or protein constituents of Barley in the shape of gluten, together with a certain amount of cellulose, which is valuable; and are as effective in nourishing as an equivalent weight of the original unmalted grain."

A correspondent points out to us how desirable it is that the weekly country returns now being made by inspectors or chief constables, as to the progress or condition of the foot-and-mouth disease, and pleuropneumonia, in the several counties should, in order to the presentation of a complete picture of our losses, also publish the losses which had taken place prior to the adoption of the Act.

A case before the magistrate at the Thames Police Court on Monday last, in which a young man was accused of stealing 64 stones of suet, reveals the existence of a Dutch butter factory near Bromley. Mr. CHARLES YOUNG, solicitor, said he was prosecuting a case of nuisance on Bow Common a year ago, and Mr. LEWIS, solicitor, produced some of the fat from the Dutch butter factory, and said it was sent to Holland and mixed with Dutch butter, and re-exported to England. The Dutch butter factory manufactures tons upon tons of the stuff, and it is sold in our shops as "real Dorset" and "real Cambridge," or "genuine dairy-fed butter."

THE FARMING AND PEASANTRY OF THE CONTINENT.

The following is a condensed report of the Paper read by Mr. James Howard, M.P., at the meeting of the London Farmers' Club on Monday evening.)

FRENCH FARMING.

I WOULD first invite attention to the agriculture of France. French agriculture has long had what many have advocated for England—viz., a Government Department of Agriculture, presided over by a Minister, who takes under his paternal wing the whole family of agricultural colleges, the collection of statistics, farms, mechanical museums, schools, roads, drainage, horse-breeding, chemistry, the necessary supply of food for the people, an experimental implement factory, and a hundred other things are under his control, and the expense of these various institutions is defrayed by the State. Again, the State establishes horse shows and agricultural meetings. The whole country has been divided into 12 districts, in each of which a show (termed a "Concours Regional") is held, and large sums are distributed, with a view to stimulate improve-

* Milburn & Co.'s desiccated.

† Good average.

ments in the various departments of farming. This shows everything is under the control of the Inspector-General of Agriculture, the whole being borne by the State. Further, the Government, with a view to raise the general level of farming, offers in each of the districts a silver cup worth another 120l., called the "Prize of Honour," as a prize for the best-managed farm, which the most useful improvements have produced. With all these various agencies at work, one might expect that agriculture throughout France would be stripped of everything primitive, and the motto of the new French Agriculture, "Practice with Science, Progress with Prudence" would be everywhere realised.

If an intelligent English agriculturist were to estimate of French farming by what he sees from the railway between Calais and Paris, and from the small number of animals and other conditions, come to the conclusion that the whole was going to the bad. This, however, is not the case. Improvement is very slow, scarcely perceptible to those who make an inspection at one of the farms in England, it was years before such farms as the Duke of Leicester's in Norfolk, the Duke of Bedford's at Woburn, and Earl Spencer's in Northamptonshire exerted any marked influence in farms throughout the country. So in France, there are farms which are as far in advance of the general agriculture of the country as were the spirited noblemen I have referred to at the beginning of the present century. The farms alluded to have many of them received the "Prize of Honour," and are exerting a quiet but powerful influence in their respective neighbourhoods.

(1.) Notably among such farms is that of M. Decrombecque, at Lens, about 50 miles from Calais. Decrombecque is a very remarkable man upwards of 70 years of age he is full of energy, read in agriculture, knows England, and is too with English methods of farming, of which he has not been slow to avail himself. His farm is in extent. Half the land is his own, purchased with profits made by farming; indeed, he had a very little capital when he commenced. On the occasion of my visit in the harvest of the Wheat crop was very fine. I saw also Beetroot, all on the ridge, without a single bush in any part. He estimated that the produce weighed about 13 tons per acre. The land had been ploughed 16 to 18 inches deep, with huge ploughs by ox-teams, 16 in a team. On all the farms I visited I found two sets of ploughs, one set for *profonde* ploughing, and the other for deep work called *profonde*. Thirty horses and 80 working oxen kept, the latter only working half time. M. Decrombecque has had a sugar factory on his farm for 20 years; he thinks that farming without the sugar must be a very slow affair. 300 to 400 cattle are fattened on pulp from the sugar factory. He adopted the "box" system, which he came to England to see nearly 20 years ago. He has the advantage in keeping the cattle in covered stalls, and he has found that they are much sooner ready for the butcher than when kept in daylight. An open-sided shed was a great improvement, and as soon as, and sometimes before, the wheat was a heavy flexible or chain spiked harrows were used on the surface with a view to set the annual weeds shed corn germinating. The operation is expensive and not very costly; and M. Decrombecque, by many years' experience, finds he is amply repaid for the trouble. He prefers it to any system of deep or shallow ploughing.

(2.) Another highly cultivated farm is that of M. Gustave Hamoir, at Sautain, near Valenciennes, about 200 miles north of Paris. This gentleman is a very superior and intelligent man—quite my model of what a farmer ought to be—observant, shrewd, informed, and in manners the gentleman. M. Hamoir's district the country is covered with factories, and the properties are much subdivided. 25 acres in one plot being considered quite a large one. One-third, and even one-half the land is cropped with Beetroot. There are a few farms of 100 to 200 acres, but the general run is about 30 to 40 acres. For years M. Hamoir has had fully half of his farm cropped with Beet, all the rest Wheat, except small plots for growing fodder, Clover, and Lucerne. Beet becoming less esteemed, as it does not produce so much Sugar-Beet as oil-cake (rape cake), which now is sold to the land as manure. M. Hamoir, like M. Decrombecque, ploughs his land some 16 inches deep for the crop. The rent in this district is higher than in other I know—the average is 2l. to 2.5l. per acre. In large plots it sells for as high a price as 100l. per acre. The price of land is enhanced from the fact that a French farmer does not and will not appropriate almost any price when the opportunity offers. Hamoir says he has known land sell as high as 1000l. per acre. His opinion is that it would be better for interests that the small farmer should not be a proprietor or landowner, especially at the present time. The interest of his money invested in securities would enable him to hire, even at a high rate, double the quantity of land he can hold as owner; but this course is not adopted because of ignorance which prevails, and the fear of money in other ways. Another reason, says M. Hamoir, and at least as painful a one, is that of the short duration of leases, which are for nine years. The tenant stands in fear and dread that at the end of his lease may be ousted for some other competitor.

(3.) I will now give you a picture of a very fine district, that of Sologne, about 150 miles from Paris, in which M. Edouard Lecouteux, Editor of a

soil. Like France, agriculture in Belgium is in possession of a State department; and, like France, the land is much subdivided. There are a quarter of a million peasant farms under 2 acres, about 20,000 farms of 30 acres, about 10,000 farms of 100 acres, and about 1000 farms of 250 acres and upwards—the average being about 11 acres. Rather more than half the country is cultivated by the owners of the soil. But in Flanders, however, there are few proprietors; the rent of land, as has been asserted, is by no means extravagant; nor do I think you will conclude that the peasantry are overpaid. In Hainault, the highest rented province (and very fine lands, according to the last official returns), the rent averaged 35s. per acre; in Luxemburg, the lowest, it was 12s. 9d. per acre, the average throughout Belgium was 27s. per acre. The average wages of the farm labourer is 1s. 1d. per day, without food, the maximum being 1s. 8d. and the minimum 8d. per day; wages, nevertheless, are said to have advanced 25 to 30 per cent. since 1840. From inquiries I made among the older labourers, I found that 6d. per day was no unusual pay but a few years ago. I had travelled through Belgium several times, but had never set foot upon a farm until last year, when I went over to Brussels to act as a judge of implements. The trial of mowing-machines took place a few miles from the city. The meadow selected was naturally a rich soil, but the crop of Grass was poor, and the field had evidently not been invaded by the roller for many a long day. The farmer attributed the poorness of the crop to Providence—he had expected a better one, as he had got the priest to pray for it! I remarked that Providence should not be held responsible for the omission of rolling; whilst my colleague, M. Hamoir, dryly told him he thought the prayers would be answered if he put on plenty of dung! I mention this as one of many instances I have met with of superstition. It is not an uncommon sight, especially in the Rhenish provinces, to see the image of a patron saint erected at the head of a field, in the hope that the crops would be thereby protected. On the occasion of my visit to the Brussels Show, I went across the plains of Waterloo; it was just previous to harvest. The farms here are large, much of the land is fine, but neither my brother nor I thought the crops, considering the fine season, anything remarkable.

In July last, landing at Ostend, I stayed there a few days, and made excursions in the neighbourhood. The farmers seemed plain, plodding people, knew very little of what was going on in the agricultural world: their houses seemed comfortless, and their living very frugal. The rotation of many farms is Rye, Oats, Potatoes, or Sugar-Beet, then Rye; no Wheat. I found very little in farm produce worth noting down. The practice of ploughing up the land before the crop is carted is general in this, as well as in most parts of the Continent. One farmer showed me his flock, of which he appeared very proud. The Flemish breed are long-legged, small-scragged, narrow animals, which cannot pay the farmer to breed. The same man has some really good Shorthorns and pigs. Boars in this neighbourhood travel like stallions, fresh blood being obtained every year. The labourers seemed dejected and in a low condition. I looked in at the village inn and had a conversation with the landlady, from whom I learned that she never saw a farm labourer in her house, except after dinner on Sunday, when a few would drop in to have a glass of beer. She drew a gloomy picture of their condition, remarking, "Poor things! they have not much comfort in this life."

(1) At Baron Peers', at Oostcamp, near Bruges, I found a better state of things—good cattle, Hampshire Down and Oxfordshire sheep, white Yorkshire pigs, better paid and better fed labourers, and higher rents. The Baron adopts the following rotation:—Wheat, Rye, Oats, Clover, Flax, Potatoes or Mangel. Two, and, as in this case, three white straw crops in succession is not an uncommon practice: to an Englishman it seems unscientific, and none but thorough good land could long stand such treatment. The Baron thinks highly of the practice of growing a little Chicory, which he sows in May; the tops are cut twice during the summer and autumn for green food: the roots remain in the ground all the winter, and are said to be the best food to give to ewes after lambing. At Bearnem, a few miles beyond Baron Peers', is a large Government reformatory, well worthy of a visit; a farm of 600 acres and a garden of 10 acres is attached. The lads receive an excellent training, but I have not time to describe what I saw. A few miles from Brussels is the parish of Dilbeck, containing 2750 acres. In this village, which may be considered an average specimen, there are five or six farms of 85 to 150 acres, ten from 37 to 45 acres, many of about 20 acres, and a large number of 2, 3, and 4 acres. M. Verheyden is the principal farmer of the place, occupying 140 acres, at a rental of 240l., and is a plain, but keen thoughtful man. The cottier farmers work for the larger ones, and get 1s. 3d. per day. M. Verheyden told me that the small farmers above the cottiers could never live and pay their way by mere farming; that their mainstay was fruit, vegetables, and poultry; that, if not too far from a large town, a steady man with a careful wife might get on. The rent of a 10-acre farm, with house, is about 55s. per acre in this parish, and he further said that the farms in his neighbourhood were increasing in size; that wages had more than doubled—20 years ago they were only 6d. per day, without food. Leases are for nine years, without covenant as to crops. He informed me that farmers were no politicians, and voted as their landlord wished. I heard from M. Verheyden a good deal on practical matters; but I must not dwell, for I wish to say something of the finest farm I saw in Belgium—

(2) That of M. Dumont, of Chassart, near Fleurus. The extent is about 1500 acres, divided into five farms, with a homestead to each. At the central homestead is a large sugar factory and grain distillery. The homesteads are connected by iron tramways, which inter-

sect the whole farm: 12 kilometres or eight miles of tramway in one farm was a novel sight. The rail is used to bring home the Beet and other crops—to take back manure, pulp, &c. I had been for days previously among the cottier farmers, who almost invariably use great wheelbarrows for carrying off their crops. Two-thirds of the land is the property of M. Dumont; the other one-third is hired. The rotation adopted is—1st, Beet; 2d, Wheat and Oats, half of each; 3d, Clover and Flax, half of each; 4th, Wheat. M. Dumont adopts the English practice of cutting Wheat before becoming quite ripe. The almost universal practice on the Continent is the very uneconomical one of leaving it till dead ripe. I saw one splendid field of Sugar-Beet, of 175 acres, which was estimated at over 20 tons an acre. The tops of the Sugar-Beet are cut off, and given to the sheep on the pastures. An acre of Flax is on the average worth 21l. M. Dumont keeps over 600 head of cattle. Large numbers are fed upon pulp and the residuum of the distillery. Pleuro-pneumonia has made such ravages that M. Dumont and many others have adopted the practice of inoculation; the pus is obtained from the State Veterinary College, and inserted at the tail. If the operation is performed in hot weather the tail drops off through mortification setting in, but when done in cool weather no injurious consequences ensue. Having suffered much from this fatal disease among my cattle I was determined to try it, but have hitherto been prevented by order of the veterinary inspector of the county, who has acted on the advice of Professor Simonds. The Professor opposes the practice; but those practical Belgian farmers who have had extensive experience regard it, to use M. Dumont's own words, as a "sovereign remedy." For foot-rot in sheep M. Dumont gave me the following recipe, which he has found an unfailing remedy:—

"One pound of Egyptian, half a pound of sulphate of copper reduced to a fine powder, one ounce avoirdupois of bi chloride of mercury reduced to a very fine powder, these materials should be mixed up with strong vinegar until they assume a proper consistency."

The sheep are fed under cover, the prevailing plan on the Continent; a sheepfold is a very rare sight. The food is 12 lb of pulp per head per day. Wages on the farm are 2 francs per day in summer, and 1 franc 50 cents in winter—no board and lodging, but the employment is continuous, and not intermittent, as in the small-farm districts. The people seemed comparatively well off. Chassart is in the Walloon district, Waterloo being in sight; it is the district for large farms; however, I passed a good many large homesteads unused, the land belonging thereto having been cut up into small farms. That such holdings required no such accommodation is a suggestive fact. M. Dumont's farm is one well worth a journey to see, and the pleasure of my visit was greatly enhanced by the kindness and hospitable reception I met with.

Soon after my return from Belgium, I was greatly surprised at the contents of a letter addressed by Mr. C. W. Hoskyns, M.P., to the *Times*, affirming that Belgium produced a larger amount of animal food in proportion than was raised in England. I confess that a very different impression was produced by my visit. Except upon the large farms, very little stock is to be seen. I have taken the trouble to ascertain the relative number of cattle in the two countries. The Inspector-General of Agriculture in Belgium has favoured me with the following most recent published return: Cattle, 1,257,649; sheep, 5,348,515; pigs, 158,418. The taxation of Belgium does not appear to weigh heavily on the land. There are no poor-rates—no taxation for the church. The cost of punishment of crime and the support of the prisons is borne by the state. The whole amount of taxation which falls upon the land is about 2s. 6d. per acre per annum. Schools for boys and girls exist all over the country. Education is not compulsory; but few parents neglect to send their children to school: the expense is borne partly by the State and partly by the parish.

IRRIGATION.

I will now for a few moments direct your attention to the subject of irrigation. Some four years ago I spent a few weeks in Egypt. I was so impressed with the astonishing results obtained by the simple application of water to land in the valley of the Nile, that I came home under a strong conviction that in England, notwithstanding the difference between the two climates, we do not reap half the advantages we might do from the water which a beneficent Providence sends us. By the aid of very primitive pumps, worked by a mule or bullock, or a couple of donkeys, sufficient water is often raised by the Egyptian farmer to irrigate 30, 40, or 50 acres of land, which fields produce prodigious crops of a kind of Clover called "Burseem." My recent visit to Italy and Switzerland has confirmed me in this opinion. I am aware that water-meadows in England are almost as old as the hills. The practice of irrigation is, however, confined to a very few localities—not one farmer in 500 in England, I venture to say, knows anything of the subject, or has ever given the matter serious consideration; and I believe there are reasons which have produced the indifference, for which, I think, the State is in great measure answerable. To the consideration of this part of the question I will return presently. The practice of irrigation in Europe is carried out on the greatest scale, and with probably the best results, in the plains of Lombardy and Piedmont. In Lombardy, out of a total area of 6,000,000 acres, upwards of 1,000,000 are artificially irrigated; upwards of 3000 miles of main or minor canals have been cut in the province, beside a vast extent of small arteries belonging to private individuals. Although some of the main canals are used for the purposes of navigation, they are mainly constructed with a view to a comprehensive plan for irrigating the country. The grand canal, which brings

the water of the Ticino to Milan, has been in existence some 700 years, and for this long period has the benefit of irrigation been carried on. I would also mention that for almost a longer period a portion of the sewage of Milan has been utilised. I believe the credit is due to the monks of the monastery of Chiaravalle I visited some of the fields which had been irrigated for centuries; and although not furnished with any modern appliances to be seen at the irrigated fields at Bedford, the results are most satisfactory. I mention that at Bedford the growth of Italian Grass by town sewage is a most complete success; many as six crops have been raised this year, and at some 20l. per acre. I visited an irrigated field of 90 acres at Milan, rented by a M. Antonio, and at which the water is used 11 times over, and the point at which it reaches the field is where he parts with it to his neighbour. The rent of the farm is about 61s. per acre. The land is considered a low one, as 5l. an acre is not an unusual rent. The Grass I saw growing was 24 days of growth was fit to cut. Seven crops had previously been raised since the beginning of the year. The Grass growing in irrigated fields is perennial. A good deal of the further land is susceptible of irrigation. After a Wharfedale Cabbages are planted. The Wheat in one field was cut on June 24th; on July 7th the Cabbages were planted, and on August 24th (the day I was there) the ground was completely covered. The Cabbages were sent to the Milan market. The land was irrigated once before the Cabbages were planted. On this farm I saw a fine dairy of 18 cows. Having heard much of the milk quality of the breed, I inquired into the quantity of milk produced, and found it varied from 38 to 44 gallons per day. The cows are fed on Grass from the irrigated meadows, and are milked at noon and at 10 o'clock at night. The price realised for milk, which is fetched from the farm by the buyer, is from 5d. to 5½d. per gallon. The farm of 90 acres, one-third is irrigated, the other arable. Six men, four women, and a boy, and four lads are employed. I would call attention to the mode of paying the labourers. They are paid 5l. per day all the year round. Each family, in addition one-third of the produce of 2½ acres of corn. The land is set apart for the labourer, and the labourer performs the work, and gets one-third of the produce. A good crop of Indian corn is raised, yielding 48 to 54 bushels per acre.

On this farm I had another opportunity of seeing how the labourers are lodged. A box suspended from the stable roof furnished a bed for the horse, and some adjoining rooms, without windows, I found the beds. Finding one man down with the fever I made my exit, but anything more wretched and indecent can scarcely be conceived. Families have more than one room, but often two or three families occupy the same apartment. M. Chassart, who is an engineer by profession, and also a proprietor and farmer in the neighbourhood, has a centrifugal pump, driven by a portable engine, for pumping back the water when it has reached the part of his farm, a plan with which he is well satisfied. The watered plains of Lombardy present a most luxuriant appearance; the kind of Grass is very opposite of the blue Grass found on some of the western plains of America, which, as the Yankee proverb is "as crisp as hair and wants lathering before it is mowed." On leaving the plains of Lombardy I crossed the Alps to Switzerland. Everywhere along the sides are to be seen devices for catching and storing the water on the Grass slopes; then again it is sent on its way to the valley and turned over the meadows, and fields of Maize; indeed, as the fertility of the country depends upon the utilisation of the water, every little stream is turned to the best account.

When in Spain some years ago I passed through the districts which, in the time of the Moors, were so fruitful, through being irrigated, but which, through the neglect of the Spaniards in not maintaining the works left them by the Moors, are now barren. The question is often asked by thinking men, "What is the next great step which can be taken in agriculture?" I remember some three years ago Mr. Gladstone, in talking to Mr. Clayden, Mr. Leeks, and myself, on increasing the meat supply, propounded this question. I smiled and remarked as gravely as I could that I did not see how we could make another advance until he repealed the Malt-tax. In England, the question on the best farms has arrived at a state of stagnation in the growth of cereals and root-crops. He believes it is idle to expect any very great increase in the produce per acre—the general average of the country will unquestionably be considerably increased. I am now speaking solely of the highest style of farming, with a view to discover what next great step should be taken. Putting out of sight for a moment sugar-maize, and even the repeal of the Malt-tax, I take it that the question of the day is—not so much how any more sheep or cattle can be fed on bought feeding stuffs, but how they can be raised and profitably kept upon crops raised upon the farm. In other words, how a greater amount can be economically produced. I believe no man present will differ from me in the opinion that he could always command a supply of water for the irrigation, a larger quantity of green food could be raised, and if so, it would furnish the means of supporting a greater number of animals. Is there any great difficulty, mechanical, or otherwise, in placing the power of irrigating the lands in the hands of a number of English farmers? Along our coast, where water is to be obtained in abundance, how can it be worked from the surface, a centrifugal or chain pump, worked by a horse or an engine, would supply the water for the irrigation of scores of acres. More of course, than this, I take it, is required; the water must be

ers, I maintain, should not be the exclusive property of individuals, but be free for the good of the whole people. M. Durand, a French agriculturist of remarkable energy, alive to the importance of irrigation, determined to avail himself of the water of the Arnon. For this purpose he turned a branch of the river, constructed a canal two miles long, and erected a dam at the junction. With the earth dug out he made an embankment, to prevent the flooding of 50 acres of land, whilst on the other 75 acres he turned the water brought by the canal. This arrangement enabled him to keep double the number of cattle and sheep, as well as to raise one-third more corn. For long years, however, he was at war with opponents, but at length he succeeded in putting down all opposition and was rewarded by the State with a gold medal for the work he had accomplished. The rivers and running water of France are not under the control of private individuals as in England. The water only belongs to the owner of the land through which it flows during its transit; when it passes his boundary he has no further control over it. As long ago as 1669, Louis XIV. abolished the feudal rights of the proprietor in rivers, the ownership thereof being reserved to the State. Owing to the want of energy in France, the great boon secured by this enactment has not been an advantage to any great extent. But he it is to me to advocate such spoliation or confiscation as adopted by France, but I sincerely wish that the Rivers Commission, which is yet pursuing its inquiries, see its way to recommend to Government the bringing of all rivers and watercourses under a central authority, having power to buy up the acquired rights of individual owners, in order that the water of the rivers, not only for irrigation, but in other respects, be as free for the benefit of the whole people as the air we breathe. I would also express a hope that the Commission will see its way to some plan for clearing our rivers and streams against being polluted by the fertilising matter which now runs to waste.

CONCLUSIONS.

After having seen a good deal of the Continent of Europe, I have arrived at the conclusion that, with land cut up into small farms, a greater number of people can manage to live, or exist upon it. The question then arises, What is the more desirable condition of things—a system under which the greatest production can be raised upon a given area, or a system for which the largest amount of food can be raised at least cost? That the small farmer can raise produce cheaply as it can be raised on a large scale I apprehend no practical man will maintain; and again, when conditions are favourable, as in Belgium, the crops of the cultivators of a few acres are as a rule far inferior to those of the large stock farmer. There are many at present day whose only notion about the use of land is, how it can be made to support the greatest population. Lord Palmerston once made the trite remark, "It simply meant matter in the wrong place." When a good view is taken of the subject of population—it is considered what millions of acres of virgin land throughout the world invite the industry of man, which he could subsist in comfort and independence, we must conclude that a wise and beneficent Providence has given us a world large enough; yea, far more than is required for the present family of man—alone the great prairies and plains of the Western States of America, capable of supporting millions of persons. I remember the impression the sight of them made upon me. It occurred to me that Lord Palmerston, seeing them, would have exclaimed: "Overpopulation, why it simply means men in the wrong place!" The condition of the English farm labourer has of late attracted a large share of public attention. Whilst I am sensible of the degradation and comparative poverty of the peasantry in some parts of our own country, and that I am a strenuous advocate for the better housing, better education, and the adoption of other means of raising their position, I say fearlessly that their condition is superior, and if they would spend less in beer and tobacco, and had the same amount of land as the labourer upon the Continent. I was talking over this subject the other day with two of my own men, who were engaged going about to start machinery. In this employment they have during the past 10 years been employed half over Europe, they were both brought up as agricultural labourers. One said to me, speaking of the Continental labourer, "Poor things, I have often heard them: they do live hard with their black bread and broth, and Cabbage and red-herring, and such like." He also said, "You know, sir, they can't do more than a day's work, for there is nothing inside them." This man, though no political economist, remarks, "You know, sir, their labour don't cost much, their masters don't get much work out of 'em." I have often said for reasons I have stated I am opposed to the being cut up into small holdings, I would not have supposed that I think it desirable a whole country should be divided into monster farms. To me a state of things I am equally opposed. I believe to be the best condition of things for all interests, so that a farmer with a family of sons has a choice of holding for them a choice of holdings suited to his means at his command; and notwithstanding the sentiments I have uttered, I hold that the industrious, thrifty labourer ought to be able to look upon some degree of probability to his occupancy of land in which he will not be solely dependent upon his daily labour. The notion that a minute subdivision of land has a tendency to raise wages is a great error. Go into almost any part of England where the hold now predominate, and there will be found a lower scale of wages, but, what is worse, a want of continuous employment. In a tour I made through the centre of Tipperary and Cork, and precisely the same results: work on large

farms was continuous; on small, intermittent. The same state of things I found to exist in every part of the Continent. Another conclusion I have arrived at is, that in all countries nothing tends to keep back agriculture so much as insecurity of tenure. Leases are all but universal on the Continent, but wherever I went there was the same complaint, the same reason for not making permanent improvement, the leases were said to be too short, the tenure too insecure. The province of Groningen, in Holland, possesses, I believe, the greatest agricultural wealth of any part of Europe: here the tenancy is hereditary. I mention this not by way of advocating the principle of fixity of tenure, but as a proof that the tendency of length of tenure is to increased production.

[Mr. Howard's remarks on the small farm system prevalent in France and Germany must be postponed for a week.]

Home Correspondence.

Steam Cultivation: Small and Large Tackle.—Some time ago I had a friendly passage of arms with Mr. Toepffer, on the respective merits of large and small steam cultivating apparatus. Since that time I do not remember to have met with his name until since the occasion of the Peterborough trials. These have afforded him the opportunity of mounting his great hobby, and trying to ride over everybody else. I have had some years' experience, and I have always been ready to say a word in behalf of the small roundabout; and the most apt comparison I can make is that of a little hardy horse, which over a difficult country will always beat a great ungainly brute. Let it be clearly understood that my remarks will be restricted, and apply only to farms of moderate size, say from 200 to 400 acres arable. On such farms a steam-engine should generally be found for threshing, grinding, chaff-cutting, &c., and if the hardy horse which does all this can be fetched out to give a lift with the ploughing or cultivating, it appears to me just what most of us want. With farms of large size it is my opinion that a couple of sets would then be desirable over the big set. I have spoken of ploughing as well as cultivating, for I had recently an opportunity of witnessing the performance of a very ingenious and handy plough, which was invented, and is worked unobtrusively, by Mr. T. Beards, of Stowe. It consists of a light frame, in which are fixed two double ploughs, one at each end. On reaching the end of the field, while the anchor is being shifted, the ploughman loops up one pair of ploughs by a short chain to the framework, and in turning the rope, as it tightens, raises one pair of ploughs out of the ground and draws the other pair in. This is effected by a simple but clever contrivance, which shows that the inventor has a bit of engineering skill. To those who prefer ploughing to cultivating, or may wish to use a plough occasionally, I would say, go and see the beautiful work which it being, or has been, done at Stowe. I confess my own predilection for cultivation for strong clay land, such as that which I occupy, but there are seasons and occasions when a plough may be used with advantage, and this want the latter tool of Mr. Beards would supply, for the small extra outlay of about 50*l.* The greatest mistake which, in my opinion, inventors and manufacturers of, not only steam, but also horse-drawn implements make, is attempting too much. If half the cultivators and scarifiers in use were reduced one-third or one-half in width, and made to do the work properly with a team of four horse, instead of merely going over and giving a surface scratching, we should see less Twitch, and cultivation would be regarded with more favour. Monsters, from the Great Eastern downwards, have been always more or less failures. The great ship may do for laying submarine cables, but for ordinary work she is a great failure. I have to-day walked over the Woolston farm, and certainly nothing can look better. The cultivation for the whole year has been completed. One piece of land, from which a crop of Mangels has just been removed, needed nothing, owing to the cultivation it received for the last crop, but a horse-scarifying to prepare a good seed-bed for Wheat, which was to-day being drilled. On an adjoining farm, recently purchased by Mr. Smith, the fences have all been cleared away, and a large number of men are engaged in draining, preparatory to a general smashing up, and the place is, in fact, undergoing a speedy and complete transformation; and will, no doubt, in the hands of its energetic owner, soon be on a par with the older cultivated portion of the estate. To a farmer with ordinary means, the purchase of a large set of tackle involves too much capital, and hiring is very uncertain. Joint sets, too, are objectionable, as it is hardly likely that B. will rest satisfied while A. has finished his work; and if the tackle is to be removed backwards and forwards as each has finished a field, too much time, wages, and coals are wasted in travelling. I have for several years been in the habit of cultivating for hire among my neighbours, but I never do this sort of work until my own is finished, and then the season has been sometimes too far advanced for it to have done the hirers much service. I have never coveted this kind of business. On a farm where steam is constantly used, the land is generally more or less prepared for it. In other cases it is often the reverse,—crooked fences, deep water gutters ploughed out, high-backed lands, excess of filth, &c., in fact, I find that I can never do the same amount of work abroad as I can at home. There may possibly be farms, such as Mr. Campbell's, of Buscott, where there may be room for a Leviathan set of tackle, but ordinary occupations will not justify the outlay, and the hiring system is too uncertain to depend upon. Some years since the large Suffolk drills were introduced and hired out. At the present time such an implement is, in this part of the country, rarely seen. Instead of hiring, each farmer prefers to

keep a little handy six or eight furrow drill of his own, which can be brought out at a minute's notice. Steam plough companies will, I think, never be found paving concerns, at all events I should be sorry to invest money in one. Several have come to grief, and others have enjoyed but a very limited amount of success. After 11 years' experience, I do not hesitate to say that any occupier, if he has over 200 acres of strong land, will find it answer his purpose to become the owner of a set of the small tackle for his own use, and, if inclined, he may, when he has finished, give his neighbours a lift and reduce the cost of his own. This is what I have done, and, so far, I am satisfied with the result. F. W. Bignell, November 2.

"Agricola" (p. 1120) shall have the particulars for which he asks," writes Mr. Smith; and he would lecture me; "for it is not gentlemanly to openly doubt statements when a sufficient reference is given." If Mr. Smith will kindly and attentively read over my last communication, he will observe I wished to obtain the required particulars from Mr. Toepffer, as a champion of the larger and more expensive tackle, versus the smaller or Woolston system. Can Mr. Toepffer, or any gentleman using the larger tackle, question the correctness of the *Agricultural Gazette* of January 20, 1868—if so, will they point out the error? Mr. Smith puts forward Mr. Bates' evidence, as given in his letter in the *Times* of August 9, 1869. I asked, has Mr. Toepffer any knowledge of such evidence? and has he any reason to doubt Mr. Smith's figures, as given in the *Agricultural Gazette* of October 16? These are the particulars I require, and long to see the gap in *Bell's Messenger* filled up. Mr. Smith's last sentence I will not notice, but let me hope that he may reply to the postscript of mine of October 23. Having referred me to your paper of January 20, 1866, it gave me an opportunity of reading over his several communications on this subject, also those of "West Indian." Will Mr. Toepffer give his experience on the waggoning of corn? or is the instance at the Britannia Farms, Bedford, of a traction engine being thus used, the first on record? *Agricola*.

Mangel Running to Seed.—The letter of Mr. Bignell in your last week's impression, in reference to the above subject, says one half of the 5 acres of Mangel he sowed "bolted" very badly; the other, which was sown from seed supplied by Messrs. Sutton, was not near so bad, there having been only one day's difference in the sowing, and all treated alike. Mr. B. says this does away with the theory of the season being the cause. I must beg leave to differ on the point with Mr. B., as I have this season seen and examined a few fields of Mangels, several of which were sown from seed supplied by Messrs. Sutton, and in no single instance can I find them less seeded than the others, or better in either quantity or quality. Francis Hutchinson, Northallerton.

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

MONTHLY COUNCIL: Wednesday, November 8.—Present the Duke of Devonshire, K.G., in the chair; the Earl of Lichfield, Lord Chesham, Lord Kesteven, Lord Tredegar, Sir Watkin W. Wynn, Bart., M.P.; Mr. Baldwin, Mr. Barthropp, Mr. Booth, Mr. Bowly, Mr. Bramston, Mr. Cintrell, Colonel Caulloner, Mr. Clayden, Mr. Clive, Mr. Davies, Mr. Druce, Mr. Brandreth Gibbs, Mr. Holland, Mr. Hornsby, Mr. Wren Hoskyns, M.P., Colonel Kingscote, M.P.; Mr. Leeds, Mr. Milward, Mr. Pann, Mr. Rixden, Mr. Sanday, Mr. Shuttleworth, Mr. Thompson, Mr. Torr, Mr. Wells, M.P.; Major Wilson, Mr. Jacob Wilson, Professor Simonds, and Dr. Voelcker.

The following new members were elected:—
Aitkin, James, Peterborough
Bradshaw, Richard, Tubury House, Abingdon
Brown, Wm. Henry, Brookfield House, Bellbroughton, Stourbridge
Dear, Henry Charles, North Stonham Park, Southampton
De Schroder, Baron, The Dell, Staines, Berkshire
Godson, Nicholls S., Hook Norton, Chipping Norton
Hilton, Robert S., Miltstead Rectory, Sittingbourne
Jonas, Henry, 4, Whitehall, London, S.W.
Maxwell, Captain J. R. Heron, Springkell, Ecclefechan, Dumfries
Merriman, Edward Bayerstock, Marlborough
Neve, Richard, Benenden, Staplehurst
Parkin, Paxton W., Ridgemount, Bassett, Southampton
Perkins, William, Minster, Hamgate
Rayment, Edward D., 307, Vauxhall Road, Liverpool
Sadler, William, Ferrygate, Drem, N.B.
Senior, James, The Parsonage, Stafford
Wyles, Robert, Little Ponton, Grantham

FINANCES.—Colonel Kingscote, M.P., presented the report, from which it appeared that the Secretary's receipts during the past three months had been duly examined by the Committee, and by Messrs. Quilter, Ball & Co., the Society's accountants, and found correct. The balance in the hands of the bankers on October 31, was 1311*l.* 10*s.* 1*d.* The quarterly statement of subscriptions and arrears to September 30 and the quarterly cash account were laid on the table. The arrears then amounted to 1572*l.* The funded property had been raised to the sum of 20,000*l.* New Three per Cents, and an additional sum, the balance of 8000*l.* which had been ordered to be invested as a Reserve Show Fund, had purchased 1612*l.* 7*s.* 8*d.* New Three per Cents. This report having been adopted, Colonel Kingscote stated that the committee had received two letters from members of the Council asking for payment of their services as judges at the Manchester meeting, which the committee begged to lay before the Council. A discussion having ensued on the laws of the Society as bearing on the subject, as also on the custom of the Council with respect to it, the President suggested that notice of a debate resolution on the subject should be given. Mr. Sanday therefore gave notice that at the next monthly Council he should move "that the rule for the non-

payment of judges who are members of the Council be rescinded."

JOURNAL. — Mr. Thompson (chairman) reported that the Editor and Dr. Voelker had carried out their tour in Belgium very successfully, and that their report will be published in the next Number of the Journal; they had applied to be allowed to have an illustrative map lithographed, at a cost not exceeding 40l., which application the committee had endorsed. The committee also recommended that not more than 6000 copies of the next Number of the Journal be printed.—This report was adopted.

SELECTION.—Mr. Thompson (chairman) reported that the gentleman who had been highly recommended as a member of Council to represent the county of Kent had died within the last few days; they therefore recommended that the election of a member of Council to fill the existing vacancy be postponed until December. This report having been adopted, Mr. Thompson called attention to the pending revision of the bye-laws, and suggested that the existing rules as to weekly Councils should be made applicable to only one intermediate meeting between the monthly Councils during the session of Parliament. This suggestion, having been seconded by Colonel Challoner, was carried unanimously.

GENERAL, OXFORD.—Colonel Challoner reported that the authorities of Oxford having requested information as to the water supply of the showyard, the Secretary had been instructed to acquaint them with the conditions of their agreement. This report having been adopted, it was moved by Mr. Torr, seconded by Mr. Milward, and carried unanimously, that the names of Mr. M. W. Ridley, M.P., and Mr. Robert Leeds, be added to the list of the committee.

IMPLEMENT.—Colonel Challoner (chairman) reported that the proof of the Oxford prize sheet, with conditions, had been adopted, subject to a few minor alterations.—This report was adopted.

STOCK PRIZES.—Mr. Milward reported that a list of prizes for the Oxford meeting had been provisionally agreed to and ordered to be printed. It was recommended that the name of Mr. N Stone be added to the list of the committee.—This report was adopted.

A letter having been read from Mr. Mason, High Sheriff of Oxfordshire, it was proposed by Mr. Thompson, seconded by Mr. Jacob Wilson, and carried unanimously, "that Mr. Mason's offer to give a piece of plate of the value of 100 guineas for the best managed farm in a district named by him near Oxford be accepted; that the Council, however, are not prepared to offer a second prize; and that the Society do appoint, and defray the expenses of, judges and a reporter, and fix the conditions of competition, all details to be arranged by the Journal Committee after communicating with Mr. Mason, it being understood that the report shall be first published in the Journal of the Society."

A memorial from the breeders of Norfolk and Suffolk polled cattle having been read, the Secretary was instructed to inform the memorialists that the Stock Prizes Committee had complied with their request, viz., that prizes should be offered for the above breed of cattle at the next country meeting of the Society.

A letter from Mr. Swannick, on the subject of pigs being entered for exhibition which do not comply with the regulation of having had a litter within a certain time, or being so far gone in farrow as to farrow before September 1, was referred to the Stock Prizes Committee.

EDUCATION.—Mr. Holland (chairman), in applying for the renewal of the grant of 200l., gave an outline of the result of this year's examinations, as has already been published in the last report of the Council, and stated that all those gentlemen who had passed the examinations were, with one exception, about to become either farmers or land-agents. Mr. Thompson having asked whether the result of this year's experiment had been satisfactory to the committee, and received a reply in the affirmative, a discussion arose as to the maximum age at which candidates should be admitted to compete for the Society's prizes; but the recommendation of the committee, that the maximum age be fixed at 21, was ultimately adopted, and the grant was unanimously renewed for the year 1870.

The judges of Potato-diggers reported that the adjourned trials had taken place on October 6, at Manchester, and that the prize of 10l. had been awarded to No. 573, Messrs. Coleman & Morton.

A protest having been lodged against Mr. Nixey's Devon cow "Pink" (No. 680), on the ground that she had not produced a calf within the time specified in the conditions (12 months before the date of the show), and Mr. Nixey being unable to certify that she had—the Council decided that the prize awarded to the above-mentioned cow had been forfeited.

An application to have an authorised inscription engraved on a piece of plate, purchased with prize-money won at Manchester, was granted.

The Oxford meeting was arranged to commence on Monday, July 18, and to close on Friday, July 22, at 4 o'clock.

Reports on the recent International Horticultural Exhibition at Hamburg, and on the taking of samples for analysis of the guano from the Guanape Islands, both forwarded by the Secretary of State for Foreign Affairs, as well as a report on the exhibition of the Agricultural Society of New South Wales, held at Sydney, forwarded by the Secretary of State for the Colonies, were laid before the Council.

It was moved by Mr. Thompson, seconded by Col. Kingscote, M.P., and carried unanimously:— (1) That the Council at its rising to-day stand adjourned to Wednesday, December 8, at 12 o'clock. (2) That a committee consisting of any members of Council who are willing to attend, shall meet on Tuesday the 7th of December, at 12 o'clock, to prepare

a report to the general meeting,—the report to be laid before the Council the following day. (3) That the half-yearly general meeting of the Society be held on Thursday, December 9, at 12 o'clock.

The Council then adjourned until Wednesday, December 8, at 12 o'clock.

SMITHFIELD CLUB.

A COUNCIL meeting was held November 3. Present—His Grace the Duke of Marlborough, President, in the chair; Hugh Aylmer, John Baldwin, J. N. Beasley, W. B. Canning, John Clayden, Joseph Druce, Samuel Druce, Thomas Duckham, Brandreth Gibbs, Hon. Secretary; Richard Hornsby, Charles Howard, James Howard, M.P.; H. W. Keary, Robert Leeds, E. W. Moore, Henry Overman, John Painter, Wm. Sunday, J. T. Senior, Wm. Torr, Lord Tredegar, Vice-President; J. S. Turner, Jacob Wilson.

The honorary secretary was authorised to apply for the usual license from the Privy Council for holding the Club show.

A committee was appointed to make the necessary arrangements as to disinfecting cattle conveyances. The Council prepared a house list of the eight members whom they recommend to be selected on the Council, in place of those who retire by rotation at the close of the ensuing show.

The offer of the Agricultural Hall Company to prepare, at a cost of 15l., temporary accommodation for any animals that may be taken ill during the show was accepted.

It was determined that the Club's annual dinner shall take place in the new dining hall attached to the show, on Monday, Dec. 6, at 4.30 punctually. The stewards and hon. secretary were requested to make the necessary arrangements connected therewith.

Authority was given for the preparation of the pieces of plate and silver cups offered by the Club at the ensuing show.

The following were duly elected members of the Club:—The Earl of March, M.P.; Charles M'Niven, Perysfield, Godstone; Mr. Milburn, 76, Church Lane, E.; Rowland Wood, Clapton, Oundle, John Unite, 291, Edgeware Road; James G. Unite, 291, Edgeware Road; James Hart, 244, Whitechapel Road; Nathaniel Stalgoe, Manor Farm, Adderbury, Oxfordshire; Wm. T. Franklin, Ascot, Wallingford, Joseph Pulley, Lower Eaton, Hereford, Francis Dodd, Rush Court, Wallingford, C. Stephenson, Woburn, Beds., John C. F. Ramsden, Busbridge Hall, Godalming, J. E. Heasman, Angmering, Arundel; Eli Benjifield, Stalbridge, Dorsetshire, James Mason, Lynsham Hall, Witney, Thomas Franklin, Ascot, Wallingford; Joseph Franklin, Milton, Wheatley, Oxon; Philip Turner, The Leen, Pembridge, Hereford; Sir Anthony D. Rothschild, Bart., Aston, Clinton, Tring; James Reid, Graystone, Alford, Aberdeen. Thomas C. Booth, Warlaby, Northampton; the Earl of Radnor, Coleshill, Highworth.

The Council determined that the report on the live stock exhibited at the show be written, as for the last two years, by Mr. H. H. Dixon.

The Council, having considered whether by the rules certain entries of live stock could be received, came to decisions on the same, and gave instructions accordingly.

The best thanks of the meeting were voted to his Grace the President for his able conduct in the chair.

Farmers' Clubs.

LONDON.

Nov. 1: Continental Farming.—After Mr. Howard's lecture, reported in another page, a short discussion ensued.

Mr. J. K. FOWLER had seen much of the farming on the Continent, and regretted that Mr. Howard had not more fully described its dairy management. He quite agreed with him that Sugar-Beet would make great headway in this country; but distilling from Beet would not pay, as the spirit was so inferior to Grape spirit. Another subject was the sheep and cattle imports to the Continent from this country. English machinery did not take so well, as in many instances there were not mechanics capable of repairing our highly-finished and expensive productions. In some instances, however, as on the large farms and estates of noblemen and princes, machinery has been successfully used. He referred to the Continental beer. He had never seen anything in which so great an improvement had occurred in the last few years as had taken place in Continental beer. This he attributed to the fact that there was no odious Malt-tax.

Mr. READ, M.P., said the paper just heard would be as valuable in a political as in an agricultural sense. He was glad to find that the labourers in this country were better cared for than they were on the Continent. John Bull is apt to be very conceited and stupid. It must be remembered, however, that though 20 years ago the Continental farmers were in the very depths of misery, if we do not mind, they will go on improving till, instead of our being first in the race, we shall be very far behind.

Dr. VOELCKER was very pleased to hear Mr. Read say that the agriculture of some parts of the Continent had greatly improved during the last 20 years. But he regretted that this could not be applied to Belgium, for during his recent tour with Mr. Jenkins, after an interval of 16 years, he only saw a certain improvement in stock, which he traced to strains of English animals. He believed the corn grown was better formerly than now. He must not, however, say more about Belgian farming, or he should take the gilt off their coming report. He might remark, however, that the Belgians on more than one occasion expressed their astonishment at finding English gentlemen coming over to look at their farming, as everything which was good there had, they said, been learned in England, or

by reading English publications. In regard to Beet, he believed England was better growing this root than was the case elsewhere. If any English farmer wanted a Sugar-Beet, he must not go to Belgium, Germany, in the neighbourhood of Metz, then described minutely the proper soil for the Sugar-Beet root, the gist of which should vegetate entirely below the soil. The results of analysis which he recollects there was only one-half as much sugar above the ground as there was in that soil.

Mr. CROSSKILL questioned whether the profitable growth of Sugar-Beet on the Continent not due to the protective system under which, viz., the high duty on colonial sugar, that Continental farmers had improved more than English farmers had during the war, then referred to Mr. Fowler's remarks on Yorkshire, who was wont to exclaim, "year great civiliser of the human race. Manufacture sent beer to precede them; they took to themselves; thus they were able to congregate to Christianity!" This was of course intended to create a laugh, but it was appropriate to Mr. Fowler's conclusions. For his part he thought better to teach the labourer to avoid the temptation of beer.

Mr. EVE had found the bear on the farm. He could not but remark on the production of eggs and even milk, which was London milk, and very much purer, than that of the country.

Mr. PELL, M.P., said Mr. Howard's culture and large farming were the improvement only in large farms, touched on cottier farming. He thought that the conclusions of Mr. Howard's culture and large farming were the erroneous impression to the Club. He were very likely to be arrived at by Howard, who has done so much for the of English agriculture. As regards the sewage of our towns might be more profitable extent. The water, too, might also be raised for irrigation small cost in many cases. As regards (Mr. Pell) did not place much faith in the English farmer to compete with the in producing sugar. With beef and 9l a pound, he thought the principle, both for the farmer and the his part he would rather preserve a flock of sheep than sell his roots in a factory.

The CHAIRMAN thanked Mr. Howard for character of the subject had made a lecture and less suitable for the time. He would be better able to understand what thing was perfectly clear from Mr. Howard's viz., that the labourer on the Continent harder for much less pay.

Mr. HOWARD, in regard to Mr. Pell's that he had not advised the English system, he had not only described what regards large farms and peasant culture. were present, he would advise him to next year "On the Pasture Farming of in reply to Mr. Crosskill's observations, if we had a free breakfast table, as would be nothing for the British of in regard to the sugar duties.

LAVERNHAM.

Annual Meeting.—At the annual Club last week there was quite an eloquence, and we take the following report in the Suffolk Chronicle.

Mr. T. P. HITCHCOCK said we had lately of the condition of the labourer. Now, the primary object of the Club was to improve the condition of the labourer. If they offered prizes for them to compete for them they would and made them more skilful, and by them to earn more money, and by social condition. At the late Social Canon Girdlestone, the world-be-come cultural labourer, said no deduction from wages for beer or cider or as if they were to claim for the time, alone of all classes perfect immunity that flesh is heir to." They might labourers should never be ill, should and should never be like every other that to be? It was perfect did not pretend to be philanthropic among their labourers, their interests extent identified with those of the was sure they were as much the as those theorists and visionaries about the country talking of what

Mr. J. J. MECHI said he was man to propose the health of the President, whose absence they would, perhaps, be expected of a word or two about agriculture. apron-string farmer, but still a farmer—a scientific farmer if formed certain views upon the agriculture of the kingdom, but to the general subject they would

been very much interested in what he had seen day. He had been exceedingly pleased and glad in their comparatively retired part of the country they were luxuriating in steam, not only in their mills but also in the conversion of their produce into articles of every day use—sugar. The sugar manufactory was a very fine and splendid undertaking, and he had been exceedingly interested in going over that day, and if they studied the operations going on at that manufactory they would find that science had almost everything to do with the rendering those operations profitable, and they would conclude that it would be well for agriculture to seek the aid of science to render its pursuit more profitable to the community at large than at present. We were in a transition state—coming from the primitive pastoral state, when the farms were few and Grass superabundant to one in which there was a treble population. We now had a population of 32 millions instead of 10 millions in the year 1800. Those millions who were engaged in manufactures required to be fed every day, and looked to their brother countrymen, who were agriculturists, to produce more than they used to do by the investment of greater capital and enlarged intelligence. It came the question—has that been done, or has the limit of it been exhausted? He thought they would agree with him that we were only on the threshold of agricultural progress. It was only the other day that we discarded the flail for the horse threshing machine, and soon after doing so we found steam-power was a further and see if steam is not also applicable to the cultivation of the land? To show them the extent of the power of steam he would tell them that he asked an engine-driver that day what was the power of the engine of 14-horse power which he was driving competitively with horses, and also the pressure per inch which he was working? and he was rather surprised to learn that at a pressure of 160 lb to the square inch, and with the power fully applied, it was equal to 100 horses. What did they see in the great marine engines? One of these was nominally of a 1000-horse power, but was equal to 6000 actual horses. Let us measure their minds never to use a man where we could use a horse, and never to use a horse where we could use a steam-engine. This brought him to the question "Have we capital enough for the purpose?" It could not be denied that we were going now from the expenditure of a small capital to the necessity for a large one in agriculture—much larger one—and if they had not got it themselves they must get it from some one who had got it. They did that practically in the matter of steam-engines, for if they could not afford to have one on their farm, or if the farm was not large enough to employ a full engine, they went to some one who had capital and bought an engine which he was willing upon interest to let to them. But he was a believer in agriculture being short of capital. Go where you would, he could find a number of comfortable men with very large capital invested in everything but agriculture. He could point to a near him, where a very respectable gentleman told him he could not afford to put up covered yards and steam-engines, but he (Mr. Mechi) knew that gentleman had got out in loans and mortgages. He would admit that there was a want of capital, what was the belief in the power they had to invest in capital. They were not in a different position to manufacturers, for the history of all manufactures that those engaged in them were at first opposed to the most profitable and interesting inventions were brought to bear upon those manufactures. They remember how, in the early days of railways, the cities looked upon the railway-engine as a terrible thing, and would not have the lines brought to them, and what had been the consequence? They had had to make lines at great expense to bring them into communication with the great towns, simply because they would not believe in the advantage of railways in the first instance. Let both landlord and tenant open their minds to this fact, for the fact that agricultural improvement must be done by landlord and tenant for their mutual benefit. The improvement must strike every landlord, as it struck him that day, when he saw a nasty awkward farmer of the field they were cultivating interfering with those two engines of Fowler's. A great nuisance had there, causing loss to the farmer and deterioration of the value of the land, so that the tenant could not pay to the landlord the full value of the farm. A great many years ago he (Mr. Mechi) made war on the landlords of Suffolk, and he believed it had done a good deal of good, although he was a good deal abused at the time, that a good many of these nonsensical politicians had succumbed to the attack. But they had not done the work yet; and their enlightened landlords—they were enlightened, but, like the tenants, their prejudices could not be overcome at once—must be overcome on another point. They still retained a prejudice arising from the many hedgerows and small fields, but when they thoroughly understood that the loss both to themselves and to the tenants invested £100 or £1000 in engines for steam cultivation, they would no longer wish them to exist. He could afford to pay a better rent to his landlord, and, practically, that was what would follow their movements. Are they aware what is the produce of this land per acre? He had had to look out what the produce came to, taking the United Kingdom, and he had from the best authorities our present produce did not exceed 3/ 12s. per acre. He would tell them it was. Half the United Kingdom is in pasture,

and a great deal of it is poor, miserable, wretched pasture, which is robbed for the sake of the uplands and other good land. Before our country can take her proper position, before she produces the 365,000,000 eggs a year that Colonel Parker told them we import from abroad, these worthless grass lands, which on the average do not produce more than 10c a year, must be made by cultivation to produce, as some of theirs produced as he had heard that day, 20 tons of good Beet, worth 20/ an acre. Was it right for them to allow the present state of things, when this land could be made to produce more? Let landlords and tenants lay their heads together and give up old prejudices, and the belief that they were short of capital when they were not, because they were lending millions to foreigners—something like 300,000,000/ sterling—and cease to cry out "Where is the money come from?"—that was a little piece of hyperisry; and when they were convinced (as they were being convinced), that it answered their purpose to take 20/ an acre for a good crop of Beetroot, let them not spend it all when they had got it, but put a little back in the shape of cake, and a little in corn. This led him to the question whether it was profitable for them to support this excellent sugar manufactory—the only one existing in the United Kingdom. To arrive at a proper conclusion, he would ask them—What would the bullocks pay for this 20 tons of Beetroot, and how much the manure they make was worth? The question was not yet solved, whether it would pay them better to sell the Beet to the sugar maker, or to feed bullocks on it. He had heard it said that it takes a ton of Beet to make 14 lb. of meat, and, perhaps 5s or 6s worth of manure, and if that calculation were correct, and they could grow 20 tons of Beet an acre, it would pay them very handsomely to sell it to the sugar maker. He had been laughed at a great many times, but he farmed for profit, and he obtained it by draining his land, throwing down fences, having all the land growing something, feeding a large quantity of cake and corn which did not grow on his land. He thus made a profit for both landlord and tenant. Did they believe in his profits? [A Voice No. He thought not. Cheers and laughter. That was a very honest answer, and he expected some such reply from some quarter, but he was there to speak the truth, and he could only tell them this—that on his farm, which was almost all arable—he had only 14 acres of Grass—he found he had 14/ an acre capital as tenant, and he found that was not enough, and he could not hold his corn as he would like, but had to sell a good deal of it to buy bullocks. He wanted 20/ an acre capital as tenant. If they asked how it was invested he would tell them. There was 6/ an acre in live stock when he took stock, which was at Christmas, his tillages, which were deep and included all manure, came to 3/ 10s. per acre; horses, 1/ per acre; implements, between 2/ and 3/ and the unsold stock, corn, &c., he had come to 3/ or 4/ an acre, which brought up his capital to 16/ an acre; but he could make a greater profit if he had 20/ or 24/ an acre to land all arable, excepting 14 acres. That was a question of pounds, shillings, and pence. Was it better to put 20/ on 1 acre than on 2 acres with two rents, tithes, and taxes, two seeds, and so on? [Mr. H. BIDDELL. And two crops.] They would grow maximum crops as large on one acre as with ordinary farming they would on two, and that was the way he made his profits, and when he told them his profit, as landlord and tenant, on 170 acres was something like 612/ a year, they would think it was not so very bad considering that he was an apron-string farmer. He could not do it with 10/ an acre capital, nor with 12/ but he could with 16/ and he could do more with 20/. He knew many thought 10/ an acre was ample, and if they had plenty of poor Grass it was, but not if they had all arable land. The great want, especially if they grew roots to sell off their farm, was more manure; and there was no way, his experience had taught him, of producing that manure so cheaply and of such good quality as by feeding animals under cover on what did not grow on the farm—cake, especially, and corn—that was better than all the artificial manure, except in some peculiar soils where superphosphate was needed. Then, as to the treatment of manure, when they had got guano it would not do to put it down in the farmyard and let the rains of heaven wash it away—if a man were to do that they would think he was insane or a great fool; but that was just what they did when they allowed that still better guano they made at home to be so washed and turned over and made into muck heaps by the side of the road and rained upon. They were, in so doing, making a fatal economical mistake. Those who had seen his crops would know whether the estimate he was going to give them were correct. He got his bailiff to measure his root crops before he came, and he found on each square rod 78 roots averaging 7 lb. each, representing 39 1/2 tons of long red Mangels per acre; and the globe Mangels, with the same number of roots to the rod, came to 37 1/2 tons an acre. How were such crops produced on poor land which let before he had it at 18s. or 20s. an acre? It was by drainage, deep cultivation, and above all by the consumption of 20 tons of cake and corn fed under shelter, taken like hotch-potch pudding directly from under the animals and put on to the land and ploughed in like guano. The finish of the rotation on part of his farm was two Wheat crops—White Wheat followed by Rivetts. He was asked what he had after Wheat, and he replied that he rested it with 40 tons of Mangels. That was his resting crop, and he could not make it except with the quantity of stock he kept, and if he could get it off in time he went in for another Wheat crop. Let them have their land clean, and get their landlord to drain it for them and put up good buildings, paying him a fair interest, and they could increase the food for the people grown in the kingdom from 3/ to 10/ or 12/ an acre, and thus retain in the kingdom a

large proportion of the 70,000,000/ a year we pay for foreign produce, including tea and articles of that kind. But then came the question, did they put all this food which they consumed on to the land again and thus increase their crops? No, we are only coming gradually to that, and the gentlemen in Ipswich, Norwich, and other large places are just coming to believe that 30,000,000 of sheep being good for the land 130,000,000 of people were added to the 30,000,000 of sheep in manual power we should be in a different position with regard to the production of meat and other food to that we now occupied. That was a question for the towns, and it was a question for the agriculturists too. He knew a party who had the grant of the sewage of North London for 50 years, but what was the use of carrying gas or coals to people who would not have it? He believed the Corporation of Norwich had taken 1800 acres of land, and were going to pump their sewage on to it, and they had already been bid 6/ an acre for the land on which the sewage would be used. A very eminent man connected with Liverpool had informed him that people were willing to give 25s. a-day for the use of a 2-inch pipe of sewage, and at that rate they would get a very good return for the large investment in machinery. That enormous stream of food that goes into London should come out again. It can come out again into the country provided they were all prepared to say—landlords particularly, for it was to their especial interest—that when it is brought they would pay a fair price for it—such a price as would leave a satisfactory profit, because none of these things would be done without a profit. Let them believe him, it was for their interest that landlords as well as tenants should work together to make agriculturists as free as they could. He could not agree with the statement that if Manchester was in ruins the land would still prosper. Don't believe it. Your beef, mutton, and corn would not fetch the prices they do now if you could sweep away from England that which employs the largest number of her children—her manufactures. It was her manufactures that made her great and wealthy, and it is through them that she will retain her greatness. I hope we shall see town and country united for their mutual good, and with no jealousy between them—and that buyer and seller may see that they are necessary for each other's profit and the good of the country. Mr. HITCHCOCK said Mr. Mechi misrepresented him when he said that he (Mr. Hitchcock) stated that the country would prosper if these great towns were in ruins. He said no such thing. What he said was that their fields would be cultivated then, and in proof of his assertion he pointed to the Campagna of Rome, which was cultivated though Rome had fallen. He did not mean that they would be equally prosperous, and, said Mr. Hitchcock, when I said "you," I did not mean you, but your posterity long years to come. Mr. WM. BIDDELL, the Vice-Chairman, returned thanks, and after an allusion to the flourishing condition of the Lavenham Farmers' Club, said they had been asked for their opinions with regard to the Sugar-Beet. He had not experienced those great crops that the sanguine among them expected last year, but he had come so near them that he was inclined to grow a greater breadth next year if Mr. Duncan would offer the same inducements that he had done this year. He believed when they selected their seed they would improve both in the bulk and quality of their crops, for he could not but think the seed they had was very bad. For his own part Mr. Mechi's statement required a great deal of digestion before they became assimilated into his (Mr. Biddell's) agricultural system—but at the same time they had to thank Mr. Mechi for a great many things. He did not agree with all Mr. Mechi's experiments, and he should not be wrong if he said that he agreed with very few of them, but as Mr. Mechi had become public property, and possessed such a wonderfully good temper—he did not feel any diffidence in making some comments upon them. He must think Mr. Mechi, when called to a better world, would leave his mark upon the day in which he lived. Did they know what had been the effect of his crusade against thick sowing? He would tell them. There were about 3 1/2 million acres of Wheat grown a year in the country, and he did not exaggerate when he said Mr. Mechi had decreased the quantity of seed by half a peck per acre; and, spread over the whole breadth grown, that half peck per acre became a great saving of food, and a gain to the country of between 100,000,000 and 200,000,000. A man who had done that deserved well of his country, to say nothing of his war against pollards and his advocacy of deep draining. Not that he (Mr. Biddell) was altogether one of those who believed in 5 or 6 feet draining, but they were going wrong when Mr. Mechi set them right. Mr. Mechi was one of the sanguine people who were the leaders of the world. It was they who took steps in advance of the common run of people—sometimes they broke their necks over the obstacles, but without them we should not have advanced as we have. As to the heavy outlay of which Mr. Mechi spoke, he could understand that by making a double outlay of 20/ an acre he could largely increase his produce, but the difficulty remained that they could not get two crops in one year. He had never seen the year when a double crop was obtained to pay for this double outlay of capital. Mr. H. BIDDELL said the gentleman who alluded to the condition of the agricultural labourer only went into the question a little way. He got as far as Canon Gardlestone, and there he pulled up, and just where he pulled up, he (Mr. Biddell) wanted to begin. The Canon had been from one end of the kingdom to the other preaching right and left that the agricultural labourer is not paid sufficient to keep body and soul together; but while he was preaching this they saw him linked hand in hand with men like Mr. Patten,

Mr. Beales, and Professor Fawcett, who were bringing forth resolutions which they said they were going to press, the effect of which was, that we are to have compulsory education. Whether the labouring man can keep his children or not, still he shall educate them. Whether they should put the child to work at eight, or 10, or 12, was another question; but he should like to put this question—if a man with five or six children gets 10s. a week, which Canon Girdlestone protests is more than they earn in his neighbourhood, and one of the children earns 2s. and another 3s. a week, if you compel that man to drop 50 per cent. of his income by preventing his children from earning anything and compelling them to be educated, how are the man, his wife, and children to live on 10s. a-week? That was a point he wanted cleared up, and the man who brought the matter to that point should clear it up. He was no enemy to education. He thought every man should be able to read and write, and to see a man neither able to read his Bible nor sign his name was a state of things no one wished to continue. At the same time, if a labourer and his family had hardly enough to subsist on it was a cruel thing, because you persist that his children shall be educated, to say he shall have less to support them upon. He could see no solution to the question at all, but would be very much gratified to see it solved. No doubt it was gratifying to see a clergyman of a parish where the inspector came round, to find the children at his schools ready at once with the latitude and longitude of Seringapatam, and able to answer all sorts of questions of that sort, but if this knowledge were gained at the expense of a glass of beer to the father and a piece of meat to the mother, when in a weak state, they had no right to expect it. Till we have put labourers in a condition to keep themselves and their children, and have their children at school, we have no right to force them to go there. The last resolution of the National Educational League was, that education should be compulsory, and he could not conceive of compulsion without imprisonment as the alternative of disobedience, and the effect would be that whether the father had the money to feed his children or not he must not take advantage of their labour on pain of being sent to gaol. That wanted very careful handling. He did not want to stand up as an enemy to education—he wished to further it, and if a Bill were introduced into the House of Commons he would not counsel factious opposition to it, and he would ask his brother farmers to give their information and assistance to their members, in order that such a bill might be framed as would meet the case, but he would at all times protest against compulsory education, which would bring compulsory starvation in its wake. He knew the same parties who formed the Education League would tell us it was not the plodding man—it was the brilliant intellect and the faculty of inventive genius that we want to further, but to such he would say as the Spanish minister said to his Queen, "It is not so much philosophers your Majesty stands in need of as happy and contented subjects." He did not wish to follow Mr. Hitchcock into the agricultural subjects that are not connected with agriculture, on which that gentleman had spoken. He had heard Mr. Mechi allude to the land he occupied at Tiptree, as being poor land. The question he was going to put to Mr. Mechi was not in the spirit of opposition, but it was a plain question, which he knew he would answer. He had heard it asserted by gentlemen living in the neighbourhood of Tiptree, whose integrity he could not doubt and whose veracity it would be folly to question, that a good part of the land Mr. Mechi occupies was capable and did produce on an average 4 quarters of Wheat an acre before he took the farm. Now land that did that could not be very poor land, or we had a vast quantity of very poor land in the best districts of Suffolk. He hoped wherever Mr. Mechi went he would be received in the manner which his equal temper entitled him to expect. He had had to meet attacks in which the writers and speakers would have done well to copy the equal temper of the man they attacked, and they would have got out of it a little better. He (Mr. Biddell) did not disbelieve Mr. Mechi's word, but he disbelieved the conclusions at which he arrived, and he was not a believer in the profits of the Tiptree Hall Farm.

Mr. MECHI, in reply, said Mr. Biddell said he did not believe his statements. That was a point on which he (Mr. Mechi) could not argue, but Mr. Biddell said that Tiptree Hall land was not poor land. The other day some of the land adjoining his, of the same quality as his was, unimproved, undrained, and with fences like his had when he bought, it was sold for 20l. an acre. He had no doubt there were portions of his farm on which 4 quarters an acre had been grown—perhaps 35 acres. In 1842, his land was undrained and full of fences, and he was told that the yield of Wheat that year was 1 1/4 quarter an acre. Last year he had 75 acres of Wheat which averaged 6 quarters an acre, and that was some improvement. Having built a very large barn he was told by all his friends that he should never fill it, and consequently he was rather sparing in his first purchase of rick frames, but bought four, the next year he bought four more, and then added another four, and this year he had his barn and rick frames full and stacks besides. He believed the time was coming when no bullocks would be allowed to range on the land or pastures but all would be kept under cover; and he advocated folding sheep on the land with iron hurdles, changing them twice a day, and taking the proper mixed food to them, and they would make more meat at a cheaper rate and manure the land better than by being allowed to range on the old system. Another thing he wished to mention was, that whilst everyone around him had the foot-and-mouth disease none of his bullocks under cover had taken it, and in the same way he escaped the cattle plague.

Farm Memoranda.

ROXBURGHSHIRE, TWEEDSIDE, October 30—There has been a good deal of grain brought into the markets this month, and we have now a good idea how the crops are going to yield. Barley was very bulky, and is threshing out a capital crop; in the earliest districts it was cut and carried without getting a single shower, the colour is not so fine as last year, but the weight much the same—from 57 to 60 lb. per bushel, and it fetches from 33s. to 40s per quarter. In the later districts they were caught by the broken weather, which discoloured the grain, and a good deal of it was carried in bad order, and heated, which accounts for the large number of inferior samples that are coming into the markets. Oats were generally short in the straw, and will be a light crop—they were very much damaged by the weather, not only in the stook, but also in the stack, particularly where they were not thatched, for the heavy rains drenched them down, and they had to be carted out dry. There is also a large quantity spoiled by heating, especially in the high districts the samples that were got in early are fine and heavy. Potatoes are a capital crop, and we have heard of no disease amongst them; Turnips are also very good. Stock of all kinds has done well through the summer, and are put on to Turnips in capital condition. The murrain has been prevalent amongst the cattle, and in a few cases the sheep have taken it also, but it has been of a mild type, and has not thrown them very much back. There is a good demand for the cattle that are coming into the markets, and high prices are given for them. Sheep have also been much inquired after, and are selling dear. Draft ewes will be up from 8s. to 10s. a head from last year. A number of farms have been advertised to let this month, for which there has been a great competition, and are letting at a considerable rise over the old rents. II.

Calendar of Operations.

NOVEMBER.—Wheat-sowing on autumn fallows that have been manured should now be concluded with all possible despatch, and after root crops as soon as they are removed from the ground. Although Wheat likes a stale furrow seed-bed, it is beside the question, practically speaking, to talk of a stale seed-bed in lands ploughed during November, which is generally cold and rainy. There are no doubt exceptions to this, viz., long periods of dry frosty weather. But even in such cases November weather should not be trusted to a single night, and therefore the safest plan is for the steam tackle to go back to the seed-drill and harrows, and bring up the seeding every day close to the ploughing; for if rain falls over-night the seed-bed is better to-day than to-morrow, and if it continues dry and frosty the land will make the seed-bed improve just as well, if not in many cases better, after being seeded than before.

Mangel Wurzel, however favourable the weather may have been hitherto, should now be stored without delay, as directed during last month. If frost has set in before they are lifted, so as to affect the roots, it may be advisable to give them a few days fresh weather to recover; but if the risk is greater than the prospect of advantage, pull and store in pits of a less size. The roots thus stored will require to be examined in the course of ten days or so, as the pits may need to be turned, and any frost-bitten roots which have not recovered thrown out. The pits may be so made that in turning them two or three may be made into one of twice or thrice the size, and, as a rule, if Mangels are the least touched with frost they should be thus stored and turned before being finally earthed up for the winter. The expense is little compared with the safety of so valuable a crop. Select a fine drying day for turning, and throw aside all roots in the slightest degree affected, the bulk of which may be turned to some account in feeding store stock.

Early lambs for Christmas should now be forced forward, bearing in mind that the fineness of the quality depends upon the food of the ewes and what little the lambs themselves eat exclusive of milk, and that plenty of rich milk is the natural and best food for making lamb which will fetch the top price in the London market; and further, that quantity of milk will not make up for quality. Corn is better than cake for making rich milk, Clover hay than meadow hay, Cabbages than Turnips, and the yellow-fleshed varieties of Turnips are to be preferred to the white-fleshed. Sheltered pastures should be set apart for ewes and lambs, and where there is not shelter naturally, stuffed hurdles should be used or straw webbing, as directed in spring-time, one row above the other slanting so as to form a semi-roof for the ewes and lambs to go under in rainy weather. This will also serve the ewes that are lambing to supply the demands of the new year, and the season onwards. As a rule the skins of ewes and lambs must be kept dry, and if this cannot be done outdoors, it is better to house the flock at once in roomy pens, and feed wholly on artificial food. W. B.

Notices to Correspondents.

MANGELS AND FROST W. M. If "W. M." means that he moved and bruised his Mangels whilst frozen, then, probably, they will not keep long. But Mangels will now stand a good bit of Autumn frost if left untouched till their frozen condition has been altered by a change of temperature.

PEDIGREE IN LIVE STOCK.—Mr. Willoughby's Woolst paper on this subject must, unfortunately, be delayed a week.

THE WOOLSTON ACCIDENT OF STEAM CUBINATION G. A. H. and Mr. Smith.—We have letters from both of these gentlemen, and must ask them to forgive the delay of a week. The Farmers' Club reports have taken all our available space.

SULPHURIC ACID L. S. D. Your question about gas water has been forwarded to a competent authority, and will be answered next week. Do not mix it in composts. An alkali would be more serviceable than an acid for such a use. Vegetable composts will rot under the influence of moisture, air, and time, without any other aid.

Caution to Gardeners.—When you buy SAYNOR AND COOKE'S WARRANTED PRUNING and BUDDING KNIVES, observe the mark SAYNOR, also the Corporate Warranted without which none are genuine. S. & C. regret having to caution Gardeners and others compelled to do so, in consequence of an imitation of quality, having been sold for the genuine one, and which many complaints to be made to them of Knives which they make all of which are warranted both by Saynor & Cooke and S. & C.'s PRUNING and BUDDING KNIVES are the cheapest in the market. Faxon Works, Sheffield. Established upwards of 40 years.

Horticultural Glass Warehouses. THOMAS MILLINGTON 457, 87, Bishopsgate Street Without, London, E.C. NEW LIST FOR ORCHARD-HOUSE GLASS at Wholesale and Retail, the Nobility, Gentry, Mr. Rivers, and the Cultivators of the United Kingdom. ORCHARD-HOUSE GLASS.

Pelargoniums for the Million.

JAMES HULDEK'S unrivalled Collection of French, Fancy, and Show varieties is now ready, at the following low prices—100 plants, distinct sorts, for 50s.; 50 plants for 30s.; or 25 plants, distinct sorts, for 20s., hamper and postage included. Crown Nursery, Reading.

VARIEGATED PELARGONIUMS.—Mrs Dix. Pictus, Spanish Beauty, Jock o' Hazeldan, Louisa Smith, Lizzie, Carolina Longford, Oberon, Dragon, Countess Tyrconnell, Golden Circle, Glen Eyre Beauty. CABSON and SON, Gravel Walk Nursery, Peterborough.

Special Offer.—Madame Lemoine. WILLIAM BADMAN offers strong plants of this most beautiful of Double Pelargoniums, in single pots, 6s per dozen. LORD DERBY, finest Pelargonium grown, 4s per dozen. Package included. Terms cash. Cemetery Nursery, Gravesend.

British Fern Catalogue. ROBERT SIM will send, post free for six postage stamps, Part I (British Ferns and their varieties, 98 pages, including prices of Exotic Ferns), of his PRICED DESCRIPTIVE CATALOGUE of BRITISH and EXOTIC FERNS, No. 7. Foot's Cray Nursery, Sidcup Hill, Kent.

Choice Seeds and Spores, for present Sowing. JOHN H LEY, NURSERYMAN, Croydon, has saved with great care SPORES from his extensive Collection of EXOTIC FERNS. If sown now in the manner described on each packet, would produce many fine varieties next season. Per packet, 1s. 6d and 1s. 3d. CENTAUREA CANDIDISSIMA, good Seeds, 1s. per packet. PIRETHRUM GOLDEN FEATHER, 500 ditto, 1s., post free.

Everlasting and Dried Natural Flowers. JAMES CARTER, DUNNETT, and BEALE'S WHOLESALE LIST of the above is now ready, and will be forwarded immediately on application. 237 and 238, High Holborn, London, W.C.

JAMES CARTER AND CO. have a beautiful Stock of Seedlings, in excellent condition, of their choicest Strains of CALIFORNIA, CINERARIA, and PRIMULA, in 50-pots, fit for potting on immediately for early Spring Blooming. Worthy the attention of those who have omitted to sow at proper time. Price, 12s per 100, 1s per dozen. JAMES CARTER AND CO., 237 and 238, High Holborn, W.C.; and Crystal Palace Nurseries, Forest Hill, S.E.

Gladioli—New Roses. EUGENE VERDIER Fils Aîné, NURSERYMAN, 3, Rue Dunois, Paris, publishes in August and September of each year complete and descriptive CATALOGUES, with prices. They comprise all the finest and newest varieties of Gladioli, Paeonies, and New Roses. Gratis and post free on application.

A VAN GEERT, NURSERYMAN, Ghent, Belgium, has to announce that he has still some large plants of LAMELLIAS left, with flower buds, at 7s. 6d. to 15s. each; seedling plants of ABIES BRACTEATA, 2-yr. old, at 60s. per dozen. Strong plants of UVARIA GRANDIFLORA, at 4s. per dozen. Also plants of LANTANA HORBONICA, at 7s. 6d.; CHAMEROPS BUMBUS, at 15s.; and CORYPHA AUSTRALIS at 10s. 6d.

New Japanese and other Chrysanthemums. JOHN SALTER AND SON beg to announce that the CHRYSANTHEMUMS are unusually fine this season. Their large Collection, NOW IN BLOOM in the Winter Garden, may be seen throughout the months of November and December, every day except Sunday. Admission free. Versailles Nursery, William Street, Vale Place, Hammersmith, W. near Kensington Railway Bridge.

New Catalogue of Dutch Bulbs, Plants, &c. ROBERT PARKER begs to announce that his NEW CATALOGUE containing Select Descriptive and Priced Lists of American Grasses, Cyclamens, Gladioli, Hyacinths, Lilies, Narcissus, Tulips, and other bulbs, Mosses, and other Plants, Fruit Trees, Sweet Violets, &c., is now published, and will be forwarded on application. Forest Nursery, Tooting, Surrey, S.W.

Dutch and other Bulbs. WM CUTRUSH AND SON are celebrated for HYACINTHS, TULIPS, CROCUSES, and other DUTCH BULBS. All the great Prizes, including the Two Special Prizes offered by the London Gardeners, awarded to their Collection one year ago in the Spring. Their report is of one quality, therefore Customers may rely upon having the finest Bulbs. CATALOGUES post free. H. G. Cutrush Nursery, L. near N.

Dutch Flower Roots. FRANCIS & ARTHUR DICKSON & SONS, have received from the most celebrated Growers in Holland their large importation of the above, and have the satisfaction to say that the Bulbs are large, sound, and well ripened. Early orders respectfully solicited. DESCRIPTIVE PRICED CATALOGUES sent free on application. The "Old" Established Seed Warehouse, 106, Eastgate Street, London, E.C.

Hyacinths, Tulips, &c. BUTLER, McCULLOCH AND CO. beg to announce the publication of their AUTUMN CATALOGUE of the above, which will be sent gratis and post paid on application. Orders for Bulbs can now be executed. BUTLER, McCULLOCH AND CO., South Row, Covent Garden Market, London, W.C. Established upwards of a Century.

Arrival of Bulbs. A R R AND S U G D E N, 12, King Street, Covent Garden, W.C. CATALOGUE containing much additional valuable information is ready, and on application sent free to the Readers of the Chronicle. BULBS for Early Flowering now ready to be put out, of first-class quality.

The Gardeners' Chronicle. SATURDAY, NOVEMBER 13, 1869.

MEETINGS FOR THE ENSUING WEEK. Royal Horticultural (Fruit and Floral Committees), at South Kensington .. 11 A.M. Ditto (General Meeting) 3 P.M. .. 5 P.M. .. 14—Lincoln

COMPLICATED as is the geographical distribution of organised beings, it would have been adered still more so if, at an earlier stage of our knowledge, the two great ISTHMIUSES of the world those of DARIEN and SUEZ—had been cut under by the agency of man, so as to allow of unrestricted spread of such plants and animals are now found in their neighbourhood. There are many reasons to believe that at an early period the present geological epoch, North and South America were not connected by that great bridge which now separates the Atlantic and Pacific Oceans, but that this was formed by one of the great upheavings which have added to the coast of Peru, Bolivia, and Chili, a greater part of its desert tracts, and but seldom being covered by vegetation, and but seldom

visited by actual rain. In the narrowest part of the Isthmus of Darien we find beds of oyster shells, formed by a species still existing in a living state on the Pacific coast; the majority of the fishes, both fresh and salt water, as Dr. GUNTHER has clearly shown in his admirable treatise in the "Zoological Transactions," are found on the coast of both the Atlantic and the Pacific; and the maritime and shore vegetation, consisting of plants chained to the water's edge, and therefore not able to spread overland, is identically the same on both sides. Curiously enough the same conditions do not seem to prevail on the Isthmus of Suez—the fish fauna of the Red Sea, Dr. GUNTHER reminds us, being absolutely different from that of the Mediterranean. It will be interesting to watch how far this state of things will be influenced by the great work now completed, we mean the canal across the Isthmus of Suez.

These and similar reflections are naturally forced upon us as the day approaches when one of the greatest engineering feats of our time, certainly one of the greatest our French neighbours have achieved, is to be thrown open to the commerce of the world, when trade is invited to resume its old channels—that trade which, in days of yore, when navigators did not pass by the Cape of Good Hope, covered the terraced gardens of the Mediterranean with precious works of art, and enabled the German merchant princes to heat their rooms with Cinnamon wood from India. It is humiliating to think that some of our greatest engineers, probably influenced more by political than other reasons, boldly pronounced against the possibility of a canal, and thereby added not a little to the embarrassments of that great entrepreneur, M. DE LESSEPS. Yet for all of that, like GALILEO'S world, the great project continued to move on, to progress, till at last it stands before us an accomplished task. But at this stage a difficulty begins to make itself felt, which, indeed, has long been foreseen, but requires now to be dealt with. This is the task of preventing the canal from silting up. On both sides of the canal we have typhoons—hills of loose sand—which, like the *melanchols* of the Peruvian deserts, are set in motion by moderately strong winds, and constantly change their position. Enormous quantities of this sand would in certain seasons of the year drift into the canal and cause, if not a complete choking up, at all events a serious outlay for dredging. What is to be done to prevent this mischief—to keep, in fact, the desert under control? You cannot pave so extensive a tract of country, but you can do the next best thing, you can cover it with vegetation. It is a question whether the gardener or the engineer shall be called in, whether cultivation or dredging is the cheapest method of dealing with this difficulty; and we are hardly in a position to work out the question of £ s. d. until we have more facts than are at present at our command. But we have no doubt that if cultivation is determined upon, we shall be able to establish our mastery over the sand. We have overcome much greater obstacles in Ascension—where, it will be remembered, that, acting under the advice of the late Dr. LINDLEY and of Dr. HOOKER, we took in hand an island which was a mere heap of ashes and cinders, without any water and no vegetation, save that of a few Ferns and Lichens at the very top of the highest hill, but which, by judiciously adding to the scanty flora Nature had provided, now possesses large trees, produces quantities of vegetables and abundant supplies of water for shipping. With such triumphant results achieved, gardeners need not shrink from the difficulties presented by the Isthmus of Suez.

NEGRETTI has drawn attention to the great danger from sand which threatens the canal from the western side, but the late Dr. KORSCHY, who was attached to the mission of inquiry despatched to Suez by the Austrian Government some years ago, points out with justice that the eastern side is still more to be feared as a sand supply. If Suez were a fresh-water canal, nothing would be more easy than to establish such irrigating works as would speedily convert the desert into a garden; but being salt water we must commence by availing ourselves, in the first instance, of the little moisture that is found around the wells. There everything must be done to extend the existing vegetation. This would have the immediate effect of causing more dew, mist and rain, and would enable us gradually to connect these different centres of plant life, until the whole desert, as far as required, was put under the gardener's control. Of course, it

would be desirable that this green covering should consist, as nearly as possible, of useful plants; but that would be merely an after-consideration. In the first instance, it would be desirable that every plant that will grow in a bare and heated soil of sand or gravel, such as a great part of the Isthmus is, should be sown. KORSCHY has published a long list of such plants as he thinks suitable for this purpose; and we think that his list might be considerably extended by adding some of those found in arid parts of California, Peru, Chili, and Australia. The most suitable are species such as those whose roots penetrate deeply into the soil, and whose branches and foliage are sufficiently thick to act as a kind of break towards the clouds of sand that are raised; less useful, though also acceptable, would be those which creep along the ground, and keep the sand down; and of still minor importance, all annuals which can be made to grow.

AN appeal is made, at p. 1161, for information respecting the influence of FUNGUS SPAWN on the ROOTS of CONIFERS. Unfortunately gardeners must still be haunted by the nightmare of "this horrid Fungus," and it is well if they are frightened into more diligent guarding against a very pressing evil. Nothing new is to be said upon the subject. Cases from time to time have been reported both as to the pernicious effects of fungous spawn, and of the benefit of lifting and cutting off the diseased roots. There is great unwillingness even in more scientific quarters to believe that Fungi can affect healthy plants or tissues. This, however, has been proved again and again in the case of Potato mould, Vine mildew, and other Fungi which attack leaves. The rapidly destructive powers of the threads of Mucor on the tissues of Apples was long since pointed out by Dr. HASSALL, and any cultivator may find confirmation of the fact for himself if he will observe closely what takes place in plants when they are shifted. A little piece of stick in the mould, should spawn grow upon it, will be a source of deadly mischief. Little threads are thrown off to the healthy roots, which soon decay, and if the mischief is not stopped, serious injury is almost sure to follow. We had ourselves an opportunity, in shifting some cuttings of Pelargoniums a few days since, of witnessing an incontrovertible instance of the way in which spawn travels to the healthy roots and destroys their vitality. The same thing unfortunately is sometimes experienced to an alarming extent in the case of the moulds belonging to the genus Polyactis. Mischief to the extent of many hundred pounds in a single nursery has ensued from these little moulds seizing on the branchlets of Conifers, Heaths, &c., and at once causing the decay of the subjacent tissues whereon they settled. It is seldom possible to ascertain precisely to what especial Fungus the spawn affecting roots belongs, but in the few cases where it has been fully developed it has always proved to belong to one of our commonest Polypori. No tree should ever be planted where one has stood before without the most careful grubbing up of the old roots. It is more frequently to the influence of fungous spawn that failure is due, than to the old theory of the soil being exhausted and not capable of supplying the necessary nutriment. M. J. B.

— WE are informed that at the meeting of the ROYAL HORTICULTURAL SOCIETY to be held on Tuesday, November 16, the following prizes will be offered, viz. —

- By W WILSON SAUNDERS, Esq., V.P.R.H.S.—Collection of winter bedding plants, to be exhibited in pots or boxes, 2l. 1l. By the Society.—4 Chrysanthemums, large-flowered, in pots, distinct (open), 1l, 15s., 10s.; 4 Chrysanthemums, Pompons, in pots, distinct (open), 1l, 15s., 10s.; 12 Chrysanthemums, cut blooms, distinct (nurserymen), 10s., 7s., 5s.; 5 Chrysanthemums, cut blooms, distinct (amateurs), 10s., 7s., 5s.; 12 plants bearing decorative fruits, in pots, varied (open), 1l, 5s., 1l, 15s.; 6 plants bearing decorative fruits, in pots, varied (open), 15s., 10s., 5s.

— Through the courtesy of M. NAUDIN we have received some particulars of the METEOROLOGICAL OBSERVATORY, recently established by M. CHARLES ST. CLAIRE DEVILLE, in the park "Mont Souris," in the immediate neighbourhood of Paris. This establishment has been founded for the purpose of observing and recording meteorological phenomena *per se*, and also with special reference to agriculture and horticulture. The park is of large extent, and will soon be one of the prettiest near Paris. The observatory is provided with all the numerous instruments now required for ascertaining the temperature, pressure, humidity, rainfall, electric and magnetic conditions of the atmosphere, &c., as well as for observations on the direction and force of the winds, the nature and intensity of light, the forms of clouds, and other matters, not excepting shooting stars and earthquakes. It will

... have been so much altered...
 ... own risers could hardly recognise...
 ... growing kinds I had, almost as a rule...
 ... adapted to dry soils, there is less tendency...
 ... and the produce is less coarse in shape...
 ... of high quality. A contrary remark applies to...
 ... more robust constitution as these...
 ... and, this is especially the...
 ... with such short-knued kinds as *St. Albans*,
 ... *Kidney*, *Countess*, and *Onward*—kinds...
 ... large from cropping on dry...
 ... and do well, with plenty of...
 ... Mr. Penn will be pleased to hear the latter...
 ... Somerset as "producing as good a crop...
 ... and will prove a favourite with...
 ... to the *Gardeners' Chronicle*...

I purpose to inflict upon them the...
 ... of all the 110 varieties. Let me...
 ... their fears. I shall not do so, for it would...
 ... and looking at the peculiar conditions...
 ... under which many of the trials take place, a writer is...
 ... often justified in publishing a disparaging opinion.
 ... Somerset friend mentions a grievance against many...
 ... that I fully endorse; it is this—seed Potatoes...
 ... often sent out that have been, in consequence...
 ... and the...
 ... to expose to get any...
 ... the...
 ... and personally I have to complain...
 ... of my failures in the spring resulted from...
 ... and to be saved than from any of my own...
 ... red stocks. Housing seed for the winter is of the...
 ... importance, and no man or firm can do his or...
 ... his customer's justice who does not make this a...
 ... primary consideration. Buyers, however, have the...
 ... body in their own hands, and it is one that will give...
 ... themselves and tradesmen equal satisfaction—Buy in...
 ... as early, and do not leave it until planting...
 ... time. This is before me are specially valuable in one...
 ... respect, there are in each of the columns, the first for...
 ... "quality," the third for "shape,"...
 ... the second, the feature being the maximum, and...
 ... somewhat singular that out of the entire number...
 ... more than two dozen varieties get the full number...
 ... marks, but it would be unfair to publish the names...
 ... those only as there are a large number that are but...
 ... or two short of the maximum, whilst also in both...
 ... cases, in relation to new kinds, the appended note...
 ... "just give it another trial," is of frequent occurrence...
 ... have a strong bias of that, as between the trade and the...
 ... public, there are but two ways of arriving at anything...
 ... so just a decision as to the merits of all the various...
 ... kinds of Potatoes in the market. The first is a public...
 ... trial in some public grounds, say at Chiswick, for...
 ... instance, at which a given quantity of tubers of every...
 ... available kind shall be simultaneously planted, and...
 ... occasionally overlooked by a reliable committee of...
 ... gentlemen thoroughly competent for the purpose, so that...
 ... the...
 ... taken at certain stages of growth...
 ... the whole should take place not later...
 ... than August, when the number of marks...
 ... awarded to each under the several heads of "earliness,"...
 ... "size," and "shape," might be entered. The matter of...
 ... trial quality could be easily adjudicated upon by...
 ... a member of the committee separately at their own...
 ... expense. A fair and complete report, with any...
 ... observations thereon that the committee may think...
 ... desirable to make, should be published as early as...
 ... possible not only for the satisfaction or otherwise of...
 ... persons supplying seed, but also for the information...
 ... of the public. The committee should have the...
 ... power to award First-class Certificates to those kinds...
 ... obtained the full number of marks only; Second-...
 ... Certificates to those that obtained three-fourths...
 ... upwards, and Third-class Certificates to those that...
 ... obtained one half the number.
 ... It is to be hoped that there was an unanimous agreement...
 ... the part of all concerned, to accept, first, the offer of...
 ... trial, and second, the verdict pronounced, it...
 ... would have the beneficial result of at once making...
 ... known to all the world what are the best kinds of...
 ... Potatoes we have, and of cutting down to something...
 ... reasonable dimensions our existing plethora of...
 ... varieties that are good, bad, and indifferent. My...
 ... proposal, failing the first, would be to estab-...
 ... a preconcerted and simultaneous trial by...
 ... able persons in various parts of the country...
 ... growing the same kinds, under as nearly as...
 ... possible the same conditions. Reports of these trials...
 ... should also be published, but it is manifest that any-...
 ... thing like the weight and importance that would...
 ... attach to the verdict of a central and responsible body...
 ... could not be given in the latter case. What should...
 ... constitute a Potato first-class qualification? I...
 ... do not know, but in other things "doctors will differ,"...
 ... and on minor points only; however, there...
 ... would be an expediency in getting half-a-dozen capable...
 ... persons to agree, in the first place, that where earliness is...
 ... more important than its neighbour, shall have a...
 ... Potato first-class qualification, and be fit for table as soon as...
 ... its neighbour, and of course, if less productive than its neighbour, shall have a...
 ... second-class qualification. If you get high quality combined with...
 ... early maturity and free production, here is at once...
 ... a first-class qualification. But the bulk of...
 ... the...
 ... second and main croppers, should be...
 ... under the heads already mentioned. And first...
 ... that a good variety should be a free cropper, an...
 ... abundant bearer—one that will fill up the bushel...
 ... fully. Secondly, the quality should be of the...
 ... best; but what constitutes high quality? white...
 ... texture, perfect freedom from core, and...
 ... flavour. We have many fine yellow Potatoes, of...
 ... flavour and usefulness, but the colour is...
 ... very objectionable. As to the texture, some...
 ... of the very best kinds vary as to dryness when cooked...
 ... from a moderately dry flesh will generally be more...
 ... associated than one excessively so. Mr. Penn,

in his note on York-shire Hero, says that "it is a little...
 ... too dry in its eating to please the palates of an extreme...
 ... few." I find the same fault with it, and think that...
 ... not "an extreme few" will be able to give it. It has...
 ... a roughness to the tongue that other good kinds do not...
 ... quite so dry do not possess, still the variety affords a...
 ... capital criterion by which to judge of the mealy...
 ... texture of other kinds. Thus, as to shape deep or...
 ... protruding eyes should bring disqualification, and the...
 ... surface should be even, and the outline graceful, the...
 ... handsomest round kinds are oval or pebble-shaped, and...
 ... many of these are almost perfect. Royal Albert, Scotch...
 ... Blue, and Emperor, are examples. One of the truest...
 ... rounds is the Red Regent, a coarse-growing kind; but...
 ... almost as a rule in strong growers a coarse and uneven...
 ... shape is to be found. Kidneys are outgrowing the old...
 ... kidney form of round at one end and pointed at the...
 ... other; and all the best kinds develop an improved form...
 ... For a time, handsome show variety, the Waterloo Kidney...
 ... beats all I have yet seen; but this is close run by...
 ... Dickson's Premier, Huntington Kidney, the King of Potatoes...
 ... Daintree's Kidney, and a few others. All of these will...
 ... turn out with me tubers as smooth as though scraped...
 ... with glass, and in form almost faultless. All of these...
 ... kinds afford good guides as to what should constitute...
 ... form. I do trust that my suggestion as to a central...
 ... trial will be taken up in good earnest, and that it may...
 ... be made a practical reality. I am willing to send for...
 ... judgment any of my own varieties. Who else will offer to...
 ... "do likewise?" Alex. Dean.

REVIEW OF THE GENUS NARCISSUS.—VI

Group III. (Continued).—PARVICORNATE: crown less than half as long as the divisions of the perianth.

The autumn-flowering species, with a star-like limb with narrow acute linear divisions, are three in number. I am not aware that any of them are in cultivation in England now.

18. *N. penduliflorus* (Schreb.) Moric fasc 1 t 2.—Bulb small, globose, producing 1-2 slender terete fistulose leaves about a foot long, at the same time as the flower. Scape slender, 1-4 flowered, spathe equalling or exceeding the pedicels. Flower with a Jonquil odour, the tube 7-8 lines long, the divisions slightly shorter, greenish, linear, very acute, spreading horizontally, not more than a line broad in the lower part. Crown very minute, the same colour as the leaves, with six redish brown stigma lobes. Anthers sessile, basical, at the top of the tube. Siliques, 1-2 long. *Hort. Kew*, p. 76; *Calceolaria*, p. 10; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1.

A native of Spain and Barbary. It resembles the next in general habit, but may easily be known by its green flowers, and subterete leaves.

19. *N. elapsus* (Spain. Veg. Phan. 12, p. 452).—Bulb roundish, an inch or less in thickness. Leaves one or rarely two appearing at the same time as the flowers, flattish, finely channelled, a line or less broad, equalling or exceeding the pedicels. Scape slender, 1-4 flowered, spathe equalling or exceeding the pedicels. Flower with a Jonquil odour, the tube 7-8 lines long, the divisions slightly shorter, greenish, linear, very acute, spreading horizontally, not more than a line broad in the lower part. Crown very minute, the same colour as the leaves, with six redish brown stigma lobes. Anthers sessile, basical, at the top of the tube. Siliques, 1-2 long. *Hort. Kew*, p. 76; *Calceolaria*, p. 10; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1.

A native of Italy, Sicily, and Algiers. Differs from the next by its more robust habit, several flowers, and leaves contemporaneous with them.

20. *N. repens* (Lam.) Sp. Plant. p. 411.—Bulb ovoid, 6-8 lines thick. Leaves solitary or two together, filiform, subterete, usually not appearing till after the scape has risen. Scape usually one, rarely two-flowered, very slender, under a foot high. Pedicel 6-9 lines long, shorter than the spathe. Tube, segments, crown and stamens, like those of the preceding. *Hort. Kew*, p. 76; *Calceolaria*, p. 10; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1.

Extends from Spain through the south of Europe to the Barbary States, Greece, and Palestine. Flowers in September and October.

21. *N. Broussonetii* (Lagasca, Nov. Gen. p. 13).—Bulb ovoid, as large as a hen's egg. Leaves about four to a scape, 4-6 lines broad, about as long as the scape. Scape about a foot high, 4-8 flowered. Pedicels 6-10 lines long, shorter than the spathe. Tube 8-9 lines long, exclusive of the ovary, under a line thick, greenish at the base, white upwards. Divisions of the limb subcampanulate erecto-patent, pure white, oblong-lanceolate, about half an inch long by a quarter of an inch broad, narrowed to a point at the base. Anthers sessile, basical, at the top of the tube. Siliques, 1-2 long. *Hort. Kew*, p. 76; *Calceolaria*, p. 10; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1; *Herb. Bot. Reg.*, p. 22, fig. 1.

A very rare and little known plant, gathered at Mogadore by Broussonet. I have seen a single dried specimen from the herbarium of Gay at Kew. It is exceedingly well-marked from all the other Parvicornate by its nearly obsolete crown, subcampanulate flower, and developed filaments; in fact, it is a plant so distinct in habit and characters, that M. Gay proposed that it should have a genus to itself. This concludes my review of the known species. T. G. Baker.

Home Correspondence.

Vine Roots.—That roots are often made without any corresponding action taking place in the branches, is a common occurrence, and can be demonstrated by any gardener. Many years ago, I was set to take up a number of Gooseberry bushes in the autumn, just as they had lost all their leaves; these were put away for a few

weeks before being permanently planted out, and in the meantime there had grown a number of young roots, in fact, when removed to be planted into their permanent quarters many of them were made up of young roots, from 1 to 1 1/2 inch thick. Of course, there was no corresponding action taking place with the leaves at the time. Now, will you consider a particular season of the year, and under certain conditions, one part of a plant will have a very evident evidence of vitality and active growth, while another portion of the same plant may be in a perfectly dormant state. Where is the mystery here? Reverse the seasons, and then we shall see that portion of the plant which is acted upon by the atmosphere first manifest vitality, and development in the branches will become apparent before such is the case in regard to the roots. You may call this stored up force or energy, or anything else by which it may be better known, but still the simple facts remain the same. We have seen some trees, after being cut down and lying on the ground, throw out leaves and shoots of some inches in length. More than 20 years ago I took charge of a greenhouse that had Vines in it. The first winter proved mild, with little rain. The Vines broke tolerably well, and at first gave out average-sized leaves; but about the time when the bunches of Grapes should have begun to hang down, and open their flowers, both foliage and bunches seemed to have withered. Six weeks passed over before the leaves began to recover, when young wood began to make new leaves, but still many of the young clusters retained a twist in the stem of the bunch, and several of them even in the bunch itself. I could not satisfy myself as to the cause, and fancied the house might have been opened too early some cold early morning. As the season advanced we gave them every attention, as also in the season following, but with no better results. They had made plenty of wood, although rather late, and perhaps some of it was scarcely well ripened, but as there was very little young wood left at pruning time, this unripeness could not have been the cause of the failure. Next winter we examined the roots, and here we found the evil. The border had not been made many years; but the Vines were there before the border had been renewed, and their roots had been cut in beyond any leaders, and replanted too deeply in an over-adhesive, not properly drained border. Was not the first growth of these Vines, the development of their first leaves, and the showing of the bunches, all due to atmospheric influences, without assistance from the roots? Did not the check which they received occur before the root-action began to be of any service to them? When the summer's sun had to some extent warmed the border, then their second growth took place. When we examined the border we found that several of the Vines had begun to throw out young roots just under where they entered the soil; and I inferred that, had they been allowed to grow on without being disturbed, they might have made a large and valuable crop. I had made mistakes, growth takes place in parts exposed to atmospheric action before root-action commences. Most practical men are aware that Nature does not keep such things in nutshells for the few to speculate on. G. Dawson.

—Last February, in order to ease the Vines of their labour, I cut off the remainder of our Lady Downe's Grapes, with the entire spur attached to the bunch, and inserted the end of the wood in about bottles of water containing a little pounded charcoal. The last of the Grapes were cut in May when the spurs had commenced growing, and the flavour of the Grapes of course was nearly gone, owing to the growth on the spur. Out of curiosity I put half a dozen as they were in the bottles of water, into one of our vases, and with the extra heat thus given the young shoots lengthened themselves to 7 inches and bunches were also freely developed on each shoot. No roots up to this time were visible, but some of them had calused over, and no doubt roots would have shown themselves in time, had not a too hot bulk of sun one day ended my experiment. Reasonably, if a branch of a Vine will produce growth in this way without the action of roots, a long broomstick-like Vine full of sap will surely do the same thing, after a little heat and dewing is applied, without the roots being in action. Those familiar with pot Vine culture—and I mean those who understand the advantage of having more roots in the pot than soil, after the young cane is matured—know well that root and bud do not move simultaneously till the bud is developed into a shoot and leaf. And if this be a fact, which I have no doubt about, where root and branch are in the same temperature, I am persuaded that root action does not take place as far as with Vines planted in an outside border. I believe Vines in all many cases, when planted in cold heavy soils, be advanced to the stoning period before real root-action takes place, and hence the great advantage in having Vine borders as much under command as a Vine in a pot, i.e., heated or protected in such a way that cold, rain, snow, or frost may not lower the temperature of the soil too much. Mr. Thomson, I believe, gives slight artificial bottom-heat, in order to raise the soil to a proper temperature preparatory to root-action, and he increases it greatly as soon as root and branch work simultaneously together, but not before—as after this a greater amount of bottom-heat may be maintained with advantage; and this is exactly in accordance with what we find the Vine enjoying in its natural state, which he knows well, and which he attributes to an ear as he is able. At the sub-Congress at Mr. Williams', to which Mr. Anderson refers, when this question was mooted, I was not so fully prepared to adhere to the opinion I then expressed as I am now, namely, that root-action does not take place in cold borders till some weeks after shoots are formed; this I believed in then—that Vine buds swell and form shoots before root-action takes place, when root and branch are in equal

temperatures, as in the case of pot Vines: this I believe in now—and I have a firm conviction, that when the roots are subjected to a greater heat than the branch, that even then growth is the forerunner of root manufacture. H. Knight, Floors Castle Gardens ["Taties" begin to sprout before they begin to form roots. Eds.]

Vine Budding.—Some seven or eight years since, you were so good as to publish a short paper of mine on Vine budding, as being much the neatest and most certain way of working the Vine. It is only necessary to have the bud perfectly ripe, and to cut it off with a small portion of wood, for the operation to be as certain as any other kind of budding. In the paper alluded to above, I endeavoured to point out the great benefit likely to be obtained by working some of our weaker growing and delicately rooted Vines, on free-growing, vigorous stocks, such as the Trebbiano, Gros Guillaume, and White Nice; and I am yet of opinion that worked Vines will ultimately become an important branch of trade with our nurserymen. It would be most interesting to try what effect such stocks would have on the late-keeping properties of Muscats and other Grapes. Any Vine that retains its foliage very late in the season would appear a most desirable stock to bud late kinds on. J. Sheppard, Woolverstone Park.

—At p. 1137 D. Bain asks: "Is Vine budding a new discovery?" This was asked in reference to what Mr. Stevens has done rather cleverly, by budding a whole house of Vines at Trentham. Mr. Bain states that his superior had budded Vines eight years ago. I have a prior claim to that. Above 20 years ago I had a young Vine sent me, said to be a very early black kind. As I had no vacant situation for it, the thought struck me that I might try a bud on one of the old Vines. I took off a bud in the usual way, leaving the wood on, and inserted it in the thick stem of an old Vine. It was a very weak bud. It began to push rather weakly at first, but the longer it grew the stronger it grew, and eventually it ripened a good cane. It was cut down to about 4½ feet, and ripened eight bunches the following year. In Mr. Stevens' case he had fine young Vines to operate upon, while I had the stem of an old Vine. Vine budding is useful in many cases where grafting cannot be applied. On the naked stem of an old Vine, where you want a shoot, insert a bud, and the end is soon attained. W. Hutchison, Llynndu House, Abergeenny.

Potting Lilies.—Your correspondent "M." has afforded no new facts in confirmation of his former statements regarding the proper time to pot Lihums. He has rather chosen to rest his defence upon some minor phrases incorporated with my last few observations, which are, however, extraneous to the point at issue. What I meant by "authoritative tone of denial" I have already explained, and it is simply this: that whilst "J. D." offered advice which he himself had acted successfully upon, and seen others do likewise, "M." differed in toto therewith. "M." questions the propriety of the advice offered by "J. D." it is not a question of differing with him as to his practice. I have referred to "the last week in January—previously to the advent of their natural swelling and root-making," as being a good time in which to perform the operation: not as "M." puts it, "somewhere in January." Surely "M." would not have me fix a given day when to do so. I take "J. D.'s" statement, "till spring," in its broadest sense, to imply "early time," as some authorities have it, and as it is accepted literally by gardeners generally, especially when speaking of greenhouse plants, or such as are cultivated under glass, as potted Lihums are. Now then, as to "M.'s" statements regarding the real subject at issue. "M." says, the moment the stems are dead we may infer the advent of the resting period is long past, through the fact that certain roots at the base of each stem exist alone to support the stems. Such a theory I can by no means support, i. e., that living roots exist but to waste their energies upon dying stems, when the scaly bulbs below are actively engaged in collecting support from the stems continuously whilst an iota of life remains. I must needs go further: even after observable superficial activity is past, the long rambling succulent roots which have taken friendly hold of the soil comprising the ball, are yet, whilst slowly dying away, affording an additional aid to the same, until each bulb, replete with vitality—the collective working of root and stem during the growing season—is again prepared to shoot forth. Furthermore, I would attach some little weight to that amount of sympathetic action which necessarily exists between the roots and the soil in which they are imbedded, as being more suitable to them than when the roots are torn rudely therefrom, and placed loosely in other soil at a time when no immediate action is possible. So much for actual practice, but past observation has long suggested to my mind that we should not rest here—that, taking Nature as our guide, we are acting wrongly in "drying off" the balls containing Lihums, and more especially so in regard to the L. auratum. Let any one who may have L. lanceifolium planted in the open ground, take up the bulbs in the early spring, and an examination of them will, I think, convince him of this fact. "M." rather taxes his imagination when he says Mr. Smith says "absolutely nothing" about potting his Lihum. I need do no more than make the following quotation from Mr. Smith's paper in regard to this. He says "In 1868 the plant was transferred to a larger pot, and placed in a temperate house in the month of February." "In 1869 it was turned out of the pot, and a small portion of the old soil removed, it was then potted and treated as before, the plant producing 193 blooms." Understand, this was all done in 1869!—the very month when potting was performed being given above. "Blooming past (he says, confirmatory of the above), they are cut down, and stored away until the season arrives to start them into growth." The primary

remarks of "M." regarding "the Calendar," I cannot pass over unheeded. Perhaps there is not in connection with periodical literature a more monotonous task or a more thankless office than that of writing a "weekly calendar" for a leading gardening paper. I have likened it to an infant, which week by week you may nurse for long years and yet it never grows. You may never put it into "short clothes." The long clothes of routine must be kept to, and practices, however obsolete with some, in some way referred to. You may prime it up with a few modern scraps, and that is all—that is, if you would fall in with the views of all, and that "week after week," as he considerably has it. I thank "M." for his complimentary remarks. Wm. Earley.

Ornamental-foliaged Pelargonium.—My friend and neighbour, Mr. D. T. Fish, in concluding some very interesting remarks on the coloration of the leaves of the Ivy-leaved Pelargonium L'Elegante (see p. 1138) asks the following question—"How is it that so many of our tricolor Pelargoniums are so much more perfectly coloured in the autumn than at any other season?" Now, I am not about to answer this question, for the best possible reason, viz., that I do not know how it is. But I can fully corroborate his statement as to such being the case; and what is more, I may also state that, under favourable conditions, they will retain this degree of brilliancy with little or no diminution during the entire winter months. This circumstance has induced me for some time past to regard these plants as being of the greatest importance for the purpose of winter decoration. And so convinced am I of their adaptability to this purpose that, in the second edition of my "Ornamental-foliaged Pelargoniums," I have earnestly recommended the use of a separate erection for their cultivation, more particularly during the winter and spring months. The great beauty of these interesting plants renders them, I think, worthy of the consideration which may be regarded as to some extent necessary, as the ordinary greenhouse is found to be too cold, and in other respects unsuited to their successful cultivation during winter; while the plant stove, on the other hand, is too close and warm. This being found to be the case, I am sanguine enough to think it quite possible that before long a "tricolor house" will be quite as likely to be found forming part of many extensive horticultural establishments as an orchard-house is at the present time; and certainly the former will be found to be fully as enjoyable, and possibly little less interesting than the latter. Nearly all that is really necessary to keep the various classes of ornamental-foliaged Pelargoniums in healthy and vigorous condition, and to continue to produce abundance of brilliantly coloured foliage throughout the winter and spring months, is moderate warmth, abundance of air, without subjecting the plants to sharp draughts, a position moderately close to the glass, or where little or no obstruction exists to the direct rays of light, and carefully avoiding overcrowding the plants. All these conditions can be best secured in a not over lofty span-roofed erection. P. Griene, Culford.

Yellow Bedding Plants.—I have not yet observed in the discussion that has taken place concerning yellow bedding-plants, that anyone has recommended for that purpose the double Tagetes patula nana, or dwarf orange French Marigold. This is certainly one of the best of all the yellow annuals for bedding or ribbons. It grows to an even height of about 7 inches, commences blooming very early, and continues to do so until cut down by frost. It will also succeed much better on dry soils than will either the Pansy or Calceolaria. The dwarf bedding Tropaeolums are also fast developing some good things; but the compactum section has beaten the Tom Thumbs out of the field, not only as regards habit, but also the quality and quantity of flower. Golden King of Tom Thumbs might have made a showy bedder, but for the very undesirable habit it has (common alike to all the Tom Thumbs) of crowding up its bloom with foliage. Those who have grown it, and been disappointed with the result, should not allow themselves to be prejudiced against the plants of the compactum section, as they are quite free from that defect. Luteum Improved is a capital thing; and there are some fine orange colours also to be had. Indeed, one might make a flower garden exclusively from dwarf Tropaeolums, so great is the variety of colours that occur amongst them. I heartily acknowledge the good qualities of the yellow Pansy and Viola lutea grandiflora, but in arranging masses different heights are necessary, and, to meet this want, a variety of plants must be resorted to. Alex. Dean.

Coloration of Leaves.—Mr. D. T. Fish, in his essay upon this subject (p. 1133), has laboured hard to show that the pink colour occasionally seen in the foliage of the Ivy-leaved Pelargonium, L'Elegante, is necessarily the result of some unnatural contortion of the leaf-stalks. How far his argument holds good the following little fact may show. Not long since I was at the establishment of Messrs Elcombe & Son, of Romsey, and in one of the houses there saw a lot of plants of this Pelargonium standing upon a shelf, where they had been for some time, with the foliage hanging downward all round the pots, but not a coloured leaf was there among them. On the stage, just opposite to these, however, was one plant that was beautifully coloured deep pink. On seeing this, I at once said to Mr. Elcombe, "I suppose you have been twisting the stalks or branches of this," but he replied, "Oh dear, no! nothing of the kind—the simple reason of it is, the plant has been allowed to go dry;" and this I found, on closer observation, to be the case. As to the bright coloration that Mr. Fish writes of as being so marked in some of the tricolor Pelargoniums in the autumn, it may seem cruel to cast a matter-of-fact stone at that gentleman's highly imaginative and poetical tablet of suppositions, but is it not really the case that the cool and humid atmo-

sphere of autumn, combined with the fact that the soil is warm and root action excessive, constitute the real cause of this high development of beauty, its being the "hectic flush of coming death," or, in other words, nonsense; high coloration in a tricolor Pelargonium being the accompaniment of rude health, not of delicate beauty. Alex. Dean.

Seedling Ferns.—The following fact may be of interest to those of your readers who are anxious to raise Ferns from spores. A few weeks since I received spores of Nothochlana candida, which I sowed freely. I now see that each seedling is distinguished with silver, causing the whole mass to have a bright silvery appearance. I have raised many sorts of Silver Ferns, but never observed this occurrence. J. H. Ley.

Pruning the Wellingtonia.—I have a number of plants of Wellingtonia gigantea, would my correspondents kindly inform me if it is necessary for them to cut off the lower branches, and at what time of the year to do it? T. T. [To the above, which we submitted to Mr. Frost, of Drogheda, a gentleman replies:—I would never think of the lower branches of the Wellingtonia—what is to be done? If it is absolutely necessary, I would cut off at once. We never prune here, with the exception of taking out forked leaders where they are doing us any harm, we keep the trees to one stem.]

An Oak Tree Decaying.—I should be obliged by your advice regarding an Oak tree some years has been very sickly—it is, I think, a tree of middle age. The branches at the top are withered and sickly look. I am told that if cut off at this season would restore it. May I ask for your opinion? and if so, how, and in what way should guano to water, how often, and at what time should manure it?—whether for the purpose of the soil should be dug round the tree, which stands in a lawn? An Old Subscriber. [We sent your query to Mr. Ingram, of Belvoir, who obliges us with the following reply. Eds.:—The premature decay of the tree may result from poverty of soil, a wet subsoil with pyrites, or gravelly bed with ferruginous glomerates, or many other circumstances equally obnoxious to timber trees; but as the soil has not been mentioned, a remedy can scarcely be given. It is advisable to ascertain the character of the subsoil, this may be done by digging a hole in depth, near, but not close enough to injure the roots. If the subsoil exhibits a tendency to dryness, due to a sloping position, or drench with manure-water made with cow-dung and a little superphosphate this latter will destroy Fungus, which may have begun to attack the roots of the tree. If the soil be manure poor, or unsuitable as above described, preparing a compost, the primary ingredients should be a good strong loam, or new red marl, mixed with leaf-soil, road-scraps, granite road, so much the better, and a little gypsum. Pare the turf carefully beneath the tree to a distance equal to the distance covered by the roots, then spread the compost 4 inches in thickness in where practicable; carefully avoid the roots; then water abundantly, and relay the soil, not let the raised soil come in contact with the tree—place bricks or stones round the tree, highly stimulating manure, such as guano, is a hazardous application. A trench dug round the tree would probably destroy many valuable roots.]

Potato Grafting.—Some years since I was engaged in grafting on a small scale, but soon gave it up, being likely to lead to any improvement. Some time held the opinion, that if any improvement could be effected it must be by grafting the shoots. This idea will perhaps be thought a little wild one, yet I do not start this notion without experience, which I consider applicable to both as to its practicability and its probability to produce. Many years since I grafted seedling Tulips, and it is a well-known fact that the seedling Tulip to continue for years, the seedling, or what florists call a breeder, should be broken into colours or flume and feathered, or broken into so many experiments have been made during the last hundred years, diameters Ten or twelve years ago, and for two or three running, several of the above-named Tulips were experimented on by grafting, for the purpose of making them break into colour. The operation was a complete success. In every case the graft took and grew, that bulb the next year produced a feathered or flamed flower. From this it is evident that the graft produced a positive and desirable effect on the stock or root, and I also presume that a Tulip can be grafted, so may the Potato. The method of grafting was to take a feathered or flamed Tulip with the Tulip was to take a feathered or flamed Tulip just at the time it was commencing to grow, cutting it off with the leaf on the stem, and fixing it off the flower of the seedling, fixing it on as usual, as possible. I may also state that some of the best grafted flowers lived and bloomed, some three or four weeks, some a fortnight, some three or four days, following is the plan I would recommend for grafting the Potato:—Provide as many and as small as may be thought proper, and cut out all the eyes, one in each Potato, plant them as usual, in the most convenient for performing the operation, either in pots or the open ground, and place a part of the Potato with the eye uppermost, and even with the surface of the soil; place a feathered or flamed Tulip shoot to each; cut off the other side shoots as they appear, encourage them to grow with a little fine earth, grow them as usual, to sun and weather as possible, so as to be ready

hardy; and keep each shoot tied up to the stake. When the shoots have grown 8 or 10 inches long, perform the operation by the transfer of the shoots. Having provided some slips of soft matting, a little thin, soft but close-textured paper—if oiled paper all the better—also a little softened tallow, with a very sharp knife cut the shoot at 3 or 4 inches up the stem by a sloping cut; fix it on without any cleft or tongue; wrap a small piece of paper round it, binding it tight with the matting, after which rub over with the tallow. Then carefully tie and bind up all the grafts to the stake, so that no part may droop or hang down. For a few days a hand-glass might help; at any rate shade from the sun. Earth them up to the graft and expose them to sun and weather, still keeping the grafts tied up to the stakes all the season, and cutting off the tips of any shoots that may make their appearance from below the grafts. If I were asked what the result of these experiments would be if successfully carried out, I would say that each variety will still continue to produce its kind. But may not each imbibe something of the quality of the other—some of its richness, some of its vigour and prolificacy. What I should value most would be any seed that may be produced on the grafted plants. Should grafting fail, perhaps inarching might succeed. I think "S. S." (p. 1137) erred in one or two points in his operations. The shoots should not have been joined nearer to the set than from 3 to 4 inches, that being the part to produce the Potato; one of the shoots ought to have been cut off as soon as the union had taken place, as also the root of the other; there should have been no pruning of the tops except such shoots as sprang from below the grafts, and of these only the tips cut off as soon as they appeared, just below the surface of the soil. *Wm. Burnett, Monk Gate, York.*

Planting the Deodar for Timber.—About 15 or 20 years ago there was a dispute in your columns whether Deodar timber, grown in this country, would be valuable. The opinions about it were very conflicting; and I do not recollect, and cannot find out, that either side got the better of the argument. As I wish to make some plantations, I should be much obliged for your opinion, as more must be known about it now than was known 15 years ago. Would you also tell me whether trees grown from cuttings are as vigorous and well-shaped as seedlings? This also was a disputed point in your paper; and as most nurserymen raise their stock of Conifers from cuttings, it is a very important matter. *O. M.* [We sent the above to Mr. Frost, of Dropmore, who kindly replies as follows:—The Deodar should now be planted extensively; it is a fast grower, and there cannot be any doubt about the quality of the timber. We have some fine Deodars growing here from cuttings, which I have raised, and which are equal to the seedling plants: no one can see any difference. *Abies Douglasii* here, also raised from a cutting, is admired by all who see it. *Picea grandis* or *amabilis*, raised from a cutting by myself, is now a much handsomer plant than the parent tree; if they start with good leading shoots, I like them, if not, they are useless. *Pinus insignis* grows into fine specimens from cuttings; quite equal to seedlings with us.]

Californian Conifers.—For the following information respecting the "big tree" and other Californian Conifers in the Mariposa Grove, I am indebted to Mr. Olmsted, the well-known American garden architect, who, having spent many years in California, is well acquainted with its vegetable productions, and vouches for the truth of the subjoined measurements, which have been supplied by the person to whom the care of the Grove in question has been entrusted:—Of *Wellingtonia gigantea* (the big tree) there are 600 in the Mariposa Grove, and the largest measures between 90 and 100 feet in circumference near the ground. These trees seed pretty abundantly, and the seeds themselves meet with a ready market in San Francisco; indeed, all Conifers seed pretty abundantly here, except *Picea nobilis*, which furnishes cones but sparingly. *Pinus Lambertiana* and *contorta* are abundant. Of *P. amabilis* the largest specimens measure from 20 to 25 feet in circumference, and over or near 200 feet in height. Seeds of these are not generally good, being liable to be injured by worms. We have also *P. grandis*, and of Douglas Fir we have some fine specimens; of the latter some measure 20 feet in circumference, and 150 feet in height. Of *Abies Williamsoni*, the largest trees are 2 or 3 feet in diameter, and nearly 100 feet in height. Specimens of *Libocedrus decurrens* are 6 feet in diameter, and 200 feet in height. The largest trees of *Pinus Jeffreyi* measure from 4 to 5 feet in diameter, and 150 feet in height. *P. ponderosa* is 8 or 10 feet in diameter, and 200 feet in height. *P. Lambertiana* is of similar size with *ponderosa*, and its cones measure from 15 to 22 inches in length. *P. Sabiniana* is rather a scrubby Pine, measuring from about 3 feet in diameter, and from 25 to 100 feet in height. Of *P. contorta*, the largest trees are from 3 feet in diameter, and 100 feet in height. The seeds of this tree are very small. About *P. Benthamiana* I am not certain; it is called here sometimes *Cembra* and sometimes *Cembroides*. It grows on the summit of the Nevada Mountains, and is a scrubby Pine, with five leaves, and short thick chocolate-coloured cones, the seeds in which are about the size of a small Pea, and are difficult to obtain. *P. monticola* grows high up on the mountains, has a rather smooth light-coloured bark, is 5-leaved, and measures from 2 to 3 feet in diameter, with cones an inch in diameter, and about 6 inches in length. Of many of the finest specimens of these trees I have seen photographs in Mr. Olmsted's office in New York, and their appearance bears out what has just been said respecting their size. Of the value of the Douglas Fir as a timber tree, too much can scarcely be said; indeed its merits are all but universally appreciated, and most of the other kinds are also favourites in this country, in which, however, they seed but sparingly. In California the reverse is the case, and as I expect samples of seed

from all the finest specimens there in the course of a few weeks, I shall be pleased to share my contributions with cultivators wishing to possess seeds of native growth. *Joseph Newton, 74, Oxford Terrace, Hyde Park.*

Salisburia adiantifolia.—There is a handsome specimen of the Maiden-hair Tree in Mr. Caldwell's nurseries at Knutsford, which, though not so large as either of the plants previously mentioned, is, nevertheless, of an unusual size for this kind of tree, being over 20 feet high, and proportionately large. With its beautiful pyramidal form, it well deserves the description given by Mr. Paul of the one at Panshanger. *Old Sub, Knutsford.*

Croton elegans.—In this very popular class of foliage plants, *Croton elegans* seems to be but little known. I have seldom met with it in my travels, and I cannot call to mind ever seeing but one specimen, independently of my own, placed on the exhibition table. I have a pyramid upwards of 6½ feet high, beautifully coloured; indeed I consider it one of the handsomest of the high-coloured varieties I have seen—I do not include Mr. Veitch's latest introductions, for it is impossible to form a correct opinion of these from small plants, since with age, if properly treated, they improve in colour. *Croton elegans* is smaller in the foliage than many of the other varieties, but equally free in its growth. Although, generally speaking, Crotons are free-growing plants, they require a little management to grow them well, and a good deal of skill to colour them properly. I have seen large specimens very indifferently coloured and some perfectly green; plenty of light is essential to the development of variegation, and they should never be shaded unless the sun is very powerful; even then, if they could enjoy a free circulation of air around them, they would be better without shade. Too frequent pottings and imperfect drainage will also prevent them colouring well. I have two immense plants, upwards of 7 feet high, viz. *C. variegatum* and *C. angustifolium*, that look like pillars of gold; the latter, with its beautiful drooping leaves, may justly be styled the golden fountain plant. These plants are fully exposed to the light and receive as much air as possible; they are the admiration of every one that has seen them, in consequence of their high colouring. I have forwarded a branch of *C. elegans* for your inspection; I have also sent some of its foliage, as well as that of the beautiful *Sanchezia nobilis*. *Edward Bennett, Osberton.* [The specimens sent were magnificent examples. Eds.]

Fairy Rings.—The way in which Mr. Lees (p. 1158) gives the mole the credit of being instrumental in preparing a suitable habitat for the Fungus which forms "fairy rings," is ingenious, but faulty. How will he account for the presence of fairy rings in Ireland, where they are most common, and where the mole does not exist? In the case of the rings which have a circular outline, I am inclined to think the appearance is caused by the spawn of the Fungus having originally started from a given point, whence it has uniformly radiated, till at length the fructification appears above the ground in a more or less regular manner. It would be interesting to note what species of Fungus produce these appearances; I once saw a most perfect ring, of about 3 yards in diameter, formed of the common Mushroom, on a lawn which was kept regularly cut with a machine. *W. H. F.*

Peruvian Name for Potato.—I see from your editorial note that your contemporary, the "Revue Horticole," says that "Papas" is good Peruvian for Potatoes. It is certainly the name given to Potatoes by all Spanish Americans, including Peruvians. There is no Peruvian language, properly so called. The Court language of ancient Peru (still spoken over a great part of the Andes of South America) was the Quichua, but that had no name for Potato. In the language of one of the tribes of the coast (the native country of the Potato) the esculent was called "Ascu," at least so says Tschudi, who gave much thought to the subject. Curiously enough, though there was no name for Potato in Quichua, I found one for sweet Potato, which is "Cumar," and, still more curious, this is the name by which this Convolvulacea is known throughout the South Sea Islands, as far even as Fiji. *Berthold Seemann.*

Judging Melons at Edinburgh.—We often hear it said that there is nothing new under the sun; but it would seem that your correspondent "J. O." has found out the last new thing in Melon judging. Whatever was new in the means adopted by the judges to find out the merits of the Melons in question, they (the judges) are not entitled to the praise if the method was a success; neither are they deserving of censure if it was a failure, they being strictly enjoined by the assistant secretary and managers of the exhibition not to cut the Melons. "J. O." does not say that the judges were unsuccessful in their efforts to carry out this new system, which is very satisfactory to me as one of the judges, and I doubt not, will be equally so to Mr. Speed, of Chatsworth, and Mr. Westcott, of Baby, who, like myself, were engaged in carrying out the new plan. And it is not quite clear to me but that very much may be said in its favour; it is sight and smell versus taste—two senses to one; and it is two to one the taste is more likely to be vitiated either by the morning dram or pipe, or from the extra glass of toddy indulged in over-night at great shows like the one in Edinburgh. It was rather a singular circumstance, and in favour of my argument, that both the 1st prizes for Melons were awarded to the same grower, and he from the sunny south "J. O." has mentioned what a reporter has said in the matter. It would be better both for exhibitors and judges if reporters would give the particulars of such exhibitions with less of the censorial spirit; it is but a very cursory view they take, and often their report is second-hand. It is, to say the least of it, ill-judged to condemn the decisions of the men who are appointed as judges, and

who try to the best of their ability to do justice. *George Thomson, Stansted Park, Sussex.*

Golden Champion and White Lady Downe's Grapes.—I availed myself of a recent visit to Edinburgh to inspect these two new Grapes at Dalkeith. The former can be seen growing under various circumstances, but always with the most robust growth and vigorous development. Mr. Thomson has it on its own roots, and also grafted on the following stocks: Black Hamburg, Muscat of Alexandria, White Tokay, Lady Downe's, Muscat Troveren, and Raisin de Calabre, and in each instance the growth is all that could be desired. So vigorous is it, that it actually causes the stocks to swell out, and thicken much more than any other Grape. It has another valuable characteristic: though the berries are covered with rich bloom, this does not rub off readily by any means, and when fully ripe, the bloom appears to be even more tenacious of its hold on the berry. This is suggestive of its being a good traveller. I saw the new White Lady Downe's both on its own roots and worked on the Black Hamburg; on its own roots it was the most vigorous grower, though there was no room to find fault with its development on the Black Hamburg; but the flavour appeared best in the Grapes taken from the Vine on its own roots,—there certainly did seem to be a smack of the Muscat flavour about them. The Fruit Committee will soon have an opportunity of testing the value of the Grape for themselves, as Mr. Thomson intends sending some bunches of it to London shortly. I think it very improbable that a similar charge to that brought against the Golden Champion, namely, delicacy of constitution will be laid against the White Lady Downe's. The canes I saw looked as stout and healthy as could be desired. *E. D.*

Vanda cœrulea and Rogiera gratissima.—Blooming specimens of these two plants are now to be seen at Dalkeith. There is a magnificent example of this grand Orchid: the plant is about 28 inches in height, the foliage good, though not so well furnished as in the case of Lord Lonsborough's largest plant. It has two spikes of flowers: one has 23 expanded flowers and four buds, the other 21 expanded flowers and four buds, making, inclusive of the buds, 53 flowers. It is a striking object just now in the Orchid-house at Dalkeith. The Rogiera is, under the conditions by which it is cultivated at Dalkeith, an invaluable autumn and winter-blooming plant. It has bold trusses of deep bluish-coloured flowers, not unlike those of the *Laurustinus* in appearance, and these are freely produced. Mr. Thomson states that it remains in bloom for a long time, and in his opinion would make a valuable window plant for large towns. *R. D.*

Wellingtonia gigantea.—The following are the dimensions of one now growing at Stoke Bishop, near Bristol. I planted it in June, 1859. It was then 18 inches high. On measuring it a few days since I found its height to be 30 feet 8 inches, and the circumference of the stem, at 3 feet from the ground, 4 feet 6 inches. The branches, where they meet on the trunk, measure about 44 feet round. *Wm. Tothill, jun., Torquay.*—I have one *Wellingtonia*, planted from a pot, about a foot high, in October, 1858. It has never been affected by any changes in temperature, not even in the severe winter of 1866-67, which destroyed two large specimens of the *Pinus insignis*, and damaged so many evergreen shrubs. It measures now 26 feet 2 inches in height, and makes yearly growth of about 2 feet 6 inches to 3 feet. I should say that the county is Kent, and the soil, of course, excellent. *G. F.*

Protecting Fruit Trees.—Mr. D. T. Fish has fully illustrated the great want of some efficient means of protection for our wall fruits. As most of our ordinary appliances have failed, it is time to look about us and decide what is to be done for next season. In addition to other aids, I have found old herring nets most valuable protectors; and as these can be had cheap, and are in great request for protecting fruit from the ravages of birds, no garden should be without a good supply for the double purpose. We have some strong wires, strained from the top of the wall just under the coping to some small Oak posts, standing about a foot out of the ground, 5 feet apart, and 2 feet from the wall. On these we strain a double net, and as the meshes cross each other, with the net supported at a sharp angle from the trees, it forms a most admirable screen against pelting hail, snow, and rain, which are generally more fatal to the tender blossoms than cold winds or actual frost. It was perfectly delightful, standing behind the nets placed in this way during last season, to see the way they repelled the heavy storms of snow and rain; but the springs of late have been so exceptional as to set all ordinary means of protection at defiance, so that it has at last become a question of glass versus nets, canvas, &c.; and I doubt not but in the long run glass will be found the cheapest, as it can be turned to so many useful purposes as soon as the crop is safe. Sir J. Paxton's patent lights appear to me to be by far the most suitable for this double purpose, as they are so thoroughly portable, cheap, and durable. They can be moved from place to place with the greatest facility—in fact, just as easily as the lights of a pit or frame, thereby effecting a great saving of time and risk in removal over such structures as require taking to pieces before moving them. The system of ventilation, too, is of the most perfect kind, as every leaf is kept in motion, and as fruit-screens or protectors, I feel I cannot too strongly recommend them. We have some of the 14-foot sashes in use here as a Peach-house, giving us a good-looking house 6½ feet by 11 feet 6 inches, through which I have just run a flow and return pipe, that we may be well prepared to cope with a spring like the past. The trees in this house have again made from 3 to 5 feet of short-jointed fruit-bearing wood, and are of the most perfect kind. *J. Sheppard, Woolverstone Park.*

Foreign Correspondence.

CENTRAL PARK, NEW YORK.—The accompanying representation from one of your former volumes (p. 456, 1858) will give your readers a good idea of the general appearance of this park, although the details of the plan have been somewhat altered in transferring them to the ground. It will be seen that it is rectangular in form, a description of outline which associates best with outside buildings, especially with those of New York, which are all placed along the sides of straight streets, themselves being again intersected by straight avenues—an arrangement which, together with the numbering of the streets, certainly has the advantage of enabling strangers to find any particular locality with greater facility than can be done in English towns of similar size.

The outlines of the park being straight, it may be imagined that the interior of it, near the boundary, has a formal appearance: but, owing to both natural and artificial undulations of the ground, together with skilful planting, such is not the case. Indeed, a person may often be within a few yards of the retaining wall without knowing he is near it, so well has it been concealed from view, and when the plantations shall have attained full size even surrounding buildings will be imperceptible.

One point worthy of remark in reference to American parks is that all work done in connection with them is done well, the garden architects having the full control not only of operations within the park, but also of those in connection with the new streets and avenues in its vicinity—the whole of which belongs to the Park Commissioners, who receive annually an improved rental from such property, which they buy up, and take care to keep in good condition. All unsightly objects are thus removed from the boundaries of American parks, which become interesting centres to wealthy neighbourhoods.

Nor is the garden architect bound down, as with us, to a certain contract. An approximate estimate is, as a matter of course, made in the first instance for the guidance of the Park Commissioners, but, if it is seen afterwards that more money is absolutely needed, it is obtained. Not so with us in London, except in the

while the plantations are young, but which will become apparent when they have become full grown. If first cost, however, is not a consideration, overcrowding can be easily relieved by means of judicious thinning. "Plant thickly," say nurserymen; "but thin in time, that being the proper way of securing good woodland scenery;" and I quite agree with them; but in practice I have often to act differently on the score of economy. The island on which New York, properly so called, is placed, contains about 30 square miles. The park to which I have been advertising occupies its centre, and the value of land in its vicinity has risen from comparatively nothing to some 30,000 dollars per block of 100 by 25 feet; and so satisfied are the Americans with the benefits of town improvements of this description, that no fewer than 22 parks and open spaces, varying from one to 843 acres, belong to New York alone. Need I state, therefore, that in few cities has the march of improvement been carried on to a greater extent during these last ten years than in that of New York. Joseph Newton.

Societies.

SCOTTISH ARBORICULTURAL SOCIETY.—2 Annual General Meeting.—The Sixteenth Annual General Meeting was held at Edinburgh, Robert Hutchison, Esq., of Carlisle, F.R.S.E., President, in the chair. After the minutes of the last meeting had been read, the President delivered the Inaugural Address, from which we extract the following passages:—"We are called upon to assist in endeavouring to ascertain exactly the influence which vegetation has, or rather the influence which woods exert, on the health of the country, both directly and indirectly, through their bearing on the rainfall. This is a most important and most interesting branch of arboricultural science, and one which is yet completely in its infancy. The attention of scientific men has only lately been aroused to the fact, that trees modify very materially both the climate and the rainfall of a country; and in order to ascertain the precise nature and extent of the influence they exercise, very minute and careful observations, and a series of registrations in different localities, under different circumstances, must be made. This is a work which falls very particularly within our immediate province as a society, and we must not shrink it, but must each one carefully, and conscientiously, do the portion of it which falls to his hand to do; and by all labouring together, an immense amount of light may be thrown on this important question, which may be useful to the more purely scientific minds and associations; and should we, in our humble in-

energy and shrewdness is not unequal to... Let us then, gentlemen, endeavour of the... such a way as a Society, by our scientific... in the van of arboriculture that are... ship in the Scottish Arboricultural Society will... not for a Government appointment to... let our ranks be the source to which not our own... but that of other countries, will look for the... advanced foresters. But, gentlemen, to attain... we must labour hard in the work of self-education... in mind that the best, and indeed the only... that which a man gives himself by training his... of close and accurate observation, and by accustoming... to classify and arrange the facts he has ascertained... wait long, and reasoning from these facts to general... and laws. And let us never forget, gentlemen, the... quality of our country, "caution." We must be... that our theories are based upon facts, and not... theories. The rock on which many scientific men... is theorising first and observing afterwards, and... and perverting facts to suit pre-conceived ideas... must not be discouraged if at first, in our... any department of Nature, it appears "a... quite without a plan." If we only persevere... to dawn through the darkness, and order to emerge... we had thought was chaos—the facts which... presented a mere jumble of discordant and... matter will group and arrange themselves into... shall be rewarded by understanding the method... reason of Nature's workmanship, and of finding... aid in modifying its effects to suit the wants and... of the human race. In cultivating arboricultural... spirit we shall also find our interest in every... knowledge and inquiry awakened and excited... remarked, all knowledge is one, and as arboriculture... climate and rainfall, these again influence the... of the soil, and the health of man and beast... spring, in endless ramifications, all the... industry and knowledge: so in first labouring... sincerely in our own calling, we shall find... freemen of the great world of science and art.

A very fine collection of cones of the... sent for exhibition, from Drogheda, by... created considerable interest.

The anniversary dinner of the Society (whose... number upwards of 500) was held in the... conclusion of the meeting—Robert Hutchison, Esq.,... acting as chairman, and Professor Balcanquhall, Esq.,... M'Corquodale, V.P., as croupiers.

LINSEAN.—Mr. G. Beatham, Esq., President... Mr. W. G. Smith exhibited a fine...

case of Government works. Let us see how the matter stands in reference to Finsbury Park, which the garden architect asserted would take some 9000*l.* to execute properly. For this work tenders were invited from contractors, the range of whose estimates varied from 4500*l.* to 12,500*l.*—the cheapest man getting the work to do; but, as might have been expected, he "broke down." Under such conditions how could the architect's plan be satisfactorily carried out? But, as I have said, they do things better in America.

Having the surroundings of a park under the direction of its architect is a great advantage, too, in the way of economy, for in preparing the plan for the park another is made for the neighbourhood. The situations of its streets and avenues are all set out, and the foundations of the residences excavated; if, therefore, additional soil is wanted in the park for boundary concealment, or for mounds, the quantity at command can be calculated to a nicety, and the sources from which it can be derived accurately determined.

From what has been stated about improved surroundings, it may be thought that American parks are made chiefly for the benefit of the rich, but that is not the case. They are intended to furnish healthful recreation for the poor as well as the wealthy, the young and the old, all of whom make good use of them; and although situated in the midst of a population approaching two millions, of diverse origin, the park regulations are as a rule well observed. Occasionally, a person who would not willingly be classed among the uneducated is found to take peculiar satisfaction in evading a rule, or, in the absence of the eye of authority, in violating some minor regulation. Such misdemeanors are happily exceptional. In short, the inhabitants as a whole, one and all, seem to feel that, while a large amount of money has been spent in its formation, a park has been produced which, for the extent of its area, the taste, elegance, and beauty of its adornment stands unrivalled; and, therefore, the interest in maintaining it unblemished is all but universal. Of 1,195,695 persons who visited this park in one year, but 135 arrests were made for violation of the regulations, the most frequent misdemeanour being fast driving.

The way in which the public roads have been carried across the park so as to conceal their traffic, is worthy of all praise, and indeed, against the carrying out of the plan in general I have little to say; the treatment of the water, drives, walks, and rides, is all that can be desired. The only thing with which I would be disposed to find fault is the planting, of which in my opinion there is a little too much; not at present,

investigations, and thereby in defining laws by which our country will be benefited, both in the increased health of its inhabitants, and in the improved abundance of its harvests, the reward of the pains and trouble expended will be a rich one. But, gentlemen, besides the good we may help, by God's blessing, in doing to our countrymen, we shall certainly be conferring a great boon on ourselves by cultivating a habit of intelligent observation. We cease to be like "dumb driven cattle," and become "heroes in the strife," when we lift our daily work out of the mere routine of petty drudgery, into the willing co-operation in the great battle of knowledge against ignorance; and every day, as we go on striving, the field of our view will open up and enlarge, and we shall find an intensified interest in our lives, and in everything that surrounds us. The dignity and importance of arboriculture as a science, is at last, I am happy to say, forcing itself upon public attention; and the work of the forester is making itself felt as an agency of immense power for good or for evil, according as it is performed. Unfortunately, in former years, from ignorance of climatic and hygienic laws, which are now acknowledged, forestry was regarded as mainly a necessary work of destruction. This is now authoritatively admitted and referred to by the Under-Secretary of State for India—Mr. Grant Duff—who, in introducing his financial statement in the House of Commons, in the last session of Parliament, said (referring to Indian forest conservancy)—"No one who had not looked into this subject had the faintest idea how terrible were the effects, over wide regions of the globe, of carelessness in keeping up a proper proportion of trees. Let anyone to whom the whole matter is new, turn to the remarkable work of the American minister at Florence, Mr. Marsh, upon 'Physical Geography as Modified by Human Action,' and he will shudder at the dangers which we have only just escaped. If our predecessors in India had known what we know, much of the enormous expense which we are now being put to with regard to irrigation would have been quite unnecessary. But the mistakes of former days are past praying for, and we can only now rejoice that the conservation of the forest has been recognised as a great State necessity, and that a regular forest department has been inaugurated, which will take to India the science of France and Germany." Now, gentlemen, with regard to this species of the Indian Secretary, I have a remark to make. The schools of forestry in these countries are famous, and deservedly so, but I am proud to say that, in my humble opinion, Scotland, without any school of forestry, is equally famous in this department. And one of the necessary qualifications, in fact the concluding touch to the education of those young foresters, who are, according to Mr. Grant Duff, "to carry to the East the science of France and Germany," is, that they must for a time, after being in France and Germany, have studied under some approved Scotch forester in Scotland—to rectify, I suppose, any erroneous ideas imbibed in France and Germany previously. Yes, gentlemen, in the ranks of this Society there have been found many scientific foresters, who have been chosen by the Government, and sent forth to our Indian Empire; and at the present moment, if I am not mistaken, two young men—members of the Scottish Arboricultural Society—are about to follow these pioneers, who have carried the name of our Society to the jungle and the Himalayan peak, and who are already showing that Scotch

Notices of Books.

The Scenery of England and Wales; its Character and Origin, &c. By D Mackintosh, F.G.S. Longmans.

Here is a book which we may recommend alike to the naturalist and to the attention of those who may be contemplating a similar "outing" next year.

Upheavals and depressions there may have been in former epochs, and still are to a limited extent in this country, but its diversified surface is principally caused by what geologists call "denudation."

Two new journals have recently put in a first appearance. The first, called the Academy (Murray), is devoted mainly to literature with a dash of science.

The Apiary.

GLASS HIVES.—Will you kindly inform me what is the best kind of glass beehive in which the bees can be seen at work, and from which the honey can most easily be taken?

cover the box with any cloths or wrappers, or any other protection than is sufficient to throw off rain.

I LOOKED at my hives to-day (October 31), to see in what condition the bees are, and am glad to give a good report of them: they were all living and merry; but, strange to say, the hybrid Egyptians were the best of all.

It may be remembered that this stock was originally a condemned lot of bees, driven from a cottager's common hive situated at a considerable distance from the apiary in which the pure Egyptian colony was kept.

Garden Memoranda.

MR. SALTER'S NURSERY, HAMMERSMITH.—A visit to Mr. Salter's in the autumn season is almost one of the necessities of life to those who look affectionately on Chrysanthemums; and we can assure all such persons that, as in former years, such a visit will gratify them now, and create a yearning for some of the novelties to be offered for their home decoration hereafter.

The novelties seem this year to run very much on the Japanese strain, and certainly some very decided acquisitions to these grotesque forms—forms admirable for conservatory decoration, true painters' flowers, but not at all modelled after the florist's standard—have been obtained.

Amongst the novelties of the Chinese breed, occur some very pleasing flowers. Foremost we must place Duke of Edinburgh, a large incurved sort with abundant material, and of a handsome rosy lilac colour, paler towards the crown.

Of older sorts the following were blooming well.—Incurved sort—Pink Perfection, large delicate pink, very fine; Beethoven, large bronze-red, yellow at the back.

also red; and Fingal, large, deep rosy violet, paler on the reverse of the florets. Aurea multiflora, pale clear yellow; Mrs. Rundle, pure white; and Rotundiflora, a pale rosy lilac, white-centred sport from Golden Beverley, are all smallish-flowered incurved varieties, but with the flower-heads so deep as to form a complete ball, and so closely similar in style as to form pretty companion kinds.

The whole collection, owing doubtless to the fine autumn weather, has even a brighter appearance than usual, and many of the varieties are certainly blooming finer than they are generally seen.

MR. A. FORSYTH, BRUNSWICK NURSERY, STOKES NEWINGTON, has, as usual, an excellent display. His show-house is now remarkably gay, the centre being filled with specimens grown in the usual manner to produce fine show blooms, and the outside stages effectively and tastefully arranged with well-grown and flowered specimens of the large-flowering and Pompon kinds.

AT the TEMPLE GARDENS Messrs Deane and Broom have their plants arranged, as usual, in their vinery in the gardens. They are this year better than usual. The best flowers of the large-flowering kinds in Mr. Dale's collection (which, by the way, is not quite so large as formerly) were Cherub, golden-amber, finely incurved;

JAMES CARTER AND CO. beg to call attention to their new and improved full particulars of which are given in their Descriptive Catalogue. Copies forwarded post free on application.

SPRING FLOWERING BULBS and PLANTS, for Shrubberies and Lawns, for House Decors on. JAMES CARTER AND CO'S COLLECTION OF PLANTS. 1. 132 Hardy Plants, price 2s. 2. 261 Spring flowering Bedding Plants, price 42s. 3. 50 Half-wooded Greenhouse Plants, price 35s. 4. 50 Hardy Plants, price 70s. 5. 50 Hardy Plants, price 70s. 6. 50 Hardy Plants, price 70s. 7. 50 Hardy Plants, price 70s. 8. 50 Hardy Plants, price 70s. 9. 50 Hardy Plants, price 70s. 10. 50 Hardy Plants, price 70s. 11. 50 Hardy Plants, price 70s. 12. 50 Hardy Plants, price 70s. 13. 50 Hardy Plants, price 70s. 14. 50 Hardy Plants, price 70s. 15. 50 Hardy Plants, price 70s. 16. 50 Hardy Plants, price 70s. 17. 50 Hardy Plants, price 70s. 18. 50 Hardy Plants, price 70s. 19. 50 Hardy Plants, price 70s. 20. 50 Hardy Plants, price 70s. 21. 50 Hardy Plants, price 70s. 22. 50 Hardy Plants, price 70s. 23. 50 Hardy Plants, price 70s. 24. 50 Hardy Plants, price 70s. 25. 50 Hardy Plants, price 70s. 26. 50 Hardy Plants, price 70s. 27. 50 Hardy Plants, price 70s. 28. 50 Hardy Plants, price 70s. 29. 50 Hardy Plants, price 70s. 30. 50 Hardy Plants, price 70s. 31. 50 Hardy Plants, price 70s. 32. 50 Hardy Plants, price 70s. 33. 50 Hardy Plants, price 70s. 34. 50 Hardy Plants, price 70s. 35. 50 Hardy Plants, price 70s. 36. 50 Hardy Plants, price 70s. 37. 50 Hardy Plants, price 70s. 38. 50 Hardy Plants, price 70s. 39. 50 Hardy Plants, price 70s. 40. 50 Hardy Plants, price 70s. 41. 50 Hardy Plants, price 70s. 42. 50 Hardy Plants, price 70s. 43. 50 Hardy Plants, price 70s. 44. 50 Hardy Plants, price 70s. 45. 50 Hardy Plants, price 70s. 46. 50 Hardy Plants, price 70s. 47. 50 Hardy Plants, price 70s. 48. 50 Hardy Plants, price 70s. 49. 50 Hardy Plants, price 70s. 50. 50 Hardy Plants, price 70s. 51. 50 Hardy Plants, price 70s. 52. 50 Hardy Plants, price 70s. 53. 50 Hardy Plants, price 70s. 54. 50 Hardy Plants, price 70s. 55. 50 Hardy Plants, price 70s. 56. 50 Hardy Plants, price 70s. 57. 50 Hardy Plants, price 70s. 58. 50 Hardy Plants, price 70s. 59. 50 Hardy Plants, price 70s. 60. 50 Hardy Plants, price 70s. 61. 50 Hardy Plants, price 70s. 62. 50 Hardy Plants, price 70s. 63. 50 Hardy Plants, price 70s. 64. 50 Hardy Plants, price 70s. 65. 50 Hardy Plants, price 70s. 66. 50 Hardy Plants, price 70s. 67. 50 Hardy Plants, price 70s. 68. 50 Hardy Plants, price 70s. 69. 50 Hardy Plants, price 70s. 70. 50 Hardy Plants, price 70s. 71. 50 Hardy Plants, price 70s. 72. 50 Hardy Plants, price 70s. 73. 50 Hardy Plants, price 70s. 74. 50 Hardy Plants, price 70s. 75. 50 Hardy Plants, price 70s. 76. 50 Hardy Plants, price 70s. 77. 50 Hardy Plants, price 70s. 78. 50 Hardy Plants, price 70s. 79. 50 Hardy Plants, price 70s. 80. 50 Hardy Plants, price 70s. 81. 50 Hardy Plants, price 70s. 82. 50 Hardy Plants, price 70s. 83. 50 Hardy Plants, price 70s. 84. 50 Hardy Plants, price 70s. 85. 50 Hardy Plants, price 70s. 86. 50 Hardy Plants, price 70s. 87. 50 Hardy Plants, price 70s. 88. 50 Hardy Plants, price 70s. 89. 50 Hardy Plants, price 70s. 90. 50 Hardy Plants, price 70s. 91. 50 Hardy Plants, price 70s. 92. 50 Hardy Plants, price 70s. 93. 50 Hardy Plants, price 70s. 94. 50 Hardy Plants, price 70s. 95. 50 Hardy Plants, price 70s. 96. 50 Hardy Plants, price 70s. 97. 50 Hardy Plants, price 70s. 98. 50 Hardy Plants, price 70s. 99. 50 Hardy Plants, price 70s. 100. 50 Hardy Plants, price 70s.

NEW TRICOLOR GERANIUMS, to be distributed in the Spring. Clivedon Bedding Plants. New Hardy Clematis. New and Rare Plants. New Coleus. ORNAMENTAL FOLIAGE PLANTS. Greenhouse, Conservatory, and Outdoor Plants, for Autumn growing. M. J. AREN'S PROLIFIC RASPBERRY. Collections of TREES and SHRUBS (see Catalogue), consisting of Standard Ornamentals, Trees of large size. Plants for Hedges. Evergreen Shrubs. Rhododendrons. Evergreen Trees and Shrubs. Herbaceous Plants. Fruited Trees. American Plants. Conifers. Hardy Climbers and Shrubs. Herbaceous Plants. Apples. Apricots. Cherries. Currants. Raspberries, and other miscellaneous Fruit Trees. NEW CONTINENTAL STRAWBERRIES. STRAWBERRIES, older varieties. VINES. ROSES - Provence, Hybrid China, Moss, Hybrid Bourbon, Damask, Climbing, Rosa Alba, China Roses. Austrian Hiberna and Double Yellow, Climbing Perpetual Musk, Noisette, Tea-scented, Hybrid Perpetual, Perpetual Moss, Ile de Bourbon. COLLECTIONS OF ROSES. Dwarf Hybrid Perpetual Roses, in pots, for Forcing. JAMES CARTER AND CO., 237 and 238, High Holborn, London, W.C.; and Crystal Palace Nurseries, Forest Hill, S.E.

LARGE CEDRUS DEODARA, 10, 15, and 20 ft. high; Green and Variegated HOLLIES, 9 to 12 feet high; ENGLISH YEW, 7 feet high; TARTARIAN ARBOR-VITAE, 9 to 12 feet high; PINUS CEMBRA, 10 to 15 feet high, and SPANISH CHESTNUTS, 15 to 20 feet high. Also a beautiful specimen of the HAIR TREE (SALISBURYA ADIANTIFOLIA), over 10 feet high, perfect pyramidal form. Price on application.

WILLIAM HEALE, Deceased. - All Persons having any CLAIM or DEMAND against the Estate of WILLIAM HEALE, late of Calne and Chippenham, Nurseryman, Seedman, and Florist, Deceased, are requested to send Particulars thereof in writing, either to Mrs. MARIA KIRBY, Calne, Executrix, or to Mr. JOHN SPENCER, Bowood, Executor, forthwith, that the same may be examined and, if found correct, Discharged. And all Persons INDEBTED to the said WILLIAM HEALE at the time of his Death are desired to PAY the same to one of the above-named parties on or before JANUARY 1, 1870.

Notice to the Public - The Business, in all its branches, will be carried on as heretofore by Mrs. MARIA KIRBY (late Heale), under the name of "HEALE AND CO." Nurserymen, Seedmen, and Florists, at Calne and Chippenham, Wiltshire, Calne, Nov. 10.

Extra large Trees for Ornamental Planting IN PARKS AND AVENUES. W. M. WOOD AND SON have to offer a magnificent STOCK of the following - Sycamores, 7 to 8 feet. Variegated, 4 to 6 feet. Horse Chestnuts, 8 to 10 feet. Scarlet, 4 to 10 feet. Catalpa sylvatica, 7 to 8 feet. Laburnums, 4 to 6 feet. Weeping Ash, ex fine, 7 to 9 feet. Ash-leaved Maple, 7 to 8 feet. Poplars, Black Italian and Lombards, 8 to 10 feet. Mountain Ash, 7 to 8 feet. Weeping, 6 to 7 ft. Peris at a lat folia, 7 to 8 feet. American Weeping Willows, 6 to 8 feet. Elm, English, Chester, Wych, 6 to 8 feet, and 8 to 10 feet. Price on application. Address - Woodlands Nursery, Marsfield, Uckfield, Sussex.

Planting Season - Walton Nursery, Liverpool. To PLANTERS of PUBLIC or PRIVATE PARKS, GARDENS, PLEASURE GROUNDS, and WOODS and FORESTS.

W. SKIRVING begs to announce that his STOCK of TREES and SHRUBS is this season very extensive and well grown, and that he is now prepared to execute orders to any amount for Trees and Shrubs of all sizes, at moderate prices. W. S. considers the present and following month two of the best for transplanting Evergreen Trees or Shrubs, and solicits Planters to inspect his Stock, which consists of many thousands of the Holly, of the most choice varieties of the Gold and Silver Variegated kinds, and of the large broad-leaved Holly (the finest of all Evergreen Trees), hundreds of which are of large size and fine specimens for giving immediate effect, with many thousands of smaller sizes for general planting. Also an immense Stock of all other cultivated Trees and Shrubs, either for Parks, Forest planting, and of Fruit Trees for Gardens or large Orchards. N.B. Fifty Acres of Walton Nursery being required for Villa Building, the Stock thereon must be cleared as soon as possible, therefore reduced prices will be accepted - October, 1869.

Victoria Nursery, Wisbeach. - Special Offer. W. WOODCOCK offers for Sale - 5000 LAURELS, 1 to 5 feet, 3s. to 15s. per 100; 1000 LAURUSTINUS, 1 1/2 to 2 feet, many in flower, 25s. per 100; 3000 OAK, stout, 3 to 5 feet, transplanted; CHESTNUT, Horse, 4 to 6 feet, in working order; MAHONIAS, 1 yr. WALNUTS, &c. &c.; 100 bushels of COMEY'S NORFOLK SELECTED and SKIRVING'S PURPLE-TOP SWEDE. WANTED, Standard CHERRIES and PLUMS, well up. A reference at once from all unknown Correspondents will save time.

BEAUTIFUL SPRING FLOWERS. Now ready, in strong Plants. HEPATICA, sorts, 4s. per doz. PRIMROSES, double & single, 4s. White, 6s. per doz. double Yellow, 8s. Purple, 6s. per doz. double Rose, 9s.; double Crimson, 12s. per doz. ROCKETS, double White and Purple, 6s. per doz. VIOLETS, 20 distinct sorts (see Catalogue), 4s. per doz. POLYANTHUS, the finest strain in the world, 2s. 6d. per doz., 15s. per 100. PANSIES, finest border varieties, 2s. 6d. per doz.; 15s. per 100. DAISIES, 6 distinct kinds, 4s. per doz. AURICULA, Perrin's Red, 3s. per doz. HOLLYHOCKS, 24 distinct kinds, to name, 3s. per doz. PAMPAS GRASS, 3s. per doz.; 20s. per 100. LEUCOCYUM VERNUM (Snowflake), 2s. 6d. per doz. AUBRETTIAS, sorts, 4s. per doz. ADONIS VERNALIS, 6s. per doz. RULBOCODIUM VERNUM, 3s. per doz. MYOSOTIS DISSIDIFLORA, 4s. per doz.; 25s. per 100. ALOPECURUS PRATENSIS AUREO VARIEGATUS (new Golden Grass) 1s. 6d. each; 12s. per doz. HOLC'S LANATUS ALBO VARIEGATUS (new Striped Grass), 1s. 6d. each; 12s. per doz. FOX GLOVE, finest Spotted, 3s. per doz.; 20s. per 100. WILDFLOWER, double Yellow and Dark, 4s. per doz. DIELIS SPECTABILIS, 6s. per doz. ARABIS ALBA VARIEGATA, 2s. 6d. per doz.; 20s. per 100. ENOTHERA MISSOURIENSIS, 1s. per doz. PHLOX NELS. N., PROCEMBENS and VERNA, 4s. per doz. PYRETHRUMS, Single and Double, to name, 6s. per doz. SPIRÆAS, sorts, 6s. per doz. TRITOMA UVARIA, 6s. per doz. CLOVES, Double Purple, Crimson and Striped, 6s. per doz. PICOTEES, fine, to colour, 6s. per doz. COWSLIP (Giant), 3s. per doz.

ROSES. - 24 choice distinct Varieties to name, Dwarf, 15s. Do. do. do. Standards, 25s. or half the number for half the amount. STRAWBERRIES, - DR. HOGG and NEW PERPETUAL PINE, 7s. 6d. per 100. Do., 40 other kinds (see List), 2s. 6d. to 5s. per 100. CHRYSANTHEMUMS - 20 New Chrysanthemums of 1869, 10s. P.O. Orders on Castle Heddingham. A CATALOGUE of Choice New Plants of 1869, Bulbs, Roses, Fruit Trees, &c., free on application. W.M. DILLISTONE, Nurseryman, &c., Sible Heddingham, Essex.

Autumn Planting. PETER LAWSON AND SON will be glad to send their CATALOGUE (just published) of FOREST and ORNAMENTAL TREES and SHRUBS, free upon application. The stock of LARCHES, SCOTCH FIRS, AUSTRIAN and COLOSSEAN PINES, &c., comprises some millions of healthy, well-grown plants, and special offers will be made for large quantities when personal inspection is not convenient. Edinburgh and London. RAYNBIRD, CALDECOTT, BAWTREE, DOWLING, and COMPANY (Limited), CORN, SEED, MANURE, and OILCARE MERCHANTS. Address, 26, Seed Market, Mark Lane, E.C., or Buxtonake. Samples and prices post free on application. Prize Medals, 1861, for Wheat; 1862, for "Excellent Seed Corn and Seeds."

Seed Potatoes. H. AND F. SHARPE'S WHOLESALE LIST of all the new and best varieties of Early and Late POTATOS is now ready, and may be had on application. The quality is very fine, and prices low. Seed growing Establishment, Wisbech.

RICHARD WALKER has the following to offer for cash - Splendid SEAKALE, for forcing, extra fine, 10s. per 100; fine GIANT ASPARAGUS, for forcing, at £1 per 1000, or 3s. per 100; ROBINSON'S CHAMPION DRUMHEAD CABBAGE plant at 2s. 6d. per 1000. RICHARD WALKER, Market Gardens, Biggleswade, Beds.

Autumn, 1869. - Special Offer. MAGNIFICENT SEAKALE ROOTS, extra strong, 10s. 6d. per 100; Magnificent ASPARAGUS ROOTS, extra strong, for forcing, 10s. 6d. per 100; good plants CABBAGE ROSES, 2s. 6d. per 100; 5 plants ROSE DE MPAUX, 2s. 6d. per dozen; 1 plant BUCKINGHAM PRANTS and GLOBE EMBELLIES, 2s. 6d. per dozen; STRAWBERRY Plants, 2s. 6d. per 100; very strong Standard and Dwarf PLUMS and PEARS, 12s. per dozen. PRICE LIST on application. WILLIAM HOOPER, New Wandsworth, S.W.

THE Cheapest and most Effectual of all PLANTS for Gams and Fox Covert, PAMPAS GRASS. Surplus stock, strong, healthy, seedling plants, twice transplanted, 25s. per 100, or £12 per 1000, delivered free to Heaings Station. BUNDY, Kengrae, Woodbridge, Suffolk.

BIRMINGHAM CATTLE and POULTRY SHOW, 1869. - THE TWENTY-FIRST GREAT ANNUAL EXHIBITION OF FAT CATTLE, SHEEP, PIGS, DOMESTIC POULTRY, ROOTS, CORN, and IMPLEMENTS, will be held in BINGLEY HALL, on SATURDAY, MONDAY, TUESDAY, WEDNESDAY, and THURSDAY, November 27, 28, and 29, and December 1 and 2. TWO THOUSAND ONE HUNDRED POUNDS in PRIZES. Admission - On Saturday, November 27 (to witness the whole of the Judging), 10s.; on Monday, November 28, 5s.; on Tuesday, November 29, 1s.; on Wednesday and Thursday, December 1 and 2, 1s. to 5s. m., after that hour, 6d. For Special Railway Arrangements, see the Advertisements and Bills of the several Companies.

The Agricultural Gazette. SATURDAY, NOVEMBER 13, 1869.

Mr. HOWARD's excellent Paper on CONTINENTAL FARMING is a sufficiently convincing proof that English agriculture, in spite of our higher northern latitude, is on the whole more productive than that of such districts as he has visited; and that taking even Belgian farming with which to compare it, and with which it has been occasionally contrasted to its discredit, the agriculture of our country is on the whole superior, whether as to its produce of grain, or of meat, or as to its maintenance of an intelligent and well-conditioned tenantry. The small farm system, and still more the small estate system, may possibly be defended on other grounds of State policy, but for its power to turn the soil to the most useful account, and for its power, or rather want of power, to "stock" the country with an intelligent middle-class population, it admits of no defence. No doubt, however, like every other existing system, those at present maintained by it upon the land will strongly object to be improved from off the face of the earth by any change. There is a multitude of families living in decent comfort, under circumstances to which they are accustomed, labouring their little plots, and living on them, who will care nothing as to the results of any English discussion of their condition. We may indeed learn little from them or their experience; but they, on the other hand, can receive no useful lesson from us. In good years they probably obtain as large a produce from the land as we do; and if they have a smaller surplus to dispose of than we send in to the towns, it is because of the much larger population living directly upon it in the country.

There are, however, certainly some large establishments in France, and Belgium, and Germany, which furnish ample instruction to the English farmer; and to one of these - one of the example farms of Europe - not mentioned by Mr. HOWARD, we may direct attention. The following are particulars supplied to us by the tenant representing the company, who, some 30 years ago, acquired the land by embankment and enclosure. The three decennial periods which have since elapsed have represented continual progress in improvement, economy, and fertility: -

Wilhelmnapolder, province of Zeeland, in Holland, contains about 2900 acres in regular cultivation, the rest is wood, &c. Of this 2825 are of a clayey description, some heavy clay, but never so stiff as in some parts of England, and always a sandy subsoil at various depths. About 150 acres are sandy and poor

EARLY SANDRINGHAM KIDNEY POTATO. THE EARLIEST, MOST PROLIFIC, AND BEST VARIETY FOR FORCING PURPOSES IN CULTIVATION. Price to the Trade and further particulars may be had on application to H. AND F. SHARPE, SEEDGROWING ESTABLISHMENT, WISBECH

JOHNSTONE'S ST. MARTIN'S RHUBARB. W. P. LAIRD & SINCLAIR, NURSERYMEN, DUNDEE, N.B.,

HAVE pleasure in offering the above NEW VARIETY of RHUBARB, which they have confidence in recommending as the earliest and best sort in cultivation. The raiser of it describes it "as one of a batch of Seedlings from 'Victoria'; the seedling plant was a fortnight earlier than any of the remainder of the lot, and grown beside 'Prince Albert' and 'Linnaeus,' always ten days earlier than them, and giving a larger quantity of superior stems to either of these varieties. It forces better than any variety I know, and has a splendid colour."

Strong Roots, 2s. 6d. each. Usual Discount to the Trade. The following TESTIMONIALS, selected from amongst many others, speak to its merits by disinterested parties - "Gentlemen - I have much pleasure in saying that Johnstone's St. Martin's Rhubarb is the best I have in my possession. It is a thick leafed variety, bears a heavy crop twice a year, and is cut early, and I have no doubt, give a third, as even ten days ago it was throwing up fresh leaves. One peculiarity it possesses of not throwing up flower-stems, only one having appeared on one of my plants in the course of two years. It makes an admirable preserve - I am, &c., "Thybank House, October 18, 1869." "Gentlemen - I have pleasure in saying that Johnstone's St. Martin's Rhubarb is the best I have in my possession. It is a thick leafed variety, bears a heavy crop twice a year, and is cut early, and I have no doubt, give a third, as even ten days ago it was throwing up fresh leaves. One peculiarity it possesses of not throwing up flower-stems, only one having appeared on one of my plants in the course of two years. It makes an admirable preserve - I am, &c., "Edinburgh, October 20, 1869." "Gentlemen - I have fully tested the merits of your Johnstone's St. Martin's Rhubarb, both by cultivation and cooking, and com-

but while the former was somewhat coarse, the latter was perhaps the best Bates bull which has been exhibited since DUKE OF NORTHUMBERLAND took the 1st prize at Oxford. If the respective pedigrees of the two bulls had been before the judges, they would probably have placed 5TH DUKE OF OXFORD in the position which he held some months later at the Royal meeting at Chester, viz, 1st in his class. It has always been a subject of regret with me that so noble an animal should not have left his mark more extensively on Bates' families.

The excellence of pure-bred animals is, however, perhaps nowhere so strikingly proved as at the shows of fat stock at Birmingham, Ilington, and elsewhere, where the animal is everything, and his pedigree as such counts for nothing. Passing over, as my limits compel me to do, the long line of winners which will doubtless recur to the recollection of your readers, I will only allude to Mr. Rowland Wood's Birmingham Gold Medal ox of 1865. The writer of the Shorthorn intelligence in *Bell's Messenger*, after enumerating many distinguished bulls to which this ox traces his descent, among which are Mr. Booth's DIAMOND, son of the Irish cow *Necklace* and Mr. Bate's 2D DUKE OF NORTHUMBERLAND, concludes by remarking that "it is not much of a marvel that so wonderful a beast should be able to show such goodly antecedents." Here, however, I must guard myself from being supposed to contend that cross-bred animals of surpassing merit do not make their appearance at our fat shows; all I desire to prove is the high standard to which the pure breeds habitually attain.

With regard to the necessity for selection in breeding animals, I entirely agree with you. We frequently see at the present day bulls brought forward for sale which, on account of colour, deficient size, want of head, or some other defect, are quite unsuited to be the sires of stock, and which consequently are worthless except at the price which they may be worth as inferior beef. And I cannot but hope that our breeders will pay more attention to the rearing of steers than they have done lately. Lord Spencer remarked long ago that an animal may make an excellent steer, which was quite unfit to be a bull. With meat at its present price a good lot of steers will pay much better than a number of inferior bulls.

In my next article I hope to say, with your permission, a few words on the inexpediency of making use of any but animals of pure blood as sires. *Willoughby Wood, Nov. 3.*

MR. SHIRREFF'S WHEAT AND OATS.

WHEN walking over a field of Wheat on the farm of Mungoswells, in the county of Haddington, in the spring of 1819, a green healthy plant attracted my attention—the crop generally then looking more dead than alive from the severity of the previous winter—and next day measures were taken to insure its vigorous growth. In the course of summer several stalks were nibbled off by hares, but, notwithstanding, 63 ears were gathered at harvest, yielding 2173 grains, which were carefully propagated—the fourth harvest producing about 40 quarters of grain. This Wheat proved to be a new variety, and was called Mungoswells'; but the name was not long of being changed, and it has been sold in Haddington market by the following names—Hunter's, Eastbarns, Fraser's, Murray's, Lady Hall, and other aliases. In the summer of 1821, a tall stack of Oats was observed growing on Mungoswells, and in the following spring its seeds were sown beside several known varieties, the plants at harvest being still conspicuous for height. This variety became the Hopetoun Oat. On the farm of Drem, in 1832, there was picked up an ear of Wheat containing 99 grains—other three having dropped out before it came into my possession. From this ear Hopetoun Wheat was propagated, and although the name has been pretty generally retained, it is sometimes known in the west of Scotland as White Hunter's. The next cereal introduced into field practice was Shirreff's Oat, which is seldom to be met with in Haddington market at the present time, but is generally to be had at Dalkeith, and also at Kelso, where it is known by the name "Make-him-rich."

Improvement had hitherto been taken up by fits and starts, and it was resolved to pursue the object systematically. With this view, Wheat fields far and near were examined, and ears selected for propagating their seeds, so that the experimental Wheat plot of 1857 contained plants of nearly all the kinds cultivated in Britain, together with plants from the seeds of ears which had been selected in the previous summer. From this mode of investigation, the following varieties have been added to the list of farm crops:—Shirreff's Bearded White, Shirreff's Bearded Red, Pringle's, Smith's, and Howden's. Efforts were likewise made to obtain superior Oats in the same way as had been done with Wheat. Twelve or fourteen ears were selected from fields in the neighbourhood of Haddington, and their seeds sown in a comparative trial plot, with 20 old kinds, in the spring of 1863, and from this source the Fellow family arose, consisting of Early Fellow, Fine Fellow, and Long Fellow. Crossing or hybridising varieties of Wheat has been attended with interesting and satisfactory results. Shirreff's Bearded White, with small, round, and pearly-looking seeds, on being fertilised with pollen from Talavera (famed for size and quality of grain), produced King Richard, scarcely equalled for length and strength of straw, and, if statements from various parts of Britain are to be relied on, unequalled for beauty of flour. Two varieties have sprung from King Richard, which have been named King Red Chaff and King Beard. Both have been handed, for the purpose of propagating, to Mr. Begbie, Barneyhill, and are likely soon to attract notice. The named varieties from this cross inherit much of size

and quality of Talavera. From experiments in the present year by crossing, new varieties are expected to be eight days earlier than the present ones.

Plants and animals play important parts in the economy of a well-managed arable farm in East Lothian. Animals, while being fattened, supply the means for promoting the growth of plants which are cultivated, and every addition to the vegetable produce increases the means of fattening live stock. Thus plants can be made to act and react upon each other, and through these agents the condition of the farm may be kept stationary, progressive, or deteriorating. But on such a farm animals ought to be considered of less importance than plants, because the latter forms the foundation and largest portion of the farmer's wealth, and without plants animals cannot exist. Agricultural associations devote almost their whole attention to animals, and the favourable change which all of them have undergone, from the ox to the bantam, testifies to the farmer's influence over the objects of his care. But, confining our view to the cereals, let us see what is done to improve this class of plants. Seed shows are held and premiums awarded, the competing parcels being previously prepared for exhibition by being frequently passed before a blower, round and round a sieve, and, if necessary, hand-picked over plates, or even tossed on a blanket. By these means the seeds of weeds are got rid of; but such appliances cannot change the nature of the grain.

The state of the cereals may be judged from what is seen at our great agricultural gatherings; and the recent meeting of the Royal Agricultural Society of England at Manchester afforded opportunity of examining into this matter. At the stall of the Society's seedsmen Wheat was displayed in small bundles of ears, in small samples of grain, and in clusters of ears arranged on pasteboard. This kind did not exceed 12 or 14, and very few were correctly named. Oats were in a similar state of neglect and confusion, small bundles of ears being artistically displayed, interspersed with the words "Black Tartar" and "White Tartar." There were also grain samples—about 20 ears—each spread separately out on pasteboard and hanging upon the wall, all numbered, but very few named. After a careful scrutiny, no member of the Fellow family could be found, and the much older Hopetoun Oat was also wanting. This extensive stall did not contain a cereal with which the name of Shirreff could be associated, unless it was the Shirreff Oat. At the last meeting of the Highland Society at Edinburgh, the most distinguished collection of seeds could boast of six varieties of Wheat in large sacks, marked with six different names; but there was little doubt of four of them being one and the same variety, and that none of the applied names was the correct one. Almost every species of plant can be modified by skilful treatment; and if improvement is seldom seen in the field than in the garden, it may perhaps be owing to farmers viewing each kind of crop as a whole, and overlooking individual plants. Besides, gardeners are brought more closely into contact with individual plants, by studying their properties and habits, but in both professions similar measures will be followed by similar results. About 40 years ago there was laid before a society in East Lothian a plan for improving cereals, which was well received and favourably inaugurated; but eventually it was strangled from dislike to its author. This public, and, perhaps, unparalleled, recognition for having been instrumental in introducing new farm plants is particularly gratifying to me, but high as the pleasure may be arising from this source, it is equalled, if not surpassed, by the evidence afforded of so many agriculturists being alive to the usefulness and propriety of improving the plants they cultivate. [The above remarks were made last week at Haddington by Mr. Patrick Shirreff, of East Lothian, on the occasion of a dinner given in his honour by his friends and neighbours.]

SEED WHEAT.

As ye sow, so shall ye reap. There is no doubt about it. Other things being equal, superior seed gives a superior return. And until we adopt, as a system, the same care and selection of growing and saving seed that the most careful breeders do in breeding for the improvement of their stock, we shall fall short of obtaining as fully developed crops as are of comparatively easy attainment. Every item of farm labour performed with care and good judgment pays well, but not one pays more abundantly than this of selecting and saving seed. A vast difference is realised, whether we plant the best seed—plump, full of nutriment—or blasted, or shrunken, where the germ of life is but just sufficient to vegetate. Such seed may come up and grow, but it is tardy in coming up, and still more tardy in growing; and being of a weakly growth, is also much more liable to disease than that from good healthy seed.

It is by careful attention to little things that the farmer is enabled to improve his crops from year to year, and thus to increase his fortune; for in farming, perhaps more than in any other calling, is good luck made up of attention to minor matters of detail.

But is it every decent looking sample that may be offered in the market that is worthy of the name of "seed wheat"? It is not. Good stocks ever do best, just as a pure-bred animal will thrive where a mongrel will starve. Take an analogous case if a half-bred ewe is put to a pure-bred tup, the produce follows the sire, and one ram lamb in ten may even seem nearly as well bred as his progenitor. But use him with a similar class of ewe, in hopes of obtaining the like results, and failure is certain. So a Wheat that has been long, carefully, and successfully grown on the same soil, possesses inherent aptitudes and peculiarities which no chance cultivation can ever reach. In the

stocks offered such qualities may be expected, vigorous prolific growth usually follows. In present prices, there is no better investment than judiciously selected seed.

The cultivation of Wheat was the subject of discussion at the East Lothian Farmers' Club at the meetings last autumn, and it is noticeable every one who took part in the discussion agreed the value of a judicious change of seed. Some of the leading speakers—Mr. Mill, Lurgate; Mr. Bearford, and others—we have in previous years the pleasure of supplying with seed. In one from us last season, Mr. Smith, of Stevenson, said "I have got the premium two years in succession with Browick Wheat."

One word as to the origin of Browick Wheat—we chiefly supply from this district, and we have Five-and-twenty years ago last month, a farmer was walking about among his reapers. A amount of personal oversight was probably more then than now—for reaping-machines were not in order of the day. In going along by the standing his eye was caught by the appearance of an ear of wheat different from the rest—fuller, and more developed from top to bottom, without dwarfing towards the apex. It was on a good stiff-stemmed and second thoughts led to its being carefully picked and carried home. In another month each ear was dibbled singly, 6 inches apart, in the farmer's ground. Towards harvest it had to be threaded to keep off birds, for they like these small patches best. The new Wheat—for a new variety it certainly proved to be—well repaid the pains and care bestowed upon it, and retained all its original characteristics of the plump grain, square, equable ear, and clean straw with little liability for being lodged or sprouting in wet season. In two years a small field was sown with it. It proved more prolific than any sown on the side; neighbours wanted to try it, and readily paid a long price for it.

This occurred on a farm at the hamlet of Wymondham and parish of Wymondham. The painstaking farmer was Mr. Robert Banham, who is, we are glad to still alive. May many happy days be in store for him. It was first offered to the public in 1848, and annually been so ever since. From the beginning, Browick Wheat has extended in area and wide, until it is probably the most extensively grown Wheat in England. Nor is it confined itself to this country; for a Wheat near Dieppe informed us some time since that in season purchases 80 quarters of it in Mark Lane sent over for his own sowing. Ten years ago I was requested to send to a French marquis, in the department of Vaucluse, one quarter of it for trial, and only half its produce year by year been sown would now supply seed Wheat sufficient for the "Let no one despise the day of small things."

The secret of Mr. Banham's success is probably He has repeatedly re-selected his stock, starting from the finest ear he could obtain; thus getting the highest sense of the term, a "pedigree" of Wheat. And hence also the oft-noticed and accounted for, that seed obtained direct from a greater robustness of growth than when grown years on the same farm without the change. On this principle any farmer has it in his power to obtain fresh seed, as it were, on his own farm, by taking the proper pains. Nothing that is worth in the world can be done without pains. The repeated quotation about the man who made blades of Grass grow where only one grew before a benefactor to his race, is surely in a high degree applicable to Mr. Banham. Therefore "to whom honour is due." *The Autumn Circular, Bowick & Co., Bedford.*

Home Correspondent.

Interest and Wear and Tear.—According to "G. A. H." (p. 114) I am a bad "accountant" implies that he is a good one, inasmuch as he himself up as a judge in such matters. This is true, yet for all that he is a bad one at "accounting" or he would not have "reckoned" my farm at 225 acres a year. The work on my farm for 15 years been regularly recorded, and never once year did it reach 100 acres, and here is the result it has done so this year. On September 1st entered upon 131 acres more land, of which 70 are Grass, and 61 are under the plough. The heavy clay, adjoining my old heavy clay-lane has made it necessary that I should re-plough farm. 10 acres of this additional ploughed land have been sown for permanent Grass, and the 51 acres have been thrown together with the ploughed land. The fields now stand thus:—164 acres, No. 2, 224 acres, No. 3, 33 acres, No. 4, 23 acres. The two former represent ploughed land, and the two latter represent new ploughed land, and if you look at my published last week you may see that I did 200 No. 3. This it is that has raised my quantity of year to over 100 acres. My occupation of arable land 112 acres: hereafter it will be 163 acres. "G. A. H." should "estimate" my year's work at 225 acres I want to know, for he has not till now that my occupation was over 100. If he had been careful in reading my letters he would have known that I never go twice over my land with steam-power for a crop, and he would have known that I condemn such practice as is out by others who do. My letter last week was to him that my work this year on my 131 acres 109 acres, and that is all, excepting 17 acres of work next March for Peas. You have estimated him the 1s. 6d. per acre for interest and wear and

but let me remind him that the Royal Agricultural Society took 200 days as the datum on which they made their calculations when they awarded the great 500l. prize at Chester, therefore I have no trouble to clear myself of his "alleged miscalculations;" and if Mr. Mechi can get out of his mess as easily he will not hurt. My great object in the application of steam-power to the cultivation of the soil is to get deep and clean seed-beds at the cheapest cost. This year I have got a seed-bed on 51 acres of Wheat at 6s. 8d. per acre on 6 acres, after Mangels for Wheat, at 2s. per acre, and my ridging and subsoiling, from 10 to 12 inches deep, stands at 6s. 7d. per acre. These are figures that I pride myself in being able to show, and I am proud to support them (when questioned) with the data on which they are based, and I will show the condition of my land against any man's land; but I will not work land over by steam-power for the sake of appearances, and being busy with my tackle for no useful purpose. If "G. A. H." is learned as "an accountant," he has got a lot to learn about steam-power and culture; therefore, let me give him this little dose. I must, however, give him my "account of repairs:"—

1 new share to ridging plough	£0 2 0
2 new shares to smasher	0 8 0
Total	£0 10 0

Since writing the preceding, it has occurred to me that I ought to have gone into the interest of money, and wear and tear question, to show that in my case no extra capital is needed to work my farm by steam. My old arable land needed six horses to work it under horse culture. Under steam culture I have never used but three, and they, as I have heretofore shown, only work 118 days a-year. On the farm that I have just bought, four horses have always been kept to work the heavy arable land, and I never knew a profit made by a horse on it, yet I have known of many a dead one. I have started off with five to do the two farms, and this week will complete their work for the year, excepting job work, and that will be very light, for nearly the whole of the tiles are already drawn, and laid upon the new portion of my farm for draining. Therefore, I am a gainer of six horses, let us put them with their tackle and implements to work with, at 40l. each. I need less capital, upon that point, 240l. Now fix their keeping (less the value of their manure) at 25l. each; in this way, at the end of the year, I save 150l. Now, let us put the case, taking the half of the engine and tackle, as "G. A. H." says, at 375l. Now, for the other side—

Six horses, with their tackle and imple- ments (less needed)	240 0 0
Keep for a year of six horses	150 0 0
Total	£390 0 0

This gives a gain to me at the end of the first year of 15l., therefore no extra money is needed, and I am a gainer every year afterwards of 150l. for horse-keeping, to say nothing about the cleaner and deeper farming and increased produce that I get; but I must say something about increased produce, for it has been, and will be, very considerable. My old heavy land under horse culture needed and had a dead fallow every fourth year, yet under steam culture it has never had one, neither will it ever need one, therefore I am a gainer of one-fourth in produce upon that point; and the farm that I have just entered upon has had a portion of dead fallow yearly, this year it had some, and I had to pay by valuation for three ploughings with four horses each ploughing and two scufflings, with half a year's rent and taxes for making them, without getting any produce. Now I shall never need any dead fallow or fallow of any kind upon this farm again, therefore I must hereafter be a great gainer in the shape of increased produce. I take it that "G. A. H." is a traction engineman; I have read a lot about these wonderful things of late, that they are getting them up to from 20 to 40 tons in weight. Years ago I read of less weighty things than these having got stuck in the mud, and it may be that some misty morning or other we may hear of the heavy weights in upon in any weather. Look at my letter last week. It comes out just at the moment when I want it, does the work when work is very valuable, and then gets packed up for the year, and everybody else must have it at the right time if they mean to be gainers by using it as well as having the work done cheap and well. *William Smith Woolston, Blechley Station, Bucks, Nov. 1.*

Woolston Steam Ploughing.—I cannot see why you should assume (see p. 1115) that 1s. 6d. per acre means 12s. per day, and then say that 100 days would give 60l. for interest, and wear and depreciation. Does Mr. Smith work his tackle for 100 days? I trow not, otherwise he ploughs only an acre a day. Mr. Smith professed to give us facts and not theory, and if he does not keep his engine at work ploughing for 100 days, what right has he to put down 1s. 6d. per acre as the actual cost for interest and wear and tear? If Mr. Mechi did anything so utterly contrary to honest accounts, I warrant Woolston would be down upon Tip-tree with a vengeance. If Mr. Toepffer were fool enough to tell his shareholders that 1s. 6d. per acre was ample to cover "interest and wear and tear," and were to advise them to set that sum aside for that purpose, and if he were, moreover, to hold his tongue about "depreciation," no one would laugh more loudly than Mr. Smith at the "blind advice." Yet, what is the blind advice that Mr. Smith is giving to his brother farmers? Why, simply to buy a set of steam ploughing tackle to cultivate 100 acres with. And then he says they will be able to make seed-beds for Wheat at 6s. 8d. per acre and seed-beds for roots or Beans at 6s. 7d. per acre. When Mr. Smith says he has made a seed-bed for 6s. 8d. per acre, I tell him he is deceiving himself, and in deceiving himself he is deceiving the public; for the sum of 1s. 6d. per acre put down for interest and wear and tear is a "mere

estimate" (and a very ridiculous one); and besides this, he keeps out of sight altogether a very material item in the cost, viz., "depreciation." If I mistake not, Mr. Smith began with a much smaller engine than he has now. How much did he lose in it when he sold it? How much, too, did his present large engine cost? and how much does he suppose he will lose on it when in two or three years' time he replaces it with a road locomotive? It will not do for Mr. Smith to tell us he brings down his expenses, and makes up the interest and wear and tear by hiring out his ploughing apparatus to his neighbours (if he does do so), for a horse farmer might as reasonably say that his seed-bed only costs him so and so, because he makes a profit by hiring out his horses and waggons to the parson or the squire when they want some coal drawn. Moreover, if I mistake not, there was not long ago a terrible row kicked up because in the Tip-tree accounts a small sum was put down as having been received by Mr. Mechi from his neighbours for grinding some corn with his little fixed engine which he has had for the last 20 years. If, too, Mr. Smith can scuffle heavy clay-land with horses for 2s. per acre, I think he must be a hen. A hen could scratch, and so could he; but I do not think that either of them would scratch it very deep. I have a 5-tine Coleman cultivator that works 3½ feet wide; and it is very hard work for four horses to do three and a half acres per day, and that costs me 11s., or 1s. per acre. *G. A. H.*

Wages and Education.—Upon the condition of the agricultural labourer of the fens, allow me to give my experience as an employer and practical farmer. Much has been said about the "down-trodden," helpless state of the labouring class, but I must at once protest against those terms being applied to the labourer in this district (the Isle of Ely). I am now paying my men 12s. per week, some of whom have boys also working for me at 5s. and 6s. a week; and nearly all last month the wife, when she could go to work, was earning 1s. 3d. per day Potato picking, and in the spring for many weeks together women here obtain employment at 1s. per day weeding. Looking over the harvest labour account, I find that each set—that is, the man, his wife, and a child, or in some cases two children, during the 12 days they were cutting, earned on an average about 8l.; after this time, for 10 days, the men received 3s. 6d. and six pints of beer a day, whilst carting, stacking, &c. It may be said that this does not affect the question of their down-trodden state, but I think it will be allowed that a man who knows his work and does it, also knows that his labour is worth the wage he receives; and that at the end of the week when paid, he and his master are under no obligations the one to the other. That several—I cannot say many—of my best labourers, men who have been working for me for more than 20 years, can neither read nor write, is, I confess, a matter of regret; but in every case where these men have children, they have received a sufficient education to be able to read the Bible to their parents, to write fairly, and to tell, with a little consideration and a scratch of the head—for that process seems to have some occult virtue in calculation—the number of 7 lb. linseed cakes required to be crushed to give 24 fattening bullocks 6 lb. each; and I think that such an education is sufficient for them, in the station in life to which they have been called. What earthly use would it be to teach these lads astronomy, or the use of the globes? We cannot all be classical scholars, like Canon Girdlestone, or Mr. Beales, M.A., and I fancy those gentlemen would not be thanked by the labourer for his proposed compulsory education, for the poor man, and particularly the agricultural labourer, is very jealous of interference, and any attempt at coercion in connection with the training of his children would only tend to create ill-feeling between him and the authorities. It is not to be supposed that the education of the working-class will be as defective in the next generation as it has been; for as improvement is being carried on in all other matters, so education will continue to keep pace with them. But not by forcing can this be done. The labourer will see the advantage of knowledge, and avail himself of the opportunities afforded him for obtaining it. *Nemesia, Nov. 9.*

Mangel Running to Seed.—Having seen in the *Agricultural Gazette* several paragraphs on Mangels running this year, I give my experience from seed purchased of Messrs. Sutton & Co., sown April 24. A finer or more handsome lot of roots I have never seen. They were the admiration of all who saw them, not one showing the least sign of running. The sorts were the Berkshire Prize Yellow Intermediate, and Long Red and Yellow Mammoth. Having weighed several ranks, in different parts of the field, I found the average was 10 tons per acre. *Thos. Andrews, Box, Nov. 9.*

Foot-and-Mouth Disease.—In one of my byres my herdmen and myself estimate a destruction by the disease of from 80 to 100 stone (of 14 lb.); but this is only a small portion, for the suffering herd has had to be fed almost totally with expensive food—boiled linseed, bran, barley-meal, soaked oil-cake, &c., which, had the cattle been free from the disease, would have produced a large additional amount of beef; besides, my "fag" and pastures are wasting and deteriorating rapidly at this season, and which should have been assisting in producing the people's food. Again, as I have herds in other places free from disease, the lands should be with their horses upon the arable land preparing for next year's crops. I have, however, been obliged to employ them in attending to the unafflicted stock, and thus the horses are partly idle, and considerably dis-jointing the farm operations. I was also put to serious inconvenience by Yarm Fair, as the highway rans, or more properly speaking, twists through and round the pastures in which I had 70 head

of cattle, and prudence induced me to order these to be removed to fields adjoining the Tees, in which they were overcrowded, with a short supply of Grass for the whole; further, I was most desirous to buy in for winter 40 to 50 Scotch highlanders, but the risk of introducing the foot-and-mouth disease upon my farms deterred me, and therefore the Grass which would have fed these will be greatly wasted. I have also, for coguate reasons, bought no sheep or lambs, and farmers around are deterred sending their cows away from home for breeding purposes. No doubt, if I can preserve the 90 head, which are separated from the contaminated lots, the reader sale and increased price they are realising will go some way to liquidate the losses, from the disease wasting the cattle attacked; but, then, I am disposing of fattening animals which are scarcely fit for market, and thus is inflicted an injury upon the country—as, were it not for the risks of the "foot-and-mouth," I should not push them into the market. *W. A. W. W. Sadberge Hall, Oct. 27.*

Shirreff's Bearded Wheats.—I read with great pleasure in your journal the proposal of a testimonial to Mr. Patrick Shirreff, as from perusal of the papers he has written, from correspondence, and from experience in the growth of his valuable varieties of Wheat, I am convinced that few persons more deserve an acknowledgment of their services to agriculture. Having had some share in introducing his varieties into Suffolk I can speak highly of the quality of both his red and white bearded Wheats. I notice that your scientific correspondent (Mr. Brown, in a letter written a few weeks back, says he is informed there are no first-rate bearded varieties; I should be happy to send him an ear and a few kernels of Shirreff's White to prove the contrary, and for his comparative experiments, as to rust, &c., if he continues them this year. This kind has a plump, short kernel, and weighs well this year; the weight here was 18½ stones nett per sack, i.e., 64½ lb. per bushel; last year it reached 19 stones, or 66½ lb. per bushel. The land in this neighbourhood (near Bury St. Edmund's) is not sufficiently strong or fertile to produce extraordinary Wheat crops, nor can a fine White Wheat vie in point of quality with the coarser Browick or Spalding, yet both the red and white kinds have produced with us 10 sacks per acre. Mr. Brown, in his suggestive letter, is of opinion that vigour of Wheat is shown by the beard, and that probably the fungoid disease (the Take-all) of Australia, might be rendered less destructive by growing vigorous bearded varieties, less subject to blight or rust. I believe this idea is correct, and if so, Shirreff's Wheat would be well worth an Australian trial. I would make another suggestion—the Hessian fly is in many districts in America so very destructive to the grains of Wheat, that the cultivators have been compelled to grow a coarse kind of Rivetta, there called "anti-fly," which is guard by its beard from the attack of the egg-producing fly. Now, if Shirreff's bearded Wheats should prove similarly exempt from attack, what a gain is here, both to Australian and America, and what an inducement to the suffering cultivators there to assist in the proposed testimonial. Whether bearded varieties are exempt from attacks of fly and Fungus, and if so, to what extent, is well worth investigation and experiment, and I would wish to call the attention of Mr. Brown, and other scientific men, to the subject. *W. R., November 3.*

Foreign Correspondence.

TORONTO Canadian Agriculture.—The *Toronto Weekly Globe* of October 15 contains two articles on the remarks of a writer in the *Agricultural Gazette* of August 28, the substance of which you will no doubt be glad to lay before your readers. The difficulties in the way of Wheat growing on both sides of the St. Lawrence, to which your contributor had referred, lie not in any extreme rigour of the climate north of the river which he points out, or in any natural poverty of so much of the soil, but in the prevalence of the Wheat midge. It is this which has for a number of years past "devastated our Wheat crops, and caused that falling off in exports which we all feel so acutely, and suffer from so much." It is, however, from another article in the same paper that I shall ask you to give your readers some extracts. The writer says—"I have lived in Canada 37 years, and during that time have been intimately acquainted with the Wheat-producing capabilities of every section of this Province, from Kingston to Sarnia, and northward from Lake Ontario to Cabot's Head, as well as those of very many portions of the United States, and must beg to differ most maternally from the writer in the *Agricultural Gazette*, and the excellent authorities whom he quotes. Canada has not, as far as the land in Canada is concerned, disappointed any reasonable practical agriculturist in regard to her Wheat-growing powers. I have myself a hundred times verified by actual measurement very large yields of the best Wheat, often 30 to 40 and 50 bushels per acre—those yields occasionally extending over large areas. Only last year a tenant of mine harvested and measured 37½ bushels of good fall Wheat per acre from a field of about 18 acres, and the country papers are often found to contain statements, in which name, lot and concession are mentioned, where 50 bushels of excellent Wheat are harvested to the acre. Instances can be mentioned to the thousand of such yields as 30 to 35 bushels to the acre, and for Barley, Peas, and Oats, there is no country that will and does produce per acre more of these so-called coarser grains. It is not the fault of the land or climate—it is simply want of knowledge, capital, and above all, the low prices of produce, compared with the high cost of labour, deterring the Canadian husbandman from the necessary draining, and the heavy expenditure for manures that the English agriculturist so freely lavishes his money on. These are causes that render Wheat growing here more proce-

less because slack hands (for such will get in among us) have an idea that it is not needful to work so hard for the squire as for other employers. It is an excellent and praiseworthy plan to let the hands on Saturday afternoon, say at four o'clock, summer or winter. It is a boon which they will value; its value to the employer is not appreciable, and it affords an ample worthy of imitation.

Upon the owner himself a beneficial influence will undoubtedly be exerted, if he gives moderate attention to his farm in his own occupation. He gets a greater insight into rural affairs, he is better able to judge of that pertains thereto, and he can more readily sympathise with the losses which his tenants at any one experience."

Pharmacopœia, including the Outlines of Materia Medica, &c., for the Use of Practitioners and Students of Veterinary Medicine. By Richard V. Fuson, F.C.S., Professor of Chemistry and Materia Medica at the Royal Veterinary College, &c. John Churchill & Son, New Burlington Street.

A trustworthy dictionary of the various substances used in veterinary medicine, with their synonyms, composition, modes of preparation, actions and uses, and modes of application, antidotes, &c. Professor Fuson is an unquestionable authority on all these subjects.

Farm Memoranda.

HAMPSHIRE.—This, our usual record of agricultural matters, has been somewhat delayed by other pressing engagements. It is, however, an interesting period of a year to all engaged in the occupation of land, as it now that the various crops of grain and Pulse have been tested by threshing, and the various root crops food for cattle are showing and promising in their bulk and value. The aggregate produce of the county generally was never better, reckoning the food for man and cattle. It is true the produce of the Wheat crop is this year more difficult to estimate than usual, owing to the great disparity in produce, which, in some instances, amounts to only half a crop, in others a full crop, in fields of similar soil and cultivation, it must, therefore, be written as a bare average, and this view the case is somewhat strengthened by the rates at which it is selling. Barley is a fair average crop, of different quality. Oats a little over an average, both weight and quantity. Beans and Peas are a good average produce. Hay, both field and meadow produce, as a full crop and well saved. There is a good bulk and quality of early crops, both Mangel and Swedish turnips, and also the latter varieties of common turnips are very promising, and more than usually so at the chalk hill farms. Cabbages of various sorts are coming into use more than formerly in field cultivation, being found good wholesome food for all the stock of the farm, and are ready for use earlier than other root crops. Cabbages this year planted the last week in June were fit for use September 1, and by cutting after a green crop they are certain to succeed. The large provision of cattle food has led to a very great and rapid rise in the price of store stock, and from Wilton Fair, September 13, to Winchester Fair, October 23, the increased value may be stated at 7s. to 8s. per head, and even at this price it may fairly be expected that sheep will give an increase of value over cost price equal to the average of seasons. The breeders of stock on the hill farms ought to be justified with present prices, for although their stock sold very low last year, the average of three years must be satisfactory. In anticipation of prices for meat through the winter and spring months, many parties consider that it must be lower on account of the large quantity of cattle food to be consumed; but it should be remembered that we used to get, years ago, a large number of well-fed sheep and cattle at our fairs. But this is not the case at present, excepting exhibition stock, showing there is no accumulation of fat stock, and that the requirements of the consumer are so great that we are (notwithstanding an over average breed of lambs for the past three years) drawing very hard upon our supplies to meet the demand, and our Government statistics are to be relied on, we are now 1,360,000 sheep short in number as compared with the previous year in the United Kingdom. If this is true, mutton and beef, notwithstanding foreign supplies, must be dearer rather than cheaper. It is satisfactory to know that the flocks of sheep in this county were never more healthy, and that the large numbers of horned ewes which usually come into the southern division at this period are yielding a very numerous fall of lambs, which, together with the ewes, are in fine condition. It is much to be regretted that the same cannot be said of cow cattle, for the foot-and-mouth disease is very prevalent in different parts of the county, and it is generally admitted that recent regulations upon the question are not sufficient to check its extension. We are still receiving large importations of store cattle from Ireland, which sell readily in our fairs and markets, owing to the abundance of fodder and roots. These are of a better description of stock than formerly, and are nearly allied to the Shorthorn breed, but they do not pay for wintering in straw yards, like well-bred North Devon cattle, nor do they meet with so ready a sale in the spring. Unfortunately the supply of Devon cattle is very limited, hence the ready sale for the Irish importations. *Joseph Blundell, Southampton, Nov. 8.*

and hard that they cannot make fair wages, and the hunting meets are arranged with the proviso that, unless rain falls, the hounds will not be brought out. In Lancashire Potato raising has been carried on as fast as was practicable, considering the wet weather. The produce is good as to both quantity and quality; but, unfortunately, the disease has set in, and two-thirds of the crop are lost. Growers, for this reason, are hurrying their tubers to market, and will accept very low prices in order to get rid of them. A large grower informed me to-day that his crop, which looked magnificent a few weeks ago, is completely spoiled, and that he has never had so much disease since the fatal Irish famine year. It is fortunate for the community that there is little or no disease in the warp soils in Marshland (Yorkshire), and in Scotland; but the losses in the Ormskirk and Southport districts, where the crop is extensively cultivated, will be serious. Fortunately for them, too, their Wheat crop was remarkably good, and, contrary to the experience of other districts, threshes out well. Their early Potatoes, besides, were a sound and profitable crop. It would seem that the warm, muggy weather, and the thunder and lightning in the early part of October, brought on the disease which caught the later sorts. The results of the year's cropping in this district have been,—Grass and hay, very good—much above the average. Wheat very good. Oats very good, but many of them caught by the rain before carried and injured; early Potatoes, an excellent crop, late Potatoes, a large produce, but two-thirds spoiled. Barley and Turnips are not much cultivated in this district, but where Swedes and Mangels are grown, the crops are magnificent. It is now excessively cold, and this morning the ground was covered with snow. *W. H. B., Nov. 10.*

The Poultry Yard.

Does Poultry Keeping Pay?—This homely question is frequently asked, but not often answered, or if answered, the replies are not altogether satisfactory. I am not prepared to give other than a general reply, founded upon observation. It is an unquestionable fact that a vast increase in our stock of poultry has taken place within the past few years; ergo the keeping of poultry must be profitable, or they would not be so widely extended or so numerous bred. The rearing and management of farmyard poultry has become quite a scientific business in itself. The old-fashioned farmer's dame is gone, and her broods gone with her. Her geese and her poultry were desirable on the farm when she entered her new husband's home; these she personally tended, and these stock breeders remained till death, natural death, took them off. The modern dame has altogether new ideas of poultry economy. The majority of these modern farmer's dames, I regret to say, abjure for the most part personal attendance, but they have the poultry woman, and to her is committed the management of the poultry of the farm subject to their supervision and I must say it is in the wrong direction, for be it fully known that the breeding and management of poultry has become as much a question of scientific breeding, of choice and selection, of judgment and careful crossing, as in any other department of farm practice or high breeding. Our highly interesting and beautiful poultry shows abundantly testify to this truth. Surprising birds are continually exhibited, and it is from these that fresh stocks are constantly raised. The best birds are speedily brought up, and go to replenish stale stocks, or for the improvement of the breed in many a farmyard the great aim being to propagate the best breeds of healthy character, coming to great size in the shortest time. To accomplish this desideratum, judicious crossings of the very many breeds of poultry are resorted to in keeping to a true breed, the finest specimens alone are retained for breeding purposes. This is again aided by pure and choice selections of the same breed from fresh stocks. A cockerill should never be retained more than two years for service in the same yard, and the hens should be sold off before arriving at old age. Pullets should be kept from the cockerills till they are well grown, otherwise their full growth and development is much retarded, if not altogether curtailed. Most farmers' dames prefer the breeding and raising of poultry for sale, but there are many who prefer keeping a stock of poultry entirely for the production of eggs for sale, and these contend that their's is the most profitable course. It is true that certain breeds of poultry do produce an astonishing number of eggs, for which there is always a ready sale; but to do this a large stock of hens (layers) must be kept, which also entails some rearing to keep up the stock. This large stock is probably more costly to support than a moderate stock of breeding hens with their chickens. I certainly prefer the breeding and rearing for sale, and the way in which most poultry keepers get them up is novel and good. The poultry woman has usually near her residence, or in the farmyard poultry houses, suitable conveniences and nests for the hens to lay and sit in. As they come off, well sheltered hen coops are placed upon some dry spot, and in a warm situation. There the chicks are raised till they are able to provide for themselves. They are then taken to the poultry houses, which are distributed about the farm, and are fixed in the most suitable places upon the farm, and least likely to be detrimental to the cropping by trespass. These poultry houses are generally wooden frame houses, so as to be readily moved from place to place. Occasionally they are used for layers and sitters. They are from 6 to 10 feet square and 7 or 8 feet in height, and are provided with suitable roosts, entrance, &c., and nests. The young cockerels are taken to a house apart from the pullets, and at a distance sufficient to keep them separate for a considerable time. At these houses they are fed daily, but their chief sustenance is derived from

their strolling about in search of worms, flies, insects, berries, roots, weeds, &c., upon which they do well. Prior to harvest they are taken up to the yards, to prevent their mischievous attacks upon the crops. As soon as a field is clear, they are returned to their home and encouraged to pick the stubbles, to which they soon get accustomed. It is in this way that many large poultry establishments are upheld. The fattening is a separate department, and is done in houses or hovels, especially provided with corn, meal, Potatoes, bran, &c. *O. F.*

Miscellaneous.

The Condition of the Agricultural Labourer.—At a recent meeting of the Ougar Labourers' Friend Society, the Rev. F. A. Fane, one of the vice-presidents, delivered a speech which produced some astonishment. Gesticulating somewhat violently, the rev. gentleman said it was all very well for them to meet and chatter, and praise their good doings, and represent everything they did for the labouring classes in *couleur de rose*; but he was one of those who thought, if there were any points the discussion of which might add either to the improvement of themselves or others, they should "blurt out" their opinions upon them. He thought they ought not to be too squeamish in what they said. He was then understood to recommend wholesome and decent cottages for the respectable poor, and to speak in favour of beer-houses and public-houses being put under better control, rather than closed entirely; for, he said, he drank beer, they (the company) drank beer, and he did not see why they should altogether prevent the working classes from drinking it. What he proposed they should do was to raise the character of the labouring man, and then he would not go to the public-house. They should teach him that the money he spent there was wanted by his wife and family at home. And then they ought to get rid of the Poor-law. He believed that that "horrid law" encouraged improvidence, the parent of all vices, that it destroyed those kind feelings which ought to exist in families, that it separated class from class, that it encouraged fraud, dissipation, and lying. He believed that that law counteracted that which they all wished to encourage—providence, self-support, self-dependence, and frugality. He believed that that law filled our lanes with vagrants, and our public-houses with lazy drunkards. These were startling statements. Then they would ask him what remedy he had to suggest. Was he going to allow the poor to starve, and the sick and infirm to lie upon the roads and die? All who knew him would acquit him of any such thought? He wished to elevate the poor man. He did not wish to see him degraded and disgraced by the Poor-law. He was not very fond of trades' unions in one way, yet in another he admired them, and thought they had done an immensity of good. In some respects, indeed, trades' unions had been a blessing to them. They had shown them what men could do—that men could support themselves in sickness and infirmity, and in times when they wished to contend against their masters, by their little weekly contributions. Going to things more local, there was a society in this district of 12,000 people; in that society there were between 700 and 800 labourers, and at the present moment it had \$5000, to distribute among them in times of necessity, thus rendering them independent of the world and their parish, and enabling them to hold up their heads as Englishmen. Who, then, would tell him that the working classes could not support themselves? It was the vagabond and the rogue who came upon the parish, the liar and the thief. It would be of the greatest advantage to society in general, and it would be of the greatest benefit, morally and socially, to the poor man himself, if they could lift him from that degraded condition of going and walking before the board of guardians with his head down, to ask a morsel of bread from his brother rate-payers. These were novel views. He knew they struck some hard. He never looked upon the Poor-law as a charitable law, for charity meant ransom, and who ever saw an overseer with a Poor-rate book in his hand, and looked with any love upon him? The Poor-law system was not a charitable one; it was nothing of the sort; it was a maudlin sympathy, and by it they were keeping down the poor man whom they wanted to elevate to take a position among the citizens of this great country. —Mr Chisenhale-Marsh rose and said he thought it was to be regretted that Mr. Fane had marred an otherwise excellent speech by the comments which he made at the opening of it. It so happened that on the subject of the inefficiency of the Poor-law he agreed with Mr. Fane, but even if he had not he wished to assure Mr. Fane that, so far from his speaking on any subject connected with the welfare of the poor against the will of anybody present, it was, on the contrary, with their thorough acquiescence. God forgive him if he did not meet them there as a true friend of the working man, prepared to listen to any suggestion for his improvement, without its being in any way "blurted out." All he objected to in Mr. Fane's speech was the accusation that they met there to cockle themselves up with the good things of this world, and only to pretend to be the friends of the poor. Did they think he would leave his comfortable home to come there—but, pshaw! why talk of himself? Did they think Mr. Stall-brass would toil as he had done, or Mr. Shepherd, of the Roding society, or Mr. Wentworth, of Harlow, if they had not the welfare of the poor really at heart? He hoped Mr. Fane would not in future intersperse the good things which he said with the insinuation that he was speaking to unwilling ears.—Mr. Fane said he made no accusations. He only wanted people to take his suggestions into consideration.—Mr Chisenhale-Marsh: Sir, you remember the end, but forget the beginning of your speech. I wish it to be thoroughly understood

SOUTH LANCASHIRE.—The differences of climate in this little island of Great Britain are most surprising. In Lancashire we have had two months of wet and broken weather, interfering seriously with the raising of Potatoes and the sowing of Wheat, while in the Midland Counties farmers complain of a want of rain to enable them to work their land. Drainers there will not take piece-work, because the ground is so dry

that we meet here for the welfare of the poor, and those who do not wish well to the poor are better out of our society.—Mr. Welch was sure Mr. Fane did not mean what he said at the beginning of his speech. He had often sat under Mr. Fane as a preacher, and no man uttered more truth with greater effect. His heart was so good that he hardly knew what he said.—Mr. Fane I beg most emphatically to say that I don't retract a single word I have uttered. I adhere to what I have stated in toto, and I hope the reporters will say so in the newspapers.—Mr. Chisenhale-Marsh: And I hope the reporters will say that that observation was received with a loud laugh.

Calendar of Operations.

NOVEMBER: Stubble lands.—In late seasons in the North, where corn harvest is seldom concluded before the end of October, turning over the stubbles is the main work of the ploughs in November. In early seasons, when the harvest is finished by the end of September and beginning of October, and the weather is settled and dry, it is common to autumn fallow, by ploughing, scarifying, and cleaning the land, and also to apply manure; but in late seasons, and even in ordinary ones, the winter furrow is all that the land gets, and when intended for Turnips the following season it is common to plough deep with four horses, or subsoil as directed below. For Peas and Beans farm-yard manure is not unfrequently spread upon the stubbles, and either ploughed or ribbed in. Manuring in December is preferred to manuring in early spring, on the twofold ground that it suits the Bean crop better, and that any injury done to the land in carting is rectified by the frost of winter. Up to a recent date the work of ribbing was exclusively done by horses and oxen, but it is now cheaper and much more effectually performed by steam ridging ploughs,—the covering of the manure and the leaving of the land exposed to the weather being both better done.

Lea ploughing follows stubble ploughing, South and North—a large breadth being turned over for spring corn during the current month. Where wireworm is suspected skim-plough the green sod into the open furrows, covering it well with the bottom slice, as this rots all vegetable matter, and thus deprives the insects of food in the spring, while it at the same time starts the spring corn—Oats or Wheat—more rapidly. Whereas, a green seam of Grass between every furrow slice robs the land of manure, and supplies food—fresh Grass roots—for the insects in the spring before the roots of the corn are available.

Claying and Compost.—Manuring open, porous, gravelly, sandy, and peaty soils, and marling and chalking clayey and peaty soils, are operations successfully performed during the month, as the frosts and rains that follow continue the process of disintegration throughout the winter months, thereby giving to poor sickly Clover and stunted Grass when spring comes a totally different appearance. Whenever it can be profitably done, so much ground should be gone over yearly. Some marly clays are sufficiently friable to be broken fine in the spreading, and worked in by chain-harrows, others require frost to break them down. All composts should be broken as fine as possible, and chain-harrowed. In some cases a bush-harrow or seed-harrows work better than chain-harrows, more especially when heavy top-dressings are given, as from 200 to 400 cartloads per acre for changing the texture of poor sandy, gravelly, or peaty soils. Drifted chalk, or chalk drift as it is otherwise termed, is found in some places under a thin stratum of clay, and so broken, when dug from the pits, as to be fit for application to heavy clay-lands adjoining, or to other soils within reach, to which it can be profitably applied. On farms where the ploughing is done by steam, such works form profitable employment for the teams during any spare time they have this month.

Water Meadows.—If the water has been let on during the last week in October, it may have to be shut off the second in November, according to the weather. If the sluices have been opened earlier, the meadows may be ready for another flooding by this time, and so on, the alternate process requiring close watching. Where there is a limited supply of water, provision if possible should be made, so that when the water is shut off one field it may be turned on to another, the periods of flooding and drying being timed accordingly.

Town Sewage and Farm Sewage continue to apply during the month. The yield of Italian Rye-grass now decreases rapidly, but the average of the month will run from a third to the half of the midsummer cuttings, and with an extra handful of meal the Grass forms the best food for milch cows at this season. Give Clover hay chaff along with it, or well browned meadow hay in the absence of Clover hay. Owing to the decrease of solar light the Grass is more liable to blanch towards the bottom, and therefore should be more frequently cut than in the summer time.

Turnip harvesting.—Swedes and yellow-fleshed varieties are stored in pits, in the same way as Mangel Wurzel are in our southern counties, but in the northern they are more commonly left in the drills. There are, however, not a few exceptions to this in the North, for we have seen them as successfully stored both in pits and barns in the counties of Inverness, Ross, and Caithness, as in Kent, Surrey, and Sussex; and it has often occurred to us that the exceptional practice of Scotland should become the rule, owing to the heavy loss sustained in giving frozen Turnips to live stock, either neat cattle or sheep. To obviate this, most farmers during winter keep 14 days' or a month's Turnips stored in barns or heaps outside to supply the wants of a snowstorm or season of hard frosty weather. Others pull and set the Turnips close to each other in clamps, technically termed clamping, in the field for sheep, or in some paddock adjoining the homestead for

housed stock. But such supplies seldom meet the demands of northern winters. In those places where the climate and weather is favourable, the southern practice is becoming more general, but in the more exposed and elevated situations the great difficulty experienced is the unfavourable weather at this season for storing, as winter sets in before the roots are fully grown and ready for pulling. But this is no reason why farmers should not store when the weather permits, and the Turnips are in a state fit for it. As for the green tops, although they may be of some value in November for feeding, it is generally otherwise through the winter, so that they are worth more for ploughing in as green manure at this season, than for feeding material even during the current month. In storing in the field for sheep some make small round pits, one for each shift of the nets or folding of the sheep if the flock is small, or two or more pits if the flock is large. One turnip-cutter is required at each pit, the cut Turnips being carried in baskets by the shepherd or shepherds to the troughs. Others make larger pits, and distribute with a horse and cart. Some cast out a double furrow, and store in this 10 or 12 drills. Some store half the crop in the field for sheep, the other half at the homestead for housed stock. Globe, or white-fleshed Turnips, are generally pulled as required, or eaten off in the drills by sheep. Sometimes part of the crop is carted off, and consumed on stubble or grass-land; in other cases, the whole crop is so treated. Autumn Turnips are consumed in the same way; but in favourable seasons they continue to swell during this month, and may not be consumed until next. Some varieties are hardy, and may be kept on longer on dry land for sheep feed.

Potatoes, Carrots, and Parsnips.—Finish digging as soon as possible. If in any way frost bitten, store in pits smaller than usual, and turn as directed for Mangel Wurzel. When stored in barns, spread them rather thinly over the floor for a month or so, using some other house as a temporary store, until they will permit of being all stored in the barn of the usual depth.

Kohl Rabi, store as Swedes, taking care not to cut or injure the root in topping and tailing, for although hardy when whole, it is otherwise when broken. This applies also to Swedes, and indeed to all the root crops with greater force than is generally credited. Cutting the top and tail off a Turnip should be deferred till the time of consumption.

Live Stock.—In some of the southern counties, store cattle and sheep are still abroad in the pastures, but the former would be better in the strawyards, and the latter should now be greatly thinned. When the inclosures adjoin, it is common to leave the gates between open, so as to give the flock, or division of the flock, as the case may be, the run of the whole at pleasure. Fields possessing peculiar shelter should be reserved for breeding ewes in stormy weather, and when shelter does not exist naturally, it should be provided artificially, for in-lamb ewes should be kept dry and sheltered, and so should young store sheep. W. B.

Notices to Correspondents.

CHINESE SWINE: H V asks where he can procure a sow of the pure black Chinese breed?

FROZEN MANGELS: W M. Mangels covered by their leaf, and by the soil in which they are standing, will bear a little frost uninjured; but if they have been pulled, and are lying exposed, a very little frost is certain to end in their rotting in the pit. Such roots had therefore better be eaten at once—pulped, and mixed with chaff.

GAS-WATER: Hillsborough. The quantity of sulphuric acid required depends entirely on the strength of the gas liquor. For the gas-liquor you are likely to get, about 7 oz. of acid per gallon will be required; but be very careful how you mix it, on account of the sulphuretted hydrogen given off.

GRAINS: Midburn & Co. Next week.

MAIZE, DRIED GRAINS, AND MARK LANE: Amateur. The relative value of Maize for feeding animals will depend on the kind of animals to be fed. For fattening it has of late been cheaper than any other food; but for hard working horses, which exhaust a large amount of muscle, more nitrogenous food, as Beans and Oats, would probably be more profitably used. The value of dried grains for pigs is likely to be very low. What fresh grains are as food for pigs, desiccated grains are when re-scalded. The Mark Lane Corn Exchange is free to casual visitors and purchasers of corn, &c.

MOWING MACHINES: North Staffordshire. Wood's combined mower and reaper has been used to our knowledge with satisfactory results upon a hill-side dairy farm. But, as a rule, it is better to use a mowing machine for Grass and a reaper for corn.

THRESHING CLOVER: Cor. In reply to a question as to the method of getting the seed from a lot of ripe Clover hay, we extract the following from an American periodical—"The Alsike Clover bears its seed in its first blossoms each year, consequently, when I wish to save seed, I let the Clover stand about two weeks longer than I would for a hay crop alone; then cut, and house it as soon as cured, the same as for hay. About November 1, so that I can have the hay for winter use, I employ a Clover-thresher, of which there are plenty here (they cost about 120 dol., gold), and thresh it out. They will thresh about 20 bushels in a day, and it will be about as clean as Wheat when it comes from the threshing machine. I then run it through my fanning mill, which blows out the dust and fine dirt, but it will still be full of bits of broken hay, and if there are any other seeds in it, they will be there still. I then take a very fine wire sieve, that will, with considerable shaking, let the Alsike seed through, and nothing else. Red Clover, when saved for seed, is managed in the same way, with the exception of the cutting. The Red Clover bears its seed in the second blossom, consequently it has to be cut for hay early in the season, then allowed to grow up the second time, and when ripe, cut and saved for seed, then threshed, and managed the same as the Alsike. The Alsike will yield from six to eight bushels to the acre, the Red Clover from four to six. Red Clover, when saved for seed, is worthless for hay, as it becomes dry and black, and when threshed it all goes to chaff. Such is not the case with the Alsike,—its stalks and leaves are as green and fresh after having ripened its seed as the Red Clover when cut in its prime; and after it has been threshed it makes as good hay for horses, or stock of any kind, as the Red Clover at its best."

Autumn Gardening. SEAKALE, ASPARAGUS, and RHUBARB. JAMES CARTER AND CO. offer the splendid quality—SEAKALE, extra fine roots, for Forcing, 15s. per 100 very fine roots, for Forcing, 10s. 6d. per 100 large, 7s. 6d. per 100. ASPARAGUS, Giant, extra large plants, for Forcing, 10s. 6d. per 100 strong, 3 yr old, 6s. per 100 strong, 2 yr old, 4s. per 100. RHUBARB ROOTS, Baldry's Scarlet, extra strong, in the other varieties, extra strong, in the best M track, ea. per bushel the French, 4s. to 5s. 6d. per bushel. JAMES CARTER AND CO., the Royal Seedsmen, High Holborn, London, W.C.

H A L L E T T PEDIGREE HUNTER'S WHITE WHEAT ALSO THE ORIGINAL RED.

Price, including bags, Five Guineas per Quarter, by the Half-quarter; One Guinea per Bushel for less than a

delivered at the Brighton Station, in bags containing Printed Directions for Planting, and

Cheque or Post Office Order, without which it will be sent to unknown Correspondents. Less than a Bushel

Apply to Captain HALLETT, F.R.S., The Nurseries, Brighton.

REES AND CO'S BIPHOSPHATED GUANO (Registered Trade Mark, Flying Fish) ready for delivery in quantity and in fine condition. It is to be the best Artificial Manure yet produced. It is Peruvian Government Guano; it contains 12 per cent of Phosphate, 6 to 7 per cent of Ammonia with Sulphate of Potash, and Mr. Sison De Vere in 2 cwt. bags, each of which is by a leaden seal, bearing the Company's Trade Mark. This is guaranteed so long as the seals remain unbroken. Agents for the North of England—Messrs. Knapik & Co., Hull. Agents for South-West of England—Messrs. W. & G. Bristol. Agents for Kent, Surrey, Sussex, Essex, and Middlesex—G. Barry, 8, Old Jewry, London. Agents for Scotland—Messrs. Richard Connor & Co., Glasgow. Agents for Ireland—Messrs. R. F. Gladstone & Co., Dublin. Price 41 per ton, delivered free to Rail or Wharf. REES AND CO'S Biphosphated Peruvian Guano (Limited), 32, King William Street, London, E.C. PERUVIAN GOVERNMENT GUANO, 21s 10s per

Autumn Sowing. ODAM'S NITRO-PHOSPHATE OR MANURE for WHEAT—This Manure, specially prepared for Autumn Sowing, is rich in Ammonia, Phosphate, and ingredients required for the healthy growth of Grain. Analysis of Blood and the grain of Wheat show that they are deficient in phosphorus, hence the value of Blood as a Manure. It may be applied at the rate of from 3 to 4 cwt. per acre, according to the condition of the soil, either drilled with or sown broadcast. If the latter, it should be well prepared by the Patent Nitro-Phosphate or Top-dressing Manure Company, whose Members are Cultivators of 50,000 acres of land, which has been for years under manure with Manures of their own manufacture; consequently they have the best guarantee for the genuineness and cheapness of Manures manufactured by this Company. Particulars will be forwarded upon application to the Chief Office, 109, Fenchurch Street, London, E.C. Counties Branch, County Chambers, Exeter; 40, Westmoreland Street, Dublin.

LAWES' WHEAT MANURE, for AUTUMN SOWING, now ready for delivery. All other Manures and Cakes as per Price List, supplied lowest terms. Apply for prices, &c., to JOHN BENNETT & CO., 59, Mark Lane, London, E.C.; Dublin, and Shrewsbury.

THE LONDON MANURE CO. (ESTABLISHED 1840) Have now ready for delivery, in fine condition, CORN MANURE, for Spring Use DISSOLVED BONES, for Dressing Pasture Land SUPERPHOSPHATES of LIME PREPARED GUANO MANGEL and POTATO MANURES. Also Genuine PERUVIAN GUANO, and NITRATE of Soda, ex Dock Warehouse; SULPHATE of AMMONIA, E. P. ROSS, & SALT, &c. Offices, 116, Fenchurch Street, E.C.

Wheat DOWN'S FARMER'S FRIEND for PREVENTING Smut in Wheat, and the Ravages of the Smut, Green Worm, A 6d. packet is sufficient for six Bushels of wheat, which can be dressed and fit to sow in a quarter of an acre. Testimonials from the largest Wheat Growers in the Kingdom bearing testimony to its great power and efficiency. Agents, who are appointed for every district. Full directions for use are given with each packet. Prepared at the Manufactory, Woburn, Beds. CAUTION—To guard against fraudulent imitation and disappointment, see that the signature of HENRY DOWN is on the label. Agents in every Town throughout England, Scotland, and

Lilium auratum.

W^M PAUL has to offer a magnificent lot of the above, Dutch-grown roots, at 2s 6d, 2s 6d, and 1s. each, 24s, 36s, and 50s per dozen—a few extra large roots, 7s 6d each. The usual discount if the Trade off the dozen rates when ordered by the dozen. PAUL'S Nurseries, Watlington Cross, London, N.

Lilium auratum.—To the Trade and Others

HOOVER AND CO. expect to receive very fine Bulbs of the above, via the New Pacific Railway, due about January next. They are collected by a Person thoroughly acquainted with their requirements, and will doubtless arrive in the best condition. They will be in London in about 55 to 60 days from their native soil. Orders now booked, and persons requiring them will oblige by sending their orders without delay. Prices on application. HOOVER AND CO., Covent Garden, London, W.C.

British Fern Catalogue.

ROBERT SIM will send, post free for six postage stamps, Part I (British Ferns and their varieties, 34 pages, including prices of Hardy Exotic Ferns) of his PRICED DESCRIPTIVE CATALOGUE OF BRITISH AND EXOTIC FERNS, No. 7. Foot's Cray Nursery, Sidcup Hill, Kent.

New Japanese and other Chrysanthemums.

JOHN SALTER AND SON beg to announce that the CHRYSANTHEMUMS are unusually fine this season. Their large collection, NOW IN BLOOM in the Winter Garden, may be seen throughout the months of November and December, every day except Sunday. Admission free. Verschoor's Nursery, Whitehall Street, Vale Place, Hammersmith, W (near Kensington Railway Bridge).

Chrysanthemums.

ADAM FORSYTH begs to inform his Friends and the Public that his Specimen and other CHRYSANTHEMUMS are unusually fine this season, and may be seen every day (Sundays excepted). A visit is respectfully solicited. Brunswick Nursery, Stoke Newington, N.

The Gardeners' Chronicle.

SATURDAY, NOVEMBER 20, 1869.

A REPORT to the Council of the Royal Horticultural Society "On the FOREST EDUCATION on the Continent and in England respectively," from the pen of Mr. ANDREW MURRAY, is before us. Mr. MURRAY, it appears, availed himself of the opportunity afforded him by his recent visit to St. Petersburg, to inquire into the working of the forest schools in Germany and in Russia. The inquiry was made with special reference to the question, whether it be advisable or no to send candidates for forest appointments in India, to pursue the greater portion of their education in Germany or France. It may be remembered that in our remarks on this matter, when the regulations sanctioned by the India Board were under discussion, we stated that in the forest schools of the Continent there was an organisation for teaching forestry such as does not exist in this country at present. Moreover, we alluded to the much larger area of the Continental forests, and also to the system followed in their management, which is more akin to that adopted in India, than is that acted on generally in this country.

Mr. MURRAY, we find, questions some of our remarks. He contends that the German forest schools do not offer greater facilities than are to be met with here. Now, as we have at present positively no organisation whatever for the purpose, it is difficult to admit the correctness of Mr. MURRAY'S conclusions. Again, Mr. MURRAY doubts the eminence of the teachers in the forest schools, unless in the case of some particular men. Whether this be so or no, what we may term forest literature—the treatises on the management of the woods in France, Belgium, and Germany, the splendid monographs on the insects and Fungi destructive to woods—monographs, to compare with which we have few or none at all in this country, are sufficient to show what was our main object—that the organisation for teaching on the Continent is far superior to anything we possess. Nor did we write solely from paper knowledge. We had documents before us giving the *resumé* of studies pursued in the varied establishments; but more than this, our remarks were based upon considerable personal observation and experience of the practical working of these institutions, and on a knowledge of the existing state of things in India. We mention these things, as it were, in self-defence, and with no intention of carping at Mr. MURRAY'S report, which is, to our thinking, a valuable one, and one calculated to do good service. Moreover, Mr. MURRAY'S views and our own entirely coincide upon one point—after all, the most important one—that it is by no means essential, or even desirable, that the candidates for forest appointments in India should pass any lengthened time in Germany or France, if proper educational provision be made here. There is no reason whatever why not only a complete initiation into the principles of forestry science, and the numerous collateral subjects connected with it, but also a thorough training in the practical duties of a forest officer, should not be insured in this country. We have every facility for the purpose, if our resources were but organised and

utilised. We have no lack of men able and willing to teach surveying, mensuration, vegetable physiology, and the various sciences which can be taught in the class-room or laboratory. We are by no means deficient in shrewd experienced craftsmen. We have at home a now somewhat numerous body of officers who have been connected with the forest department in India, who know its requirements, and are competent to carry out measures to supply them. We have also, as Mr. MURRAY shows, an area of forest ample for all purposes of teaching, and we have, too, in our limited space, a much greater diversity of timber than is to be met with in a much larger area on the Continent. The system followed in the Oak woods of the Weald, is of course unlike that required in the Pine woods and Larch plantations of Scotland. Surely a man who, as the result of practical training, can get the best results out of his woods, whether in the shape of Hop poles, charcoal, Oak bark, loppings, timber, or what not, can be trusted to regulate the cutting of Indian forests. Such a man, while securing a due supply of sleepers for railways, or Teak for ship timber, will take care that the reckless and wanton mismanagement which has prevailed so frightfully in India in former years, shall have no place in the future.

We have the teaching both of the theory and the practice to our hands; we have ample materials for practical demonstration and experiment: by all means let us have the organisation, let us have a forest-school—a regularly ordered institute, which shall not interfere with the private tuition that we have now, but shall lead up to it, and ensure a better and more instructed class of pupils, and extend the scope of the teaching powers of the forester, at the same time that it quickens and concentrates them.

As it is now, while giving all praise to the practical acquirements of the majority of our foresters, we cannot overlook that too many of them are woefully deficient in any scientific knowledge. Many of them have, indeed, scarcely any knowledge whatever of trees, other than those with which they come daily into contact. Some of our best practical foresters, rambling through an arboretum, containing specimens of high promise as timber trees, would find it difficult to attach the right names to the trees they saw, if they did not happen to have similar ones growing under their own observation. How many foresters of experience could even tell the Douglas Fir? And, yet, these are the only men we have at present who can act as instructors in forestry. Under these circumstances it is no wonder the authorities turned to Germany and France, where at least better provision is made for instruction in forestal matters.

The Indian Forest Service is a profession intended to rank with other learned professions. Those who enter it should be as well trained in general knowledge, and as efficient in practical duties, as those who enter upon other professions of a similar character, such as civil engineering, surveying, and the like. This cannot be expected under our present want of system, but could readily be effected by proper organisation. The Institute of Surveyors has the matter in hand; the Scottish Arboricultural Society will not neglect its duties; the Royal Horticultural Society is alive to the requirements of the case. The establishment of an Arboricultural Committee would help on the cause, and contribute to better the position of the forester. So that we may look forward with confidence to the removal of the present anomalous state of things.

MR. A. W. BENNETT, in the first part of the new weekly scientific periodical, "Nature," has an article in which he shows that in some winter flowering plants, as the Gorse, the Dead Nettles, &c., the pollen is applied to the stigma of the flower while it is still unopened, and thus self-fertilisation is insured under the most favourable circumstances as regards complete protection from the weather and other adverse influences. In the *Chimonanthus præcox*, on the other hand, the stamens cover the pistil completely and discharge their pollen outwardly, so that none can fall on the stigma. As a necessary consequence, the fruit is not formed in this country, for want, at the season of flowering, of the proper insects to effect cross-fertilisation.

We may expect that many analogous observations will be forthcoming now that Mr. DARWIN has called renewed attention to this subject. It is one of great interest, and offers a fine field for observations which will commend themselves

to amateurs from the ease with which they may be made. It would be desirable to ascertain whether, if a plant should happen to flower at different seasons, it is fertilised in the same manner at all times, or whether different climatal conditions are accompanied by corresponding diversities in physiological office. The researches of DARWIN, HILDEBRAND, and others show that the "setting" of a flower by its own pollen (self-fertilisation) is a rarer phenomenon than cross-fertilisation: the cross apparently imparting greater fertility and a greater degree of vigour to the offspring than arise from self-fertilisation. This being so, it becomes a matter of great interest to ascertain how and why it is that so large a contingent of flowers are "set" in the bud, or at least in such a manner that a cross is next to impossible, and self-fertilisation rendered inevitable. We are at present in the dark as to the why and wherefore of this, though it is so frequent an occurrence that there must be some good reason for it.

As any facts bearing on so important a subject are valuable, we may here record the arrangements for securing self-fertilisation in the flower of *Alyxia daphnoides*, a pretty evergreen shrub, with orange-coloured berries, too little known in this country. On examining unopened flower-buds of this plant (now in bloom, the anthers may be seen inclining inwards and downwards in such a manner that the pollen falls on the stigma placed a little beneath them. The tube of the corolla, moreover, is lined with hairs pointing in the same downward direction, as if to direct the pollen to the stigma, which is copiously dusted over with the pollen grains. Clearly self-fertilisation is the rule in this plant; the corolla is so tightly closed that an insect would have very great difficulty in affecting an entrance, unless indeed it were to bore a hole through the side of the tube, as some insects do. DARWIN strongly insists on the great advantages that are likely to accrue from an occasional cross, even where self-fertilisation is the rule. In some instances it is difficult to see how this could be effected save by insects boring into the flower, as we have supposed in the case of the *Alyxia*.

In any case the practical inference to be drawn by gardeners desirous of securing the setting of their Grape blossoms, or other flowers needing artificial assistance, is this, that they should avoid applying the pollen of any given flower to the stigma of the same flower. They should by preference use the pollen of one flower to set the pistil of another. If the two flowers are on two different plants (of the same species or variety, of course, understood) so much the better. If the reader will watch the operations of the bees in his orchard-house next spring, he will see at a glance how the humble-bees unconsciously effect the "cross" of which we have been speaking, and how comparatively rare it is for them to brush off the pollen of one blossom on to the stigma of the same flower. Almost invariably they carry it off to some other flower. Another illustration of the motto, *Nemo sibi vivit*.

— IN the current number of the "Journal of Botany" is a full description and coloured representation of the LARGE ABROID, described originally in our columns by Dr. SEEMANN (see pp. 220, 713). It will be remembered that "Punch" suggested that this plant should be named in honour of Gog and Magog. Dr. SEEMANN has to some extent acted on the suggestion, inasmuch as the specific name given to the plant is "gigas." Generically it forms a new genus of Aroidæ, which the discoverer has named in honour of Mr. GOLWIN, the Editor of the "Builder," a gentleman well known, not only in his professional capacity as an architect, but as the persevering advocate of all measures likely to promote social improvement and refinement. "Godwinia gigas" has been exhibited by Mr. W. BULL before the Royal Horticultural Society, and will no doubt reappear at intervals, to the wonderment of the uninitiated. At some future time we shall probably cite Dr. SEEMANN'S article on the plant at greater length.

— We understand that the Council of the Royal Horticultural Society has resolved on issuing a Bronze Medal, to be called the RARE PLANT MEDAL, and to be awarded at any of the Society'S meetings, for the first exhibition in this country of plants of great botanical interest.

New Plants.

MOERMODES UNCLIA, *Rehb. fil.*, *supra*, p. 891. This species having flowered with W. Wilson Saunders, Esq., has just been published in the "Botanical Magazine," t. 5892, and named a second time, by an oversight, *Mormodes Greenii*. We are very sorry that the name, so justly deserved by Mr. Green, must give way for that of a Pardale (the Persian Uncial), a short diagnosis given by us is absolutely sufficient

complete, adding also the chief character of the callosity on the anterior disc of the lip.

If we are rightly informed, there was an impression at the meeting of the Royal Horticultural Society, when Mr. Saunders exhibited his plant, that it formed a connecting link between Mormodes and Cynoches. That is not the case. All the species of Cynoches have spherical pollinaria, all those of Mormodes have these organs ligulate, depressed, flat on the outside. H. G. Rehb. fil.

SELENIPEDIUM LONGIFOLIUM, Rehb. fil. Wawz.

Folius latius ligulatis apice attenuatis; pedunculo bene exserto pilis parvis demum deciduis pilosulis, subcalvo, apice rase moso, bracteis heliconiacis, ovaris subcalvis (scu non velutinis, sed parvis pilis nantissimis hinc sparatis pilosulis), sepalo superiori oblongo triangulo obtuse acuto crispulo, sepalo inferiori duplo latiori oblongo labellum excedente; petalis a lata basi canatis subpatulis, tritis, apice velutinis, labelli unguis emphatis lunbo aspidatis, sacci lunbo antico retusum; staminibus late triangulo (subtriangulo), limbis p...

Rehb. fil. Wawz. in v. Mold and v. Selt. Hb. Bot. Zeitung, 1852, 690! Selenipedium longifolium, Rehb. fil. Wawz. in Rehb. fil. Xenia, l. p. 3; Rehb. Beitr. Orch. Central Am. p. 44! Selenipedium Reichenbachii, Enderes, in litt. Cyripedium Reichenbachii, Enderes, in hortis.

When we first described this plant we had very bad materials—a broken leaf, pieces of three or four inflorescences, disarticulated floral organs, and a very poor sketch that would have done honour to the phantasy of modern artists. For all that, we had to thank our late friend, J. von Warszewicz, who discovered the plant in the Cordilleras of Chiriqui, at from 5000 to 8000 feet elevation. Much later, in 1867, we obtained an accurate sketch, and a very faithful description of Selenipedium Reichenbachii, from M. Enderes, who re-discovered the plant in a very inaccessible place. Next came Mr. W. Bull's Catalogue, No. 48, where, at p. 4, is a very tempting popular description of the plant. It being there named Cyripedium Reichenbachii, we may be entitled to protest against calling that black velvety back border of the staminode a moustache, for we have a better idea of that male ornament. The comparison with an elderly, ill-used old horse-brush, would perhaps have been better! We may add, that the tubercles standing right and left of the column, observed before, and noted in a very similar description of the Cyripedium carneum (or Selenipedium Pearcei) in a certain periodical, would form a very nice addition to vegetable morphology in general, and to Cyripedology in particular, if they were not those organs which botanists call anthers. Finally, the large callosity observed in the same poor C. carneum, is what we call the stigma. Excuse these morphological trifles! The Gardeners' Chronicle told us recently of the appearance of the plant at South Kensington; Messrs. Veitch inform us of its flowering with them; and we have now at hand a flower and a sketch of a leaf kindly sent from the Royal Horticultural Society's Garden, we believe, by Mr. Eyles.

The flowers remind one very much of Selenipedium dariense, Rehb. fil. in Act. Leop. Cyripedium Hartwegii, Rehb. fil. in Seemann Herald, xlv.), a very interesting earlier discovery of Dr. B. Seemann's in Darien. It is easily distinguished by the two angles at the inner base of the channelled claw or unguis of the lip. Selenipedium Hartwegii stands even nearer, yet it appears to be very distinct, by its much larger and longer bracts, by an open channel of the unguis of the lip, and by some discrepancies in the lip. The other Selenipedia, with gibbous hollows on the sides of the lip, are Czerwiakowianum and Boissierianum. Our plant appears to have the habit of the old Selenipedium caudatum. The peduncle is very curious, as far as we can ascertain from dried specimens, on account of the deciduous hairs. The inflorescence has bracts very much like those of Heliconias. The flowers are greenish, very shining outside. The dorsal sepal is nearly oblong-triangular, with a brownish border. The inferior sepal is much broader and longer, or even quite as long as the lip. The petals have a broad, subcordate base, and taper into a tail, greenish, with white borders, and two brown streaks at the base, and brown at the ends—these tails being much shorter than those of the well-known long-tailed species. The lip is highly curious for the basilar margins of the unguis overlapping one another, so that there is no channel left. The side gibbous hollows stand over the pouch of the lip. It is whitish internally, with many small purplish dots. The edges of the unguis are yellowish-green, with many inconspicuous small brownish spots. The anterior part of the sac is olive-green, with a slight brownish hue, the superior border green. The trilobular ovary is port-wine coloured, with very small and inconspicuous scattered white hairs.

It rather appears (as M. Enderes kindly informed us), that but one flower opens at once. For men of science that is a characteristic feature; for amateurs it is an interesting fact. We may, however, expect to see one day or another an artistical caricature, bearing perhaps half-a-dozen open flowers at once on the same flower-stalk. Trahit sua quemque voluptas! H. G. Rehb. fil.

DENDROBIUM SUPERBUM ["MACROPHYLLUM"] VELUTINUM.

Petalis valde hastatis, labelli tenuissimis velutinis, mento obtusissimis.

This very pretty variety has been introduced by Messrs. Veitch, who have twice kindly sent us supplies of it, so that these gentlemen would appear to flower it very freely. It is rather different from the old and not uncommon type. The mentum is singularly blunt and large. Both sepals and petals are light rosy purple. The lip bears two large dark violet-purple spots, as also two smaller ones on the base. The very hastate base of the petals is striking. The profusion of hairs on the lip is extremely rich, and gives the effect of some modern hairy winter dress or the natural cover

of an ice-bear. It comes from the Moluccas, and will form a good addition to the already numerous varieties of this fine Dendrobe. H. G. Rehb. fil.

DENDROBIUM SUPERBUM ["MACROPHYLLUM"] HUTTONI.

Perigonio candido, labelli disco ac ungue purpureis

A very striking novelty. The flowers are clear white. The disc of the lip bears two beautiful purplish blotches, and its base is of the same colour. For this beautiful thing we have to thank Messrs. Veitch, who obtained it through their late excellent collector, Mr. Hutton, from the Malayan Archipelago. H. G. Rehb. fil.

AMERICAN POTATOS.

In the spring of the year I received from the Editors of the Gardeners' Chronicle the following Potatos for trial—the Early Rose, Bresee's No. 1, Bresee's Prolific, and Chmax. Through Mr. Shirley Hibberd, I received, from Mr. Bliss, of New York, No. 1, No. 4, the King of the Earlies, No. F, No. 5, and also more tubers of the Early Rose and Bresee's Prolific. The specimens of both lots were very fine. The first lot was planted tolerably early, and the last, which arrived on June 4, was planted June 5, and was dug up October 15.

My opinion of the Early Rose is the same exactly as that expressed by the Editors. I gave a tuber or two to the Rev. Robert Price, Rector of Clui Okesford, to plant. He showed me two tubers taken from one plant, which were the finest kidney Potatos I ever saw, and beautifully shaped. I asked him to dress them, and report to me. He said they were below at the core, and not good. This was the only kidney sent to me. The others were of the line of round. I tasted several times the sorts sent, but they were not good enough for me. With the exception of a few of the Early Rose, which I shall try again, I gave them to "Steevie" to take to the dry enaly son of Rushton, where I think they will be very valuable for cottagers. They had all here the same great fault—they were not dry enough, and their colour was, except the Early Rose, of a dull white. When cooked by steam their flesh was soft and flavourless. Still I admired the Potatos much, and the raisers deserve great credit for the following excellencies—the finest foliage I ever saw (some of the leaves were 6 inches by 5), great croppers, of large size, very handsome, very white in flesh, and very fine in the grain. I never saw finer Potatos than No. 5 and No. F, still, when cooked by steam, they were soft and not good flavoured.

Dryness and firmness, combined with mealiness, are essential to a first-class Potato. The best of all the trial Potatos sent here, for quality and flavour, was Mr. Barron's Perfection. I shall plant it again. It is worth a trial. As the last lot was planted so late as June 5, it is no wonder that some of the tubers were diseased. I received from Mrs. Allen, of Shepton Mallet, the great Callao and Gleeson's Late, probably the same as Zebra. Neither are good enough for me. The last was not ripe till the first week in November, and hence was diseased. I have made up my mind to get rid of all late ripening Potatos, and I advise my readers to do the same. Two parts out of three of the late ripeners have perished already. The national wealth has been robbed to that amount, and domestic comfort has suffered in the same ratio.

The most valuable Potatos in England, so far as I have had experience, are the Royal Ashleaf, Hero, and Taylor's Hybrid. The last is not to be had; but the two former may be procured. The reason why Hero and Taylor's Hybrid are so valuable is, that they are great croppers, of first quality, come out early to escape disasters, and keep till the end of the season. If you keep three Potatos, buy these—Royal Ashleaf, Gryffe Castle, and Hero; they will carry you from June to June. Do not be led away with great croppers, and huge Potatos. There is, I am sorry to see, both as regards fruits and vegetables, a vulgar predilection for something huge or abundant, without the least reference to quality and flavour. You will find Turner's Gem Melon better far than those huge exhibition flavourless Melons!

I said in my last article that the Lapstone is apt to grow out early and supertuberate. Mr. Rivers in his letter complains that his have done so. He has sent for Hero, which he shall have. It ripens here a fortnight, three weeks, and sometimes a month before the Lapstone. Hence its great value. With your eyes closed you would not know it from the Lapstone, from which it was raised.

Till I have tried the Bryanston Kidney, I shall not say more on the subject of Potatos. I have read with pleasure and attention Mr. Dean's article. The difficulty lies here in 120 Potatos, in sorts, were planted at Chiswick, it would hardly be a trial for other soils and situations. I should like to see them tried (and also cooked) in clay soil, brown loam, chalky soil, and sandy soil. I should crown king that Potato which suited most of these conditions for seven years. I have had Hero and Taylor's Hybrid above seven years; and I never knew them go astray at any time. H. G. Radcliffe, Nov. 15.

THE ALOE.

(Abstract of a Paper read before the Scientific Committee of the Royal Horticultural Society.)

In the cultivation of Aloes it is as well to bear in mind that they grow equally well with or without roots. There is scarcely any perceptible difference in the time required for re-establishment, between an Aloe carefully dug out of the ground with all its roots, and a rootless branch that has been broken or chopped off; both are at times liable to damp off or decay at the root.

Aloes are found growing in all kinds of soil,—rich alluvial soil, leaf-mould, red clay, yellow clay, hard

limestone soil, brash soil, sandy soil,—in fact, in its Aloe or Aloes, provided always that it is rocky as far as my observation extends, they do not seem to thrive for any length of time if they are planted in such localities. I attribute the great mortality in garden Aloes to this fact; it is not because the soil is unsuitable, for, as I have before stated, they will grow in almost any description of soil, if it be rocky.

I would therefore advise all who wish to cultivate their plants successfully, in the first place to choose a moderate-sized hole—say, from 1 foot to 3 feet in length, and breadth (according to the size of the men they are intending to plant); fill this hole with rocks, allowing some of them to project above the ground (these should, if possible, be ornamentally shaped); plant the Aloe amongst the rocks, fixing it in an upright position until it is found to stand on its own; then fill up the interstices with soil—any moist good soil will answer the purpose. Do not be too liberal in the supply of water, especially at first, if the soil is moist, the Aloe will require no water at all.

After some time has elapsed, if the plant is to be looking red and unhealthy, its root should be examined, for it may have decayed; and if this is the case it should be taken up again, and the decayed part carefully removed or cut away, until you arrive at the sound and healthy part of the stem. The Aloe should then be placed in the sun for several days (if the men are large and succulent, for several weeks), and hidden before it is again put into the soil. Do not follow that the plant should be watered because it has decayed at the root, for Aloe will plant again and again, even until severely decayed, always taking the same precautionary measures.

Moreover it will be found that Aloes will recover from decay at the heart, or from that portion of the stem from whence spring the young growing leaves. It may be from two causes, viz. water lodging among the too crowded leaves, or the larva of some insect that feeds upon that portion of the plant. In this case the affected should have the greater portion of leaves removed, and the diseased parts cut away; the wound carefully washed and dried, after which will soon be found that the plant will recover, and grow again from the centre or shoot from the side.

Aloes should not be watered often nor at intervals, for the climate of South Africa is extremely variable, and subjected to great vicissitudes; in their wild state they are unaccustomed to a regular supply of water. They endure long periods of severe drought, a burning summer sun, or a strong north wind, and again, at other seasons, are deluged with torrents of rain, for such is the nature of the climate they inhabit; but from the compactness of their leaves and roots, there is no succulent matter enabled to endure these great changes. The Aloe, for in rainy seasons they extend every branch with moisture, and this supply is stored away, to be absorbed by degrees, in the drought and severity, according to the requirements of the plant; and from this store of moisture the blossoms and seeds are frequently supplied with nourishment, which supply is obtained from the succulent leaves of the plant, which then become attenuated.

Aloes should never be pruned or trimmed away whatever. The old leaves which accumulate at the base of the growing stem, and if left to themselves form an oval-shaped mass of grey and hoary-looking foliage, which forms an excellent contrast with the green leaves above, giving the Aloe its peculiar picturesque appearance. Moreover, the removal of this mass of old leaves frequently results in the decay of the plant, which is much to be regretted.

Many of the dwarf species of Aloes are much more rare within the colony than they were, for I am sorry to state that Aloes, like other succulent plants, are fast disappearing within the boundary of the colony. The sheep and goats for this country what the goats did for St. Helena, rapidly altering the nature of its flora and lands, and causing many plants to disappear through their destructive ravages, for in severe winters when there is a scarcity of grass, these animals have the habit of browsing upon succulent plants, and the bitter leaves of the Aloes are eaten with avidity. M. E. Barber. Communicated by Dr. Hooker.

CHURCH DECORATION.

It has been suggested to the country clergyman that he might be assisted in his church decoration by the use of the Holly, which is a native plant, and which may be used in a variety of ways. We applied to Mr. H. G. Rehb. for his taste in church decoration, and he has kindly furnished us with some notes on the subject, and which we shall publish from time to time, and these our long and candid notice to other nations, and anything but to our own people only; for we are convinced that every country should use such plants as they shall think best to the setting forth of their religion, and to the raising of the people to a perfect and gloriously living, with it or without it.

PERHAPS the simplest style of decoration is that with in those village churches where the church is decorated with a garland in the top of the door which divide pew from pew, and sticks in the top of Holly some 6 inches high, with a few red berries on it. The next step in advance is found in the use of small bushy pieces of the partitioning Holly in the ornamentation of the partitioning, and so on, through Arbor-vitae, and other plants, to Camellias, immortelles, exotic Fern fronds, and amazonica, and Passiflora corulea. In the use of all the different kinds of plants

for the same reason commonly laid under tribute, there is one important rule that is not sufficiently attended to generally, and it applies with greater force to churches than to any other places. It is, that the most agreeable general effect occurs where there is the least variety in the flowers, and when the display of foliage is in the proportion of three or four to one of the flowers or fruit. Whenever any combinations are employed the greatest care should be used to avoid vulgar, glaring effects. Soft, subdued tones of colouring should always be the aim of the church decorator.

As to wall decorations, so with designs. In our opinion, a church wall, covered with a museum-like collection of symbolic designs, artfully wrought in flowers and leaves, is not in good taste. A selection of two suitable designs, and their repetition alternately all round the church, will always have a better effect, not to mention the advisability of varying the form of the designs upon different occasions, in preference to the display of them all upon any one occasion.

One of the reasons why church decorations are so often displeasing arises from inattention to the latter part of the Apostolic injunction to the Corinthians, to do everything "decently and in order," or (as another translation renders it) "in a seemly and due order." All large and striking, if they are to be executed "in order," must require a considerable exercise of forethought and judgment. It is too often the case that flowers and other objects are collected almost haphazardly at the last hour, that the workers have neither thought, nor have they been told beforehand what is to be done, and that each does something as his taste or fancy directs, the natural result of which is a medley of ornaments, a display more curious than pleasing.

Another reason is, that there is so frequently no competent person to be found, possessing the ability to design, the influence and social position to direct, and the inclination to undertake the responsibility of superintending, the decoration of a church; for it is useless to attempt to ignore or deny the fact, that *quod homines, sed sententia*—many men, many minds; or, as Cicero still more pointedly puts it, *quod homines, sed causa*. The most pleasing effects invariably proceed from the orderly and systematic workings of many willing hands under the direction of one experienced head, and where any one member of a congregation has displayed such qualifications in the decorations of his or her own rooms, it would be well for the rest to resolve upon giving him or her at least one trial as their acknowledged chief for the occasion, in the decoration of their place of worship, and if he or she succeeds, to retain the chieftainship until a better can be found.

It must have occurred to many as a somewhat curious circumstance that architects rarely if ever make any provision, in their designs for churches, for floral decoration. For instance, at certain distances up the aisles and elsewhere there might easily be arrangements for placing removable octagonal flower-pots, made of the same wood as the pews, and lined with zinc, which might either hold a bouquet of flowers, or a dwarf plant of *Camellia* in bloom, or a pot of some elegant Grass. The same contrivances might be permanently fixed (if ornamentally executed), at the foot of the pillars of the church, and be used for pot-plants of climbers, such as the *Passion-flowers*, *Lapageria*, &c. Again, in the carving which so often surrounds a font, it would be so easy to provide for the occasional insertion of glass or zinc tubes of water, for keeping choice flowers from drooping, as they too frequently do.

Residents in the country who have good gardens, and still more those who are fortunate enough to possess conservatories, might do much for church decoration, by growing plants especially for that purpose. And while no person might care to grow enough of any one plant for the purpose, lest it might make his garden too much like that of a nurseryman, yet by a combination amongst several parishioners to grow each a few of that particular plant, an ample supply of it might be provided upon the special occasion when it was intended to use it. Many, too, who have no greenhouse may nevertheless be able to assist by growing such tender shrubs as *Myrtle*, *Oleander*, &c., which do well in rooms and well lighted halls.

Uniformity in the size of the flower-pots that are used for each kind of plant may seem to be a trifling matter, but is, nevertheless, one that would well repay a little attention to it. Where pot plants are to be used in rows, it looks very badly to see different-sized pots, besides which, uniformity in size of pots is more likely than anything else to ensure uniformity in the size of the plants when fit for use.

As most of the principal festivals of the Church of England occur during the coldest months of the year, it will be advisable to be prepared with some form of "seaman chair" or covered hand-barrow, in which to move the plants to and from the church. This will afford necessary protection, not only against frost, but also against easterly wind, scorching sun, or heavy show or rain, either of which might injure the blooms, if not the foliage, of many a plant.

Plants intended to be used again should not be kept in churches for a longer time than can be helped, for though some will stand changes of temperature without injury, others are much more susceptible on this point.

Gas in churches is likely to be very prejudicial to plants, unless great care be used. Not only must they be kept for as short a time as possible in places where gas is used, but the persons in charge of the gas should be cautioned about the manner in which they light it, for it is a too common practice with such people to turn on all the jets at once by a link at the main, and then to walk leisurely round the church each jet separately, a proceeding which not necessarily all will allow, though perhaps not an excessively dangerous quantity of gas to escape to the discomfort of the congregation and the injury of all flowers and foliage, whether cut or growing. Every gas-burner should be turned on and lighted before the next one is turned on, and where, as in some cases, this cannot be done because several jets are turned on and off by one cock, then two or more persons should be employed to light simultaneously, so as to reduce to a minimum the escape of unconsumed gas. Again, after a service at which gas-lights have been used, it is important to clear out the foul air and the heated products of combustion, before shutting up the church for the night, if the plants are to be left there. Much care is necessary in doing this on a frosty night, or the plants will take as much injury from the cold as they would have done from the impure air. The object to be attained is a free circulation of air without a draught.

Draughts are equally injurious to plants as they are to human beings who are not used to them. And, as invalids are sure to avoid seats near the entrance, so stove and greenhouse plants should have positions allotted to them where they will be free from such prejudicial influences.

These remarks, although made with reference to growing plants, apply with equal force to cut flowers and evergreens, which, by attention to them, can be made to keep much fresher than would otherwise be the case. *H. T.*

BOTTOM HEAT.

(A Paper read at the Manchester Congress.)

As a nurseryman, I have found bottom-heat to be of the greatest use for all kinds of propagation, not only for stove, but even for hardy plants, a great many cuttings of which cannot be made to root without it. The

best material for producing bottom-heat for this purpose, and for forwarding young plants after they have been potted off is tan. It retains its heating power for a long time, and gives out just such a genial, moist heat as all kinds of young plants, cuttings, and Orchids like. To keep up this genial heat, it is necessary to turn over the beds every six weeks or so, and add a little fresh tan at each turning.

The next best materials to tan are properly prepared dung and leaves, but they require so much management, and the heat is so changeable, that they are only adapted for a few plants, and require the exercise of great care. I now come to bottom-heat for large subjects, and for those growing in borders, such as tropical plants, Vines, &c., and it is in their case, when the heat has not been properly applied, that the abuse of bottom-heat has been seen.

There has been a good deal of controversy lately about growing early Grapes without bottom-heat. Now, I maintain that you cannot strike cuttings of the Vine without it, neither can you grow good early pot Vines without it. Then why should Vines planted out in borders dislike it? My opinion is that they do not, while for forcing Vines year after year, very early, it is positively wanted, otherwise the Vines will wear themselves out. My experience tells me that it is from the want of sufficient water that mischief arises from the use of bottom-heat. I have been a victim from this very cause, for it is scarcely possible to make men of ordinary practice believe the quantity of water that is required to supply a border where there is bottom-heat, and in which the plants are planted out. I now adopt the plan of measuring the water. I maintain that plants indoors, and especially since the heat is greater, require quite as much water as those out-of-doors, therefore, I give them 24 inches per annum, or about 12 gallons to the square foot, giving the greatest quantity when the Vines are in a growing state. I do not say that even this would insure safety with badly applied bottom-heat, such as from hot-water pipes amongst the drainage or in the border. These would be failures, for as regards extremes of heat, cold, and dryness, we should be at the mercy of the stoker and waterer. In applying bottom-heat to borders, it should be perfectly under control, and capable of being conveyed to the roots of

plants at will, and by such a method that the heating medium can be extended by means of any distance. I have paid a good deal of attention to this subject and I think the perfect method of growing early Grapes would be one built after the plan shown. It should have a span of 18 feet or more with walls on the outer walls so as to extend the borders 18 feet from the inside when wanted and also to let out the bottom-heat to the outer border, in fact to extend the roots to any distance. From the centre of the border, a, extending the whole length of the border to the upper part of the border, to let up the heat from the arch as quickly as possible to the chambers to be conveyed into the earthenware or cast-iron distributing pipes, &c., which should be laid quite level otherwise the heat will not be regular. These pipes I recommend to be placed at intervals of 2 feet apart throughout the length of the house, on a concrete bottom, with 12 inches of brick rubbish over them. I have a great opinion of a rating order for forcing plants, in fact, for all kinds of plants, therefore in a house 50 or 60 feet long, I put three pipes on each side of the house D, in communication with the heating chambers, so that in winter air can pass from the inside of the house amongst the roots of the plants, and when the borders are formed, outside provision can be made so that in summer they can be cooled from the outside. I think that with provision like this for bottom heat, air, and water, will stand hard to most of failures in forcing early Grapes. *J. H. Smith, Royal Nurseries, &c.* The publication of this paper has been unavoidably delayed. *L. S.*

SPRING BEDDING PLANTS.—No. I

SPRING bedding can be carried on at a very trifling expense every year, for after having once procured the plants to begin with, there will be but little trouble to perpetuate the stock for future supply. No expensive houses are required to protect them from the frost, all the subjects being hardy, and proof against the various vicissitudes of our fickle climate. There are, besides, many plants of great merit not adapted for bedding purposes in a general way, but which, on account of their beauty, must not be discarded, but a home found for them in the border, where they will be equally attractive. First and foremost among these border plants must be mentioned the Hepaticas, as they are among the first harbingers of spring. There are many varieties, pink, blue, red, and white, both single and double, as well as a very large flowered species from Transylvania called *angulosa*. The only rule necessary to grow these is to plant them in a sunny place, if possible, where they are partially shaded in the summer but not in the winter, and then leave them alone. Follow this rule, and you will have each succeeding year some of the most charming masses imaginable.

The double-flowered Primroses and Polyanthus stand next, as they flower about the same time, and will succeed in a similar situation to the Hepaticas. If any difference is made as to treatment, give them plenty of manure. There is almost every shade of colour to be found among them, and their lively masses of green, studded with large flowers, will amply repay care in their cultivation. There is a Hibernian species, too, of great merit, viz. *Primula concolor*, it is in the way of *P. denticulata*, but much more robust in growth. It throws up in February and March large heads of lavender-coloured flowers, from 9 to 12 inches in height, grows vigorously in the open border, and when once known will surely become a great favourite. *P. cortusoides* is another species adapted for the border; its rose-coloured flowers are produced in great abundance, and, if planted in a damp shady situation, it will continue to bloom at intervals during the whole of the summer. Most of the other Primulas require more care than can be given in the open border; therefore they should be placed upon the rock-work. Before leaving the Primulas I must mention the *Dodecatheon* or American Crayfish, they are very interesting plants and remain in flower a long time. *D. Menziesii* and its variety, and *D. droysii*, are the best.

Dielytra spectabilis is a gem of the first water, but it requires to be planted in a sheltered spot, or its delicate foliage will get injured by the early frosts. For pot culture it is very valuable. *Orobanchium vernum* is a charming leguminous plant; it forms neat bushes of light green foliage, which is smothered with its purple flowers early in the spring; there is a white-flowered variety, as well as a double-flowered form of both, all of which deserve unlimited cultivation. The old-fashioned double yellow and black *Walflowers* demand notice for spring decoration, the best place to plant them is close against a wall, where they will flower much better than in the open border. *Adonis vernalis*, the "Spring Peacock-eye" is another gem for the borders, its large deep yellow flowers—frequently as large as a five-shilling piece—are produced in great abundance. A strong plant in flower is one of the most dazzling objects a garden can possess.

Then there is the charming little *Scilla cupressifolia*, with its yellow disc-like flowers, which lay on the surface like so many Australian sovereigns fresh from the mint. This should not be planted anywhere near

the winter Aconite (*Eranthis hyemalis*). The latter should by no means be left out of any collection of early flowers. Some people say it becomes a nuisance. Why? because they disturb it, and its small roots get scattered about, and come up all over the garden. It wants planting where it will not be disturbed, and it will soon form a luxuriant mass of great beauty. One of my greatest favourites in the spring is *Trillium grandiflorum*, another is *T. pendulum*. Those who have not got them should procure them without delay, plant them in plenty of peat, and let them alone; the *Rhododendron* bed, however, is the place for them, as their foliage will be slightly protected from the wind.

There are a great many others which I could mention, but space will not permit; however, if the borders are well filled with these, and clumps of such things as *Arabis*, *Alyssum*, *Iberis*, *Saxifraga*, *Aubrieta*, *Phlox*, *Silene*, *Saponaria*, *Gentiana*, *Mycosotis*, and many others which are adapted for bedding purposes, a charming picture will be secured. With such a collection no one would ever think of discarding the perennial border for the sake of the fashionable summer bedding plants of the present day.

Let me now leave the borders, and mention a few things suitable for the beds. Edging plants will first occupy attention, and I will endeavour to adhere as much as possible to those that can be permanently used, and are alike suitable for summer or spring bedding. *Arabis alpina* fol. var. and *A. albida* fol. var. are too well known to need any comment, but too much cannot be said of them for general decorative purposes; they are very attractive the whole of the year, but more especially during the winter and spring months. In planting these I should leave a space between the edging and the grass for the introduction of such things as *Scilla bifolia*, *S. sibirica*, and others. The sky-blue flowers of those just mentioned will form a striking contrast with the rich varied foliage of the *Arabis*. *A. lucida* fol. var. is a beautiful plant, but it will not do in this list of permanent edging plants, as it will not thrive in all situations. *Aubrieta purpurea* fol. var. is another useful subject for edging; it is very uniform in growth and very lively in appearance, and groups well with almost every plant that can be used for spring or summer bedding. *Alyssum saxatile compactum* fol. var. is admirably adapted for edging purposes; it is very vigorous in growth and bold in outline, its variegation is very distinct, and in my opinion it is one of the best hardy variegated plants in cultivation. *Ajuga reptans atropurpurea* is a useful variety of the common Bugle, only much more vigorous in growth; it forms a very uniform mass of deep bronzy purple foliage, and it is a very striking object, especially when grouped with plants of a light pleasing foliage, or even with the variegated form of the common *Ajuga*.

Veronica glauca is another very neat and useful perennial, and deserves extensive cultivation. It forms a close compact mass not more than 2 inches in height, and in colour resembles the well-known *Centaurea*. It is very useful for continuous lines, as it requires no trouble to keep it in its place, and has a very pleasing appearance at all times of the year. *Veronica spicata* fol. var. is another of this class, and very similar in character to the preceding; its foliage is of a dark green colour variegated with yellow. *Pyrethrum Parthenium aureum*, the Golden Feather, must not be neglected in a selection of this character; the pleasing colour of its foliage is very attractive during the winter and spring, and it blends harmoniously with the prevailing colours of the spring garden. There are numerous others which might be mentioned for this purpose, such as the *Bellis aucubifolia*, *Trentham Blue*, *White*, *Yellow*, and *Purple Pansies*, *Sempervivum tectorum*, *Sempervivum californicum*, the incrustated kinds of *Saxifragas*, besides a goodly array of bulbous plants.

All of these which I have mentioned, from their dwarf compact growth and perennial habit, can be planted permanently as we do not depend upon their flower, but upon their rich varied foliage, which remains the same throughout the year. They may also be advantageously used for other positions in the beds, besides that of edging. For instance, take a small circular bed and plant close to the turf *Scilla sibirica*, and then *Aubrieta purpurea* fol. var. which will be considered the edging for the second row, use *Ajuga reptans atropurpurea* for the third row, plant *Arabis albida* fol. var. for the fourth row, plant *Pyrethrum Parthenium aureum* filling up the centre with *Mycosotis sylvatica*, with a few Tulips planted between. By this arrangement you will have a permanent bed, attractive the whole of the year. It will be seen that the plants used for edging must depend entirely upon the taste of the cultivator. In my next paper I will give my ideas upon those plants most suited for bedding, with their propagation, dividing them into sections, viz. those of biennial, and those of perennial duration. *A. J. P., Tottenham*

NERINES.

AMONG that class of plants that generally comes under the category of miscellaneous bulbs, there are none more worthy of attention and cultivation than the Nerines. They are eminently plants for the million—firstly, because of the ease with which they can be cultivated, the little attention in the way of greenhouse accommodation and service required; and secondly and mainly, because of the gorgeous character of the flowers, produced in umbellate heads of the most fascinating character. But unlike some of the plants, because they have an additional claim upon our notice, because their flowers do not spring from ungainly foliage, nor have they an awkward habit to provoke an offensive comparison; on the contrary, the bulbs are handsome, the glaucous foliage is during the time of inflorescence about as perfect, from its freshness and lustre, as foliage could be, and the limited

area of pot room necessary for keeping up such a respectable state of things is somewhat remarkable. An 8-inch pot is sufficient to provide the necessary food for eight bulbs, which do not favour the idea of separation, but held on together, Siamese twin-like, and have reciprocal connections for good or evil. These eight bulbs will each produce a scape, and out of the eight scapes are likely to come no less than 160 flowers, or an average of about 20 flowers to each scape. These grand floral umbels will span from 8 to 10 inches in diameter, according to cultivation. The floral envelop or perianth of most of the so-called species of the genus in question is of the most brilliant orange-scarlet conceivable. Some of the sorts, as *Pothergillii*, for instance, are tinted as if with burnished gold, so that the more brilliant the light the more dazzling is the effect, compelling on the part of even the most stolid sightseer the fullest admiration. The scape grows to about double the length of the foliage, so that nothing intervenes to mar this beautiful production of Nature. The brilliant colours are admirably relieved by the forest of stamens with their conspicuous bundles of white anthers which stand stiff and erect projecting from the respective centres of the flowers, thus heightening the beauty of the flowers. This is no exaggerated picture, but a very faint portrayal of this brilliant Amaryllid. And yet its merits are not generally known. How often do we in the course of our peregrinations note many beautiful things conspicuous by their absence, and this is one of them—a plant, forsooth, that would delight the hearts and flower-proclivities of thousands, within the reach of their pockets and establishments, and yet very few take advantage of the privilege of growing it.

The Guernsey Lily (*Nerine sarniensis*) even although the least conspicuous of the batch, is a grand object, hardy in many parts of the country, but hardy or not, available and plastic in the hands of the cultivator for brightening up "the homes" indoors during the dull months of October and November, showing up grandly against the scowling winds and leaden sky that often prevail. Opining that no more reasonable time could be hit upon, I have ventured to solicit the attention of your readers, asking them to make inquiries in their respective districts if such things can be seen—for now the plants should be in the height of their inflorescence—resting well satisfied that their eyes will be feasted, and I, if not publicly thanked, shall be at least gratefully remembered. I know there is a grand sight of the kind at Mr. Rucker's once a year and if he could be induced to transport a few of his specimens to Kensington, and the public be well advertised of the display it would create a *furor* not second in importance to the Orchidomania of days present, or the Tulipomania of days past.

There are half-a-dozen so-called species that I have grown for years, and with the view of bringing them more particularly under the notice of your readers, I will describe in some measure their characters. I am by no means clear that all those which bear specific names are species; in fact, by the canonical law of botanical nomenclature it is quite clear that the majority are only selected varieties differing so infinitesimally in habit, and chiefly in colour, as to justify the position I have assumed respecting them. I should say, *N. flexuosa*, *N. venusta*, *N. Pothergillii*, and *N. cornuca*, are only forms of one and the same species, and must be referred as varieties to the first-named. In truth the family likeness is very great, not only in respect of inflorescence, but also as to habit, habit of plant, and form of flower, which are not essentially diverse from *N. sarniensis* in either of those named above.

N. undulata, sometimes called *Nerine* or *Amaryllis crispata*, is undoubtedly a distinct species. It yields the smallest bulbs of the family, smaller considerably than those of the Jacobian Lily (*Amaryllis formosissima*), and not much larger than those of the *Atamasca* Lily (*Zephyranthes candidissima*). The bulbs are distinct, being clothed with a profusion of bulb-scales and the narrow ligulate or strap-shaped pale green leaves generally precede the flower scapes. The latter reach to a height of 12 inches, and bear numerous flowers, whose perianth segments are of a wavy or undulating outline, as its cognomen indicates, and of a soft flesh tint. It is much the smallest and least showy of the family, but, nevertheless, a distinct and beautiful object, flowering a month or two later than the *venusta* section.

N. sarniensis is a species having bulbs not much unlike a James' Keeping Onion, covered with brown scales. The foliage of this is handsome, from its shining viridescence, and the flower scapes will grow from 24 to 30 inches, bearing quantities of pale salmon-coloured flowers, the segments of the perianth being recurved at the extremity.

N. cornuca possesses by far the strongest constitution in the family, for the bulbs grow so exuberantly as to dispense with their scaly coating. The scales in the family I am describing are formed by the bases of the annual decaying leaves that envelop the bulb, but so powerful is the constitution of the variety in question that when it dispenses with its annual complement of leaves it retains the rudimentary bases in perfect health, and thus swells much faster into bulk of bulb. The flower scapes are strong, but the number of flowers is not proportionately increased. Individually they are of larger dimensions than in any other sort, but 20 seems to be about the maximum attainable, the colour is a brilliant orange-scarlet, as if the outcome of a fusion between the intensely bright *flexuosa* and the pale *sarniensis*. The reproductive parts of the flower are longer, and look, in comparison with the others, as if too far away from home to present the elegance of their compeers. The foliage is broad, oblong, entire, vigorous, light, and arching, hence sometimes the name of *curvifolia* is ascribed to it, but it is a synonym. Another variety bearing the name of *cornuca*, or rather

of *cornuca major* (for vendors have seldom any more varieties to offer), is tinted with a totally different constitution, but it is, nevertheless, a most distinct variety, evidently several removes off *sarniensis*, being largely over the other hue, and generally coming later into bloom than its more gigantic relations, so much reserved at the extremities, and the whole making altogether a handsome though by no means so showy an umbel.

N. flexuosa has very finely finished bulbs, perfect in outline, and enveloped in a transparent sheath, which is large enough to envelop the bulb, and is so tautened up, to use a nautical phrase, as to appear to be artistically dealt with. The leaves are of a less dark green, and less glaucous, than those described above, and the scapes, as a rule, are in proportion than any of the other sorts. The flowers are composed of a perianth of the most magnificent colouring, being of the most vivid crimson, tinted slightly with orange, immensely attractive, not gaudy, and when in perfection of inflorescence point of form quite the *beau ideal* of a selected Garden bouquet.

N. venusta has bulbs very much like those of *flexuosa* and seems to be a selected seedling of that variety, blended, however, in part of foliage and inflorescence with *Pothergillii*. It is exceedingly early, being among the first to flower. It is an immense border, extending laterally even more than other sorts, although it is the shyest bloomer of the lot. It never throws a scape so tall as other sorts, and may be looked upon as the most elegant of the orange-scarlet varieties.

N. Pothergillii has bulbs in point of form not unlike a fusion of *Hippocrepis* and *flexuosa*. James' Keeping Onion, surrounded with some faintly scarlet. The leaves are scarcely so broad as *flexuosa*, but they are of a beautiful gaudy hue, unlike the rest of the family, and the same tint also envelopes the flower scapes. The umbels present the most perfect outline of the family, the segments of the perianth of each individual being markedly recurved, indeed this is a characteristic of the family. The flowers are of a very pleasing color, the veins, orange-red shade being tinted with burnished gold. This is certainly the most elegant of the group, and grows with the greatest freedom in a mild atmosphere, with minimum amount of shade.

As to the rationale of culture, simplicity is the order of the day. As hinted above, the plants are but hardy, and therefore only sufficient frost to keep out frost is needed. If propagation sixteen blossoming period be desired, a little fire heat to increase house to an intermediate temperature will do very well. A dry, rather than a moist, and a less desirable food for the plants, the beauty of the inflorescence. When the resting period is over, leaf-formation and consolidation must be attended to, in order to ensure a future vigorous growth. Watering must take place until the roots are well advanced that the leaves may not suffer from signs of decay. Then let water be gradually withheld, and see that the bulbs get what is called a "resting" in the sun. Don't breed them, but after they are matured or even when they are young, unless the water pot be used judiciously, the flowers and growth of these bulbs do not winter and spring, and they rest during the portion of the year, and can be stowed in any cool corner at command. A slight watering during the resting period is attended with good effect, but a systematic watering would be decidedly injurious. Far better not to look at them for four months in summer and early autumn, than to force them out of season by injudicious watering. The soil, pot the bulbs as soon as they have done flowering, and keep them in under cover rather than over pots to induce premature inflorescence. Any soil that will grow *Polargonium*, or *Proserpinaca*, whereon fibre is largely incorporated, will grow to perfection.

Home Correspondence.

Deodar—I have observed with surprise Mr. Frost's recommendation in the last *Gardener's Chronicle* the Deodar as a timber tree. "The Deodar," he says, "should now be planted extensively, it is a really grower, and there cannot be a doubt about the utility of the timber." Speaking by the letter, I should be very much disposed to say the same, but in a contrary sense to what he means. The fact is, that a question remains exactly where it was when the Deodar came to be introduced, as to its value as timber. Additional information as has been obtained since its introduction, has not gone to confirm these opinions. But the Deodar, a though tolerably abundant in the country now, has in very few places been planted for timber, and I have heard of no place where it has not yet elapsed to test the endurance of the wood. We are still, therefore, without material to answer the very pertinent inquiry of your correspondent, to whom Mr. Frost replies, and as I think his answer will do harm by misleading those who trust to his experience and well-known skill, I hope you will permit me to enter a caveat against it. The knowledge that those who take an interest in the subject not only entertain hopes of the timber but include the belief that it is inferior, may induce your correspondent to make further inquiry before acting on Mr. Frost's advice. I am only speaking of the quality of the timber, I do not dispute the beauty of the tree, although here it scarcely comes up to its reputation. It is

beauty is in its youth. When older, the Cedar of Lebanon, to my taste, is far finer. Its habit of growth is now well known to be that of the Poplar, and any one who plants it with a view to posterity must look at it by that light, and not by the grace and elegance of its youth. *A M*—The controversy respecting the quality of the timber of the Deodar Cedar, referred to in your last number, was on this wise. At that time a large quantity of seed was imported, and land-owners were urged to plant it largely, on account of the value of its timber. I wrote a letter to the *Gardeners' Chronicle*, expressing a doubt as to whether it were desirable to do this before the quality of the timber, as grown in England, was proved, instancing the different quality of the wood of the Cedar of Lebanon, as grown in its native mountains and in England, and the very various qualities of timber produced in different countries by the Scotch Fir. I was not successful in convincing some of your readers that it required proof in this country, until Dr. Hooker was so kind as to support my view by some much stronger instances of the different qualities of the same tree, when grown under different circumstances, taken from his own experience in India. This was the end of the correspondence on the subject. I am now glad to learn from Mr. Frost that the Deodar is promising to produce valuable timber in England, and I should be very much obliged to Mr. Frost or any other of your correspondents who have experience in the matter, if they would state what are the particular qualities of the timber which the Deodar produces in England, and also what are the differences between the timber (at similar ages) of the Deodar, the Cedar of Lebanon, and the Mount Atlas Cedar, of the three the last appears to be the hardest in constitution, and the Deodar the least so. So far as I have been able to learn, this is so in Yorkshire. It would be very interesting to learn what the comparative value of the timber produced by the three is in places where they all three thrive equally well. *C. W. Strickland*

Fairy Rings.—I remember reading last year in the *Hereford Times* an article of Mr. Lees' on Fungi, but I do not remember that he then advanced the theory of the gyrations of the mole as the cause of the Fairy Rings, although it seems that he does so now. In growing Mushrooms artificially, they generally grow in clusters, and it is customary with some to cut them off with a knife. This is a bad practice, as it causes the roots to rot in the soil, and of course no more Mushrooms will grow there. Instead of cutting them off they should be pulled off by the hand, by which means the roots and top will come out together, leaving a hole in the bed. This hole should be filled with fresh soil, and pressed hard, and Mushrooms will grow again in the same spot. Now, a Fairy Ring commences by a cluster of Fungi in one spot. Why is it that it extends outwards the following year? Simply because the *pabulum* is used up, and the mycelium or spawn extends outwards in search of food for a fresh ring. Mr. Lees' theory is quite opposed to the growth of Fungi, for the furrows made by the gyrations of the mole loosen the soil, and make it quite unfit for the spawn to run in. The best Fairy Rings I ever saw were in strong Warwickshire clay, where the turf was as hard as the turnpike road. I imagine that if, when a Fairy Ring is in full growth, a piece of it, say 15 inches long and broad, was cut out with the spade to a moderate depth, filled in with fresh soil and trodden hard, the spawn would run in this and spoil the ring. Further, I believe that, by digging out the soil, a certain width inside the ring all round, and replacing with fresh soil, trod hard, you could induce the ring to grow inwards as well as outwards, and by following this up bring back the ring to where it originated. I should like to hear what others have to say on this hitherto knotty subject. *W. Hutchison, Moyndu House, Abernavenny.*

Vine Roots.—I should feel greatly obliged if any of your correspondents who are sufficiently versed in the root and branch action of the Vine, and are perfectly conversant with its adaptability to circumstances, could say from whence comes the copious flow of sap that ascends so rapidly in its branches, as a prelude to growth? *J. R.*

Grafting the Grape Vine.—If any of your correspondents who may be interested in this mode of propagation of the Vine, were to look into the *Transactions of the Horticultural Society of London*, they would find an article written, say 14 years ago, on the cuneiform mode of grafting the Vine. I have frequently practised this method successfully, and believe that it can be adopted more usefully than any other system of grafting or so-called budding. The stock as well as the scion should be ripe wood of one year's growth. An eye at the apex of the stock is allowed to grow till it is 2 inches in length. That of the scion should be kept dormant till the time of grafting. To proceed with the operation, the stock should be cleft about 2½ or 3 inches down, paring and tapering off the insides of this cleft with the utmost precision, so that it may splice exactly with the corresponding taper of the scion, but taking care not to have too closely to the base of the shoot at the top of the stock. The scion must then be inserted, and bound moderately firm with a ligature in the usual manner. The incised part should next be covered with soft clay, and the whole, excepting the shoot and the eye of the scion, should be covered with Sphagnum, which must be kept moist. When the shoot at the top of the stock has grown 10 inches, its top should be pinched off, in order that in this condition it may render more effective service to the scion, and as soon as the eye of the latter begins to push, the shoot referred to can be completely cut off. It then follows, if this simple process has been perfectly performed and cared for, that the eye will break boldly, exhibiting the embryo cluster, which in process of time will be developed into a perfect bunch; thus not only proving the

merits of a variety when desirable in one season, but also obtaining a strong cane 15 or 20 feet in length. I have not read the article referred to on this subject, but with these facts before us there seems but narrow space left for wrangling as to priority in budding the Grape Vine. *John Reid, Haigh Hall Gardens.* [The budding of the Vine, as practised by Mr. Stevens, is quite different from all the modes of inserting ripened buds on the stock which have been alluded to, and which are neither more nor less than bud-grafting. The budding process which has excited this discussion consists in taking the bud from the fully developed but still leafy shoot towards autumn, paring it off with the bark and the thinnest possible layer of wood, and inserting this in the stock exactly as in budding Peaches, and differing from Rose-budding only in the non-removal of wood cut with the bud. The bud, thus inserted, forms an union with the stock, but remains dormant till spring, when it starts into growth—exactly as in ordinary budding. *Eds.*]

The Weather in Scotland.—On Martinmas term morning (Nov. 11) I found the minimum thermometer registering out-of-doors, 4 feet above the ground, 15°, with several inches of snow lying on the ground. On the morning of the 10th it had fallen to 28°, with a rising barometer and a somewhat murky atmosphere. Snow fell uninterruptedly for five hours in Lanarkshire, which, as it sometimes does, intensified the cold to the degree recorded above. To find the same parallel of cold I require to look back over regularly recorded temperatures—which, by the way, are as accurately taken as by most other observers—to March 21, 1867. Then the minimum was 14°, and on the 16th of the same month it was 12°. Since that date we have had no severe frosts in Scotland generally. Taking the present month with the view of establishing a fairer parallel of cold, I find that we must go back to 1866, when on the 10th, 19th, and 20th, the following minima are respectively recorded: 19°, 16°, 17°, while if we take the mornings of the 11th, in 1866, 1867, 1868, and 1869, they show the respective minima of 31°, 42°, 24°, and 15°. Hence it will be observed that during last night we had 17° of frost. It would appear, after all, that the influence of the Gulf Stream is not all-potent in rescuing us, at least, from sudden variations of temperature. *J. A.*

Farnham Castle Orchids.—In answer to Professor Reichenbach's query in your last Number respecting *Catasetum saccatum*, I am sorry to say it died soon after flowering in 1853. It was imported, together with many new and interesting species of Orchids, from a savage locality near the head waters of the Marañon, in 1852, by Warszewicz. The cases were six months in reaching the port of embarkation, and upon their arrival in this country the contents were in an indescribable state of rotteness and confusion, consequently many fine things were lost. None of the living plants have changed owners since, that I am aware of, so that they are extremely rare and valuable. I presume the collectors are approaching the same locality from the Peruvian side of the continent, if so, we may expect many novelties. *Brassia Lawrenceana* var. *longissima* is now in bloom here. The lateral sepals measure 10½ inches in length, and from their extremity to the tip of the dorsal one is no less than 16 inches. The plant was Mr. Buller's, and is the same from which the figure in the "Botanical Magazine" was taken. *Cypripedium caudatum* has tails 28 inches in length, and attracts everyone's attention from its quaint and curious appearance. I grow this species in the cool house, but its variety roseum requires more heat. There is also in bloom here a very fine variety of *Cattleya maxima*; the bulbs are about 2 feet high, and the flower-spike is a foot in diameter, with nine fine flowers. The same plant has produced in former years as many as 13 flowers on a single spike, and is certainly a grand species. *J. W. Lawrence, Gr., Farnham Castle.*

Picea Pinsapo.—I fully concur with Mr. Miller's opinion as to the desirability of clearing up so important a matter as far as may be practicable; consequently I have made a re-investigation of the soil in which the *Picea* is growing, but with little material result, excepting that it was found to be in a medium state as to moisture; also that I have subsequently learnt that many years prior to the introduction of this Conifer here, a considerable quantity of other kinds of earth was added to the ground surrounding the spot in which the tree in question is growing, for the purpose of extending the carriage drive, to which the tree is in close proximity; consequently, there may be, as Mr. Miller observes, something of a pernicious character lurking in this foreign addition, such as bits of decayed wood, old roots, &c., either of which would be liable to foster Fungi, and prove mischievous to the roots of the *Picea*. That the healthy roots of trees, and of Conifers especially, are susceptible to Fungus influence, I think it would be a work of supererogation to prove, inasmuch as there are innumerable instances on record of the baneful effects of planting trees on sites where the old roots of pre-existing trees have not been grubbed up; and, if necessary, I could instance two cases in particular at present existent in this neighbourhood, both being Deodar Cedars. See also what "M. J. B." has lately stated in your columns respecting the influence of Fungus spawn, both on the shoots and roots of Conifers, &c. (p. 1181.) In conclusion, allow me to add that I have recently searched amongst some of the roots of the Tulip tree, referred to by me at the same time with the *P. Pinsapo*, but failed to discover anything to lead to the supposition that anything other than the pestilent parasite was the cause of the decay; unless it arose primarily from the roots having come in contact with something pernicious in the soil, when I find it arranged as follows—Top-soil, about 12 inches deep, on a thin layer of red sand, under which is a formation of an obdurate dry, argillaceous marl, into which

the roots do not appear to have penetrated far, but the majority of the roots, both healthy and decayed, appear to ramify in the top soil, chiefly within a dozen yards of the Tulip tree. There is growing under similar conditions a fine and healthy *Sequoia sempervirens*, upwards of 30 feet high, and it exhibits as yet no evidences of ill-health. *Wm. Gardner, The Gardens, Eaton Park, Nov 15*

Arabis or Aubrietia.—The writer of your "Calendar of Operations," referring to the effective arrangement of some flower-beds on the grassy banks of the Round Tower at Windsor, speaks of the employment of a purple *Arabis*. He would much oblige a "Lover of Spring Flowers" by giving the specific name of this very effective *Arabis*. Such a plant has long been sought for by growers of spring flowers, and its acquisition would be hailed with no inconsiderable pleasure. An *Arabis* called *purpurea*, and subsequently "rosea," was sent out a few years since, but its tint of rose is of the slightest. *Arabis blepharophylla* *superba* is really a rose-coloured *Arabis*. Has the general who marshals the flowers on the Castle bank (Peace, perturbed shade of Sir Geoffrey Wyattville!) secured a large stock of this novelty? and is this the *Arabis* referred to? or has your talented writer mistaken *Aubrietia græca*, or *purpurea*, for an *Arabis*? In either or any case, information is sought for by a *Lover of Spring Flowers*

Judging Melons at Edinburgh.—I have to thank Mr. Thomson for having thus far enlightened me on the subject of Melon judging at Edinburgh. I am not aware that the method of judging was either a success or a failure. And certainly the numbers who exhibited on the occasion referred to (many of whom are dissatisfied) can blame the committee of management for adopting a system of judging one season, and changing it the next. Whether right or wrong not to cut the fruit does not seem to be so much the complaint, as cutting them at one show, and leaving them uncut at another. It had been known that colour and smell were to have been the standard of perfection, I believe a very different-looking lot of fruit would have appeared on that exhibition table. It is the exhibitors to whom the greatest amount of credit is due for such fine displays of horticultural skill, and they have a right to be treated with common justice. Surely it is right that they should know what is expected of them. I have heard many of the leading horticulturists in England express themselves freely on the matter, but I never heard one say a word in favour of the method by which the merits of the Melons referred to were decided. It is generally acknowledged that better men as judges could not have been found, but that is no reason why their system of judging should be kept a mystery from supporters of the exhibition. The advertising of the judges was a step in the right direction, and I observe in a contemporary this week some able remarks on the subject. Mr. Thomson's remarks on "dram and pipe" I should suppose are correct, but I, providentially, having avoided both as dangerous companions, cannot make any suggestion on the matter, further than that those who judge should have none of their senses impaired. *J. O.*

Foreign Correspondence.

HORTICULTURE AT CANNES.—The only garden at Cannes which I had time to visit was that of the Duc de Vallombrosa, situated towards the western extremity of the town. The grounds are bounded on one side by the steep rocky bank of a stream, which in time of rain may be copious enough, but which is usually a scanty and ill-favoured rill flowing in a broad stony bed. On entering from the main road by a handsome lodge, a fine broad walk conducts through a tucket of Olive, Acacia and Eucalyptus along a gentle ascent in the direction of the mansion: among these trees, and partially sheltered, by them are some noble specimens of *Musa Ensete*, producing a fine effect with the other vegetation. Diverging to the left is a small collection of Orange trees, near which I must not omit to notice a bower or tent composed of woody climbers, of which *Hexacentris coccinea*, an *Acanthad* from Nepal, just now in full flower, is the most remarkable. Each flower, when pressed, exudes two or three drops of water, having a pure, non-saccharine taste. Near this arbour are specimens of *Musa Cavendishii*, one of which had a few fruits in a half-ripe condition. Here, too, as in many other parts of the grounds, were some noble plants of *Aralia papyrifera*, throwing out great diverging flower-stems, also *Bambusa arundinæa*, which I had not before seen in outdoor cultivation, but which was developing its beauty in a promising manner. Other species of *Bambusa*, tucketed as *B. nana*, *B. laourasi* and *B. lutescens*, are remarkably fine in the neighbourhood of some *jets d'eau*, which the garden is so fortunate as to possess. This reminds me to observe that water—that indispensable condition for vigorous vegetation on this coast—is plentiful in the beautiful grounds of this chateau, entering them at so great an elevation that even the highest terraces obtain a supply.

Near one of the *jets d'eau* of which I have spoken is a specimen of *Eucalyptus globulus*, which M. Opoix, the intelligent *jardinier en chef*, assured me was a seedling of 1863, and which is now a fine tree at least 40 feet in height. There are many other examples in the gardens of this country of the extremely rapid and vigorous growth of this *Eucalyptus*, which is a most valuable addition to the native vegetation, since it supports the drought of summer without suffering. But though it will grow in many situations it develops itself most rapidly in a good, deep, well-drained soil, with a fair allowance of moisture, and some preliminary shelter from other trees. Towering up out of the rounded masses of Olive, it has an admirable effect, which is not a little enhanced by the agreeable rufous tint of its bark. Several other species of this genus in

set apart for the purpose, and, being gaily decorated, had a very cheerful appearance. The proceedings commenced with a dinner at six o'clock, and later on in the evening tea was served. A considerable portion of the time was occupied with vocal and instrumental music by those employed on the establishment. The principals, with members of their families, were present the whole of the evening. The company separated at ten o'clock, highly gratified with the social intercourse enjoyed. Reading Paper.

Coal Plants.—The aspect of the abundant fossil known as Calamites was very different from that of the other plants associated with it, and of any tree in our forests; but it exhibited at that early period of the earth's history the form and appearance of one of our humble marsh plants, the Equisetum, or Horsetail. It had a tall, slender, smooth stem, marked on the lower naked portion with rings of pits from which branches had fallen. The branches were given off at intervals in rings or whorls, and these again branched and re-branched in the same way. The leaves were needle or wedge-shaped, and arranged also in whorls. The fruit was borne at the ends of the branches, and agreed in the most minute particulars with those of the Horsetail. World of Wonders.

Heliotropes as Conservatory Climbers.—In the summer of 1867 I found a plant of *H. peruvianum* had taken possession of a corner in a Peach pit; it grew at a surprising rate all through the summer and winter, and furnished an immense supply of cut flowers. This plant had been accidentally raised from seed, or some small cutting had been inserted between the stonework and soil in the pit. Every gardener knows the value of Heliotrope flowers, both for colour and perfume, in mixed bouquets or for decorative purposes. The plant is now a large bush, and might have been 3 or 4 feet in height had it not been cut in so much for the flowers. Where room can be spared for it, there is no plant that I know of more worthy than the Heliotrope of being planted out either as a climber or bush in the greenhouse or conservatory. The surprising growth and beauty of the plant is never seen when grown in a pot, and when planted out in the open air the winter settles its pretensions before it arrives at any great size. William Tillery, in "Florist and Pomologist."

Obituary.

AT Sydenham Nursery, Kelso, on the 11th inst., Mr. HENRY TAIT, for 36 years nurseryman and seedsman in that town.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

IN connection with plant culture there is a simple practice, which is generally of far greater importance than to most casual observers would seem possible. I refer to the necessity which exists of periodically turning round such plants as are grown in old lean-to and other structures, so that what little sun there is may be advantageously used to the benefit of all sides of the plants alike. Such facts are well known by those who grow the best of our showy New Holland plants into fine specimens, but are often entirely overlooked by less pretentious cultivators. Again, soft-wooded plants and such as are very succulent, form much finer plants in far less time when turned round, say once a week, than others which are left to take care of themselves. Thoughtful and observant cultivators are aware how very much simply shifting a pot plant from one place to another is conducive to drying the ball. Here, then, is a fact confirmatory of the above remark, to say nothing of the good accruing to each plant by a uniform exposure of all its upper parts. If we have the means—and they are within our reach as above shown—of causing the roots to require fresh water a little oftener than is their wont at this dull humid period, we have a powerful incentive to a good onward growth, and should make the most of it. These facts are particularly useful in regard to *Cinerarias*, *Primulas*, and the like, when in full growth. *Poinsettias* are now showing the young bracts, and according to the treatment they receive so in proportion will be their fineness. A nice amount of bottom-heat, and a little weak guano-water applied to the roots will greatly assist them, and should by all means be afforded if possible, together with frequent dampings over-head with a syringe or fine-rosed water-pot.

FORCING HOUSES.

Early forced Vines, whether grown in pots, boxes, or otherwise—such, in fact, as were started late in September, or during the first week of October—should, if proper attention has been paid them, now be pushing into growth. Great care will therefore be necessary not to let the temperature by night exceed a moderate and safe maximum. More harm is likely to accrue to them through inattention to this matter than from most other causes. It is perhaps needless for me to observe, that whilst the heat should never be permitted to fall below temperate (55°), both in regard to Vines and all other subjects which are assuming the young leaf at this period, yet a few degrees above it may be safely admissible. I would therefore fix 58° as being the nearest approach, at such a juncture, to a safe and necessary mean. By day some 12° or 14° rise may be permitted safely by artificial means alone, with a moderate supply of fresh air, with a further increase of 8° to 10° should bright sunshine diffuse its warmth. I repeat, that additional moisture, both directly to the roots, and indirectly in the form of moist vapour for the surface growth, must be afforded constantly in conformity with the rise of the temperature. Gently start the second early Vineries (doubtless the first with some), acting upon the same safe old principles during cold weather. Begin with an artificial tem-

perature of 46° by night, with an increase of 4° or 5° when the external weather is mild and less forced. I have before alluded to the great advantage of having a heap of fermenting materials placed in the house at the starting time; the moderate amount of warm steam which is constantly and uniformly given off tends greatly to soften the canes, which greatly helps them in pushing the buds, or in "breaking," as the operation is styled in gardening phraseology. Independently of what I have already said in regard to outside Vine borders, it may be well to suggest that that of the third house should have a thorough good covering of protecting materials placed upon it to keep out frost. Various means will suggest themselves, such as bracken Fern, which is one of the best materials for the purpose when attainable. In respect to the early Peach and Nectarine-houses, which I intimated last week might be started by this time, I may state that, as regards the temperature proper, from 15° to 17° will be a good mean, as an artificial night temperature, with a day one of from 50° to 52°. I also suggested last week the desirability of once damping the young wood, to induce a more ready activity in the buds. Push forward the necessary preparation of the later houses, keep them scrupulously clean, as it is upon a very strict application of this simple practice that freedom from a variety of evils is assured some few months hence. Prepare some pits or frames in which to plant successional beds of *Asparagus* for forcing. Let all the materials be as firm as possible at the time of planting, and especially is it necessary that the soil should be firmly pressed around each root when the crowns are planted in the beds. Place a few pots of *Tarragon* into a forcing-house or other similar structure, that a supply of young growths may be obtained when that which is now in use is finished. It seems somewhat early to suggest the putting in heat of a box or two of *Mint*; but I may here state suggestively that fine lambs, by the hundred, already exist in this neighbourhood (Herts).

HARDY FLOWER GARDEN

If there is one season of the year when our old favourite flower, the *Auricula*, needs more attention than at another, it is during the present and the next two or three months. Remove every form of decay from around the stems, and indeed from the frame or pit containing them, immediately it is discernible, and keep everything about them as fresh and sweet as is possible. Abundance of air should always be freely admitted on proper occasions, consistently with safety from frosts severe enough to harm them. *Hardy Annuals*, which were sown some weeks since, such as *Nemophylas*, *Limnanthes*, and other varieties, somewhat succulent, in their nature, should now be nicely thinned out, otherwise fluctuations in the weather will cause them, when grown too thickly, to rot or damp off, and thereby cause vacant or patchy places in the beds. Sometimes good show varieties of *Polyanthuses* grown in pots push up flower-spikes irregularly at this season. In all such instances the buds should be taken carefully out of the hearts while yet in the embryo state, and before they have made much growth, otherwise, if left to develop themselves, they prevent the plants from making a full and fine display in the early spring. Where alterations of any form are in contemplation in this department, they may be freely entered on now, during mild and convenient periods, as trees and grass, &c, may be removed with perfect immunity from risks of any sort.

HARDY FRUIT GARDEN.

I need add little under this heading to my suggestions of last week. Do not, however, delay longer the placing of a moderate mulching of manure over the roots of all recently planted trees, including those which were transplanted in exposed situations last autumn; as it is more than probable that many of the young roots exist very near the surface. Those who meditate taking dwarf pyramidal fruit trees up this season, for the purpose of pruning their roots, may likewise choose the first favourable opportunity for so doing. In all cases where this is done, attend to the proper staking of them as a protection against high winds, even if it be but to steady them against a slight oscillation only, as much injury may be done to the roots near to the collar of the trees.

KITCHEN GARDEN.

Appearances at the time of writing seem to foretell a somewhat rainy period; hence it may not be possible to do much upon the ground in this department. There is ample work, however, to fetch up in the matter of digging vacant spaces in the manner described last week. As soon as the green foliage can be safely removed from *Seakale*, there may be a few pots placed over some of the crowns, and fermenting materials added, so that a nice gentle warmth be insured at the first, increasing in slight gradations until a fair maximum of from 90° to 95° is insured; this in view of forcing the stools so operated on for a supply at an early date. The same remarks apply equally to *Rhubarb*, where it is intended to force it in the open ground. W. E.

TOWN GARDENING.

THOSE plants that have been stored away in frames should now be looked over. All the dead leaves should be at once removed, and the plants will be much benefited if the soil is stirred a little, and the pots turned round. At all times when the weather is fine the lights should be taken off, but when it is wet, foggy, or windy they should be kept on, and should be slightly tilted at the apex. Should the weather turn frosty, cover the frames up with mats, loose litter, &c. The *Helleborus niger*, or Christmas Rose, a useful and pleasing flower for town gardens, will flower freely if covered with a hand-glass, which should be at once placed over it, and be slightly tilted. Another plant which flowers about the same time, and is, moreover, sweet-scented, is the *Tussilago fragrans*, which likewise requires a little similar protection to flower

it well. The flowers of these two plants, or a few sprigs of Holly, make a nice Christmas bouquet. As flowers suitable for the decoration of vestibules, &c., are now scarce, such places may be enlivened by a few nice bushy evergreens in pots, mixed with plants of *Solanum Capsicastrum*, &c., *Capsicum*, and *Acacia lophantha*. These plants, by a very pleasing display at this season, and their indoor confinement in winter very well, and if they are taken out and syringed occasionally when done with, they are planted out in the garden they soon recover their strength and vigour. The planting-out of *Hyacinths*, *Tulips*, &c., as directed at p. 1116, is completed, and satisfactory will be the display in spring.

STATE OF THE WEATHER AT CHISWICK, GREAT BRITAIN

Table with columns: Moon's Age, BAROMETER (Max, Min), TEMPERATURE (Of the Air: Max, Min, Mean; Of the Earth: 1 foot, 2 feet, 3 feet, 4 feet, 5 feet, 6 feet, 7 feet, 8 feet, 9 feet, 10 feet, 11 feet, 12 feet). Rows for Nov 11-17 and Average.

MEETINGS FOR THE TWO FOLLOWING WEEKS. Nov. 22 Institution of Surveyors, 12, Great George Street, West...

THE annual report of experience on a sewage farm which has now for some years appeared with reference to the Lodge Farm, Barking, has just been published. The farm has for the last two years been under the direction of the Hon. HENRY W. PETRE...

The change in public opinion which we thus foresee, will be due in no small degree to the simple, lucid, unpretentious way in which...

every autumn Mr. PETRE has stated the results of his own management. For the full details we refer the reader to his pamphlet.

We may, however, mention here that 7 acres have yielded 1800 tons of Grass in 1869—that the Grass has been found serviceable, not only as cow food, but for fattening cattle and for stable use...

During the year 300,000 tons of sewage have been sufficient to render highly productive 120 acres of the Lodge Farm. Of this quantity 53 acres have been in Rye-grass, bearing an average of 100 crops in that time...

Mr. PETRE is not singular in the regret which he expresses in the last sentence of his pamphlet, that "the means of rendering many thousand acres (much in need of it) in the highest degree productive, should be still running to waste into the Thames...

THE subject of excessive game preservation was discussed the other day before the Leicester Chamber of Agriculture, who resolved, upon the motion of Mr. FORSTER...

That the over-preservation of ground game is fraught with much mischief; seriously tends to diminish the profits of the occupier of the soil, tends to increase crime in the rural districts...

Most of these propositions were strenuously disputed and denied by Lord BERNERS; but his lordship's amendment, to the effect that the subject was not one for legislation, and must be left to mutual arrangement between landlord and tenant, was not accepted by the meeting.

He (Lord BERNERS) was opposed to the over-preservation of game; but he never was called upon to pay a single penny for damage. Game was one of the most certain rents they could have. If he did not want his shooting, instantly a man would give him 100l. for the partridge shooting in September...

Notes for the Year Ending 1869. Upon the Sewage Cultivation of Lodge Farm, Barking, by the Hon. Henry W. Petre. Llangosta Water, &c. Exchange.

turned on to a piece of Swedes, and remarked at the time that the tenant would come at Christmas, and say, 'See how the Swedes have been eaten by the game.' (Cries of 'Oh, oh' and a voice, 'It's false.') He was telling them a fact. He would tell them another case: A man came to him and said the game was doing a great deal of mischief. He said, 'Will you show it me?' and they went into a field next the stackyard, and found the Swedes very much bitten. He (Lord BERNERS) turned round and said, 'Just look here you tell me the hares have eaten these; there is scarcely a Turnip-top but what rats have been at; you have not killed the rats. There were tracks all across a 6 or 7-acre field, and the rats had done it. He said 'If you will take me to the cover side where there are 100 or 500 hares, and show me 5s. worth of damage done, I will pay it you.' He took him round the farm, and said, 'Now show me 5s. worth of damage,' and he (the tenant) said he could not. He asked the man why he had not taken up his Swedes, and he replied that they were caught by the frost or he should have done so. He could not point out any damage. He (Lord BERNERS) simply said, what he began with, that the question should be one of agreement between landlord and tenant. On an estate of a deceased baronet who was passionately fond of sporting there was a farm nearly adjoining his house, the land of which was miserably bad, and the tenants had hardly cultivated it, and at one time did not cultivate it at all—it was all given up to game. That was what the landlord chose to do with it. The landlord could do just as he liked with his own, and he gave up that to game and took no rent, but let his own sheep run across the land. He wished on all occasions that people should look on that question fairly."

THE question as to drainage, whether 3 feet is an efficient or a sufficient depth at which to lay the channel through which the otherwise stagnant water of the soil and subsoil is to press its way out of the field, and thus establish that current within their substance on which fertility in so many ways depends,—this question seems not to have excited much interest of late among our correspondents. Raised by a memorandum from Mr. C. PAGE, of Ruddington Grange, Nottingham, and since referred to by one or two, we had hoped that before winter drainage should have commenced we might have known from men in all parts of the country what the experience in various soils has been of 30 inches, 3 feet, 4 feet drainage. It is still not too late for such a record of experience to be immediately serviceable, and we venture again to recommend the subject as one to which our correspondents might most usefully address themselves.

Looking at the subject from the standpoint whence water is regarded not as a nuisance, poisoner, choker, but a feeder, fertiliser, deepener of the soil, we prefer the deeper drain; but experience as to the good influence, and even the sufficiency of the shallower, is worth recording, and we shall be glad to receive it. Meanwhile, for those of our readers who are disposed to take the latter view—biased, perhaps, by the impression that by drainage they ought to seek the cheapest way of getting rid of water—let us state the case once more, employing for the purpose the words of our excellent correspondent, Mr. D. T. FISHER, which he used the other day in a most suggestive speech before the Lavenham Farmers' Club:—

"You look upon water as a thing to be got rid of in the easiest manner. For year after year you allowed it to water-log your land until it was licked up by the sun, or dismissed into the nearest ditch. By deep and thorough drainage the land is converted into a sieve. The rain-water falls upon the earth freighted with carbonic acid gas and ammonia. It is robbed of the valuable essence in its passage, and dismissed from your deep drains pure. More than this, every drop of water exerts a cleaving force on the land. It splits the ground into fragments, and thus forms a fine and friable tilth. Besides, where water goes air can follow, and the passage of water and presence of air bring the heat of the sun with them, and thus the rough drainage quickens the earth with warmth and enters it with gases at the same time. Then why should these soil-forming processes be arrested at a depth of 6 or 8 inches from the surface? To look into the bottom of your furrows, one would suppose that you farmers were all devoted worshippers of the god Pan—not, indeed, the poetical deity of the shepherds, but that most impenetrable crust which is found at the bottom of your fields. Years ago, gardeners sent their sharp spades through this barrier, and thus increased the depth and productive power of the earth. Other conditions of climate and quality being the same, the productive power of the soil is in the direct ratio of its mass. There is not one of you that does not want more land for yourselves or your

sons. I will tell you how to get it without any increase of rent or taxes—go deeper down for it. Steam has familiarised us with the term horsepower. Now I wish to apply a similar mode of reckoning to the land. Its power of production can be measured by its depth in inches. By examining your tilths we can tell whether your farm is a 4, 6, 8, 10, 12, 14, 16, or 18-inch power farm. Every inch you add to your depth you gain 100 tons per acre of working force. By mucking this deep tilth, such results as Mr. MEECH has brought before us may readily be reached, and the average produce of the nation be raised from 37. or 47. to 207. per acre."

— AT Mark Lane and throughout the country the price of Wheat has declined—home-grown 1s., and foreign 2s. per quarter. The quotations now show that at Mark Lane even, where the most inferior samples are not sent, prices for this year's growth have dropped to 38s. or below 5s. per bushel. Ordinary Barley is 1s. per qr. cheaper, Oats a trifle dearer, other feeding-stuff at last week's prices.—With the large supply of 4,583 beasts, on Monday at the Metropolitan Market, there was a good demand for all the prime qualities, and the high price of 5s. 8d. per stone was maintained. Sheep, were in brisk demand, at 5s. 10d. per stone for best kinds. These prices were obtained on Thursday.—The agricultural seed trade, with the exception of a speculative demand for White Clover seed, is in a very quiet state.—English wool still stands at previous low prices.

— We receive the following from Mr. C. S. READ, M.P., just as we go to press. It relates to a subject mooted some weeks ago by a correspondent—'If I remember aright, a correspondent of the *Agricultural Gazette* a few weeks since asked for information on the best mode of preventing hillocks of sea sand from blowing. I hoped that some one better qualified than I am to offer advice would have answered the question, but as no one has spoken, I will give the result of my small experience. Plant the hills over with large patches of the Seamat weed or Sedge (*Arundo arenaria*); it will spread its lateral roots quickly, and do much to stop the sand from moving. Anywhere on the west coast of England or in Ireland, Grass will in a short time spring up with the Sedge, and when the Grass produces a sward, the Sedge, having done its mission, will presently die out. Rabbits must be exterminated, as they should be everywhere else, save in warrens. Their continual scratching exposes the fresh sand to the action of the wind, and effectually prevents the Sedge from growing."

— An important meeting on the Transit of Cattle, a subject to which the interest and interference of Miss BURDETT COURTIS have of late largely contributed to direct public attention, was held last week at Peterborough. After a very instructive and energetic address by Mr. WALLER, Secretary of the Home Cattle Defence Association, the following resolutions were adopted by the Chamber of Agriculture:—

"1. That after careful consideration of the inquiries upon which their views have been asked by the Privy Council, they are of opinion that their suggestions should be confined to the simple question—'How a sufficient supply of food and water may be provided for all animals carried by railway in Great Britain?'

"2. That they consider themselves precluded from offering any suggestions with reference to the inland transit of foreign animals, holding as they do more strongly than ever the view that all foreign animals should be slaughtered at the port of landing.

"3. That it will be advisable in any future legislation to compel railway companies to improve the construction of their trucks for the transit of cattle, and to make them liable for damages for unnecessary delay arising in the transit of cattle."

— The following letter, referring incidentally to the seeding of Mangel plants, a subject which was dismissed last week, is nevertheless published because of the very striking testimony which it contains to the serviceableness of town sewage as the best possible manure for succulent growth. Dry and solid manure is more likely to promote the early running of a biennial plant to seed, than a manure dissolved in water, which tends to develop leaf and bulb. Mr. MORGAN, in treating of the Metropolitan Sewage Company, writes as follows from Lodge Farm, Barking:—'I observe in last Saturday's *Agricultural Gazette*, that Messrs. SUTTON'S Mangel seeds had grown fine roots, and that the crop had not run. Our experience on 4 acres of Mangels, under irrigation—half being sown with seed from Messrs. SUTTON, and the other half with seed from Messrs. CARTER—agrees with the observation made by Mr. ANDREWS. The crop was a very good one—a very even one—the land being well covered and the roots close, and the number of runners was very small, if compared with crops on other farms. I wish, however, to add for your information, that the same seed, *i.e.*, similarly procured, put into the land on a different part of the farm, which had farmyard manure, and which was not under sewage irrigation, did produce runners in average numbers. I think our experience rather confirms the belief that has been previously expressed, namely, that if the root is kept moist it does not run. The same seed planted in the lands at the Creek so sewage presented a like satisfactory appearance, and the contrast which it presented to the crop of Sugar-Beet which grew alongside it, and which threw up a perfect forest of heads, was very marked. In contrasting the two crops of Mangels to which I have referred, I must give you the weight of each crop. That taken off the land under sewage (4 acres 1 rood 12 poles, weighed 201 tons. That taken off the other land (10 acres), which had received a dressing of about 20 loads of dung, weighed 200 tons.

The whole crop was passed over the wheel and a correct account kept. The result from Long Red Mangel seed (the crop being Yellow Globe) in between 2 roods 6 poles, has given us 15 tons of roots, aided by sewage dressings. The nearest neighbours both put land under the purpose of growing Mangel so; and I hear from one of them that he has tons an acre, and that he is perfectly satisfied. The other, I believe, claims to have a greater yield in part. The arrangement made with the gentlemen was that they should pay a price for the crop, and that dressings should be put on as seemed needed. The price per acre was fixed (as an experiment) at 47. an acre. We gave them good dressings, and when their land is better dressed with less sewage than that which they received for them better crops."

OUR LIVE STOCK.

MR. STRAFFORD has advertised the pedigree Shorthorns at Shobnall Grange for sale. They have been long and carefully bred by its present owner, J. Meakin, and represents some of the most valuable strains of blood. The 40 animals composing the stock offered to the public on the 15th of next month.

— That serious changes are pending in the subject of animal food is evident to every one who has even no great difficulty, in preserving meat for an indefinite length of time, and now that the scientific and commercial speculators have begun to put their ingenuity to the test, no great time can elapse before their ingenuity will begin to show itself. These changes are due to the very spirited account recently given by Professor Gamgee before the Midland Farmers' Association. The Professor has been engaged during the last year in working out a problem, which may be considered as finally settled. He is now about to prove that meat can be kept moist and sweet from all taint by inexpensive means. It is his intention here to fully describe Prof. Gamgee's process. It consists in causing sulphurous acid gas and oxide to act upon carcases of animals in chambers. The air is removed by a pump from containing the meat, and carbonic oxide is subsequently a certain amount of sulphurous acid added, which completes the operation. About 1000 Professor Gamgee, consignments of meat are now reaching us regularly from America. He also takes an apparatus can be provided for about 2000, which 500 sheep could be cured daily. When in connection with the above statements the facilities for the transport of living cattle in trade of this country may well be looked upon as in a transition state. Professor Gamgee says that the meat of a quality which would be considered in the metropolitan market might be sold in Export prices varying from 4d. to 5d. per lb. Such a result, if realised, would exert a modifying influence on agriculture; nevertheless, we concur in the view of Mr. Masfen said in the discussion following Prof. Gamgee's remarks, that any feasible suggestion would enable the poor to obtain a larger amount heretofore of good substantial food should be met with delight.

— The Hampshire Down sheep, according to E. P. Squairey, originated from the crossing of the Wiltshire horned sheep, and the old Berkshire with the Southdowns which were introduced into Wiltshire and Hampshire early in the present century. These crosses were made with varying success, owing on the instinctive capacity of the farmer to select proper animals for the purpose. From 1840 to 1850 the Hampshire Downs of North Hants and the South Wilts were, owing to the different character which constituted a good sheep, totally different in character. The Wiltshire sheep was larger and less handsome, and not so uniform with respect to colour as those of Hampshire, and a ewe with a face and ears was not necessarily drafted, provided she was possessed of other good points. To Mr. HAZEL of Oak Ash, near Newbury, is due, in a great measure, the present character and position of the Hampshire Down sheep. This agriculturist effected the improvement by careful crossing with the largest and best-fleshed of the Babraham Southdown flock. This was applied with wonderful ability, and at a great cost at length resulted in the present perfect animal. An old Hampshire type is still well represented in flocks of Mr. F. Budd, Messrs. Parker, Barking, and others.

ON FIXITY OF TENURE v. TENANT-RIGHT.

Now, when our crops have been gathered in, and harvest homes celebrated, and farmers have had an opportunity to attend agricultural meetings and talk over their affairs, it seems a favourable opportunity to open again the question of the security enjoyed by the tenant-farmer, or claimed in his behalf, and to canvass the possibility by legislation or otherwise of encouraging him to improve his holding, while at the same time abridging the right of the owner, what he likes with his own property. It is a subject that the Irishman should earnestly consider in the coming winter, as if there were no ground to be procured on this side of the Channel. And it seems to us that the principle of sance for the goose being applicable in the matter, that any remedial measure applicable to the tenant might be useful also to us. In approaching the subject of what is called tenant-right here or fixity of tenure in Ireland, let us first consider what are the differences that exist between the different countries.

ploughs, when the handle is once set no guidance is needed, and so four furrows were thrown simultaneously without a hand being put to the plough. Arrived at the end of the field, it turned with far greater ease than horses could do, and ploughed its way back again up a hill with inclines of 1 in 12. The ploughs were set as deep as possible, and the work done was quite first-rate. The contrast between the road-steamer and the plough-horses was most remarkable. Whilst three horses were painfully struggling along with one double-furrow plough through the exceedingly hard, dry, stiff soil, it was drawing its two double-furrow ploughs with such facility that it was evident there was an immense supply of power to spare, and that it could have taken another couple of double furrow-ploughs behind it; indeed, the furnace-door had to be kept open the whole time. The road-steamer, too, was quite free from the dilemmas to which horses are liable, such as getting their feet entangled in the chains, &c., and when occasionally it accelerated its speed a little too much, a single "Woa!" would bring it to a stand. It ran in front of the ploughs on the unploughed ground, thus avoiding all possibility of compressing or poaching the soil after it had been turned up. The road-steamer ploughed its allotted portion without meeting with a single difficulty or impediment of any kind, and when it was led away all who had witnessed its performance declared that its behaviour was perfect, and that it could at once be put to practical work. It promises to be of incalculable advantage to farmers, as it will enable them to dispense almost entirely with horses, since it can fetch its own fuel and water, and can be employed in ploughing, reaping, and mowing, in carrying manure, and taking produce to market. Great gratification was expressed by all present, and a brilliant future predicted for the road-steamer.

THE CONSEQUENCES OF INTRODUCING MONGREL BLOOD.

ALTHOUGH good animals are, as I have shown, produced by pure breeds, I by no means deny that individual specimens of equal, or even occasionally of superior excellence, may be found among crosses. Thus if cows of any good Scotch breed are crossed with a Shorthorn bull, the off-spring usually unite the hardihood and fine grained meat of the dam with the size and early maturity of the sire. Steers of this character would probably be worth more per lb. than pure Shorthorns, and be heavier than pure Scots of the same age. Mr. Darwin appears to consider increased vigour to be the general result of crossing two distinct breeds of domestic animals. This is probably part of the law which makes the union of near affinities injurious, when continued too long. While even a slight change of blood is beneficial, a complete cross appears, from the facts collected by Mr. Darwin, to have the effect of imparting peculiar vigour to the offspring. The success of a first cross is indeed proverbial, and where circumstances are favourable there is no better mode of producing animals for the butcher than the union of two distinct breeds. When, however, you ask, "Does it follow because an animal has a splendid lineage he is necessarily better than one less favoured in this particular?" I reply, that as an animal for the consumer, it is by no means a necessary consequence. We have seen cross-bred oxen take the medal at our great fat shows against all the pure breeds. The celebrated Durham ox himself was a son of Favourite, from a cow without a pedigree. But suppose that the half-bred steer, which has won the Gold Medal at Islington or Birmingham had been a bull, what would have been his value? As a breeding animal, absolutely nil. If there be any one point on which all breeders of reputation may be considered unanimous, it is that of never using a mongrel sire. Common sense indeed points out that, where we are uncertain of the antecedent parentage of an animal, we cannot place the same reliance upon the uniformity of his progeny as we can on that of one whom we know that for many generations back his ancestors have all belonged to one race. The liability to "breed back," as it is popularly termed, is a universally recognised fact, but it was reserved for Mr. Darwin fully to investigate this intricate subject, and to throw a light upon the laws which regulate "reversion," which must eventually expand our knowledge far beyond its present limits. By elaborate and accurate experiments, both with pigeons and with poultry, Mr. Darwin has conclusively shown that the result of crossing two pure breeds is "to give an impulse towards reversion, as shown by the reappearance of long-lost characters. The proof lies in certain peculiarities, which do not characterise the immediate parents, and therefore cannot have been derived from them, frequently appearing in the offspring of two breeds when crossed, which peculiarities never appear, or appear with extreme rarity in these same breeds, as long as they are precluded from crossing." My limits will not permit me to attempt even an abridgment of the mass of evidence on which Mr. Darwin's important discovery rests. I refer my readers, therefore, to chapters 6 and 7 in the first volume of the work from which I have quoted, where Mr. Darwin relates his experiments in breeding pigeons and poultry, and then to chapter 13 in the second volume, where he recapitulates his views on the subject of inheritance, and more particularly of reversion. The general result of crossing certain breeds of poultry and of pigeons was to produce in the mongrel offspring certain characters which do not belong to the parents on either side, but which appear to have been derived from the wild species from which they originally descended. A similar effect is also shown sometimes to follow the crossing of sheep. The

liability of black lambs to occur even in the best bred Leicester and Southdown flocks is well known, and, along with other evidence, points to the probability that the earliest sheep were brown or black. The following instance of reversion, given by Mr. Darwin, is curious—"The Rev. W. D. Fox was informed that seven white Southdown ewes were put to a so-called Spanish ram, which had two small black spots in his side, and they produced 13 lambs, all perfectly black. Mr. F. believes that this ram belonged to a breed which he himself kept, and which is always spotted with black and white; and he finds that Leicester sheep crossed by rams of this breed always produce black lambs. He has gone on recrossing those crossed sheep with pure white Leicesters during three successive generations, but always with the same result. Mr. F. was also told by the friend from whom the spotted breed was procured, that he likewise had gone on for six or seven generations crossing with white sheep, but still black lambs were invariably produced."

Here another principle evidently was at work, viz., "prepotency," as Mr. Darwin terms the stronger influence of one breed over another on the offspring; and I am inclined to estimate the prepotency of aboriginal or early breeds more highly than he does. When prepotency appears to characterise more recent breeds, such as Leicester sheep and Shorthorn cattle, which undoubtedly have swallowed up a large proportion of rival races, this may be caused by the persistent use of near affinities, which has impressed upon them a unity of character not easily to be attained by more miscellaneous breeding. When we see, however, how persistent is the latent force of primeval character, it is to be hoped that all who desire to improve their herds will perceive the danger of using mongrel sires. The risk is not an imaginary one, for at local shows prizes are not unfrequently given to animals of whose pedigree all that is known is the name of the sire. Nay, I have never known a case in which a prize for breeding stock was given to a heifer which had been purchased at a market, and whose pedigree was utterly unknown. She might have combined the blood of Scotch, Hereford, Welsh, Shorthorn, Loughorn, and countless other breeds. The injury which may accrue to a herd from the introduction of impure blood, can scarcely be over-estimated. So far from the official sanction of prizes being awarded to such mongrels, every influence ought to be brought to bear to induce farmers to secure for their herds sires of pure pedigree. Although they are becoming more alive to the value of blood than formerly, still a considerable proportion of farmers deem it a mere fancy. If it were otherwise, we should hardly see well-bred bulls sold below their store value so frequently as is now the case. Take, for example, the recent sale at the Prebendal Farm, when the bulls, chiefly of Knightley blood, went for prices quite disproportioned to those made by their dams. Thus, one yearling, whose dam was sold for 120 gs., only made 24 gs. And I remember at the Birmingham sale last spring seeing a very nice young bull of the Princess family, for which not even a bid was made. On the whole, I am still of opinion that benefit would arise from placing the pedigrees of breeding animals before the judges, as one of the elements for enabling them to arrive at a sound decision respecting their merits. *Willoughby Wood, Holly Bank, Nov. 12.*

Home Correspondence.

Steam Cultivation Charges.—My letter at p. 1193, when speaking of the horses kept to work the heavy land just bought, should read thus. "Five horses have always been kept to work the heavy arable land." "G. A. H." was in a great hurry to give me another wip with his stick, in fact, has "fallen foul" of me by giving me a second blow before I could get upon my legs to defend myself. At p. 1141 he charged me with having "fallen foul of another opponent," whereas it was Mr. Greig and Mr. Teopffer who "fell foul" of the roundabout tackle at Peterborough, and I stood up to defend it, yet for all that I was to be thrashed. Well, never mind, his blows do not hurt me; and I take it that the back-handed blow at you, about the 1s. 6d. an acre for wear and tear, did not fret you. My letter (p. 1193) has done all that is necessary for me to do upon the eighteen penny question; therefore, I will follow "G. A. H." to Tiptree, where, "if Mr. Mechi did anything so utterly contrary to honest accounts, I warrant Woolston would be down upon Tiptree with a vengeance." Now, I have never been "down upon Tiptree with a vengeance;" for all I have done has been merely to show up Mr. Mechi's own figures; and all the good "G. A. H." is now doing, to his friend Mr. Mechi, is to keep the raw place open. I will not fret about his reference to "depreciation," for you all know that I have never concealed that or any other point upon the question of steam cultivation, and if my advice to the farmer is blind advice, it is what I am practising myself, in buying it very profitable. Although my occupation was only 112 acres arable, and is only 163 acres now, I am not deceived about the cost of my seed-beds, nor am I wrong about the bit after Mangels, although it stands at only 2s. per acre. People on the spot who see never express a doubt, and when "G. A. H." falls upon me about the change of engine, he gets no ground, for I have long since told you that, 11 years ago, I gave my first 7-horse engine and 100l. for the engine I now use, and it is in capital trim, although it has done no end of threshing and grinding as well as my ploughing; and its cost in repairs during the whole period has not been so much as it would cost to shoe 10 horses during the same period, and he is vastly wrong when he says thus—"How much does he suppose he will lose on it when in two

or three years' time he replaces it with a more active?" I will not lose money in that way, I will keep my good old engine that I can depend upon in any weather and at any work, that has served me faithfully for 11 years, and will for 11 years more, doubt. Anthe is also vastly wrong when he says "bring out my ploughing apparatus," for I have done a bit of that work, neither will I, for I have demned the practice from the start. At 1s. 6d. that work must be done at the right time, and at the loss "interest of money, depreciation," and all else out of the question to make a man a traction-engine man. Here he is upon his high horse, him ride it, and I will leave him and Mr. Biddell on with their millering. Mr. Biddell is right upon that point. But I must have a word about his "hen scratching." The system of regular way of charging such work has been done each horse 2s. 6d. per day, the man 2s., and the boy 6d. each. They do 6 or 8 acres a day, therefore the price comes out at 2s. per acre. Now let us take the dead fallow that I have just paid for, and taking these figures as our mode of calculation, three quarters of an acre as a day's work, and an acre a day the last two days, and thus find out the cost per acre.

One ploughing, 4 horses, a man and a boy, 1 acre per day	1s. 6d.
Two ploughings, at an acre a day, 4 horses, a man and a boy—two days	3s. 0d.
Two cultivatings, at 2s. per acre each time	4s. 0d.
Half a year's rent and taxes	10s. 0d.

I paid that and get no produce. Woolston calls that hen scratching? It is not my Mangel land, scratched over at a good price, is, and well, too. It is of no use for hard horse-trodden work, that may be done on an acre, with mine: for he does not take into account the beautiful condition the previous year's roots had left it for me to work upon. Mr. Bignell tells him all about it. Mr. Bignell's neighbour, sees for himself, and tells you there is a wide contrast between the two. There is a wide contrast between the two, and his neighbour, Mr. H. Biddell, who gives credit for intentional truthfulness, writes (p. 1171) that he did not believe his neighbours. "G. A. H." will learn a lesson. *William Smith, Woolston, Bucks, Nov. 13.*

Woolston Steam Ploughing.—I observe Mr. Smith adopts your explanation of the 1s. 6d. for interest and wear and tear, in which it means 8 acres daily, at 1s. 6d., or 128 acres in 100 days of ploughing in each year. Now, if ploughing at 8 acres per day, would run up 100 days, but if a farm be worked on the usual system without bare fallows, the actual ploughing is but three-fourths of that unit rotation, for only every year in grass-seeds and Clover. Each acre, then, of actual plough represents justly a rotation, but every farm has some waste on some small portion in permanent Grass, and we safely assume that 1067 acres under rotation of a farm of at least 1100 acres. So then it is, that in order to carry out the Woolston steam "smashing," at Mr. Smith's estimate, a man must have a farm of 1100 acres. Now, a wonderful discovery Mr. Smith has made, "smashing" on the Woolston roundabout, actually will pay on a farm of 1100 acres, however, be misled; this is not what Mr. Smith to prove, or rather to insinuate, and though I p. 1192) I am not to be frightened by the mode of defence, and I have too keen a sense drawn off by a red-herring drawn across the question is this: Mr. Smith declares that the power, and the partial assistance of horse and Woolston "actually made a seed-bed for the cost of 6s. 8d. per acre." I assert that his own figures prove his declaration to be a foundation; that he is, in fact, as I said, "deceiving himself, and, in deceiving him, deceiving the public." He tells me that year he never ploughed a much as 100 acres, and yet he has the hardihood to assert that an acre, which on "less" than 100 acres would be "less" than 7l. 10s. per annum, is enough interest and wear and tear upon a set of machinery costing 375l.,—that is to say, 1s. 7s. 6d. per cent. per annum for interest and wear. The little question of "depreciation" he veniently ignores, and goes on to talk of keeping six horses. But what have we to do with Woolston? We are not talking about the cost of ploughing, but we are not even comparing the cost by steam with the "actual cost" of making a seed-bed by horse-power, we are simply inquiring the power at Woolston, which Mr. Smith has "actually made" for 6s. 8d. per acre, but which distinctly prove by his own figures he has not am quite willing to admit that if he had 1100 acres, and was able to plough 800 acres with his present tackle, he might have done so, has not got 1100 acres, and he has not ploughed in the year. What I complain of in Mr. Smith he endeavours to persuade small farmers to buy 100 acres to plough every year, that is, to them to purchase "for their own use only" steam tackle, and that when they have done so, seed-bed for Wheat will only cost them 1s. 6d. an acre. That is what I declare to be a fallacy is a

* "Variation of Domestic Animals," Vol. II, p. 39.

immediately begin and go on in the heap, I find it better to suffer this, and apply it in a rotten state to the crops, especially to those kinds that are rapid in their growth, and come early to maturity. Turnips and Potatoes grow a better crop with short than with long dung. A braird of the former is sometimes got by using well-rotted dung, where it fails with that unfermented and recently made. Most kinds of crops thrive best when the land is dunged just before sowing. Beans are, perhaps, an exception. I think that though the land is dunged in November or December previous, and allowed to lie in that seemingly careless state—spread on the surface and exposed to all sorts of weather till ploughed in spring at sowing time—the crop turns out as good as the more recently manured portions. With Turnips and other green crops it turns out quite different. It certainly saves labour at a very busy season, by dunging in autumn and winter; but they never do so well as putting it in the drill before sowing, and allowing exposure in the heap drill as short a time as possible.

Mr. JAMES M'LAREN, Spittal, said—I at one time had an opportunity, under favourable circumstances, of testing whether liquid manure of good quality would pay the expense of pumping and carting; but I, like most others, after three years' trial, gave it up as an unprofitable speculation. When liquid can be made available over meadows by natural gravitation, there can be no doubt of its utility; but when this cannot be done, I have found it profitable to retain the liquid and return it back over the manure-heap frequently, or allow the liquid to pass slowly over a tank or large ditch, occasionally coated over thinly with any waste substances, such as dried wreck or weeds, Potato tops, or peat moss, &c. I have for years collected several hundred tons of good Turnip manure from the last mentioned plan.

Mr. J. FINLAYSON, Penbreich—The enlargement of the manure heap on the farm is most important, and whatever can be got off weeds, gathered off the land, sawdust, or the like, should be collected and spread amongst it; for, though these may be almost valueless apart and in themselves, all of them, and many things else beside, become valuable manures when mixed together and decomposed. It would be an immense saving, on dry field farms especially, if the strawyards were roofed in, as, where there is such dependence generally placed on the breeding and rearing of stock, all the straw requires to be used for fodder; but, as matters stand, a little of the above-mentioned ingredients, or such-like, spread under the cattle occasionally, will help to keep them dry, and augment the manure-heap. I believe that sawdust is very much under ban as a manure, but having used it so long as bedding for my feeding cattle and milch cow sheds, I find that it absorbs a great deal of the surplus liquid in the byres, and becomes, when mixed in the dunghill and decomposed, an excellent fertiliser for Potato, Turnip, and cereal crops, and although I have not experienced it, I believe it will be more so for clay land.

Mr. CHARLES WINGATE, Corntown, said—It appears that lime and animal and vegetable substances have been applied to land for many ages, without any definite knowledge higher than the experience of repeated application producing similar results; but chemistry has to some extent dispelled our ignorance, by disclosing the component parts of animal, vegetable, and mineral substances. We are told that vegetables have carbonic acid, water, and ammonia as their chief aliment, in combination with certain mineral substances, as these are found in plants—namely, lime, potash, soda, magnesia, silica, sulphates, and phosphates; and as these are taken from the soil, the quantity requisite for the growth and health of plants becomes exhausted, or so much reduced that means are resorted to, to supply the waste, and bring the various substances immediately essential within the reach of the roots of the grain and Grass plants destined to provide food for man and beast; that carbonic acid and ammonia, through the agency of the sun, are decomposed and assimilated by plants; that potash is essential for cultivated plants, and is supplied to a large extent from decayed Clover and Turnips, that soda, which is usually in union with potash, is found in the dunghill, that sulphur is found in all plants, and phosphoric acid is essential to their healthy growth; hence the increased and increasing demand for various sulphates and phosphates now so familiar in commerce. The sulphates of magnesia and lime are useful in the production of Turnips and Potatoes, and lime is held as the only reliable substance for the cure of "finger-and-toe" in Turnips; that nitrates and salts of ammonia also increase the growth of cultivated plants when accompanied with the suitable mineral substances already alluded to. Lime decomposes all vegetable matter in the soil, and corrects acidity in the organic matter, that it assists in the decomposition of certain salts whose bases form the food of plants—in fact, it is an excellent solvent when applied in proper quantity and at the proper time. In regard to farmyard manure, this seems, from every account, to be the most important of manures to the farmer, as it contains all the elements upon which plants live. The richer the food is of the stock kept, the richer will the manure be. The loss sustained by the soil owing to the withdrawal to market of grain, hay, and dairy produce, can only be supplied timeously by artificial manures, which are happily so well understood. Farmyard manure is required for the nourishment of Potatoes and also of Beans, and it is of the utmost importance in the production of Clovers and Grasses. The question, however, before us is, what is the best mode of preparing this manure? It may be difficult to decide it, as seasons and places may be so unlike each other. However, there is one mode which is recommended; it is, that the liquids should be allowed to flow from the stables or byres into tanks or pits

placed 3 or 4 feet below the level of the ground, the solids being placed on the top, so as to admit of their absorbing the gases as they escape from the ground.

DORCHESTER.

Agricultural Cottages.—The following is an abridgement of a paper on this subject read by Mr. HOMER, of Martinstown, at a past meeting of this club, to which we have not hitherto given publication. He said—The subject I have to bring before the club this evening for discussion is cottage accommodation on farms, and the way in which the cottage system affects generally the employer and employed. In the first place I will look at the present state of the cottages in general in the agricultural parishes, which I consider insufficient to meet the wants of a growing population. Take, for instance, the census from 1851 to 1861, and you will find that there has been no increase in many parishes, and it is solely attributable, in my opinion, to the want of houses to live in, and many good labourers are under the necessity of taking houses or lodgings in the nearest town, where they have to pay a high rent, and walk miles to their work. Many do this during the summer months, when work is plentiful; but in the winter, when work is short, they are driven to the greatest extremities. I know it has been said that by building more cottages in your parish the population would increase, and the poor's rate would increase also; but this would be so very trifling under the present system of union rating that I do not think this argument holds good, the union being assessed alike for the maintenance of the poor.

We will now look at the present state of some of the cottages, and the improvements we think necessary to be made. For some years past, upon many of the large estates in our county, these improvements have been carried out, by building new cottages of a more commodious and better description, adding greatly to the comfort of the poor. Still there is a great deal more that ought to be done, as in many cases the old cottages have but one bedroom, and in the majority only two, and, where the families are large, both sexes are obliged to sleep in the same bedroom, which is a great evil. Every cottage should have three bedrooms, and all other appliances for decency, which would improve very much the morals and health of the labouring classes. There is another improvement I think would greatly add to the comfort of old people after they are receiving parish pay. At present these old people must either receive out-door relief and live with their children or friends or go to the union workhouse. The former they always prefer, if possible, as they term the latter a prison, the man and his wife being separated after having lived perhaps 10 or 20 years together. Still these old people are adding to the family, the houses being generally in a crowded state before. In this case I will suggest a plan, which I think, if carried out, would add greatly to their comfort, and that is, to build small cottages of two rooms on the same floor, one for a sitting and the other a bedroom, with small offices attached and a little garden, and call them charity or alms houses, the overseers of the parish to have the sole control of them, to put deserving old people in, rent-free, for their lives.

We will now come to our subject—viz, on cottage accommodation on farms. In many cases there are sufficient for the use of the farm; in many others only two or three are allowed for the carters and shepherds, and I know a few cases when even these are withheld. For some years past many of our landed proprietors thought it expedient for the good of the farm labourer to take the cottages (with the exception of the two or three before-named) and let them at a low rent to the labourers, so that the men should be independent of any particular master, and get his work at the best market. I will give these gentlemen full credit for their philanthropy, but I think I shall be able to prove that the labourer has not been benefited by the change.

We will now consider whether it is an advantage for men to hire their cottages, or to have them rent-free, found by the employers. Take first the man that hires his cottage, and depends for his work at the best market, and make a calculation of his earnings. The first six months from Lady-day to Michaelmas, I calculate (if a good workman) 12s. per week; from Michaelmas to Lady-day, 9s.; making an average of 10s. 6d. per week for the year. He will have to pay at least 2s. per week for Louse rent, fuel, and rates, leaving 8s. 6d. per week for his maintenance. This I believe to be up to the general average of wages for out-door labourers, as there will be several weeks lost by bad weather and other things, and not always certain of getting work. Take another instance of a man renting his house. This man may hire himself for a year as a general labourer at 10s. per week; 20s. and his liquor extra for harvest. This man will have to pay his rent and rates, and also to buy fuel, which will leave him barely with 9s. per week. This man, however, I think better off than the man always depending on the labour market, as he has his regular pay, and loses no time from bad weather. The two cases that I have brought before you will not apply generally to all men renting their cottages, as there are some who from want of skill and perseverance cannot earn the wages first described, and others will not hire themselves by the year; consequently during the winter they are often out of work, and poaching and petty thieving are resorted to.

We will now take the case of the yearly servant, who is provided with his house on the farm. He is hired for a year at 8s. per week common work, to have piece-work, such as hedging, draining, mowing, reaping, and Turnip-hoeing, which will add from 1s. to 2s. per week more to the wages (this, however, must depend on the man, as some will earn much more at piece-work than others); to have his grist—from 2 to 4 bushels of Wheat per month, according to his working family—at 5s. per bushel, cottage, garden, and rates free, fuel,

such as furze or wood faggots, for cutting, and coals given to some extent; from 20 to 30 Potatoes per acre, the ground prepared for planting; and a liquor found him for the year, which I calculate, is equal to 12s. or 13s. per week, being always near his work. In many cases, however, not allowed, and 1s. per week more is given; but the men in general prefer the former, their Wheat at (on an average) 1d. per bushel, bread is much better for family purposes than men, I consider, are 2s. per week better than renting their cottages and depending on the market.

We will now look at the disadvantages to the occupier of land and the labourers in many cases from want of cottage accommodation. I secure certain labour for the whole year, and know that good farming cannot be carried on without sufficient manual labour, and certain labour secured without cottages for the men to live in to the farm or in the parish. We will take a farm requiring 10 cottages, and it has the consequence is, you must all those cottages to working families, if possible, who in many cases crowded together regardless of common sense, also causes constant change, because as the men grow up they leave their father to look after themselves or get married. The consequence is, a good young man for want of a cottage to live in, and the father is obliged to leave too, or to live in a not large enough; so a constant change is made yearly, which is a great disadvantage. Take another instance, there are many cottages, or more from any parish, with only one or two cottages,—and I know cases of this sort, must then depend on the neighbouring parishes for labourers. We will allow there are plenty of men, and they are hired at an extra 1s. per week, men will have to walk a mile every morning, and night, which will take one hour every day, an extra time, 626 miles extra to walk during the year, more than the men living on the farm. These, however, are very uncertain, and the labour is frequently put to great inconvenience in the winter when the men can get work nearer home.

We will now consider the general advantages to labourers, farmers, and landlords, of having cottages attached to the farms. Take first the farmer. There cannot be a doubt but that a man who is near his work and comfortably housed, will derive more benefit from his work than he who is far from it. He takes his meals at home with his family, and when wet and tired walks home. Another advantage he has, is that he can spend in his garden during the spring and summer months, more than the man that has to go from his work. The farmer derives a great deal of benefit from having certain labour without fluctuation, and the farm going on regularly; his labourers, and families being near he has an opportunity of seeing their general conduct, and also assisting them in various other ways, and adding to their comfort. But here I must observe that he does not get his labour cheaper, as the cottages are filled for the summer months; but in the winter there is more than is really required for the work on the farm. The landlord, by building cottages, is letting them with the farms, would be a great advantage, as I believe every farm with a good accommodation is worth 10 per cent. more than without it, besides having his farm managed in a much better way.

Let us now see what number of cottages are required for every 100 acres of land, and depend in a great measure whether the land is a pasture farm, the former requiring more labour than the latter; therefore the general rule laid down. Small farms and large farms, in proportion than larger holdings. We will take an arable and sheep farm of 100 acres. These farms, I calculate, ought to have 10 cottages to every 100 acres at the best market. This, I think, would be sufficient for all the ordinary work of the farm with a view to harvest, &c. I have now endeavoured to present before you the principal points on which I have to bear, and have put my ideas in as plain a manner as possible, so that as much time as you may spend in observations to be made in the present.

Reviews.

The Irish Land Question. By James C. O'Brien. Our recent notice of this pamphlet, we are glad to hear that a second edition is now issued, one particular barely accurate, and in many respects it was deficient. It is not right to say of Mr. O'Brien's even, "as it were," enforce the lease of the land for years upon either landlord or tenant, though he be, because of its proved inability in its power to promote agriculture, and general industry, and fertility, and general improvement, yet no proposal in his pages to induce the enactment between the owner of the land and the tenant a reasonable use whatever he may desire of his property. Mr. O'Brien does, indeed, demand for a term of years which he says is their political advisers are now making in the intended sense, yet is "sound in principle," and that the operations of agriculture, and the most primitive kind, naturally extend beyond a single year, and outlays made in cultivating and enriching his land be recovered in the first crop. What he proposes, therefore, is not an average

ld be hindered from making any agreement just as with a tenant, for as short a time as he may please, that, where no agreement exists, the presumption is that under such circumstances now gives the tenant 12 months' peaceable possession should, except for what in the face of costly outlay, certainly not unreasonable—a period of at least five years be recommended that various specified encouragements to a voluntary grant of leases for a still longer period be also given by enactment.

The following are the changes which he recommends the consideration of Government—

- 1. That the law as to buildings and other permanent improvements on land should be altered so that the tenant should be freed from all obligations of repair, at present time.
- 2. A tenant, on writing with it written leave to be secured by the Government of the law (except for failure to rent for an equitable term, say five years, sufficient to pay the expenditure necessary to a proper system of irrigation).
- 3. That management to be given to the system of leases for a term, by the Government loans for land improvement made on leases of not less than 20 years.
- 4. That the law as to the right of the tenant to be secured by the Government of the law (except for failure to rent for an equitable term, say five years, sufficient to pay the expenditure necessary to a proper system of irrigation).
- 5. That the law as to the right of the tenant to be secured by the Government of the law (except for failure to rent for an equitable term, say five years, sufficient to pay the expenditure necessary to a proper system of irrigation).
- 6. That the law as to the right of the tenant to be secured by the Government of the law (except for failure to rent for an equitable term, say five years, sufficient to pay the expenditure necessary to a proper system of irrigation).
- 7. That the law as to the right of the tenant to be secured by the Government of the law (except for failure to rent for an equitable term, say five years, sufficient to pay the expenditure necessary to a proper system of irrigation).

These proposals, in addition to Mr. Bright's plan of Government assistance to tenants willing to buy farms from owners willing to sell, are what seem to Mr. Carl to embrace the main conditions required to enable the Irish people to work out for themselves agricultural prosperity of their country. And to a concise and discussion of these proposals the pamphlet addressed.

Farm Memoranda.

FIELD OF ELY (AYLESBY HOUSE, CHATTERIS).
Nov. 13.—The summer of 1869 will long be remembered as one of the most remarkable that agriculturists have experienced. The summer heat of April, and the cold and wintry cold of May and June, the alternations of heat and cold, dry and wet, during the summer months, have left impressions and produced results which will not easily be forgotten. And the autumn and winter appear to be equally strange and exceptional. The 9th and 11th of October reminded us of the intense heat and oppressive temperature of the memorable summer of 1868, and were quickly followed by snow and frost equal in intensity to what generally look for in mid-winter—so sudden and severe have been the changes. But one of the most striking peculiarities of the last two months has been almost incessant gales that have been blowing. Lead of the proverbial November fogs and damp atmosphere, we have had November dust blowing in gusts, not only from the roads, but from the fields, in instances leaving the Wheat, where sown, well uncovered. Drifts of dust like snowdrifts, except colour, have accumulated against hedgerows, and had to be again carted on to the land. Five times to the completion of harvest we have seen the corn blown from the corn stack, and many may now be seen half stripped, and still the wind is blowing a

reshing has been proceeded with, with great activity, and it has sometimes appeared as though the people must all be blown away together. The stormy weather has doubtless been one agent in reducing the supplies of English-grown Wheat to shorter and more limited at market; but the designer, as though anticipating our difficulties, has not us most liberally supplied—too much so, probably, in his own interest as well as for ours, but for the benefit, doubtless, of the community at large. One more confirming the truth of the old adage, "It is an ill wind that blows nobody any good." The price of Wheat is quite unremunerative to the grower, and corn-producing farms, where but few stock can be kept, will afford a poor return for the capital and skill employed in their cultivation. On farms where large quantities of cattle and sheep are bred and fattened the prospect brighter. Meat is high, and likely to continue so, grazing is conducted at a good profit, and happy the man who are favoured with the facilities for making as well as for corn-growing, as the profits on the one will help to recoup them for the losses on the other, and they have a fair chance of making "both ends and the middle meet;" but we fear it will be far otherwise with some, less favourably circumstanced.

The threshing test proves the yield of Wheat to be very various. The heavy laid crops turn out very well, whilst some of the brighter and up-standing crops are yielding very well. The quality of the bulky crop is far better than could have been expected, though the yield in many instances is fearfully short. A better class of crops—say about 50 per cent. of the whole—will produce an average yield; the remainder will be seriously deficient, probably 30 per cent. below average. These are the conclusions we have arrived

at, from the knowledge obtained by the threshing test up to the present time.

Barley is yielding rather worse than we expected, probably the difference between our estimate and the actual yield will be about a quarter per acre.

As far as we have tried the Oat crop, we are inclined to regard it as the most satisfactory on the farm, but the good yield is to some extent neutralised by the low price. Beans and Peas are comparative failures.

The crop of hay was good, and has been followed by good average crops of Mungels and Kail Rab. We are taking them up and storing them now, and they are turning out well. Cereals were a good crop, but the cold wind and frosts of the last week in October did many of them serious mischief, reducing their value 30 per cent. or more. Potatoes vary very much, but are reported as largely diseased. The Wheat seeding is in progress. We have finished, but many people are still busy. The late and long harvest made the preparations late, and threw work very much "in heaps," a state of things always undesirable and perplexing. Much land too has been unfit to sow for want of moisture, and even now is too dry and unyielding. We are ploughing some stiff land for Beans, and it breaks up very hard and dry at bottom. Wheats where early sown come up very slowly, and seem to want a little warmer and moister weather. Foot-and-mouth disease has appeared amongst us, but not generally in a severe form, and we have heard of no losses of life amongst the cattle. Importation of foreign cattle and disease appear to resemble cause and effect, and if we are to be free from the one we must forbid the other. A. S. R.

MERSE OF BERWICKSHIRE. Nov. 13.—The legitimate test of threshing has now been tried, what might have been suspected from the turning over and carting out of stacks at the close of harvest, that our crop has suffered more from bad weather than it has done for these 12 years past. Fully one-half was a field when the rain came on, Sept. 10. Much that was in stack had better been out, and badly built stacks were drowned by continuous rain. Things were worst under active management, as this made the work of twice or thrice carting. Slow coaches were content to keep their stacks a foot, and wait for fair weather. And a right wind it was when it did come, for it soon dried everything, but colour was lost, sprouting more or less general, and very bad in sheltered places.

Of course, it comforted us during that weary time of rain and heat to learn from our "leading journal" that the bulk of the crop in Scotland was secured, and it would benefit the Turnips. And so it did, but winter's wind came too soon after this and cut down the tops, so that we need look for no farther increase. As it is, the crop is quite superior to any we have seen these three years past. There is not much grass in the fields for ewes, now that tapping is done, but there will be no lack of Turnips for them when the time comes, and artichoke feet won't do instead of Turnips, here, at least, we find it so. Although there have fallen 2½ inches of rain since harvest, yet the ground is dry and firm for folding of sheep and storing of Swedes. Streams have been very little moved, and water is rather scarce for threshing mills, much to the advantage of those that travel for hire.

In spite of legislative wisdom and police surveillance, foot-and-mouth disease (our name of murrain is less clumsy) has kept its line across country. To well-conditioned cattle it does no harm, but on lean beasts and cows it is oppressive, not so much so, however, as the Aot, which would actually compel a beast to remain in the field where first attacked, when he would be so much more comfortable in a straw-yard or shed. Care may delay the march of the disease—nothing can stop it, and we would rather take our chance and be free from inspection. Why not compel farmers, "in the interest of the consuming public," to keep twice as many cattle as they at present think they are able to do? J. T.

NORTH RIDING OF YORKSHIRE. November 17.—Since the date of our last report we have in this district experienced weather of a very chequered description. Twice within the month we have had a cover of snow and about 6' of frost, and accompanied with strong north winds. We have had this interspersed with some days of fine mild weather, but the general character of the month has been wintry.

Several farmers brought their fattening cattle into the yards during the first week of November, and all store cattle have since been housed, being quite three weeks before the average time of housing.

A commencement has been made with pulling and storing the root crops. Swedes are a full plant but in size the bulbs are short of an average. White Turnips sown early are in many places a failure; the late sown have done better, and are pulling off fairly; but, on the whole, our roots can scarcely come up to an average.

Potatoes proved a good crop, and very little disease in this district. Some farmers sold in the field at from 15s. to 18s. an acre. The price now is about 3s. a bushel.

Wheat is threshing out quite as well as was expected, but on some farms the yield of Barley is complained of.

Store cattle have gone up in price, and sheep very much so, the latter quite 10s. a-head from the prices current at this date last year.

Foot-and-mouth disease still lingers in the district, and in the case of fat cattle we hear very serious losses have been sustained.

Early-sown Wheats have come up well, and so far look promising. W. J. M.

CAPRERA.—We have heard but little of late about Garibaldi's doings. Some of his most melancholy anniversaries occur in this and the forthcoming autumn months, and his best friends must rejoice at

the almost perfect certainty that nothing this year will tempt him out of his island home—that home which he would never have quitted for his disastrous exploits of Aspromonte and Mentana had not the seductions of some of his friends got the better of his sound, but not sedulently self-relying judgment. At Caprera, and away from the turmoil of politics, Garibaldi is himself again, and shows himself possessed of the practical brains as well as the kind heart for which the world gives him credit. There can be nothing more charming than the account some of the General's recent visitors give of the manner in which his love and labour have in little more than ten or 12 years contrived to turn a bare rock near the coast of Sardinia, not only into a smiling garden, but also into a richly productive estate.

It was natural to expect that a man of Garibaldi's simple tastes and abstemious habits would have chosen his island hermitage for the mere sake of its barren and desolate look, and that the tilling of a few acres for Wheat, and the growth of the commonest vegetables, should have met all his requirements. But the cultivation of the mere necessities of life would not have filled up the cravings of an extraordinarily active mind. Unlike most of his countrymen, Garibaldi did not gratify his ambition by setting masons to work. He charged Nature with the embellishment of his home, and so marvellous is that Mediterranean climate, that in this short time luxuriant groves of Laurel and Myrtle have sprung up to overshadow his low roof. All round, in the hollows, wherever shelter could be found or made, the Orange and Lemon are growing in thickets, while on more exposed sites there spreads a wide plantation of Olive and Almond, over-topped by the Cypress, the Pine, and even the Date Palm, though the latter bears no fruit. Garibaldi himself drinks no wine, but he is, nevertheless, a wine-grower on a large scale. His hill sides are covered with low, closely pruned Vine stocks, an importation from the most celebrated Piedmontese and Tuscan vineyards, the young Vines, planted in straight rows at a metre's distance from one another, are never suffered to rise above 2 or 3 feet from the ground, and never bear more than two or three bunches of Grapes. By this thrift the hospitable General is enabled to place choice wine before the guests who crowd upon him, while the Marsala and Malaga Grapes growing at will on his lofty arbours supply the dessert with such luscious fruit as the south alone knows of. The General's orchards do not yield many Apples, Pears, or Peaches, but the Prickly Pear and the Carob Tree are so prolific, that their produce is thrown with a full hand to fatten swine. Garibaldi's dairy is supplied with milk and butter by six cows of the tall Cremona breed, but numerous herds of cattle roam at large in the island, needing no shelter at any time in the year, and providing the establishment with mountain-fed butcher's meat, in return for the Lucerne and Clover which the General mows out of artificial meadows, where the Grass is cut five times in the year. The same constant prosperity does not attend all the General's undertakings. All his efforts to root out a poisonous weed with which the island once teemed have not been altogether successful, and the propagation of his flocks and herds is thereby sensibly checked. In the same manner the attempt to acclimatise the silkworm has turned out a failure, the soil being unpropitious to the growth of the Mulberry. Garibaldi, however, points with exultation to the flourishing condition of his Potato fields. No species of the favourite tuber is neglected, and there is no treat he so heartily enjoys as a dish of his own Potatoes, baked under embers, with his own hand, in the open air—a treat which calls up reminiscences of his camp life on the Tonale or the Stelvio, or of his pioneer's experience in the backwoods of Mississippi or the Plate. Garibaldi indulges in the luxury of a flower-garden, but the bees which he has lately introduced, and of which he has already nine hives, "the object of assiduous and almost paternal care," are not dependent on his beds for their honey, but cull it out of the fragrant shrubs with which both Caprera and the adjoining Maddalena are covered. To get hives to do well on so gusty a spot as that bleak rock of Caprera has been accounted little less than a prodigy. On the coasts of his own island, all round Maddalena and along the shore of Sardinia, Garibaldi's nets have the pick of the Mediterranean fishery: white quails, partridges, and wild goats afford him plentiful home sports, without reckoning the pheasant and the wild boar, with which he has stocked some of the most unreclaimed heaths of his domain.

We must admit that Garibaldi has not been single-handed in these movements. His right and left hands have been one Barberan, from Parma, for many years the General's companion at Caprera, and a German named Weber, whose aid and example supplied theory and practice to a man who could bring to his work little more than an amateur's earnestness and good-will. It should also be borne in mind that the General's friends are legion, and there is nothing in the shape of garden implements and agricultural machines, nothing under the denomination of seed, plant, or graft, of dead or live stock, nothing that could minister to his wants or gratify his fancy, that has not been forced upon him. Still, it is not every man who could turn such advantages to so good a purpose. Garibaldi, however, loves work for work's own sake; and he brings to his work that energy of will and that magnetic ascendancy over other people's will which fit a man for the task of a ruler of men, and enable him to wield all subordinate forces as a mere instrument, whether the work in hand be the conduct of a campaign, the government of a state, or the mere management of a large farming establishment. It is, in the meanwhile, not a little interesting to see a man who has played so striking and yet so unequal a part in contemporary events, who has had his sublime, and again his next-door-to-sublime moments—to see such

"A garden with empty flower-beds is like a house without furniture."

BARR & SUGDEN,

12, KING STREET, COVENT GARDEN, W.C.

November is the month to provide for a display of Flowers in Spring. The most desirable Bulbs to plant are

- Hyacinths Narcissus Tulips Crocus Snowdrops Water Aconites Iris Ranunculus Anemones Belladonna Muscari Lily of the Valley Triteleias &c., &c.

The most desirable Plants for a Spring display are

- Alyssum Arabis Aubrietia Daisies Forget-me-Not (Myosotis) Hepaticas Pansies Polyanthus Dwarf Phloxes Primroses Snowdrops Wallflowers Gentiana acaulis, &c.

With the above a display in the Flower Garden can be effected far surpassing, in beauty and in general effect, the most brilliant productions of summer gardening. The Bulbs and Plants are all perfectly hardy. Designs the most elaborate may be carried out with a greater certainty of result than can be attained with summer-flowering plants. This has been eminently illustrated by Mr. Fleming at Cliveden, and Mr. Roger at Berryhill.

Purchasers of Spring-flowering

BULBS AND PLANTS,

SHOULD SEND FOR A COPY OF

BARR AND SUGDEN'S DESCRIPTIVE PRICED AUTUMN CATALOGUE.

Collections of Bulbs for the Spring Flower Garden, 10s 6d., 21s., 30s., 42s., 63s., 84s., 105s. and upwards.

Collections of Bulbs for Indoor Decoration, 10s. 6d., 21s., 30s., 42s., 63s., 84s., 105s., and upwards.

Collections of Plants for the Spring Flower Garden, 15s., 28s., 55s., 105s. and upwards.

In quantities of 100 or 1000,

THE FOLLOWING BULBS

are very cheap:—

- HYACINTHS NARCISSUS TULIPS CROCUS WINTER ACONITES SCILLAS IRIS ANEMONES RANUNCULUS TRITELEIAS, &c. ALSO THE FOLLOWING PLANTS:— DWARF PHLOXES PRIMROSES WHITE PINKS SILENE VIOLA of sorts WALLFLOWER GENTIANA ACAULIS.

EARLY and LATE SUMMER FLOWERS.

- IRIS IXIAS SPARAXIS AMARYLLI CROCOSMIA LILIES GLADIOLI &c., &c.

Are all fully described and priced in the

AUTUMN CATALOGUE,

which may be had free on application.

BARR AND SUGDEN,

12 KING STREET, COVENT GARDEN, W.C.

SUTTONS' FRESH IMPORTED FLOWER ROOTS

FOR WINTER AND SPRING BLOOMING.

Messrs. Suttons' FLOWER ROOTS

Have been selected from the principal Growers in Holland.

Messrs. Sutton DELIVER ALL FLOWER ROOTS, Except very small parcels, Carriage Free by Rail.

Special Estimates for large quantities on application.

Suttons' Complete £1 1s. Collection, For Cultivation in Pots and GLASSES, Carriage Free.

- 12 fine Hyacinths, by name 3 Persian Iris 6 Miniature Hyacinths, by name 3 Peacock Iris 6 Polyanthus Narcissus, do 50 fine Crocus, by name 6 Large Double Jonquils 6 choice Ixias 6 Single Sweet Jonquils 3 choice Sparaxis 6 Sol la princeps 3 choice Oxalis 6 Single Duc Van Thol Tulips 1 Jacobaea Lily 6 Double Tournesol Tulips 1 Lillium lanceifolium album 25 Early Tulips, 5 sorts 1 " " rubrum

Suttons' Fine New Crocus for Pots.

SUTTONS' SUPERB DUTCH HYACINTHS FOR CULTIVATION IN POTS OR GLASSES.

The best 12 HYACINTHS for 12s.

Messrs. SUTTONS' COLLECTION of HYACINTHS consists of more than 200 varieties. A PRICED and DESCRIPTIVE LIST of which may be had on application.

Suttons' Collections of Named Hyacinths.

- 100 HYACINTHS in 100 very choice sorts .. £4 4 0 100 " 50 very choice sorts .. 3 10 0 50 " 50 very choice sorts .. 2 2 0 50 " 25 very choice sorts .. 1 15 0 25 " 25 very choice sorts .. 1 1 0 12 " 12 extra fine sorts .. 0 12 0 12 " 12 choice sorts .. 0 9 0 12 " 12 good sorts .. 0 6 0

The order should specify whether they are intended to be grown in water or earth, as all kinds are not equally suited to both purposes. It should also be stated whether single or double blossomed kinds are preferred; otherwise we usually supply about two-thirds double and one-third single. The single varieties generally thrive best in water, but their merits are never apparent until the flowers are fully expanded.

SUTTONS' MIXED HYACINTHS for Beds or Open Borders—Double, Single, and various colours, 2s. 6d. per doz., 17s. 6d. per 100.

SUTTONS' HYACINTHS in DISTINCT COLOURS for Bedding, Bedding, Ribbon Gardening, &c.—Double and Single, various shades, separate, 4s. per dozen, 30s. per 100.

Suttons' Complete £1 1s. Collection

FOR OPEN GROUND CULTIVATION, Carriage Free.

- 12 fine mixed Border Hyacinths 6 fine mixed Gladioli 6 Polyanthus Narcissus 12 Duc Van Thol Tulips 12 Pheasant's Eye Narcissus 6 mixed Single Early Tulips 12 Double White Narcissus 6 fine mixed Double Tulips 25 Double Daffodils 6 " Parrot Tulips 6 large Campernelle Jonquils 6 Germaniana Tulips 60 fine mixed Double Ranunculus 25 fine mixed Tulips 50 Scarlet Turban Ranunculus 6 " English Iris 12 fine mixed Double Anemones 6 " Spanish Iris 12 " Single Anemones 3 Lilies, of sorts 50 Crocus, three sorts 3 Ferraria pavonia 50 Snowdrops 6 Dog's-Tooth Violets 25 Winter Aconites 3 Crown Imperials

For further particulars and Prices of GLADIOLUS, RANUNCULUS, ANEMONES, &c., see SUTTONS' AUTUMN CATALOGUE, gratis and post free on application.

SUTTON AND SONS, SEEDSMEN TO THE QUEEN, READING, BERKS.

New Japanese and other Chrysanthemums. JOHN SALTER and SON beg to announce that the CHRYSANTHEMUMS are unusual for this season. Their large collection, now in bloom in the Winter Garden, may be seen throughout the months of November and December, every day except Sunday. Adm. free. Verney Nursery, William Street, Yale Place, Hammermith, W. (near Kensington), Railway Bridge.

New Chrysanthemums. H. CANNELL has now a splendid Stock of H. 217 varieties, consisting of all the New, and best older varieties in cultivation, and will supply them either as Cuttings or Rooted Cuttings, or Potted Plants, at the very lowest price consistent with quality and economy. See H.C.'s FLORAL GUIDE, giving particulars how to grow the Japan and other varieties. Other kinds are classed according to what they are best adapted for, and a great deal of other valuable information, including the Second Chapter on the Art of Gardening and the Natural Requirements of Plants. Free for Four Stamps. New Florist Flower and Florist Flower Seed Merchant, Woolwich.

Lilium auratum.—To the Trade and others HOOPER and CO. expect to receive very fine Bulbs of the above, via the New Pacific Railway, due about January next. They are collected by a Person thoroughly acquainted with their requirements, and will be unless arrive in the best condition. They will be in London in about 55 to 60 days from their native soil. Orders now booked, and persons requiring them will oblige by sending their orders without delay. Prices on application. HOOPER and CO., Covent Garden, London, W.C.

Camellias, Azaleas, and Epacris. HENRY WALTON, having a large stock of the above, finest plants possible, well set with bud, being all home worked, can with confidence recommend them. AZALEAS, 24s. to 63s. per doz. CAMPELLIAS, 24s. to 63s. per doz. EPACRIS, 15s. to 24s. per dozen. Having several hundreds of beautiful trained Azaleas, from 2 to 4 feet, fine for exhibition purposes, for 6d. to 12s. each, also fine Half and Specimen Camellias, 10s. 6d. to 10s. each—this is a favourable opportunity for parties furnishing new houses or improving their present collections. Trade liberally dealt with. CATALOGUES on application. Edge End, Marston, near Banbury, Lancashire.

New Geraniums. JOHN KEYNES begs to announce that he has secured the stock of those two first-rate flowers which have excited so much admiration at the Royal Horticultural Society, First-Class Certificates have been awarded them. They comprise COLESHILL (Eckron), bright scarlet Zinnia, the finest of its class; and LADY EDITH, a bright purplish pink variety. These are the two best acquisitions of the season. They will be sent out in April next, at 10s. 6d. each. Drawings may be had on receipt of 15 postage stamps. Castle Street Nursery, Salisbury.

Pelargoniums for the Million. JAMES H. LUDER'S unrivalled Collection of French, Fancy, and Show varieties is now ready, at the following low prices—100 plants, distinct sorts, for 50s.; 50 plants for 30s.; or 25 plants, distinct sorts, for 20s., hamper and package included. Crown Nursery, Reading.

JAMES CARTER and CO. have a beautiful Stock of Seedlings, in excellent condition, of their choicest Strains of CALCEOLARIA, CINERARIA, and PRIMULA, in 60-pots fit for potting on immediately for early Spring Blooming. Worthy the attention of those who have omitted to sow at proper time. Price, 21s. per 100, 3s. per dozen. JAMES CARTER and CO., 237 and 238, High Holborn, W.C.; and Crystal Palace Nurseries, Forest Hill, S.E.

The Gardeners' Chronicle. SATURDAY, NOVEMBER 27, 1869.

MEETING FOR THE ENSUING WEEK. THURSDAY, Dec. 2.—Linscott 8 P.M.

THOSE who have travelled through districts where mineral fuel is scarce, and where in consequence TREES are looked too to yield some heating material, have no doubt noticed what are called "pollard" trees, that is, trees from which the branches are periodically cut for faggots and cord wood; and others—long, lean, lanky things—trimmed up like a whip-stick, and with heads scarcely larger than a crow's nest. These are trees which rarely attain the timber size, and if they do they are such as the timber merchant, when he comes to purchase, will veto as being unsuitable for his purpose, unless perchance the incessant pruning may have given them a gnarled growth, and then they may yield a little veneer. Look into the primæval forest, where in the struggle for existence, might has crushed out right, and the few trees remaining have become monarchs of their locality, or go into the park or dressed grounds of the proprietor close by, where room has been given, but the pruning-hook has never gained admittance, and what do we find? Trees, possibly of the same age as the pollards or whip-sticks, each containing hundreds of feet of timber, and worth, it may be, scores of pounds; and what is the reason? Just this—the pollards had been pruned out of existence; while the trees where Nature had been allowed its natural action—where root and branch reciprocated each others services—had become in reality "property," ornaments of the country, cash to the owner, and such as we Britons are proud of.

We are not, however, going to write an essay upon forestry; our object is widely different; and we merely cite the preceding facts to illustrate a more utilitarian object, viz., the GROWTH OF FRUIT.

A few weeks back a correspondent gave the history of the Bishop Stortford VINES, concluding with the intelligence that, being worn out, they were to be rooted up, and new ones planted in their places. Upon reading the fact, the exclamation involuntarily rose to our lips—'Pollard Vines! Poor things, they have been dwarfed (pruned) if not to death, out of all useful existence!' Now, what is the difference between these Vines, and the pollard trees to which we

have before referred? Just this, that while the pollard may have been decapitated, or denuded of its branches every second or third year, or even less frequently, these Vines have been "whip-sticked" every year; and, not content with that, the more they attempted to develop themselves through the growing season, the more determinedly did the gardener, by his perpetual "pinching" process, say—"So far shalt thou go, but no further; Nature may know her ways, but we, the gardeners, are superior to Nature, and you, the plants, must submit to our ways as being better for you."

A quarter of a century ago, and for many years subsequently, the Vines in question were the pride of the country. Every autumn Covent Garden market revelled in the splendour of their produce, and now, in what ought to be considered their prime, they are to be rooted up and cast into the fire. Are we to regard this as an illustration of "fast life," wherein, by high feeding, hard drinking, and the neglect of hygienic rules, a man lives seven years in one, and at the age of 30 finds himself constitutionally a sexagenarian? Practically we think this to be the fact, and that constant pinching in the summer, and close pruning in the winter, engenders a something akin to those zymotic diseases, such as slow, low, and intermittent fevers, which, while they do not actually kill the patient, allow him to drag on but a wretched existence. When these Vines first came into bearing most of the great gardeners of that day wished to see them. Dr. LINDLEY wrote a glowing panegyric upon their cultivation, demonstrating the porosity of the border, by asserting that he could "push his walking-stick up to the handle anywhere into it." We accompanied GLENDINNING and BARNES, CHARLES MACINTOSH and BAILEY, of Nuneham, to see them; indeed, a gardener who had not seen Mr. JONES NASH'S Vines was scarcely recognised as belonging to progressive horticultural life. And what are they now? Just at the time when they ought to be in their prime they are "used up," "pumped out," useless cumberers of the ground. There must be a reason for this, and what is it? It is of no use to beat about the bush, but let us grapple honestly with their lives' history.

We say the reason may be found in the slow and tormenting process of the pollard or restrictive system; and the fact that these Vines, notwithstanding the vigour of their early youth, have been pruned to death—have, in fact, by the hands of the gardener, been systematically deprived of that breathing space of foliage which was not only necessary but indispensable to their profitable existence. These Vines have been kept to the single-rod, restrictive, and close-pruning systems, and they have failed, as thousands of Vines have done before them. Had one of them, instead of being confined closely to a single rafter, been allowed gradually, year by year, to have filled 15 or 16 of them—in fact, a whole house, it is not improbable that, like the unrestricted monarchs of the forest, they would annually have accumulated strength, and been now in the full vigour of their youth. Such an inference is not improbable; on the contrary, it is in perfect accord with physiological induction and practical experience. By the process of restrictive pruning, we must have restricted root action. We cannot have one without the other, and though we may think to regulate and balance the forces, we do so at the expense of natural vigour; and though the plant may seemingly submit to our restrictions, it will be, by the dwarfing process, at the ultimate sacrifice of the vital force. These Vines are ~~ruined~~ and the man in charge says there "is no knowing where the roots are." From the experience we had many years ago in lifting a quantity of old Vines originally planted by SPEECHLEY, we venture to say that the Stortford Vine roots have rambled little beyond the area of the border. When the branches are restricted, the roots follow the same law; and it is surprising how few and small they are, even upon Vines half a century old. Even if they did ramble at Stortford, they could scarcely in that elevated spot take any injury.

Here we pause for the present, with the intention of resuming our remarks shortly. P.

THE natural history of the different species of INSECTS which attack exotic species of ORCHIDACEÆ is necessarily but little known. The collector of such plants naturally selects, in their native haunts, only healthy specimens

which, free from the attacks of insects, are able to bear the journey to England in good health; and it can but rarely happen that the economy of the insect parasites are likely to be investigated on the spot, because the collector, even if he were inclined to undertake such an investigation, remains but a short time on the same locality, and is hence unable to pursue the examination during the often long period which is necessary for the transformations of the different insects to be perfected. These remarks are necessary by way of apology for the incomplete history of the two species of insects represented in the accompanying engraving, the central figure of which represents the basal portion of the overlapping leaves of the bud of an exotic species of Orchid, to which the attention of the members of the Scientific Committee of the Horticultural Society was directed by Mr. BATEMAN on March 2, 1869. The species of Orchid attacked was unfortunately undetermined. Securely nestled between the overlapping leaves were two white fleshy grub-like larvae, with chestnut-coloured shining heads of the natural size represented in the central figure. In this position they were feeding upon the thickened substance of the leaves, the upper surface of which was eaten off to some distance, without any hole being gnawed through the leaf.

The upper surface of the body, shown in the right-hand figure, is very much wrinkled, and on the underside the anterior segments are entirely destitute of articulated legs, their place being represented by fleshy tubercles. The mouth is furnished with two very strong, triangular, horny jaws, the inner margin of which is somewhat irregular, the right jaw having two small conical teeth, which are only blunt swellings in the left jaw. The under jaws are of a less robust consistence, having a somewhat oval terminal lobe, armed with about eight strong, short, blunt bristles, on the outside of which is the short maxillary palpus, consisting of only two joints. The lower lip is more fleshy, and rather heart-shaped, with the fore margin nearly straight, and having the two minute two-jointed labial palpi affixed near the anterior lateral angles. From the characters thus exhibited by these insects we have no hesitation in arriving at the conclusion that the larvae before us are those of one of the weevil family, of which several thousand distinct species are known, and all of which are vegetable feeders.

Too little is known of the distinctive characters of the larvae of the different sections of this great family to enable us to conjecture to what genus or even sub-family the insect belongs—unfortunately one of the larvae had received an injury and died, as did also the second specimen soon after we had examined it.

Immediately in the vicinity of these larvae were also found within the bud several minute dead pupæ, lying in a mass of hard dry particles of dark-coloured matter, which we had no difficulty in recognising as the excrement of the larvae from which these pupæ had been developed. These pupæ, represented of the natural size in our central figure, and more highly magnified in the upper left-hand figure, evidently belonged to a species of the extremely numerous family Chalcididæ, and by very carefully scaling off the outer horny pellicle, under the microscope, we were enabled to extract the imago, or perfect

insect, and to extend its limbs, as represented in the middle left-hand figure, magnified to same degree as the pupæ. The insect brought to the light of day proved to be the female of a species of Eurytomidæ, a sub-family of Hymenopterous (Chalcididæ, and on comparing other specimens of the pupæ we obtained from the female of the same species, the male of the antennæ more strongly setose, with five intermediate joints of the flagellum angulated on the inner margin, whereas the joints are oval and less setose in the female antenna, which is represented in the upper right-hand figure, and that of the male in the lower left-hand figure.

As the Chalcididæ have been almost universally regarded as parasites upon other insects like the Ichneumonidæ, the question of the relation of this species before us with the larva or with the above-described pupæ, has not been determined. Certain it is that the larvae were uninjured, and the pupæ were no longer in a condition to attack them parasitically, so that the minute larvae must have fed either upon the curculionideous larva or upon the pupæ. The possibility of the latter suggestion is greatly increased by some observations which have been made upon the habits of an American species of Eurytomidæ (the name of joint-worms from being found in the joints of the straws of Barley) by Mr. T. W. HARRIS, in his fine work upon the various insects of the United States, and by Mr. WALSH, in the eighth Number of the "Entomologist," in which the non-parasitic habits of these particular species of Eurytomidæ were insisted upon, Mr. WALSH having shown that they belong to a distinct subgenus, whereas the typical Eurytomæ are parasitic. The insects which we have examined from the pupæ before us belong not to the genus but to the restricted genus Isosoma, so that it is most probable that they fed upon the curculionideous larva upon the pupæ, and were not parasites on the white grub before described. For identification we propose the name of Isosoma Orchidearum for the insects. I. O. W.

— It is officially announced that His Majesty the KING of the BELGIANS intends to honour the Horticultural Society's Gardens, at South Kensington, with a visit this morning. Many of the leading men have signified their desire to exhibit a promenade and band will commence at 12 o'clock instead of 2 P.M. Scarcely even the Voluntary more reason to acknowledge gratefully the hospitality extended to them on various occasions by the Belgian King and his people, than have the horticulturists. We hope that the Council of the Society, as the representatives of British Horticulturists, what in them lies to show how deeply we are indebted alike to the King and his subjects for their courtesy and good feeling.

— We are informed that Lieut. Colonel R.E. F.L.S., Honorary Secretary of the Horticultural Society, offers for competition at the first meeting in 1870 (viz., January 19) an Essay on the PRINCIPLES of CRITICISM.

— When alluding to the SEVER CANALS two since, we alluded to the probability that a gardener would have to be called in to the engineer. An extract from the "British Journal" of the 10th April last will show that already been done by the gardener at Ismailia, a ground on which stands Ismailia, a town of 200,000 inhabitants, and the headquarters of the army, but a few years since, a dry sandy desert, on which was never known to fall. All is now transformed into an old dried-up basin of Lake Timsah, has been filled with water from the Nile by a freshwater canal, the shrubs, and plants of all descriptions, and wherever the soil is irrigated, and the air widens fast. Accompanying this extraordinary formation of the aspect of the place, there is a corresponding change in the climate. At Ismailia, during eight months of the year, the mean temperature for the four months (September is 94°, the following four months, the four winter months, 45°. Until two years ago, it was unknown, but in the twelve months last, there were actually 14 days on which no later than Sunday last there fell a shower of rain, a phenomenon which had never previously witnessed. Rain is a country deprived of its forests, or of violent storms. Here we see rain returning to a desert on restoring the trees.

— Our French neighbours have got to us. Under the auspices of the Imperial Horticultural Society of France, a Treaty is open to makers of all nations—is to be the object of the trial is to ascertain by examination, under similar circumstances, or kind of apparatus heats a definite quantity

...regularly, rapidly, and con-
tinuously. Here is an opportunity for some of our
manufacturers. Here is a chance for enthusiastic
inventors, who would have us believe that they get
more heat out of a basket of coal than was ever put
into it by Sam, the great fireman.

Our Edinburgh contemporary, The Farmer,
gives the following particulars respecting MELVILLE'S
PERFUMED MUSCAT GRAPE, a new variety, raised by
Mr MELVILLE of the Dalmeu Park Gardens, in the
vicinity of that city. Compared with the well-known
White Muscat of Alexandria, says our northern con-
temporany, the variety is a good deal like it both in
taste and berry, but of a more golden-yellow colour
when fully ripe. It is, however, decidedly sharper,
richer, and more perfumed in flavour, very thin-
skinned, tender-fleshed, and dissolving in the mouth, so
that it may be looked forward to as one likely to stand
in successful competition with the Ducness of Buccleuch
and other best flavoured white sorts. But its most
distinguished peculiarity is the delicate agreeable per-
fume which it possesses, and which is distinctly appre-
ciable on entering the vinery where it is growing, as
well as at the dessert table. It is said to have been
obtained from "Snow's Muscat," by which we presume
meant the Muscat of Hamburgh, at the Black Muscat
of Alexandria.

We inadvertently endorsed a statement of
Mr A. W. BENNETT's last week (p. 120), to the effect
that the CHIMONANTHUS PRÆCOX does not fruit in
this country for want, at the season of flowering, of the
proper insects to effect cross-fertilisation. We are
convinced that the plant in question does occasionally
fruit in this country, though rarely.

New Plants.

MACADAMIA TERNIFOLIA, F von Mueller.

...dentatis, lanceolato-dentatis, ovato v. ob-
longo-lanceolatis, v. ovatis, glabris, breviter petiolatis, raro
fere utrinque rarius, pinnis oppositis; pedicellulis axilla, caliceo
...
The plant is Macadama (Proteacea) was originally
described by our indefatigable friend, Dr. von Mueller,
who afterwards referred it to Helicia. More recently
a further and more complete supply of specimens and
the fruit have induced him to consider his first
impressions as correct, as the fruit distinguishes the
present plant from Helicia. Some small plants of the
species, of which the above is the technical description,
were cultivated by Messrs. B. G. Henderson & Son at the
meeting of the Royal Committee, on November 13, but
before Mr Bull was the first to introduce the
plant into cultivation, some two or three years ago.
Its native country (Moreton Bay) it is described
as a tree sometimes attaining a height of 100 feet, but
usually of about 30-40 feet, with leaves in whorls of
two or four or rarely two, each shortly stalked, leathery,
being glabrous, ovate or oblongo-lanceolate, entire
dentate at the margin, from 4-6 inches to a foot
long, by one inch and upwards in breadth. The
flowers, which are not very showy, are arranged in a
long-stalked raceme, each subtended by a single bract,
and described as having four linear spoon-shaped
lobes reflexed at the points. The stamens are four in
number, inserted near the middle of the calyx-tube;
the filaments are longer than the anthers, which latter
are linear, with a lengthened connective. The ovary
is sessile, surrounded at the base by a denticulate ring.
The style is thread-like, terminated by a thickened
 stigma. The fruit is a kind of drupe, with a fleshy
pericarp, encasing a hard shell, like that of a Walnut,
and within a walnut is a kernel, described by Mr
Berkeley as particularly sweet and agreeable to the
taste, thus confirming the statement of its discoverer,
Mr Water Hill, who compares the flavour to that of
Almonds. This circumstance is the more noteworthy
in view of the paucity of native fruits in Australia,
and the rarity of any edible seed among Proteaceae.
As a conservatory plant it will be grown in this
country for the sake of its shining Brexia-like foliage.
It is altogether a very interesting but not very
valuable addition to our list of conservatory plants; and
should some fortunate cultivator succeed in inducing
the plant to produce its seeds, great will be the delight
of the Fruit Committee after the eulogium pronounced
by Mr Berkeley on the imported fruit. M. F. M.

VINE SOILS.

...as may be almost every subject per-
taining to viticulture, we were nevertheless favoured
by Mr Cramb, in his interesting paper, read at the
Manchester meeting, with some new food for discussion.
In respect to the desirability of certain soils for Vines,
we are indebted to Mr Cramb, who is one of our best
practical vintners, and is moreover one of long
experience, for suggesting a-thinking on the subject. We
are inclined to him for bringing certain facts of his
own observation before us relating to the important
subject of soils. It is a subject of considerable import-
ance, and one but very little understood. We turn to
the back pages of this paper, to all sorts
of treatises on the Vine, to the many scores of
pieces of wonderful Vines, and the way to make
the best berries-but we learn nothing further, how-
ever, than that the said borders have been com-
posed of good turfy loam, which is so vague a term,
and from which the one hand to sand on the other,
and practically the information is worth nothing
nearly all the writers on Vine culture recommend the

admixture of "old lime rubbish," besides manures of
various kinds. But few, however, like Mr. Cramb, have
ever ventured in the fields of the geologist and chemist
to search for the secret of success or non-success in
Grape cultivation.

In my plain, matter-of-fact sort of article on the
Vines at Trentham (p. 1051), I had the courtesy to
make some remarks on Mr Cramb's theory. I ven-
tured in some measure to disagree with Mr. Cramb in
his wholesale condemnation of calcareous soils, and to
state that "facts would hardly bear out his assump-
tions," &c., and for this (see p. 1107) I am somewhat
severely (I think) called to account. Mr Cramb lays
his statement before us, and presumes to invite dis-
cussion. I have been expecting to see it ably
discussed-to have our Grape cultivators, whether
successful ones or not, bringing their facts forward,
not in the spirit of contradiction or opposition, but
with an honourable desire thus to gain some useful
and reliable information. It may not be a pleasant
thing to Mr. Cramb for anyone like myself to try to
upset such a long-cherished pet theory as this has
been. It has, as it were, become so wound up in his
very existence, that, lover-like, he can see in it
no blemishes, nor listen to one word of argu-
ment against his pet, from whatever quarter
it may come. Therefore, although I have but little
hope of convincing Mr Cramb by any fact or argu-
ment of mine, I hope he will believe in my sincerity. I
would just suggest to Mr Cramb, that it is not a
particularly nice part of self-justification to accuse his
opponents of false motives. Let me assure Mr Cramb
that I have not only read his paper carefully, but I had
also the pleasure of hearing the author himself read
it. I am told that I have "no right to salt up truth,"
whatever that rather ambiguous expression may mean.
Is Mr. Cramb, himself, the personification of truth,
that his writings must be accepted as the veriest
gospel? Mr. Cramb gives us a few facts, which are
valuable, and it is a pity he did not confine himself to
these-the rest is belief or matter of opinion. Very
dogmatic opinion, too, the reasonings of which I dispute.

It is impossible for any one to rise up from a perusal
of Mr Cramb's paper without feeling that it was not
so much to ask, or even to prove "what soil is best
suited for the production of Grapes," although we
have his verdict in favour of the siliceous soil of the old
red sandstone (not excluding others), as a laboured
attempt to prove bad, and a wholesale condemnation
of all calcareous matter in our Vine borders. The question,
then, is not that with which Mr. Cramb deals in his
paper, but are calcareous soils injurious to Vines?
Or are calcareous soils to be recommended for the
formation of our Vine borders?

I hope I have shown in my previous writings that I
can be very liberal minded as regards Vines and
their cultivation, not an exclusive advocate for
any one kind of soil, whether the major portion of it be
either calcareous, siliceous, or aluminous. I believe
more in its mechanical than in its chemical compo-
sition. The texture of the soil, its porosity and
permeability in its relations to heat and moisture, and
its power of retaining and transmitting under all
circumstances, wet and dry, the necessary quantities of
moisture, are of ten times more consequence than its
mere chemical constituents, for as Anderson, in "The
Elements of Agricultural Chemistry," says-"The
soil must not merely be considered as the source of the
inorganic food of plants, for it has to act also as a
support for them while growing, and to retain a
sufficient quantity of moisture to support their life,
and unless it possess all the properties which fit it for
this purpose it may contain all the elements of the food
of plants, and yet be nearly or altogether barren."
Vegetation is by no means a sure indication of the
chemical constituents of a soil, for analysts have
proved, over and over again, that plants frequently
possess in a great degree that which is almost entirely
absent from the soil, and it must never be forgotten
that the essential food of plants is found in water with
light and air; where these, therefore, can be best
supplied will the plants best succeed.

There are abundant examples to prove that the
Vine is one of the most accommodating of plants
as to soil, &c. 'Tis but to-day, on making some
alterations in our Vine-borders, that I have had
to note another illustration of my statement. I
do not find the roots in the finely prepared
borders of Wimbledon loam. I do not find them
greedily devouring the top-dressings of manure which
have been oft applied. I find them, however in the
gravel walk; I find them clustering round the broken
bricks, coal-clinkers, &c. I wonder how much there would be
present, &c. 'Tis not so very long ago since Dr.
Lindley, in the columns of this paper, wrote a glowing
account of Mr. Wilmot's Vines at Isleworth, telling
us that their roots were almost entirely in coal ashes
and coal clinkers, which set everybody with any of these
commodities to spare to turn them to good account
in their Vine-borders. But I need not multiply
instances; one grows good Grapes in one kind of soil-
it may be siliceous; another in another, which may be
calcareous; and a good gardener who knows how to
compose and manipulate his soil will grow good Grapes
in either, despite Mr. Cramb's disclaimers. How is it,
for instance, that our neighbours, who grow their
Grapes in exactly the same sort of soil as we do should
generally have Grapes more inferior to ours? Is it, or
can it be, owing to soil, or management?

I am not about to dispute for one moment that
Mr. Cramb has not found the siliceous soil superior to
the calcareous mixture, as he has found it at Tort-
worth, or that he has not good grounds for preferring
the one to the other. Are we, however, to be led from
this solitary example, on the extremely limited actual
experience of Mr. Cramb, to such a hasty conclusion,
and protest against the presence of all calcareous

matter? I hope not. I hope the subject now agitated
will be thoroughly discussed.

Mr. Cramb's guilt of a grievous error in accounting
for the bad effects of the calcareous soil when he states
that "the caustic property of the lime worked all the
mischief." Did Mr. Cramb apply lime to his borders
in a caustic state? because such a thing as caustic lime
does not exist in a state of Nature. It has to be made
so by an artificial process, that of burning. Again,
Mr. Cramb says, "the nearer it approaches to a state of
carbonate, the more fatal the effect." It is difficult to
understand what is clearly meant by this, whether it is
carbonate of lime, which is virtually the limestone
itself, or chalk, or effete lime, or whether it is carbonate
of magnesia, which is a component part of the
magnesian limestone, which, when in a caustic state,
rendered so by burning, is said to be injurious to
vegetation. A very sagacious acquaintance with chemistry
ought to have enabled Mr. Cramb to understand this.
Telling us that the nearer the calcareous particles of
soil approach to a state of carbonate, &c.-like saying that
the nearer water approaches the liquid state the hotter
it becomes. Chalk and limestone when burnt, form
lime; the burning drive off the carbonic acid; it is then
caustic. By exposure to the air, &c., it again absorbs
the carbonic acid gas, and returns to its original state
of carbonate of lime, or, in other words, to the same
chemical nature as powder of chalk or limestone, which
is merely a earthly ingredient of the soil, improving
its texture in its relation to absorption, &c. These are
the opinions of the most learned chemists, including
Sir H. Davy. The evil, therefore, of which Mr. Cramb
complains must be traced to the magnesia, and not to
the lime, yet it is difficult to account for it even here,
as the soils on the magnesian limestone are as fertile
as any others. The question which will come upper-
most is this-Is not this a mere supposition of
Mr. Cramb's?

All fertile soils, say our learned chemists, contain
some portion of calcareous earth. The three earths
which constitute the principal ingredients in all culti-
vated soils, are lime, clay (alumina), flint (silica); not
one of these singly can be considered fertile, and the
richest soils are those in which these three earths are
mixed in the most intimate proportions. As note our
great river valleys-that of the Thames, for example:
where do we find richer land, or land more favourable
for the cultivation of the Vine, using it in what we are
pleased to call its natural state, without any admixture
whatever? These are called alluvial loams, being the
deposits by water from the various formations, along
with decayed vegetable matter. In these alluvial
loams there is a good percentage of calcareous matter,
without which they would probably be almost sterile.
Calcareous soils attract more moisture than siliceous
soils, which being sandy are very open and porous, and
consequently require a more abundant and continuous
supply of moisture than the former. In a rainy county
like Gloucestershire, it is not then at all remarkable that a
siliceous soil should prove the best, simply because its
great porosity allows the superabundant moisture to
readily pass away. Siliceous soils are hungry soils, and
decompose manure faster than do either of the other
two. This Mr. Cramb confirms somewhat by having
for the cultivation of his pot Vines to use one-third
part manure, which must strike every practitioner as
being a very large proportion, and tempts one to fancy
that the siliceous had not, after all, such a great deal to do
with the success. B.

(To be Continued)

EVERBEARING STRAWBERRY.

DURING the last two seasons the agricultural and
horticultural world in America has been much
interested by the advent of a Strawberry, claimed to be
new by its introducers, and affirmed to be an old
variety under a new name by its traducers. As it
really is a curiosity, and about taking part with
either its proprietors or users, I will proceed to
describe it for the benefit of your readers.

The plant is called by its proprietors the "Mexican
Everbearing Strawberry;" it has been most extensively
advertised and puffed by one portion of the Press, and
considerably decried by the other. Strange to say,
those who decry the plant, "don't advertise it;"
whether from not being paid to do so, or from con-
scientious motives, it would be difficult to decide, but it
is quite clear that the advertisements are very long,
highly illustrated, and must be exceedingly costly. In
the beginning of the present season, about May, the
writer procured some of the plants, and set them in his
garden. They had been a good deal injured by detention
in transit, and were therefore some time before they
recovered; but no sooner did they take hold of the
ground, and throw out new leaves, than they also
began to blossom and bear fruit, and they have con-
tinued bearing ever since, the plants never having been
three days without ripe fruit on them, and now
(October 8) each plant has a considerable number of
berries on it in every stage, from the blossom to the
ripe fruit. By actual measurement of some just picked,
they are one and one-tenth of an inch long, six-tenths
of an inch broad at the upper end, tapering to a blunt
point; they are a pretty lively scarlet, covered with
yellow seeds, highly fragrant to the smell, but not
highly flavoured to the taste: they are, however, pos-
sessed of the true Strawberry flavour, and though not
so acid as many kinds they are very pleasant.

They would not be much noticed during the season
of the ordinary Strawberries, but later they become a
rarity and a treat; they all part from the crown in
gathering, and are very light in weight compared with
their size. The flower is perfect, and requires no other
to fructify it, it is very small, and the plants are, as a
matter of course, continually covered with blossoms.
The plants do not throw many offsets, but many of
these blossom before being well rooted and bear fruit.

and sometimes the second offset does so too. The proprietors claim perhaps more than it deserves, and as they sell the plants at two dollars and a half a dozen (10s. sterling), temptation is strong to do so; but that it is an "everbearing" variety, the writer can vouch, as he has gathered them more or less every week during the present season, and they show for fruit now as much as ever.

Whether it is a new variety or not, botanists alone can decide, but that it is a Mexican variety, the writer is certain. A gentleman just from Mexico recognised it, and said that he had been in the place from whence it was brought, i.e., the mountain range near Jalapa, Mexico; that he had there seen it in a wild state, bearing profusely, from early spring throughout the year, until the frost stopped it. Of course the frosts in Mexico are not severe, but the plant comes from the high Andean chain of mountains which form the highlands of Mexico, from 5000 to 10,000 feet above the sea. The berries there are much larger than they are here, and higher flavoured. In Mexico they are delicious, but there all fruits come to greater perfection than elsewhere. It grows well under glass, and in pots.

As a native of a hot climate, and from its everbearing habits, it would I should imagine be a valuable variety for forcing in England, and I have no doubt that a proper house devoted to this purpose would be a productive speculation. At all events to those to whom such fruit all the year round is an object, the experiment would be worth trying; the plants could easily be sent from here by steamship at a small expense during the proper season. The traducers of the plant say that it is nothing but the old bush Alpine revamped up; but it is strange that the old bush Alpine has a much rounder berry, and is a very shy, though perpetual bearer, whereas this is a long slender berry and a profuse bearer. That it is an "Alpine" or rather an "Andean" plant there can be no doubt, for we have good evidence of its existence in a wild state in the Andean range, and in great profusion.

The plant with the writer is not a strong grower, but it spreads into a stock of several inches across in one season, and thus each plant becomes a considerable tuft. The leaves are not large, nor hairy, they are of a lighter green, and different character from any of the ordinary cultivated varieties. They have not had fair play in the writer's garden, which four years ago was a mere sand-bed, bearing nothing but the poorest kinds of grass and Sorrel, though now brought up to tolerable fertility by manure. No Strawberry, however, does well in this garden, and hitherto all have died out but the "scarlet" and the present Mexican. The latter has not yet stood the winter here; but the growers assure us of, and warrant, its perfect hardiness.

As a stock for raising new seedlings from, it must be valuable; hybridised with others to increase its size and flavour, and care being taken to retain its everbearing qualities, it must become a useful variety for the forcing house, if for nothing else. *Vectis, Lower Canada, October 8.*

POTATO CULTURE.

I HAVE just secured a most satisfactory crop of Potatoes, exhibiting all that could be desired in size, quality, and quantity, and as the results obtained are by no means general this season, I feel more satisfied that my success is in some measure due to the system of culture I pursue,—a system, it should be remarked, calculated to counteract the disadvantages that attend the cultivation of Potatoes on cold clay soils, and which may be called, by way of distinction, the super-surface plan of planting. The system was devised to meet certain difficulties attendant on the growth of Potatoes on cold retentive soils; but its general applicability to all descriptions of land is not for a moment asserted.

It would be wrong to dogmatise on modes of culture practised in the case of Potatoes, so various are the circumstances of soil and position which exist in every district; but if every large grower of Potatoes were to try to learn lessons by his failures, and borrow hints from his successes, and so adapt his management to the special peculiarities of his land, we should hear of fewer failures in the Potato crop. My Potatoes are grown in well worked but strong soil, resting on clay. By following the old plan of drawing deep drills 4 or 5 inches in depth, the Potato sets were within 6 inches of the cold subsoil: so placed, the roots of the plant soon struck down and suffered from the low temperature and dampness of the retentive subsoil. Potato crops of inferior quality, and more often badly diseased than not, were too often the result.

The plan I now pursue is based on the principle that the Potato, being a tender exotic, requires all the heat and light we can give it, deep good mould, and immunity from sour soil, in which water rests and stagnates. I place the sets on the surface 18 inches apart, having well dusted the ground with burnt earth and wood ashes. The Potato rows are drawn out 3 feet apart from each other. The soil for 18 inches on each side of the row is drawn over the sets in a continuous ridge. The furrows thus formed are made deeper than the natural level, and in this way the sets enjoy the advantage of being above the surface, and heavy rains never rest among the tubers. The Potato thus placed has 12 inches of good soil below it, with a base of 36 inches laterally for its roots to ramify in. The rows are run east and west, so that one side of the ridge is fully exposed to the sun.

In the winter preparation of the land I avoid the use of fresh manure, and if employed at all a light dressing is all I think necessary to apply. Burnt earth and wood ashes is an application rich in the best manure for Potatoes; potash is more liberally applied, but this is not all. In digging I have as much of the subsoil brought to the surface as the weather is likely to operate upon. As soon as wind and frost and rain

have caused these heavy, sulky lumps of clay to break up, a dusting of burnt earth is thrown upon them, and the cohesion of the lumps is destroyed for ever. In thus treating the land the Potato gets a certain quantity of fresh soil, and this, with the dry warm dressing of ashes, its elevated position securing all possible heat, free space, air, and light, without obstruction, it is perhaps no wonder that, even in our old kitchen gardens, crops of excellent Potatoes, averaging 20 tons to the acre, are obtained. *William Ingram, Belvoir.*

Home Correspondence.

Colouring of Pelargonium Leaves.—By the leave of you grand editors I the sooth, I want to hae a word wi' twa o' your writers, that ca' the hectic flush o' comin' death nonsense. If that's nonsense, it is a kind of fulery that Nature—that mustna be ca'd a fule—indulges in gie muckle. A' the woods are flushed ower wi' this nonsense jist afore the bonnie leaves fa' down and dee. And in a' sic cases the flush is no a proof o' robust health, but jist the sign o' comin' death. And hoo does Mr. Sandy Dean ken that it is jist the contrarie in Pelargonium leaves? At ony rate, he disna prove his pint by telling us a' that a droothy bottom and excessive root action baith alike paint the cheeks of the Pelargonium leaves sae prettily. Nae man, gin Sandy had ever suffered frae whusky drooth he would hae kent brawly that that makes pale faces; whereas, when oor feet are under a weel-spread table, they become a bonnie red colour; and I am no sure that it wadna be jist sae wi' the plants. But I canna see hoo the starving o' the roots in the Elegant Pelargonium could cause the robust health that makes the high development o' beauty. Neither is it sae easy to unnerstan hoo warm or nimble feet (roots) can mak a rosy face or bright leaves. Gin it be sae, oor fair leddies hae only to put their feet in het water, and their hands oot in the cauld, to mak the roses on their cheeks bloom tae perfection; which seems rather a nonsensical and dangerous proceeding, no to be followed by leddies or plants, without we kent mair about it than Mr. Sandy Dean has yet tellt us. *A Canny Scot.*

Judging Melons.—It would perhaps be well if the managers of our horticultural shows would follow the rule laid down for judging Melons at the Edinburgh show. I am of opinion that it is not necessary to cut a Melon to arrive at a pretty correct estimation of its qualities, unless it be a new or unknown kind. The present system of judging fruit by flavour is, to my mind, most unsatisfactory. It is simply impossible for any one to go over a multitude of dishes and make just awards by flavour alone. If we are to judge our fruits at horticultural exhibitions by flavour, it will often be at the expense of good cultivation. Rather let us place this in the foreground, and judge with our eyes, and we shall not often err in forming a correct judgment of the qualities of most fruits. A repetition of tasting cloy the palate, and often misleads, but it is an easy matter to run the eye over a large number of dishes and pick out the best, and as your correspondent has it, there are the two senses to guide to a decision, viz., sight and smell, *versus* taste, but if the number of dishes are thus reduced by selecting the best grown, it is easy to decide by flavour, if the competition is very close. We much want a code of fixed rules to judge by, as it is not uncommon to find at one show that the judges have cut a fruit on almost every dish, and perhaps an inferior looking collection has the award, while at the next show size and general appearance have carried the day. *J. Sheppard, Woolverstone Park.*

Melon Judging at Edinburgh.—Mr. Thompson has explained a' about hoo it was that the grumbli' arose about the Melon judging. It seems that the Caledonian Society, after scoorin the countrie for able judges, sent their officers to those same judges to tell them hoo to dae their wark. They might look at and smell the fruit, but daurna cut nor taste them. Weel-a-weel, wonders will never cease. If sic a mode o' judging the Melons was to be adopted the Society needna hae sent sae far for judges. The nearest grocer body has a pair o' scales, and ony bit o' a painter frae the Schule o' Design could hae judged the Melons as weel, or better, than the best gairdner in Britain. A' that was needed was an ee to see the beauty, a hand to clap the fruit into the scales, and a nose to sniff it a wee bit. Then, presto! begone! 1st prize heaviest, handsomest, fullsomest. Weel-a-weel, sic a display o' judgment is simple at least; an' ance admit that Melons are only grown to be eed and smelt and no eaten, and the plan is a' right enough. But, then, on sic a plan we might jist as weel grow Gourds or Squashes, which are larger an' handsomer than mony Melons; an' they could be scented wi' Eau-de-Cologne or ither gude stuff. If twa senses can but be pleased, wha cares about the taste? Sae at least thinks ane o' the judges, wha has written to approve o' the tasteless mode o' judgment. He likewise gangs on to haud up the practice on the queerest ground ever heard o' this side o' the Tweed. Scotch tobacco and whusky toddy are no only strong but irresistible to oor southern judges. But it seems that while sic things dunt or destroy the taste, they leave the senses o' smell an' sicht strong an' clear as afore. Noo, it is weel kent that this doesna square wi' oor experience. Toddy will mak the een see dooble; and it is kent gie weel that onything that benumbs or bemuddles the palate blunts the smell as weel as sends the taste wrang. Besides, we dinna want either toddy-muddled or 'bacca-numbered judges, we hae plenty o' the sort at hame, without scoorin England for them at show times. But Mr. Thompson has mair to say in favour o' ee-an'-nose judging. He will hae it that it beats the ither mode o' tasting a'thegither, because it gies us twa senses to ane. Weel, that beats a' I ever heard! Suppose we jist let in the taste, wouldna that gie us

three senses against twa? Or does Mr. Thompson mean to say that the judges wha insist on baith up their noses an' close their een? Surely baith see an' smell when he is tastin'; in fact, baith better after the Melon is cut than afore. The skin shuts in the best o' the perfume and quality. I' the face o' Mr. Thompson's wise officers o' the Caledonian Horticultural Society whase rules he admires, I mak best o' the sense they shut oot is weel kent; the ither put thegither, an' in fact in the oocht to be first considered. If Melons were to be worn as chignons, or suspended as nose rings, then ee-an'-nose judgment oocht to rule; but as they are grown for to please the sense o' taste oocht to be consulted an' hae the there need be nae rivalry ava atween the judging sic fruits. It's no a question o' twa ane, o' three against twa even, but it is a question o' senses doing their very utmost to fin' out the best. An' Melons are sic kittle fruit to judge, an' sharp nose, a keen ee, an' a weel seasoned tongue o' them numberd wi' 'bacca, nor muddled wi' fin' oot the best. Mr. Thompson seems to hae been a' right because baith the prizes were to the same grower. Noo, I confess, I thought until I read Mr. Thompson's letter. But on o' the toddy, the interference o' the oocht senses pitied against the ane, &c., I hae no mair in saying that I think the judgment, rather than a meddle an' muddle frae beginning to the final award a loup i' the dark. An' it shows, a gude mony o' us will rather keep hame than hae them sniffed at an' passed over in fashion. The proof o' the Melon, fit for puddin', is i' the preeing o't; an' it is jist an attempt to judge the former wi' a look o' the sniff o' the nose, as it would be to test the puddin' i' the same way. If the fruit is better o' than the prize, let it be kept at hame, an' name o' common sense let's no gang on quality without testing for it like some o' us. Even insects winna eat their fruit without see if it's gude; and surely oor judges o' muckle sense as a wee bit waspy. *A Canny Scot.*

Herbaceous Grafting.—A correspondent's writing on Potato grafting, reminds me of experiments tried in herbaceous grafting during the part of the present season, and which were described in a paper read by me at the Congress, "On the Influence of the Stock, Scion, &c.," and subsequently published in *Gardeners' Chronicle*. The writer at Burnett) says:—"What I value most seeds that may be produced on the grafted. This is precisely my view of the subject, carefully preserved seeds produced by Beans, Scarlet Runners, &c., with a view whether or not the stock will produce any influence upon the produce of the scion. This cannot be ascertained before next season, at present wished to allude to, was the luxuriance with which the Scarlet Runner grafted upon the common dwarf French was contrary to my expectation, and the necessary sustenance through the fragile dwarf Bean, and this without any effort on the scion to emit roots above the junction; the other hand, dwarf French Beans grafted on the Scarlet Runner were considerably less than the same varieties growing upon their own roots in neither of the cases can I perceive any in the seeds so produced from that of the grafted. *P. Grant draws P.S.* In my remarks at p. 1184, on "Orchid-foliaged Pelargoniums for the purpose of decoration," I intended to say Orchid-house an orchard-house, as there printed.

Potting Lilliums.—Hark! Nature loudly calls to "W. E." to discountinue the off" of the bulbs of these plants. He is and we see him apologising to the old because she has been saying the same. Now if "W. E." will follow Nature, there little difference between us—and that theory. "W. E." will persist in writing week of January," while I am writing has not turned out Lilliums yet, or he such—will he pardon me?—nonsense, supporting dead stems, for the roots with the stem—and the "scaly bulbs engaged in collecting support" from the is some of "W. E.'s" theory, not mine. fresh! and fresh! I say—pot your stem is dead, as being the time when the bulb is least active, for the bulbs of the opinion never "rest," in the fullest The bulbs cease to make new roots at stem begins to decay, this may be called of its resting period. While the stem bulb seems to draw up the required succulent roots, thereby charging the to make other roots, and at the same the "invisible" part "W. E." speaks as this process is completed, if the soil the bulb will begin again to make roots, prepare itself to throw up another the stem is vis ble by this practice laid such a foundation in the way of stem will not be those "drawn reads" I must refer "W. E." to Mr. Tan gentleman has so well disposed of have been raised that I need not explanation. I must own I was

content to abide by the teaching of our forefathers, but as, like "W. E." awakened by the teaching of nature, by following up the process by which she so wonderfully carries the Liliun round with the year, like "J. D.'s" note, it is candid. I hope he will in November potting, and report: I must leave to you the task of explaining "spring." I would so respectfully ask Mr. Smith to give us the interpretation of his time of "potting" Liliuns. I would advise "Youngster," and all—I question if there are many—who have not tried November potting, thinning, as the case may require, to prove it, and gain at once. M.

Vine Roots.—When I propounded the question (see 1137), Do Vines make leaves and branches without the aid of new rootlets? I expected that it would be intelligently understood, and debated upon its merits. It seemed to me to be a very suggestive question, interesting to science and practice combined, where the men of the spade and the men of science could actually co-operate to settle the question. In order that there might be no misunderstanding of the text, I averred that it appeared to me that spongiole or spongy rootlet formation, was more the consequence of the cause of leaf and branch manufacture. This is no foregone conclusion, but warranted by repeated observations of Vine plants growing under different circumstances, all tending to demonstrate and confirm the theory propounded. Mr. Knight's additional experience since 1868 is more emphatic, and enables me to speak with more decision and power, while Mr. Dawson's observations also go to establish the simple fact, so far as Vines are concerned. But I was apt to run away with the idea that because spongiole manufacture does not take place simultaneously with leaf-and-branch development, that since the supporters of that theory are committed to the idea that the established roots are dormant, and that the leaves and branches are entirely indebted to the stem, which is supposed to be like a river and its tributaries. Only there is this difference, to be true to metaphor—the river of sap which is manufactured into such extension flows uphill. Mr. M'Millan, who has given particular attention to this subject for a considerable time, seems to fully appreciate and understand the hydraulic pressure of sap in active motion, and its tendency to ooze out and "bleed" at fracture, when it cannot be otherwise utilised; but utterances upon other physiological questions—such, for instance, as "a vacuum left somewhere equivalent to the increased bulk of every bud upon the tree," and the theory as to leaf-fall, viz., "by their (the roots) desire to go to rest refuse to supply the food necessary for keeping the leaves on the trees,"—are more original than sound; and in fact, to borrow the line of his own imagery, never had the "fang" most people know that the ascending sap is manufactured into leaves and branches, and the descending sap into spongioles. [Loose physiology in Eds.] Between root and branch there is the most intimate relationship, and because we see leaves and branches forming in Vines and deciduous trees generally as precursors to new roots, it would be a series of unwisdom to surmise, and then credit, that root action was fast asleep, or that every available particle of sap was withdrawn without the old roots retaining the power to replenish themselves. That seems to me to be the foregone idea upon which the whole action turns. As to the time occupied before the ascending sap elaborates itself, and manufactures additional feeders, it depends upon circumstances of situation, of heat and moisture, and of plant constitution. A heated Vine border will accelerate the work, but only in degree, as has been abundantly testified by pot Vines, where root and branch are living in the same heat and atmosphere. But by far the most important lesson to be drawn from the subject is, that spongiole formation, following, and not preceding, nor going hand in hand with branch extension, follows on after the wood is apparently ripe. If the ascending sap takes priority in force during spring, the descending claims a given time to finish up the activity of the year. Hence, the simple adduced by Mr. Dawson with the Gooseberry Vines, and the oft-observed habit of orchard trees generally having spongiole-like roots after the trees are defoliated. The Vine plant shows the same habit, and illustrates the same theory, as anyone may see by observing his Vine borders that the white spongioles, appearing by the eye, are crying "Give! give!" when the wood is apparently ripe, and plants seemingly in winter repose. There may be such a thing, therefore, as too early pruning; and is there a crying necessity for the conservancy of these choice plants at that particular season? A border exposed to the elements, particularly during autumnal rain and cold, bodes no good results to the extended Vine roots, and therefore there is much better plea for autumn than even early winter protection. This root finishing must be going on when, as you remarked in a recent leader, the cells in the vascular layer are filling with starch, and when the spongiole and is consolidating nutritive material. Buds and bulbous plants generally differ from other plants; the roots in all cases precede the growth, as any one can see with a Hyacinth bulb in a Pseudobulbous plants, again, as in the case of Orchids, borrow life from their established connection, and are only furnished with roots on their own account when the young growths probably are from two to three months old. In the case of Lilies it is also patent that in the pot in which they are growing may be well furnished with roots before their crowns show symptoms of upward growth; and hence the necessity for the water-studying their various habits and catering for them accordingly. To be sure there are plenty of

abnormal instances that might be placed on record, as for example, that of Hyacinths being destroyed at the root base and pushing leaves by a reversion of the sap, but death was ultimately the consequence. It is possible also to adduce instances of any deciduous scion of a fruit tree having its eyes either accidentally or intentionally rubbed off, and the scion by the force of the sap emitting roots without leaves, but death, too, ultimately took place. To the best of my belief, founded on several observations, I am bound to declare upon the side of those upon whose banner is inscribed "spongiole formation is the consequence of leaf and branch extension." James Anderson, Nov. 22.—Do Vines commence growth without root action taking place? Buds certainly cannot expand without a flow of sap takes place, nor "tatties" sprout from the same cause, or, more properly, I should say, without expansion taking place. Neither can life exist either in the animal or vegetable world without a continuous supply of life's juice, or a sufficiency of it stored up, as in bulbous roots, to expand, flow on, perpetuate, and multiply their kind. If a Potato or other fleshy root were kept in a very low temperature, probably growth would not take place. Apply heat, and the stored-up sap at once expands, finding a natural outlet in the production of shoots. It is the same in a large tree if cut down early and full of sap, the return of spring causes an expansion of this locked-up moisture, and probably an immense pressure is brought to bear, at least it is often sufficient to push the buds into leaf. Any one who has attempted to stop a Vine bleeding can form some idea of the immense pressure caused by the flow of sap. Do what you may it will escape somewhere. The more active this root action, so in proportion will the sap be propelled, resulting in robust shoots and handsome clusters. Your correspondent, Mr. Knight, infers, that because his Vine shoots, inserted in claret bottles of water, lived and pushed into leaf, that a long broomstick-like Vine will do the same thing without the action of roots, after a little heat and dewing is applied. It is just this heat and dewing that causes the sap to flow more actively, and a corresponding activity at once takes place in the roots to supply the increased demand. If your correspondent wants proof of this fallacy of Vines starting into growth without root action, let him sever all connection between roots and top of one Vine just before starting his house, and wait the result. I will venture to predict that scarcely a bud will break. I am of opinion that roots are ever at work in a greater or less degree, and that the circulation of sap is as continuous. If it were not so, the branches of every tree would be dried up by the winds and frost of winter, and plants would cease to exist. Mr. Dawson appears to have fallen into a similar error in the case of his Gooseberry bushes, as he says at the time they were forming roots, there was no corresponding action taking place aboveground. The roots had had their allotted work, viz., to supply wood, rind, and bud with sap, and keep the whole plump, ready to push forth fresh leaves at the proper time; and who shall say that no increase of rind or stem was taking place because not visible to our ken? J. Sheppard, Gr. to J. Burners, Esq., Woolerstone Park.

Fuchsia Princess Beatrice.—To all lovers of Fuchsias allow me to recommend the above. A cutting was given me in February last; I struck it at once, grew it on, and began flowering it in the first week in August. A finer plant for its age I have never seen. It measured 8 feet high and 4 feet 6 inches in diameter at the bottom—a grand pyramid. Besides being a free flowering variety it is a splendid grower, with good habit and foliage. These two points, I think, are generally forgotten by the raisers. What we want is something that will grow, make a specimen, and repay us for our trouble. T. P. Turner, Gr. to E. S. Simpson, Esq., Walton, York.

Yellow Bedding Plants.—I find *Oenothera macrocarpa* a most efficient plant for bedding or ribbons; it grows evenly to a height of 8 to 9 inches, but should be pegged down to 5 or 6 inches; it is a hardy, herbaceous plant and a free grower, and lasts all the summer in bloom. I have two round beds of it, planted 16 years ago, and it continues as beautiful as when first planted. This old plant has succeeded better than anything I have tried, and it suits itself to almost any soils and seasons. It is easily increased by seed and divisions of the roots, and cuttings may be struck under a hand-glass in any soil in the spring, when the cuttings are 3 inches long. William Smythe, The Gardens, Elmham.

Amaryllis Johnsoni.—I have here at present a bulb of *Amaryllis Johnsoni*, with two large blooms on it, each bloom is 7½ inches in diameter. About the middle of last January it showed three blooms, which were large and fine; as soon as they were over it showed three other blooms, which were fully out in May—they were equally large and fine. The last four years it has had six flowers in each year. I should like to know if it is an unusual thing to have this plant flower a third time in the year. Robert Stokoe, Gr. to H. C. Marshall, Esq., Westwood Hall, Leeds. [We suppose this to have been a case of "anticipation," where the buds, destined under ordinary circumstances for future seasons, become developed before their time. Eds.]

Cordons and Calvilles.—In your report of the last meeting of the Royal Horticultural Society, it is stated that "from Mr. Shepherd, gardener to P. N. Laurie, Esq., Parxhill Park, Sussex, came a good dish of Calville Blanc Apples from small trees on the Paradise stock;" and further, that to these Apples a Special Certificate was given. It may interest some of your readers to learn that these Apples were gathered from trees worked on the true French Paradise stock; that the trees (maidens) were planted during the spring of the present year, and that the fruit was matured against a south wall. It need hardly be added that the Calville is usually grown in the orchard-house at

Trentham and other large gardens, where it is much esteemed. Compared to these, other Calvilles grown in the open air, and shown at Kensington lately were mere Crabs. The trees from which these Calvilles were gathered are not small in the sense of being pushed into dwarf bushes, but long, handsome, vigorous rods, from 6 to 10 feet long, and with plump fruit-buds from base to apex. Mr. A. McKenzie, of Alexandra Park, also sent a box containing a considerable variety of fruit gathered from cordons planted during the past spring, and a plant showing the beautiful and abundant way the trees are furnished with buds for the coming year, without betraying a trace of the contortions or nakedness of dwarf trees grafted on other stocks when submitted to the cordon form. Both fruit and tree came too late for notice. In doing me the honour of reproducing figure 143 from my "Parks, Promenades, and Gardens of Paris"—a cut which shows how the Calville Blanc, Lady Apple, American Mother, Newtown Pippin, and all the finer and tenderer French, American, and British Apples may be grown to a perfection they have never yet attained in this country—you praise the system "for small gardens." I should never have devoted a page to it were I not certain that it will prove of infinitely greater use in all the large gardens in these islands. In the gardens where there is space and light and intelligence to give it a fair chance the hardier kinds round the open border, such kinds as those above named on low walls, the faces of pits, &c.—in the gardens where there is a large fruit room to be stocked, and where discriminating tastes both in dining room and kitchen have to be catered for, in these it will be found in good time all I have asserted it to be. I may add that I have had some of the finest Apples and Pears I ever saw either in France or England grown on this system in the past unfavourable season from Mr. Tillery, of Welbeck,—one of the largest and noblest gardens we have; and I hear that Mr. Stevens, of Trentham, is also trying the system on a large scale. W. Robinson.

Salisburia adiantifolia.—The fine specimens of *Salisburia adiantifolia*, mentioned in your last Numbers, are all surpassed by one in the Botanical Garden at Pisa. In January last it attained 2.95 m. in girth (i. e. 9 feet 7 inches), at 3 feet above ground. I could not take an exact measure of its height, but I am sure that it must range between 75 and 90 feet. It was received from England, and planted in 1787. It is a splendid tree, and very remarkable for the rich golden colour which the leaves assume before falling. Two other large specimens are in the same garden, both under 6 feet, and unluckily male trees, like the first. I think that this must be one of the largest, if not the largest, of its kind in Europe. The Ginkgo, of Montpellier, is only 2.04 m., and is regarded as the largest in France. In the same garden at Pisa, among many interesting plants, are also to be found a *Cedrus Libani*, introduced from England in 1787—girth 11 feet 6 inches, a *Magnolia grandiflora*, of the same age, which measures 6 feet—it is a perfect cone of verdure, the spreading branches covering an area of almost 60 feet in diameter; a *Laurus Camphora*, planted in 1842, measures 4 feet 6 inches; and last, but first for age, the veteran of the garden, *Aesculus Hippocastanum*, planted in 1597, has attained 10 feet 6 inches. I will send by-and-by some other notices about remarkable trees in Italy, which may perhaps interest your readers. Our country is really in her gardens, and in the beautiful remains of her ancient forests, more rich in rare and gigantic trees than is generally believed. E. Fenzl.

[We cordially thank our correspondent for his communication, and shall be pleased to receive the notices he speaks of. Eds.]

Cedrus Deodara for Timber.—I would advise your correspondent "O. M." to be cautious how he plants the Deodar for timber. If his land lies low, and is well sheltered, it will do; but in a high and cold situation it will barely live, and never become much more than a shrub. I have some on my lawn, 1100 feet above the sea. They were planted nine years ago. The best of them is sheltered from the south-west by a high bank, and it is now not quite 6 feet high, and two others more exposed are scarcely 3 feet. Wellingtonias planted at the same time are more than 10 feet high, stout and healthy. G. A. H. [It is quite clear there are Deodars and Deodars. The severe frost of a few winters since destroyed the tops of several and left other adjacent trees unscathed. We can scarcely recommend the Deodar as a timber tree in the midland or northern counties, unless under exceptional circumstances. Eds.]

Iberis gibraltaria.—May I record a few words of praise of a very beautiful hardy plant not generally known in cultivation? Of the perennial species of *Iberis*, none are so ornamental as the Candytuft, which decorates and takes its name from the Rock of Gibraltar. Last April I procured and sent home plants which have almost ever since been continuously in flower; and one specimen in the open border, which was frozen hard three weeks ago, is now (Nov. 19) covered with delicate lilac flowers. The corymbs and individual flowers are twice the size of those of *Iberis sempervirens*, and the foliage and habit is also much larger. It seems to differ from all the other species in being a continuous bloomer, the lateral shoots outgrowing and hiding the old flowers as they decay. It is readily propagated from cuttings. The usual colour of the flowers is a delicate lilac, but I found in the mountains south of Tetuan, in Barbary, a variety with pure white flowers. I did not, however, succeed in preserving it in a living state. Messrs. Backhouse, I believe, imported the plant from Gibraltar last year. George Maw, F.L.S., Benthall Hall, Brossley, Nov. 19. [See an article on this plant and its allies, at p. 711, 1868. Eds.]

Melastoma granulosa.—The cultivation of this showy and attractive plant is very simple. It grows freely in

rough sandy peat, treated as a stove plant during the winter. The most luxuriant shoots should be kept stopped until spring; then shift, and grow the plant in an airy greenhouse till autumn, when it is sure to blossom freely. I do not stop after March. Young shoots, not too luxuriant, root freely in bottom-heat under a bell or hand-glass. I have a young plant here now, not more than 2 feet high, which a week ago had three large bunches of flowers on it. The plant is not by any means tender; the stove in which it is grown during the winter is often below 45°. I have not seen the least injury done to the plant by a low temperature. *P. Frost, Drogheda.* The specimens forwarded by Mr. Frost were very beautiful. *EDS.*

Blue Viola.—Mr. Dodds, of Bower Ashton, has this day called my attention to Mr. Dean's remarks respecting the Blue Viola, which he saw in bloom here last August, and I hope I may be pardoned for correcting a mistake which has been made regarding it. It is not Blue Perfection, but was sent out a few years ago under the somewhat alarming name, Good Gracious, at least, such was the name which I received with it, and which I have every reason to believe correct. Whether it is, or is not, synonymous with the variety sent to South Kensington by Mr. Jobson, I cannot say: but in respect to its good qualities of healthy constitution, free and perpetual blooming, and deep blue colour, I may say that I have not seen its equal either in the spring or summer garden. Many visitors to Wilton House, have been much pleased with the effect it produced. Allow me to add, if any one is particularly desirous to possess it, that I shall be happy to make an exchange for a white Pansy, possessing the same good qualities of habit and constitution. *Thomas Challis, The Gardens, Wilton House.*

Monstera deliciosa.—This luscious fruit has been brought to great perfection by W. Addison, Esq., of Oak Lawn, near Leatherhead; fine fruit, measuring upwards of 13 inches in length and 11 inches girth, have ripened most successfully, the scales swelling most prominently and separating distinctly when matured, exposing a delicious amber-coloured fleshy fruit of unsurpassed flavour. The course of treatment pursued by this gentleman was such as to offer a hint to any one wishing to grow and mature tropical fruits. In an ordinary span stove a brick arched chamber was constructed, through which the flow and return pipes passed, a false bottom was laid on, and the *Monstera* planted out in a bed of loamy soil of about 2½ feet in depth. During the growing season water was plentifully supplied, but almost withheld after the spikes of flower were set. The subterranean warmth was kept up correspondingly to that of the atmosphere. The result of this treatment is that while fine fruit have been cut for table up to a few days ago, the auxiliary buds upon the terminal shoots have all again set flower. Thus the fruiting of this tropical delicacy, and indeed many others, may be periodically secured if the alternation of seasons, together with the terrestrial condition of the countries of which the plants are indigenous are studied, and a system of treatment based upon these principles adopted. *W. Addison, Esq., Oak Lawn, Leatherhead.*

Green Peas in November.—Mr. Carmichael, of the Sandringham, has for three years past kept up a good supply of green Peas through the winter by sowing, early in September, about five or six Peas in a pot of Maclean's Little Gem, a delicious early Marrowfat kind, which is coming into general use for early work, and is undoubtedly the best for that purpose. These, when sown, are placed in a cold frame, and towards the end of October they are removed to the shelves in the various houses, to come in in succession. Mr. Carmichael gathered the first dish on the 11th inst., full-sized Peas—truly a dish to set before a prince at this time of year; and a succession will now be kept up for some weeks. Maclean's Little Gem must not be confounded with Beck's Little Gem, and greatly indebted as we are to the late Dr. Maclean for so many fine Peas, we must especially welcome for early use two such first-class early Marrowfats as Maclean's Little Gem and Advancer. We want now an early Pea possessing the character of Advancer, with the earliness of First Crop or Dillistone's *H. D.*—I am still obtaining Peas, which were supplied to me for Daniel O'Rourke, that have been grown without any protection, and were sown in the first week in August. Another, of which I do not know the name, yielded well up to the end of last week. It was sown about the middle of July, in mistake for Dickson's Favourite, which I have always found, since its introduction in 1853 or 1854, the best of all varieties for my last crop. I remember gathering from it one year as late as December 2. A row of Ring-leader, sown July 14 last, produced only a small quantity of unfilled little pods, so that, however desirable this variety may be for a first crop, my experience proves to me it is quite worthless for a last one. I find no difficulty in obtaining late Peas, provided the frost does not come on so severely as to destroy them. The only conditions are to put plenty of moist well decomposed manure in the trench where they are sown, and never to allow the earth about their roots to become afterwards quite dry. Also, in the event of very dry weather occurring during their period of growth, to syringe them well overhead occasionally with a mixture of soft water and sulphur, in order to prevent the mildew appearing—with which, as every one knows, late Peas are almost invariably attacked. *Amateur, Whitland, Carmarthenshire, Nov. 18.*

Foreign Correspondence.

PROSPECT PARK, BROOKLYN.—This new park, the laying-out of which has been entrusted to the same garden architects as that at New York, is nearly completed, and must be pronounced to be one of the finest of American public parks. In extent (about 550 acres) and variety of surface and decoration it is fully equal

to the Central Park, while it has already even a more aged appearance, owing to the skilful retention of some grown-up timber trees that happened to be on the place. The new planting, too, has been done with material sufficiently large to give immediate effect, and, owing to skilful previous preparation, the trees, since they have been put in, have thriven unusually well.

It will thus be seen that in selecting a site for a park it is important that such natural advantages should be secured as are found in well-grown woods—an agreeable variety of surface, and fair prospects, both of distant and local scope. It is true that a site may be deficient in any of these characteristics, and yet with time enough and money enough be convertible, by well-directed skill and labour, into a park of varied and attractive scenery. If, however, such conditions as are most desirable to be added should have been already provided by Nature in the immediate vicinity of a site, it would be felt on the one hand to be an extravagance to repeat them upon it by artificial means, while on the other the disadvantage of its being without them would be greater, because more obvious. Moreover, there are two possible misfortunes in a site which, in no period of time and by no expenditure of labour, can ever be remedied: these are, inadequate dimensions and inconvenient shape. Small parks are of little use, a sense of enlarged freedom is to all, at all times, the most certain and the most valuable gratification afforded by a park.

The scenery which favours this gratification is, therefore, more desirable to be secured than any other, and the various topographical conditions and circumstances of a site thus in reality become important, very much in the proportion by which they give the means of increasing the general impression of undeigned limit. The degree of this impression which will be found in any particular park must unquestionably depend very much upon the manner in which it is laid out: that is to say, on the manner in which the original topographical conditions are turned to account by the designers. The latter must first determine what accommodations are desirable within the park, and next how these shall be situated with reference to one another and to exterior circumstances; for the best possible way to release the mind wholly from matters of business is to interest it in objects agreeable to the taste, and, at the same time, entirely different from the objects connected with those occupations by which the faculties have been overtaken. And this is what ought to be found by townspeople in a park, in which to maintain anything of a rural, natural, or tranquillising character; the driving room, riding room, walking room, skating, sailing, and playing room, must be not only liberally designed, but must be studied and adapted to all natural circumstances of the site with the greatest care.

These points have not been overlooked in Brooklyn Park, and I may add that one feature peculiar to American parks is having in them what are called "concourses," i. e., places for congregation and rest adapted to the assemblage of large numbers of people. Three of these are to be found in Prospect Park. The first of them is designated the "look-out," an elevated position from which is obtained a view of the neighbouring harbour, the distant mountain ranges of New Jersey, the ocean offing, and other scenery of interest; while from its occupying the highest ground in the park, it is exposed to refreshing sea breezes, and at the same time a view can be had from it of military spectacles held occasionally on the parade-ground attached to the park. It is proposed to form here a terraced platform 100 feet in length, with seats and awnings connected, by a broad terrace walk and staircase, with an oval court for carriages, 300 feet long, and 150 feet wide. From this "look-out" broad walks lead across the park to the east end of the lake, where, at a point commanding the largest water view, together with a rich open verdant landscape backed up by evergreens, arrangements for open air concerts have been made.

The orchestra is to be situated on an island in a bay of the lake, so that it can be seen from three sides. On the main land, within a distance of 275 yards at which distance the music of a well-appointed band can be perfectly appreciated, standing room is provided for horses and carriages in a circular space about 500 feet in diameter, and in an oval space at a higher elevation, 300 feet long, and 175 feet wide, while in front, at a distance varying from 100 to 500 feet, a space is provided to be occupied by seated seats sufficient to accommodate upwards of 10,000 people.

Midway between what is termed the "look-out" and the "music concourse," and with approaches from both, a series of terraces and arcades is provided, connected with which is room for a large restaurant. These terraces look out upon the lake, and the floor of the lower arcade being nearly on a level with the surface of the lake, it can be readily entered from the ice in winter or from boats in summer. The upper terrace is 500 feet in length by 40 feet in width, and the floor-space of the structure 175 feet by 200 feet. These arcades are intended to form the principal architectural feature of the park.

Of sylvan characteristics there are four of considerable importance. First, upon the green sward and slopes of the upper lake some of the finest American forest trees stand singly and in open groups, so as to admit of the amplest individual development. Second, in the central portion of the park is an open grove of forest trees, in which visitors may ramble in shade, without impediment from underwood. Third, a collection of the more delicate shrubs, especially evergreens, both Conifers and what we call in England American plants, such as *Rhododendrons*, *Kalmias*, *Azaleas*, and *Andromedas*, is arranged in a natural way. Fourth, there are picturesque groups of evergreens and deciduous trees and shrubs on the shore of the lake, while near the boundary and central portion of the park is a

considerable amount of woodland scenery. A flat piece of grass of large dimensions is apart as a playground or common for rural sports, and is open to all persons on foot. Grazing grounds within the park.

As regards water, this park, like that at New York, has its lake of considerable extent, the feeling meander through other parts of the ground in the form of streamlets for a long distance before reaching the lake. Water for supplying these is to be pumped from the lake to aid a spring on the side of a distant hill, so as to have always a supply from that point, the pump for this purpose worked by steam-power. The stream thus intended to take first the character of a small mountain rivulet taking a very irregular course with numerous small rapids, falls and rocks and ferns, until it emerges from the wood upon a grassy slope; then it flows quietly until, after falling over a body of water in connection with a foot bridge on the shore of the park opposite that on which it started, it has the appearance of a small river with high banks and at length, passing what is called the "concourse," empties itself into the eastern bay of the lake. Here, on the north shore, is a small island planted with large trees and small thickets of the latter overhanging the water. In the recesses of the water lakes and other aquatic plants are appropriately ornament some portions of the water, giving some interest and variety to the scenery.

In shape Prospect Park is somewhat "singularly enough," remarked a French visitor, "the entrances are at the corners." But this could only be seen, I think they were not their positions had not been in judiciously chosen principal approach is, indeed, quite a masterpiece of constructive ability, and is an entrance to a park comparable with it, except the *Place de la Concorde* in Paris. It is made to pass through an oval gate 100 feet in length and 800 feet in width, the gate just cuts off the sharp angle of the park, the avenues lined with trees pierce its opposite sides in various directions. It is belted by a fountain in its centre forms an elegant and at least two of the main thoroughfares that the ornamental appearance has also been given to the looking reservoir contiguous to this gateway. A judicious treatment of the ground connects the

As to drives, the principal one, commencing at a width of 60 feet at the entrance, just as it is carried in a southerly direction for some distance but diverges slightly to the east, so as to terminate itself to some high ground in the neighbourhood, there branches to the south-east and west, which has a part of what is called the "concourse" which has an average width of 40 feet, and an easterly branch leads nearly directly into the park. It commands, moreover, from a point opposite the entrance, a view lengthwise of an extensive grassy glade, dotted with trees and small masses. Continuing on the course indicated, this road soon curves to the left, ascends to a point from which it is proposed to have an extensive view in a westerly direction of the principal open ground of the park. From this point the road descends into a woody dell, intended to have some architectural features, a battle which is reported to have been fought near this spot. Passing through a glade of turf to the left, bounded on the opposite side by thick coppice wood, the drive continues to pass through a narrow path by which means full advantage is taken of existing opportunities for shade, and the drive continues to run in a southerly direction, approaches what is termed the "concourse" boundary line, at this point it divides into two branches enlarges almost directly into the "concourse" called the music concourse. The other branch of the drive after passing the two entrances to the "concourse" is carried round the head of the lake, and is termed the refractory. It then curves towards the west side of Look-out Hill, where there is nothing in the natural scenery so remarkable, yet agreeable views are to be obtained across the water, the north shore of the lake, and a system of bridle roads are introduced as to connect all the principal points of interest within easy access of each other.

One point in connection with American parks is to receive more attention than with European parks, ground outside their boundaries. This is to be built on, or is planted ornamentally, so as to be out from view anything which would be either with, or counteractive to the park design. The designs of American parks thus either belong to the class of those which are to be carefully laid-out ground of a highly artistic character. How we manage such matters is amply illustrated by the surrounding of New York Park, and those at *Frisbury* and *Southbury* in Boston, *Baltimore*, *Philadelphia*, and *Washington*. Cities can also boast of public parks; but these are not materially different from those at New York, and shall not occupy further space in this paper.

plants of the new A. Ordianus. A very remarkable circumstance in connection with this house is, that since the plants have been placed in it they have nearly all commenced to make new growth at the roots, in a very decided manner, sending out numerous strong green "feeders" in every direction; even old dry stems, about 18 inches in height, are throwing out roots all down the stems, showing plainly that they like their situation.

The winter garden has recently been improved by removing one side of a span-roof that formerly marred the view from the entrance, and the wooden latticed framework that did duty as a path down the centre has been replaced by a handsome arrangement of Minton's tiles. This path being much more effective, inasmuch as the contrast in colour between it and the sombre green tints of the Tree Ferns and other fine-foliage plants, is very pleasing.

In one of the other houses we noticed the largest of two specimens of the wonderful Aroid, Godwinia gigas, with its top cut off, an attempt being made to flower it by first inducing it to rest. Another plant, new to this country, is Psychotria cyanocarpa, which is just now bearing small fruit of a rich bright indigo-blue colour. It was introduced by Dr Seemann from South America. The new Bertolonia primulaeflora was also blooming very freely. The plant is a neat compact grower, and produces its clear soft rose coloured flowers in profusion. It is a fine introduction to our stoves, from Ecuador. In the same structure was also a specimen of the plant producing strychnine, Strychnos nuxvomica, from the East Indies. In a cool house devoted to Palms, of which highly ornamental class of plants there is here a large collection, is a species of Artocarpus named grandis, which was thought to bear a considerable resemblance to the Bread-fruit tree, Artocarpus incisa, but proves to be more hardy, and has broader and more deeply lobed leaves than the latter species. This plant is doing well in a cool house, whereas the leaves of the Bread-fruit tree turned yellow in the same temperature, and the plant had to be transferred to its proper place, a stove.

Amongst the Palms there are many species deserving a more extended notice, on account of their graceful habit and general adaptability for the adornment of our homes, but though we have now so many species we have only a few variegated ones. Amongst them Mr. Bull has three or four species, including Rhapsis flabelliformis aureo-variegata, one of Mr. Fortune's fine introductions, and Chamedorea Ghiesbreghtii fol. var. Curculigo recurvata variegata, though not a Palm, is a fine substitute for one, the leaves being long and recurved, of a fine green tint, banded clearly with white stripes,—an extremely ornamental stove perennial. A new species, named Welfia regia, is extremely pretty in its young state. It has smooth slender leaf-stalks and bilobed leaves, which, when young, are of a pleasing bronzy chocolate colour.

Obituary.

MANY visitors to the nurseries of Messrs. Rivers, of Sawbridgeworth, will regret to hear of the decease, on the 20th inst., of Mr. W. H. PERRY, for nearly 50 years in the employ of that firm. Mr. Perry was well known as a judge at the metropolitan Rose shows, and had an extensive acquaintance with fruits.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

THOUGH not so much labour is required in Orchid-houses at this period of the year as during the growing season, they nevertheless require daily—nay, almost hourly—supervision and attention to their sundry minor wants. As unimpeded light is of the utmost importance in connection with their successful cultivation, it will be necessary to keep the glass as clean and free from dirt or other accumulations as is possible. Resort should, therefore, be frequently had to actual cleansings with clear water. At no period of the year, moreover, is it more essential than it is at present, that the plants be separated and kept in at least two different temperatures, &c. I refer to those two divisions known popularly as the Mexican and the Indian Orchids. The former, if kept at this time in the higher temperature which is needful to the well-being of those which are natives of the tropics are sure to suffer in a variety of ways; not the least of which results from the want of a proper season of rest. Some little variation from the ordinary course may have to be made in the case of such varieties as are from time to time pushing up spikes preliminary to flowering, when a few degrees more warmth will tend to increase the beauty of the Mexican or Indian sorts. This increased heat may be afforded with greater immunity from risks, because any moderate amount of excitement which may be given will exhaust its powers in giving greater magnitude to the spikes, or increased size to the individual blooms. Those gems amongst Orchids, the Sophronitis, will now be blooming, and they may be maintained longer in beauty by hanging the blocks upon which they grow in a cool dry corner of the house. Cymbidium insigne, which affords such a delightful fragrance about Christmas, will now be showing its spikes, and may safely receive a slight aid as above. Plants of Cypripedium insigne, which may have been grown in cool greenhouses, &c., during the past summer months, may be induced to flower more freely, and to produce finer flowers, by introducing them into stoves or other similar structures, where a moderate warmth exists. In regard to the mean temperature best suited to the two divisions before alluded to, the Mexican or cooler house should range somewhere between 48° and 50° by night, with an increase of from 6° to 9° by day, according to the amount of sunlight. The Indian house may be from 9° to 10° higher

at all times. Be very careful, when water is needed by any plant, not to pour it immediately on to the pseudo-bulbs, or they may rot off. Pour it carefully round the inner rims of the pots, and thus avoid this and other similar risks. Do not let water stand about more than is absolutely necessary, whether in tanks or otherwise, at this time. With a supply of pipes sufficient to distribute the heat, without much forcing, a very fair supply of humidity will pervade the house from the pots, &c. without resorting to other means. Cinerarias and Pelargoniums of the Cape section, which are intended to bloom somewhat late in the ensuing summer months, cannot possibly have too much air on all proper occasions, as it gives them a sturdy form of growth, and greatly increases their future flowering capabilities. Where they have begun to push their crowns up, and where the pots are well filled with roots, they should have alternate waterings with liquid manures, this may be afforded tolerably strong, as they are rather gross feeders. Where it is practicable to deluge them overhead with fresh water without running antagonistic to the wants of other inmates, this should be done occasionally in the fore-part of fine days.

FORCING HOUSES.

Those Vineries which were started a few weeks ago will now be swelling their buds somewhat prominently, hence very uniform treatment must be entered upon. The moderate amount of night temperature which I have often suggested must still be maintained, as undue forcing by night too surely ends in a stunted growth. Maintain, therefore, an average temperature of 50° to 51° by night, and from 60° to 62° by day, with a rise of 8° or 10° by actual sun-heat or external atmospheric influences alone for some few weeks to come. Moisture may be freely permitted within such vineries at this time, and until the shoots have pushed. Give a good soaking with water, at a warmth of about 85°, to the internal border, if at all dry. In instances where the borders are outside keep a nice uniform warmth of 70° to 75°. By no means let it exceed a maximum of 90°, as I have previously intimated. Let both heat and moisture decline gradually as we approach the month of December; a day temperature by artificial means of about 66° will now be ample, and 62° will suffice by night. Watch the bottom-heat contained in tan-beds; if it exceeds the requisite temperature, give it vent by sinking holes into the material, and if it declines materially, let a moderate quantity of hot water be poured into it, sufficient to produce a fresh supply of warmth in process of fermentation. In regard to such structures, let air be now given at all times when the thermometer reaches 60°; and as soon as the buds commence swelling, let them be damped over two or three times daily. In instances where Peach or Nectarine-trees are already in flower, if any so early do exist, I suggest the desirability of setting the blooms artificially. Bring forward a few Strawberries where early forcing is intended, and place them into a light airy pit or cool vinery, after first well washing the pots.

HARDY FLOWER GARDEN.

Do not let fallen leaves and other similar litter accumulate too thickly around freshly planted subjects, such as Saponarias, Silenes, Pyrethrums, &c., otherwise they will become so drawn and weakly that they will not be able to withstand such frosts as may visit us before the winter is over. Look occasionally over beds of Pansies, Pinks, and Carnations, and should any have become loosened in consequence of the action of the wind, let them be pegged down or otherwise made firm at the base forthwith. If any have not yet planted their Tulips, let them do so immediately. I beg to thank a "Lover of Spring Flowers," for drawing my attention to the Calendar at p. 1188. What I meant and should have written was Aubrietia, and not Arabis, as he seems to surmise. The general who, as your correspondent seems aware, "marshals the flowers around the Tower," deserves the thanks of all visitors to the Castle for the fine display afforded upon such a steep and confined space during both spring and summer. Those who have delayed placing ashes or other kind of protection around stools of Tritomas, should do so without further delay, for we may expect such an amount of frost as would be likely to injure them at any time. Proceed with the customary forking over of all Shrubbery Borders as soon as the leaves have fallen from surrounding deciduous trees, and there is a fair likelihood that they may remain tidy afterwards. I have frequently referred to the fact that walks which are kept regularly rolled during the autumn and winter months, mild weather prevailing, of course amply repay the labour expended on them by being firmer and cleaner in consequence, during the ensuing summer, independently of the fact that they afford so much more pleasure and comfort to the pedestrian during the winter. Good clean walks are indeed a feature to be commended in any place; they afford a certain amount of cheerfulness when all around is dull.

KITCHEN GARDEN.

Place successional batches of Seakale in Mushroom-houses or other similar places. This, of course, where this mode of growing it is practised. When grown in Mushroom-houses, where a little air is needed, it is a good plan to place a nice layer of fresh leaves over the crowns after they are placed in the house; this not only tends to ward off direct air-currents, but obstructs the passage of any light which may be admitted. These remarks apply to Chicory and to Endive, in instances where it is desirable to push them along quickly. Now that we have had some rather searching frosts, it may be desirable to make use of the supply of Red Cabbage before any symptoms of decay appear. These Cabbages, as is well-known, are far better after having been submitted to the influences of a frost or two. As I have previously stated, Parsnips should not be taken

up otherwise than as they are required for use, to lose their chief characteristic properties by being packed away to afterwards. W. E.

TOWN GARDENING.

THE Chrysanthemums should all be corrected before cutting down, as the arrangement for the next season much depends on this process. The labels I find are those made from yellow lead, with white lead and oil; and if written on the inscription will be indelible. Go over the plants, and, before digging, prune as required all the shoots of last summer's growth. Cut out all suckers that come up from the roots; let the branches of two or more shrubs interlace with another, or interlace, but keep each one separate, this is more orderly and pleasing to the eye. See that the drains in the walks are not choked clear them at once and set them right before the worms at this season, if the walks are bottomed, make a great mess with their crowns, walks should be well watered with a strong salt and water, which will suffice to clear them, and if the walks be well rolled after, they will be clean for the winter. The grass plots should be frequently rolled, which will improve them, make it agreeable to look upon. J. D.

STATE OF THE WEATHER AT CHISWICK, MIDDLESEX, For the Week ending Nov. 24, 1869, as observed at the Kew Observatory.

Table with columns: Nov, Moon's Age, BAROMETER (Max, Min), TEMPERATURE (Of the Air, Max, Min, Mean), Wind, Rain.

Nov 18—Dense fog, very fine, clear and cold. 19—Overcast, cloudy, but fine, clear and cold. 20—Clear and frosty, very fine, clear and fine. 21—Sharp frost, very fine, densely overcast. 22—Slight rain, heavy rain, cloudy. 23—Densely overcast, overcast, densely overcast. 24—Densely overcast, overcast, densely overcast. Mean temperature of the week, 53.10 deg, below zero.

STATE OF THE WEATHER AT CHISWICK, DURING THE LAST 43 YEARS, FOR THE ENSUING WEEK, ENDING DECEMBER 1, 1869.

Table with columns: November and Day, Average Height of Barometer, Average Temperature, Mean Temperature, No of Years in which it Rained, Greatest Quantity of Rain.

The highest temperature during the above period since 1st 1827 therm. 65 deg., and the lowest on the 30th, 14 deg.

Notices to Correspondents.

CHEAP GREENHOUSES. T.P.S. Consult our advertising. Unless you have sufficient knowledge to plan a plan carried out, you had better avail yourself of the services of a hot-house builder, stating the kind of require. GLASS: Anon. Messrs. Chance Brothers & Co., Street Buildings, Moorgate Street, E.C. are makers of green glass. We are not aware that this is a special recommendation for propagating purposes, slight green tint is not injurious. MANURING VINE BORDERS.—In answer to our (p. 1159) that have been made as to the manure for top-dress my Vine border, I may say that it is of the following ingredients, viz., two good loads of partially rotted yellow turfy loam from pasture, one barrow-load of well-decomposed cow manure, half a peck of superphosphate of lime. The well mixed and incorporated together before use the surface of the bed, which extends 25 feet in length is 5 feet 4 inches in width. S.N. NAMES OF FRUITS: M.N.O. Peas: 1 Broom 2, Eyewood.—H.P. Apples: 2, Caroline, 3, Pippins; 5, Rhode Island Greening; 6, Barron's 8, Winter Nonsuch. The others had the names of the small angular fruit being Winter Codlin, unknown. Peas: 7, Knight's Winter Cassino; Bergamotte d'Esperen; 9, not known; 10, 11, Susette de Bay; 12, Cl. de Morecan. NAMES OF PLANTS: T.C.P.G. Nipholobus longum destortum, 1, Aspidium trifoliatum, 2, Pteridium, 3, Asplenium Fabianum, 4, Pteridium, 5, Asplenium, 6, Salvinella, 7, Nephrolepis tuberosa, 8, Selaginella, 9, Asplenium, 10, Asplenium, 11, Cheilanthes, 12, Monocotyledon, 13, Goniopteris, 14, Fraxinifolia, 15, A.K. Abies Nordmanniana, 16, Agave mon Hornbeam.—F.M. The Agave but the attenuated stem is not a specific character, delayed, owing to a misarrangement of the parts. The common pear-shaped Puff-balls, pyriform.—Anatolus, 1, Rhus Cotinus. S.N. SLEPENTHS: T.C.P.G. These plants are freely seeds, whenever obtainable. Otherwise they may be taken off the offshoots which spring from the plants after they have acquired some age. POT VINES: Enquirer. The vines should not be kept the roots intact, start them gently, feed them by placing a false rim of turf in the space with a rich compost.—Anatolus. See reply. You must start the vines very gently, of treatment will be from time to time in the Calendar. SUCCEULENTS: A.W. If you read French there are and cheap little books by M. Lemaitre, on the Succulents and Cacti. See p. 140. ERRATUM. At p. 1159, col. c, last line of 5th column "streaked or imperfect berry" read "shaded berry." COMMUNICATIONS RECEIVED.—A. J.—T. S.—J. H. These animals had been taken from Grass, and conveyed in the usual cattle truck 100 miles to Edinburgh. They were placed in Mr. RED's truck at 4.30 P.M. on Saturday, and left the Waverley Goods Station of the North British Railway at 8.0 P.M. the same night. At Carlisle the truck passed on to the North Western line; at Ingleton it was transferred to the Midland; and it reached London at 2.20 A.M. on Monday morning. The cattle never left the truck from 4.30 P.M. on Saturday until 6.30 A.M. on Monday, when they were taken out and driven to the Islington market. At starting there were 42 gallons of water in the tank which is fitted to the truck, and the whole of it was consumed by 7 o'clock on Sunday night, before reaching Trent. At that station 12 more gallons were run into the water trough, which were drunk before the train started. No more was given until reaching London, when the heifers drank about 7 gallons. Of hay the animals ate 2½ stones, 10 stones having been placed in the tank at starting, and, in addition to the hay, 3 stones of oatmeal were consumed with the water. The cost of this food was 10s. for hay, and 6s. for oatmeal; and the fine appearance of the beasts was the subject of general comment in the market.

It is plain that Miss BURDETT COURTS could not have adopted a more effectual plan of illustrating the position maintained in her published letter than by an experiment of this kind. She had asserted in her letter that, under the present system, cattle in railway trucks suffer a great amount of bodily distress during their conveyance from place to place. And this may be confidently inferred from the result of her experiment. Thus, it is shown that in the journey from Edinburgh, in a comfortable carriage, these cattle drank 61 gallons of water and ate 13 stones of hay and oats. How much greater would have been their need, then, if crowded in an ordinary truck? Again, if they drank 61 gallons of water in a convenient truck during 38 hours in November, how much would they have wanted in an ordinary crowded and unsheltered truck in July or August? But suppose them sent in this ordinary truck, with a desire to drink 61 gallons of water, and not a single drop attainable to soften their parched throats—not a mouthful of food given for them to masticate and to ruminate upon, so as to produce the saliva necessary to keep the life moist, and the tongue from cleaving to the mouth!

This, then, is the great lesson the experiment teaches.—Water and food are necessary in winter when cattle are in a comfortable truck; in summer, therefore, they are much more necessary.

In addition to its proof of the inhumanity now practised on railways in the conveyance of cattle, it certainly gives other results that will facilitate the adoption of a better system than now exists. In the first place, whether the present truck used by Miss COURTS be the one that best combines efficiency and economy of construction, or not, is of no importance. If there be a better, so much the better, but even this demonstrates the following facts: That the cattle, if not actually improved in appearance by the journey in a truck, where they can feed and drink, are not at all deteriorated by the journey. They were, in fact, sold readily at more money than they would have fetched if they had been conveyed in the ordinary manner.

Here, then, is a sum of money in the hands of the salesman greater than he would have had if the cattle had not received this humane treatment, and this will pay for the food and water and attention. Taken at option, and comfortably, such provision is as valuable to the animal system as any food it has received during the time that it has undergone feeding. And the farmer must not grumble about the cost of it. As to the railway companies, whether the better trucks be more expensive ones or not, it is certain that they have no right to practise systematic cruelty because it will cost money to build proper carriages. The costermonger, whose horse's collar galls its shoulder, is obliged to give up his horse's work till he recovers, to get a new collar, or pay a fine or go to prison. There is little sympathy shown when the policeman pounces on him and shuts up his trade in this manner. Railway companies have been too big to be dealt with by the ordinary Act. Now, however, that the Special Act is about to catch them, the obligation on their part to provide proper carriages for the traffic of live stock becomes imperative.

The experiment now alluded to can, for these reasons, have no other than a favourable influ-

ence in promoting the establishment of a better, more comfortable, and more humane mode of conveying animals by railway during long journeys. At the same time it most clearly shows to what extent to which animals undergo a deprivation that is of all others the most painful to endure; and Miss COURTS has rendered one of her many good services to society by calling attention to a very serious evil, capable of so easy a remedy.

Whether the particular mode of conveyance on rails she has tried be the one to be adopted or not, the experiment has at least done this great good—it has shown positively that animals do suffer hunger and thirst on the road, and that the public opinion she has raised throughout the country, denouncing the system now in practice, is well founded.

THE Report of Mr. HOPE's Paper on sewage utilisation before the Institution of Surveyors last Monday, will be read with interest, as the latest utterance on this subject of the man to whom, more than any other, will be awarded the credit of having achieved the success, when the country shall have been aroused to the enormous loss it now sustains in this particular way. Only the former part of the lecture is here given. The facts at Barking and at Parsloes, and those regarding the utilisation scheme at Romford, of which Mr. HOPE has taken the whole burden on himself, are here related, and on the whole they are sufficiently encouraging. At any rate the discouragements and failures are stated as frankly as the successes; and the reader may judge with confidence for himself. We think that the conclusion to which he will come is, that for most ordinary English agricultural crops sewage, applied with discretion, is the most fertilising manure he ever heard of; but that for crops to which our climate is of only occasional, or of doubtful fitness, sewage, like other manures, will produce only occasional or doubtful results. The life and character of a plant are, in fact, an unalterable "quantity" in all our agricultural calculations. They may be improvable within very narrow limits, but no enthusiastic belief in the power of any new agency in agriculture should blind us to the fact that however animals—and, *a fortiori*, men—who are capable of influence by many other motives than the merely material ones may improve under education, plants have very limited capacities indeed.

We may educate our animals to some extent to bear with, and perhaps to profit by, an unaccustomed set of circumstances; plants, however, must be simply selected for their ascertained natural aptitudes. And however wonderful may be the produce, for example, of the Maize plant under its own climate, we must not think that, even with the aid of sewage, anything more than an occasional success, in a year like 1868, will be attainable in ours. Happily, however, there are plants enough for which our climate is well adapted, by which we can most perfectly utilise this wonderful agency. Italian Rye-grass, Mangel Wurzel, Cabbages, Celery, Strawberries, Asparagus—all these prosper wonderfully under its influence; and even grain crops, judiciously treated, will answer satisfactorily to the sewage whip.

The latter part of Mr. HOPE's lecture was a clever argument, based upon the fact, which he had just enumerated, in which sarcastic criticism and exuberant fluency of rhetorical illustration are brought to bear upon the assertion—"It won't pay." An extract will suffice:—

"When a sailor wishes to describe a peculiarly desperate situation, he says that a man is between the devil and the deep sea. Now, if we substitute for the devil the enemy of mankind the Court of Chancery—and there are some persons who would think the substitution not altogether ill-fitting—we very accurately define the present position of most of the towns in England. These towns utilise their sewage in some way or other, the deep sea, far away from all oyster beds and bathing machines, salmon fisheries and salt pans, is the only place where the Court of Chancery will allow sewage to be discharged, and even in such a case as this I am strongly of opinion that, if a respectable and duly qualified merchant mormul or water baby applied to the Court for an injunction, the present Lord CHANCELLOR, who is such a conscientious disciple of Mrs. DUMAS, would decide that the petitioner had a *case made*, or, perhaps *case made*, and I would prohibit the further pollution of the deep sea."

"But in the case of London what says poor Father Thames? Poor old fellow, for nearly centuries past he has been in the large so many indignities, that it was apparently considered that one more could not do him any very great harm; nevertheless, this last piece of ingratitude seems to have been too much for him, and his fatal stream of sewage seems to have been the last drop that made his bitter exposure flow; for his official spokesman, the Solicitor to the Conservancy, has just inserted an advertisement in the *Times*, giving notice of a Bill that he is going to apply for to Parliament this next session, to prohibit the discharge of solid matter into the river

Thames from the sewers and drains of the Metropolitan Area of Works, at Barking, in the county of Essex, and of the Metropolitan Area of Works, in the county of Kent, and from any other place belonging to them, or any other body or person, and to compel the Metropolitan Board of Works to do all that is necessary to prevent the effluent waters of the Metropolitan Area of Works from flowing into the river Thames."

"I smiled when my friend brought this advertisement of anguish from Father Thames. 'Hallo! what a man,' said I, 'deed-dare the sewage of London. Don't you wish you may get it? Why, if it were possible to pay to deodorise it? Then I began to think what the Court of Chancery had said in one or two cases, and began to think that perhaps Parliament would do whether it 'paid' or not, to do what the old law would and would say that he had as much right to be kept out of his body else. But the dry weather sewage of London, in the Thames, is alone sufficient to fill a lake of 1000 acres 3 feet deep, every 24 hours; so how is it within the bounds of practical possibility to 'deodorise' this mass, unless by allowing it to deodorise itself in the air and through the land?"

"In fact, it is quite plain that the days of the state of things are numbered, and that the will of sewage 'has got to be done,' as the expressive *Times* goes, and 'done' it will be, for truth will triumph in spite of all opposition and all assertion, and which latter is so often the greatest impediment to improvement."

— GREAT depression has continued in the trade throughout the markets of the kingdom, although the large foreign arrivals have been readily at 2s. per quarter further reduction, and the retail trade has resulted, as confidence in the prices is still wanting. The trade in spring wheat is depressed; there is a reduction of 1s. to 2s. upon Beans, Peas, and Best Barley, and the sorts of Barley and Oats are 6d. to 1s. lower.—In the seed market there is a general inquiry for Clover seed; and for the best advance of 2s. to 3s. per cwt. has taken place.—Potato trade dull and slow.—In the cattle market of Monday the supply of beasts was short in the previous week, and trade was brisk, and there was a slight advance in the prices of the qualities of beef. Sheep, too, were not plentiful, and were readily disposed of at an advance on the previous Monday's prices. On Thursday there was a large supply of English beasts, but a short supply, so that trade was again active at the quotations, and a fair clearance was effected in kinds of cattle. Sheep were more plentiful in stock, and prices were lower for the small and business transactions.—Wool trade improved for qualities prices a shade higher. Trade in tanning districts slack, and though a large quantity of wool is being used, the profits are very meagre.

— Compared with former years, we are glad that the entries for the Birmingham Cattle and Show are far above the average. The prizes for having been much increased, a grand display is expected, particularly from the local Shropshire breed, whilst there is no doubt that the exhibition will maintain its character as one of the first kind in the kingdom. The raising of the fees on poultry slightly diminished the numbers, but 2500 of nearly every known variety of fowls and pigeons certainly be as many as most visitors will inspect. The root and corn show forms a most and interesting feature, and will be far better anticipated in the earlier part of the season. As the space appropriated to my lements and miscellanea articles, we understand that the applications for allotment have been unprecedentedly numerous, much so, indeed, that in nearly all cases they had to be curtailed.

— The second report of the Commission appointed to inquire into the employment of women and children in agriculture has just been issued. We shall refer in detail to the substance of its conclusions next week. The two gentlemen to whom the task of framing recommendations, upon the points which they have collected, has been committed, as to the lessons which it teaches, and has accordingly issued separate reports on the subject.

OUR LIVE STOCK.

THE Shobnall Grange catalogue, just issued, contains the pedigrees of 28 cows and heifers, and 11 bulls, names of the sires lately used in Mr. Meakin's evidence of the pains which has been taken in the stock of first-rate quality. DUKER OF CHAMBERLAIN (21,584), by Mr. Tanqueray's MARMADUCE 33 and of the Bates *Cambridge* Rose tribe, is the seven of the lots; GRAND DUKE OF ESSEX 28 ROYAL WHARFDALL (22,507), and from Lady BUCKINGHAM, by THE BUCK (13,530), and therefore spanned by the sire of two promising young bulls of the Zeal and Zeal families, and ROYAL MASTER BUTTERFIELD is represented by two excellent heifers. First list we notice Zeal 9th by LENTON FAVORITE from Zeal 6th descended from Zeal 1st of ROYAL, previously from Chilton stock. Two younger ones of the same family will also be offered on the sale day. We anticipate some competition for *Charming Maid* by LORD LIVERPOOL, and of the DUKE OF ESSEX 5TH will not be without notice. Lastly we mention *Fidget 7th*, a 3-yr-old Bull, 3d Lord Oxford, and from Captain Blaine's *Fidget 6th* by 7TH DUKE OF YORK, the pedigree cross having been the renowned Bates are, DUKER OF NORTH MELLEND.

— The Belmont sale on the 18th inst. was successful one. The very fair average of 327 7s. 6d. realised upon the 20 animals offered, while 33s. 10d. the average of the 17 females. *Amelia* by *St. Albans* (20,932), and of the *Asia* or *Account* purchased by Mr. Savage for 51 gs.; *Ruth* by *Duke*

done." The engineers said so when Stevenson proposed to drag trains of carriages on a tramway by means of locomotives, at even the moderate pace of 12 miles an hour. But once show them a railway with the trains of carriages running on it, get them into the new groove, and they will make railways under the metropolis, or over it, or across the Alps, or the Channel, if anybody will pay for them. The idea of steam navigation across the Atlantic was met by a shout of "Can't be done!" and the idea of saving the larger half of the manure due to the land, and using it profitably is met with a similar exclamation. Yet it will be done; and we shall then no longer find extensive arable districts, and even whole counties, where steam tillage is scarcely adopted by a single tenant-farmer.

Steam cultivation will advance rapidly when the land is properly fed; it cannot advance while it is starved, any more than it can go into the Great Sahara to drive a cotton-mill where there is no cotton, or plough up the sand which is sterile. We don't say that English agriculture is literally starved, it is the best in the world; but the price of feeding it is, as we have said, constantly increasing; and it is because English agriculturists feel this that they are shy at present of steam tillage, knowing as they do that deep cultivation increases the appetite for manure, sooner or later.

I believe that the duty of writers is not to side with obstructives who take "can't" for their motto, but to endeavour to rouse the public opinion when it slumbers, as it does on the important subject we have referred to. It is quite unnecessary to patronise or defend steam tillage, which with a fair field and no favour can take care of itself. "Steam" and "progress" are words of some pretension, and the way in which they are sometime used reminds one of the story of the old woman's hen and her cat, who so sadly bullied their visitor, the young swan. If he ventured to express his ideas they put him down at once; "Can you catch mice, lay eggs, mew and purr?"—"No." "Then hold your tongue!" H. E.

THE CONDITION OF MANURES.

A MOVEMENT is being adopted in some districts for farmers to club together and contract for large quantities of superphosphate, supplied by tender. Although the plan, no doubt, offers advantages in cases where a large quantity of soluble phosphate is the chief consideration, it may be questioned whether it is generally desirable for obtaining the best class of manures,—that is, if the condition of the manure and the character of the phosphates of which it is made be taken into account. In such cases it behoves the purchaser to make sure, by having the bulk delivered to him tested, that it is really of the quality guaranteed.

The "condition" of manures has of late attracted more attention amongst farmers, since it is well proved by experience that a well-mellowed, powdery manure, which runs easily through the drill, is of much more practical value than one having the same composition but wanting in these physical qualities. In fact a good condition is almost tantamount to an additional quantity of soluble phosphate, since it allows of that which is present being applied to much better advantage through the more complete incorporation with the soil.

A word should also be added with respect to the "precipitated" phosphate, of which a good deal has been heard of late, and the nature of which I explained in my last report. The following passages are extracted from a paper of mine on the method I adopt for estimating this constituent of manures, and which appeared in the *Chemical News* of Sept. 10, 1869:—

"The fact of superphosphates 'going back,' or losing in soluble phosphate on keeping, will hardly at present be disputed,—the question at issue being whether the phosphate so reduced can be estimated or not.

"It often happens that a quantity of superphosphate which when freshly made contains, say 25 per cent. of soluble phosphate, is found after keeping (in some cases only a short time) to have lost 2, 3, 5, or even more per cent. of its soluble phosphate."

The process for the estimation of the phosphate so reduced is then described:—

"I need scarcely say that it is not my intention to introduce the determination of precipitated phosphate into my ordinary analysis of superphosphate, nor include it in the usual determination of soluble phosphate, unless specially requested, and then to state it separately,—since whatever its agricultural value may be (space forbids me entering into this part of the subject), it is no longer soluble phosphate, and will not obviously pass as such when a definite percentage of soluble is bargained for: its value is, however, at the same time, very superior, I consider, to the undecomposed or ordinary insoluble phosphates."

The following remarks are offered more especially to manufacturers, or those connected with the preparation of manures:—

1. *The Relation between the Total Phosphates in the Manure (the Phosphate made soluble, and the insoluble together) and the Acid used.*—It is evident that the less acid used, the more total phosphates will be present, but the less of them will be soluble. The converse is also evident: viz., that the more acid used, the less total phosphates, but the more of them will be soluble, but not necessarily the higher percentage in the manure. Thus, supposing we were to use 200 parts of bone-ash of 70 per cent. phosphate, and 100 parts of acid, we should have in the product 140 parts of phosphate in 300 of material (leaving out for simplicity the loss referred to in my last), or about 46½ per cent., which is obviously too little acid. If, on the other hand, 100 parts of ash were dissolved with 200 parts of acid, we have only 70 parts of phosphate in the 300 of material, or only about 23½ per cent., which is as much too little (the right quantity lying evidently between the two). Although this is, of course, an extreme case, it is mentioned to prove the fact that beyond a

certain point more acid will lessen the percentage of soluble phosphate instead of increasing it,—simply because it brings down the total phosphates too low, notwithstanding the whole of this (as far as practicable) may be made soluble.

The same rules of proportion of course apply to the addition of any other materials which may be added to superphosphate, or other materials mixed together in the preparation of special manures. Thus the addition of any extra quantity of water in mixing of course lowers the percentage of everything in the manure: many makers take no account of the weight of the water used (the better plan is to use a weaker acid and no water); and, when left to the men engaged in the operation, is the commonest source of variation in the product—especially as a little extra water gets the work on quicker. If a bone manure, when freshly made, is found to contain—say 25 per cent. of soluble, but does not dry up well, and it is thought advisable to add a little drying material, the mass will not have 25 per cent. after the addition of such material, since the same quantity of phosphate is spread over the increased quantity of material. Although this may appear self-evident to some, it would seem to be incomprehensible to others, to judge by the correspondence I sometimes receive.

2. *As regards the Soluble Phosphate Produced from a given weight of Acid*—the theoretical quantity is 80 parts of real acid (SO³) for 156 parts of tribasic phosphate; or for 100 parts of bone ash, as above, 55½ parts of ordinary brown acid.

Bone ash, however, also contains, as is well known, variable quantities of carbonate of lime as well as phosphate,—while other phosphatic materials often contain much more carbonate, and also oxide of iron, alumina, &c.; but, taking all these into account, it is found, as well known, in practice, that more than the theoretical quantity of acid is always needed, and which may, I think, be due to the following causes:—

(a) To the necessarily imperfect state of division of the phosphatic materials operated on, even when ground as fine as practically possible, and by which a portion of the phosphate of lime escapes actual contact with the acid, even under the best mechanical arrangements. This is shown by the fact that the finer the state of division the more complete the decomposition,—it being almost instantaneous in the case of chemically divided phosphate. A too rapid decomposition is not, however, the most desirable in practice hence the necessary excess of acid is borne with for practical considerations presently to be touched on.

(b) To acid consumed in decomposing phosphates which are not rendered actually soluble, and on which the question of "precipitated" phosphates I think throws some light. This is especially noticeable in well-made bone manures in which the greater part and sometimes the whole of the bone has evidently undergone decomposition, as proved by its mellow and pulverulent condition, although only a portion of it is obtained as actual soluble phosphate on analysis, but considerably more when the "precipitated" is determined.

The primary object of the skilful manufacturer is thus to obtain the most marketable article,—that is, a superphosphate having the largest amount of soluble phosphate, associated with the best mechanical condition (the difficulty of preserving the latter increasing with the former) without a strict regard to the greatest economy of acid—this at present prices especially—being usually considered a secondary consideration.

To attain this end a certain amount of chemical information is, of course, indispensable, but a good deal besides is requisite, since it is just the point on which the individual experience and skill of the manufacturer is needed, and which no rules can altogether replace. *Alfred Sibson, F.C.S., Consulting and Analytical Chemist, 11, Eaton Terrace, St. John's Wood.*

FARMING IN THE NEW FOREST.

HAVING introduced in 1845, by the request of the late Duke of Richmond and Lord Portman, the Italian Rye-grass, and the mode of growing nine crops a year, about 70 tons per acre (*Royal Agricultural Society's Journal*, p. 576), and again by their request in 1847, with further illustrations (*Royal Society's Journal*, p. 572), I may presume I am not altogether a stranger to the agriculturists of that period, and hope no apology will be required for troubling them with my present farming operations; and that those of the present will excuse me if I am troublesome by taking this opportunity of introducing myself through the medium of the year's produce of the farm of which I am a tenant, in the New Forest, where there are between 60,000 and 90,000 acres of land in a wild state, growing little else than a few Oaks, many Firs, an immense quantity of Furze, Fern, and Heather; grazed from May to November by those who have forest rights, with an interior class of ponies, worse cattle, and bad pigs, where anyone turning out animals of a better kind are not sure they will take them up again. My year's produce consists of white and red Wheat, Barley, Oats, Mangels of both kinds, Swedes, Carrots, Cabbages, Australian Prairie Grass and Italian Rye-grass. Samples of the white Chidham Wheat, Mangels of both kinds, Swedes, Carrots and Cabbages, have gone to the Birmingham Exhibition for competition against all England, Ireland and Scotland. Others are sent, through the kindness of Mr. George Gibbs, of Down Street, Piccadilly, to the Smithfield Fat Cattle Show, Islington, for the inspection of the public.

He has my white Chidham Wheat, 63 lb. per bushel; April Wheat, 66 lb.; Chevalier Barley, 58 lb.; Winter Oats, 43 lb.; Mangels of both kinds, Swedes, Carrots, and two specimens of the Australian Prairie Grass, dug up and potted, from one of which three crops were cut, between October 10, 1868, and October 11, 1869; one

pound of which was dried in the kitchen in the warmer in the day, upon the oven at night, and so dried; the rate of 30 tons of hay per acre per annum since October 11 last,—the specimen indeed was of the summer, and has not been cut. The Grass of excellent quality, and eaten freely by every animal, from the horse to the pig.

I have been asked whether it or the Italian grass is the more productive, to this I must be content at present to reply that 70 tons of Italian Grass has been grown by others as well as by me—at Barking instance; therefore that is an established fact. I do not lose more than from 5 to 2 by artificial drying, which I was satisfied 20 years since; the three crops of Australian Grass amounted to 55 tons, and was drying from 16 to 9. The Italian was very well received one dressing of liquid manure (horse water) after every cutting—the Australian manure at all; I have some now growing under liquid dressing.

I know of no plant that pays so well for high feeding as I know no limit to its produce well fed. I know no plant so productive without manure as the Australian Rye-grass, and after which such crops of Wheat, Barley, and Oats can be grown. All my corn and roots are grown after Italian Rye-grass. My Chidham Wheat which had the 2d prize at Birmingham last year, was grown after it, and it was sold at Guildford on two distinct market days, by Messrs. Legg & Co., who stated that on those two days there was no other sample of Wheat in the market that sold so high a price. *William Dickinson, New Park, Hants.*

Home Correspondence.

Depth of Drains.—I willingly respond to the invitation which you have given to practical men to communicate their experience, and the inference which they have drawn from it in respect to the depth of drains, is really advisable for drainage. I adopt unreservedly the well-motivated opinion of Mr. Paget on this subject, possess land which I believe to be of similar formation, and I have a well-founded confidence in his judgment. I have long experience to guide me in the most prudent course for our new red sandy soils, for I have provided during 49 years of management of my own property, under my own observation not less than 7,000,000 of draining tiles for the use of myself and my tenants. When I began in the year 1820 to give them every encouragement to be during the winter their own labourers at the work, and followed the same practice on my own land, I acted chiefly with the motive of employing the labour which at that period was so redundant that it was a waste of life, and the poor-rates were unequal to cope with the distress occasioned by the want of work on our clay soils. I, therefore, catered for the labour employment in my tile-yard and on my own land, which, in the prevalent culture of clay land, then seemed to me the only remunerative application of drainage, I had practised and recommended a depth of 2 feet as adequate to the purpose, for with no wet or pervious subsoils except in rare patches of ground, and only casual fissures on shaly strata, which which springs can find a course, but the common has been that a great deal of the work was ill-done, and has required to be rectified or supplemented since the practice of subsoiling has been resorted to. I usually adopt 3 feet as the depth, though in stiff clay I would not go deeper into meadows than 2½ feet; for I have often seen the water over drains when sunk deeper, and I have seen this still more remarkably in the Oxfordshire while within the same park it was necessary to go to the depth of 4 or 5 feet in order to tap the spongy subsoil of the overlying upper green sand gault; and I have found the same necessity where, on the top of a hill, a basin of sandy soil on the clay for a space of 100 acres. The result, therefore, of my experience is, that no rigid rule ought to be laid down, and that the requirements of the Government and of the drainage companies in this question are arbitrary. The effect of the drainage on my estate has been wonderful in the promotion of the cultivation of Turnips and Mangel Wurzel, and Barley and the consequent improvement of sheep husbandry and the prosperity of landlord and tenants. *O. E. Grove.*

Sugar-Beet.—So much has been said about the growing, and the advantages derived from its cultivation, that my employer was induced to obtain seed this spring direct from Mr. Duncan. The here is perhaps as good for the cultivation of the beet as any in the country: at least, if we judge from the fact that it has produced—if not always, frequently for years—the heaviest Mangel roots which have been shown at the Smithfield Club Show. My experience with Beetroot, which was grown on the same land, received the same treatment in every respect as the above is as follows,—while the Mangels weighed 25 tons per acre, the Beetroot weighed 16 tons only. How the difference in weight occurred I am unable to account for, and would be under an obligation to any of our correspondents who could assist me to a solution of the question. The Beetroot did not produce a considerable tap-root. That portion of the root which penetrated the soil was divided more or less into roots of various dimensions; and I should suppose, even taken together, a diminution in weight from that of an individual root. The top was also much larger than the Mangels, and had more disposition to produce seed. On our Mangel crop of this year—about 100 acres, seed of which came from several firms—I know

observed that peculiar "bolting" tendency which some of your correspondents have experienced; however we do not recognise such aspirants, for so soon as the disposition to run up is apparent, the offender's top is cut off and often more than once during the season. The consequence is, at storing time there is little difference between the would-be seeder and his next neighbour. To my eye there is nothing more offensive in a Mangel field than a lot of seed-stalks towering all the season, and I am sure there cannot be a more mischievous weed. P. Mitchell, Rainham, Nov. 16.

Steam Cultivation.—Let me tell "G. A. H." that I am very busy this week with about 30 men, all at job work, stocking, digging and delving; some knocking down trees, some pulling up hedges, some clearing away trees, &c., and some filling in clay pits, for I cannot get on with my draining; the ground a few inches under the surface is much too hard for that work; therefore I cannot attend to his "interest of money and depreciation" question now, but by another week I will prove that mine is the fair way of calculating it, and the way that has been accepted by all excepting him. Please give him my letter from the Times of Saturday last, to let him see what can be done on a small occupation. William Smith, Woolston, Bletchley Station, Bucks, Nov. 23.—[The following is Mr Smith's letter to the Times:—

Sir,—I have made up my book on Steam Cultivation for the 14 years ending March, 1869, showing the operations both by steam and horse-power, and the cost and cropping on the several fields during the whole period. Here is a summary of it—

HEAVY LAND.—Field No. 1.
One ridge-ploughing and subsoiling by steam-power £0 7 3
Ten smashings by steam-power 3 6 8
Eight cultivatings with horses 0 18 0
One subsoiling by horses 0 3 0
Two ploughings with horses 1 4 0
Total £5 19 11

Or an average of 8s. 7d. an acre a-year. The cropping has been. Oats one, Clover two, Wheat four, Swedes one, Barley two, and Beans four.

Field No. 2
Two ridge-ploughings and subsoilings by steam-power £1 0 4
Eight smashings by steam-power 2 11 5
Two cultivatings and drilling at one operation by steam power 0 10 0
Five cultivatings with horses 0 11 6
Two subsoilings with horses 0 6 0
One ridge-ploughing with horses 0 4 0
Total £5 3 3

Or an average of 7s. 4d. an acre a-year. Crops: Beans five, Wheat five, Swedes one, Barley two, and Clover one.

Field No. 3
Two ridge-ploughings and subsoilings by steam-power £1 0 4
Eleven smashings by steam-power 3 11 5
Three cultivatings and drillings by steam-power 0 17 0
Seven cultivatings with horses 0 14 0
One subsoiling with horses 0 3 0
One ridge-ploughing with horses 0 4 0
Total £5 9 9

Or an average of 9s. 8d. an acre a-year. Crops: Peas one, Barley two, Beans five, Wheat five, and Swedes one.

Field No. 4
Two ridge ploughings and subsoilings by steam-power £0 17 5
Ten smashings by steam-power 3 6 8
Three cultivatings and drillings by steam-power 0 17 0
Nine cultivatings with horses 0 18 0
One subsoiling with horses 0 3 0
One ploughing with horses 0 12 0
Total £5 14 1

Or an average of 9s. 7d. an acre a-year. Crops: Wheat five, Beans six, Barley two, and Swedes one.

LIGHT LAND.—Field No. 1.
Three ridge ploughings and subsoilings by steam-power £1 10 6
Five smashings by steam-power 1 11 5
Three cultivatings and drillings by steam power 0 19 0
Seven cultivatings by horses 0 14 0
One subsoiling by horses 0 3 0
Two ploughings by horses 1 1 0
One ridge-ploughing by horses 0 4 0
Total £6 2 11

Or an average of 8s. 9d. an acre a-year. Crops: Beans three, Wheat five, roots two, Barley two, Clover one, and Peas one.

Field No. 2
Two ridge ploughings and subsoilings by steam-power £1 0 4
Five smashings by steam power 1 13 4
Two cultivatings and drillings by steam-power 0 12 0
Six cultivatings by horses 0 12 0
One subsoiling by horses 0 3 0
Three ploughings by horses 1 8 0
One ridge ploughing by horses 0 4 0
Total £5 12 8

Or an average of 8s. 0d. an acre a-year. Crops: Roots three, Wheat five, Clover two, Beans two, and Barley two.

Field No. 3
Three ridge-ploughings and subsoilings by steam-power £1 7 7
Six smashings by steam power 2 0 0
Ten cultivatings by horses 1 2 0
Two subsoilings by horses 0 6 0
Two ploughings by horses 1 1 0
Total £5 16 7

Or an average of 8s. 4d. an acre a-year. Crops: Wheat five, roots three, Barley two, Beans three, and Clover one.

Field No. 4
Four ridge ploughings and subsoilings by steam-power £1 17 0
Two smashings 0 13 4
One cultivating and drilling by steam-power 0 7 0
Four cultivatings by horses 0 10 0
Two subsoilings with horses 0 6 0
Four ploughings by horses 1 15 0
Total £5 9 1

Or an average of 7s. 9d. an acre a-year. Crops: Wheat five, Beans three, roots two, Barley two, and Clover two.

Field No. 5
Three ridge-ploughings and subsoilings by steam-power £1 10 6
One smashing by steam-power 0 6 8
One cultivating and drilling by steam power 0 7 0
Six cultivatings with horses 0 12 0
One subsoiling with horses 0 3 0
Four ploughings with horses 1 11 6
One ridge-ploughing with horses 0 4 0
Total £4 14 8

Or an average of 6s. 9d. an acre a-year. Crops: Clover three, Wheat five, Beans two, Barley two, and roots two.

Field No. 6
One ridge-ploughing and subsoiling by steam-power £0 7 3
Three smashings by steam-power 1 0 0
One cultivating and drilling by steam-power 0 7 0
Nine cultivatings with horses 1 0 0
One subsoiling by horses 0 3 0
Three ploughings with horses 1 11 6
One ridge-ploughing with horses 0 4 0
Total £4 12 0

Or an average of 6s. 7d. an acre a-year. Crops: Wheat four, Clover three, Oats two, roots one, Barley three, and Peas one.

My land was not clean at starting, but it is clean now. The heavy land part of my farm under horse culture had a dead fallow every fourth year; under steam culture it has had none, yet it is clean.

The turnover plough has not been in Nos. 2 and 3 heavy land during the whole period of 14 years. It has been upon No. 1 twice, and No. 4 once, and that is all, thereby proving that the plough on heavy land, under steam culture, is of little or no use. On the light land part of my farm it has been more used—twice on No. 1, thrice on No. 2, twice on No. 3, four times on No. 4, four times on No. 5, and three on No. 6, worked on all by horse power, thereby showing that on lighter soils it is more needed.

The average cost of seed beds, as may be seen above, has been on the heavy land 18s. 8d. an acre, and on the lighter land 7s. 4d. an acre. Under horse culture the former would cost over 1l., and the latter would cost near upon 1l. per acre; therefore I have effected a great saving.

The saving in horse-keeping has been very great. Under horse culture I used six to work my farm, not over 6 inches deep. Under steam culture I have kept only three, and they on an average have worked only 118 days a year. Now, if we fix the cost of the keeping of a horse, with shoeing, &c., at 25l. a year, exclusive of the value of its manure, I save 75l. a year by the reduction of six horses to three. This, for 14 years, gives a total of 1050l., the cost of two complete sets of tackle—even three sets, if we set off half the engines to threshing.

The increased produce question I went into in August last, in a letter that you published, showing that it had been quite 2 quarters per acre upon my heavy land. Therefore, if we calculate it upon my 40 acres of heavy land, leaving the light land unnoticed, we get a gain of 80 quarters a year for 14 years, which gives a total of 1120 quarters, and at 40s. per quarter a value of 2240l.

You see that there is not only a saving in the cost of seed-beds, and in the keeping of horses, but there is also on heavy clay land a great gain by increased produce, and the land can always be kept clean and ready for crop at the cost shown above, provided the work is done at proper time.

Will the landlords and farmers of England, with these facts before them, still turn a deaf ear to what I say and let their 800,000 acres of land fallow as shown by the Board of Trade, still remain under dead fallow, when it were so easy and could work and keep it clean for ever.

I now start a new book under altered circumstances, viz., with 181 acres of land added to my farm. The arable heavy land part joining my old heavy land, therefore a re-arrangement of field is required. This has been done, and this year's work has been entered into it accordingly. Hereafter my saving in horse keep will be greatly increased, and my produce will also be greatly increased, for a dead fallow has been the rule on the new part of my farm. I had to pay by valuation for some this year, I shall not have to do so another year.]

Glass Coverings for Stableyards.—In these days, when glass structures are so cheap and essential, I often wonder glass is not more frequently used for the purpose of covering in stable-yards. Two years before the death of my late employer, Sir O. P. Wakeman, Bart., of Perdiswell Hall, Worcester, he consulted me on the propriety of covering in the stable-yard, at the same time he also wished to know if Vines could not be grown and trained under the roof, both for shade and profit. My answer was decidedly in favour of his proposition. Accordingly the yard was covered in (ventilation being admitted at the sides), and the Vines planted; but how the latter have succeeded I never heard, for at his death, the place, after erasing several of the glass structures, was let, and very indifferently kept up. I left to fulfil another appointment, and within a few months left the neighbourhood for my present situation. Now, whether the Vines succeeded or not, the covering-in of the yard was a grand idea, and proved of immense service both in the winter and in wet weather. In the former, when the ground was frozen and covered with snow, it proved a fine place to exercise the horses in, and in wet weather it proved equally useful for washing the carriages, &c., in; but, above all, it was appreciated and found most serviceable upon party nights, especially in a snow storm, a pelting heavy rain, or strong dews, everything being nice and snug under cover; there was no running with coats here and rugs there on the approach of a storm, but just as the conveyance was backed into the yard so it remained with all its paraphernalia, a great boon to the owners, drivers, and helpers. Indeed I heard Sir Olfley say, it would pay the cost of outlay in a very short time, by the extra care the servants bestowed on his property. This can easily be understood, it being so much more pleasant to work in the dry, that things could be properly attended to at once, instead of being put off for a more favourable day to-morrow. What can be a more miserable sight than to see a lot of splendid equipages standing out for hours in the wet and snow? And this occurs every season on party nights, for it is seldom there is convenience for housing more than the family conveyances. Now most stable-yards are available for covering, either by a span or ridge-and-furrow roof, and the expense would be very trifling. Indeed, if the roof is covered with Vines it would repay the outlay in a few years, I would certainly recommend the practice, and I feel convinced

if our great hothouse builders would take the hint, and add the covering in of stable-yards to their advertisements, they would stimulate the proprietors of such to have them enclosed. At any rate, give them the cue. Edward Bennett, Osberton, Worksop.

Foreign Correspondence.

PARIS.—Some time since the Emperor purchased about 3000 acres of marsh land at Arx, in the neighbourhood of Cape Breton. A portion of this estate has been thoroughly reclaimed, and is now devoted to the formation of a model agricultural colony. The other day, as it were, the domain was nothing more than a huge morass; but the waters have been drawn off by the formation of about 18 miles of canal, varying in width from 30 to 60 feet, and connected with another for navigation, which passes across the low lands to the port of Cape Breton. The portion reclaimed is furnished with excellent macadamised roads, bringing the 30 farms already formed in the domain into communication with the surrounding neighbourhood.

This large plot of ground was the hotbed of fevers, which at times ravaged the neighbouring villages fearfully, and its reclamation and cultivation are the greatest benefits that could possibly be conferred upon the district. The use of wealth and power is felt when applied to such objects as these.

A judge has made a wonderful discovery, if the account of it is to be relied on, namely, that the soil of the department of the Haute-Saône contains a stratum of rich mineral manure, lying just beneath the surface, and being from 120 to 300 feet in thickness. The analysis of this wondrous manure, which is described as bearing about the same relation to dung that coal does to wood, gives the following result:—

Mineral oil 40
Nitrate of ammonia 28
Nitrate of potash 58
Carbonate of lime 40.0
Silica 25.0
Oxide of iron 0.5
Sulphur 0.6
Carbon 0.1

The precious deposit is described as the result of the decomposition of fish, animals, molluscs, &c. But the most wonderful part of the story is that it is to be found in almost every part of France, lying close to the surface. Research is being continued, and further results are promised shortly.

Important changes have been made this autumn in the arrangements of the Imperial Schools of Agriculture. Until the other day the rules remained the same as they were at their establishment, 20 years ago. Formerly all the pupils were boarders in the school. Day scholars and what are called free scholars are now added. The age of admission for all classes is raised from 17 to 18 years, in order that they may come to the school better prepared for the higher branches of agricultural science. The course of study, on the other hand, is now reduced from three to two years, the number of lessons being increased, and the practical lessons in cultivation reduced. Each school will now have six bursarships per annum to award to its boarders. There are three of these Imperial schools in France. Candidates who possess the diploma of Bachelor of Science are admitted without examination, but all others, with the exception of the free scholars, who are admitted by special authority of the Minister of Agriculture, are examined before admission by a jury appointed by the Minister for each school, in the following subjects—Surveying, levelling, and plan-drawing, arithmetic, as far as progression; geometry; the elements of natural philosophy and chemistry; the geography of Europe, and especially of France. At the end of the term of study the re-examination of the out-going pupils consists of a written composition on a given subject, oral examination by the masters, and a dissertation on a subject drawn by lot, or on a mode of culture which has been practised in the month preceding the examination. Each pupil who passes in a satisfactory manner receives a diploma of Agricultural Instruction, and the first and second gold and silver medals in addition.

Those pupils who stand well on the list are allowed to study two years longer in public or private establishments, obtain commissions to travel and collect statistics and information, their expenses being paid by the State.

The courses of study comprise—1, Natural history, chemistry, mineralogy, and geology; 2, rural engineering, mechanics, and construction; 3, agriculture, proper and comparative; 4, zoology and zootechny, applied to agriculture; 5, horticulture, arboriculture, and botany; 6, rural economy, legislation, &c.; 7, agricultural book-keeping. In addition to the collegiate instruction, the pupils are practically taught the use of all implements, and all modes of culture.

The fees are—for boarders, 30l. a year, for board, lodging, medical attendance, fire, lighting, washing, and instruction; and the day scholars 10l. a year, for instruction only, each paying an examination fee of 1l. on quitting the school.

Born or naturalised French subjects alone have the right of admission as boarders in these schools, but the Minister of Agriculture can present a foreigner as a special favour. The day school is open to all the world on examination, so long as there are vacancies existing.

Societies.

INSTITUTION OF SURVEYORS.

The Distribution and Agricultural Use of Town Sewage: Nov. 22.—Mr William Hope, V.C., Associate of the Institution, read a Paper on this subject, from which we make the following extracts.—I have been asked to re-open the adjourned discussion on the utilisation of town sewage, by furnishing a

short account of some of our successes and some of our disappointments at Barking during the past season. And to this I will add such general observations as further experience has enabled me to make.

I will commence with my disappointments, or rather with a few of them, because as they belong to the order of mischances termed by the Registrar-General "preventable," were I to finish with them I should leave an erroneous impression on your minds.

DISAPPOINTMENTS.

Italian Rye-grass.—With regard then to the best known sewage crop, namely Italian Rye-grass, I stated in the spring that, under proper cultivation, 10 crops, averaging 9 or 10 tons each per acre, would always be obtained in one season by the application of a sufficient quantity of sewage, if the Grass were sown at the right time of the year, namely in the month of August. This statement I repeat now, and further experience has only confirmed me in this view, yet I am sorry to say that in actual production I can only bring you 1 ton nearer the promised 100 than before. On my own land I have, as yet, no Rye-grass under sewage, but on the Metropolis Sewage Company's farm one piece of ground had been sown in the month which I had so frequently recommended, and I was in great hopes even although it had been somewhat starved in the winter, yet that it would have been sufficiently liberally dealt with during the growing season to have given a result approaching, at all events, to the standard of 100 tons. If you consider that it is now upwards of eight years since I first began to labour towards the utilisation of sewage of London, you will better understand the disappointment that it was to me on finding that when there seemed at last to be a chance of a fair experiment, this chance should have been thrown away and the desired result postponed until the end of the ninth or perhaps tenth year. I say, or perhaps tenth year, because, as I shall presently explain, it is now fortunately in my power to make reliable quantitative experiments, independently of the Metropolis Sewage Company, who have for so long stopped the way. But as full result can only be looked for from Grass sown in the month of August, I cannot obtain that full result next year. I must wait for the year following, which will be the tenth of my labours. Let us hope that there may be something lucky and auspicious in that figure, and that the tenth crop of Grass cut at the close of the tenth year of work will complete the last 10 tons required to make up the promised 100.

Maize.—I have to record another disappointment with regard to Maize. I had, and still have, great hopes of this as the cereal pre-eminently adapted to utilise large quantities of sewage, and to yield maximum quantities of food per acre whether for man or beast. I stated, that so forcing was the effect of liquid food upon this crop, that I had every expectation that I should be able to ripen it in any year in the climate of Essex, because the growth of the plant in its early stages would be so hastened, that it would be able to avail itself, for ripening, of the heat which we always have in August and September. This expectation I still entertain, but with one modification, and that is, that to guard against the effect of a cold spring, followed by a cold early summer, such as we had this year, it is absolutely essential that the seed should be sown in an open porous soil, so that when the sun does come, it may penetrate and warm the soil and roots of the plant in the shortest possible time. The soil in which I ripened the Maize last year, and in which I have failed to ripen it this year, was a cold dense brick-earth, which was never thoroughly warmed this year at all. The 3 inches a day, or one-eighth of an inch an hour, as Mr. Bramwall forcibly put it, which the sewage enabled the Indian corn to grow last year for a month continuously, was never attained this year for a single day. No sooner had it struggled above the surface of the stiff earth, than the cold north winds in June nipped it, and, in fact, it was frost-bitten, so much so, that down to the middle of July it was completely white and blanched, like Celery or Seakale, and appeared to be all but dead. However, having entire confidence in the stimulating powers of sewage, I then commenced applying it with an obstinacy in proportion to the strength of the previous north wind, and the result was that the colour rapidly reappeared, towards the end of July it began to grow; and, at last, in the middle of October, it attained the proportions you see in this plant; the cobs being about two-thirds formed. I have no doubt, from what I observed this year, that even in an exceptional season, such as the past, the crop would ripen if sown in an open warm soil such as I have described. As it was, the result has been in one respect very satisfactory, for it has proved to me that Maize would always be a paying crop for a sewage farmer to grow, even if it did not ripen. The piece of land on which I grew it this year was exactly the ninth part of an acre, and from this I obtained a weight of Maize-straw of no less than 2½ tons, although it was partially dried by the bitter north wind, which you will recollect in the latter half of October. Every ounce of this was valuable food, whether for horses or cattle, and all classes of stock are ravenously fond of it, leaving all other food to feast upon it, it is therefore difficult to place the feeding value of the straw in this state, including the half-formed cobs, at less than 30s. per ton, for the percentage of sugar in the straw is very large, besides which there is the partially formed starch in the cob. It is clear that 22½ tons of such food per acre would effectually protect a farmer against any possibility of loss, and, in fact bring him in a very handsome profit.

With regard to the calculations which I made, but which I did not venture to put before you on the previous occasion, as to the probable amount of grain to be obtained per acre from this crop, under sewage cultivation, I am happy to say that I have since been

informed by Mr. Henry Evershed, the well-known agricultural writer, that these calculations are borne out in every place in the United States where there is anything approaching to a careful and exhaustive cultivation. The calculations I made were based upon the average weight of a great number of different seeds of Maize, which I weighed individually. I then carefully observed the nature of the plant, and compared my observations with written accounts, and I came to the conclusion that if Maize were planted at the rate of one plant to every 4 square feet, which I am satisfied would not be a bit too close—and well fed—the return in grain would amount to the astonishing quantity of from 20 to 30 quarters per acre, and this not in the cob, but after being shelled. Now, if we consider that this is a grain which weighs 60 lb. to the bushel, and that its analysis shows a feeding value very little, if at all, inferior to Wheat, it is quite clear that for stock-feeding and for horse-keep it is one of the most profitable crops that a sewage-farmer can grow for home consumption; and even if he sells it at the low price which it usually commands in our markets, say 30s a quarter, he will get a return, including the further value of the straw, equal to about double that which he can hope for from the finest crop of Wheat.

Strawberries, &c.—Among the minor disappointments of the year have been—first, Strawberries, which suffer, of course, as much from cold north winds under sewage as under any other kind of cultivation; secondly, Lettuces, which, under the combined influence of a cold clay soil and cold north wind, were very much retarded in their growth, and, although moderately good, never attained maximum size; thirdly, I may mention all other kinds of market-garden produce, which I tried in my own stiff land, with the exception of Celery, Scarlet Runners, and common Beetroot.

The Celery, which is one of the most difficult and expensive crops to produce under ordinary cultivation, has succeeded in a remarkable degree, and I have brought here a plant as a specimen. I am assured that the rent of the rich black mould to the south of London, where the greater part of the Celery for market is produced, is no less than 16l. an acre. This I was informed on the best possible authority, namely, that of the gentleman who is agent for a great part of the land, and who was more struck, on a visit which he paid me a couple of months ago, by the appearance of the Celery than by anything else.

SUCCESSSES.

Among the successes of the season, either at the Lodge Farm or on my own ground, may be mentioned also the following:—

Grain Crops.—A crop of Wheat on 4½ acres, the land being a poor gravel, and the crop being the third crop of Wheat in succession, gave just under 4 quarters to the acre of grain, weighing 61 lb. to the bushel, from an application of about 700 tons of sewage per acre; however, in the judgment of Professor Voelcker as well as in my own, this crop was starved and mismanged at a critical period of its growth.

Two acres of Oats, following two successive white crops, with green catch crops in between, received, on a poor yellow gravel, some 600 tons of sewage per acre, and yielded 10½ quarters of grain to the acre, weighing 41 lb. to the bushel.

Six acres of Barley, following two successive white crops, on a poor gravel, and said to have received rather more sewage, yielded 4½ quarters to the acre, weighing 52 lb. to the bushel.

Green Crops.—An acre of Beans received 800 tons of sewage, and yielded 5 quarters of grain.

Four acres 1 rood and 12 poles of Mangel received a more uncertain quantity of sewage, and produced altogether 201 tons of roots, or not far short of 50 tons per acre; but this was starved for many weeks together.

Three roods 10 poles of Potatoes realised nearly 26l. in the Borough market; the quantity of sewage uncertain.

An acre of Carrots, which received about 1000 tons of sewage, realised 36l. 10s.

An acre and three quarters of Onions, which received one light dressing and two heavy ones, sold for 80l. 12s. 11d., or about 46l. an acre.

An acre of Sugar-Beetroot, grown experimentally according to the directions, as regards distance apart between the roots, of some eminent Belgian sugar manufacturers, yielded 22½ tons from the application of about 1000 tons of sewage; but the seed was not very good, and the amount of top was enormous, and out of all proportion to the roots, partly, as Mr. Duncan believes, owing to the inferior seed, and partly, I have no doubt, owing to their being too close together. Next year, with better seed, and a distance between the roots better adapted to the particularly forcing character of sewage manure, I shall get much superior results. Nevertheless, this is, I believe, a greater weight than has been obtained by any of the farmers at Lavenham. Still it is a question whether, in view of the large returns to be obtained by the growth of other crops, Sugar-Beetroot will be a paying crop for a sewage farmer to grow: for it must be recollected that it is almost impossible to precede it by any winter catch crop, and that it remains in the ground so late that it can hardly be followed by any other crop, unless it is desired to take a crop of cereals off the ground, for which, however, it would not be a very good preparation, inasmuch as full dressings of manure cannot be applied to it without the risk of reducing the percentage of crystallisable sugar, or, rather, increasing the difficulty and expense of crystallisation, and therefore, of course, diminishing the value of the root.

PARSLOES EXPERIMENTAL FIELD.

Many now present are aware, from personal observation, of the peculiarly sticky, ungenial character of the soil of the experimental field on which I have been

working. Those who have not seen the field themselves will, perhaps, be interested in seeing which is a perfectly fair sample of the soil, gentlemen, however, who gave me the personal visit during the summer, will be struck by the peculiarly backward, unprofitable appearance of the field then presented. It is not, therefore, some satisfaction that I am able to produce a specimen of Mangel, which I selected, and being taken up, as among the best of the field, weighed when taken up, 31 lb. The total weight of the Parsloes; but I have measured it accurately, and 4½ acres I have obtained 352 cubic yards of weight of a cubic yard I find to be about 10½ cwt. Consequently, as from the whole of the 352 cubic yards, equal to 184 tons of weight, would be almost 41 tons per acre, which would be considered a satisfactory result by a high standard of the ordinary system, with moderately good soil, I venture to submit, as remarkable a result, as sticky yellow brick-earth as the Parsloes alluded to.

SEWAGE FARM AT ROMFORD.

I have said that, for the future, I shall be able to record accurate quantitative experiments in the cultivation of town sewage. This is because I have taken a lease of another farm about three miles from London, together with a lease of the town of Romford. I am informed that the town contains a population of about 8000, of whom 6500 are believed to be "sewered," as they are at the present time. However, correct information can be obtained in the course of the coming year, the actual amount of population drained by the sewerage.

The farm consists of about 120 acres, of which greater part is a light sandy and gravelly soil, admirably adapted for sewage irrigation, but exceedingly poor land. For the land, with buildings, I pay a rent of 300l. a year. For the delivered upon the farm, I pay a rent which is the largest dead rent paid for the sewage of any town, no matter what the population, up to the present time—namely, 600l. a year. For instance, the town of Croydon only gets about 800l. a year, or half as much, for the sewage of a population nearly as great as that at present drained by the Romford sewerage. Nevertheless, I believe that I have got a very good bargain, as I have got the sewage for only like 2s. per head of the present population, in intention, so soon as I have got the land ready for the proper distribution of the sewage, soon as I can procure a self-recording meter, will not become clogged with the dirt of the sewer, and commence a series of quantitative experiments, a correct and rigid account shall be kept for the benefit of the public.

Having this farm to lay out, which is laid almost in a ring fence, and having it entirely in my own control, I am anxious, of course, to make a model sewage farm in every respect, and I have very great pains to ascertain the best method in which to lay land out for irrigation. I have, in consideration, first, the effect of running ploughing channels, in arable land; secondly, the niceness for distributing an equal quantity of sewage over each square yard of the bed; thirdly, the result of both in laying out the land and in the ploughing and cultivating it after it was laid out; and, as a result of many careful observations and experiments, was, that the breadth which combined the advantages was 15 feet from the ridge to the furrow, with as great a length as possible; I therefore desire to amend the statement made in my last paper, to the effect that the width of bed was from 10 to 45 feet from the furrow; and I find that after the shallow and cross ploughings that may be necessary to obliterate the former cultivation, two ploughings are amply sufficient to lay the land up to the slope of 1 in 25, and as two ploughings are considered too much for ordinary cultivation, of preparing the surface for sewage irrigation itself into the labour necessary to obliterate the former cultivation, plus, in the case of flat land, that to give the necessary fall along the ridge of the bed will therefore be seen, that further experience served to cheapen the process of laying out, and that it is not one of those cases where fresh experiments arise the more the subject is investigated.

For the distribution of the sewage over the field, wherever to obtain a sufficient fall a height of 30 inches given to the carrier of over 30 inches. I am given of the description of sheet-iron trough which I gave in my former paper, with a slight improvement, to in my former paper, with a slight improvement, addition to the prolongation of the sides, to give stiffness, and so to admit of a greater distance between the supports, the top of the sides will be as a flange, to give lateral strength. The troughs will be tied together every three feet by a pair of uprights to take the bottom of the trough, with a cross-piece to take the bottom of the uprights. The uprights will spread 1 foot from the base, and will be mortised into a sleeper 1 foot below the surface. There will be a cross-piece every 30 feet, with a simple water-tight joint between every down-pipe, and a shutter in the main trough, which the further flow of the sewage can be stopped or stopped altogether at pleasure. The area of the main trough will be equal to the area of an 18-inch pipe: and the contract price will be 10s. with supports and shutters, with two cross-pieces fixed in position, ready for work, 1s. 6d. per yard forward, with an extra 5s. for each opening, and down-pipe; making a total, including the cost of the pipe, of 7s. 2d. per yard forward, which is a very economical method. The contractor is Mr. Edwin

or are to be put over pipes with the view of getting them out of the way, open two or three drains at one side; put pipes in these; trench the two or three ridges between, one ridge being trenched in advance of the other, and the stones gathered into small wooden boxes may be carried across to fill the next set of drains being opened. In this way we have drained and trenched large areas of old and new land, the whole work being done by contract at about 10s. per acre—the land the following season being under Turnips, after bonedust dibbled in on the trenched surface. In examples of very bad, poisonous bottoms, the top spit or furrow only is turned over, the bottom being loosened with the pick, dug over, to remove stones, or subsoiled. When done by the plough, the bottom may require to be subsoiled several times before it is fit for being mixed with the staple or arable soil. In such cases it is a prudent plan to deepen by degrees, bringing up an inch or so at a time, and exposing it on the surface as much as possible to the influence of the weather before seed time.

The Stable.—As the days shorten some horsekeepers reduce the daily allowance of corn, others take nearly as much work out of their teams this month as any other, whether ploughing or carting, &c., they plough deep, and hence do not reduce the feed. As a rule, horses should be kept in good working condition this month.

Breeding Ewes.—Attend to as last month. As the weather becomes colder they require more food and shelter; the latter being equivalent to so much of the former. In the lowlands of Scotland and northern counties of England, the rams are generally taken from the ewes about the latter week of the month; but in Highland sheep-walks, or rather if ewes have to lamb there, the rams are only put to the ewes about this time. The bathing or smearing of blackfaced and Cheviot hogs is concluded about the same time. Flocks leave the more elevated districts of Scotland for the low country grazings, where they remain during the winter months, returning hence in the spring, the times of departure and return depending upon the nature of the season. Thus Heather, and some of the mountain Grasses, are in their prime during November, and when the weather is open they supply an abundance of feed, not only relished by sheep, but by black cattle also, and both do well upon it. Milch cows, when turned out about mid-day for an hour or two, browse the young Heath greedily; but the change from open to stormy weather is often rapid, and stocks must be shifted accordingly to their winter quarters, to avoid being "storm-stayed."

The Dairy, in the common acceptation of the phrase, is now a secondary question as regards the daily produce in milk; but to this old rule there are exceptions, more in number than formerly. According to the old plan, two or three cows were timed to calve about this season, or else calvers were bought in, and the remainder of the herd allowed to run dry—not all at once, but to suit the calving in spring time. But improvements in stock management enable dairy-men now to produce more and richer and better milk during the winter months than formerly, so that those who supply our large towns with milk and fresh butter by railway endeavour to produce at this season what their customers require, the daily supply being little short of that of summer. But to accomplish this, the newly or recently-calved milch cows must be kept uniformly warm, and well fed on proper food; and if this is done, they will yield an abundance of rich milk throughout the winter months. Dry cows, and those nearly so, should be kept fresh on plenty of Turnips, but not fattened; and equal attention requires to be paid to their warmth; frosty Turnips and winter hay highly objectionable. The currycomb and brush, more especially the latter, should be freely used on both the calved and in-calf, to keep up a healthy clean state of the skin.

Gorse comes into use when the sewage Grass fails. When properly bruised, it is excellent food for milch cows, and it should be more extensively grown for this purpose than at present. If a man can cut as much in a day as will serve 16 cows, and if an acre and a-half of Gorse will feed the 16 cows for a month, the value of an acre compared with Grass is easily calculated by any dairyman. As to the crushing, the engine that threshes, cuts chaff, &c., will also work the Gorse mill. The above calculation is at the rate of three bushels of bruised Gorse to a cow daily, but at 2 bushels daily, with Turnips, an acre would serve the 16 cows a month, and so on.

The Pig-stye.—Bacon-hogs fatten as the days shorten. Increase the allowance of sour food as you force them forward. This latter applies also to small porkers. Breeding sows serve about the end of the month to bring forth towards the end of March. *W. B.*

Notices to Correspondents.

JERSEY Cows A G writes—"On October 29 a Jersey heifer calved three weeks before her time, and the calf (a dead one) had to be taken from her. She recovered, and went on well till about 10 days since, when her milk became so tainted as to be quite useless, and her breath smells as badly as the milk. I can only compare it to bad fish. We are at a loss what to do, and I should feel much obliged if you could give me a hint, as the cow is a valuable one, and a great pet." [It is possible that the cow may have eaten some putrid substance. Were the foetal membranes removed out of her reach? Try the effect of 2 ounces of hyposulphite of soda dissolved in the drink-water twice a-day, or give it as a drench in a quart of warm water. We conclude from your letter that the cow is in good health.]

POULTRY BOOK Dehnam Tegetmeier's "Poultry Book" is a very handsome and serviceable work; Bally's (113, Mount Street, Grosvenor Square, W.) little book on poultry is practical and instructive.

SALT R.A.R. 4 cwt. per acre will not kill weeds on light land. You must get the weeds up by scarifying, harrowing, gathering, and burning. Earlier in the year you might have done a good deal to it by more sunshine.

Peill's Conical GREENHOUSES, Tubular Boiler.
HOTHOUSES, CONSERVATORIES, CHURCHES, PUBLIC BUILDINGS, &c.

HOT-WATER PIPES at wholesale prices, Elbows, T Pieces, Syphons, and every other connection kept in stock.

WROUGHT and CAST IRON CONICAL, SADDLE, and IMPROVED PEILL'S and ELLIPTIC BOILERS, from 24s. each.
IMPROVED and EXTRA STRONG CAST IRON TUBULAR BOILERS, with or without Water Bars, from 52s. 6d. each.
CAST and WROUGHT IRON PORTABLE BOILERS on STAND, for use without brickwork, from 60s. each.
PATENT and IMPROVED THROTTLE and other VALVES, FURNACE DOORS, BARS, and FURNACE WORK of every description and size.

LYNCH WHITE.
Old Barge Iron Wharf, Upper Ground Street, London, S.E. (Surrey side Blackfriars Bridge).
Price List on application.

Heating by Hot-water.

SHANKS' IMPROVED WROUGHT-IRON BOILER.
This Boiler is made on the principle of the Saddle and Tubular combined. The Tubes, Fire-box, and Shell-plates are all of Wrought-iron, and consequently are not liable to break from expansion and contraction of the metal, as Cast-iron Boilers are. The Tubes are placed in the Fire-box, and so arranged as to expose a very large effective heating surface to the direct action of the fire, the advantage of which is obvious.

A. S. and SON will be glad to furnish their IMPROVED BOILERS separately, or to furnish Plans and Estimates for Erecting Hot-water Apparatus complete in any part of the country.

HORTICULTURAL BUILDINGS, IN IRON or WOOD.
Catalogue, containing Designs of Houses, &c., will be forwarded on application. Special Plans and Estimates for Ranges of Houses to be erected in any part of the country will also be furnished.

A. SHANKS and SON, Dens Iron Works, Arbroath, N.B.; and 27, Leadenhall Street, London, E.C.

T. G. MESSENGER, MIDLAND STEAM POWER HORTICULTURAL WORKS, HOT-WATER APPARATUS, VALVE MANUFACTURER, LOUGHBOROUGH.

Honourable Mention awarded at the International Exhibition, 1862, and at the Dublin Exhibition, 1865; also a First-class Certificate by the Royal Horticultural Society.

T. G. MESSENGER, Patentee of many important improvements in Buildings and Implements connected with Horticulture, and which meet with unqualified approbation, is prepared to give reference to hundreds of works entrusted to him and pre-eminently answering the purpose for which they were constructed.

Any House Glazed, single or double, with or without putty. The mode adopted by T. G. MESSENGER for Heating and Ventilating Forcing Houses is particularly successful, drip being entirely prevented.

Houses can be constructed on his Patent Ventilating principle to open the whole of roof and sides as though the glass were entirely removed, at once placing the plants in the external atmosphere.

T. G. MESSENGER'S Boiler possesses all the advantages of the Tubular and Saddle combined, has hollow furnace bars, requires but a shallow stokehole, exposes as much surface to the direct action of the fire as can possibly be obtained, the whole of which can be easily cleaned; and it is an important fact, that out of upwards of 500 now at work made upon the improved principle not one has cracked.

T. G. MESSENGER'S Valve (single or double) is effective, simple, easy to work, and as durable as the pipe to which it is attached. Designs and estimates supplied for all kinds of Horticultural Work, and guaranteed to answer the purpose for which they may be intended. A richly illustrated Catalogue, with descriptions, forwarded post free on receipt of 33 stamps.

LOOKER'S PATENT EARTHENWARE PROPAGATING BOXES.—The most simple, effective, and by far the cheapest arrangement for Raising Seeds, Striking Cuttings, and other Horticultural purposes. Price, complete, from 1s. each.—Hooper & Co., Covent Garden, Roacher & Co., Upper Ground Street, Blackfriars, Kingsland Road, and Queen's Road West, Chelsea; and Dixon & Co. 48a, Moorgate Street.

BENJAMIN LOOKER, Inventor and Sole Manufacturer, Kingston-on-Thames.

SMITH'S PREPARED CHARCOAL.
An economic Fuel of the day for Warming Stoves. Will burn in Smokeless Stoves; only needs replenishing 12 hours. Price, 2-bushel bag, 3s. Two bags delivered free. G. SMITH, 24, Cavendish Street, New North Street.

Rosher's Garden Edging Tiles.

THE above and many other PATTERNS of Terra-Metallic Ware, Terra-Cotta, Stoneware, and other materials, especially suited for KITCHEN, Bath, and other little labour, and once put down further labour and expense, as Edgings, consequently being suitable for GARDEN VASES, FOUNTAINS, Artificial Stone, of great superior finish, and in much variety.

F. & G. ROSHER, Manufacturers, Upper Ground Street, Queen's Road West, Chelsea, S.W.; Kingsland Road, Essex. Illustrated Price Lists free by post. The Trade only.

ORNAMENTAL PAVING TILES for Courts, Halls, Corridors, Balconies, &c., as cheap and of designs. Likewise more elaborate designs of Pavements, with prices, forwarded for selection.

WHITE GLAZED TILES, for Lining Walls of Kitchens, Ranges, Baths, &c. Grooved and other Bricks of great durability, Dutch and Adamantine Copings, Red and Stoneware Drain Pipes, Sinks, &c.

To be obtained of F. & G. ROSHER, at their premises.

SILVER SAND (REIGATE), at the above price 14s. per Ton, 1s. 2d. per Bushel, 2s. per Ton more for within three miles, and to any London Railway or Water of 4 Tons, 1s. per Ton, less. A coarser grained Sand, for samples of Sand by post or receipt of stamp.

FLINTS and BRICK BURNS for Rockeries of every PEAF and LOAM supplied at lowest rates.

F. & G. ROSHER—Addresses see above. N.B. Orders promptly executed by Railway and a liberal discount to the Trade.

SHANKS' PATENT LAWN MOWERS
The Patent Improvements recently introduced SHANKS' MACHINE

Several important advantages possessed by this PATENT DOUBLE-EDGED SOLE-PLATE MOWER. The unprecedented Sale for 1883, notwithstanding the Season, forms the most convincing testimony to the advantages have been appreciated.

ALEXANDER SHANKS & SON beg to intimate that, as Exhibitors of Lawn Mowers at the Paris Exhibition, only Firm to whom the Jury awarded a Medal. The then awarded is the highest Prize ever given to any Lawn Mowers.

ALEXANDER SHANKS & SON have for some time past the Revolving Cutter of their Machines Self-Sharpening, with Steel on both Sides of each Blade, so that when it becomes blunt by running one way, it can be reversed, so the opposite or sharp edge of the Cutter to cut again. In addition to this, A. S. & SON now make the Bottom Blade of their Machine with Two Edges—two usual, and one in reserve at the back, when the first worn down, the plate has only to be unscrewed and the second brought to the front. It will be seen at a glance that this arrangement enables the cutting parts to last twice as long as machines, where the single-edged Sole-plate must be renewed when the edge is worn down.

A Wind-Guard has also been introduced to prevent Grass being blown past the box, and the preservation of the blades. There is no ribbing with these Machines. The Lawn Mower has a most beautiful appearance, being smooth and simple.

Every Machine warranted to give ample satisfaction, approved of can be at once returned.

Illustrated Circulars, with full particulars, sent free of charge. A. SHANKS and SONS, Dens Iron Works, Arbroath, N.B., Leadenhall Street, London, E.C.

A Stock of all sizes of Lawn Mowers kept at 27, Leadenhall Street.

GREEN'S PATENT SILENT MOWERS
or NOISELESS LAWN MOWING, BROAD COLLECTING MACHINES for 1884.

Every Machine is warranted to give entire satisfaction, approved of, can be returned at once unconditionally.

PRIZE MEDALS AWARDED TO GREEN'S PATENT LAWN MOWERS

First Prize Medal at the International Exhibition, London 1862.
First Prize Medal at the International Exhibition, Dublin 1865.
First Prize Medal at the Paris Exhibition, 1867.
First Prize Medal at the Gand Exhibition, 1868.
First Prize Medal at the London Exhibition, 1873.
First Prize Medal at the Antwerp Exhibition, 1876.
First Prize Medal at the Brussels Exhibition, 1879.
First Prize Medal at the Hamburg Exhibition, 1874.

GREEN'S Patent Lawn Mowers have proved to be the most successful in every Prize that has been given, and have carried off every Prize that has been given, in every competition.

The extraordinary success of GREEN'S Patent Lawn Mowers is an established fact. During the last five years their sales have been unprecedented, which alone is a proof of their superiority over others. The following are their characteristics:—Simplicity of construction, every part being free of ornament, are worked with far greater ease than any other Lawn Mowers. They are the least liable to get out of order.

GREEN'S Patent Lawn Mowers combine a blunt edge, which sharpens, and when the cutters become blunt by use, they can be reversed again and again, bringing the sharp edge of the cutters against the bottom blade, which operation is done by any inexperienced person, and is the peculiarity of GREEN'S Machine, which is possessed by no other. Illustrated Price Lists free on application.

THOMAS GREEN and SON, Smithfield Iron Works, 54 and 56, Blackfriars Road, London, S.

N.B.—All orders are executed on the day they are received.

a little and the fragments arrange themselves differently, but still they are the same fragments—and throughout their almost infinite permutations one common semblance runs; and so in these Potatoes the "blood" of one or other parent was to be manifestly traced in greater or less degree throughout—the combinations were diverse to a wonderful extent, but the material was the same. The most interesting fact, physiologically, was the production of a small, round, mottled tuber, almost precisely identical with the wild forms introduced to Chiswick from Peru. But this reversion, however interesting as a matter of science, affords an illustration of the necessity of getting out of the rut, and of striking out a new course. We don't want endless combinations of old forms, still less do we want, for practical purposes, to go back. In the matter of the Potato, our Hibernian friends even would object to advance backwards.

But how are we to get out of the beaten track—how are we to make real progress—how baffle disease—how improve constitution—how secure new and really improved varieties? Numerous methods have been recommended, and all sorts of schemes proposed. Here is another, probably not a new, suggestion:—There are several hundreds of species of the genus *Solanum*. In the case of the great majority there would probably be no good result forthcoming from an attempt to cross-fertilise their flowers with those of the Potato, but there are some few with which it would be quite worth while to make the attempt—such as *S. Magha*, *S. immitis*, *S. Commersoni*, *S. demissum*, *S. cardiophyllum*, *S. verrucosum*. We should look to our Botanic Gardens to introduce the plants where necessary, and to carry out the preliminary trials; should such trials be sufficiently promising, the experiment might be pursued by private individuals, abandoned if unsuccessful, or followed up on the large scale by growers for sale. It is quite clear that in-and-in breeding has been carried on long enough—a little new blood is required, but we don't know how it can be supplied, except by some such means as we have pointed out.

THERE are two distinct forms of *Picea Pinsapo* cultivated in our gardens: the one with obtuse leaves, which has borne cones plentifully this year in different parts of the kingdom; and the other with acute leaves, of which a fine specimen was in Mr. STANDISH'S collection at South Kensington on Nov. 16, of which we have never seen fruit, and which is sometimes confounded with *Picea cephalonica*. This is the form of which an authentic specimen from BOISSIER is contained in the Kew Herbarium; but on reference to his plate and text we find that it is considered as a sterile branch of the obtuse-leaved *Pinsapo*. Be this as it may, large plants exist in this country like that exhibited by Mr. STANDISH, and time alone will show whether when old they exhibit the characters of the obtuse-leaved tree.

A supposed variety of the species, named *var. baboriensis*, from the locality in which it has been found, has been described from Algiers; a specimen of this, with ripe cones, is in the Kew collection. The locality in question is noted as the upper woody region of the mountains Babor and Tababor, in Eastern Kabilia. An important difference, however, appears in the leaves, though the cones seem identical. In both the acute and obtuse leaved *Pinsapo* the leaves come straight from the branches, a character by which they are distinguished from the Silver Fir; but in the *baboriensis* variety there is the same twist at the base, and the leaves have much the character of those of the Silver Fir. Now, exactly as in the *Pinsapo*, there is an acute-leaved variety named *P. cephalonica* or *P. Apollinis*,* and the ordinary obtuse-leaved form of the Silver Fir; and Mr. Cox lately sent up to South Kensington a branch with cones, referred, both by himself and subsequently by Mr. ANDREW MURRAY, to *P. cephalonica*, with obtuse leaves; confirming the judgment of PARLATORE in considering it a variety of *Picea Abies*.

It appears, then, either that the variety *baboriensis* must be considered as an intermediate species,† with the leaves of the Silver Fir and

the cones of *Pinsapo*, or there will be reason to believe that, however different they may be, the three are forms of one highly variable species. It is particularly requested that if any one has fruiting plants of the acute-leaved *Pinsapo*, specimens may be sent to the meeting at South Kensington on December 21. M. J. B.

IN accordance with the announcement made in our last, HIS MAJESTY the KING OF THE BELGIANS, attended by Viscount TORRINGTON, General GREY, and several other members of his suite, visited the gardens and art collection at South Kensington. The KING was received at the Museum by Mr. FOSTER, Mr. H. COLE, C.B., Mr. OWEN, Mr. THOMPSON, and Mr. REDGRAVE, R.A., and was for two hours occupied with the inspection of the whole establishment. From the Museum HIS MAJESTY proceeded to the gardens of the Royal Horticultural Society, where he was received, at the north-east entrance, by Mr. W. W. SAUNDERS, F.R.S., and Mr. JAMES BATEMAN, F.R.S., vice-presidents of the Society, and by other members of the Council. The deplorably wretched state of the weather prevented any attempt to enjoy the sight which, even at this time of the year, the open grounds afford; but in the large conservatory, where a numerous company of Fellows had assembled, a beautiful and extensive exhibition was furnished by the principal nurserymen and florists.

There are, we believe, but few gardeners who ever grow their SHALLOTS FROM SEED. This doubtless arises from the seed not coming to perfection regularly in our climate. Nevertheless, we recently saw some very fine specimens grown in this manner by Mr. TRIGG, of Hayling, Hampshire, five of which weighed 1 lb. 7 oz. Mr. TRIGG informed us that to obtain them he planted the offsets in the usual manner, and allowed them to seed, which they do the second year. He sowed the seed in good rich soil, at the same time as he sowed his Onion seed, and obtained the crop from which the above were taken as fair average specimens. When growing in rows in the same manner as Onions, they much resemble the latter for some time, until they begin to divide into offsets, when the peculiar difference between them is readily distinguished. These improved examples are said to be much milder in flavour than those obtained in the usual manner.

We believe that SCHACHT was the first who pointed out that the FALL of the LEAF was due to the formation of a few loose, powdery-looking cells formed between the living and dying portions of the plant. This is equally the case in the curious phenomena called Cladotaxis, in which twigs of the Oak, Willow, and some other trees are thrown off by a process of natural pruning. This is especially visible in the nodes below the point from whence the stalk of the Pear has been thrown off, each internode in its turn separating from that below. In no case, however, have we seen it more strongly exemplified than in the Vine, where the cells are so abundant that they may be easily rubbed off, in the shape of a thick glittering dust, by the finger. What, however, we wish to call attention to at present, is a fact which we have not ourselves observed before, neither has it been noticed by our most distinguished British pomologist (the word being taken in its widest sense), viz., that the blade of the leaf in the Vine is often thrown off before the petiole, the denuded petioles remaining still attached to the shoot. This is, of course, the indication that the leaf of the Vine is essentially compound, though only one leaflet is developed, a circumstance which might be expected from the habit of many of its near relations. This is at first not so manifest as in some other apparently simple leaves, as for example in the Orange, though a swelling will be observed at the point of junction, which is indicative of the true nature of the case. It is very probable that this fact may have been recorded before, but it was a useful doctrine of Professor HENSLOW, that it is very desirable to record as soon as possible such observations, as their publication can do no harm, and may very possibly direct attention to points which might otherwise be long overlooked. M. J. B. [The phenomenon alluded to has once or twice only come under our own notice. V. MOHL and others have shown the gradual formation of a very delicate layer of cells athwart the leaf-stalk at right angles to the direction of the other tissues, and which act as a knife edge would do in separating the leaf. These cells are formed originally long before the leaf falls; and we presume that it is these cells enlarged, and often filled with starch grains, which furnish the white mealy substance alluded to by "M. J. B.," but we do not recollect whether the whole course of development has been continuously watched. Eps.]

The employment of sublimed SULPHUR in our HOP GROUNDS has, beyond all doubt, been a great boon to cultivators in checking mildew, and its use is now pretty general, having outlived the unreasonable prejudices which were at first raised against it, as indeed is the case with all innovations. Powdered sulphur was found to be less efficacious, though not entirely without benefit. A communication was, however, lately made to the French Academy by M. MARÉS with reference to the change which flowers of sulphur or ground sulphur undergo when cast on the soil of vineyards. It is found that it is converted into sulphuric acid, which then combines with the lime in the soil to make sulphate of lime. Whether the chemical change takes place merely from the direct action of the oxygen of the atmosphere, or from the sulphuretted hydrogen emanating from the manure in contact with the sulphur, does not appear certain, though no odour of sulphuretted hydrogen is perceptible; but it is found

that its effects are very beneficial in the case of the Vine mildew. It would clearly be a great boon to Hop growers if the parasite could be destroyed before the bine springs out from the soil, and would be well worth the attention of our more intelligent cultivators if they would make the experiment. The parasite could not be stamped out immediately the wind would bring spores of the mildew to neighbouring Hop grounds, where matters would be sure to take their course; but if it was once checked that sulphur applied to the soil was effective in a comparative case of the application would be adopted. The subject is scarcely less important to our GRAPE GROWERS, who still continue to suffer from the mildew, and we recommend their careful consideration. M. J. B. [These into the composition of whose Vine wine enters! Eps.]

New Plants.

—*STANHOPEA GIBROSA*, sp. n. aff. Stanhopea Wardii hypochilio incurvo, lobis superiori uncarinato, lato, pectore argute profunde angustissimo, aperte, portione apposita lato angustata utrinque, cornibus filicatis ligulatis, apice acuto, basi gibbero solido magno, columna ovata his angusto triangularis, alis semiovatis angustis auriculis usque.

A species in the way of *Stanhopea Wardii* distinct. We obtained it from Messrs. H. G. Rehb. fl.

—*RESTREPIA ANTENNIFERA*, H. B. K. Sepalo dorsali triangulo caudato apice clavato sepalo inferiori lato ligulato apice bifido lobis petalis sepalo superiori subaequalibus, bracteis triobovatis; labello ima basi auriculis geminis erectis, unguiculato, a latiori basi ligulato apice clavato basin versus in setam exsertente, ceterum gracilenta clavata. — *Restrepia antennifera*, H. B. Kth. Syn. i. 341.

Restrepias of the original shape are regarded with favour by amateurs. The *Restrepia elegans* is known in gardens, though rather rare. It is a curious plant, easily offended, and thus often do well for long together. We found it in a state in the Hamburg garden, but it has since divided and partially lost without our knowledge. The remainder of the three great patches got into a state in the Hamburg garden, but it has since divided and partially lost without our knowledge. The remainder of the three great patches got into a state in the Hamburg garden, but it has since divided and partially lost without our knowledge. The remainder of the three great patches got into a state in the Hamburg garden, but it has since divided and partially lost without our knowledge.

—*TRICHOCEROS PARVIFLORUS*, H. B. K. Calice nudo, pseudobulbis parvis crassis mucositate hirsutis apice seu in apiculis redactis lobis ad 5, inferioribus ad vaginas reductis, apice racemose cetera elongato axillari, paucifloro longidistantibus. Flores "postici." Ovaria bracteis triangularibus multoties exsertentibus. Sepala triangula viridia vitta brunnea. Petala cuneiformia acuta, maculis transversis brunneis tripartita, partibus laterales lineares ovatae, line ciliatae partibus mediae excavatae disco labellata, imbo brevissimo ciliatae, mediae maculis brunneis transverse, partibus laterales maculis viridibus. Columna brevis clavata, apice bifido lobis semiovatis ciliolata acuta adnata, rostellum triangulum apice retusum lobis fovea immersa limbo erecto subpentagono; antheram valde violaceo-barbata, in superficie antica vitta brunnea; pollinia incumbentia pyriformia bifaria connectiva canaliculata linearis glandula orata. — *Trichoceros parviflorus*, H. B. K. in Kth. Sp.

Formerly *Trichoceros* was a great curiosity, the lateral parts of the lip being regarded as staminodes, a mistake we have long ago. It comes near *Telipogon*, but all have an uncinata glandule. The small green with violaceous and brown spots and bars of botanical interest, yet the hairy column of one of the head of a puss, though violaceous, not to be found. We have at hand dried specimens from Humboldt, Bonpland, Hartweg, Epling, Mandon. Mr. Gustav Wallis sent it alive to Linden, with whom, and with W. Wilson Esq., it is now flowering. H. G. Rehb. fl.

SPRING BEDDING PLANTS.

BIENNIAL plants for spring flowering are of our attention, and these I will notice in their superiority for this purpose. The Forget-me-Nots furnish such beauty to the garden, that we cannot, or do not, wish to do without them. There are several beautiful varieties of which very little is at present known. *M. sylvatica* is the species so generally cultivated in den and other places where this system of bedding is carried on. It is very free-flowering, and a charming mass of bright blue flowers in the spring. It grows from 12 to 18 inches in height, this depends in a great measure upon soil and circumstances. *M. sylvatica* alba is a pure white variety of the above. It is very pleasing, and we have seen it growing with the typical plant. *M. sylvatica* is a new variety, which I see offered for sale by a well-known firm for this class of plants in flower last season, and considered it a very valuable acquisition, its pleasing mass of rose-coloured blossoms blending harmoniously with those of the typical. *M. dissitiflora* is a very distinct and beautiful species, introduced under the name of

* There is an obtuse-leaved form of *P. Apollinis*, from Attica, in the Kew Herbarium, as well as an acute-leaved form marked "Greece."
† Of this Mount Babor or Tababor Fir, there is an excellent coloured figure in Van Houtte's "Flore des Serres" (vol. xvii. p. 9, t. 1717 1718), under the name of *Abies numidica*, and we saw young plants of the same Fir growing in M. Van Houtte's nursery in the early part of last year. Eps.

think there has been sufficient said of this in the papers of last spring, to obviate the necessity of my saying a word. It grows from 6 to 9 inches in height, and when in bloom presents a beautiful mass of sky-blue flowers with yellow eyes. For massing this stands pre-eminent.

Myosotis asorica is a very dwarf-growing species obtained from the Azores, scarcely exceeding 1 inches in height. Its flowers are light blue, with a yellow centre, and are produced in innumerable quantities. M. asorica alba is a pure white variety of the above, equally as dwarf, and a charming companion for the blue one. M. asorica caerulea is another charming variety, of which too much cannot be said. It claims special attention from every lover of spring flowers, on account of its dwarf distinct habit, its free-flowering capabilities, and the heavenly blue colour of its flowers. I saw it for the first time at Erfurt, in Prussia, during the past season, and I think I never saw anything more lovely. There was a bed containing some 3000 of these sturdy little plants, not more than 4 inches in height, each forming a distinct, compact, pyramidal little bush, and not a plant varying the slightest, either in size or height. Every plant was smothered with flowers of a magnificent deep blue colour. It reproduces itself freely from seed, and it must be considered one of the greatest acquisitions for the spring garden that has been raised for many years. A bed of these varieties of M. asorica, edged with Arabis lucida variegata, would make one of the sweetest beds imaginable.

There are other species of the Myosotis, but those I have mentioned constitute the cream of the family. Most of them may be considered perennials, but as they are all freely obtained from seed this is the best way of procuring them, and the plants thus raised grow and flower more freely than those propagated in the usual way. The best time to sow the Myosotis is in August. Prepare the bed by digging, and rake it rather fine; water the bed some days before the seed is sown, so that it will not readily get dry. After the seed is sown the bed should be shaded with some light material, but as soon as the seed appears gradually remove it, until the plants are strong enough to bear the sun. By the end of September or beginning of October they should be removed to their winter quarters, care

plants strong enough to flower the following season. Pyrethrum Parthenium aureum, or the Golden Feather, should be treated in the same way as the Myosotis, and will be found invaluable for spring decoration.

Among other plants of this character may be mentioned Collinsia bicolor, C. grandiflora and C. verna, Nemophila insignis, N. bicolor, and N. atomaria, Clarkia pulcherrima fl.-pl. and the double white var. Candytuft, Limnanthes Douglasii, Lathænia, and the Vesicaria. These should also be sown about the middle of July, and should be transplanted as soon as ready into their winter quarters. There are also many other places where these plants may be used with a very pleasing effect, such as in the vacant places in the shrubbery; if these plants are once located there, they will reproduce themselves every year, without any further trouble. The Myosotis and Sineses would grow much more vigorously and flower more freely there than in the borders where they are fully exposed to the sun. You could introduce many more, such as Primroses, Polyanthus, Violets, and such-like plants, which would greatly enliven the scene. I know of a walk about half-a-mile in length, at Walthamstow, around a piece of ornamental water; it is surrounded by high trees, and under these thousands of Primroses grow luxuriantly, and perpetuate themselves without any trouble. Besides masses of such plants as I have mentioned, here and there we find a complete carpet of the common Anemone nemorosa and A. apennina. I live in hopes of seeing our shrubbery borders and waste places thus filled, and until we endeavour to imitate Nature by the cultivation of these hardy plants, our gardens will only prove to what a low ebb horticulture has subsided. In my next paper I shall give some descriptive notes upon perennials adapted for spring decoration, with hints upon their cultivation and propagation. A. J. P., Tottenham.

CHURCH DECORATION.—No. II.

Drawing and Making Designs.—There are few kinds of handywork which illustrate so forcibly the truth of the maxim that "what is worth doing at all is worth

ruling a line between every other mark or point, the required triangle will be produced, and its three sides will be equal, so that by whichever angle you hang it up, it will look always the same.

We will next assume that the triangle which you have drawn is larger than you want, and that you require one of a different size. Upon Figure 2 you will find a dotted triangle, of the same size as that in Figure 1. You will also find that dotted lines have been drawn from the centre to the angles of the dotted triangle, and that a smaller circle has been described, and, lastly, you will see that a smaller triangle has been formed by ruling lines between the points where the circle crosses the dotted lines from the centre.

Upon Figure 2 will also be found a larger triangle, which it is scarcely necessary to explain has been obtained in like manner by means of a larger circle. It is only by thus correctly drawing one triangle within another, that a proper form is to be obtained, for covering with evergreens or everlasting flowers.

In order to produce the very pleasing design of two triangles interlacing, it will be seen, on reference to Figure 3, that by dividing the circumference of a circle, as before, into six parts, and by ruling lines between every other mark, you get two large triangles. Then describe a smaller circle from the same centre, and determine the six points upon its circumference by ruling lines (as shown by the dotted one) from the centre to the angles of the large triangle; then connect by straight lines every other one of these points, and you will find that you have two smaller triangles, arranged perfectly symmetrically with the two larger triangles. By erasing or rubbing out a little piece of the lines where you wish another triangle to appear to pass over, the effect of interlacing is produced.

Hanging or Fixing-up Designs.—It is grievous to see, as we have so often observed, really nicely-made designs so fixed up as to deprive one of all pleasure in looking at them. We well know that it is not an easy matter to use a hammer upon the top of a tall ladder unless by those used to such work, nevertheless, designs must be hung horizontally, perpendicularly, and at regular distances apart, or otherwise the effect which they are intended to produce will be seriously marred.

FIG. 1.

FIG. 2.

FIG. 3.

being taken not to plant them too closely. A very small space in the kitchen garden will suffice to produce many thousands of these plants. I find one of the best places is under the Gooseberry and Currant trees, where they can receive protection from the heat of the sun, in the alleys of the Asparagus beds, shading them with the tops of the Asparagus. But I should recommend devoting a small piece of the kitchen garden to them as a nursery, for the propagation of these plants, as they can then be looked after more effectually.

Another capital plant for this kind of gardening is the Silene pendula, it is very free in growth, and from its pleasing colour is indispensable to the spring garden. It grows from 18 to 24 inches in height, and forms a dense mass of lively rose-coloured flowers, which have a very pleasing appearance. There is a white-flowered variety, which forms a fine contrast with the former. Sown in August, similar to the Myosotis, and they will then be strong enough to plant out with them. Campanula calabrica is another charming biennial, and admirably adapted for grouping with such as the dwarf Myosotis. It forms dense cushions, about 4 inches in height of bright pink-coloured flowers, which remain a bloom a long time. It is one of the loveliest of the spring flowers, and deserves unlimited cultivation. There is a white-flowered variety of this also, which is very pleasing. Sow at the same time as Silene, and treat in the same way. Another very important plant for the spring garden is the old-fashioned purple Honesty, Lunaria annua, it is admirably adapted for the centre beds, as it grows about 2 feet in height, it is of a very vigorous habit, and an abundant bloomer, and is very easily raised from seed. Sow in August, and treat in the same way as Myosotis.

The Wallflowers next claim our attention. The single yellow Italian Wallflower is a charming addition to the spring garden, to which it stands in the same relation as the Calceolaria does to the summer garden. It is exceedingly dwarf, not exceeding 12 inches in height, it flowers as freely as the common wallflower, but the flowers are of a bright dazzling yellow. This plant is strictly perennial, and it can be moved without any risk, but as it comes from seed there is no occasion for troubling about them, unless you transfer them to the border. The seed of this should be sown as soon as ripe, or you will not get

doing well," as that of drawing designs; for unless they are produced correctly, the effect is anything but pleasing to either the educated or the uneducated eye; the former will at once observe their inaccuracy and want of symmetry, while the latter will be impressed with an indescribable feeling of something being somehow or somewhere not quite what it ought to be, without being able to point out, or even recognise, what is wrong.

When we speak of a design being incorrectly drawn, we mean that certain lines which should be of the same length, are not of equal length, or that certain points which should be at equal distances from each other are not so. If there be any doubt as to the correctness of any design, it can be determined by describing a circle upon it from the centre of the design, and measuring the distances from its various points to the circumference of that circle.

It will consequently be found to be the best plan in all cases to commence by drawing a circle, within or around which the design should be drawn. A square piece of soft deal should be provided—2 or 3 feet square would be a convenient size,—over this the paper to be drawn upon should be fastened, either by pins to the edge of the board, or by pasting the edges of the paper upon the board. The advantage of the soft deal is, that if you do not possess a large pair of compasses you can fix in a pin for the centre of your circle, and having prepared a piece of fine string or strong thread with a loop at each end, you can put one loop over the pin, and put a pencil-point through the other loop, and thus draw a circle without compasses.

Let us begin with a triangle which is not only one of the designs most frequently required for church decoration, but at the same time one of those in which the least inaccuracy of drawing is readily observed. Let us suppose that you have drawn a circle of 12 inches diameter, that is to say, that it is 6 inches from the centre to any part of the circumference. Now, if you start from a point at the top of the circle and mark off distances of 6 inches all round the circle, you will find that you have made six marks. A reference to Figure 1 will show that by ruling a line between every mark you make a hexagon, while by

For instance, an equal-sided triangle looks better when fixed with one angle pointing upwards than with one angle pointing downwards, but in either case the side opposite to that angle must be perfectly horizontal. Again, a star composed of an odd number of rays, such as 5, 7, or 9, must always have one of its rays pointing upwards, and must be so fixed that when a plumb-line is dropped from that opposite point it shall pass exactly midway between the two lowermost points. But if the star have an even number of rays, say 6, 8, 10, or 12, it does not matter whether the highest part of it is a ray-point or an imaginary line connecting two of the ray-points; in the latter case, however, the imaginary line must be a horizontal one, or in other words, a plumb-line placed at a point equally distant from the two topmost ray-points must, when the star is correctly fixed, pass exactly half-way between the two lowermost ray-points. W. T.

VINE SOILS.

(Continued from p. 1231.)

I AM asked to bring forward my facts in order to prove where Grapes are grown to perfection in soils composed in a great part of calcareous matter. This is intended as a "clapper," no doubt, but "B." is no partisan of either one soil or the other. To the question, however, Calcareous soils are widely distributed over the country. I do not possess acquaintance with all. Calcareous matter is found in almost every soil. Soils, however, which may be termed strongly calcareous, are to be found in the counties of Kent, Sussex, and Hampshire, and in these counties can it be said that good Grapes are not cultivated? I would refer Mr. Cramp to the Vines and Vine-borders at Denbies, Dorking, under the management of the veteran Mr. Drewett. These borders were formed in 1853-4, and contain a very large quantity of calcareous matter, purposely provided for them by Mr. Drewett, who, unlike Mr. Cramp, believes in the efficiency of lime for the Vine. Since their formation to the present time, Mr. Drewett has never failed to have satisfactory crops; and I am informed that the "Denbies" Trebbianos to be seen at the present moment are worth going a long way to see. Mr. Drewett's success at the metropolitan shows for

duty to assist one another. Why has Vine budding been kept so long a secret? B.

Root Action.—Questions have been mooted in your columns respecting the priority of action of roots or stems, especially in Vines, as bearing on the application of bottom-heat; also as to the cause of their bleeding. The rationale of the process of their life and growth is this:—In the seed the radicle is the first to start, nourished by the cotyledons under the influence of heat and moisture; from it descends a chain of cells, the extreme one collects water from below, in which nutritious elements are dissolved. These ascend through the stem by virtue of the power named endosmose by Dutrochet, while the stem returns by exosmose a fluid elaborated by the leaves or other surface exposed to light. It has lately been proved by Professor Graham that without any influence of vitality all crystalloid liquids, as water, &c., will, in definite proportions, pass through any septum to take the place, by diffusion, of any colloid liquid, as gum, &c., which in less quantity will pass to the opposite side: this is the explanation of the transfusion in the animal system of the chyle, the blood, and the liquids conveyed by absorbents and glands. During cold weather or drought, the sap contained in the vessels of the roots, and of the stem, and leaves, is in a state of equilibrium, and therefore no action occurs in deciduous trees, but a slight movement continues in evergreens, as it does in hibernating animal life. It may be seen accordingly that snow melts first on evergreens. Warmth, however, causes the buds to swell which had been stored with starchy materials in autumn, arrested by cold in their progress of cell structure: thus a vacuum, or at least a line of less resistance becomes established, which calls into action the principle of endosmose. That growth proceeds first downwards is exhibited in the roots which descend in the Pandanus from considerable heights of the stem, and from the simple example of the Duckweed, which sends roots down from each of its leaves, thus creating a gradually increasing family of plants. It has been found by recent researches that the copious transpiration from plants, which is the effective cause of the active pumping by the spongiole of the root, takes place chiefly from the smooth or upper surface of the leaf; and the red and yellow rays of light chiefly operate on it. It has also been shown by Dehérain to the French Academy that this transpiration takes place equally in a saturated atmosphere, and therefore depends on light, and not on simple evaporation. It is also worthy of notice that the process of diffusion is not dependent, except secondarily, on capillary attraction, to which it is commonly attributed, because the sap passes upwards and downwards, not through tubes, but through a succession of closed cells, each of which is subject to the aforesaid law of endosmose. Doubtless bottom-heat would accelerate the movement, and may, if carefully restricted, be useful to the Vine, but should not be used to originate its action, and it demands abundant supplies of water. G. H. F.

Salisbury adiantifolia.—There was a fine healthy specimen of the Maiden-hair tree growing in the pleasure grounds of the Marquis of Bath's, at Longleat, about 14 years since. If still in existence, it must now be one of the largest in this country, as at that time I should say it was at least 40 feet high. Perhaps the present gardener will be so good as to give a few particulars of this plant. Specimens of the Tulip tree (Liriodendron tulipifera) were grand at the same place. If this noble tree will stand the atmosphere of London, it would be one of the handsomest and most suitable for the Thames Embankment, rivalling the Plane for rapidity of growth [?] and singularly out foliage; and, in addition, its autumnal tints are of the most varied and beautiful character, and of the most exquisite polish. J. Sheppard, Woolverstone Park.—Our foreman, a native of Surrey, informs me that 18 or 20 years ago there grew a splendid specimen of the Maiden-hair tree at Milford, in that county. The tree was between 60 and 70 feet high, growing side by side with a noble specimen of the deciduous Cypress (Taxodium distichum), that measured nearly 20 yards through. Will any of your numerous correspondents kindly inform me if the two plants mentioned above are still at Milford? Solihull.

Barbe de Capucin.—I procured a packet of this salad plant from Messrs. Barr & Sugden last spring, seeing that it is so highly prized by our neighbours across the Channel. I think it ought to be grown by all who have hitherto used chicory for salads. It is equally free in growth, hardiness, &c., whilst the leaves, in lieu of the Dandelion-like narrow ones of the chicory, resemble more nearly those of the Batavian Endive, really forming in some instances a heart of their own accord; which characteristic they carry with them and maintain in process of secondary growth and blanching. William Earley, Welwyn.

Heliotropea.—It may interest some of your readers to know, in corroboration of an extract from the "Florist and Pomologist," at p. 1212, that I have a plant of Heliotrope, planted more than 15 years ago against a wall in a cold conservatory, the stem of which at 3 inches from the ground is now 12 inches in circumference, and has from the main stem two branches, which are each fully 6 inches in circumference. The plant is kept down to about 8 feet by frequent pruning, and is covered periodically with an abundance of bloom. H. W.

The "Acharnesorricher" Melon.—[Phœbus, what a name!]—Seeing this Melon favourably mentioned in a catalogue sent out by a London firm as a "hardy ridge" variety, I obtained from them a packet, which contained eight seeds. These I sowed on April 3 in two 5-inch pots, four seeds in each, and placed them in a moderate hotbed, used for raising half-hardy annuals. Out of the whole, four seeds vegetated, and when the plants had acquired a

couple of leaves they were transferred singly into the same sized pots and replaced in the bed, where they remained till June 4, by which time the heat had entirely departed from it. I then planted out, without disturbing the ball of earth, one each on two separate ridges, prepared exactly as is done for ridge Cucumbers. Over one of these was placed a 4 feet square glazed frame, the other was left wholly exposed to the weather. A third plant was taken out of the pot and inserted in the original bed, the frame not being removed. The fourth plant was unfortunately destroyed by a slug, so that I had but three plants altogether. The whole grew in a very healthy vigorous state, but the two in the frames much more rapidly than the unprotected one. They all produced, I observed, numerous male flowers before the shoots had extended far, without any female ones appearing; but afterwards, when the male blooms had all withered, and the shoots become more lengthened, a number of females presented themselves instead, which turned yellow and dropped off without swelling. This circumstance I attribute to the want of impregnation, which was not attended to by me owing to my previous ignorance of the habits of the plant, and, no doubt, was the reason of my obtaining the small return of fruit that I did eventually. The following is a statement of the results. The ridge plant within the frame produced three fruit, which weighed 2 lb. 13 oz., 2 lb. 11 oz., and 1 lb. 11 oz., and all ripened perfectly during September. That in the other frame had but one fruit, which came to full maturity the first week of October, the weight of it being 3 lb. 5 oz. The open ridge plant set five fruit, three of which had attained the size of an Orange, and two rather less, when a slight frost that occurred on the 1st or 2d of August, though it did not injure my Dablias or other flowers, nor even my Tomatos, so curled and blackened the leaves of the Melon, that it never rallied, and consequently the produce did not ripen. From my experience, then, of this Melon, as above adduced, I should say that owing to the vicissitude of the weather about the time of its ripening, it cannot be grown in this country as an open-air variety with any degree of certainty, but that it will answer well in the generality of seasons, without artificial heat being applied, if simply protected by a frame, and may be made very prolific by care being taken with regard to impregnation, as I have before mentioned, the fruit weighing from 2½ lb. to 3½ lb. each, or perhaps more. As to the qualities of the fruit, it is not only very handsome in appearance, but its flavour surpasses that of many of the more tender-constituted kinds, that are grown at so much greater an expense and trouble in a hotbed or pit expressly prepared for them. The form is completely circular, evenly quartered, and flattened at both top and bottom; the skin roughish, mottled with a dark and paler green, which turns yellow when ripe, and slightly netted. The flesh is pretty thick, deep orange-coloured in the centre, passing to yellow-green next the skin, melting, juicy, and agreeable to the palate; but it does not possess so powerful an aroma as some of the more tender-growing kinds. I think, therefore, considering its cheap and easy management, as well as other qualifications, this Melon is decidedly an acquisition, worthy of more extensive cultivation; and it appears to me surprising that, although introduced some years ago, its existence should be so little known throughout the country. I had visits from two first-class provincial nurserymen, and also an extensive grower of Melons for the market, as well as private gardeners, who all told me they had never before seen, or even heard of, such a variety; nor am I aware of its ever having been noticed in any of the horticultural publications. As it is my intention, if I be still in the land of the living, to give it another trial next year, I shall feel greatly obliged by some one of your correspondents who has grown it, affording me, through the medium of your paper, a statement of his experience, as well as opinion of its merits, which will also, I have no doubt, prove interesting and serviceable to many others of your readers besides myself. Amateur, Whitland, Carmarthen Nov. 26.

Colouring of Pelargonium Leaves.—"A Canny Scot" has given us such a display of his "learning" on this subject, that we poor "bogles awa' doon sooth" ought to be quite dumbfounded—but we are not; we are "na sae daft" as to be deceived by his "whigmaleery," and still think that the expression of "the hectic flush of coming death," as applied to tricolor Pelargoniums, is sheer nonsense. What on earth has the fall of the leaf in autumn to do with the question? or does he class Pelargoniums with deciduous trees, and expect them to shed their foliage in the autumn also? What if I were to go into his stove at midsummer, and in the presence of his Caladiums, then rich with glorious colour but still in robust health, tell him such nonsense? or take him to his plantations, and point to some magnificent Purple Beech, and there repeat it? If he did not "c." me a fule," he certainly would think it. Then why should not tricolor Pelargoniums be subject to the same conditions. His remarks about Pelargonium L'Élegante are not to the point. Mr. Fish has shown how pink coloration would be obtained in the leaves of this variety by twisting the leaf-stalk. I simply stated that like results were obtained by excessive drought, but I did not set up the absurd theory that coloration in this variety was the result of rude health; it is not a tricolor at all, but a simple bicolor, and has no third colour under any conditions but those mentioned. When pink appears it is as a discoloration of the white edge only, and not as a zone. But the remarks of Mr. Fish and myself, in the latter portion of our notices respectively, did apply to the tricolor Pelargoniums, a class of plants that I maintain are most healthy, and growing under the most favourable conditions, when exhibiting their richest colours. "A Canny Scot" seems to

think that foliage only is healthy when it is the densest green, and that all departures from the colour of Dame Nature's dress must necessarily be unhealthy; but he forgets that the "old lady" of ladies of the present day, like bright young things, whether in the form of beautiful flowers or foliage. I "ken naething about the whyny" of usually cool my tongue with the drink of Adam; but I can tell him that the "old lady" whether of plants or "ladies," are the true bright leaves or rosy cheeks. To talk about their feet in hot water, and their hands in cold, is rubbish. When next our "Old Lady" gets pale in the face, and "c." in his pair him, instead of putting them into "hot water" them "nimble" by running a mile or two, and then realise what he as yet "canna name" nimble warm feet are the accompaniments of cheeks. Alex. Dean.

Judging Melons.—Are we to understand George Thomson that Melons are to be judged by sight and smell, and not by taste? He has offered a very weak argument. In the first place, I would ask, what is a Melon worth without flavour? Let scent and appearance be what they may, I say that no judge should give a prize to a Melon without first tasting it. I think it ought to be allowed at all exhibitions to have wax fruit, and give up growing Melons for all parties. A rule should be laid down for growers and judges. I always make it a rule to award a prize. I may mention that I have seen green-fleshed Melons exhibited as red-fleshed, and vice versa. I was judge at Paisley years since, when Mr. Wilkins showed a Gem a very fine green-fleshed variety, of quality, and to all appearances just like the one Mr. Wilkins informed me that he had seen from Scarlet Gem. The first point of merit was the thickness of flesh, and a more beautiful shaped fruit. Those large, coarse Melons too often take 1st prizes should not be so. William Smythe, The Gardens, Elphinstone.

Scot" asks, "if two senses can but be placed about the taste?" And then he thinks one of the judges, who has written of the tasteless mode of judgment." "A Canny Scot" is in error if he thinks my object in defending the non-tasting principle; it was to defend myself and co-judges from the reproach we had introduced a new system by which we were to be judged. In doing so I hinted that much might be said in favour of the non-tasting of judging. When one has tasted a good one, a bad one, it is a difficult matter to tell what one is like. Fancy tasting, before breakfast, Melons as were shown at Edinburgh, and some as green and hard as Swedes. "A Canny Scot" had seen such Melons but seen get prizes from the tasting test, he would not think them handsome enough for nose or credit to the growers, and would have been at home "A Canny Scot" is not very expert in comparing the Melon to the Gourds or Cucumbers, although he might grow either to please his scent them to please his nose, he would not be satisfied to have his sense of taste might, if he cut a Melon that had been tasted and smell only. George Thomson, Stranraer.

Pears at the Liverpool Show.—The display visited upon Mr. Manley's collection of Pears, at the recent exhibition of the Liverpool Horticultural Society, has been upheld by Mr. Barron of Chiswick. At my desire a fruit of Duchesse d'Angoulême, one of the Pears set up as Duchesse d'Angoulême submitted to him, and he pronounced both to be the latter. I shall be glad if you will publish this matter; and as it was well known the fruit submitted to Mr. Barron, many will be satisfied with his decision thereon. Mr. Manderson's tree bearing the fruit set up as Duchesse d'Angoulême came from Mr. Rivers under that name, and as the fruit had that somewhat tapering, yellow appearance, similar to the Duchesse d'Angoulême, I was led to suppose to be the latter. The circumstance shows a variety in character when grown under different conditions, and in different aspects. I may mention that the judges were Mr. Tillyard, of Brockton, and Mr. Stevens, of Trentham. Your Reporter.

Foreign Correspondence

ANTIBES.—Among private gardens in France there is none, I believe, to compare with that of M. Gustave Thuret, and whether on account of its extent, richness, or the perfect manner in which it is kept, 12 years have elapsed since M. Thuret's planting operations on this spot, which was covered with Olive trees, Vines and other trees, like the adjacent country is at the present time. Before attempting any description of the villa which indeed can be but very imperfectly done, that Antibes is an ancient walled seaport, 12 miles from Cannes, and that it is on the promontory, which, stretching into the sea, separates the Golfe de Juan from the northern extremity of which lies Nice. The villa of M. Thuret, which is situated on the

A... lawn is impossible in this dry country, but the... has a spacious grassy slope, bounded by a fine... of wood, to the beauty of which some lofty... largely contribute. The lawn is adorned about its circumference with some very noble groups, of which a mass of *Gynerium argenteum* is the finest I have seen. Another striking plant in this situation is *Yucca...*... together... I was... not... to the lawn, let me say that some part of it which is more or less dotted over with Pines, has been planted with *Arenarum*, which are very beautiful in the winter and spring. The rough lawns in this country allow this fashion of ornamentation, and I have seen even *Ixias* flowering among the grass with very good effect.

Gravel, which forms such good paths in our English gardens is not procurable here, nor in so dry a climate would it be of any value. In its place a loose white boulders is employed, while for edging a variety of small plants is used—two species of *Statice*, *Gazania splendens*, *Santolina viridis*, and *Mesembryanthemum* do duty for the neat and useful Box.

The... roadway leading to the house is bordered with Orange trees and Date Palms, the latter still in a leafless condition. There are several other Palms about the grounds, as *Jubaea spectabilis*, *Coryphæa australis*, *Sabal Palmetto*, and *Chamærops excelsa*, a good part of *Cycas revoluta*, which is perfectly hardy in this climate. *Acave americana* is cultivated as in all the warmer parts of Mediterranean France, but I have seen no specimens of such magnificent dimensions here. Several other species of *Agave*, grown in the open ground, are also exceedingly fine, as *A. litchii*, *A. mexicana*, *A. Seelyi* and *A. coccinea*.

It is impossible for me to enumerate the mass of miscellaneous plants which line the walks, or even with a few sheets of a letter to notice the more interesting. I shall therefore pass on to the more botanical part of the grounds, which with a spacious garden and vineyard, occupies a plot somewhat removed from the rest. Here, planted on some blackwood under a south wall, is a collection of *Cactaceæ*, as *Locustia*, *Euphorbia* and *Stapelia*; also a large number of plants in pots. Near by are long ranges of frames used for propagating, and also for the preservation of some of the rarer or more tender plants in winter. These frames, with a small unheated greenhouse used as a nursery, are the only glass shelters about the grounds.

Among the more noteworthy plants on this portion of the property I observed with pleasure *Diospyros kaki*, producing a fruit which for shape or size reminded me of a green walnut. When mature, it is said to have a well-flavoured pulp resembling plum jam. *Psidium Cattleianum*, growing to the size of a small Currant bush and bearing its ripe fruits, was also in this part of the garden. Here too are some beds of *Cistus*, a genus which has afforded material for long and laborious studies on hybridization to M. Thuret's friend, Dr. E. Bornet. Both gentlemen are devoted to botanical pursuits, of which the striking evidence is the patient care bestowed on correctly naming the plants in the garden. All, moreover, are beautifully ticketed with labels of the most permanent kind, and a copious catalogue is kept of the plants in cultivation. Daniel Hanbury, Palazzo Orango, near Mentone, Nov. 17, 1869.

for bloom very prominently. Both thrive well in a cool place,—any locality, in fact, will suit them, provided the frost is kept out, and all the light and sunshine possible afforded them. Some of the main stock, or second early *Cinerarias*, may be induced to form more compact and spreading heads of bloom if the points are pinched back just as they show symptoms of starting for flower. The forwardest ones, being now well pot-bound, will be much benefited by frequent applications of wholesome manure-water. Let the temperature in all stoves be still further reduced; from 56° to 59° will now be ample by night, with an increase by day in proportion to the brightness of the weather. Attend well to the cleaning of the foliage of trees of *Oranges, Citrons, &c.*, during this their season of rest. Give them but a moderate supply of root-waterings at this time. The conservatory should now be kept gay with relays of blooming plants obtained from any other houses which the grower may be in possession of. A slight amount of heat may be kept constantly in those conservatories which are kept as show-houses, and which are not used as growing houses. Under these circumstances most plants when in bloom may be safely placed therein, even *Orchidaceous plants*, especially such as the showy *Phajus, Brassias, Oncidiums, Zygopetalums*, and such *Dendrobiums* as *D. chrysanthum, D. nobile, D. Pierardi, &c.* Root-waterings should, however, be withheld, as I have before intimated, as in all instances where a minimum temperature is maintained sufficient moisture exists in the air for all their presents wants. Make as much advance as possible from this time with all subjects intended for indoor and other decorations at Christmas. *Poinsettias, Euphorbias*, especially *E. jacquiniflora* and *White Camellias* are all more or less useful, and likely to be made good use of, if at hand at that time. Even plants of the Christmas Rose, *Helleborus niger*, taken up at once and forced, may come in very acceptable. Flowering *Chrysanthemums* which have become in the least degree shabby should be removed immediately. Healthy foliage plants, even if but sparingly intermixed with other blooming plants, will be far more pleasing to the eye than the above. In our efforts to make a rather large display, we are most of us rather prone to crowd unduly such valuable subjects as *Azaleas, Ericas, Epacris, &c.* Immediately an opportunity offers, by the removal of the *Chrysanthemums*, let not a moment be lost in thinning out the stock, so that as much light and air as possible at this dull season may fall to the lot of each specimen alike.

FORCING HOUSES.

Be very cautious not to allow the temperature to fluctuate materially in those *Vineries* in which the buds, having swelled to the full, are about bursting into leaf. Let those rods which have been bent down to assure a more uniform growth throughout, be now placed and tied securely into their permanent quarters. Do this before the buds push forth more prominently, as in that case there will be greater risk of breaking them in the performance. The vinery at such a stage cannot well be kept too moist, all other circumstances being favourable to a good growth. If the borders are within doors, the requirements of the roots, in regard to the necessary waterings, must have constant attention. Always use tepid water, and even though the season be as infelicitous as it well can be, the fact must not be overlooked, that, with an active surface growth, the roots must have such an amount of supply as they would require under like circumstances at a more natural growing season. The frequency with which water at the root is needed must depend wholly upon the site, and depth, and drainage of the border, the age of the Vines, and so many other circumstances that it is not possible to offer advice on this point. When water is really requisite, let it be afforded liberally. Too frequently at this season we err on the side of affording a too meagre supply. Moreover, occasional surface-sloppings, consisting of three or four 4-gallon watering-pots-full, are far more likely to cause a stagnation than are any over copious waterings at regular intervals. By too frequent surface-waterings we benight the surface soil, that it becomes perfectly impervious to air—a state of things which is most injurious to healthy root formation or active vegetation. Where the borders are outside keep the warmth of the fermenting materials as near to a mean of 85° as is possible. This will afford to the surface of the border a moderate warmth of from 65° to 70°. *Peach* and *Nectarine* trees, which are advancing to the blooming stage, having been started as previously suggested, must be kept constantly syringed from two to four times a day, according to the state of the weather. Keep up an average temperature of about 58°, by means of artificial heat, of giving air at all times when the outer atmosphere is capable of influencing this by a rise of 3° or 4°. Do not stop a drop of water about more than is absolutely needful for a week or so previously to the first flowers opening, and use every endeavour to make the internal surfaces as dry as possible preparatory for that event. Make a successional sowing of *Dwarf Kidney Beans* if necessary.

HARDY FLOWER GARDEN.

Amateurs with limited means at their disposal take a larger amount of interest in this department of our Calendar than do most others. I will therefore commence at this, the planting season, to direct attention to a few such hardy plants as are likely to be useful herein. I will begin with *Hardy Climbing Plants*, which are so desirable in all confined or enclosed spaces, apparently extending, as they do, the area by the beauty of their display, and concealing most unsightly objects. As staple plants for backgrounds, and to climb high if needed, the *Virginian Creeper (Ampelopsis hederacea)*, the *Trumpet-flower (Bignonia radicans)*, the *Chinese Wistaria (Glycine sinensis)*, the sweet white *Jasmine (Jasminum officinale)*, *Magnolia*

conspicua, and sundry climbing *Roses*, such as varieties of the *Boursault, multiflora, Ayshire*, and *semper-virens* groups, and, though less hardy, the *Banksian*, with certain hybrid climbing varieties, are amongst the best of deciduous plants. Amongst evergreen climbing plants, of which there is rather a dearth at the present time, though we hope to see the number extended, we have the following:—*Ivies* with variegated foliage, such as *Hedera Helix latifolia variegata, H. argentea variegata, H. rhombea variegata, H. elegantissima*, and *H. maculata*. As a very strong grower, with large heart-shaped leaves, bright, shining, and constant, the *H. colchica (Rægneriana)* is not to be surpassed, attaching itself freely and firmly to the driest walls, &c.

KITCHEN GARDEN.

In continuation of some previous remarks regarding a system of successional cropping, I pass on to what is a very general crop with all. I refer to the plantations of *Spring Cabbages*. If these have been planted upon the current year's Onion-bed, as I have frequently urged, seeing that they do so much better thereon, the beds will have become somewhat impoverished. The only way to thoroughly renovate them will therefore be to either bastard-trench, or thoroughly trench them over, placing at the bottom a good layer of manure, and another at from 4 to 5 inches below the surface. So treated, this will then be the best possible site for the summer crop of *Peas*, as here they may find appropriate nutriment during the greatest drought. One thing I would observe, however, even if it be necessary to take some of the old stumps up at the present time and lay them by in some corner, let the ground be operated upon as soon as possible if at all light in its nature. It will then have ample time to settle down firmly. This is a matter of no little importance. Another hint should not be overlooked in connection with light hungry soils, which is, that the cruder or less decayed the manure, if given in the same quantities as spit-manure would be, so much the better. The soil will have ample time to turn it to account ere required by the roots. The soil is so hungry in some places, as also here, that if a man leaves his coat by chance on the ground all night, the buttons thereon are well-nigh consumed by morning! Do not be concerned as yet in regard to the necessary space for next summer's *Onion-bed*. Those who are in possession of light dry soil may now make a sowing of *Peas*, for the early crops. I have purposely waited till this time, as for the last two or three years November-sown *Peas* have become too winter-proud. Sown now, they will be soon enough, if at all favourable weather ensue. Those who have a cold retentive soil should sow in boxes or frames in the spring, and transplant in the usual manner. *W. E.*

TOWN GARDENING.

If to convert sooty spots into agreeable gardens be the object in view, the soil should now be attended to at once. It is quite certain that in many instances the ground is actually poisoned with soot, and choked with the accumulated rubbish of years. Therefore as much of the old soil as is unfit for supporting vegetation should be at once removed, and its place supplied with fresh loam from the country, with a mixture of rotten dung. There should not be less than 2 feet deep for the beds and borders, and 6 inches for the grass plots. This will greatly improve the vegetation, and also have a tendency to purify the atmosphere. The arrangement and laying-out of the garden embrace a variety of considerations, such as situation, exposure, &c. The beds and borders should be exposed to the sun as far as possible, but the form must be left to the taste of the owner, which should now be put in action—so that the groundwork can be done in time for planting and turfing in February. Walks should be bottomed with brick rubbish, ready to receive the gravel after all other work is done. *British Ferns* do well in town in the most confined situations in fresh soil, and the present is a good time to throw up a bank of earth to build the rockery on. This should be built of an irregular outline: the material best suited for this purpose being "clinkers," from glass works, and burnt bricks. These should be so placed that vacancies are left between the rockwork, to be filled with such soil as is likely to suit each individual species. *J. D.*

STATE OF THE WEATHER AT CHISWICK, NEAR LONDON, For the Week ending Dec. 11, 1869, as observed at the Horticultural Gardens.

Nov and Dec	Moon's Age	BAROMETER.		TEMPERATURE.					Wind	Rain

The highest temperature during the above period occurred on the 11th, 1844—therm. 63 deg., and the lowest on the 8th and 9th, 1867—therm. 13 deg.

Notices to Correspondents.

** We regret to have to repeat the announcement in our columns several months since that Mr. Mellish now in no way connected with the *Gardener's Chronicle* is the Publisher; editorial communications should be sent to the office, 41, Wellington Street, Covent Garden.

APPLE TREES DESTROYED WITH INSECTS: *W. G.* The bark sent are covered with the Apple-bark louse, *Conchiformis*. We hope shortly to publish an article on this subject, wherein several remedies are suggested.

BEST: *T. C.* A fine sample of the purple-stemmed *Beta Cyclis*, which is commonly grown in gardens under the name of *Beta brasiliensis*.

BOOKS: *Rumford Street, Manchester* (signature illegible). 1, Hoopes' "Book of Evergreens," a book, to be had of any foreign bookseller; 2, an advertisement column. Apply to Lovell, 1, 2, to Mr. Casbourn, *Herald Office, Newbury*; 3, M. Chatin's little book on Watercresses, with Cresson," published in 1866 by Baulière Paris.

CUCUMBER: *G. Edeard* Your Cucumber, raised from Eclipse cross with Craig's Prolific, and which is one of the strongest constitution and most prolific known, belongs to the spined class. The sample sent are good-looking, evenly swelled, of moderate and of good average quality as to flesh, flavor, &c. These latter points, however, we do not equal to Telegraph and other varieties of that name.

DECAYED SOUTH AMERICAN BEEF: *Manurba*, W. practical experience in its use for Vine-budding, should be loth to try it.

EVERBEARING STRAWBERRIES: *L. W. Magnificus* and *Sir Charles Napier* and *British Queen* Strawberry shown at South Kensington not quite six weeks ago had been grown in the open air. There are strawberries like yours which possess the property of being, &c. The alpine varieties are, however, those which can lay any claim to the character of everbearing and that in a very modified sense, to which we strongly suspect this new American will be found to be equal. We think so from the description given of it by respondent, "Vectis." The habit of growth, but the fruit, are all in character. We have long had yours, the examples of which you send, of a different character, a form of our ordinary *Everbearing*, possessing, as you state, the character of *everbearing*.

FLORAL CRITICISM: *Thorn*. Our correspondent, Sec. of the Secretary of the Royal Horticultural Society, Florist and Pomologist: *F. W.* Published 11, Fleet Street, E.C.

GARDENERS' EXAMINATIONS: *An Enquirer*, *London*, &c., to James Richards, Esq., Royal Horticultural Society, South Kensington, W., and to P. Le Neve, Secretary, Society of Arts, Adelphi, London, E.C.

GARDEN MEMORANDA: *A. D.* At present we are done with such articles. We trust shortly to be arrangements, which will give us more space for other matters. We must, however, request respondents to confine themselves strictly to what are peculiar to the places visited, and not to generalities. If brevity be the soul of wit, it is to possess the soul if not the body of that faculty, both are happily combined in one need fear not. The proverb, *Res est laboro, obscurus fit*, has in this case.

GRAFTED VINES: *R. W. S.* You have not only grafted well by grafting your Black Hamburg Vine varieties, which late results will no doubt your own experience has already proved that late on Black Hamburgs succeed fully better than varieties are grown on their own roots. You are a wise man: your second was otherwise. Since on Black Hamburg by all means. *Black* is a good early white grape, having far sized berries of a very pleasant sweetwater flavor, what difficult to set well, yet, when well grown, handsome and hangs well on the Vine. It is synonymous with Scotch White Cluster.

GRAFTING WAX: *H. B.* Mix tallow, beeswax, in equal parts, or you may put a little more tallow, more pliable.

HEATING APPARATUS: *J. P.* If the pipes get so cold cannot bear your hand upon them, then your piping. If this is not the case, your boiler probably requires cleaning. We would advise a man who arranged it look it over.

INSECTS: *P. P.* Your larva are those of some species possibly of the destructive *Othiorhynchus* which arrives at the perfect state in the spring. As more communicative as to their habits, we might more decidedly in our reply.

LABRUS REBANS: *A. C.* *Labrus rebans* in Britain, awarded us, through Messrs. Lawson, some fine shrub in berry, under the impression that it was bear see in England. We never saw the fruit to be rather larger than the berry of the common *Labrus*.

NAMES OF FRUITS: *T. B. A.* *Baldwin*, *Baldwin*, *Hacott's* *Imperial*; *B. de* *Beurre de Capucins*; *B. de* *4, Thompson*; *4, Vicar of Wankfield*; *4, rotten*; *5, Passo d'Ascar*; *6, Comte de Lancy*.

NAMES OF PLANTS: *R. J.* No. 1 is *Glycystris* No. 2, *Taxodium distichum*. It is a *Glycystris* whether they are the same or not. The foliage is alike, and the *Glycystris* never perfects the one is from China, and the other from the *sub-julian* by *A. M.* Probably you are making out any real difference between the *sub-julian* and *imperialis*—*B. de* *Lilonia* *horibunda*, *Lil. Lycastris* *cruenta*, although the latter has a clouded spot.

SALISBURY ADIANTUM: *Y. B.* *Adiantum* *fordi* is still in existence, but is not, we believe, you imagine.

SHRUBS OF THE BANKS OF A GULLY: *Thorn* to *Rhododendrons*, you may plant any of the group of *Cotoneasters*, *Portugal Laurel*, *Winnif*, the double flowered *Gorse*, and the *Yew* planted along the top would be very effective wood, the *Ivy* and *St. John's Wort*, *Hypocissis* are good subjects.

SPRUCE FIR DRAIN: *H. D. F.* The information to enable any one to form an opinion upon the correspondent will tell us something about the state of drainage, and the condition of the strata, we shall then say what we think would be mere conjecture to name a course.

TRANSPARATION OF PLANTS: *H. T.* forgets that on botany or horticulture contains the information. The fact is abundantly well established.

VARIATED LAUREL: *N. A. B.* A pretty species, others as good in cultivation.

COMMUNICATIONS RECEIVED: *H. W. C.* (signature illegible); *G. G.*—*J. McM.*—*Rustic*—*H. L. B.*—*J. M.*—*R. C. S.*—*G. E. J. P.*—*G. R. A.*—*J. M.*—*H. C. S.* (next week)—*J. B.*—*T. P.*—*L. C. N.*—*A. D.*

JAMES CARTER AND CO beg to call attention to their stock, as under, full particulars of which are given in their DESCRIPTIVE CATALOGUE. Copies forwarded post free on application.

- SPRING FLOWERING BULBS and PLANTS, for Shrubbery and Flower Beds.
JAMES CARTER AND CO'S COLLECTION of PLANTS.
No. 1, containing 132 Hardy Plants, price 15s.
No. 2, containing 204 Spring flowering Bedding Plants, price 42s.
No. 3, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 4, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 5, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 6, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 7, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 8, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 9, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 10, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 11, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 12, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 13, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 14, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 15, containing 50 in. flowered Greenhouse Plants, price 3s.
No. 16, containing 50 in. flowered Greenhouse Plants, price 3s.

NEW TRICOLOR GERANIUMS, to be distributed in the Spring of 1870.
New Zebra Tree or Geraniums
New Ivy-leaved Geraniums
New Variegated Geraniums of 1868
New Double Geraniums
Cividen Bedding Plants
New Hardy Clematis
New and Rare Plants
New Coleus

ORNAMENTAL FOLIAGE PLANTS.
Store, Greenhouse, Conservatory, and Outdoor Plants, for Autumn growing.

M'LAREN'S PROLIFIC RASPBERRY.
Collections of TREES and SHRUBS (see Catalogue), consisting of Standard Ornamental Trees of large size
Plants for Hedges
Evergreen Shrubs
Rhododendrons
Fragrant Trees and Shrubs
Herbaceous Perennials
Transplanted Forest Trees
American Plants
Conifers
Hardy Climbers and Shrubs
Herbaceous Plants

FRUIT TREES.
Apples
Peaches
Apricots
Pears
Cherries
Quinces
Currants
Raspberries, in 10 other in continuous Fruit Trees.

NEW CONTINENTAL STRAWBERRIES.
STRAWBERRIES, older varieties.
VINES.

COLLECTIONS OF ROSES.
Dwarf Hybrid Perpetuals, in pots, for Foreign
JAMES CARTER AND CO., 37 and 238, High Holborn, London, W.C., and Crystal Palace Nurseries, Forest Hill, S.E.

Autumn Planting.
PETER LAWSON AND SON will be glad to send their CATALOGUE (last published) of FOREST and ORNAMENTAL TREES and SHRUBS, free upon application.
The stock of LARCHES, SCOTCH FIRS, AUSTRIAN and CORSIKIAN PINES, &c., comprises some millions of healthy, well-grown plants, and special offers will be made for large quantities when personal inspection is not convenient.
Edinburgh and London.

Planting Season.
DICKSONS AND CO., NURSERYMEN and SEEDSMEN.
1, Waterloo Place, Edinburgh, beg to call the attention of those about to plant to their very large and healthy stock of FOREST TREES, FRUIT TREES, ORNAMENTAL TREES and SHRUBS, which are low in price and of the finest quality. They are all well and very exposed ground, are fully rooted, and their wood is thoroughly ripened. Samples and Catalogues on application. Special prices will be quoted where large quantities are taken.

RICHARD SMITH'S LIST of EVERGREEN and RAPID-GROWING SHRUBS, RHODODENDRONS, STANDARD ORNAMENTAL TREES, CLIMBING and TWINING PLANTS, with their generic, specific, and English names, native country, height, time of flowering, colour, &c., and general remarks, free by post.
RICHARD SMITH, Nurseryman and Seedsmen, Worcester

CADLY AND SON, NURSERYMEN and SEEDSMEN.
Colebrook, Ireland, have to offer a large stock of COMMON LAUREL, PORTUGAL ditto, LAURUSTINUS, IRISH YEW, Common ditto, at 1 Nursery Staff generally, which will be sold Cheap. They will be delivered on board the London Steamboat at Belfast free. Prices on application. Orders sent to Messrs. HURST and SON, London, will have prompt attention.

Cedrus Deodara.
FINE SPECIMENS, 7, 8, 9, 10, to 15 feet, at 1s per foot.
W.M. MAULE and SONS have to offer a large supply of extra fine EVERGREEN TREES and SHRUBS, calculated to give immediate effect to Parks, Cemeteries, and Plantations, and suitable for screening and blocking out new Buildings, that are springing up daily in the vicinity of all large towns.
The Nurseries, Bristol

To the Trade.
SPECIAL OFFER of LAURESTINUS PYRAMIDALIS (NEW)
W.M. KNIGHT solicits orders for the above new variety of LAURESTINUS, having now grown it for five years past for Stock. It has been seen growing in his Nursery by many eminent Nurserymen, by whom it has been pronounced a fine hardy, compact plant, of sterling merit, the habit being robust, compact, flowers pure white, nearly twice the size of the old varieties, and very sweet-scented, with a continuation of flowers during the most severe weather.

W.M. KNIGHT's great confidence in offering it in fine specimens, 4 to 6 feet, full of bud, per pair, 10s; second size, 3 to 4 feet, do, 10s.; third size, 2 to 3 feet, do, 7s.; fourth size, 1 1/2 to 2 feet, do, 5s.
Floral Nursery, Hailsham, Sussex.

THORNTON begs to intimate to the Trade that the Stock offered below cannot be surpassed for health and vigorous roots. All been grown in maiden soil, and the stock, very extensive, is offered at low prices.
Pines, Austrian, 9 to 15 inches
Spruce Fir, 1 to 2, and 2 to 2 1/2 feet
Pines, Italian, 15 inches
Larcel, 1 to 1 1/2 feet
Pines, French, 2 to 3 feet
Turkey Oak, 1 to 2 feet
Pines, Austrian, 1 to 1 1/2 feet
Cryptomeria japonica, 12 to 15 inches
Pines, Italian, 2 to 3, and 3 to 4 feet
Chinese Arbor-vitae, 9 to 15 inches
Pines, Austrian, 9 to 15 inches
Thomas Thornton, Heathcote, Bagshot, Surrey.

Limes, Purple Bech, &c.
LIMES, best Red-twigged Variety, 6 to 10 feet, 15s to 30s per dozen.
PURPLE and COPPER BEECH, very fine, transplanted in spring of 1869, 6 to 10 feet, 15s to 25s per dozen.
WEEPING BEECH, very fine, 2 1/2 to 3 1/2 feet per dozen.
FLAWS, Chestnut and Hertfordshire, 8 to 14 feet, 12s to 30s per doz.
Price Lists on application to
JAMES CARTER AND CO., The Royal Norfolk Nurseries, Norwich

PARSONS' NEW HYBRID TREE MIGNONETTE.—
This new Tree Mignonette has no equal, it is robust in growth, of very compact habit, and deliciously sweet.
G.P. has been improving it by careful selection for the last ten years, as the result certain it will become a universal favourite, he has grown plants of it 3 feet in height, and 5 feet in circumference, in three months from the time of sowing; moderate sized plants take about 9 or 10 months from the time of sowing. In sealed packets, 1s.
To be had from G. PARSONS, Nurseryman and Seedsmen by appointment to her Majesty, 47 and 23, Western Road Brighton, and Hisscock's Gate, Keynour, Hursley, Hampshire. May also be had at HURST and SONS, 6, Leadenhall Street, London, E.C.

RAYNBIRD, CALDECOTT, RAWTREE, DOWLING, AND COMPANY (Limited),
COCK SEED, MATHS, and OYSTERS MERCHANTS.
Address: 20, Seed Market, Mark Lane, E.C., or Basingstoke
Samples and prices post free on application. Prize Medals, 1851, for Wheat, 1862, for "Excellent Seed Corn and Seeds"

To the Wholesale Trade.
HERBERT H. NICHOLSON, SEEDGROWER, Great Clacton (near St. Osyth), Essex, has the following SEEDS to offer, for cash only:—
ROBINSON'S PRIZE CHAMPION OX CABBAGE, 20s per cwt.
NON-PAREIL CABBAGE 11s.
WHITE CELERY (Levathan) 10s.
SELECTED DARK RED BERT 10s.
STUDENT PARSNIP 8s.
MYATT'S CURLED PARSLEY 7s per bush
STOBBLE TURNIP 18s.
&c. Also all the Annual FLOWER SEEDS, at low prices.

Johnstone's St. Martin's Rhubarb.
W.P. LAIRD AND SINCLAIR, NURSERYMEN, Dundee, N.B., have pleasure in offering the above NEW VARIETY of RHUBARB, which they have confidence in recommending as the earliest and best sort in cultivation. The raiser of it describes it "as one of a batch of seedlings from 'Victoria,' the seedling plant was a fortnight earlier than any of the remainder of the lot, and grown beside 'Prince Albert' and 'Linnaeus,' always ten days earlier than them, and giving a larger quantity of superior stems to either of these varieties. It forces better than any variety I know, and has a splendid colour."
Strong Roots, 2s. 6d. each. Usual Discount to the Trade.

The following Testimonials, selected from amongst many others, speak to its merits by disinterested parties:—

From CHAS. GUTHRIE, Esq., of Tullymore, Dundee, a celebrated Horticulturist.—Taybank House, October 18, 1869.
"Gentlemen.—I have much pleasure in saying that Johnstone's St. Martin's Rhubarb is the best I have in my possession. It is a thick fleshy-stalked variety, bears a heavy crop twice a year, and if cut early, would, I have no doubt, give a third, as even ten days ago it was throwing up fresh leaves. Its peculiarity it possesses of not throwing up flower-stems, only one having appeared in one of my plants in the course of two years. It makes an admirable preserve.—I am, &c. "CHAS. GUTHRIE"

From Wm. GORRIE, Esq., Horticultural Editor of "The Farmer" Edinburgh, October 20, 1869.

"Gentlemen.—I have fully tested the merits of your Johnstone's St. Martin's Rhubarb, both by cultivation and cooking, and compared with the well-known Victoria variety, I find it to be considerably earlier in spring, to yield fully a heavier crop, and to stand out later in autumn, while in quality it is much milder and decidedly more agreeable flavoured, requiring considerably less sugar, which is no inconsiderable advantage in the estimation of cottage gardeners, and others with limited incomes. "WILLIAM GORRIE"

From Mr. LAUR, Restaurateur, Dundee.—October 19, 1869.
"Gentlemen.—I have pleasure in testifying to the fine quality of your St. Martin's Rhubarb. In the course of my business I use Rhubarb to a very large extent—many times during the season I have seen the first supplied to me from the open air, and I always give a preference to it over others in the market. "THOMAS LAMB"

London Agents—Messrs. Hooper & Co., Covent Garden Market, W.C. May be had true from the following Firms, who have it direct from us:—

- Sheffield Messrs. Fisher, Holmes & Co.
Leeds Mr. Edward Holmes.
Exeter Messrs. Scator & Co.
Andover Mr. Wm. Miller.
Glasgow Messrs. Austin & McAlan.
Dublin Joseph Berry & Sons.
Further names published as received.

GENERAL TRADE NURSERY LIST may be had on application.

To the Trade.
JOHN PERKINS, Sen., begs to offer the following FRUIT TREES, all of the finest quality:—
STANDARD PEARS, 3 to 7 feet stems, with good heads, at 50s per 100, consisting of the following and other early varieties:
Louis Bonne of Jersey
Comte de Flandro
Williams' Bon Chretien
Lemon | Marie Louise
Jargonelle | Swan's Egg, &c. &c.
Bourre de Amanlis
STANDARD MAYDUKE CHERRIES, 5 to 6 ft. stem, 76s. per 100. Dwarf-trained do, do., ex fine, 6 to 10 shoots, 18s per doz; 130s p. 100. Do. do MORELLO do, do. 6 to 10 do, 18s per doz; 130s per 100. All letters to be addressed JOHN PERKINS, Sen., 22, Market Square, Northampton.

Special Offer of Specimen Conifers, Evergreens, &c.
W.M. KNIGHT solicits Orders for the following TREES and PLANTS, which have been recently transplanted, are in perfect health, and cannot be surpassed in the Trade:—

- Arancaria imbricata, 3 to 10 feet
Large Spruce Fir, perfect specimen, from 7 to 10 feet
Abies Douglasii, 4 to 8 feet
Laurustinus, specimen in bud, 4 to 6 feet
Cryptomeria Japonica, 6 to 11 feet
Portuga Laurels, 3 to 6 ft. (6 ft. Common Laurels, 4 to 8 feet)
Picea mariana, 3 to 5 feet
Arbutus, 3 to 5 feet
" grandis, 5 to 8 feet
" nobilis gaulca, 2 to 4 feet
Rhododendron ponticum, fine plants, in bud, 2 to 4 feet
Pinus nigra, 4 to 6 feet
Hollyhocks, finest named, including sorts, well budded.
" austriaca, 4 to 6 feet
Wellingtonia gigantea, 4 to 8 feet
ROSES, 50,000, all heights, 3 to the finest and best.
FRUIT TREES, 100,000, all the leading sorts, may give a good crop the first season.
ORNAMENTAL TREES, 100,000, all kinds.
CLIMBING PLANTS, ROSES, and other Plants, great variety, very cheap.
CATALOGUES and special prices on application.
Floral Nursery, Hailsham, Hursley, Sussex.

SURPLUS STOCK. Reduced Prices. Mostly transplanted in 1868 and 1869.
Abies Nordmanniana, 4, 6, 9, to 12 feet
Ash, Common, 9 to 12 feet
12 inches, ditto, 1 to 2 feet
Deutzia crenata flore pleno, 2 to 3 ft.
Juniperus chinensis, 3, 4, to 5 feet
Laurels, Common, 2 to 3 feet
Pinus austriaca, 1 to 2 feet
Laurels, Portugal, 1, 2, to 3 feet
Thuja Warrena, 3 to 4 1/2 feet
3 to 4 feet
Fir Larch, 10 to 12 feet
Pines, Hex-leaved, 3 to 4 feet
All well furnished, bushy, and good rooted.
Standard and Pyramid Pears and Pines, one, besides a general stock of Fruit and Rose Trees, American Plants, Conifers, Hardy Evergreen and Deciduous Trees and shrubs, Climbers, and Forest Trees, &c. Prices on application to
GEO. JACKMAN and SON, Woking Nursery, Surrey

DOWNIE, LAIRD, AND LAING beg to offer the undermentioned VALUABLE NURSERY STOCK, which is all in the best possible health. To ensure a sale, the whole will be offered at (as near as possible) one-half the usual sale price. The Fruit Trees are all of the finest sorts, and true to name. Inspection invited.
45,000 Oak, English, 2 1/2, 3, to 4 ft.
30 Cupressus Lawsoniana, 2 to 3 feet.
200 Portugal Laurel, 3 to 5 ft., very fine.
30 Cupressus Lawsoniana, 4 to 6 feet.
5,000 Laurel, Bay, 3 to 4 feet.
100 Thujaopsis borealis, 2 to 3 feet.
40 Irish Yew, 7 to 8 feet.
150 Tree Box, 3 feet.
12 Wellingtonia gigantea, 5 to 7 feet, very fine.
200 Thuja sibirica, 3 to 4 feet.
300 Maculoseous Shrubs
50 Picea Nordmanniana, 1 to 1 1/2 feet, fine.
1,000 Dwarf Trained Apples, sorts named.
6 Thuja gigantea, 7 to 8 feet.
1,000 Dwarf Trained Pears, sorts named.
3 Arancaria imbricata, 4 to 6 feet, very fine.
20 Cedrus Deodara, 4, 5, to 6 feet.
500 Dwarf Trained Cherries, sorts named.
20 Cedrus Deodara, 4, 5, to 6 feet.
1,000 Gooseberries, sorts named.
200 Aucuba japonica, 2 to 2 1/2 feet, very fine.
1,000 Currants, sorts named.
N.B.—As the above must shortly be cleared off to make way for building purposes, early orders are respectfully solicited.
West Coates Nursery, Edinburgh.—November 20.

The Smithfield Club Cattle Show—Stand 77.
SUTTON AND SONS, THE QUEEN'S SEEDSMEN, Reading, will exhibit specimens of:—
SUTTON'S MAMMOTH LONG RED MANGEL, weighing 40 lb. each.
SUTTON'S YELL-OW INTERMEDIATE MANGEL.
SUTTON'S FERNS PRIZE YELL-OW GLOBE MANGEL.
SUTTON'S CHAMPION SWED.
SUTTON'S IMPROVE VARIETY OF TURNIPS.
SUTTON'S KOHL RABI, CALIA, & CARLOTS, &c.
SUTTON'S GLASS SEEDS OF ALL SORTS.
CHOICE POTATOS, for Planting.
And will receive Orders for the same at moderate prices.
STAND 77—SUTTON AND SONS.

Special Offer for Sale, to Clear Out.
ASPARAGUS ROOTS, 1-yr. old, 10s. per 1000; 2-yr. old, 15s. per 1000; 3-yr. old, 22s. per 1000. SEAKALE ROOTS, 1-yr. old, 6s. per 100; 2-yr. old, 10s. per 100; 3-yr. old, 12s. per 100, extra strong, 15s. per 100.
GLADIOLUS BRANCHLEYENSIS, 10s. per 100.
Mr. MASTERMAN, 11, New Ring Lane.

Autumn Gardening.
SEAKALE, ASIATIC, & 3rd EARLY ROOTS, &c.
JAMES CARTER AND CO. offer the following in special quantities:—
SEAKALE, extra fine roots, for Forcing, 15s. per 100 very fine roots, for Forcing, 20s. 6d. per 100 large, 7s. 6d. per 100.
ASPARAGUS, Giant, extra large plants, for Forcing, 10s. per 100 strong, 3-yr. old, 6s. per 100.
" " strong, 2-yr. old, 4s. per 100.
RHUBARB ROOTS, Baldry's Scarlet, extra strong, 1s. 6d. each other varieties, extra strong, 2s. to 12s. p. doz.
MUSHROOM SPAWN, best Millrace, 6s. per bushel. the French 4s. to 6s. 6d. per box.
JAMES CARTER AND CO., 37 and 238, High Holborn, London, W.C.

CENTRAL CHAMBER OF AGRICULTURE.—
The GENERAL BUSINESS COMMITTEE will meet at the Salisbury Hotel, Fleet Street, on WEDNESDAY, December 8, at 1 o'clock.
Same day, at 2 o'clock, MEETING of the COUNCIL, consisting of the Deputed Members from the Provincial Chambers, and of the Elected Members of Council.
Same day, at 3 o'clock, when the business of the Council is concluded, ANNUAL MEETING of the Members of the Central Chamber.
AGENDA:—
To receive the Report of the Council for the year 1870.
To elect a Vice-Chairman for the year 1870.
To elect eight Members of the Central Chamber to be Members of Council, in lieu of the following, who retire by rotation, but who are eligible for re-election:—Mr. H. Massey, Mr. R. Jasper More, Mr. J. Payne, Mr. Albert Bell, M.P., Mr. Charles Bea, Mr. C. S. Road, M.P., Mr. Edmund Riley, Mr. John Smyth.
To appoint Auditors, and to transact other business.
JOHN ALGERNON CLARKE, Secretary.
The Salisbury Hotel, Fleet Street, E.C.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—
The GENERAL MEETING of MEMBERS will be held at the Society's House, 12, Hanover Square, on THURSDAY, December 9, at 12 o'clock, when the REPORT from the COUNCIL will be read, and the Election of Auditors will take place.
By Order of the Council. W. M. JENKINS, Secretary.

The Agricultural Gazette. SATURDAY, DECEMBER 4, 1869.

- MEETINGS FOR THE ENSUING WEEK.
Dec. 5 } Smithfield Club Cattle Show, at Agricultural Hall, Finsbury
Dec. 10 } Land & Farmers Club, Mr. R. H. Massey on Farm Agreements, at Salisbury Hotel, E.C.
" 11 } Salisbury Club General Meeting, at the West End Hotel, E.C.
" 12 } London Farmers Club (General Meeting) at Salisbury Hotel, E.C.
" 13 } Dinner, Dinner—5.30 p.m.
" 14 } North of England Chamber of Agriculture, at Newcastle-on-Tyne.
" 15 } Royal Agricultural Society (Council Meeting), at Hanover Square—Noon.
" 16 } General Chamber of Agriculture (General Meeting), at Salisbury Hotel, E.C.
" 17 } Royal Agricultural Society General Meeting—Noon.

THE above list of meetings shows that we are to have a busy agricultural time next week. The Smithfield Club will open its annual show on Monday morning, at 9 A.M., when the judges will commence their labours, and when members of the Society and the representatives of the Press—and the general public on payment of 5s.—will be admitted to witness the awards. By the way we find we are mistaken as to the general public—they are excluded till 2 P.M., when the process of selecting the prize animals is concluded; though why they should not be admitted with the others is hard to understand. In the evening of this day, at the Salisbury Hotel, the important subject of farm agreements, to which we refer below, will be introduced by Mr. MASIEN, to be discussed for the 50th time, with, as it seems to us, wonderfully little result. It would be a capital effort of what may be called the statistical department of the Royal Agricultural Society—which seems to have awakened to the fact that a description of things as they are is really better than all the direct agricultural teaching in the world—if an attempt were made to ascertain how much more land in this country is now let on lease or low let on a formal farm agreement than was so let 20 years ago. It would, we fear, be found that there had been marvellously little direct result of all the writing, publishing, and specifiying on this vexed question, whatever the fruits indirectly may have been.
On Tuesday the general meetings of members of the Smithfield Club and Farmers Club will take place at twelve and half-past three respectively. The Farmers Club dinner will take place at 5.30 P.M., at the Salisbury Hotel, where Mr. NEWTON, the retiring chairman of the year, will preside and introduce his successor, Mr. JAMES HOWARD, M.P., the elected President for 1870. The monthly Council meeting of the Royal

STEAM CULTIVATION.

A HEALTHY discussion has followed my letter last month on the Peterborough steam cultivation trials. Mr Smith writes that his... (text continues)

father has nursed and nursed it and kept it in its swaddling clothes, until it runs a danger of being smothered by these very kindnesses. Let it have its liberty and the use of its legs to emerge from its cramped-up position a giant. Richard Thompson, 56, Newland, Lincoln.

The following letter, by Mr Avering, of Rochester, has appeared in a local paper, and is reproduced here as an extremely fair comparison of the rival systems:—

The great importance of steam cultivation, not only to tenant-farmers, but to the landlords of this country, must be my excuse for asking your permission to bring the subject before your readers.

It is now 15 years since I first introduced steam ploughing into this county, and many will remember the constant breakages and other annoyances which then occurred, some due to the want of management, but more from weakness of the machinery itself for the work, but since that time many thousands of pounds have been expended in perfecting it.

The thanks of all interested in steam cultivation are due to the gentlemen who in its early stages became purchasers of machinery, and who have since adopted, and by their perseverance assisted in carrying out, each improvement as it arose. Among the pioneers in this county the names of Messrs. Nunn, Messrs. Pye, and Mr. James Lane will come to your ears.

Of the many systems and systems which have been practically brought before the public, two only stand out as the simplest and have proved the most successful.

In both of these the traction power is transmitted to the implement through a steel wire-rope winding upon a drum. In the one case the two winding drums are fixed in a winch frame, and connected to a stationary steam-engine, and can be worked from one corner of a field, the rope being led all round the land intended to be ploughed, through pulley-sheaves anchored in convenient positions. One end of each rope being made fast to the plough, the implement is drawn backwards and forwards, by the drums pulling alternately, and the pulley-sheaves and anchors at each end of the furrow are moved forward as the plough proceeds.

In the other system each of the winding drums is placed under the boiler of a self-moving steam-engine, and one engine at each end of the furrow working alternately and pulling the plough towards it, the other moving forward into position, ready for the return of the plough.

These two systems are known as the single engine, or roundabout, and the double engine, or direct system of steam cultivation.

The advantages of the roundabout system are in the cheapness of the machinery, as the tackle can be drawn by an ordinary portable engine, and in its superior fitness for very hilly and for awkwardly-shaped fields.

Its disadvantages consist in loss of power, great length of wire-rope, useless expenditure of time in returns, and great quantity of apparatus necessary.

The advantages of the direct system are:—Short length of rope required, and consequent economy of power, the little time taken in getting to work, and the small amount of wear and tear due to the simplicity of the tackle.

Its disadvantages are its first cost, the width of the headlands left, and the difficulty in moving the engines on wet land. This last difficulty has been almost entirely removed by increasing the diameter and width of the driving wheels.

For large farms and for letting for hire the double engine or direct system is the best, and has proved itself to be capable of doing more work per day at a less cost than any other. With this tackle I find from experience that 10 acres can be ploughed from 8 to 9 inches deep in a day of 9 hours, at this time of year, in ordinary soils, with a pair of 12-horse power engines, and a 6-furrow plough, at a cost in no case exceeding the following estimate:—

Table with 2 columns: Item and Price. Items include Chief engineer, Second, Ploughman, Assistant ploughman, Two boys, 15 cwt. of coal, Water, Oil &c., Depreciation, renewals, interest of capital, &c., to replace in 19 years at 3% per acre on 10 acres.

Or 7s. 6d. per acre. The lowest price at which this work could be done by horse-power is 15s. per acre, many farmers having stated it would cost them 20s., and some of them that such price for 100 acres of similar land as that referred to above.

That "good work" can now be made by the steam plough is shown by the remarks of the judges at the several ploughing matches where these machines have worked this season, more especially at the meeting of the Isle of Thanet Association, where it was acknowledged by all that the horse ploughs were fairly beaten.

A very considerable increase in the yield, amounting in some cases to as much as three sacks per acre, has been found to result on the application of steam-power to the cultivation of heavy clay lands, and this is not surprising when we consider the damaging effect to the drainage of such lands caused by four horses following each other in the furrows when ploughing it, and the low temperature of the soil consequent upon the water being unable to find its way to the drains. I believe that great advantages will also be found to follow the application of steam-power to the drilling and harrowing in the seed on heavy soils, as there is, without question, much injury done by the horses' foot-marks, every one of which, acting like a dish, will hold the water if gathered until it be evaporated by the sun's rays.

The following remarks on the quantity of food in the form of hay required for horned stock are translated from Moll and Gayot's excellent work on cattle. The authors quote from M. Reesdel, who paid much attention to the subject of feeding milch cows, and who sums up his experience in a manner singularly concise and exact. — To preserve life, or more correctly to maintain the animal at the same weight, requires a quantity of nutritive principles proportional to the live weight of the animal. If the nutritive principles contained in the food are insufficient, the animal diminishes in weight, if, on the contrary, there is an excess of nutritive principles, he increases in weight, fattens, grows, or furnishes other products, as work, milk, &c. The maintenance of life among horned cattle requires 830 grammes (183 lbs.) of hay, or the equivalent, for each 50 kilogrammes (110 lbs.) of the animal's live weight, or 1-60th of his live weight. For to satisfy the animal completely he must have hay equal to 1-30th of his live weight per day. Besides the 30th part of his weight in dry substances, the animal requires 1-30ths of his weight of water, or of liquid contained in his food. If to be completely satisfied a horned beast has need of a quantity of nutriment equal to 3/4 for every 100 of his weight, and if 1/3 are necessary to preserve life, it follows that half of the rations is for maintenance (nourriture de soutien), and that the other half is productive (nourriture de production), from which results fat in fattening animals, growth among young stock, milk and the growth of the foetus in cows, &c. Forage of production (this forage being always supposed to be hay or the equivalent) produces among milch cows, for each kilogramme (2.2 lb.) of forage, one kilogramme of milk, or 23 grammes of increase in the calf in the womb of the mother, and among young stock and fattening cattle 10 kilogrammes of forage give 1 kilogramme of increase in the weight of the animal. It follows from this that a cow eats in one year (or 360 days), to make a round sum) 3.0 times 1600 grammes, or 4800 kilogrammes (10,500 lb.) of hay for every 50 kilogrammes (110 lb.) of her weight, or, what is the same thing, 12 times her own live weight. If, then, a cow weighs 500 kilogrammes (1100 lb.), she eats in one year 12 times 500 kilogrammes or 3500 kilogrammes (7920 lb.) of hay, if she weighs 600 kilogrammes she eats double, or 7200 kilogrammes (15,840 lb.) of hay.

I think it possible that some injury to the cause of steam ploughing has resulted from an indiscriminate use of deep ploughing for whatever crop the land may have been intended. I am of opinion that for green crops, &c., the land should be cultivated at least from 12 to 14 inches in depth, say once in every four years, stirring up the subsoil but not bringing it to the surface, and thus enabling the air and water to descend; but that where Wheat, &c., is to be grown, especially on light lands, the depth of the ploughing should not exceed from 4 to 5 inches, leaving a good firm subsoil with no horse-trodden "pan" to obstruct the roots of the corn in their downward growth. Both heavy and light lands would thus be kept at a more even temperature, the heavy lands not suffering from excess of water in the spring time, and the light lands from drought in the summer.

In conclusion I should say that steam cultivation will enable the farmer to become more independent of seasons, and better able to take advantage of the proper time for getting in the seed; he will be able to dispense with a large number of horses, whose food can then be applied to better purposes, the steam engine consuming nothing except when actually at work, and requiring no attention on Sundays; and the land can by its means be cultivated to a depth practically unattainable by animal power. It is also an important advantage of steam tillage that, the land being once thoroughly broken up by it, every succeeding operation is performed more rapidly and at less cost.

It would be difficult to show in what other direction farmers are to look for the means of meeting their constantly increasing expenses. *Thomas Aveling, Rochester, Nov. 19.*

THE DEPTH OF DRAINS.

I SHOULD have responded to your desire for practical information with regard to the depth of drains, had I not deemed it best to wait until the weather had been sufficiently wet to afford a fair test of the state of the grass-field which I drained last winter, at a depth of 3 feet, at 18 yards apart. For, although after the heavy rainfall during the spring, the field was perfectly dry, this might have been regarded as due to the exceptional action of drains which have been recently executed. I can now, however, state that, having carefully examined every part of it, there is no trace of stagnant moisture to be found; but, on the contrary, the whole field presents the appearance of well-drained land. In this case, therefore, drains 3 feet deep and 18 yards apart have proved a decided success. Granting, for the sake of argument, that 4 feet at 12 yards apart might have been equally successful, the expense would have been nearly double. In reply to your question whether it is not an advantage to obtain on turf land an additional foot of dry subsoil, I shall answer in the affirmative, as a general rule. But where, as in my field, the subsoil partakes more or less of the nature of rubble from between 2 and 3 feet below the surface, after which it becomes a bed of solid clay, it is doubtful whether, by placing the drains a foot deeper, this extra foot of dry subsoil would in practice be obtained; for, owing to the tenacity of the clay, the water would be a longer time making its way into the drains than at present, and thus the clay would become thoroughly saturated before they began to run. This slowness of filtration I take to be the principal cause of the failure of 4-foot drainage in another of my fields, which I have recorded in your columns. During continuously wet weather the whole mass of the soil becomes saturated with wet up to the top, so that I have actually witnessed water standing in pools above drains which were discharging much more water than they ought to have done. In the other case—of drains laid so as to be immediately below the open gravelly or rubbly subsoil, and which consequently quickly remove the greater part of the surface water—I think that if the foot of soil between them were tested, it would be found drier than if the drains had been laid a foot deeper. I consider that success in draining, as in every other agricultural operation, requires experience and practical tact. There is nothing on which an unbending rule can be laid down to suit all soils, climates, and circumstances.

Thick or thin seeding, early or late sowing, shallow or deep ploughing, permanent pasture or alternate husbandry, breeding or feeding, may each be advisable in its proper place and time. But there is no agricultural question to which there is not another side. As regards draining, I am a decided advocate for depth, where the circumstances are favourable. But as cost is so important a consideration, I am certain that where drains 3 feet, at 18 yards apart, are more effectual than those of 4 feet at 12 yards, the owners and occupiers of land will prefer the former.

I had written thus far when the instructive letter of Mr. William Smith to *Bell's Weekly Messenger* came under my notice. While advocating deep draining in general, that gentleman says, "I have no rule as to depth. Judgment, moderation, and a regard to cost is my motto." As illustrating how he carries out this principle, he gives the following interesting statement.—"Forty years ago the grass-land at the back of my house was (although a good field) very wet in the winter. It is mixed gravel and clay. At that period it was drained 2 feet deep, 8 yards from drain to drain. Up the furrows from then till now it has been dry, let the weather be ever so wet, and it has not had a tittle the matter with any of its drains. This is what I call good draining on such a soil."

It is instructive to note how the practical sagacity of Mr. Smith enables him to meet a difficult case with totally different treatment. "Sixteen years ago I drained my field No. 5, light land. It is gravel mixed with patches of clay. I put the drains in from 1 to 6 feet deep, 60 yards from drain to drain. The cost per dram for labour was 10s. 6d., and I put in

4-inch pipes. This field in a wet time used to be very wet; since I drained it, it has always been very dry." Some strong land Mr. Smith has drained at 4 feet, and finds that—especially since it has been steam cultivated—it has been dry ever since. In like manner I found, many years ago, that a large grass-field, which had been drained by my predecessor, at a depth of about 2 feet 6 inches, was in parts still wet. The land is strong, but interspersed to a considerable depth with rubble. I have completely cured these wet places by 4-foot drains, running into a new main, which in some places is 6 feet deep. These deep drains invariably run after wet sooner than the shallow ones. In short, an occupier who has his eyes open will generally drain his own land both more effectually and at less cost than a stranger, who comes with preconceived ideas of depth and distance. And draining is so expensive an operation that it is important that it should be carried out both effectually and economically. *Willoughby Wood, Holly Bank, Nov. 30.*

ON THE PRODUCTION OF SUCCESSIVE GREEN CROPS.

THE Strines Calico Printworks are in Derbyshire, distant from Manchester 14 miles, Stockport 7, and Buxton 12. They employ from 500 to 600 work-people, and in connection with them is a farm of about 105 acres. Part of the land is in Derbyshire, and the remainder in Cheshire, the river Goyt passing through the midst. About 50 acres are level and low-lying, the remainder being elevated. The climate is late, especially if east or north-east winds prevail in the spring, and there is not much growth before the month of May.

The stock at present on the farm consists of 14 horses, 1 mule, 1 ass, 21 cows, 13 young cattle, 26 sheep, and 3 pigs.

The horses are heavy draught horses, and are mostly used for draught purposes at the works, as also are the mule and ass; the cow-manure is used for dyeing purposes at the works.

A good supply of manure is obtained from the works, consisting of a mixture of human excrement, flue-ashes, and ammonia-water from the gas manufactory; also a supply of gas-lime. I have had charge of the above farm for nearly nine years, and have conducted the following operations, by means of which I have obtained a continuous succession of green crops:—

- 40 acres meadow land, Grass cut and made into hay; aftermath grazed.
- 43 acres grazed.
- 22 acres under cultivation.

105 acres.

Sixteen acres of the 22 are about half a mile distant from the works and farmyard, and on high ground; they are cultivated under a four-course rotation, namely,—4 acres Oats, 4 acres Swedes, 4 acres Barley or Oats, and 4 acres Rye-grass and Clover.

The Turnips are pulled and carted home in October and November; the Rye-grass and Clover are ready to cut the first time the fourth week in June; the second cutting being ready about the second or third week in August. Thus, for distinction, I will call the 16 acres.

The other six acres are near the works and farmyard, and are level, with a good strong soil, gravelly subsoil, and good natural drainage. They have been devoted entirely to the production of successive green crops for the last seven years.

The six acres have been divided into five as equal parts as possible, which I will call Nos. 1, 2, 3, 4, 5.

No. 1 is manured during the autumn with gas-lime, which is ploughed in; the land is prepared during the spring; in the third week of April drills, 27 inches apart, are made; the land is manured with farmyard manure, and Potatoes (the early sort) are planted in alternate drills. In the first week of May Ox Cabbage plants, 30 inches apart, are put in the drills remaining (the Ox Cabbage seed having been sown the previous August and pricked out during the autumn); during the months of May and June the land is hoed, cleaned, and the plants earthed up; in August the Potatoes are dug, and sold at once, the small and diseased ones being steamed and stored for pigs.

Immediately the Potatoes are cleared the land is scarified, and the cabbages earthed up, as they will soon cover the vacant space. In October the outer leaves are taken off, and the Cabbages are ready to cut in November.

No. 2.—In January or February the Cabbage-stalks are ploughed out, and gathered off; the land is harrowed and ploughed, and sown with spring Tares, with Rye and a few Beans to hold up the crop. The sowing is made in February or March (according to weather), and the crop is ready to cut in July.

No. 3.—Immediately the Tares are cleared the land is manured with manure from the works, which is ploughed in; it is then prepared for sowing Italian Rye-grass not later than August. During the autumn, winter, and more especially in the spring, liquid manure from the farmyard is applied; the first cutting is generally ready to cut in the beginning of May, and the last cutting not later than the first or second week in September. Under ordinary circumstances there will be three cuttings, and if the land is well supplied with liquid manure between each cutting, there will be four.

No. 4.—Immediately the Italian Rye-grass is cleared off, the land is dressed with manure from the works, which is ploughed in, and winter Tares are sown, to be ready to cut in May and June. The crop is cut up in small strips at a time; and as a strip is cleared the land is ploughed, manured with manure from the works, and drilled 21 inches apart; Savoy Cabbages are then planted 18 inches apart (the Savoy Cabbage-seed having been sown in February or March, and pricked out in April or May, and held in readiness),

each successive strip is treated in the same manner, in case the last strip should be rather late. The strips are put in a little thicker there. The sowing will be ready to cut in January.

No. 5.—The Cabbage-stalks are ploughed out, and sown with spring Tares, with Rye and Beans to hold up the crop. The sowing is made twice, one in April the other in May; the first is ready to cut in August, the other in September.

Having described the mode of culture of the green crops, I will now describe the mode of cutting them.

May.—A supply of Italian Rye-grass from Nos. 3 and 4 is cut and carted to the farmyard, and the greater part passed through Richmond's chaff-cutters (attached to the steam engine). When too succulent, they are mixed with chaff. All the horses, the mule, the ass, and get an allowance, the young cattle being cut in May.

June.—Winter Tares from No. 4, and Rye-grass from the 16 acres, form the supply for the month; the winter Tares are now strong, and be cut into chaff. All the horses, mule, and Cows, consume Tares and make ready for Cabbages. When the Tares are all cut, six of the horses are put out on the pasture at night, and the cows are more at pasture with the supply from the 16 acres, and the second cutting of Italian Rye-grass come in. All the young cattle are out at grass; what is not required of the second cutting and Clover is made into hay.

July.—Spring Tares from No. 2 now come in, and a strong heavy crop requires cutting. To these are added Rye-grass and Clover, prepared in the same manner as the winter Tares. The Rye-grass off No. 3. The six horses are put out during the night, the cows are partly cut, and young cattle entirely.

August.—Spring Tares are obtained from the sowing Italian Rye-grass, a third cutting of Rye-grass and Clover from the 16 acres if required. The horses are at pasture during the night, all receiving green food; all the cows are at pasture aftermath, and the young cattle are also at pasture.

September.—Italian Rye-grass from No. 4, and Tares from No. 5 (second sowing), a straw cut through the cutting-machine, and the 16 acres are got this month. All the cows are at pasture, but all the cows and young cattle are at pasture.

October.—Ox Cabbage leaves from No. 1, and tops from the 16 acres, are used this month. The cows are receiving a small quantity of Turnips from the 16 acres, and the cows a cartload per day of leaves or Turnip-tops, carted out into the field and spread there, so that all can be consumed by the young cattle at grass.

November.—Ox Cabbages are got from No. 1, two feeds per day for the cows, and one for the young cattle (or Turnip-tops); the Cabbages are as near to the ground as possible with a strong bill; each Cabbage is cut in four quarters, and to cleave the stalk up the middle, as they are valuable eating in it. The horses have a small quantity of steamed Turnips the last week.

December.—Ox Cabbages continue to be cut from No. 1, viz., two feeds per day for the cows, and one for the young cattle. A week's supply is always kept cut beforehand, in case frost sets in, as the Cabbage breaks like glass in frost. If the weather seems settled for frost, another week's stock is got in; and if the storm is longer, Turnips are substituted, the sheep getting a few Cabbages this month, and the horses getting a quantity of steamed Turnips, as in November.

January.—Savoy Cabbages from No. 4 are cut, and a supply is kept cut beforehand in December. The cows obtain two feeds per day of the young cattle one; the sheep also get a few feeds of the same as during last month.

February.—Same as in January.

March.—Swede Turnips are used from No. 2, all the cows receiving two feeds per day, and the young cattle one. The young cattle get one feed per day, being out at pasture a few hours per day. The cows have a few steamed Turnips as before, and a small quantity also.

April.—Swede Turnips continue to be cut from No. 2, all the cows receiving two feeds per day, and the young cattle one. The young cattle get one feed per day, being out at pasture a few hours per day. The cows have a few steamed Turnips as before, and a small quantity also.

REMARKS ON THE ABOVE

No. 1. *Potato or Cabbage System.*—The system of growing Swede Turnips, Mangels, and Cabbages in the place of the Cabbages and Potatoes is not answer so well as the present system. Cabbages are not of much size before the first cutting in July, and after that the Potato-tops are cut, and the Cabbages, now beginning to spread their leaves, would cover up the Potatoes if they were cut out. I have frequently seen the stems of Cabbages projecting over each other, and when the stems have been 54 inches apart, the Potatoes are readily sold to the work-people at a good price. In getting the Potatoes, the drill is dug out first, and in a few days the rows will incline over the vacant space, and be covered by a turnpike road.

No. 2. *Spring Tares, with Rye and Beans.*—I have tried Tares with Oats, but could not keep them with the above it will stand either rain or drought, and not go down. If the crop did go down, it would be a great loss.

have to be consumed at once or made into hay, and it would leave a vacancy in the continuous supply which could not be filled up. The above crop is too heavy and strong to admit of Italian Rye-grass being sown in the spring.

No. 3. Italian Rye-grass.—This is an excellent crop, with its three or four cuttings, and it is always ready. I have had but one failure in this crop during the last seven years, and that was caused by my not being able to attend to the sowing at the proper time.

No. 4. Winter Tares and Rye.—I have tried Tares with Wheat, but could not keep the crop up; sown with Rye it is sure to stand. I have tried Swede Turnips, and also Yellow Turnips, after the Tares, but have not succeeded in raising a full crop, as the season is too far advanced in this locality, as I find from experience in the 16 acres that the first or second week in May is the best time in this district; and, as the Yellow Turnips come in at a time when not required, I am in favour of the Savoy Cabbages, for I have never yet failed in raising a full crop, and the Savoy Cabbages come just when the others are done.

No. 5. Spring Tares, with Rye and Beans.—(Same as No. 2.) I have tried them with Oats, but could not make the crop stand.

The Spring Tares in Nos. 2 and 5, and the Winter Tares in No. 4, ought not to be cut until they are at their full growth, if it can be avoided, as there is no second cutting like that yielded by Italian Rye-grass, each cutting of which ought not to be allowed to grow too long, as by so doing it interferes with the next. There is sufficient time, after each crop is cleared, to prepare and sow or plant the next, and there will not be any failure if the dates given are attended to.

The result may be thus briefly summed up: the land has grown heavier crops each succeeding year; and, by careful management, a supply of green food has been kept up for each succeeding day in the year. John Chambers, Bailiff to the Strines Calico-Printing Company, in the "Journal of the English Agricultural Society."

Home Correspondence.

Manures on Grass Land.—In the belief that the results of an experiment tried by me this year on eight half-acre plots of permanent pasture, may interest your readers, I annex a table showing the results. The quality of the soil and the character of the herbage was the same throughout. It will be observed that the only plot which gave a profit was that dressed with lime and salt, the quality of the hay, too, from this plot was the best of all. I propose to allow the land to remain unmanured for the next two seasons, with the view of testing the value of the manure left in the soil by the subsequent yield of hay. Coles Child, Bromley Palace, Kent, Nov. 24.

together being 3607; which added to the 8007 for beasts sold fat, would make 11607 from a breeding stock, instead of 16807 from a dairy stock: which still shows a balance of 5200 in favour of the dairy. These few simple figures will, I think, satisfy most people that dairy farming is much more profitable than breeding or growing beef. G. A. H.

Mangel Wurzel and Sugar-Beet.—Mr. Mitchell asks for a solution of the question as to the growth of Beet, as compared with Mangel. The weight is, I think, confessedly in favour of Mangel, even when the Beet is closely cultivated. I have grown Beet in alternate rows with Mangel, from seed from Mr. Duncan, and I have seen it grown from other seed elsewhere on various soils. The weight of the crop seems to be much in proportion to the depth of cultivation more than liberal treatment with manure. On the deeper cultivation the roots carried their size well into the soil, on the shallower, that portion of the root that penetrated the soil was divided more or less into roots of inferior dimensions; the Mangel grown under the same conditions were remarkably fine. On cultivation exceptionally deep in a clay soil, the root seemed to force itself into the soil without the division into roots of inferior dimensions. Deep cultivation seems to be the secret of success in growing Beet. J. C. C.

Sugar-Beet.—Will you allow me to correct a statement which appeared in your journal touching the cultivation of this crop? It is supposed that no crop can immediately precede or immediately follow Sugar-Beet. This is an error, as our experience at this farm will show. The best return of Sugar-Beet which we have had this year is that from 7 acres of land, which yielded 196 tons, or 28 tons an acre. This crop followed immediately upon the removal of Winter Rye and Winter Onions (the heaviest Beet came after the latter), and a close crop of Cabbages and Wheat followed at once the removal of the Beet. The land destined for Beet-growing next year is now in Grass, which will be allowed to stand as long as possible, and will be ploughed up only when we are ready to put in the Sugar-Beet seed. Henry J. Morgan, Lodge Farm, Barking, December 1.

Woolston Steam Cultivation.—I am afraid Mr. Smith has got a dig in the ribs which he does not feel very comfortable under. He talks of having 30 men employed, and therefore has no time to attend to "G. A. H." and his "interest of money and depreciation," but as these men are all employed, as he himself says, at "jobwork," why need they take up so much of his time? I, too, have a great many men employed (far more than 30), and fully half of them are at day work, not jobwork, yet I can find time to poke through Mr. Smith's figures and point out his fallacies. What was the use of asking you to reprint his letter to the Times? I read the Times and have seen it there, but what is the value of it? It is a "mere estimate," and

forth into the streets of Ascalon—I actually believe that Tiptree has done more good to British agriculture than Woolston has—ten times over. I hope Mr. Smith will understand that I am still waiting patiently for his reply when his 30 men have finished their job. G. A. H. [Neither "G. A. H." nor his readers must imagine, from the silence of Mr. Smith, that he has not an answer to his clever assailant. We have received a long report on the subject from Woolston, for which we are unable to find room this week.]

Foreign Correspondence.

TORONTO Turkey Raising.—The turkey is a native of the American continent, and is found in the wild state all through the Western States, and often in the south-western part of Upper Canada. The wild mix with the tame, and do not produce males, and are therefore, doubtless, of exactly the same species. The tame turkeys often associate with the wild, and join their flocks, breeding with them, and sometimes coming home to the barn-yard in the winter with some of their progeny.

Turkeys, in their wild state, always separate after the breeding season, the males and females into separate flocks, and they seem to associate with other, they certainly migrate to considerable distances, and there is no known rule for their returning: the separation between the sexes seems to be complete, and if they ever meet again in pairs it is undoubtedly chance. It has been observed that the broods of the wild bird are very large, whilst the broods of those kept in confinement are often very small. American turkey breeders assert that the cause of small broods is that the same male bird is kept year after year, and those who look to their turkeys for profit, therefore, spare no pains to change the male bird every year, replacing him by one from as great a distance as possible. Many who have tried it say that, with the same male, they get good broods the first year, poor broods the second, and very bad ones the third year. This is a piece of "henwife lore" that may be worth putting in force in England, where, for some reason or other, they do not raise one young turkey where they raise ten in America. It can do no harm to try the experiment. Vectis, Toronto, Canada, October 8.

Societies.

BATH AND WEST OF ENGLAND.

November 30.—At a special meeting of the Council at Bristol, Sir J. T. B. Duckworth, Bart., in the chair. Guildford Meeting, 1871.—The deputation which visited Guildford, on the 4th November last, reported in highly favourable terms of the site in Shalford Park, proposed to be placed at the disposal of the Society for the meeting to be held in 1871, and it was resolved by the Council that the invitation from the inhabitants of Guildford be accepted, and that the usual conditions be signed by the secretary on behalf the Council, and interchanged with the conditions already signed by the authorities at Guildford.

Privileges of Members.—Several new members were proposed for election at the next meeting of the Council to be held on Tuesday, February 22; and it transpired that no person not proposed on or before that day will be eligible to exhibit at the Taunton meeting on the same terms of advantage as those enjoyed by duly elected members.

BIRMINGHAM AND MIDLAND COUNTIES.

The 21st meeting of this Society was opened on Saturday last, when the judges, from the uneven character of the cattle, got through their complicated duties with unusual ease. We say "complicated duties," because there are so many extra and special prizes offered by this Society that some of the animals come before the judges as many as five times. This was the case, as will be seen by our prize list, with the Earl of Aylesford's steer, for in addition to the 1st prize of his class, he was awarded the extra prize for the best Shorthorn, the gold medal for the best male, the Innkeeper's Prize for the best animal in the Hall, and so on; the value of the whole amounting to upwards of 1200, or more than double the intrinsic value of the steer himself.

A remarkable feature of the Bingley Hall cattle was their inferiority as compared with last year. Then there was the most uniformly good collection of cattle that we ever saw together, and in addition to their regular fatness, their fine firm touch had never been equalled. The animals which have just been dismissed from the show, however, besides being very irregular, were in many cases very infirm, or oily, instead of being firmly fat, under the hand. This, of course, has nothing to do with the directors and managers of the Bingley Hall show, as they do not select the animals which appear in response to their prize list. But in this contrast we infer there is a great practical lesson for us to learn, for last year there was scarcely a bit of fine quality or wholesome green food to be had during the six months preceding the Christmas shows, while this year there has been an ample supply, and in some places almost a superabundance of green food and roots for our live stock. The conclusion we may therefore draw is that, if our breeders and graziers could see their way clear to keeping their domestic animals free from foreign diseases, and otherwise be assured that a more certain direct profit on feeding stock would accrue, not only might the quality of our animal food be greatly improved, but its home-produce might be increased to any extent. The means for effecting both these desirable ends consist, of course, in the supply and use of a much larger amount of foreign corn. If these shows, with the wide differences in the quality of the animals in question, do not teach this practical lesson, of what practical value are they?

Table with 10 columns: Manure applied, Quantity, Cost at per acre, When applied, When cut, Produce at per acre, Value at 80s. per load, Profit, Loss, Remarks. Rows include Farmyard manure from open yard, Ditto from covered yard, Sulphate of ammonia, Soda, Potash, Salt, Dried clay, Superphos lime, Guano, Nitrate of soda, and Manure.

Dairy Farming against Breeding.—It seems to me that very few people appreciate the benefits of dairy farming. The same sort of land which rears and fattens good stock will produce first-rate dairy produce. Now, let us look at the relative returns from each. Suppose I have a farm which will keep 40 breeding cows, my regular winter stock will be 160 head—40 cows, 40 calves, 6 to 12 months old; 40 beasts, 1 1/2 to 2 years old; 40 beasts 2 1/2 to 3 years old, which will be sold off just before the new crop of calves come. Now all the beasts, except the calves, eat a full average ration, and the calves I consider will eat half a ration—that is to say, 40 calves will eat as much as 20 beasts. Therefore I have to provide rations for 140 head instead of 160 head. But if instead of breeding I kept a dairy of 40 cows, the same food would keep them. Now, let us compare the money returns. Every one will admit that a good average cow will produce at the very least 127 a year in butter and cheese, so that 140 cows would give at this low estimate, 16800. But if I keep a breeding stock of 160 head, say 40 breeding cows, I should sell off every year 10 fat beasts three years old, worth, say 200 each, and bringing in only 8000, or less than half what a dairy using the same food would bring in. But it may be said, "if you have 40 breeding cows you will not use all the milk for the calves; you may make 20 cows bring up the 40 calves, which will leave you 20 cows for a dairy, and at the end of three months you may wean the calves, and get the other 20 cows for the dairy for the remainder of their time, during which they will give you about half profit." Let us then see how much this would add to the profit. Twenty cows at 127 would be 2540, and 20 cows at 61 (half profit after calves are off), would be 1200, the two

therefore simply "trash." So I quote against himself his own words, addressed to Mr. Toepfler (see p. 1097), "let him give over talking of what he can do, and instead tell us what he does do." Mr. Smith proposed to give us "facts," and I have already shown by his own figures that his so-called "facts" are fallacies, and that he never has made a seed-bed for Wheat at 6s. 8d. per acre, because his own figures prove that in order to do so he must occupy a farm on which he has 1067 acres under rotation on the four-field system, and of which 800 acres must be actually ploughed or, as he calls it, "smashed" each year. Now he never has occupied such a farm, and therefore he never has made a seed-bed for Wheat at 6s. 8d. per acre. He has, in fact, been telling us, not what he does do, but what he estimates he can do. This is a hard nut for Mr. Smith to crack, and I think he will break his teeth before he does it. And now one word about Mr. Mechi. Mr. Smith evidently thinks that I am a great friend of Mr. Mechi, and that my attack on the Woolston fallacies was a retaliation for the attack on Mr. Mechi's accounts, and he accuses me of keeping open "the raw" which he fancies he has established. I suspect Mr. Mechi's hide is too tough to be rubbed into a raw by Mr. Smith's criticisms; he must employ a professional accountant to assist him before his critique of the Tiptree accounts is any better than henscratching. As to my friendship for Mr. Mechi, I never saw him in my life, and he is no more my friend than he is the friend of every gentleman in England who takes an interest in agriculture. I may occasionally smile at his enthusiasm, but I most thoroughly respect his honesty of purpose and his truthfulness. Nay—tell it not in Gath, let it not go

cultivation, there was nothing new or novel in the ba...

Farm Memoranda.

LISCARIA, BIRKENHEAD. - Having a few hours to spare when in Liverpool last autumn, and being within 14 miles of Mr. Lathdale's model farm at Laward, I determined to avail myself of the opportunity of seeing this well-known establishment.

Mr. J. A. C. ... Mr. J. A. C. ... Mr. J. A. C. ...

birds. In the class for chickens (No. 2), Mrs. Arkwright again won 1st, and took the cup as well. The competition in this class was very great, and the result showed that the old breeders hold their own pretty well.

Classes 3 and 4, for hens and pullets, grey Dorkings, but not silver greys. More than 90 pairs competed, Mr. John Fox winning for hens, and Mr. Crossley 1st and cup for pullets.

Mr. Thomas Raines had 1st prize for a very handsome silver grey cock, and Mr. E. D. Holt 1st for a pair of hens of great merit. The appearance of this latter class was extremely interesting, from the symmetry of shape and beauty of plumage.

We think we may report progress and improvement in the white Dorkings; they show more frame and stamina. Mr. John Choyce was 1st for cock birds, and Mr. J. Robinson for hens or pullets.

Mr. W. A. Taylor may be proud of the adult Cochin cock that won him Mr. Mapplebeck's cup, and Mr. Zurhorst's 2d prize bird was well worthy of his position.

Mr. William Sanday was 1st for cocks of 1869, with a young bird that will, we think, be hard to beat in future; Mr. Cattell was 2d, and Captain Heaton 3d. These names will give some idea as to the quality of the birds sent.

The classes for buff Cochin hens and pullets were an exhibition in themselves. All the best known breeders competed, and hard was the struggle, many who have been accustomed to substantial honours having to content themselves with commendations. Mr. W. A. Taylor took 1st for hens, and Mr. Cattell for pullets. The brown and partridge-feathered Cochins do not make progress. By dint of pushing they were made to take a more prominent place a year or two back, but they do not hold it either in quality or numbers. Mr. White and Mr. Amies won 1st for cock birds (old and young), and Messrs. Taylor and Tudman for hens and pullets.

Mr. A. O. Worthington and Mr. Swindell were the winners of the two 1st prizes for white Cochin cocks, and Mr. Smalley and Mr. Williamson for hens and pullets.

The competition in dark Brahmas was immense, the entries numerous, and the quality very high. The winning bird in the class for adult cocks was one that has seldom been equalled. He was exhibited by Mrs. Hunt, of Aldermasley. The Rev. John Bowen won 1st for young birds with an excellent chicken, in a competition of 70 birds. Mr. Lingwood was 1st for hens, and Mrs. Hurt for pullets. The light Brahmas have been fostered, praised, and pushed into notice by their own admirers, but they will never take the place of the dark ones, nor do we think they will ever equal them. The entries of them were small. Mr. Lacy and Mr. Crook won 1sts for cocks, Mr. Williamson and Mr. Crook 1sts for pullets and hens. Eighteen pens of Malays divided into four classes made but a poor show. A young Malay cock is not a bird that appears to advantage in a pen by himself: he gives one the idea of a boy in corduroys too small for him. The Crevecoeurs were excellent; seldom, if ever, has the class for the cocks of this breed been equalled. The increase of frame and size is great, and the improved constitution and stamina of the birds speak for the pains that have been bestowed on their development. Mr. W. R. Park won 1st prize, Mr. Zurhorst 2d. Mr. Park also won 1st with a pair of hens; Mr. Durbell for Houdan cocks, and Mr. C. Morris for hens. The Hon. C. W. FitzWilliam took all the 1st prizes for the La Flèche fowls.

Mr. H. Lane won in a canter 1st prize for Spanish cocks (adults). He won, but not so easily, the 1st for chickens. The Hon. Miss Pennant 1st for hens, and Mrs. Hyde for pullets. Black Hamburgs having made themselves a position, keep it. The birds shown were very good. Messrs. Mason & Walker were 1st for cocks, and the Rev. W. Sergeantson for pullets. In golden pencilled Mr. Whittaker won 1st in the class for cocks, and Mr. H. Beldon for pullets; this latter exhibitor was 1st for silver pencilled cocks, and the Duke of Sutherland took 1st prize for pullets.

Mr. W. A. Hyde took the 1st honours for golden spangled Hamburgs in both classes; Mr. H. Pickles for the best cock bird, and Miss E. Browne for the best pullets in the silver spangled.

Mr. Shaw took both the 1st prizes for black Polish, Mr. Nicholls for cocks, and Mr. Harvey for pullets in the golden spangled, but the competition was poor.

Mr. G. C. Adkins took a double first in silver Poland, winning both for cocks and pullets. The class for silver Poland cocks was a very good one indeed.

Class 59, for "any other variety," was more interesting than usual, the 1st prize being taken by Mr. Montresor, with a pen of very handsome Indian game called "Bajsa." The second was awarded to silkies, the 3d to Andalusians, and high commendations and commendations were distributed freely.

(To be Concluded next week.)

Calendar of Operations.

DECEMBER.—Steam Culture, in favourable climates, ought to be finished before this time, as stated in previous months; but to the general rule there are many exceptions. Lands, however, which could not be cultivated at an earlier date, should now be ploughed or smashed up without delay. And besides the exceptional examples of ordinary tillage, this is one of the best months for trenching and deepening old pastures or worn-out arable soils. To get the newly deepened or reclaimed land turned up to the frost and rains of winter is a cardinal point, upon which much of the success of the work depends; hence, as much as possible should be done over by steam in the early part of the month, for the alternate washing by heavy rains

and freezing of newly broken-up land has a powerful effect in sweetening it and preparing it for manure and the growth of crops. Indeed, without this preparation, it is in many cases hopeless to put manure or seed into it. Often exceptional examples, calcareous, gravelly, and sandy stubbles, leys and fallows, may be cultivated by steam as successfully just now as at an earlier period, so far as the mere work of tillage is concerned. It is otherwise with tenacious clay soils, which by this time have absorbed their maximum of water; and hence they more or less "squeeze" and "paste;" whereas, when worked in a comparatively dry state the furrow-slice breaks up into a thousand fragments, thus exposing nearly as much surface to the weather as do gravelly and sandy soils when ploughed or smashed at this season.

Horse Ploughing (in the absence of steam) is general this month in open weather. In early and ordinary seasons the stubbles are ploughed before this in the northern counties of Scotland, but in late seasons it is otherwise; and when much rain falls, the ploughs may have to be sent to the ley until the stubbles become sufficiently dry. Beans are sometimes sown upon the stubbles in February, and covered thinly by ribbing or ridging, in preference to poaching the land in December; and if frosty weather intervenes, manure may be carted and spread upon the stubbles. In favourable springs fine crops of Beans have been thus grown; but the practice can only be commended as the least of two evils. It is, however, only the heavier class of soils that are thus left to spring. When the ploughs have been removed from stubbles adapted for the growth of Turnips, they may be returned in a day or two after the rain ceases, and on no account should they be allowed to lie over uncultivated during the winter months; and now that steam can be hired in every county, there is no occasion for poaching.

Draining operations continue to be carried on with vigour, as stated last month. There is still a large breadth of the country undrained, and much that has been drained is only half done, while not a few of the pipes in the earlier drained land are beginning to give way, thus proving that the artificial drainage of land is not a permanent work. It further proves that the useful duration of a drain is anything but a uniform period. The practical conclusion to be deduced from this is manifest, viz., the drains require to be carefully examined at this season after every storm, to see if they are all flowing freely; and this is not all, for the fields upwards require close examination also, to see if wet places are making their appearance—in other words, to see if the whole field is being thoroughly drained. Where a drain ceases to act in young Wheats, Clovers, &c., the wet spots should be marked either by stake, or pit, or the intersection of cross lines, so that the injury can be repaired at the close of harvest, when no such wet spot may be perceptible. But when the old drain or a new one can be opened, the sooner the reparation is made the better. Where there are doubts as to the whereabouts of the defect in the drain, it is better to open cross-drains above and below, and to put new drains half-way between the old, than to open the old ones. The cross-drain should be sufficiently far above and below to make sure work. Two or three main drains angularly across the bottom of the field, when drains cease to drain off the water properly in wet weather, afford instant relief, and, in putting in such mains, the common drains crossed should be carefully examined, one by one, and new drains put in half-way between, when needful. On comparatively level land the drains, whether filled with stones or pipes, are liable to be silted up, and when there is much declivity, the water is liable to flow below the pipes, here and there, washing away soil, and thus derange the continuity of the flow in the drains. The soil above is also liable to be washed into the pipes. When such defects are suspected a cross-cut should be made in time and the drains examined.

Fat Stock.—December is pre-eminently a season when the fattening properties of our different breeds of cattle, and the merits of individuals in each breed are discussed and tested in various ways, so as to determine which is the most profitable for producers and consumers. The great fat stock exhibitions have begun, and it has been complained that in getting up stock for these meetings the fattening process is carried to an extreme; but the objection is no longer generally applicable. The process of fattening is a natural one, and where wholesome food is given in buildings properly lighted and ventilated, and when animals have a sufficiency of daily exercise, there is no fear of the abnormal productions complained of. The best kind of food for fattening neat cattle, sheep, and pigs, is no doubt, for each, an open question, which is subject to no little diversity of opinion. But although it applies to the few animals exhibited at our winter fat stock shows, it is otherwise with the great bulk of stock fattening for the shambles; for, generally speaking, the relative price of cake and corn, with the quantity and quality of the root-crops, hay, and straw grown on the farm, form together the practical solution of the question. It follows that each farmer has to solve it for himself. That which was the most profitable dietary last year may not be the best this year. Diversity of breed and age have each their peculiar demands, so that those who purchase stock for fattening select animals according to the food they have to give. Some Scotch and Welsh breeds pay more for corn than for cake generally; and corn, when ground into meal and mutton than oilcake. Of late years the consumption of meal has been on the increase, along with pulped roots and chaff, with a still greater increase in the weight of corn-fed meat from a given quantity of food consumed; and there cannot be a doubt that the improvement is based on sound principles, and therefore permanent. W. B.

SUTTONS' HOME-GROWN SEEDS.

SEASON 1869 AND 1870.

THE FORWARDEST PEA KNOWN IS SUTTONS' RINGLEADER.

The Royal Horticultural Society tested carefully the merits of the leading kinds of Early Peas, and in the *Gardener's Chronicle*, June 27, 1868, the following brief but emphatic statement appeared:—"The earliest form of all was Ringleader. Several of the Peas blossomed at the same time, but Ringleader was fit to gather first."

SUTTONS' RINGLEADER PEA is also the Best Variety for very Late Sowing. The following is extracted from the *Gardener's Chronicle*:—"Late Peas are indeed a luxury. I sowed Suttons' Ringleader the second week in July, and gathered one peck of well-filled pods the second week in September. I sowed two rows a fortnight later, and gathered Peas on October 6—a really good dish—much to the satisfaction of my employers. I have to-day (October 13) picked another good dish of Peas from plants which show no appearance of milder."—E. HAWTHORN, Gr. to P. Kemp, Esq., *Goldwell House*.

The following UNSOLICITED Testimonials are selected from a large number received to the same effect—

1868.—From Mr. CHARLES TURNER, *The Royal Nurseries*:—"We had our first gathering of Early Peas this day for dinner—Ringleader, sown in November in the open ground, and has never had any predecessor."

1868.—From Mr. H. BEANS, Gr. to Sir Charles Presley, *Fern Hill*:—"I gathered a fine good dish of your far-famed Ringleader Pea. I had it in row three seasons in succession, and never began gathering later than May 24."

1868.—From Mr. T. HOLLOWAY, Gr. to Lord Grantley:—"I picked your Ringleader Pea a week ago from this day."

1869.—From Mr. W. H. BARNES, Gr. to Major Roys, *The Oaks, Deal, Kent*:—"Your Ringleader Pea is still the earliest in cultivation and the best I ever crop. I planted them out in the spring, and gathered them on May 21 and sowed some of the seed, and planted again on August 20, and gathered from them the middle of October till November 4, 1868."

Price 2s. per quart, cheaper in large quantities.

The Largest and best EARLY PEA for Market Gardening purposes is

SUTTONS' IMPROVED EARLY CHAMPION.

This excellent large-podded Early Pea is only four days later than our "Ringleader," and quite a week earlier than *Drum O'Rourke* or *Sangster's No. 1*. It produces a crop of fine large green pods, and is specially adapted for growing in large quantities to pick green for market. The numerous Testimonials we have received, together with the increasing demand, prove its great superiority over the sorts usually grown for that purpose.

Price 1s. 6d. per quart, or much cheaper in large quantities.

THE THREE best POTATOS for the ensuing season are, for the Earliest Crop,

SUTTONS' EARLY RACEHORSE KIDNEY

The forwardest in cultivation.

The tubers nearly double the size of Walnut-leaf. Of the many Early Kidney Potatos sent out for some years past we know of none at all equal in earliness or productiveness to this. We speak with confidence, having planted in our trial grounds every new variety offered for sale. We have hitherto always sold out long before the season closed, and as our stock is limited, early orders are necessary to secure a supply.

Price 5s. per peck, cheaper by the bushel.

For the Main Crop,

SUTTONS' BERKSHIRE KIDNEY,

Raised and selected from among 40 Seedlings of the *Fluke*. Having planted it side by side with the different varieties of that class, we have proved it to be by far the best of them all, and quite a fortnight earlier. The tubers are of good size, very numerous, and remarkably clear skin. It is most valuable for the main garden crop, and has been remarkably free from disease, while other varieties growing close by were almost destroyed.

Price 5s. per peck, cheaper by the bushel.

For the Latest Crop,

SUTTONS' RED-SKINNED FLOUR-BALL.

This Potato has the peculiar merit of producing tubers all of full size, and weighing from 12 to 20 ounces each. While most other red varieties boil yellow, this is white, and is most correctly described as Flour-ball. For supplying the London dining rooms especially, we feel confident it will supersede every other kind when sufficiently known. In a field where many other sorts were all more or less diseased, our Red-skinned Flour-ball was entirely free, which we can only attribute to its remarkably vigorous growth. It is a Seedling, and we offer it now for the first season.

Price 7s. 6d. per peck, cheaper by the bush.

SUTTONS' NEW CATALOGUE for 1870

Is now in course of delivery.

Intending Purchasers can obtain it Gratis on application.

All Goods Carriage Free.

SUTTON AND SONS, SEEDSMEN TO THE QUEEN, READING, BERKS.

JAMES CARTER AND CO. have a beautiful Stock of Seedlings, in excellent condition, of their choicest Strains of CALCEOLARIA, CINERARIA, and PRIMUM, in 60-pots, fit for potting on immediately for early Spring Blooming. Worth the attention of those who have omitted to sow at proper time. Price, 2s. per 100, 3s. per 1 dozen.

JAMES CARTER AND CO. 27 and 28 High Holborn, W.C. and Crystal Palace Nurseries, Forest Hill, S.E.

New Geraniums

JOHN KEYNES begs to announce that he has secured the stocks of these two first-rate flowers which have excited so much admiration at the Royal Horticultural Society. First-class Certificates have been awarded them. They comprise *COLLENSHILL* (Escarbol), bright scarlet 7-petal, the finest of its class, and *LALY EDITH*, a bright purple 7-petal. These are the two best acquisitions of the season. They will be sent out in April next, at 10s. 6d. each. Drawings may be had on receipt of 15 postage stamps. (Cast a Street Nurseries, Secretary)

French Roses.—To Florists and Nurserymen.

LÉVEQUE ET FILS, 12 and 14, Boulevard de l'Hôpital, Paris, beg to state that they have a large Stock of strong Dwarf's of the best sorts of ROSES employed in Paris for the Market Flowers, such as *Ju de Margottin*, *Triumph de l'Exposition*, *Dr. Ru*, *Séateur Vainqueur*, *Baronne Prevost*, *Mme. Boll*, *Gloire de Dijon*, *Charles Margottin*, &c. Prices, 2s. per 100, and 25c. per 1000. Also Dwarf's of all good sorts (their choice), 2s. per 100, 25c. per 1000. TEA SORTS, NEW ROSES, and others. See previous Advertisements.

Autumn Planting.

PETER LAWSON AND SON will be glad to send their CATALOGUE of choice and useful TREES and ORNAMENTAL TREES and SHRUBS, free upon application. The stock of LARCHES, BOUTCH FIR, AUSTRIAN and CORSIAN PINES, &c., comprises some millions of healthy, well-grown plants, and special offers will be made for large quantities when personal inspection is not convenient. Edinburgh and London.

RICHARD SMITH'S LIST of EVERGREEN and DECIDUOUS SHRUBS, RHODODENDRONS, STANDARD ORNAMENTAL TREES, CLIMBING and TWINING PLANTS, with their generic, specific, and English names, native country, height, time of flowering, colour, &c., and general remarks, free by post.

RICHARD SMITH, Nurseryman and Seedsman, Worcester.

JAMES FAIRHEAD AND SON, SEED GROWERS and Merchants, 7, Borough Market, London, S.E., beg to inform their Friends and the Public, that their WHOLESALE CATALOGUE of SEEDS is now ready, and will be forwarded post free on application. Early orders are recommended, which will meet with prompt attention.

Established 1806

T. HANDASYDE AND DAVIDSON have to intimate that their CATALOGUE of NURSERY STOCK is now ready, and will be forwarded on application. Seed Warehouse: 24, Cockburn Street, Edinburgh. Nurseries: Brunstain Glen, Musselburgh.

WEBB'S NEW GIANT POLYANTHUS, Florist Flower, and GIANT COWSLIP SEEDS; also Plants of all the varieties, with double PRIMROSES of different colours. AURICULAS, both Single and Double; with every sort of Early Spring Flowers. LIST on application.—Mr WEBB, Calcut, Reading.

The Gardeners' Chronicle.

SATURDAY, DECEMBER 11, 1869.

MEETING FOR THE ENSUING WEEK

THURSDAY, Dec. 16—London 8 P.M.

THE EXTENSION SYSTEM of VINE MANAGEMENT is silently working its way. Those cultivators who tacitly ignore its claims to notice, find it advantageous to increase the breadth of foliage upon their Vines. Some allow the leading shoot to take its course down the back wall of the house; others, who have been in the habit, after the Vines have been stopped at the spring dressing, to remove every lateral branchlet except the leading one, and to stop that most resolutely as fast as it makes a fresh growth, now find it convenient to leave all the laterals, and not to be too particular about stopping them; while many allow the laterals to run entirely wild for the remainder of the season after the fruit is cut. Calling in the autumn upon a noted Grape grower, whose Vines are planted with a naked stem outside the house, we found a whole forest of shoots running wild over and almost covering the border; and upon going inside the houses we found that anything but close pinching or stopping had been practised. Our friend said he was afraid we should consider him a very slovenly Grape grower; but rallying him upon his change of practice, he confessed that the Vines the preceding season had carried an exceedingly heavy crop, and as they showed the effects of it in the following crop refusing to colour, the plants had been allowed to run comparatively wild, with the hope of increasing the root action. Quite right! But if a more extended leafage increases the root action one season, why not every season? And if it is good to restore the plants to luxuriance after being overcropped, why should it not be good for them at all times? To answer these questions would, however, open up a field much too wide for us to explore at the present.

The early failure of the Bishop Stortford Vines comes before us as a severe condemnation of the restrictive system of cultivating the Vine. While we have been exclaiming against worn-out borders and roots having gone wrong, it is not impossible that, if we could probe Nature's secrets to their ultimate result, we should find that the loss of vigour consequent upon the dwarfing system of pruning has had as much to do with our failures as unsuitable soil. A word of caution may also be gathered from this case, relative to excessively light and to the now fashionable aerated borders.

The Stortford borders, properly speaking, are not aerated—that is, no special provision was made for the purpose by piercing them with air drains; but from the exceeding porosity of the material of the borders, viz., London street garbage, local loam, brick rubbish, and bones, and the care which Mr. NASH took to prevent a foot being at any time set upon them, it is probable they were as well aerated as those where more trouble had been taken to secure that purpose. According to Mr. FOWLER, ten years may be considered the life of a Vine grown upon the Castle Kennedy plan; and if such is the fact, we must confess that the light is not worth the candle, especially when we know that Vines 10 to 15, or perhaps 20 times their age, grown upon the extension plan, continue to produce good fruit. Upon this latter point we have a fact or two to record.

In the county of Leicester, not far from Ashby-de-la-Zouch, are some fine old Vines, the history of which we had recently the curiosity to ascertain, and here it is—"The Vines here are 50 years old, and have been pruned upon the extension system for more than 20 years. I began to compete at Chiswick in 1841, and at the Royal Botanic Garden in 1848. I took the first prize the first time I exhibited at the latter place—the first time I showed Black Hamburgs; I took it on June 30 last, and have seldom missed the first prize during the whole time. I know I took it every show at the Botanic, for three years without intermission, and if I remember rightly for 12 lb., as well as for the single dish. I have had four first prizes for Grapes in one day, and I exhibited Hamburgs eight times in one season, and was first each time. I have exhibited at the Crystal Palace and many local shows, but have no conception of the number of prizes I have taken altogether." We need scarcely say the gentleman here referred to is the veteran Grape grower, Mr. M. HENDERSON, gardener to Sir GEORGE BEAUMONT, Bart. The Vineries at Cole Orton are limited in extent, so much so that probably the whole area is not so much as that of one of the vineries at Bishop Stortford; yet the Vines are in vigorous condition after 28 years of hard firing, and continue to produce fruit such as for general excellence can rarely be excelled. These Vines are pruned upon the "cut to the best bud" principle, and it matters not whether that be the first, fifth, or fifteenth—to that bud will the shoot be shortened. The quantity of old wood left in them is something remarkable, there being at the least four times the quantity that would be considered necessary for a systematic method of training. But there it is, and, viewing the results, we cannot say it is without its use. Not a strip of bark has been removed, we should think, for 20 years, and so gnarled and ragged do the Vines look, that if a young gardener from one of the modern fashionable Grape-growing establishments could be dropped into the gardens without knowing the history of the Vines, we have no doubt his first and fixed impression, until he saw the produce, would be to root them out, and cast them to the rubbish heap. But these Vines have yet good service to perform, and perhaps we shall hear of them and their produce when some of the modern wonders have sunk into insignificance.

Recurring to the Bishop Stortford Vines, if they are not already destroyed, it would be an exceedingly interesting and perhaps valuable experiment if Mr. NASH would test the feasibility of filling one of the houses with two or more of the old Vines. This could be effected by laying two or three of the best Vines down horizontally, and at proper distances, taking up a shoot to each rafter, and stopping or removing the remainder. If the increased growth should be accompanied by increased root action, which it must be, then fresh vigour would be imparted to the plants, and possibly they might go on bearing for a century or more. At Cliveden, where Mr. JOHN FLEMING found a mixed house of Muscats and Hamburgs a complete failure, shaking and shrivelling constantly taking place, he cut out all the Vines except one Muscat, from which he filled the house, and it answers completely. Why should not the Bishop Stortford Vines do the same? We hope Mr. NASH will make the experiment, not only for his own gain, but in the interest of practical investigation.

The engraving which we here introduce, shows how the Vines retained for such an experiment may be trained into a systematic form. Presuming the old Vines to be closely pruned and left

down horizontally we would select, when they broke into growth in the spring, the strongest shoots at about 30 inches to 3 feet apart, and stop all the other shoots at the fourth or fifth leaf, as root encouragers, until such time as the shoots retained got fully established. Then, supposing the rafter to be 15 or 20 feet long, we would establish spurs or gnaws at 3 feet or 4 feet apart, and nearly opposite each other upon each branch, and from these spurs in alternate years we would take the young shoots which would produce the crop in the following season. The engraving supposes the Vine to be thoroughly established, and pruned for the succeeding year. B are the young shoots that will produce the crop next season, say 1870, and will then be cut out to the bud nearest the main stem; while A are the spurs from which the shoots will be produced to carry the crop in 1871. In this way it will be seen the pruning of the Vine is reduced to some half-dozen cuts upon each rod, and the removal of the laterals—a system which any person may understand.

The advantages of the system will be a very large reservoir of sap stored up in the Vine at all times, ready to repair any shortcomings on the part of the roots, consequent upon cold weather; and, secondly, a regular succession of young shoots which have not borne fruit, for the following season. These we regard as root

A. Bearing branches for next year
B. Spurs for successional crop

promoters, and our experience is much at fault, and our physiological knowledge also, if they would not be found to play a most important part in the economy of the plant. With such shoots we must get fine well-matured buds; and such buds—the treatment being suitable—are the precursors of fine crops of well-matured fruit. P.

— WE are requested to state that the PRIZE of 5*l.* 5*s.* offered by Lieut.-Col. SCOTT, R.E., secretary of the Royal Horticultural Society, for an essay on the PRINCIPLES OF FLORAL CRITICISM, will be awarded on Wednesday, May 4, 1870, and not on January 19, as previously announced. We may add that many correspondents complain of the vagueness of the proposal, and ask whether an essay on the "correct standard" for florists' flowers be intended, or one on the proper method of judging plants in general at exhibitions. Perhaps some light might be thrown on the matter, if the names of the judges were announced. The subject is one of so much interest and importance that we trust fuller information may be forthcoming, and for our own parts we should like to see the matter treated in a broad catholic spirit.

— The following communication relating to the EVERBEARING ANDINE STRAWBERRY, from Dr. SPRUCK, the South American traveller, whose services in the cause of botany and horticulture are beyond all praise, will be read with much interest:—"The 'Ever-bearing Strawberry,' from the highlands of Mexico, so well described by your Canadian correspondent, 'Vesta,' is doubtless one of those varieties of *Fragaria vesca* commonly cultivated throughout the Andes within the tropics, where the perpetual spring of that favoured region has had the effect of rendering the Strawberry perennially fruitful, and many of the deciduous-leaved trees of Europe evergreen. In the Equatorial Andes the province of Ambato is famed for its Strawberries, which equal in size and flavour some of our best varieties, and which are to be seen exposed for sale in the market place of Ambato every day in the year. They are cultivated at an altitude of from 7000 to 9500 feet above the sea, where the mean temperature of the year ranges between 59° and 67°; but the best are grown a little way out of Ambato, as you go towards Guayaquil, on the slopes of Guachi (lat. 1½° S.), at near 9000 feet, and in a mean temperature of 60°; where, however, the thermometer does sometimes descend to the freezing point in the early morning, perhaps half-a-dozen times in the year, and scarcely ever on two successive days. Down-right rainy weather is almost as rare as frost, and the climate is, on the whole, dry. The soil is entirely derived from matters ejected by the adjacent volcanoes, and consists chiefly of loose sand and

baked mud, to appearance almost utterly sterile, but by the aid of irrigation it is rendered exceedingly fertile, gardens, corn fields, and meadows meeting the eye on all sides, wherever water can be thrown over the soil. From the main 'acequia,' or watercourse, water is every day turned into the furrows that alternate with the rows of Strawberries, or Maize, or Alfalfa (*Medicago sativa*), or Meadow-grass. A native poet, describing this very spot, speaks of the fertilising streamlets—

'Entre cespes dormidas ó entre frescas.'
(Sleeping in the turf, or among Strawberries.)

Without this artificial aid, a moisture-loving plant, like the Strawberry, would hardly survive under the vertical sun of the equator, even at that great altitude; but near Quito, where the climate is much moister—10 months out of the 12 being rainy—little irrigation is needed. Quito, however, is near the upper limit of Strawberry cultivation, and the fruit is much inferior to that of Ambato. The Strawberry is generally considered a true native of the Andes of Ecuador, and I have seen it wild in two or three places, especially on the northern declivity of Pichincha, at 10,000 feet; but even there it grew by the side of a much-frequented path; and as the Indians appear to have no native name for it, but call it by its Spanish names 'Fresa' and 'Frutilla,' I can only consider it an introduced plant. However that may be, it is known to have been cultivated there fully 800 years; and its character of perennial fruitfulness—whether native to it or acquired—would doubtless be preserved in any other locality (so far as changed conditions would allow) for a good number of years, especially if propagated by stolons; so that its introduction to England, as the foundation of (at least) an autumn-fruiting Strawberry, seems highly desirable. Whether it will retain its everbearing property here when raised from seed, will, I hope, soon be tested, as seeds of it, obtained from Ambato, have already been sown near London, by Mr. D. HANBURY."

— The Royal Horticultural Society of Ireland has announced its intention to hold a SPRING EXHIBITION of HYACINTHS on the 24th of March next. The exhibition is to include Tulips, Narcissi, and Crocuses, as well as other spring flowers. Of Hyacinths there are four classes provided for amateurs and two for nurserymen, besides various special prizes, one of which is a Gardeners' Cup, to be provided by subscription, and held by the gardener who wins the greatest number of prizes at this show.

— Don't say modest worth is not appreciated. Of course not, when neither time, season, nor place are favourable for the exercise of the softer virtues; but alter the conditions, and then see. Here is an illustration from the *Natal Mercury*, published at Durban, on September 25 of the present year:—"Mr. PEBBIN has kindly left at our office a nice little *Primrose* and a fine *Dandelion*, both grown in his garden. The latter grows admirably, and the former with care in a moist and shady spot. These are only some of the many plants which Mr. PEBBIN has carefully planted and reared in his garden in the city."

— MM. PLANCHON and LICHTENSTEIN, in recently commenting on the fact of the existence on Vine leaves of GALLS which shelter families of Phylloxera, similar to the Phylloxera vastatrix of the roots, suggest that the insect found on the leaves is probably a transitory form—in itself injurious—of that which destroys the roots, and with them the entire stem of the Vine. According to this hypothesis, it will be necessary to admit two states of the Phylloxera vastatrix—the gall-inhabiting and the root-inhabiting. The former, they go on to say, should be carefully compared with the Pemphigus vitis folii of ASA FITCH, which, according to that learned entomologist, produces galls upon the leaves of Vines in the United States of America. The latter has perhaps its analogue in the so-called thrips, which, according to M. SÉBIGNÉ, of Narbonne, infests the Vines of the same country. Nothing is easier than to recognise the galls, which are often very numerous on the leaves, especially towards the ends of the twigs, to which they give a crisped appearance.

— Dr. TÉLÉPHE DESMARTIS communicates to the *Indicateur Vinicole* the following intelligence concerning a REMEDY for the VINE DISEASE. In the vineyard under his observation there were in the spring about 60 Vine stocks attacked with the disease. They were treated with earth mixed in the proportion of 8 or 10 per cent with coal-tar. Of the 60 stocks, 50 have now recovered their vigour perfectly, and the Grapes have swollen and ripened; five present a doubtful appearance, and the remainder have succumbed to the disease. M. DESMARTIS also mentions having found the Phylloxera on the leaves, from which he concludes that the evil is progressing. The insecticide of M. GORREAU, of Saint-Loubès, is favourably spoken of.

— The Friday evening meetings of the ROYAL INSTITUTION are arranged to commence on the 21st of January. The evening discourses before Easter will probably be given by Prof. TYNDALL, Prof. ODLING, Prof. RUSKIN, Dr. CARPENTER, Mr. CLIFFORD, Prof. SYLVESTER, Dr. ROLLESTON, Prof. ROSCOE, Prof. HUXLEY, Prof. WILLIAMSON, and Dr. BLACKIE. The Christmas lectures (adapted to a juvenile auditory) will be by Prof. TYNDALL, who has chosen Light for his subject; the first will be delivered on the 28th inst. at 3 o'clock. Arrangements have been made for the following courses before Easter:—On the Architecture of the Human Body, by Prof. HUMPHREY, F.R.S.; on the Vegetable Products of Chemistry, by Prof. ODLING, F.R.S.; on Meteorology, by Mr. ROBERT SCOTT; on Plant Life as contrasted to that of Animals, by Dr. MASTERS, F.L.S.; Deductions from the Comparative Anatomy of the Nervous System, by Prof. ROLLESTON,

F.R.S.; an Introduction to the Science of Botany, by Prof. MAX MÜLLER; on the Sun, by J. LOCKYER, F.R.S. After Easter, the following will be delivered:—On the Principles of Political Philosophy, by Prof. BLACKIE, F.R.S.; on the Principles of Astronomy, by Prof. TYNDALL, F.R.S.; on the Principles of Geology, by Prof. ROLLESTON, F.R.S.; on the Principles of History, by Prof. ROLLESTON, F.R.S.

— We perceive that the Editorship of "GARDENER" is in future to be entrusted to Mr. THOMSON (Dalkeith), and Mr. RICHARDS (London), *Arcades ambo*. We hope that the success of this well conducted magazine will be enhanced by the new arrangements.

— We are informed that at the meeting of the Royal Horticultural Society, on Tuesday, December 21, the following prizes were offered for competition, viz:—By the Rev. G. KEMP, F.R.S., and member of the Fruit Committee.—1. For the best winter dessert of Apples and 3 dishes of each. 3*l.*, 2*l.*

PLANT PORTRAITS.

ALOCASIA JENNINGSII.—*Flores des Serres*, t. 11, p. 11. *Illustr. Hort.*, t. 535. Araceæ. This beautiful plant which has the large cordate ovate bright green leaves in sections between the veins with broad wedge-shaped brown patches, and is now pretty generally known, is represented in the above cited coloured figures.

ANTHELIUM LANCEOLATUM.—*Bot. Beech.*, t. 14, p. 14. A stove perennial, with lanceolate stem 1/2 green leaves long, narrowed to the base. The tall peduncles support brown spadix, which issues from a sheath of yellowish green spathe. The plant was introduced to the Royal Gardens at Kew from the West Indies.

APHELANDRA ACUTIFOLIA.—*Bull. Mag.*, t. 538, p. 14. One of the most brilliant flowers of the present group. It forms a stove shrub of erect habit, the stems furnished with broad oblong ovate acuminate leaves terminated by imbricated spikes 4 to 6 inches long of deep vermilion red flowers, the upper lip of which is and projects forward, while the lower lip consists of oblong-obovate spreading lobes. It has been introduced to Peru by Messrs. Veitch & Sons.

ASPARAGUS SCANDENS.—*Rej.*, t. 21, p. 11. A remarkably elegant climbing greenhouse perennial, first met with in cultivation, and recently re-introduced from Africa by Mr. Wilson Saunders. The annual, unarmoured stems bear usually in threes, numerous linear-pointed leaves, which on the ultimate branches nearly in one plane. The whitish pendent flowers on these ultimate branchlets, and are succeeded by orange-coloured berries. It is an admirable climber in greenhouses or conservatories, and will readily climb up a small cord, and may then be readily removed to any position it may be required to occupy.

BETULA ALBA PENDULA ELEGANS.—*Rej.*, t. 11, p. 11. fig. 33. Betulaceæ. A deciduous weeping tree, of ornamental character, differing from the ordinary Birch (which has the branches curving downwards) in its rounded form to the head in having the long and flexible branches directed perpendicularly towards the stem, which gives to the tree a distinct and truly weeping aspect. It has been introduced to MM. Bonamy frères, of Toulouse.

CAUCANTARIA HENRICI.—*Bot. Mag.*, t. 572, p. 11. Scrophulariaceæ. This elegant greenhouse or half-airly shrub has been introduced by Mr. Anderson-Henry, after whom it is named the Amies of Guayaquil, whence it was sent by Prof. A. It is of slender erect habit, with rather large elongated leaves, downy beneath, and produces for some time a profusion of small yellow flowers, both upper and lower lip inflated, so as entirely to close the mouth. It is allied to *C. hysopifolia*.

CERUS LINDLEYI.—*Bot. Mag.*, t. 577, p. 11. Cactaceæ. Described by Dr. Hooker as being one of the most beautiful columnar Cacti in the succulent house at Kew. It is erect and very sparingly branched habit, and has a height of 12 feet, and a diameter of from 4 to 6 inches, stems being 5 or 6 angled, contracted or jointed at the base with thick, flat, straight, rounded ribs, an inch in depth, and bearing on the terminal joint one or two flowers, 10 inches in diameter, which are white, with a green tinge towards the outside. It is a native of the Guayra, and Curaçoa, and has recently been introduced from the United States by Mr. W. Bull.

COREOPSIS ARISTATA.—*Hort.*, t. 18, p. 18. fig. 18. *Hort.*, 1869, 72, with tab. Composite. A much-branched glabrous annual, growing about 3 feet high, and with deep pinnatifid leaves, living corolla lanceolate, segments, and producing large rayed flowers, the inner rays of a small single fluted tube, and the outer rays of a single panel, and of a fine orange colour.

CORYLINA GILGOLLEYI.—*Bot. Mag.*, t. 568, p. 11. A greenhouse shrub, of considerable promise as an ornamental plant, with the usual erect, palm-like habit of the tree, forming a neat head of recurved leaves, and a small branch in breadth, striated in an oblique direction with white, and in age acquiring more or less of a red tinge, especially at the margin. It has not, however, been highly coloured in the figure above given. It has been found in New Zealand and Australia, by Mr. Gilgoley, and was first exhibited at the Ghent show in 1868, by M. Ambroise Verachaffelt.

CROCUS ORPHANIDES.—*Bot. Mag.*, t. 576, p. 11. Iridaceæ. A flowering and very distinct ornamental variety. It is furnished with large bottle-shaped corolla, with elongate leaves, which are developed with the pedicels, and are without flowers, which latter spread to a diameter of 2 or more, and are yellow in the throat, whence numerous multifid stigmas of a deep orange-red. It is a native of Greece, and was received at Kew from Professor Orphanides, Athens.

GEONOMA LACERATA.—*Floral Mag.*, t. 446, p. 11. A visional garden name for a neat-growing stove Palm, of dwarf close habit, the leaf-stalks of which are sheathing at the base, and terminate in broad bilobed leaves with an excurrent thread in the sinus, the lobes laterally split at the apex, and the surface ribbed, appear plicate. It is a native of Central America, and seeds were brought home by Dr. Seemann.

GEONOMA SEEMANNI.—*Floral Mag.*, t. 446, p. 11. A visional garden name for a remarkably distinct and dwarf stove Palm, remarkable for the young state for its leafy character, and for its established plants, which are from the top of the angular petiole, and form the fish-tail-like lobes. Introduced by Dr. Seemann from America, and cultivated by Mr. Bull.

ILEX AQUIFOLIUM CILIATA AUREO-MARGINATA.—*Floral Mag.*, t. 1811. Aquifoliaceæ. An elegant hardy shrub, of a somewhat close, erect, formal habit, and quite the character of the small saw-leaved green Holly, is not uncommon in gardens. In this case the lanceolate leaves, which are finely saw-toothed at the

... and give the plant a bright ...

THE DEODAR.

I OBSERVE that some correspondence has taken
 ... this noble tree, the Cedrus Deodara,
 ... I do not find that much fresh light has
 ... thrown on the subject. I fully concur with my
 ... friend, Mr. Frost, in recommending the Deodar to
 ... planted to a large extent, if only as a noble free-
 ... tree, and I have observed that it grows well
 ... almost any kind of soil. It is one of the noblest
 ... grandest trees we have for our landscapes, on
 ... of its distinct colour and elegant growth, white
 ... invaluable for early game cover, for making
 ... a shelter against winds and storms, or for
 ... in open cleared places in our woods and parks,
 ... in ravines, and on the slopes of hills, either
 ... other Conifers or along with deciduous trees.
 ... introduced, now grand it would be in our
 ... every day in the year, but more particularly
 ... autumn.

I have observed that the Deodar stands bravely
 ... the sea breezes, and will grow well in the
 ... of the sea. For evidence that it will also grow
 ... on poor sandy and brashy soils we have only to
 ... at its condition about Farnborough and Aldershot
 ... vicinity of the Haldon Hills, and in many other
 ... sandy hungry soils, where it may be seen in a
 ... thriving state.

There is in this country—not only in Hants, Surrey,
 ... Devon, but in other counties also—thousands and
 ... of thousands of acres of poor, hungry, sandy,
 ... shaly, gravelly, uncultivated soil, that has not yet
 ... turned to any account, and which might be
 ... planted with various Conifers, if trenched,
 ... ditched, or in some way loosened up by steam-
 ... or other means. Thus treated they would add
 ... beauty of our landscapes, would be of great import-
 ... affording shelter to exposed tracts of country,
 ... time would also greatly add to our wealth, were
 ... to be methodically set about and carried out
 ... principle. Besides, after thus yielding a
 ... of timber trees, this now poor useless soil, not
 ... brought into cultivation, would for a future gener-
 ... than Rye-grass, Clover, and other herbage for feed-
 ... making meat and butter. The growing
 ... crops would follow after; and at length the
 ... be available for forming into noble parks,
 ... and farms, for the maintenance of deer,
 ... and bullocks, if only it were judiciously cleared
 ... trees enough were left to form a shelter to the
 ... country and adjacent crops. This
 ... also be the means of enticing the clouds
 ... such localities there to drop their moisture and
 ... and of breaking the brunt of the cold, searing,
 ... wind. If a mixture of the beautiful Conifers
 ... introduced into the country during the last 50 years
 ... planted, rising up with the older com-
 ... kinds as sheltering nurses, to be methodically
 ... in due season, one might soon observe what
 ... would prove most suitable for the various soils,
 ... and aspects. The new, good, and well-known
 ... varieties could be first planted at from 50 to
 ... feet apart, according to kind and circumstances;
 ... up with others at half the distance, and
 ... up with the common *Pinus* as

... to the Deodar as a timber tree, I do not
 ... at the present time there is any reliable
 ... obtainable as to its value as grown in this
 ... nor has any tree, fully grown, been taken
 ... and sawn up in the United Kingdom. Like all
 ... Cedars and Conifers, it requires considerable
 ... In my opinion, nothing under a century can
 ... its value, and then, as with the Scotch Fir,
 ... and other Conifers, it must be grown on various
 ... and in different situations and aspects, through-
 ... the Kingdom, before any fair estimate can be formed
 ... its value. I have not yet seen a tree above
 ... not more than 30 feet high, though I have
 ... the produce cones for years, and have seen
 ... produced from home-grown plants, as well
 ... from the home-grown seed.

The Deodar will strike freely from cuttings, and
 ... the plants thus obtained will grow into as hard-
 ... seedlings is well-known, so that any
 ... plants can now be produced. As to waiting
 ... the value of Deodar timber of our own
 ... that is nonsense, for the question is one, the
 ... of which must be left to coming
 ... I have, however, seen enough of this
 ... and noble tree in different places, and under

various aspects, to justify me in saying, plant—yes,
 ... plant it extensively. Those of us who live with enjoy
 ... its beauty as a distinct and splendid landscape tree,
 ... there is little doubt that future generations will
 ... both enjoy its beauty, and have the satisfaction of
 ... turning it to account as a useful timber tree. James
 ... Barnes, 1, Rolle Street, Ermslow.

ORCHID-EATING INSECTS.

Centrinus laticornis.—Will you allow me to add a
 ... word to "I.O.W.'s" interesting chapter on the above
 ... subject at p. 1230 of the *Gardeners' Chronicle*? I think
 ... I am due to stamp out his tale by identifying the cur-
 ... culionidous larva, of which he found two specimens in
 ... the green Orchid leaves, attached to him. Some time
 ... after he received these (and while he was, I believe,
 ... abroad) I received two perfect curculionidous insects
 ... from the same source whence he got the larva. They
 ... correspond in size to them, and are, I have little doubt,
 ... the perfect insect into which other larvae, the same as
 ... his, but which had escaped notice, had turned after
 ... undergoing their metamorphoses.

The species belongs to the genus *Centrinus*, and in
 ... size and appearance comes close to the North
 ... American species, named by Say, *Centrinus scutellum-
 ... album*, but is quite distinct. There are also one or two
 ... Brazilian species which are very like it, both in size and
 ... sculpture, but neither does it correspond with any of
 ... them. I cannot find in the books any species described
 ... which agrees with it; nor is it represented in the
 ... British Museum. Considering how rich that museum
 ... is in Curculionids, I have therefore little hesitation in
 ... regarding it as new, and describing it as such.

I have made inquiry as to the source from which it
 ... has originally been imported, but find that this is not
 ... known, although it was thought that it might be South
 ... America, as its finders had received importations not
 ... long before from that continent. It was only discovered
 ... by its eating the leaves of the Orchids, and it does not
 ... particularly attack any kind or species, but all such as
 ... have soft leaves, as *Dendrobium* and *Epidendrum*.
 ... It gets down into the heart of the shoot, and it is
 ... only when the leaves grow up that the damage it has
 ... done is perceived. As it attacks both *Dendrobium*
 ... from India and *Epidendrum* from South America,
 ... its food gives us no clue to its native country, but as
 ... the genus *Centrinus* is exclusively American, and the
 ... present species is generally reputed to know American
 ... species, and the gentleman who found it had lately
 ... imported species from South America, there can be no
 ... doubt that it comes from the New World, and in all
 ... probability from South America. For the same
 ... reasons we may rest assured that its natural food
 ... is not *Dendrobium* but *Epidendrum*, and I therefore
 ... think I am warranted in describing it under the name
 ... of *Centrinus Epidendri*.

CENTRINUS EPIDENDRI.

Affinis *C. scutellum-album*, totus niger, thorax punctato-
 ... punctatus ante basin latiore. Elytra humeris promin-
 ... tibus, cancellato-punctato-striata, long. 2 1/2 lin., lat. 1 1/2 lin.
 ... Habitat in America meridionali.

Of the same size and very similar to *Centrinus scutellum-
 ... album*, but wholly black, somewhat narrower, and
 ... with the rostrum stronger, the thorax more deeply
 ... punctate, more convex, and widest a little before the
 ... base instead of being widest at the base. The shoulders
 ... of the elytra are more prominent, the striae are
 ... cancellate-punctate-striate and more distinctly defined.
 ... A. M.

CONTINUITY OF GROWTH.

I HAVE read all that has appeared on the subject of
 ... root versus top action with great interest. The argu-
 ... ments on both sides seem somewhat weakened in force,
 ... by ignoring the great fact that growth is continuous in
 ... both root and top. The rest of plants is not the torpor
 ... of death, but something more akin to the sleep of
 ... animals. Now, in sleep, no vital function is arrested.
 ... The repose of the body may check the energy of their
 ... working, but they work on nevertheless, and the circula-
 ... tion of fluids never stops from birth to death. In a
 ... lesser degree this is likewise probably true of plants.
 ... At no period of their existence is there a complete
 ... stoppage of fluids, unless indeed the life of both root
 ... and branch is arrested, and bound hard and fast in the
 ... iron fetters of frost. Therefore, instead of dwelling
 ... on the question when the sap begins to flow in either
 ... root or branch, it would be more pertinent to inquire
 ... when, if ever, it ceases flowing?

This question elicits another of great importance to
 ... this inquiry, and that is, whether there may not be
 ... a circulation of fluids without any apparent extension
 ... of parts? We know that in the animal economy every
 ... vital function may be performed for years without any
 ... addition to the size and weight of the body. The new
 ... matter simply supplies the waste of the old, and the
 ... equilibrium between the two forces of waste and
 ... supply is maintained. Now, is it not possible that
 ... something like this may take place during the wintry
 ... sleep or rest of plants? The languid action of root and
 ... branch during the cold winter season may simply
 ... supply the waste incident to the season, and in a
 ... normal state of the plant do but little more, in an
 ... abnormal condition the roots, at least, can so ration
 ... nutrients and feeds from themselves as to repair
 ... the aid of water as must be well known to every
 ... practical man. I do not profess that there is no
 ... stagnation of fluids, and makes an inextinguishable root in
 ... the theory that spongioles cannot be formed without
 ... the ministry of the water, sending down new matter
 ... for that purpose. Now every winter millions of such
 ... spongioles are emitted by thousands upon thousands of
 ... transplanted plants, in such profusion and with a power
 ... and persistency that destroys the basis of any such
 ... absolute theory. But leaving this matter, and turning

to the point that there may possibly be actual circula-
 ... tion and nutrition without the addition of new matter
 ... or any extension of parts at all it is much more obvious
 ... that there may be extension of parts which we cannot
 ... see by a mere superficial examination with the naked
 ... eye. Growth is so slow in its advance, so hidden in
 ... its progress, that we can only see it by a long and
 ... visible program. We cannot even for certain say
 ... positively whether it is in a growing state. Hence the
 ... uncertainty and worthlessness of the phrases, roots
 ... had or had not begun to grow. The roots had never
 ... ceased growing, and at the very moment that they
 ... were pronounced torpid, they were doubtless feeding
 ... the plant with all necessary supplies. The very position
 ... of the roots, far down in the ground beyond the reach
 ... of ordinary frost, preserves them from the effects
 ... of the cold. And thus, doubtless, in what is termed the
 ... dormant season, they are not dead, but they are dormant. But
 ... this expression, the dead season, applied to plants, is
 ... misleading. The truth is, it has nothing whatever to
 ... do with death, it is but another and a different phase
 ... of life.

Even the leaf falls, as Professor Owen has so beauti-
 ... fully told us, not because an old leaf dies, but because
 ... a new leaf is born; and this new leaf all the winter
 ... light and beauty next year. True, the baby leaf may
 ... be cradled in storm, swaddled round with gummy robes
 ... of shivering ice, and furnished with a swan's-down
 ... cloak of drifting snow, but all these but work together
 ... for its good, and long to send it forth in the best time,
 ... and in the most beautiful array. And all these
 ... apparent hardships, even a season of sunlight, every
 ... passing zephyr nears the baby with warmth,
 ... and comforts it as with a mother's lullaby. The
 ... warmth of spring does not find the bud as the winds of
 ... autumn do it, slowly and successively it has been advancing,
 ... like the chrysalis, through its long place, and when
 ... spring comes its mission is not to arouse the dead, but
 ... to furnish a suitable air medium for the manifestation
 ... of the living. Leaves leaf out from their scaly
 ... envelopes, and seeds from their tiny cells, less from
 ... an invitation from without, than by the irrepressible
 ... impulses of a struggling and advancing life within.

The theory of a continuity of circulation and
 ... nutrition, if accepted, will enable us at least to assess
 ... of their proper worth the terms—dormancy and growth.
 ... It may also help to explain some of the facts that have
 ... been adduced by your correspondents, for I believe
 ... that this continuous tendency to grow is not confined
 ... to any particular part of a plant. It is manifested
 ... by root and branch, leaf and bark, and when any
 ... of these parts are separated the one, or the other, the
 ... detached portion make a new growth, as if it were
 ... growth as before, and it is not until the spring, for
 ... how long a time such a cutting may be kept in the
 ... ground, and have been noticed to live and form branches for one,
 ... two, or even three years, without a vestige of root.

Roots, as already observed, are likewise frequently
 ... formed without the aid of leaves. More marvellous
 ... still, roots have the power, not only of living, but
 ... actually creating both stems and leaves for themselves,
 ... and thus forming every portion of a plant; while the
 ... universal practice of striking cuttings shows that stems
 ... have the power, not only of subsisting without roots,
 ... but likewise of creating them. Mr. Knight, of Floors,
 ... gives a case at p. 1183 of this growth of shoots without
 ... the formation of roots. Last winter, or rather this
 ... spring, I had more than a hundred illustrations of the
 ... formation of roots in abundance without the develop-
 ... ment of a single leaf. This happens often when an
 ... Oleander leaf is struck as a cutting in water, we
 ... have seen such a leaf produce roots in abundance
 ... year after year for several years, but not a single
 ... leaf (Eds.) On the 24th of December last year
 ... I cut half a house of Muscat Grapes, and stored
 ... them away on the French method. The last of
 ... these Grapes were used on the last day of April. As
 ... they were cut during the spring, I observed that most
 ... of the spurs of wood were forming roots, and as the
 ... water continued sweet, the spurs were left until
 ... September, when the fruit-room was cleared for summer
 ... fruit. At that time most of the bottles were half full of
 ... roots, though in no case had a single leaf been fully
 ... developed. The fruit room was cool and dark—hence
 ... I presume the energy or growing power of the spur
 ... went rootwards, instead of, as in Mr. Knight's case,
 ... leaf and shootwards, thus confirming Mr. G. Dawson's
 ... view, that the direction of growth is much dependent
 ... on atmospheric or other circumstances. The fact of my
 ... Vine shoots forming roots so plentifully without leaves
 ... also knocks an unmendable hole in the theory so con-
 ... fidently advanced by Mr. M'Millan (p. 1161), that the
 ... roots have absolute and entire control over the entire
 ... tree, and that spongioles cannot be formed without the
 ... aid of leaves. In all these cases the shoots acted wholly
 ... without roots, and formed them in plenty, mostly
 ... thick spongioles too, without a leaf at all. However,
 ... as this gentleman proceeds to say that the leaf draws
 ... the sap to it in much the same way as a valve draws
 ... water in a pump, and as a pump valve does not draw
 ... water at all, the two theories may be dismissed together.

In the case cited by Mr. Gull at p. 1164, that has
 ... originated this discussion—the growth of the roots of
 ... one Vine ceasing when grafted upon another,—this
 ... case, if I understand it rightly might be due to the
 ... mere substitution of force. I have read Mr. Gull's
 ... short note carefully, and it seems that the roots of one
 ... Vine were left in the ground, and that when the
 ... union of the Muscat was completed upon the Royal
 ... Vineyard, the roots of the Muscat Vine ceased to grow.
 ... If such is the true version of the case there is no
 ... mystery about it, and the present discussion has not
 ... touched the question involved in it. So far, that case
 ... is not a matter of top versus root, or of root versus
 ... top, but simply of one root versus another, and of the

stronger superseding the weaker. The two sets of roots were more than were needed for the sustentation of one shoot, and the stock set aside the roots of the scion as soon as the union by approach was consummated. When two currents of unequal volume meet, the stronger will dam up the weaker, and that may possibly be all that happened here.

The other cases advanced seem to be sufficiently explained by the continuity of growth here contended for. In what direction that growth will be first manifested, will be to a large extent determined by external circumstances, and the internal wants of the plant. In cases of injury, especially underground, the growing powers will be first directed to their repair. This is abundantly proved by the extraordinary activity of roots injured by transplantation. There is not only an unusual effort made to restore the loss of absorbing power, but likewise to extend the roots, so as to hold the plant firmly in its place. Call it plant instinct, the faculty of self-preservation, or what you will, the fact remains indisputable, that there is an abnormal activity of root action in all transplanted plants immediately after their removal, compared with those that have not been disturbed. Mr. Anderson (p. 1064) cites a case to the contrary, but that case, as it stands, is not conclusive; we need other data to determine its value, chiefly the time of removal, and the bottom and top temperature afterwards. If the Vine tops were immediately placed in a higher temperature than the roots, or even if the temperatures were equal, and growth instantly excited in the top, the result would be as Mr. Anderson states. But had the roots been placed in a higher temperature than the stems, and especially had sufficient time been allowed the roots to repair the injury of removal, the order of growth would most probably have been reversed.

In a state of nature, I believe, root and top action proceed simultaneously. Under artificial or accidental circumstances either root or top growth may be made to precede the other at pleasure to a limited extent. But growth is ever continuous, and there is no such thing during the life of the plant as an entire stagnation of fluids, unless induced by frost or intense drought. While each plant is a whole, that whole is made up of an endless series of independent units, most or all of which have an individual power of growth in themselves, while contributing their quota to the growing force, strength, and beauty of the entire plant. Moreover, growth can be hindered or accelerated, but not entirely arrested, by art, without the destruction of the plant. As to the precedence of root or branch it is more safe and successful practice to stimulate the roots into vigour by the application of heat and moisture, before exciting the top, as without doubt the supplies sent forward by the roots are essential to the healthy development of leaf, flower, and branch, and to the maturation of the fruit. Continuous root action is needed to supply the wants and stimulate the vigour of the whole plant; and notwithstanding what may be said to the contrary, most practical men will agree with me that it is quite possible to excite root action, and cause it far to outrun that of the top. Bulbs may be held to be exceptional cases, possessing in themselves sufficient stores of organisable matter to develop either root or stem without external aid. But ripened buds are endowed with somewhat similar powers, and by keeping the crowns of bulbs and of buds alike cool and dry, while the roots of both are warm, root growth can be made without arousing the top into activity. Our mode of treating bulbs after potting is a daily illustration of this, and I

have seen Rose pots, destined for early blooming, crammed full of spongioles before a single bud had burst into leaflet, by simply plunging the pots in bottom-heat out-of-doors in November. D. T. Fish.

NEW PEAS.

WE are indebted to Messrs. Carter & Co. for the use of the block representing one of their newly-raised Peas—the Cook's Favourite—concerning which we reported as follows in August last:—"The most promising variety in this lot appeared to be one called Hundredfold or the Cook's Favourite, which was obtained from Laxton's Prolific and Ne Plus Ultra, height 4 feet, a late prolific variety (about fourteen days later than Supreme), with remarkably fine pods, which are slightly curved, and of the fine deep colour of Ne Plus Ultra, with a very fine bloom. The Peas

the first rank (as a town tree), whose overwhelming majority will protest against the condemnation of the Lime. Here, however, the matter of taste; and although it would be exceptional, and do not apply to the application of the tree, we prefer to be shaken by Mr. Robinson's pleading, to give young Limes growing in our parks, the beauty and fragrance, which, when they diffuse all around them." D. T. Fish.

Tricks of the Trade.—As this is the time when nurserymen's catalogues abound, and you let me tell you what has happened among the plants I cultivate are the good ones in their native forests, will give the

when boiled are said to be of a fine dark green colour. The seed is of a distinct pale olive-green. This is a sort that is likely to become popular both for marketing and garden use." The woodcut has been taken from a photograph, which we have had the opportunity of inspecting. Next season we may have the chance of ascertaining whether the promise of the present be fulfilled in the future.

Home Correspondence.

The Lime as a Town Tree.—It will be remembered that I was pretty severely handled for recommending the Lime for this purpose in your pages. It therefore affords me considerable satisfaction to find my favourable impression of the Lime confirmed by the able critique of Mr. Robinson's work on "The Parks, Promenades, and Gardens of Paris," in the last number of the "Edinburgh Review." The reviewer states at p. 467 that "If a formidable minority will dissent from Mr. Robinson's exaltation of the Plane into

untainted, as I thought, with the character could sustain the I order them from what I a sure quarter; and in due time which only half are my own choice remainder were substituted for the course I am told they happened to kinds I wanted, that those which I equal on the average to those which I am requested to pay for Roses I seems to me very like a tailor sending when you ordered a blue, and expressing it was quite as good, and suited to your If a tradesman is able to send you a one you may have in ignorance ordered better, but the superiority must be object not merely to fill up an order. agricultural dinner in Ireland a waiter a gentleman to inform a friend at some he would be happy to take wine with conveyed the information to some

explained that the one "gentleman being in action," thought the other, who had finished his dinner, would do just as well. I dare say many have met with the same experience as I have. It is time that nurserymen should become accurate in naming, not give quantities to plants they hardly possess, or try to do in the unwary by extravagant descriptions. *B. M.*

Salisburya adiantifolia.—It may interest some of our readers to know that one of the best specimens of this tree is to be seen at the Highgate Nurseries of Messrs. Cutbush & Son. This plant is about 50 feet in height, beautifully symmetrical, strong, healthy, and vigorous. Another older tree, but perhaps not in such good condition, may be seen at Caen Wood, Highgate, the seat of the Earl of Mansfield. *J. P., Highgate.*—In the garden at Hespall Hall, Bakewell, Derbyshire, there probably is to be seen about as fine a plant of this tree as can be found in this country. I saw it there a few years ago, and was told that only one larger than it existed in England. The specimen certainly was a splendid one. *Mor.* [Can any correspondent give us with fuller particulars of this specimen?]—I believe that the oldest and best known maiden-hair tree in England is to be found in the grounds of Lord Ravensworth, Waltham Green, Waltham, Middlesex. A letter just received from Mr. Wood, his lordship's gardener, gives the height of the maiden-hair at Purser's Cross, Waltham Green, as 17 feet, that is 17 feet higher than the Panshanger tree, and according to historical accounts, Lord Ravensworth's tree was planted in the year 1767, which is 22 years before the date of planting the Rev. Mr. Dives's tree (see p. 1158). The oldest in England of the following trees are said to be found in the parish of Waltham (an account of height, age, and by whom planted, will be given in another paper, if you think proper)—*Quercus Suber* (Cork tree), Pomegranate, *Cercis Siliquastrum*, &c. *D. Cunningham.* [We shall gladly receive this information. EDS.]

Potato Grafting.—More than 18 years ago, when residing in the neighbourhood of Dumfries, I read an account of a Scotch minister having successfully grafted Potatoes, and I tried the experiment. The minister led on his graft. My plan was to cut a goose quill square, and use it like a cheese-taster, going down over the eye of a Potato, and then with a turn extracting the eye; next to take another Potato, the one desired to be the improver, and do the same with it, inserting that eye in the hole. This was done with another eye, in case the first failed, and then the remaining eyes were cut away, so that if the grafted Potato grew, it must be from the inserted eyes. At my first attempt I grew a set of Potatoes which received the award of merit at the Dumfries Horticultural Society's show, if I remember right, in September, 1850. I explained to Messrs. Downie, Laird & Laing's agent the process he asked me why I had tried the Regent—what was the matter with that? I answered, because it was a good medium. "Now is my Potato better than a Regent?" He said, "It is." "That, then," I said, "is true enough." My cross was a Flour-ball on a Prince Regent. I gave away the whole stock, and do not know what the ultimate result was. By using a coarse graft to breed back, and the produce becomes coarser than the original *Archibald Grant*.—When doctors and dentists differ, who shall decide? On the vexed question now at issue respecting Potato grafting, the opinions of editors certainly differ, for while the editors of this Paper evidently lean to the method of grafting practised by Mr. Fenn to obtain hybrids, the editor of the "Magazine" does not believe in any such thing, and your correspondent is a mere delusion; the experiments at Stoke Newington and other places are ample to prove the fact. I am quite prepared to admit the perfect adhesion of scion and stock, and that it will grow, and this is all I am prepared to admit. To produce true hybrids by this method I believe to be impossible, much more to change the colour of the tuber by graft, or a sprout, taken from a Potato, is self-supporting at such a very early period, as shown by me in an article on the American Rose Potato in the "Florist," that it scarcely requires to draw any nourishment from the stock to aid it in growth. A sprout, 1/2 inch long, is self-supporting, and a scion would grow equally well if placed in a piece of Turnip, Carrot, or Artichoke, as if inserted into a Potato. It is stated on p. 1253, that "the scion has to draw upon the set for its nourishment," and that it does so when union has been perfect is shown, we think, by the fact that in such cases the set is so exhausted that it remains in a shrivelled and an empty bag of skin. Whereas, on the other hand, when no union has taken place, the set remains plump. This is a fallacy for the very opposite often occurs. Again, it is said that "one excellent variety positively stated to have thus originated, and, one, why not more?" It never has been shown satisfactorily to my mind that any one variety ever was raised by the process of grafting. I believe the variety in question was obtained by a sport. I am "not steeled against conviction," but I must see, and feel, before I can be convinced. What about the experiments with the two Beets (see *Gardeners' Chronicle*, 1855, p. 20)? I shall return again to this subject after it has been well ventilated. *Edward Rennell, Osberton, Worksop.* We do not overlook the case of the Beet. We take it as a fact and trust we shall get more of the same kind in future assertions. EDS.]

longest. It is sometimes found good on poor clay, but certainly the most durable Scotch Fir timber is found on boulder gravel at from 600 to 1200 feet and upwards above the sea level. For roofing and building purposes, if manufactured, prepared and seasoned the same as Baltic timber, it is, if of age, and off the soils, &c., I have named, much superior, yea very much superior to quantities of Norway small logs imported into this country, and sold as Baltic timber at the present day. Many proprietors who have the machinery for cutting up old timber on their estates, sell good Scotch Fir at a nominal price per foot, and buy, at three times its price, foreign timber which is no better in quality, and often not so good. Where the soil is of a good deep loam, and rich vegetable soil, Scotch Fir, being pushed beyond its natural growth, never lives so long, and does not commence to form heart-wood, but frequently bursts out, forming ulcerated places on the surface of the bole, at ages varying from 40 to 50 or 60 years. This frequently occurs in hollow places in the natural forests in the North of Scotland. The time I would prefer to have it felled would be from October 1 to March 1. I know Scotch Fir, felled in June and July, soon turns black under the bark, and under these conditions seems to me to decay more rapidly than when cut at any other time. I have myself seen four-barred fencing cut and sawn out of the natural forest in the North, the posts, no doubt, taken from the root ends of trees, which, at 25 years old, seemed to me quite good. No greater mistakes are made than in the purchasing of wood, and it frequently happens that both buyer and seller are totally ignorant of what they deal in. What in regard to Oak and to Ash, could be said of the soil, which has everything to do with its durability and elasticity—but not more so than in the case of the Scotch Fir? For my own part, I would have a good hard-grown Scotch Fir in preference to Larch in a fast grown unhearted state. With regard to fanking Scotch Fir so much used by railways, I could go into the natural forest and pick out Scotch Fir trees that would sink in water to the bottom. No Oak could last longer. In such cases it would be an utter absurdity to attempt to force out the natural sap, as the sap in such trees is a solid mass of resin, and were the timber to undergo any chemical process known at the present day, it would not compare in point of durability to the same timber in its natural state. With regard to Scotch Fir gate-posts, if you procure root-cuts of old hard-grown trees, they will last much longer than Oak grown in light, thin, and gravelly soils. *W. G., York.*

Vanda cœrulea.—I observed some time ago, in the *Gardeners' Chronicle*, a notice of a fine specimen of *Vanda cœrulea*, flowered by Mr. Thomson, gardener to the Duke of Buccleuch. I am tempted to tell you that we flowered here this season a plant of this beautiful Orchid, which produced five fine spikes of flowers. The three lower spikes had 20 and 21 flowers respectively, and the two upper 17 and 15, making 93 blooms. Since 1853 we have flowered this plant every year, and we have had spikes with more flowers than this season. It came to us from Calcutta in a box with other Orchids. We have observed that every year the flowers last a shorter time. In 1853 it bloomed in October, and in January the flowers were still fresh enough to remain in the drawing-room. This year the flowers remained fresh for about six weeks. *J. M. D., Dale Park, Arundel.*

Garden Ivies.—At p. 1259 you give a brief abstract of a paper on garden Ivies, submitted by Mr. S. Hibberd to the Linnæan Society, and of which I have also seen the full report. Mr. Hibberd does me the honour of adopting, though without acknowledgment, my interpretation of the genus *Hedera*, and the species composing it, as published in my "Revision of *Hederaceæ*," pp. 29-36, illustrated with woodcuts and plates. He tells us that, during the last 15 years, he has assiduously collected and studied the species and varieties (so-called), representing the three well-known types, viz., *H. Helix*, L., *H. canariensis*, Willd., and *H. colchica*, C. Koch. Now, I don't think that, until I, by excluding 85 species, reduced the genus *Hedera* to intelligible limits, representing nothing more nor less than what are termed Ivies by gardeners, any approach was made towards disentangling any specific types from several hundred kinds known to exist, either wild or cultivated. That these three types are well-known, as Mr. Hibberd asserts, may be doubted, though I have tried hard, both by description, woodcuts, and plates, to make them so. I could find no specific character in the form of leaf, and had to rely in *H. colchica* upon the scaly covering of the axils and petioel, in *H. Helix* and *H. canariensis* upon the nature of the stellate hairs covering the same organs, these hairs having from 6-8 rays in *H. Helix*, and from 13-15 in *H. canariensis*, besides being smaller in the latter, and the species itself having a distinct geographical range. I have no fear that any transitions between the scaly and the stellate-haired Ivies will be discovered, but it is quite within the range of possibility that some may turn up which may obliterate altogether the characters relied upon for distinguishing *H. Helix* from *H. canariensis*. A careful study of our garden Ivies might thus prove of direct scientific value, and I was in hopes that Mr. Hibberd's paper would have been the result of such a study. But I cannot help thinking that he has been ill-advised to submit his researches in their present raw state to the consideration of the Linnæan Society. He is altogether wrong, as every botanist will tell him, to change well established specific names—absolutely inassailable as far as their right of priority is concerned,—because they do not harmonise with the system of nomenclature set up for his varieties. Who would dream of following him in rejecting the name of *colchica* for that of *coriacea*, all Ivy leaves being coriaceous, and that of *canariensis* for the (relative) name of *grandifolia*? Nor do I think that the author has any very clear notions of the object and

character of classification. He puts the varieties of the different species in four divisions. This of course would be a convenience to any one searching them out by diagnoses arranged under these headings. But unfortunately, the different divisions break down, so that some varieties, as he tells us, may be classed under several of them. The scandent Ivies may become fructing and arborescent if you wait long enough, and the arborescent have an inclination to become scandent if opportunity presents itself (proximity of an old wall, rich soil, &c.). This should have taught Mr. Hibberd that his classification is absolutely useless, and that he ought to try to find in another direction more reliable characters for his purpose. At all events that is the lesson it would convey to botanists. To lead in any question it is necessary to make oneself acquainted with all that has been written thereon, and then endeavour by additional study to advance it. I do not think that Mr. Hibberd has done this. There are many observations about the varieties of Ivies of which he does not seem to have taken cognizance, and hence his paper is not up to the mark. He is perfectly mistaken, for instance, in considering the Irish Ivy of gardens as a variety of *Hedera canariensis*; it remains yet to be shown that it is not a variety of *H. Helix*. *H. Helix* is a very variable plant, and it is the large-leaved Irish Ivy (*Sten. Rev. Hed. tub. B.*), which is a form of *H. canariensis*. It is, therefore, most reprehensible to change the name of *H. canariensis* for *H. grandifolia*, when this large-leaved, quickly growing form of *H. Helix* has nothing whatever to do with *H. canariensis* true. Again, about *H. Helix poetica*. Is not this the *H. poetum* (*H. chrysoarpa*, Walsh, in Hort. Soc. Trans. 1825), which has yellow fruit, and is the classical Ivy or Kiosos, the plant of which Pliny speaks as *Eleric genus chrysoarpon*? And why is it placed amongst Mr. Hibberd's scandent, non-fructing division? What strikes one as singular is that some varieties, of which (if I understand Mr. Hibberd aright) the flowers have never been seen, are classed under *H. Helix* and *H. canariensis* respectively. Now, as the flowers are absolutely necessary to distinguish the species, how does Mr. Hibberd manage to classify his varieties under these two species? If the characters I have relied upon for distinguishing the three species hold good, the most simple way of classifying their varieties would be to divide them in the first instance into black fruited, yellow-fruited, and white-fruited kinds, and then again into subdivisions, characterised by the form and nature of their leaves and general habit. I have never yet been able to find out, and perhaps some of your correspondents may be able to answer the question, whether Ivies with white blotched leaves have white fruit, and those with yellow blotched leaves yellow fruit. If so, it would materially simplify the classification. Biologically, too, some of the varieties may be distinguished, some being liable to be killed by a temperature which others will stand without any ill effects; and again, while the tints of the leaves of some are not affected by temperature, others undergo a perceptible change as soon as the thermometer sinks below a certain degree. All this and a great deal more will have to be fairly met before we are in a position to deal definitively with the classification and nature of our garden Ivies. Mr. Hibberd, I trust, will not be discouraged by this and kindred criticisms from pursuing the subject, but rather regard it as a spur to a further series of observations, which may help to set a question at rest in which scientific botany and horticulture are alike interested. *Beethold Seemann.*

Vine Soils.—Your correspondent, Mr. Cramb, has undoubtedly attributed the failure of which he complained in his Vines, to the wrong cause, when he attributes it to the presence of lime in his soil. I may be in error in attributing my success in a great measure to an addition of that element to that naturally existing in the soils of this neighbourhood. My viney is placed on the bare oolitic rock from which the thinner surface store had been raised for building. I need hardly observe that carbonate of lime is a prominent feature in that rock. Over that bare foundation was laid a foot of broken stone of the same character. On that was laid 2 feet deep of our ordinary soil, mixed with half-inch bones and rough scrapings from our limestone roads. This bed of earth is under the glass roof, and I see no way of escape for the roots from it. The Vines were planted in this nine years ago, and my visitors have been, during this season, so much struck with the size and deep green colour of the leaves, and the abundance of fine fruit, that your readers may, at least, remain satisfied that the presence of lime in the soil for their Vines is harmless. *Charles Lawrence, Cirencester.*

Vine Budding and Grafting.—That "there is really nothing new under the sun," as "B." says at p. 1257, is undoubtedly true, and this remark applies to the mode of Vine budding recently practised at Trentham, for that Mr. Stevens is unfortunately not the inventor of the process will appear on reference to p. 1137, where we have information of its being practised many years before the introduction of the Madresfield Court Muscat Grape. As Mr. Bain (p. 1137) very justly remarks, "there are many excellent practical gardeners throughout the country who never pen their experience," and for my part, I agree with "B." in thinking that this a great loss to those who wish to learn for it would be especially advantageous to have the opinions of really practical men on the controverted subjects brought before the public—much more so than is the gratuitous criticism of those who do give their experience. I, like every other gardener who desires of gaining knowledge, should be only too glad to be informed of a better mode of grafting than that described by me at p. 1260, and to be initiated into the mysteries not only of budding, but of grafting the Grape Vine, in reference to which "B." says I have much to learn. *Who* who would do a service to the public should be

Scotch Fir Timber.—Your correspondent, at p. 1257, asks at what age Scotch Fir timber may be used, and also the season of the year for cutting it down. No Scotch Fir should be cut down until 60 years of age, while 100, and, in some cases 120 years, may be allowed before it is cleared off as a matured crop. The age at which Scotch Fir timber ought to be cut will in all cases be regulated by the soil, subsoil, climate, and altitude. On bare rocky soil, on gravel, or even deep sand, it will be found to succeed the best and live the

profuse with their irony, and more generous in imparting their practical experience. If "B." can explain any method by which the budding or grafting of the Vine may be made more certain, and more prompt as regards the production of ripe Grapes, than that I have advanced, I shall be glad to hear it. *John Reid, Haigh Hall Garden, Dec 6.*—At the tail-end of a paragraph in the *Gardeners' Chronicle*, at p. 1253, I observe "a little crook-backed gentleman." My reply to him is that the budding of the Vine being slow in action, and to some extent uncertain, "practical men" find grafting so very superior in a general way that they adopt the most useful methods of it in their practice, leaving the less important, such as budding, in abeyance, so that it may be cried up at the nick of time to keep the craft awake. *J. R.*

Bottom Heat for Vines.—We have not yet been furnished by any of your numerous correspondents with any real proofs of the relative merits or demerits of the two systems of culture. Therefore I should like to see it put to some practical test, everything connected with the Vines, except the bottom-heat, being made as much alike as possible. We shall start a vinery in the second week of December, and in this house I intend subjecting six pot Vines to the test, and trust it may induce others interested in the subject to try a similar experiment; by so doing we may arrive at some practical conclusion. The Vines I shall try are in 10-inch pots, struck from eyes last spring, and have, as nearly as possible, the same length and strength of canes. They are—two Black Hamburgs, two Frankenthals, and two Royal Muscadines. One of each will be plunged in the border outside, covered with dry litter, will be brought in through the front wall, and tied to the wires. The other three will be placed inside, close to the front wall, the canes will be placed alongside of the others, and both will in every respect receive the same treatment, except that the roots in the latter case will be kept in the same temperature as the tops. With your permission I will report the result when the Grapes are cut. *J. McIndoe, The Palace Gardens, Bishopsthorpe, York.* [Pray do. Eds.]

Root Action.—An interesting controversy is being carried on in your columns as to whether spongiole or young rootlet formation is the cause or the consequence of leaf and branch manufacture. In the island of Madeira, I managed for some years a model farm, which received a subsidy from the Portuguese Government. Owing to my success in showing how the vineyards could be restored by the use of sulphur, and by a return to a proper system of cultivation, and also to the introduction of many new and useful plants, such as the *Holcus saccharatus*, the use of this plant, and of many other novelties, was insisted upon in letters to the papers, and in a book written in Portuguese describing my experiments. The seed of the *Holcus* was sown at different times of the year, with varying results. The most usual course, however, was to sow about February. In about eight or 10 days the young grasses grew up, some in their permanent location, and some in pots to be distributed amongst those who liked to try a few plants on their own lands, especially amongst my own tenants. Taking these young plants at about a month old, you saw nothing but a little grass plant with two leaves, and five or six thread-like roots. They were planted at a distance of about 18 inches, and carefully and anxiously watched from, say, March to May. The progress was most disappointing to the eye, and distracting to the enthusiastic *impresario*, who was terribly quizzed by the neighbours. May was fairly commenced, and still they showed no sign, beyond putting out two or three narrow stunted leaves. The tenants came in and asked sarcastically if that was the new Sugar-cane that was so loudly praised? In desperation, I pulled up one of the plants, and if Linnæus really fell down and worshipped a splendid specimen of Furze, he would certainly have done so on witnessing the hidden forces of Nature exemplified in the roots of the *Holcus*. There was a solid stump or neck of the plant surrounded by masses of spongioles which must have weighed some pounds—transparent, juicy rootlets, bursting with sap, and only waiting the stimulus of a slightly hotter sun to force the leafy portion into growth. The weather became hotter, and in three weeks the plant, from a little tender grass about 9 inches high, became a robust cane 6 feet high, with, in most cases, four or five other canes which had tillered from the roots. In three weeks more they had ripened their seed, and were cut down. The rootlets were then examined, and found wizened and thready, as at first; in fact pumped out dry. *Richard C. Smith, 12, Cross Lane, St. Mary-at-Hill.*—Do Vines make fresh roots or spongioles, without the action of leaves, &c., or vice versa?

I consider that much depends upon the relative temperature of the soil in which the roots are, and of the atmosphere of the house in which the Vine grows. Moreover, I believe, that in all well-made Vine borders (where means are used to ward off the autumn and winter rains, and to husband the solar heat of the previous summer), that a certain portion of the spongioles survive and act throughout the winter, instead of going entirely to rest when the leaves have fallen, as some of your correspondents seem to think. I also believe that Vines will make fresh roots without any perceptible action taking place in the branches, also that they will make leaves and branches, without fresh roots. In proof thereof, I would cite the following experiments. In February I took four Vines grown in pots, and having disentangled the roots, I placed them on four large pieces of turf, covering over with soil; they were placed in a pit, where they had a steady bottom-heat of 60°, while the minimum temperature of the atmosphere averaged 50°. Two of the canes were kept inside the pit, whilst the other two were taken out into the open air. For convenience I will style the former A. and the latter B. When

the buds of A. showed signs of bursting, we found many fresh roots. On B. the young roots were scarcely so far advanced but quite as numerous. Later, when the shoots on A. were 2 or 3 inches in length, the rootlets were from $\frac{1}{2}$ an inch to 2 inches. Whilst B. showed no perceptible increase in the size of the buds, the young roots were much increased in size and number, many of them being over $\frac{1}{2}$ an inch in length, and by the time the buds had burst the most forward were 1 $\frac{1}{2}$ inch in length. Simultaneously with this experiment I introduced a Vine rod into a plant stove, the minimum temperature of which was 60°; the roots were entirely outside. When the shoots were from 6 to 8 inches in length, the leaves flagged much in sunshine. I carefully lifted them, but failed to find a single fresh root; in fact, the smaller roots had rotted off. The Vines had been planted three years before, under circumstances over which I had no control; and the soil being a perfect morass, it was no wonder that all the smaller roots were gone. Whence, then, came the supply of food that enabled this Vine to grow from 6 to 8 inches? It must have been the sap stored up previously to the decay of the roots. It at least goes far to prove that Vines will make leaves and branches without the aid of fresh rootlets, and also without the corresponding root or branch action, provided circumstances favour the production of either. In the case of an early vinery planted in a raised bed inside the house (without bottom-heat), the Vines being old and showing want of vigour, I determined to add 2 feet of fresh soil to the border, by removing the front wall of the bed. On this being done I found many healthy spongioles, and upon disentangling the roots and removing 2 or 3 inches of the old soil, I found them still more numerous; as nearly as I could calculate, I should say one-third of them were in healthy action, whilst the remainder were seemingly inert. Now the leaves had been off those Vines two months, yet here we have a considerable porportion of the spongioles in good health, and doubtless in action; and this I believe goes on to a much greater extent than is generally supposed. May not the number of active spongioles be proportioned to the diminished wants of the plant until such time as it is again excited into action? I could cite other instances wherein fruit trees, bushes, &c., have made fresh roots in midwinter without any corresponding top action. *J. B.*

Judging Melons.—I have always been opposed to the practice of cutting every Melon exhibited for competition at horticultural shows, although when acting as a judge of such productions I have usually been compelled to do so, by the rules of the society, or in compliance with the wishes of its officers, who are generally under the impression that exhibitors would not feel satisfied unless this was done. Nevertheless, I quite agree with your correspondent, Mr. Sheppard (p. 1232), in thinking that in a majority of instances a sufficiently correct estimation of the quality of a fruit can be arrived at without actually eating a portion of it. Or why should flavour be the only quality taken into consideration in estimating the merits of a Melon, and ignoring all other qualities—such as weight, size, form, colour, &c.? I am quite aware that I may be told that Melons are grown to be eaten, and that "the proof of the pudding is the eating of it, &c." This, of course, is true enough, but there may be more than one opinion respecting a pudding even after it has been subjected to this ordeal. And Pine-apples are also grown to be eaten, but judges are neither expected nor allowed to cut them in their endeavours to decide upon their merits. It is a common saying, and it is also quite a true one, "that there is no accounting for taste," and the taste exercised by the palate is as capricious and diversified as any other. Delicate Spanish girls will slice and eat a raw Onion with as much relish as an English beauty would a ripe Peach or an Apricot; and while Mrs. A. drinks her tea nearly as sweet as sugar will make it, Mrs. B., on the other hand, abominates the minutest introduction of either cream or sugar into her beverage. And it is even possible that your correspondent, "A Canny Scot" (see p. 1233), would mightily enjoy his toddy of a degree of alcoholic potency which might compel the learned Editors of the *Gardeners' Chronicle* to make wry faces. I have also heard of sundry means being used to give the desired flavour to partially ripened fruit, which has little to do with good cultivation, and has not, I believe, been recommended by any horticultural writer, such as that referred to in the admission of the winner of a 1st prize, who confessed that at the suggestion of his "ingenious moiety" his prize fruit passed the night previous to the exhibition enveloped in moist flannel in a slow oven. But be this as it may, there is no doubting the fact that many Melons find a place upon the exhibition table which are the produce of plants which have paid the debt of Nature long before the ripening process had even commenced in the fruit. In conclusion, I think that the system recently inaugurated at Edinburgh was a step in the right direction, which, I hope, will be generally followed, and that the knife will only be appealed to as a *dernier resort* when all other means of arriving at a satisfactory decision have failed. *P. Griene, Culford.*—At the first exhibition held at the Crystal Palace I exhibited three Melons—one for the heaviest, which obtained the 1st prize; one for the best scarlet-fleshed, to which the 1st prize was awarded, one for the green-fleshed (the Green Gage), which received the 2d prize. None of the Melons were cut. The judgment went by sight and smell. I was very much disappointed at not getting the 1st prize for the Green Gage, as I knew what it could do, it having taken several 1st prizes before. And Mr. Thomson, now of Dalkeith, once being a judge at the Royal Botanic Gardens exhibition, where it got the 1st prize, said to me, "Mr. Monro, that Melon will beat the world;" so, as I had a fine fruit at the Crystal Palace, I felt disappointed

that it only got the 2d prize, but all the other bits of Melons were very much annoyed, and "That it was not fair, as the fruit had not been cut, and they would see the judges about it," which did. I said "I was very glad, and if my Green Gage not get the 1st prize I would eat it." The next day the judges came, cut all the fruit except the Green Gage, and they took the 2d prize card off my Green Gage, and put the 1st prize upon it, leaving the others were. I don't believe any person can judge a Melon without he tastes it; as for whiskey, &c., that nonsense, the taste of a bad Melon will soon be a taste of a good one out of the mouth—the same good one. A person that cannot judge a Melon without whiskey or brandy has no business to be a judge. *John Monro, Potter's Bar.* Some few years since I offered a few Green Gages for Melon judging in these columns, a portion of which again quote, thinking it may be of some use in settling the vexed question now at issue in your columns. No class of fruit, perhaps, is more difficult to judge than Melons, and I have no hesitation in stating that the showing is on this account rendered a very uninteresting one, is, indeed, hardly possible to select the best shown from among perhaps the hundred Melons staged sometimes at our great London exhibitions. It is true that the judges are at liberty to cut such Melons; some, however, are passed over in consequence of their uninviting appearance, others are chosen because the name they bear is known not to be a first-class variety; and a third group, no doubt, is disregarded for other reasons. But, even when all these things are taken into account, what some being inferior, some good, and some middle, the mouth gets sadly out of order in arriving at the hundredth or last specimen. In judging, as I have stated, therefore becomes a lottery. I do not say, however, that this is a bad case, for there is no rule without an exception. Prizes must be awarded, and although there are losers, still there must be some winners. It has been at various exhibitions myself, I can truly assert that Melons which have been awarded prizes by one set of judges would not be awarded at all from others. So much is it true, and as every man's taste is not alike, how is it to believe that the best Melons always obtain prizes? I do not for a moment insinuate the contrary; it is merely a matter of fact. What we want is some standard to guide us, but by taste alone is not sufficient, for I have seen Melons awarded 1st prizes at our great exhibitions, which are ludicrously small that I should have been asked to have sent them to my employer's table. I am of the opinion that moderate size and weight, thin skin, thick flesh, and handsome appearance should have preference over small size. In one respect Melons like Potatoes, some varieties are good in certain seasons, and under some particular course of culture, while some kinds in other places are poor and insipid. Nine years since we put up a new Melon-house at Osberton which answers admirably, the crops being very abundant. In this house I have a great many varieties of Melons now in cultivation. From experience I have come to the conclusion, just stated, viz., that the same variety, under different conditions, varies very much in flavour. In a book I find Melon lists so overburdened with names that in the case of beginners it would be a difficult thing to make a selection of any one particular variety. How different is this from years gone by, when the Beechwood and Cantaloupe were the two principal favourites. But time changes all things, and should not the judging of Melons on the old plan of tasting only, change? *Edward Bennett, Osberton.*

Dear Chrony.—Could you not settle these gardeners by asking the tasting ones if they use Melons before sending to their employer's table, do they use a cheese-piercer, and plug up against the door, or how do they use tobacco? Or how do they use the veyors for the dessert of the Belgravians and West-enders do when in Covent Garden? The Chrony owes to a weakness for tasting good Melons. *Eds.]*

Potting Lilies.—I can fully endorse all your correspondent "M.'s" remarks (see p. 1232) when you pot Lilies in November. My advice is to pot them as soon as you can in November, or should the stems be so soon, repot at once. I have always found Lilies at work even after the stems have died down in the time. I firmly believe that *Lilium auratum* is growing, as I have just turned mine out of a pot and found some splendid roots in a fine greenhouse. These I disturbed as little as possible, only moving a little of the old soil and shifting into a new pot, larger, according to the strength of the bulb. All potting is completed I place them in a cool, excluding frost, and then cover them with a layer of cocoa fibre, withholding water until they have grown to say 3 inches in length, and then gradually increase the light and air of the greenhouse. The soil is good turfy peat, with a little loam and sand, silver sand, all chopped up roughly with a spade well incorporated together. *G. Willers, Cambridge.*

—In answer to your correspondent "M." with reference to the time I pot my Lilies, I feel doubt he will be surprised to hear that I referred to in p. 1064 was potted on February. I do not mean to say that February is the best time to pot all Lilies. I consider that any one in possession of a fair collection of bulbs, and the convenience of grow them, can have a succession of bloom from the month of May up to the month of October, consequently the potting must be done at intervals, according to the time the plants are required to bloom, prefer commencing in the month of August, with smaller bulbs of the *auratum* varieties, leaving

large bulbs for late flowering. If plants be brought into flower in the month of May or June, it naturally follows they will be ready for potting before those that flower in September. Then why should we wait till November, or put those in November which ought to be deferred till January? My experience teaches me that it can be done with advantage from the month of August to the month of February. I differ from "M. A." where he says, keep them dry through the winter, in my opinion they should never be allowed to get dry. Again, he says, take away all the small bulbs, and "to shift the larger ones without disturbing them is still better." I ask, can this be done without disturbing the large bulbs, and what is the advantage of so long? I consider that, if large specimens are aimed at, we must have them entire, as we get much better-furnished plants than by taking the small bulbs away. In p. 1138 we are told that the stem is kept alive sometimes by roots emitted from itself. Independently of the bulb, these roots sustain it after the bulb has stopped its supply. But, in the absence of these roots, I ask what sustains the stem but the scaly bulbs below which we are told are gone to rest previously. In p. 1232 we find "M." has changed his mind. He there says, "for the bulbs of these plants never rest." I quite agree with him on that point. J. Smith, *G. to James Bland, Esq., Quarry Bank, Alkerton, near Liverpool.* "M."s' reply to this note is subjoined. Eds.—My object at first in writing about these bulbs, was to break through the practice—the old practice—of storing away the bulbs in winter, to be pulled to pieces in spring for fresh potting, when vigour ought to have been vigorous. Mr. Smith bears me out in this matter. Mr. Smith was fortunate in being in possession of so large a bulb of *Lilium auratum* when the price kept many—myself for one—from purchasing. That, doubtless, partially explains Mr. Smith's success, though I do not wish to detract anything from his skill. I dare say, as Mr. Smith alleges, that *Liliums* can, by potting bulbs at different times, be prolonged in flower to the period he mentions; but there must be no storing away in that practice through the winter, but rather "potting when the stem is dead." Mr. Smith differs with me on the condition of the soil through the winter, or in the state of partial dormancy. He would certainly find fault if I said, keep the soil "wet." I considered the term "dead dry," would convey my meaning—a state of soil where it is possible for anything just to live and make roots. That is the meaning I intended to convey. If Mr. Smith had his pots bursting with the quantity of bulbs contained in them, as I have had this season (not *auratum*), he would, if not inclined to disturb all his bulbs, find a means to thin them. Although Mr. Smith finds fault with this, my middle proposition, he quite agrees with my last, and what I styled the best, that is, leaving the bulbs alone as long as possible without potting. In answer to Mr. S.'s question respecting the sustenance of the stem when no roots are emitted from it, I say, as he surely knows, a dying stem requires no sustenance, the withholding of sustenance is the cause of decay. Mr. S. is wrong in his impression that I changed my mind on such a point as the resting of these plants. I do not know what better term to use that would be intelligible and give the true meaning of what I said. I said, "in the fullest sense of the term they do not rest." Mr. Smith agrees with me. I am very glad Mr. Smith has given the public the benefit of his experience, and that he has come to my aid in the endeavour to show that storing away the bulbs of those plants is wrong, as advised in this journal. M.

"Good Gracious!" Pansy.—I see at p. 1234 a notice of a blue *Viola*, called by one person "Blue Perfection," and by another "Good Gracious." Now, I remember the late Donald Beaton writing very much in favour of, I believe, this very Pansy, in the "Journal of Horticulture," some six or seven years since. Mr. Beaton said it would be the best blue bedder in cultivation, and it seems his words are likely to come true. Mr. Beaton also, in his amusing way, described how a lady acquaintance on first seeing it, held up both hands and cried, "Good gracious!" and said, "Mr. B., I don't think it could have a better name." So judging from that, it must have been sent out under that name, and poor Beaton's words are likely to come true. J. W. Kingston, *Bolton Hall Gardens.*—I have received so many inquiries during the last few days respecting the blue *Viola* referred to by Mr. Dean, that I find it too great a tax upon my time to reply to them by letter. As I before stated, I received the name I have given with it, and believed it to be the true one. As Mr. George Smith, nurseryman, Fisherton, Salisbury, supplied it to me, perhaps that gentleman will kindly give its previous history, and so clear up any mystery respecting it. I have this week been informed, by those who have seen Beaton's Good Gracious, that the two are distinct. Mr. Williams, of Holloway, to whom I sent a cutting, also says it is not like Mr. Jobson's variety. I have not a plant in bloom at the present time, but will send one at the earliest opportunity, to the Floral Committee, South Kensington, for its opinion respecting it. Thomas Challis, *The Gardens, Wilton House.* [Beaton's Good Gracious Pansy, was a double-flowered variety, and a deep purple. Eds.]

The Heliotrope and Carnation.—I can confirm all that Mr. Pillery says (see p. 1212) in favour of the Heliotrope as a very useful and desirable plant for greenhouse or conservatory decoration, either planted out and grown as a bush, or planted against a wall and trained as a climber. We have here the back and wall of the conservatory planted with Heliotrope, and at the present time, when loaded with its highly perfumed blooms, it is the admiration of all who see it. There is also another plant which, for pot culture, is worthy of more extended cultivation,—that is, the Tree, or perpetual blooming Carnation, which for its fragrance, and great variety of colour, is indispensable

for greenhouse or conservatory decoration. I have had plants in bloom for several weeks, and they are likely to continue so through the winter months, and as my employer is passionately fond of them—indeed, I don't know who is not, I am able to give him one for his button-hole every morning. I have a variety now in bloom called the Dragon, a beautiful bright crimson, measuring from 3 to 4 inches across, a bloom of which is no mean object at this season of the year, when sweet-scented flowers are both scarce and valuable, indeed, I think no greenhouse or conservatory of any pretensions ought to be without them. They are equally valuable to those who have no greenhouse at command, as I shall presently show. We have a fine collection growing in the borders of the kitchen garden, and many of them have not ceased blooming since the beginning of the summer, and, if the weather continues mild, I have no hesitation in saying that we shall be able to cut nearly up to Christmas. I may state that many of the kinds now in flower in the borders are the produce of a packet of seed. Therefore, I would say to all lovers of the Carnation "set your borders in order, and try your luck with seed or plants." I say luck, because, if from seed, all will not be prizes, or, in plain terms, perfect flowers; but nevertheless, I say to all, try, as the results from a packet of seed here are perfectly encouraging. I think if the Royal Horticultural Society of London, would take this subject in hand at another season, and offer prizes for Tree Carnations in pots, or for cut flowers, it would be an inducement for their more extended cultivation. Hear! hear! Why should they not meet with encouragement as well as the Chrysanthemum? True, they would not make such a gorgeous display as the latter; but, on the other hand, their sweetness and variety of colour ought to place them in the first rank of sweet-scented flowers. This is merely a suggestion; and as I know there are several good growers in the neighbourhood of London, perhaps they would favour the readers of the *Gardeners' Chronicle* with a few cultural hints. Perhaps some one may turn round and say they are so easily grown, that no hints are required. How often, however, do we see them neglected, or not properly cared for in due time? If these few remarks should be fruitful in bringing this much-esteemed flower into more general cultivation, I shall be glad, as I feel sure it will well repay a little extra attention. It is encouraging to see plants grown from 3 to 4 feet high in one season from cuttings. George R. Allis, *Hurtaholme Hall, Lincoln.* [See Mr. Howard's remarks on this subject in our last and present Number. Eds.]

Conifers in South Devon.—We have here a specimen of *Cupressus Lambertiana*, 36 feet in height and 90 feet round; the greatest distance through is 34 feet, and the girth of the trunk 4 feet 6 inches, the latter three measurements were taken at 3 feet from the ground. Another of *C. macrocarpa* measures 32 feet in height (fully 6 feet of top has been taken off), and at 4 feet from the earth, 68 feet round, with a trunk 4 feet in girth. We have also *Wellingtonia gigantea*, 26 feet high, 47 feet round, and 4 feet 4 inches round the stem. The above have all been planted about 11 years, and are exceedingly handsome, being well furnished throughout, and forming fine pyramids. Of *Wellingtonias*, I may observe, that, although we have upwards of 40 in the grounds here, I notice but one of them producing cones, and that by no means the largest one. This I think is somewhat unusual in this country, at least in small plants. The *Cupressus Lambertiana* mentioned has, at the present time, some hundreds of fine cones upon it. Those *Wellingtonias* that are in some degree protected by other trees, &c., from the salt-impregnated winds from the sea (about half a mile distant), present a far more healthy appearance than those exposed to its full action. *Pinus insignis* has proved nearly a failure, being subject to the ravages of a grub, which commences its havoc in June, and completely hollows out the interior of the young shoots. As I do not remember having noticed it in any other part of England to such an extent, I shall take the liberty of forwarding for your inspection some of the attacked shoots when it commences its active operations again. It is completely ruining the Pines at many places in South Devon. I may also observe that the Fig does remarkably well here, one growing on a very exposed part of the lawn being 20 feet high, 111 feet round, and having a bole 6 feet in circumference. It forms a huge compact bush. During the past autumn I have gathered from this tree several bushels of fine well-ripened fruit. John Faurey, *Gr. to T. Allcard, Esq., Hermosa, Teignmouth.*

Cedrus Deodara for Timber.—According to my experience with the *Deodar* as a timber tree, your correspondent "G. A. H." p. 1233, is quite right in dissuading anyone from planting it in large quantities, unless in very favourable situations. The severe frosts in 1860 and 1861 nearly killed all the finest specimens in the midland counties in exposed situations, and it can only be depended on to arrive at timber size in the shelter of other plantations or trees. I am not certain that its timber will be of much value either in this country, unless it is grown slowly, like the Larch and Scotch Fir, on hill-sides and in rocky soils. A few years ago I sent a slab of it to the museum of the Horticultural Society, from a tree nearly of timber size, for it measured 4 feet in circumference at the base. This tree was originally grafted on a Cedar of Lebanon, in 1838, from a branch taken from a young tree raised from the first seeds sent from India by Lord William Bentinck. It grew in a very sheltered corner in the park, on a sandy soil, and was about 25 feet in height, when it was transplanted to the shrubbery, where the situation was lower and colder. This was in 1858, and in 1861 the severe frost so injured it that it had to be cut down. The slab was taken from the centre of the tree, and showed the Lebanon and *Deodar* sections in equal proportions.

Where they had been grafted was easily seen, for the *Deodar* portion was thicker, the bark rougher, and more knots in the timber from branches, although the number of rings was the same. Mr. Murray took some cups of the timber of each kind, of equal length and thickness, to try their relative breaking powers, and found the *Deodar* wood was the toughest, but this may have arisen from the number of knots in it. To me the timber, when first sawn up, seemed much alike in colour and texture, but fine *Deodar* was the kindest from branches, and perhaps if grown slowly, and in poor soil, it might be resinous and hard, as it is said to be in its native habitat. William Tillery.—Probably it is as yet premature to speak of the quality of British grown *Deodar* timber. The wood of most of the Fir tribe is soft when young, still the *Deodar* can be compared with Spruce, Scotch, and Larch Firs of the same age, and it is softer than any of them. I have recently cut down a *Deodar* about 20 years of age and 150 feet high. It was very soft and spongy. Great chips flew from the axe in a shower, and the tree seemed to be down in the shortest possible time. As soon as it was felled I decided to test it, and found it soft throughout. The heart was small, and not much harder than the other. There was little or no resin, no perceptible perfume, and the wood in grain and quality resembled the spongiest Scotch Pine drawn up in stuffy plantations on rich soil in England. It must not for a moment be compared in quality to the mountain-grown Scotch Deal, or black Pine, which is more durable than foreign wood. And yet this tree was grown in the open, with free exposure, and no crowding. I do not anticipate any difficulty in growing the *Deodar* throughout most portions of England. Here (in East Anglia) it grows very rapidly on good soils, and with moderate shelter, and in many places without either; but I fear its timber may be of but little use after it is grown. Still the tree is highly ornamental, and splendid for hiding feathered game, while its weeping and drooping form gives it a special value in the eyes of the artistic planter and landscape artist. In all boundary belts for parks, clumps, or home scenery, and every position where beauty is held to be of more consequence than utility—the effect of the growing tree more highly prized than the commercial value of its timber—the *Cedrus Deodara* should be plentifully introduced. But the mere timber grower for profit should fight shy of the *Deodar*, lest his profits should be consumed in the billets and faggots of mere firewood that will probably be the inglorious end of his charming so-called timber trees. Observer.

Yellow Bedding Plants.—I have read with great interest the various papers under this heading, but many of your readers will concur with me in thinking that very little good has been derived from them. Therefore, "what can we get as a substitute for the Yellow *Calceolaria*?" must still be an open question. Mr. Bennett, of Osberton, recommends the *Viola* and Pansy. The latter has been tried over and over again, but has always failed as a summer bedding plant. By the end of July it is used up; then the *Viola* and other subjects, such as the *Oenothera*, introduced by other correspondents, what are they compared with the delightful yellow and glowing effect produced by the *Calceolaria*? I feel sure there would not be half the disappointment with the *Calceolaria*, if proper pains were taken with it at planting time. The soil in the beds should be taken out a foot deep, and some good rotten stable manure placed at the bottom. I find them to do better in Yorkshire than on the gravelly subsoil in Middlesex. T. P. T., *Thornhill Gardens, York.*

Tobacco Free of Duty.—What we want for horticultural uses is a good strong and cheap compound of tobacco, prepared for fumigating all kinds of greenhouses. This we want, free from sulphur and greasy matter. If the Duty-free Tobacco Company would prepare a mixture of Cayenne pepper with grains or rough chopped tobacco, that would improve the quality of the mixture for all purposes, and would destroy all kinds of insects without injuring the revenue. I have not yet found any good and cheap substance for fumigating. Tobacco-paper, if kept too long, becomes useless. I should like to have the opinions of others on this subject, and also to hear what the Duty-free Tobacco Company has to say about it. William Smythe, *The Gardens, Elmham Hall.*

Chimonanthus grandiflorus.—I herewith forward for your inspection a seed vessel of *Chimonanthus grandiflorus*, which has fruited with me during the three last seasons, although the seeds of the past season have not come to perfection, owing perhaps to the ungenial spring. I have one fruit much larger than the one sent, which I have not opened. I have never observed fruit upon the *Chimonanthus praecox*, although I have been acquainted with it for the last ten years. Rustic, *West Kent.*

Foreign Correspondence.

WASHINGTON PARK, BROOKLYN.—This is only about 30 acres in extent, and, therefore, scarcely deserves the name of a park; it is in reality what may be termed an open town space or public square, and it is on that account that I am anxious to direct special attention to it. It was once called "Fort Greene," a location in the very heart of the city, and it is for the most part elevated above the adjoining land. The rise in parts is, indeed, so considerable, that the surrounding buildings are overlooked, and interesting views are commanded, extending far up the East river, and down what is called the lower bay, bringing their ever varying scenic incidents almost within the limits of the park. An invigorating sea breeze is wafted in from the waters, which is most captivating to all who seek the higher level of the "Greene" on a warm summer's day. Owing to the advantage thus offered of fine prospect and pure air, combined with extended and varied

character of surface, the ground, out of which the park has been formed, has received a more complete and interesting arrangement of accommodations for popular recreation than can often be attempted in public squares of large towns. The chief requisites sought to be obtained were ornamental grounds in connection with convenience for public meetings, or for other incidental purposes which bring together large crowds—requirements essentially dissimilar and difficult to incorporate in grounds of limited extent intended for popular resort. This desideratum has, however, been accomplished, and that too, in a very satisfactory manner. For refreshing purity of air and beauty of prospect, the central part of the grounds is the best, and that portion has been chosen for floral decoration, while the lowest ground has been devoted to public assemblage accommodation, a space being left there sufficiently large to afford easy standing room for 30,000 persons. This ground is paved, and is provided in the centre with a "rostrum" for public speakers. It also offers a convenient site for concerts, and it is sometimes used as a drill ground. The whole space can be brilliantly lighted, and while the park, properly so called, is fenced round, so as to be closed at night, this is left open. The interior of the enclosure immediately opposite the "rostrum" has been the scene of great historical events, and for many years has been used by the citizens of Brooklyn as a place for patriotic demonstrations. A "saluting ground" has, therefore, been formed at this point, and a memorial monument for the "Prison-ship Martyrs" is to be erected at a little distance off, where they are entombed, while, with the intention of securing to visitors an agreeable walk in the immediate vicinity of the square when the gates of the enclosure are shut for the night, the adjoining side walks have been increased in width to 30 feet, and have been ornamented with a double row of trees. Gates are provided at the various angles and in the centre of each side. I may likewise add that special prominence is given to the angular approaches, which have been enlarged and symmetrically planted with trees, so that they may present a more agreeable effect to visitors entering the park than they otherwise would do, and also offer facilities for an easy turn in connection with the exterior side walks.

In the enclosed pleasure ground broad walks are so laid out that the whole space is thoroughly traversed by them, and turned to account. As has been stated, the general surface of the ground is very irregular; but it has been thought desirable to arrange for a nearly level lawn of considerable extent for boys, and for another lawn of about the same dimensions for the use of girls and children. The undulating ground has been somewhat closely planted, and is laid out so as to offer a series of shady walks that have outlooks over open grassy spaces at intervals. About the centre of the park there is to be a Vine-covered walk in the form of a cross, which will serve to furnish protection from the fierce rays of the sun in hot weather. One arm of this shelter connects it with the "saluting ground," another with a refreshment department, and a third with an observatory, while a fourth commands the most interesting view over the city that can be obtained within the limits of the property. Taken altogether this park, when completed, will, considering its size, form one of the finest public pleasure grounds in the gardenesque style anywhere to be found.

How desirable would it be if the centre of London had such an agreeably laid out open space? It is true we could not have the bold natural inequality of ground that is to be found in Washington Park; but by raising mounds artificially, and by means of skillful planting, much might be done to relieve the flat squares of London of their existing uninteresting monotony. Above all, our squares should be thrown open to the public, as is done both in America and France. Outsiders cannot be expected to take interest in them until that is done, and that they would then take a lively interest in them and thoroughly appreciate their beauties, is abundantly proved in the case of Kew Gardens, and in some of our open spaces nearer town, in which the flowers and shrubs receive but trifling injury. "Liberal hands make many friends." Let us hope that some one "in authority" may take the matter earnestly in hand, pull down the unsightly railings, and let the pent-up children of the London poor enjoy a run on the green sward, amid trees and flowers, as they annually do, during the autumn months, in the Temple Gardens. Then, and not till then, will our London squares be a public benefit. *J. Newton, Oxford Terrace, Hyde Park.*

Societies.

EDINBURGH BOTANICAL. Nov. 11.—This was the first meeting of the 34th session. Dr Cleghorn, President, in the chair. The President delivered the opening address, on the Progress and State of Botany in Britain, from which we extract a portion relating to the *Indian Forest Service*. "It is not necessary to go here to allude to the feelings for young men in the department of public service with which I have had the honour to be long connected. With the greatly extended forest operations which the formation of railways necessitated, the want of trained assistants was much felt, and the Secretary of State for India resolved, in 1868, to send out a few youths, properly trained, for service in the forests of India. The first detachment of assistants, after two years and ten months' education, chiefly on the Continent, have sailed for the East, a second party are now in the forests, and a third will undergo the preliminary examination next month. Much has been written in the *Gardener's Chronicle* and other periodicals, with reference to these appointments; and as much misapprehension exists, it seems desirable to give the facts in regard to the object of the present arrangement. In Britain, while arboriculture is conducted with the greatest skill and success, and the finest specimens of ornamental trees and artificial plantings may be seen, there is a comparatively small area of wood cultivated as a crop, and that is diminishing rapidly every year, of the wood grown for ornament or game, there is a much greater extent. It is humbling

for a Scotchman to confess that there is no school of forestry in this country where the different branches of study can be mastered. It is to be hoped that by the joint action of the Highland Society and the Scottish Arboricultural Society an organised system of instruction may be set on foot. In Germany, the system of forest science and management is most elaborate and carefully arranged. The works of Hartig, Burckhardt, &c., all published under Government auspices, show the importance attached to forestry in a country where the population depends entirely on wood for fuel. France also has large and well-regulated establishments for the conservancy of State forests. The chief training school is the Ecole Impériale Forestière at Nancy, an excellent institution; and in the immediate neighbourhood are very extensive tracts of natural forest, where the different branches of study can be mastered. Four youths are now under training in Prussia and four in France, and they are to finish their education by spending some time with a practical forester in Scotland. The experiment now being tried is of great importance, and I doubt not such alteration will be made as seems expedient. The object is to secure the largest amount of theoretical knowledge and practical training combined. It will be admitted that the youths would be imperfectly prepared for their duty in India if they had not an opportunity of seeing the timber slices of the Austrian and Bavarian mountains, the valuation surveys, economical manufacture of tar and charcoal, and the collection of various articles of forest produce. In Britain, from the force of circumstances, the forests are very small, and the system of management, though sound and suitable on the small scale, is less adapted for the vast forests of India. With regard to the development of the botanical resources of India, I may notice that the Cinchona plantations in Bengal now cover 1000 acres, and those in Madras are considerably more extensive. Vigorous efforts are also made to introduce *Cephaelis Ipecacuanha* on the same principle, and so far as it is possible to obtain a sufficient stock of plants from the botanic gardens and scientific nurseries of Britain, without a special mission to the Organ Mountains, this has been done. Dr Anderson Lopes, on his return to India, to take out sixty plants obtained in Europe. This introduction has been forced on Government by the new views in the medical treatment of dysentery, and the greatly increased price of the drug, which now sells at 9s. per lb. Some of the skilled Cinchona gardeners, set free in consequence of the completion of operations, are available for the charge of cotton farms, instituted by Government in various suitable districts." The following communications were read:—I. *On Equations to the Curved Outlines of the Leaves of Plants.* By Mr. Wm. Mitchell.—II. *Supplementary Notes on the Indian Flora of Greenland.* By W. Lauder Lindsay, M.D., F.L.S., F.R.S.E.—III. *On Dr. Sims' Arrangement of the Hepatice.* By Benjamin Carrington, M.D.—IV. *Miscellaneous Communications.* Professor Dickson, Glasgow, made some remarks regarding the formation of the fruit of *Rhipiphorus* wasps, and exhibited preserved specimens. He stated that Mr Sadler and he had paid a visit to Tsumungamo last month, where they found the plant fruting in the greatest profusion on the shore. Dr Dickson also exhibited a flower of *Tropaeolum* (Indian Creeper) having two spurs. Mr. Geric exhibited cones of *Picea cephalota* and *Cupressus Lambertiana*, produced at St. Fort, Fifeshire. Duncan Forbes, Esq., presented cones of *Picea cephalota*, taken from a tree at Culloden House, 15 feet 8 inches high. Mr Fowler, of Castle Kennedy, sent cones of *Picea Fendleri*, P. Webbiana, and *Abies orientalis*, produced there. Mr Bissett presented cones of *Picea cephalota*, produced at Moncrieffe, Perthshire. Mr. McNab exhibited cones of *Picea Nordmanniana* from the Cambridge Botanic Garden. Professor Christison presented the fruit of a species of *Strophanthus*, which yields an arrow-poison used by the African natives on the Shire.

ENTOMOLOGICAL. Nov. 15.—Mr. H. W. Bates, president, in the chair. Mr. Edwin Deane, of Hartlepool, sent for exhibition a large number of *Ichneumon* specimens, and at town, which Mr. F. Smith stated was identical with specimens of a *Ichneumon* species in the British Museum from North Bengal. Mr. F. Smith exhibited specimens illustrating the economy of *Rhipiphorus paradoxus*, which resides as a parasite in the nests of the common wasp, in opposition to the views contained in Mr. Murray's paper on this insect in the last number of the "Annals of Natural History." These specimens had been collected by the late Mr Stone, and distinctly showed the parasitic larva with its head immersed in the soft body of the wasp-grub, which was sucked dry in the course of 48 hours. In one instance a pupa of *Rhipiphorus* and one of the wasp had been found in a single cell, but both were stunted in size, and Mr Smith mentioned instances in which a parasitic larva had not succeeded in killing its victim. Professor Westwood cited the Rev. Iansdown Guilding's observations on *Horia* to the same effect. Mr Pascoe exhibited a number of new species of Australian Heterocerous beetles, including a species of *Holeus*, covered with a white secretion, which had been considered to be a Fungus growing on the insect during its lifetime. Mr Wallace, however, considered it highly doubtful whether the secretion was really vegetable and not of an animal nature. Mr Briggs exhibited *Deloipea pulchella*, taken on Oct. 1st at Fokestone, and Mr. Dairy, a number of beautifully preserved Lepidoptera larvae. Mr A. Miller made some observations on the peculiar scent emitted by *Cynips ligulella* and another taken by Mr. Salvin read a paper on *Clotilia*, a genus of beautiful American butterflies, of which he exhibited six species. Mr Bates read a paper containing descriptions of new species of Lamellicorn and Longicorn Beetles, collected at Chontales, in Nicaragua, by Messrs. Belt and Janson, and Mr. Baly sent a memoir containing descriptions of new genera and species of Hymenoptera, chiefly from the East India and South America. Mr. Herne and the Secretary communicated various observations on the great swarms of Syrphids observed by them on the southern and eastern coasts of England during the past autumn, and which were almost unanimously regarded by the members present as having been reared in this country, and not blown across the sea from abroad, the vast swarms of Aphides previously observed being sufficient to account for the extraordinary numbers of these aphidivorous flies.

Notices of Books.

Dottings on the Roadside in Panama, Nicaragua, and Mosquito. By Bedford Pim, Captain, R.N., and Berthold Seemann, Ph.D., F.L.S., F.R.G.S., &c. London: Chapman & Hall. 1869. Pp. 469. "On April 4, just when the morning star had announced that dawn of day was nigh, two solitary horsemen on muleback might have been seen slowly wending their way through the suburbs of Leon, and their Cactus and Pine-apple fences. It was yet too dark to distinguish their expression of countenance, but judging from their conversation, and the snatches of tunes one of them was whistling, they were evidently pleased." We seem to have read something very like this before, probably in one of our old friend Mr. G. P. R. James's novels; but in this true history one of the

travellers, no doubt the whistler, was Dr. Seemann and the other was Mr. John Holman, a mining captain of great experience, and who had bound east from the Pacific coast for the purpose of order to ascertain the value of certain mines, and to be, to purchase the best of them. In the latter part of (March to July, 1866) devoted to this purpose, our two travellers explored the districts on the Pacific side of Nicaragua pretty thoroughly, though somewhat disappointed with most of the places visited, they succeeded in purchasing for the gold and silver mine of Javali in the Chontales.

Javali itself is about midway between the Pacific river, which flows into the Atlantic at a place of the same name. The nearest town is Libertad, derived its name from a grog-shop where the man had liberty to do pretty much as he liked. The forest stretches away in an unbroken line to the place, and in its centre is the very productive mine.

Dr. Seemann has long ago earned his name as an investigator, but it is very evident from the way he still travels with his eyes open. His observations or jottings are certainly fascinating reading, and all going on around him, and knows the value of what he sees; added to this he possesses a store of facts collected in most parts of the world, and the power of putting his ideas into words in a clear and pleasant, if somewhat abrupt style. Not a botanist eclipsed by the practical man; quite the contrary, for when on Peza Blanca the highest peak in Chontales, he found that many of the plants had been destroyed by fire, he tells us that "a man who had kindled the flame was with me, and somewhat astonished when, instead of receiving qualified praise for having cleared the view, it was fortunate, standing as we did on the yawning precipice, that the enraged botanist was somewhat mollified by my appreciative fine landscape which he had, as it were, unriddled."

There are many notes scattered throughout of the volume on the character of the vegetation of various districts, and on individual new or rare plants some of which have been already quoted in a journal. At Leon the yards or patios in the low houses "are in some instances nearly as gardens, where one finds a few Plantain, Orange, granate, Soursop and Mango trees, as well as Cockscombs, Gomphrenas, Frangipania, Jess and Polianthes tuberosa; highly-scented flowers being to be those most cultivated." In the Chontales gold region many plants with variegated leaves observed. "There are some fine species of *Cissampelos* (including besides the well-known *C. zeylanica* several new ones); two beautiful species of *Cissua*, one with bright scarlet flowers (introduced by me into English gardens), and several *Mimosa* and *Aroides*. But the finest of these is the one named *Cyrtodeira chontalensis*, a non-vascular plant (See *Gardener's Chronicle*, p. 655, 1867).

Our author's views with reference to popular science are worth notice, and may be gathered from the following. He says: "Make it a point of popular scientific writings to have your facts correct, and you need not, in my opinion, be aware of whatever form you may choose to employ in them before those whom you have undertaken to instruct." Whilst we heartily recognise the value of truth in this sentence, we must enter a protest against its furthest application. No one can convey sound scientific information in non-technical language better than Dr. Seemann, when he tries to do it. Though one may not follow him in some of his rather bold conclusions, one cannot fail to be struck with the ease with which in ordinary conversations the discussions on pile-buildings, on the extinction of races, on the native country of the Cornut, and on the similarity in character of the rocks in the north of England and in Chiriquiare. This sort of writing is natural to him, and is such a merely popular naturalist could pen. But what Dr. Seemann labours to be over-condescending to the scientific mind, the result is far less satisfactory than shown in the story of the Mistletoe and the Apple in which the elaborate verbal machinery is altogether out of proportion to the somewhat unscientific result attained.

We should not be giving a fair view of the matter under notice were we to omit its humorous parts many parts are very amusing. What is better than the following "petition" of a new country from Jamaica, unfortunately in the character of Panama:—"My dear Gentlemen.—I have just put my Pen in hand to address you in these few lines, hoping when it reaches your hand it may have just it leaves me at present, Sir, and I have just put in favour if you could let me have something if you please for I am a Poor Stranger and I have got No Person to give nothing at all, Sir, or I am in the Chain Gang, for I for stealin, for the Holy Bible says in the 15th Chapter of Exydos Honesty is the best of Policies." Can you be surprised at hearing that the request of this interesting convict was complied with? A very following religious tale evidently loses nothing in telling:—"Whilst at breakfast in a small village, a man of the place came into the house, and stood steadily gazing at me for some time, rather startled by the information that his brother was in Panama. All I could do was to assure him that I was very sorry to hear it. But couldn't you do anything to get him out of it? he asked. I don't think that I have any direct influence in that quarter, was my reply. You have, the stranger assured me; I am going to the masses said for his soul, and should feel obliged to

your giving a few reals towards paying the cost." Of course as before, the ingenuity of the beggar was rewarded though the donor was afterwards of opinion that he had only relieved a thirsty soul.

But we must pass on to the remainder of the book. Captain Pim and Dr Seemann are old shipmates, and therefore understand one another, so that when the latter lays down his pen at the end of p. 208, the Captain starts off on a new tack on the next page, and continues in the volume. He is so well known in connection with the development of Central America that it is scarcely necessary to say that his chapters are full of information, and show how completely he has mastered the whole subject. It is chiefly the Mosquito coast that is treated of here, and especial attention is drawn to the various political events which have occurred in connection with Grey Town and Bluefields. Captain Pim, who writes with all the humour and blunt honesty of a sailor, is no admirer of United States policy, as shown in the application of the Monroe doctrine to Mosquito, which is under British protection; nor does he look upon the "irrepressible conflict" as an interesting creature, equal with, if not superior to, the white races, to be indulged to the utmost on every opportunity.

Our author's valuable and suggestive work "Gate of the Pacific," was published in 1857. Since that date he has been four times into Nicaragua, constantly endeavouring to gain up the country, and establish overland routes from sea to sea, and in spite of all the disappointments he has had to endure, his writings show how enthusiastic he still remains in his favourite project.

Perhaps the most interesting portion of Captain Pim's part of the "Dottings" is that devoted to the King of Mosquito. This monarch, however little known to European sovereigns, is, if the Captain's account is not tinged with the flattery usually tendered to royalty, well worthy of his rank. He is very anxious to improve his country by every means in his power, and especially by the cultivation of English relations. A rather singular feature in his character is a melancholy, produced by the conviction that he is the last of his race, and by the spectacle of the evident though gradual extinction of his people. It is the same in Mosquito as in all other countries where races are in contact, the old nation is dying out, slowly but surely, and here, as elsewhere, the immediate cause of extinction, from whatever this may result, is the fact that sterility constantly increases. In Mosquito, we are told, that a birth is now a very rare event among the Indians. The ugly spot in the king's character is his partiality to the bottle, but he showed a self-control in this respect, remarkable in one of his race, during the whole period of his cruise in H.M.S. Gorgon. Captain Pim having represented to him the bad example which would be set to the crew by one of his extra officers giving way to habits of excess.

We have dwelt at such length on this book to show its varied nature; and can only allude to Captain Pim's account of a 45 hours' cruise in a canoe up the Bluefields river, by which he determined with certainty that it was navigable for 65 miles from its mouth—and to Dr Seemann's very well-digested and instructive historical sketch of the rise of the bucanneers, and their invasion and destruction of Old Panama. In connection with the latter we may also draw attention to the extensive list of books and papers, arranged in chronological order, relating to Central America, which must be of very great service to all interested in the chequered history of those countries.

If the book is somewhat loosely put together, or the matter not very satisfactorily arranged, still we must remember that it does not profess to be more than a collection of "dottings." We have no hesitation in recommending it to our readers as a book containing an immense amount of accurate information on the history, topography, ethnology, and natural productions of a little known part of the world, conveyed in so amusing a style that we fancy few persons will commence reading it without finishing the volume.

Florists' Flowers.

The simplest way of getting up a stock of TREE or PERPETUAL CARNATIONS is the following:—Place the stock plants in a gentle heat at once. Take off the cuttings early in February, and put them in around the edges of 60-sized pots, in equal parts of loam, leaf-mould, and sand; then water well, and plunge in a gentle bottom-heat, taking care it is not too damp. When they are rooted, pot them off singly in 3-inch pots, and replace them in heat until they are well established, after which harden off gradually, and place in a cold frame until April. At that time, if the weather permits, plant them out on a piece of open ground, which has been well dressed with soot, dung, and lime, and trenched from 2 to 3 feet deep. Place a 4-foot stick to each plant, and keep it regularly tied up so that the winds and rains do not break it. By the middle of September it will be in a fit state to pot into a 6 or 7 inch pot, as the case may be. After potting the plants must have a good watering, and be placed in a shady place for a fortnight, being also syringed overhead twice a day in bright weather.

By the time the plants are again established, place them in the sun on a bed of ashes or boards. As soon as the autumn rains come on, get them under cover at once, but give them plenty of air. They should at once commence flowering, and continue all through the winter or spring months, if assisted with a little fire-heat and liquid manure, which latter, when they are well established, they may have once a week. They will delight in being plunged in sweet dung, so as to keep the roots cool, and will root through the bottom of the pot, and over the top. Occasionally dissolve 1 oz. of ammonia (carbonate) in a gallon of water, and water with this solution. If the plants are in a healthy

state the feathery roots may be seen on the surface in the course of a few days, after each watering with the ammonia.

I hope to be able to give you the names of a number of other varieties—English, Continental, and American—in case they prove good for anything. The best lot of seedlings that has yet come under my notice belong to a private gentleman at Arundel, who declines to circulate them in the trade, but who gives to his friends with a very liberal hand. Most people who have travelled between Arundel and Worthing, at any time within the last 12 months, must have noticed the floral display in the windows and gardens at Cross Bush. W. Howard, Barchin.

MR SALTER'S CHRYSANTHEMUMS. We supplement the remarks made at p. 1187 by the following notes on some of the novelties which have blossomed since our previous visit, among which occur some remarkably showy and novel forms. Taking the new Japanese varieties first, one of the most strikingly distinct is named Colonel Hemery. In this variety the flower-heads form a semiglobular open mass of straight, stiff, long, narrow, strap-shaped florets, and being of a deep golden-yellow colour, they are exceedingly showy. Another, named Sol, is of similar form, but of a paler hue. Greater variety is shown in the two varieties which are of the more ordinary form. Of the Japanese variety with curled florets, the Chinese variety is the most distinct, with very long and peculiar large flower-heads, and a decided improvement on the older sorts. Helen McGregor is also an advance on the varieties previously obtained, its colour being a rich deep chestnut-red, and its flower-heads very full and fringe-like. Gibrissa is another fine large sort, with the flower-heads formed of long loose florets, forming a flattish head, yellow slightly tinted with red in some stages, but eventually becoming almost entirely yellow. To another style of flower belong the two following, which are decided acquisitions, in them the florets are tubular at the base but split open at the upper end, and they form large, loose, and highly characteristic flower heads. Their names are Meg Merriles, a bold-flowered white, somewhat yellowish in the centre, and Rob Roy, very distinct as to colour, the tubular portion of the florets being of a dull purplish red, and the flattened expanded parts, which show the inner surface, of a pale amber or buff—very nearly, in fact, the colours prevalent in the wild Honeysuckle.

We have also to notice two additions to the new Chinese varieties—Beauty of Stoke, a large incurved flower of a pale yellow hue, suffused with a tint of red, which becomes more pronounced in age; and Meyerbeer, a medium-sized variety of a pale rosy tint, lighter towards the centre, and remarkable for the breadth of its neatly incurved florets. Virginals is a good addition of the present season, to the group of large white Anemone-flowered sorts.

Another very interesting plant now blooming with Mr Salter, is the variegated-leaved Sweet Violet. Its distinctly white-edged leaves, and deep purple flowers, are well-contrasted and pleasing.

Garden Memoranda.

MESSRS. E. G. HENDERSON & SON'S, WELINGTON ROAD, ST JOHN'S WOOD.—This is one of the principal emporiums for novelties in the metropolis; and especially so in regard to bedding plants, of whatever kind they may consist. It may also faithfully be said to be, not the birthplace of, but the "nursery" from which the pioneers of that now universally admired class of ornamental-foliage Pelargoniums were first introduced to our gardens, where, by their markings and colour they lend a charm which is justly appreciated by all who possess a taste for floriculture.

During the summer months Messrs Henderson's trial grounds are well worthy a visit, for here are to be seen the newest candidates for bedding-out honours, grown side by side with their more established rivals. Unfortunately our visit was made somewhat late in the season, for already many of the choicest plants had been cut up for stock. Amongst golden-foliated plants, the Puchsia has been making perhaps slow, but steady progress in making its way into the summer borders. Already several good novelties in this way have appeared; and, in some new varieties which Messrs Henderson possess, still further improvement is perceptible: of these three new varieties, named Golden Treasure, Golden Mantle, and Crown of Jewels, are not yet sent out. The former is a prostrate-growing kind, with beautiful yellowish foliage and good habit. Golden Mantle produces exceedingly fine large golden-foliated leaves, and in colour is much superior to the variety known as Crown of Jewels, sent out by this firm in 1867. Crown of Jewels is the dwarfest, or more prostrate growing form. The young growing points of the shoots are of a rich ruby colour, and as they get older they become golden coloured, making the plant somewhat suggestive of clusters of rubies on Cloth of Gold, one of the earlier breaks in this form. As seen in a small group, this variety produced an effect which is equalled by few other plants.

A comparatively new feature in bedding out, and one which is greatly rising in estimation, is the "carpet bedding," a system which seems to be much appreciated by Mr Gibson, who adorns the nooks and corners at Battersea Park in this fashion. Of plants suitable for this purpose there is here a fine collection, including also many of the choicest gems of the alpine flora, and a good selection of herbaceous border plants. Amongst the latter we noticed a dwarf free-growing form of Antirrhinum, named Tom Thumb, with orange-yellow flowers. This is a welcome addition to a pretty class of autumn flowering plants which are easily propagated by cuttings, and thrive in any good garden soil. The variety Tom Thumb, when planted out, and its roots established, should have the centre shoot

picked out, which makes the plant become dwarf and bushy, and greatly improves its appearance when flowering, which it does freely. *Cineraria scanthifolia*, a compact growing variety, is a fair substitute for the *Centaurea*, which it surpasses for ribbon borders, on account of its uniform and regular growth and its neat appearance. For growing in pots for conservatory decoration in autumn and winter, it is one of the most useful subjects of its kind. *Centaurea tenuis* compacta is a dwarf and compact growing variety, with fine silvery foliage. *Gnaphalium tomentosum* a small close-growing silvery-leaved plant, was here planted in an oblong round ceramic bed of Mrs Pim's, producing a distinct effect. A good feature in this plant is, that when planted out it can be kept to any moderate height by pinching, without backing for staff. *Acrocarpa Andersoni* was also doing well. Of this plant I may be remarked that it succeeds a variety when planted in a similar manner to Box. Another very dwarf silvery-foliated plant, more suitable for carpet bedding than for edging, is the *Achillea umbellata*.

We also remarked a fine variety of yellow Pansy, named Golden Bedder, a dwarf compact grower and profuse bloomer; a good variety for associating with the Imperial Blue. Though there are several good yellow Pansies mentioned as possible successors to the *Golden Bedder*, we saw none which we considered worth the notice of the *Golden Bedder*. It does not do well in the conservatory, but in the open air it does well. It is a good variety for ribbon borders. Of perpetual flowering Pansies there are here two good varieties, named Rose of England and Plato, the former a belted, and the latter a self-coloured rosy flower, both of which are said to flower more or less for nearly the whole year. Also a reddish-striped winter flowering Carnation named Atlanta.

Amongst early plants were fine little specimens of *Cryptomeria japonica*, a much neglected graceful-foliated Conifer, that is perfectly hardy, a golden variegated variety of Chinese Privet, which is very beautiful planted en masse. *Genista prostrata*, a capital subject for rockwork, and also for hanging baskets; *Hydrangea paniculata grandiflora*, a fine large free-flowering variety introduced about three years ago, but since almost lost sight of, until a specimen appeared at one of the autumn meetings of the Floral Committee, where its merits were judged worthy of a First-class Certificate. It is not a particularly quick grower, but it possesses the desirable qualities of hardiness and adaptability for forcing. In a collection of hardy Ferns was a specimen of *Polystichum lonchitis*, obtained from Donegal, and growing very freely here; this is said to be more free in growth than the Scotch form of the same species.

The houses are numerous, and are built on economical principles, being for the most part span-roofed structures on walls but little raised above the ground, and with a sunk path down the centre. In the manner stages are disposed with, and the plants are well exposed to the light. We noticed one house entirely filled with *Caladiums* of almost all forms and shades of colour. This class of plants, though requiring plenty of heat and moisture for its successful growth, is nevertheless admirably adapted for grouping with other plants in warm greenhouses, where the bold, varied, beautifully coloured foliage is greatly admired in summer when really good flowering plants are at a discount. In a comparatively cool damp house, containing principally *Cattleyas*, were several specimens of *Dendrobium Falconeri*, thriving and looking remarkably well, and the rare and beautiful *Cattleya Dowiana*, with numerous fine flowers. In another house was a very handsome variety of *Oncidium Papilio*, and a large specimen of the magnificent *Gloriosa superba* in full bloom. It is thought that this latter is a variety, being stronger and robuster in growth than the species in question is generally seen. *Cobaea penduliflora* is very distinct, having dark green foliage, and producing bell-shaped flowers, with long, wavy, greenish-white segments. Another plant of which little is known in this country is a species of *Napatorium*, named *gracile odoratum*, which forces well, and comes into flower about Christmas, producing sweet-scented white flowers. It is said to be largely grown in America for cut flowers, and is in much demand for wedding bouquets.

Miscellaneous.

A Fruit and Flower Fair.—They are blowing for button-holes all the year round, and the hunting men now wear yellow ones in their scarlet coats, with a background of Neapolitan Violets. From February to August from 1866 to 1869 yellow Roses are sent up per week by the first train in the morning to the establishment at Knightsbridge, for the button-holes and bouquets of the day. The yellow Roses are eight months in flower, and four at rest. Their three principal varieties are Madame Falcoo, a deep copper yellow; Isabel Sprunt, which is perhaps the *prima donna*, with its lovely pale straw colour; and Marshal Niel, "a fat flower," of a rather more decided yellow. The button-hole business has increased immensely during the last two or three years, and as *a la Russe* dinners have rather gone out, the flower has become far more profitable than the fruit trade. Bridal bouquets have the pure white *Garland* to encircle the Orange blossom, *Stephanotis* (which is in bloom for eight months next to it for the general groundwork, and the *Hedera japonica*, which is a feathery appearance, which looks up the *Stephanotis* white *Harvard* which is like variety, white Or-holes, with three *Stephanotis*, and fairy rosebuds set on silver *Stephanotis* being backed up with Fern and Myrtle. At Mrs Henderson's are employed in the composition of Court bouquets, and the place of the Orange blossom is often taken by a *Camellia*. For general business there is also a run on

the *Eucharis amazonica*, *Stephanotis*, *Jasmines*, *Carnations*, *Picotees*, *Neapolitan Violets*, *Anthurium Scherzerianum*, *Orchids*, *Camellias*, *Heaths*, *Lilies of the Valley*, *Myosotis*, and *double Pelargonium*. Perhaps no flower does more service than the *Bouvardia*, the white for bouquets, and the red for button-holes. The *Anthurium Scherzerianum* is a very favourite crimson, with a horn like a shepherd's crook from the centre: as the flower fades the horn grows larger and hardens, and becomes the pouch for the seed. Maiden-hair, with its minute black stems, comes well into a bouquet, and the *Amazonian Lily* (*Eucharis*) is first favourite for ladies' back hair, along with flowers and Ferns. We found a plant of it in one of the houses, with fifteen spikes and seven flowers on a spike. When it is rifled of these treasures it will rest till Christmas, and then take the place of white *Camellias*, and with rest it will flower three times a year. The *Italian Tuberoses* last for five months, and afford a nice autumn white flower; and *Forget-me-Not*, blue *Hyacinth*, and dark *Myosotis* have a heavy run on them when the Oxford and Cambridge boat race comes round. *Thujopsis borealis alba* takes its part among the white division all the summer, and in winter the "Ascot yellow" *Picotee* flourishes bravely. The City folks generally wear a small flower or single bloom in their button-hole, whereas the West-enders like one much larger. *The Gentleman's Magazine*.

The Tyranny of Gardeners.—In an article relating to the Royal Horticultural Society's Fungus meeting, which appeared in the *Echo* shortly afterwards, the writer thus describes the relationship between gentlemen and their gardeners:—"A gentleman who only knows the few things necessary to obtain a double first at Oxford, or perhaps to take a share in the government of this little State, indulges himself in the dream that his leisure hours, few and far between, may be advantageously passed in his own garden, amid the flowers which he loves, albeit he has no time to cherish them himself. Oh, vain delusion! He enters the sacred precincts. Perhaps he is audacious enough to keep a key, and to let himself in without humbly ringing the bell; but once inside the wall, he meets his master. The gardener approaches, courteous, though somewhat stern; and the gentleman rouses himself to make some encouraging remarks and criticisms. Poor fellow! how soon his little light is extinguished! How he is snubbed with *Cinerarias*, and brought up short with *Calceolarias*, and extinguished with *Scolopendras* (!), each and all of them having another long name tacked on to its tail. There is no use in talking about wishing this bed here, and the other there, or pleading for more sweet flowers, or asking what has become of all his old favourites. The despot settles him every time he opens his lips with a mouthful of uncouth syllables, to which it is impossible he can attach any single idea. Then he learns by degrees that gardens are not kept for their ostensible proprietors, but that flowers are grown to be exhibited, so that the gardener may obtain prizes, and three-fourths of the fruit is plucked in the blossom to allow of a few specimens attaining gigantic size and being sent to a horticultural show, to be eventually eaten by the judges."

Peach Palm. The clustered stems of the Peach Palm (*Bactris Gaspaes*) grow to 60, or even 90, feet high, and are thickly armed with long prickles. The numerous curling and drooping leaves rarely exceed 7 feet, and they have from 50 to 60 leaflets on each side, aggregate by threes and fours, and pointing in all directions. The fruits are massed into large pendulous corymbs, and if from their size and vivid colours of yellow and red they may be likened to a well-ripened Peach, in shape they more resemble a hen's egg, although usually rather more conical. The thick, firm flesh is mealy when cooked, something between a Potato and a Chestnut in flavour, and superior to either. A seedless variety is common, but the fruits are much smaller, and contain no more edible matter than those that have a stone (or endocarp) in the centre. *R. Spruce* in "Journal of the Linnean Society."

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

AMONGST the subjects which will now come in useful to maintain the display of flowers are some of the varieties of the beautiful genus *Amaryllis*. *A. aulica*, which, when grown from seedlings, affords so many shades of scarlet, we have had in bloom some time. The varieties to which I more immediately refer are *A. formosissima* (the *Jacobaea Lily*), *A. splendens*, *A. Brilliant*, and *A. solandraefolia*, &c. To insure fine blooms of either kind, a slight amount of bottom-heat may be afforded. As it does not often occur that the operator has a nice, moderately dry, warm bed of tan for the purpose—beds of fermenting materials being so moist—perhaps the best place for them would be upon a board placed either upon a pipe or a flue or other fixture near them. At this, their flowering period, moderate waterings only should be afforded, and if short, sturdy flower-stalks are required, they must be kept in as much light as can be admitted to them. The lovely *Schizostylis coccinea*, if it was turned out into the border during the summer, and potted up a month ago as advised, will now be blooming freely, and will continue to do so in an open, airy conservatory or greenhouse for some time to come. Keep the two species of *Tropaeolums*—namely, *pentalophyllum* and *speciosum*—if grown in pots, somewhat dry, and so hasten the resting period. Some varieties of the semi-hardy shrubby *Veronicas*—especially *V. Andersoni* fol. var., &c., will also afford a very gay addition to the flowering plants; the only care they require, except occasional waterings, is to keep damp from settling upon their flowers. However severe the weather may become during the

incoming week, be particular not to encourage too high a temperature, which many are very apt to do when they have fires in full work. I have frequently urged the desirability of covering up all houses during severe frosty periods with mats, or any other materials which may be at hand. It is astonishing the amount of both labour and anxiety which is saved by this simple process, especially to the amateur, who may have many other things to attract his attention apart from gardening. Besides saving fuel, it is far better for the health of the plants. Should the frost at any time—and the wonder is that this is not more frequently the case—take hold of the inmates of any structure, the only remedy which the amateur has is to increase the internal artificial heat at the earliest possible moment, watching the thermometer in its upward tendency until the freezing-point is reached, when between which point, *i. e.*, 32°, and the next degree, 33°, let every plant be copiously syringed with cold water over all the frozen parts. This being done, shade them well from the sun, and do not allow the temperature to be raised for the rest of the day above 44° or 45°. Air should be given sufficient to dry up the excess of water which has been expended. Let the temperature of all greenhouses proper be now reduced to as near a mean of 40 as possible by artificial means only. Of course an upward tendency of some 8° to 10° must at all times be admitted from sun-heat, wholly apart from any aid by artificial heating.

FORCING HOUSES.

Those *Vineries* which are in preparation for starting between the present time and the last week of this month, may now have the necessary amount of fermenting materials placed on to the outside borders. This will afford a kindly warmth by the time it is wanted. To delay this operation until the inside is being started is, to say the least, a mistaken idea. Be careful not to let those Vines which are actually growing have a night temperature exceeding a mean of 57° by night, and 61° or 62° by day, if severe weather supervene, and much forced heat is necessary to maintain such a maximum. Those persons who may be just starting their vineries should not allow the temperature to exceed a mean of 50° by night, and 55° by day; this, with frequent moistenings until such time as foliage is produced, when a somewhat modified humid regimen will have to be adopted. In regard to *Pines* it will be necessary, should severe weather exist during this month, to keep the night temperature down to as near 60° as possible. Be particular to use mats as protective coverings to all *Pine-pits*, &c., where practicable, for the reasons given above. Give as much air as possible to all *Peach* and *Nectarine trees* which may be in flower, and have recourse to artificial fertilisation. Do not force *Cherries* too quickly at first, but by beginning as low as from 44° to 46°, bring the bloom buds forth very gently, so that as much strength as possible may be given to each bloom. Those *Strawberry plants* which were introduced into cool pits or vineries a few weeks ago, may now, if early forcing is intended, have the pots plunged into bottom-heat of from 68° to 70°. Keep the tops or crowns cool for a week or longer, so that the roots may have a good start.

HARDY FRUIT GARDEN.

Bush fruits, such as *Gooseberries*, *Currants*, &c. must now be watched to see that the birds do not destroy the buds. Independently of bullfinches and blackcaps, I have known sparrows to strip the buds from both Red and White Currants at a dull, hard period. To prevent this, few things are better than to twist a few reels of white cotton conspicuously around the branches.

HARDY FLOWER GARDEN.

In continuation of my previous remarks upon *Hardy Climbing Plants*, I will now allude to such evergreens as are used to embellish walls and vacant spaces, with less rambling growth than those previously referred to, and amongst which the best variety of *Magnolia grandiflora* stands pre-eminent. *Escallonia macrantha* is another very beautiful glossy-leaved evergreen, bearing a profusion of red flowers; both these plants require the protection of a mat or two in winter. *Cotoneaster Simonsii* is a very neat foliaged plant, with bright red berries; next to which, *C. uva-ursi* is commendable for the size of its leaves. The red *Pyracantha* (*Crataegus Pyracantha*) has the peculiar merit of retaining its clusters of scarlet berries through the winter—that is, if not consumed by birds, who like them much. There also exists a white-fruited variety. Two or three of the well-known *Berberis*, if well trained, make very pretty objects for walls and the like, especially such as *B. Darwinii*. The large-leaved *Mahonia* (*B. macrophylla*), the Japanese evergreen varieties, *B. japonica*, as well as *B. dulcis*, &c., are all pretty. *Chimonanthus fragrans*, though leafless, produces very fragrant blooms at a season when they are very acceptable. *Forsythia viridissima* will afford a very pleasing variety, whilst *Jasmenum nudiflorum* endures the winter through with its plentiful yellow flowers. The Box-leaved and the azurean varieties of *Ceanothus* from Mexico are now seldom to be met with, though they do well against south walls. I would just enumerate, by the way, *Lonicera aureo-reticulata*, *Aristolochia Siphon*, a fine large-leaved plant for summer display alone, especially if trained upon poles or attached to verandahs; also *Dioscorea Batatas*, for a like purpose; the Parsley-leaved *Bramble*, and to those who would not grumble at a good 5s. worth, I may mention that there is a new Japanese variety of the *Virginian Creeper*, which is rather more compact in habit, with more colour than the old one. Then for minor fretwork, such as for small screens to embellish the base of aviaries, for fire-screens, window-sills, and every place where a healthy, thriving, minute creeper is a desideratum,

there is *Veitch's* miniature-foliaged *Virginian Creeper* (*Ampelopsis tricuspidata Veitchii*), a perfect gem in every way. I have not exhausted the list, but will now close—last, though not least—to the recent acquisition of the way of *Clematises*. From *C. Flammula*, the smallest and also the sweetest, up to *C. Thomas Moore*, the largest, there is every shade of colouring which the most fastidious could wish for; whilst as a double-flowered variety, the azure blue *C. John Gould Veitch*, should find a place in every garden. I must leave other subjects of more growth, such as shrubs, both deciduous and evergreen, for a future time.

KITCHEN GARDEN.

Continue to collect and store fallen leaves, and place any fresh soils upon beds or borders, as it is intended to renovate any this winter. Get a fortnight's supply of *Jerusalem Artichokes*, *Pumpkins*, *Horse Radish*, and all other things which are obtained during severe weather. *W. E.*

TOWN GARDENING.

THOUGH the *Chrysanthemum* is a toady plant, I have known a long and hard winter in many plants; therefore I advise that they be taken up, and laid in by the heels in rows, kept sort separate. They can then be easily covered and protected from frost. The borders will then be ready for a winter fallow, which is of great importance. It will also be advisable, where *Hyacinths* and other bulbs are planted in beds, to cover them with a layer of cocoa-nut fibre or tan 2 or 3 inches deep. During heavy showers of rain or snow a covering of mats should be superadded. In February, if the frost breaks, the covering should be nearly all removed with the hands as carefully as possible, so as not to injure the long and slender, and incapable of supporting the flowers. After this they should be protected from heavy rain and frost by mats thrown over hoops placed away in the dark should now be brought to light, and a few more firm roots placed away, as directed at p. 972. This will aid in keeping up a succession as they come into bloom in the open air. *J. D.*

STATE OF THE WEATHER AT CHISWICK, NEAR LONDON For the Week ending Dec. 8, 1889, as observed at the Horticultural Gardens.

Dec	Moon & A.S.P.	BAROMETR.		TEMPERATURE				
		Max	Min	Of the Air			Of the Earth	
Thurs	2	29.958	29.896	34	17	25.5	41	41

Satur	45.8	33.7	39.7	20	0.59	6	3

The highest temperature during the above period occurred on the 15th, 1868, therm. 69 deg., and the lowest on the 12th, 1868, therm. 7 deg.

Notices to Correspondents.

ABYSSINIAN MIXTURE F.S. Received, and under trial.
 BOOKS—C.R. Grigor's "Arboriculture" is the most complete and useful of any book we know—C. Lawrence, the "Pomologist," if not too expensive.
 DISEASED ORCHID LEAF G.G. We have never seen anything like the affection on your Orchid leaf. It is not a case of spot, nor does it in the least resemble that disease. Can you give any real cause to account for it, depending on its position in the house? It shall be submitted to the Committee at the next meeting, at South Kensington, on Dec. 11.
 INDIAN FOREST SERVICE—Const. & Rev. Secy. Write to the Secretary at the India Office.
 LOMARIA GIBBA: R.H. There are several well marked forms of this fine dwarf Tree Fern, namely, *dellii*, *major*, *minor*, *zealandica*, &c. The latter, in its aspect, in some degree approaches *Blechnum brasiliense*.
 NAMES OF FRUITS—H.L.H. 1, Suffolk Thorn; 2, Monarch; 3 and 4, Bourré d'Arnhemberg; 5, double Plus Meurle; 7, Glou Morgeant.
 NAMES OF PLANT: J.B. We will ascertain.—If P. *Agrostis squarrosa*. We do not know the work referred to you had better wait for the publication of the coming work by Mr W. Wilson Saunders and Mr. W. Smith.—R.J.B. Your plant is neither *Atriplex* nor *Podium*, but the common *Mercurialis annua*—(the Elm), *Veronica elliptica*.
 OXFORD SHOW. H.J. New arrangements will be made embodying some of your suggestions.
 PICEA PINNATA W. Wildsmith. The specimens have been received. We will exhibit them at the next meeting of the Scientific Committee, on December 21.
 PRUNING FRUIT BUSHES. H.M. Yes; but prune close.
 STRAWBERRY A.M.A. We believe not at present.
 VINE STYPTIC. Channel John Young & Son, Dalkeith. People with goods to sell should advertise them.
 COMMUNICATIONS RECEIVED.—W.F.—J.G.—G.A.H.—J.C.—D.C.—C.L.—Q.R.—G.P.—J.McM.—Sap.—Equine.—A.F.—J.B.—A.W.—P.G.—E.C.—F.S.

OUR LIVE STOCK.

The following measurements of cattle were taken during the past week at Islington. Lord Penrhyn's steer, in the Shorthorn class, not exceeding 3 years and 3 months old, is a noble-looking animal: he girths 8 feet 6 inches, and is 5 feet 4 inches long. In this case the live weight is 20 cwt. 0 qr. 13 lb.; and as he will probably yield about 70 per cent. of beef, his dead weight will not be far off 14 cwt. On the other hand, calculating his weight from measurement and using '28 as the decimal multiplier (see "Ewart's Agriculturist's Assistant"), he ought to weigh 13 1/2 cwt. We measured Mr. Outhwaite's steer (No. 81), the winner of the first place in the class for steers above 3 years and 3 months old. His girth is 8 feet 7 inches, and his length from shoulder to rump 5 feet 6 inches. His live weight is 20 cwt. 1 qr. 6 lb., which, if it yields 70 per cent. of beef, makes his carcase weight to be 113 1/2 stones. Taking the method of calculation from measurement, his weight ought to be 113 1/2 stone. The method used in the above cases in order to calculate the carcase weight is as follows. Square the girth, reducing the inches to decimals of feet, next multiply by the length in feet and decimal parts of a foot, and finally multiply by a number varying from '23, in the case of half fat inferior animals, up to '28, which would only be used in extraordinary cases, such as we are now considering. Among other extraordinary cattle may be mentioned one exhibited by Mr. Scales, of Grantham (No. 95): the girth and length of this animal were respectively 8 feet 10 inches and 5 feet 4 inches, and his live weight is 21 cwt. 3 qr. 14 lb. The fineness of bone in the case of many cattle was very remarkable, especially among the Devons. We noticed one case particularly, that of Mr. Nixey's beautifully level 4-year-old heifer, No. 29 in the catalogue: the bone immediately below the knee of this heifer was smaller than a man's wrist, only measuring 6 inches, and yet this was supporting a weight of above 12 cwt! We hope on a future occasion to be able to give the absolute weights of some of the above-mentioned animals, and also of many others whose measurements were ascertained during the Islington show week.

We have received the following communication from Mr. Willoughby Wood:—"I am happy to tell you that Oxford's Ada brought yesterday a fine rich roan heifer-calf by NORTHERN DUKE (22,431), which does great credit both to his sire and his dam. She has all the marks of high blood, together with a degree of vigour not always exhibited by the possessors of long pedigree."

COST OF STEAM CULTIVATION.

"G. A. H." says, "I observe that Mr. Smith adopts your explanation of the 1s. 6d. per acre for interest of money and wear and tear. . . . I assert that Mr. Smith's own figures prove his declaration to be totally devoid of foundation, that he is in fact deceiving himself, and in deceiving himself he is deceiving the public." And he goes on to say, "What I complain of in Mr. Smith, is that he endeavours to persuade small farmers, having only 100 acres to plough every year, that it will pay them to purchase, for their own use only, a set of steam tackle, and that when they have done so their seed-beds for Wheat will only cost them 6s. 8d. per acre."

I will take the points as they stand. In 1855 I provided myself with a 7-horse engine (cost 200l.), with a windlass, &c (cost 80l.), and with a smasher and a digger and subsoiler, made by my own blacksmith (cost together 18l.—total 298l.). With this engine and apparatus I started in December, 1855, but found the engine, windlass, and anchors all defective. I then altered the engine and windlass, and had made by my own blacksmith a set of new anchors, and got another snatch-block, and afterwards another, at a cost of 33l. This brought my total up to 331l. With the apparatus thus improved I made some further trials, and on November 13, 1856, I wrote thus to the Mark Lane Express:—

"I have since harvest ploughed by steam the whole of my farm except a bit of Wheat stubble left to try an experiment on in the spring, and a bit of Clover ley ploughed by horses. In ploughing my Bean and Pea stubble at a depth of 6 inches I did an average of 5 acres per day, including men, coal, water, and horses for shifting, at an average cost of 5s. 2d. per acre, and in ploughing my Wheat stubble at a depth of 8 inches on the heavy, and 10 inches on the light land, I did an average of 3 acres per day, at an average cost of 8s. 8d. per acre, including men, coal, water, &c. To this must be added interest, and wear and tear—say, 1s. 6d. per acre, which will be the outside, the tackle coming in nearly as good as it went out."

Now this extract does not tell us the quantity of work done in 1856, but my book on steam cultivation does. Here it is:—

Table with 4 columns: Description of work, Field No., Acres, and Days. Rows include Smasher 16 inches deep, Heavy land, Light land, Ridge-ploughing and subsoiling, Heavy land, and Light land.

Therefore the total for the year of the two kinds of work was 65 acres. After completing the work I estimated the fair amount for depreciation and interest that should be charged upon this small quantity of work done, taking into consideration that the engine was employed for threshing, &c.; and besides this, I had sold three horses off for 150l. to make way for the engine. I came to the conclusion that 1s. 6d. per acre would be a fair charge for interest and depre-

ciation, &c. That has been my charge down to this day, and it has never until now been questioned, although it has been regularly published in the Messenger every year when that paper reported my cropping, and that mode of estimating has been adopted and practised by all excepting "G. A. H."

Only the Royal Agricultural Society took two hundred days as a basis when it awarded its 500l. prize at Chester, and it has made similar estimates ever since in the award of its prizes. But let us test the point, and see whether it was fair or not. The work done was 65 acres. The total cost of tackle stood at 331l., from this I must deduct the 150l. for three horses sold off to make way for the engine; this reduced the total, and I must charge the half of the engine to threshing, 100l. These two items together reduced the total to 81l., therefore in December, 1856, there was 4l. 1s. due for interest; 1s. 6d. per acre on 65 acres would over-pay this by 16s. 6d., but 16s. 6d. would not be enough for wear and tear and depreciation, although the tackle went in without any apparent wear and tear; but I have another item to bring in—the saving of the keeping of three horses sold off to make room for the engine, &c.; this, at 25l. each, gives me 75l. Here is enough and to spare. I was not "deceived," for I knew that I was winning. And here is another item of gain that I must bring into consideration—60 quarters of Peas grown upon 12 acres of heavy clay land, that under horse culture would have been dead fallow. Surely I have said enough to show that I did not make an unfair estimate of interest and wear and tear when I fixed it at 1s. 6d. an acre.

Will "G. A. H." tell me again that I am deceived about my 6s. 8d. an acre seed-bed for Wheat, or my 1s. 6d. an acre for interest and wear and tear? The fact is, I had no extra interest to pay, and the 1s. 6d. per acre might all have been placed to wear and tear without using the word interest. I need not go into the question of 100l. for change of engine in 1859, for you see that I had already gained enough to pay it.

I will now state my case again, by taking my starting-point at Michaelmas last, when I entered upon my new occupation, bringing my total arable land up to 163 acres, showing the number and cost of horses, &c., that would have been needed to work it by horses only, and the number and cost of horses, &c., with the cost of an engine and a set of steam tackle to work it upon the Woolston system. I shall fix the cost of a horse with its tackle and implements to work with at 45l.; the cost of an engine at 300l., charging the half of it to threshing; the cost of a set of tackle with a 5-tined smasher and a ridger—the two implements I use—at 266l., the price at which they are offered by the makers to the public, and the cost of the keeping of a horse at 25l.

My 163 acres of arable land consist of 90 acres very heavy clay, hilly, and uneven; in fact, there are five hills upon it, all at points very steep, and 73 acres of what I call light land, but, in fact, not so. It is upon the flat—mixed gravel and clay. Under horse culture, to work the whole 6 inches deep, would need 10 horses; under steam culture, to work it 10 inches deep, I have started off with five. That number will not get half employment throughout the year, but as yet I have a lot of landlord's work to do, and I mean to be well up to the mark for doing all, both tenant's and landlord's, for at least this year. Now, let us look at this picture:—

Table comparing Steam power Cultivation (1869 to 1870) and Horse Culture (1869 to 1870). Columns include engine cost, tackle cost, horse costs, and balance.

This is grand; the large sum of 16l. more tenant's capital is needed to work this 163 acres farm of mine the first year, having the whole in crop, than would have been needed under horse culture having a portion of fallow. "G. A. H." will want interest on this large sum of 16l., and he shall have it, for with my extra cropping under steam culture I shall be able to pay it. Having considered the matter over again, I will not alter my estimate of 1s. 6d. per acre, therefore my seed-bed for Wheat stands at 6s. 8d. an acre.

Now there is a point about this interest on tenant's capital worth looking into. You never hear of interest being charged on horses, their tackle and implements, or on money for payment of labour. When a valuation is made horse-keeping is taken into account, their tackle and implements are also considered, and so is their doctor's bill, and the knowledge of now and then a dead horse is not tossed on one side, payment of labour is also considered, but interest of money never is. I will support my case by an extract from Mr. Morton's paper, read before the Society of Arts, Dec. 7, 1859:—

"Now the cost of horse labour on 21 farms in different parts of the country, of which the particulars have been kindly given to me: those farms employ 282 horses, and they cost for food, for depreciation of value, and saddler's and blacksmith's bills, 7815l. a year, their implements need 870l. a year to keep them good, and the ploughmen an 11,000l. a year, or 46l. a head a year in wages,—about 13,000l. in all, or 46l. per horse per annum."

The farmers had to find this 13,000l., yet interest upon it is not considered. Yet "G. A. H." will make us use the word interest when we talk about steam ploughing. I knew that I must, and I did so, although in my own case I knew that but little additional tenant's capital was needed, and more when increased

produce was brought to bear upon it. My assertion about Mr. Smith's figures being based on a foundation must fall to the ground, for the above proves that I am not "deceived," and I am not "deceiving the public."

Now for the last point. Mr. Smith endeavours to persuade small farmers. Here is an extract of a letter that, in 1858, I addressed and published among farmers of England:—

"September, October, and March are the best months for applying steam power to the cultivation of the soil, deducting Sundays and a few days for the week-end, the working days for September are 14, for October 14, and for March 14, multiplied by 14 1/2 and 14 1/2 and 14 1/2, gives 225, 225, and 225, as a set of apparatus within three months. By the application of steam power it is to be generally applied to the soil, every large farmer must have a set between them on hire, one of another, an arrangement, for September and October will see the work as to be done well, it must be done in the autumn."

My advice to the farmer has always been, and it was in 1858, "every large farmer must have a set of apparatus of his own."

"Two or three small farmers may have a set of apparatus of their own, but it will not pay them to do so, and October will not wait, and if the work is to be done it must be done in those months."

My own practice shows that it would pay a set on a very small farm of heavy clay, "G. A. H." must see that it pays well on a mine—interest wear and tear, depreciation, being considered. Then let him pick up a box about his 1100-acre farm, for he could swinging of it about we must add "deceives" name 6s. 8d. an acre is the cost of my seed-bed—Wheat—interest and wear and tear, &c. being well considered and included, and in one word more—20 acres of my growing Wheat from old heavy land are Wheat after Wheat. This will give time on my new land to drain and clear; 25 it is planted. It will all be under crop next year, part Beans and a part Peas, and it will be a very good Wheat the following autumn. We can do this when aided by steam-power. The Wheat noticed is up, and looks well, and this year the mine will never need a dead fallow, as the dead fallow has been the rule heretofore.

Now, it may be seen that in 1856 a man in 6s. 8d. an acre, and that in 1869 a seed-bed is 60 How is this? is a question that may be asked. I will tell you. In 1856 my land was raw, and the same for cleanliness with other people of the under, hard, horse-trodden surface made for water-furrows a matter of necessity. My engine could work my three-tined smasher deep, clearing a width of from 30 to 36 inches on an average 5 acres a-day. The cost for oil, and water was 5s. 2d. an acre, and I got extras at 1s. 6d. per acre, this brought it up to 6s. 8d. I use the word extra, as I will not drop it up by it 12 in. In 1869 my land, from being working by steam-power, and become dry and clean. The pitch-plaster having been smashed, my engine that I took in exchange ago could work a five-tined cultivator 4 1/2 width, and do on an average 8 acres a-day of men, coal, oil, and water, of 3s. 2d. per acre, add 1s. 6d. for extras: this brought it up to 4s. 8d. brought the total cost of seed-bed up to 6s. 8d. That is a fact, "G. A. H.," you see little before I have done with you, for I am "deceiver."

Now, I ask "G. A. H.," "Agricola" (Mr. Toepffer will not talk to), Mr. Greig, and Mr. who fell foul of the roundabout tackle at Peterborough and all the contracting men together, to tell us we can find a farm worked by steam-power on a contract plan? That is where all the business done by steam-power, the horses having been leaving just enough to do the harvest, and work, as well as the light cultivations, and Mr. Torr has been a great advocate of the matter yet he has only had a few acres a-year done on occupation, and I cannot hear of any one who has more than he. Mr. Bates in the Times, and a Berkshire farmer in Bell's Messenger, weeks ago, showed us to some extent the nature of the former had 7 1/2 acres done by steam-power over at a cost of 27s. 2d. an acre. Such a system would make beggars of any men who would continue to scatter their money for the purpose to scramble for. I do not ask Mr. Campbell the question, for he is a private worker, but I want to know when he began working "since harvest," for could not have done "since harvest" until he had cleared a bit of I cannot fix "since harvest" this year ending in the middle of August, and from that period to the thorough trials there were but 36 working days he would get over in the 36 days 1996 acres, could do "from 2000 to 3000" "since harvest" before the Peterborough trials, I cannot say Mr. Campbell would do well to explain. I must not call upon him to pay interest on his sum of money he must have spent on his seed-tackle; if he does 1s. 6d. per acre on 2s. 6d.—5 per cent. on 1000l. would come to 2000 acres, and the tackle that he has had have cost that large sum. He is an experimenter, I should charge him with his last set of trials. I am an experimentalist, and cannot stand a man all I have spent; for instance, the cost of a windlass must not be added to the cost of a

one that I have had 11 years—although I have it by me as a relic, and am proud of it, it being the first that practically worked land by steam-power, and so on, it would not require the 500*l.* to be aided that I have spent in making and improving my combined water and drill that I have condemned and cast aside as worthless, giving the public the advantage of my experience.

And now, in conclusion, let me ask "G. A. H." to look over my letter that you have kindly taken from the *Times*, and see whether a set of steam tackle would not be very valuable on small holdings of heavy clay land. Forty acres have given me a gain of 2200*l.* in 14 years, in the shape of increased produce. Will he ask how this done? I will tell him. A great portion is due to having all my land in crop instead of a fourth part of it in fallow yearly, and the remaining portion is due to greater fertility of the whole. Will he turn round and say, Smith's is an exceptional case? No, he cannot, for there are the 800,000 acres of fallow, as shown in the Board of Trade. This large number of acres may be multiplied by four, to represent the quantity of land worked under the fallow system. This gives 3,200,000 acres of heavy land especially needing steam-power upon it, and if you take my data for gains, you get a gain of over 12,000,000*l.* a year to the country. Surely such a gain as that is worth trying for, especially as it can be won without any increase of tenants' capital, excepting a little that must be cast in making the engine from the steam to the other. In putting down a house and rebuilding it, there is always a cost, so the old material ever so good, yet we seldom hear of regret or loss after it is done. *William Smith, Woolston, Bletchley Station, Bucks, Nov. 20.*

Home Correspondence.

The Yield of Sugar-Beet Contrasted with Mangel.
—In last week's *Agricultural Gazette* there is a letter from Mr. Mitchell, of Rainham, asking for an explanation of the fact, that while his Mangel yielded 25 tons per acre, his Sugar-Beet yielded but 16 tons. If, as he says, they received the same treatment in every respect, that explains the difference of yield. For there must have been a difference in regard to the distance of the plants from each other. As a rule the Sugar-Beet does not grow so large as the Mangel, and therefore, to ensure the same weight per acre, more must be grown. To make this plain, I presume that in an ordinary crop of large Mangel there will be from 60 to 80 roots to the pole. Now, in Sugar-Beet there should be about 200 roots on the same area. This increase of the number of the roots will compensate for their individual lightness, and the gross yield of Sugar-Beet will probably be as great as that of Mangel. Already they are running each other pretty close in the Lavenham district. The heaviest crop of Sugar-Beet this year weighed in the gross 31 tons per acre. The heaviest crop of Mangels seen weighed 1 ton less, or 30 tons. Weighed without tops the Mangel reached 29 tons per acre, and the Sugar-Beet 21½ tons. The number of Mangels per pole was 100 roots, of Sugar-Beet 200. These facts and figures point a lesson and indicate the direction improvement should take in regard to Sugar-Beet. Many one who remembers the first crop of Mangels, with their uncouth roots and coarse large leaves, and contrasts them with the fine stock and small leaves of the most approved sorts of to-day, will see at a glance that the same course of improvement by selection and crossing, if needful, must be pursued with the Sugar-Beet. Amongst the crops now there are great differences in regard to top and habit. These have been noted by the growers, and most of them are saving their own seed from what they consider the best samples. I believe in a few years we will have model crops of Sugar-Beet, with little or any greater development of top than among the best Mangels. Once this is accomplished the roots may go yet closer together, and as, bulk for bulk, they weigh heavier than common Mangel, it follows that by-and-by we shall have as heavy or even heavier crops of the Sugar-Beet per acre. Meanwhile, I do not think that even now there is much loss incurred by growing the Sugar-Beet, even for feeding purposes. Possibly Mr. Mitchell may get as much meat, butter, milk, or cheese out of his 16 tons of Sugars as from his 25 tons of common Mangel. True he loses a little over a third in weight, but probably that loss is converted into a gain by the doubling of his percentage of sugar. As to the bolting of such crops, I regret that it has not been discussed apart from the names of any particular farms. The public are not asked to state whose seed had or had not bolted, much or little, but whether seed that was known to be old had bolted more generally than that which was known to be new. During the hot summer of 1868 the Lavenham Sugar-beets hardly bolted at all. During the cool changeable season of 1869 the self-same seed, only a year older, bolted fearfully. Can anyone divine the cause, or determine the question on its merits, without puffing up or running down any seedman, great or small? Further, the bolting this year was by no means confined to Sugar-Beet. Since last writing on the matter I have seen many fields of common Mangel, and some of them were more seedy than any of the Lavenham Sugar crops. I highly approve of Mr. Mitchell's plan of behoarding the bolting, and thus improving immensely the appearance of the crops, and giving the runaway plants a chance of converting their growing force to useful purposes by sending it rootwards. *D. T. Fish.*

Depth of Drains.—I have read with much pleasure the very interesting paragraph on the above subject by "H. V. Grove," in your last week's paper, and I am of the same opinion as himself in regard to Government and drainage companies. Their agents or inspectors seem to be too much restricted to certain

depths; so much so, that no other person's opinion, however practical, seems to be of any value. The consequence of which is, that undoubtedly a great deal of money and labour is to some extent wasted through the rigid rules enforced. Instead of which, I find from many years' experience in draining both light and heavy land, that the depth, and distance between drains can be decided in the field only. The practice frequently adopted is to send a man forward to open holes in the fields to be drained, and for these holes to be inspected perhaps on the next day, or it may be a week afterwards, when, it matters not of what nature the subsoil may be, there will in nine cases out of ten be water found in the holes, and if the holes have been dug 3 or 4 feet, as the case may be, it will at once be considered necessary to drain to the same depth; whereas, it may be just possible that all the water in the holes has gone down from the surface instead of having risen from beneath the bottom of the drain. Now, to prevent this error, the man with the spade and the inspector should go both together; and as the man digs the hole, the inspector sees with his own eyes where the water comes from—whether from the surface or the subsoil. If a strong impervious clay bottom, the water will all be found from the surface, but if, on the contrary, an open, porous, sandy, or gravelly bottom, then the water will be found at the bottom of the hole, instead of on the surface. Now, the question to be asked is, how to drain in the best manner, and at least expense, the different kinds of land, and to find an answer to the subject I will simply give the following, which any well digger can answer, viz. We will sink a well to supply an establishment at any desired spot, and in doing so it will all depend on the nature of the subsoil whether we get water quick or not. Should the subsoil be of a strong clay nature, it is well known that 20 to 30, or even 50 feet may be sunk before getting water, whereas, on the contrary, should the subsoil be of a porous and free nature, the result is that water is found near the surface, or within a few feet, seldom over 10 to 15. Now, in draining the two different kinds of land, I find from practice that, in the case of the strong clay subsoil, what has to be considered is the best and quickest means of providing for the surface water to escape, and to accomplish which I find that from 2 feet 6 inches to 3 feet is better than a greater depth—the former more especially in grass-land, because there are no springs from beneath to contend with. The drains to be not more than 10 to 12 feet apart. But in draining the open and porous subsoil a very different practice is necessary, as we have here to contend with springs from beneath, therefore drain from 4 to 6 feet deep, and from 20 to 30 feet between the drains. As it is a matter of *£ s d.*, it behoves every landowner to consider seriously before he lays himself under the clutches of drainage companies, who may compel him to entail a burden upon his tenantry beyond what is really necessary. However good such companies may be, I consider the depth of drains should be an open question. *W. C. Kipler.*

Societies.

ROYAL AGRICULTURAL OF ENGLAND.

MONTHLY COUNCIL, Wednesday, December 8—
Present: the Duke of Devonshire, K.G., in the chair; the Earl of Powis, Viscount Bridport, Lord Chesham, Lord Kesteven, Lord Tredegar, Lord Vernon, Lord Walsingham, Sir Massey Lopes, Bart., M.P., Mr. Adant, M.P., Mr. Baldwin, Mr. Barnett, Mr. Barthrop, Mr. B. B. B., Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Draca, Mr. Brandreth Gibbs, Mr. Hassall, Mr. Holland, Mr. Hornsby, Mr. Hoskyns, M.P., Colonel Kingscote, M.P., Mr. Leeds, Mr. Milward, Mr. Pain, Mr. Randall, Mr. Ransome, Mr. Rigden, Mr. Sanday, Mr. Thompson, Mr. Torr, Mr. Turner, Mr. Webb, Mr. Wells, M.P., Mr. Jacob Wilson, Professor Simonds, and Dr. Voelcker.

Softon, the Earl of, Croxteth, Liverpool
Alison, Arthur, Elgates Forest Lodge, Crawley, Sussex
Ailison, Charles F., Crawley, Sussex

—were elected Governors of the Society. The following new members were elected—
Dutton, John, Curbridge, Farringdon, Berks
Fenton, M. K. K., Calhote Hall, Nunceaton
Franklin, William, Limer Magna, Chesby
Franklin, Joseph, Little Milton, Tewkesbury, Oxon
Mackintosh, Harwood Langton Grange, Nidley
Wilson, John, Kettleby Tharpe, near Bury
Spurr, Anthony, Downlands, Lyane Regis, Dorset
Tinley, Edward, Southwell, Nottingham
Westharp, Rev. Richard A., Berners Rectory, Ongar, Essex
Whitworth, Henry, 96, King Street, Manchester

FINANCES.—Major-General Viscount Bridport (who presided) presented the report from which it appeared that the Secretary's receipts during the past month had been duly examined by the committee, and by Messrs. Quilter, Bail & Co., the Society's accountants, and found correct. The balance in the hands of the bankers on November 30 was 3067*l.* 18*s.* 6*d.* The committee recommended that Mr. J. Gale's salary be increased 20*l.* per annum, in consideration of his long and efficient services to the Society; that a list of members in arrear with their subscriptions be sent to each member of the Council, with a request that individually he will assist in obtaining payment of such arrears; and that a sum of 2000*l.* be placed on deposit with the Society's bankers.—This report was adopted.

JOURNAL.—Mr. Thompson (chairman) reported the decision of the judges of the essays competing for the prize of 20*l.*, offered for an essay on any agricultural subject, awarding it to one of the Princes in Jersey, bearing the motto, *Practical*. The motto-paper having been opened by the President, the essay was declared to have been written by Mr. C. P. Le Cornu, of Trinity Manor, Jersey. With reference to the prize of a piece of plate, of the value of 100 *gs.*, offered by Mr. Mason to the occupier of the best managed farm within a

certain area round Oxford, the committee made the following recommendations—(1). That an entrance-fee of 2*l.* be required from candidates who are members of the Royal Agricultural Society, and of 3*l.* from all other competitors; (2). That the competition be confined to tenant-farmers; (3). That no farm be allowed to compete which does not contain at least 200 acres; (4). That a second prize of 50*l.* be awarded to the 3d best farm. (5). That no entry be received later than Saturday, February 26. And so that the certificate of entry shall contain the name and address of the candidate and of the proprietor of the farm, the kind of soil (light or heavy), the acreage of the farm, and its distance and bearing from the nearest town.—This report was adopted.

CHEMICAL.—Mr. Wells (chairman) presented the report of the committee, which contained the annual report of the *Chemical Society*. This report was referred back to the committee for the purpose of enabling them to select certain portions of it for publication in the agricultural newspapers.

VETERINARY.—Lord Liverpool (chairman) having presented the usual annual report, Mr. Jacob Wilson drew the attention of the Council to the question of the equivalent which the Society obtained for the annual grant of 200*l.* to the Royal Veterinary College. After a conversation it was resolved (with two dissentients) that the Veterinary Committee, after conferring with the governing body of the Royal Veterinary College, be requested to make a special report to the Council, on the suggestion made by Mr. Jacob Wilson, that a portion of the grant of 200*l.* be in future placed at the disposal of the Veterinary Committee to obtain reports on special subjects of interest connected with veterinary science—the committee to report to the Council at their meeting in March.

SHOWARD CONTRACTS.—Mr. Randall (chairman) reported that the plan of the showyard for 1870 had been passed in the hands of the local committee at Oxford, to enable them to proceed with the levelling required, which is now in progress, and that the arrangements for the railway siding, and for the supply of water to the ground, had been satisfactorily determined.—This report was adopted.

SELECTION.—Mr. Thompson (chairman) reported that the committee had completed the revision of the bye-laws, but desired to take the instructions of the Council as to certain points. They also recommended that a copy of the new edition of the charter, bye-laws, and resolutions of Council be sent to each member of the Council, and to all future members of the Society on their election; and that the same be printed in the next number of the Journal, and circulated amongst the present members of the Society. It was also recommended that the annual report of each standing committee shall contain a list of its members, omitting those who have absented themselves during the whole year, and that it shall contain the names of those proposed to be added to the list for the ensuing year. The questions relating to the bye-laws having been disposed of, and the other recommendations of the committee adopted, the Chairman stated that the committee had agreed to recommend Mr. Charles Whitehead, of Barming House, Maidstone, to fill the vacancy in the Council caused by the election of his Grace the Duke of Devonshire, K.G., as a Vice-President. Mr. Wells, M.P., having proposed, and Mr. Randall seconded the nomination of Mr. Whitehead, an amendment, substituting the name of Mr. R. Russell, of Farmingham, was moved by Mr. Cantrell, and seconded by Mr. Rigden. On a show of hands the amendment was lost by one vote, the numbers being, for Mr. Russell 11, and for Mr. Whitehead 12.

The Secretary was instructed to communicate with the local authorities at Chester, Shrewsbury, Stafford, and Wolverhampton, informing them that the Society's country meetings in the year 1871 will be held in the district including Cheshire, Shropshire, Staffordshire, and North Wales.

Mr. Sanday, having given notice that he would move "that the rule for the non-payment of judges who are members of Council be rescinded," stated that as no such rule could be found, his resolution was unnecessary. It was therefore moved by Mr. Milward, and seconded by Mr. Thompson, "that Mr. Sanday and Mr. Bowly be paid for their services at Manchester," whereupon, under clause 36 of the bye-laws, Lord Bridport requested that the consideration of the question be deferred until the next monthly Council. On a show of hands 13 votes were given against the postponement and 7 for it. The question being therefore deferred, Lord Vernon gave notice that at the next monthly Council he should move "That judges who are members of Council may be paid for services rendered to the Society."

The Earl of Lichfield gave notice that at the next monthly Council he will call the attention of the Council to the inconvenience arising out of the conditions of the charter fixing the date and place of holding the general meeting, and excluding from the Society's meetings the discussion of all subjects having reference to measures pending, or to be brought forward in either House of Parliament.

The standing committees for the year 1870 were appointed.

The report of the Council to the half-yearly general meeting was prepared.

A letter from Mr. W. A. Gibbs on the harvesting of hay and corn in wet seasons was referred to the Implementation Committee.

The Council having given the usual leave of absence to the secretary and clerks, adjourned over the Christmas vacation.

At a special Council, which met, by order of the President, at the rising of the monthly Council, the stock and implement prize-sheets for the Oxford

These extracts will be forwarded for publication in the course of next week. *H. M. J.*

meeting were arranged, certain prizes for Dorset sheep having been added to the draft of the former, on the motion of Lord Bridport.

THE ANNUAL MEETING of this association was held on Thursday last at the offices, Hanover Square, the Duke of Devonshire in the chair.

There was a more than ordinarily large attendance, and among those present were Mr. W. Caldwell, Colonel Challoner, Mr. H. S. Thompson, Mr. J. Fawcett, Lord Denman, Mr. J. L. Hythe, Mr. Edward Johnstone, Lord Vernon, Mr. G. A. Hankey, Sir Walter Stirling, Mr. T. C. Booth, Mr. J. Bigg, Mr. J. Yardley, Mr. C. Cadle, Mr. Duckham, Mr. G. Smythe, Mr. C. S. Roberts, Mr. C. S. Read, M.P., Mr. Fytche, Mr. Botley, &c. The proceedings were commenced by his Grace calling upon the Secretary to read the following report:—

REPORT OF THE COUNCIL.

Since the last General Meeting in May, 2 Governors and 32 Members have died, and 4 Governors and 182 Members have been elected, so that the Society now consists of 75 Life Governors, 73 Annual Governors, 1469 Life Members, 3962 Annual Members, 16 Honorary Members; making a total of 5597, and showing an increase of 86 for the year 1869.

The half-yearly statement of accounts to the 30th June, 1869, has been examined and approved by the auditors and accountants of the Society, and has been furnished to all members in the last number of the Journal. Owing to the great financial success of the Manchester meeting, the funded capital of the Society has been raised to the sum of 20,000*l.* Stock in the New Three per Cents, while an additional sum of 4612*l.* 7*s.* 8*d.* New Three per Cents, has been invested as a Reserve Show Fund. The Council regret that owing to the continued difficulty experienced in collecting arrears of subscriptions, they have been compelled to take legal proceedings against some members of the Society; but they have obtained the only satisfaction possible under such circumstances, the arrears have been paid, and the legality of the Society's claims has been most clearly established.

Under the Presidency of H. R. H. the Prince of Wales, the Manchester meeting attained an unusual degree of success. Their Royal Highnesses the Prince and Princess of Wales honoured the exhibition with their presence on two occasions. The expectations of the Council as to the magnitude of the meeting were even surpassed by the result. The entries of implements largely exceeded those at any previous meeting of the Society, and the exhibition of stock was on a still more extended scale. The crowd of members and visitors more than doubled in number those who were admitted to the show yard at Leicester, and the amount received for admission was proportionately large. The interest created by the magnificent exhibition of live stock and implements may be estimated by the fact that more than a thousand pounds was realized by the sale of catalogues.

The local committee carried out the various arrangements which had been entrusted to them with remarkable zeal and liberality, and their secretary (Mr. Whitworth), in particular, was untiring in his exertions to promote the success of the meeting. Considering that during the six days of the show it was visited by more than 200,000 people, the Council believe that no slight praise is due to the arrangements by which so large a number of persons could obtain excellent refreshments without inconvenience, and at a moderate price—the more so as these arrangements were made by Mr. Whitworth with the advantage of a considerable profit to the Society. Mr. Whitworth's indefatigable efforts on behalf of the Society induced the Council to request his acceptance of the sum of 150*g.* as an acknowledgment of his services.

The great agricultural feature of the meeting was, no doubt, the careful and prolonged trials of reaping and mowing machines, and whether tested by the interest exhibited in them each day by crowds of intelligent spectators, or by the great increase in the extent to which reapers were reported to have been used during the following harvest, there can remain no question that the Society's trials of implements at Manchester have already yielded good results.

On the two Sundays during which the stock was in the yard, Divine service was performed by the Vicar of Stretford, before large and attentive congregations chiefly composed of the servants in attendance on the animals.

The Council have fixed the commencement of the Oxford meeting for Monday, July 18. They have decided that the live stock shall all be in the yard by 4 o'clock in the afternoon of Saturday, July 16, which will allow of the animals recovering from the fatigue of the journey to the show (and thus place those which have travelled from distant counties more on an equality with others which have come only a short distance), before the judges commence their inspection on the Monday morning following. The show will close on Friday, July 23, at 4 o'clock, thus enabling most of the stock to commence their homeward journey the same evening, and to arrive at their destination before the following Sunday morning.

In addition to the usual classes contained in the stock prize-sheet, the Council have offered for competition at Oxford, prizes for Norfolk and Suffolk polled cattle, for Dorset sheep, and for Lincoln as distinguished from other long-wooled sheep. The Oxfordshire Agricultural Society has offered special prizes for pairs of dairy cows for Oxfordshire Down sheep, and for hackneys; and the local committee have offered prizes for a class of 4 year old, and 1 for another of older hunters.

The High Sheriff for Oxfordshire (James Mason, Esq.) has offered a piece of plate of the value of 100*g.* as a prize for the best managed farm in the district, included within a line drawn through the towns of Reading, Great Marlow, Aylesbury, Buckingham, Banbury, Stow-on-the-Wold, Lechlade, Wantage, and back to Reading. The Council have agreed to fix the conditions of competition; to appoint, and to defray the expenses of, the judges and a reporter; and to arrange all other details. They have determined that an entrance fee of 2*l.* be required from competitors who are members of the Society, and 3*l.* from all others, that the competition be confined to tenant farmers, that no farm shall be entered which does not contain 20 acres, that a sum of 50*g.* be given to the occupier of the second best farm, that no entry be received later than Saturday, February 26, and that every certificate of entry shall contain the name and address of the candidate, and of the proprietor of the farm, the kind of soil (light or heavy), the acreage of the farm, and its distance and bearing from the nearest town.

The schedule of prizes for implements and machinery to be awarded at Oxford contains classes for fixed steam engines, horse gears, mills, crushers, chaff-cutters, oilcake breakers, turnip cutters, steaming apparatus, dairy implements, bone mills, guano breakers, caprolite mills, flax breaking machines, tile machinery, and draining tools.

The continually increasing number of implements exhibited at the country meetings of the Society has compelled the Council to consider by what method a sufficient number of judges in each department could be appointed beforehand, and also by what means a large portion of the time of the judges, hitherto devoted to a preliminary examination, and a selection of implements for trial, could be advantageously economised. The Council have, therefore, resolved—that every implement intended by the exhibitor for competition

shall be entered in its respective section and class for trial at the time when the specification is sent in to the secretary, but notwithstanding such entry, the discretion of trial will rest with the judges; also, that no exhibitor may enter more than one implement of the same construction for competition in any one class. Further, in order to protect the interests of purchasers, it has been resolved, that although certain implements, belonging to the classes for which prizes are offered, are not entered for trial, the stewards may, on the recommendation of the judges, order any of them to be tried and their capabilities made public.

The attention of the Council having been drawn to the increasing adulteration of manures and feeding cakes, especially guano, nitrate of soda, ground bones, and linseed-cakes, Dr. Voelcker has been requested to submit to the monthly Council in March, June, and December, a report of the various samples forwarded to him by members of the Society, so that such report, together with the names of the dealers who supplied the substances analysed, shall, if the Council think fit, be published in the agricultural journals.

The Society's educational examinations in April last were conducted on the same plan as those of the previous year, and the results were so satisfactory, that the Council have renewed the grant (200*l.*) for the year 1870, with this alteration, however, viz.,—that whereas, hitherto, it has been considered advisable not to fix any limit to the ages of candidates, in order that all comers might be admitted during the earlier stages of our proceedings, it has now been thought advisable to fix a maximum of age for candidates; no one who has passed his 21st birthday before March 31, can in 1870 be admitted as a candidate for the Society's honours and prizes.—By order of the Council, H. M. JENKINS, Secretary.

Lord DENMAN, in moving the adoption of the report, said that it was one which could not be other than highly satisfactory to the Society. Their meeting at Manchester had been highly successful, and every effort must be made to make that of July next equally successful. He might mention that the disease known as blackfoot [Quarter-ill?] had appeared among cattle in his neighbourhood, and as its causes and prevention are not at all known, it might be well that it should be investigated, and some account of its prevention and cure be inserted in the Journal. He had lost many animals by it, and he dare say others had. He should be very glad to find their meeting successful next year, especially as it would be presided over by so illustrious a member of the association.

Mr. W. G. CALDWELL seconded the motion. He had only one remark to make, and that was with respect to the rules of competition for the prize offered by the High Sheriff of Oxfordshire. He observed that the acreage of the farms was to be returned distinguishing the land whether light or heavy. He thought they ought to distinguish also whether it was arable or pasture, because a dairy farmer might not be a good arable one. They ought therefore to obtain a return which would inform them in which the preponderance of arable or grass-land was. He approved of the steps taken by the Council to make the work of the judges easier, and to put an end to the terrible system of having to look at everything for two or three days before they could really tell what to do. He thought that the rule requiring competitors to send in the number and description of the implements for trial in their respective sections, and that no exhibitor should enter more than one implement of the same construction or class for trial, was an uncommonly good one. He had himself been a judge for two years consent-very, and could say that everything which would ease their shoulders a little would be of essential service and work well for the Society. He thought also it was advisable for the Council to give a more definite description of what were to be considered miscellaneous articles, which might be of use to agriculturists, so as to guide the judges as to what they might look at and what they should pass by entirely.

Mr. READ, M.P., expressed his satisfaction at the improvement in the Journal. It was now more practical and useful than anything they had hitherto had. The review of Castleacre Farm, which appeared in the last Journal, was singularly opportune, and he regretted that Mr. Hudson, who was so long a member of the Council, and a most useful member of the Society, had passed away before it was printed. That review was most important, because it proved what could be done by capital when applied to bad or, at least, to inferior land. If it was the prominent duty of the British farmer to supply the nation with corn and meat, no one performed that duty more successfully than did Mr. Hudson; but whether exceedingly high farming paid was a question not yet quite determined. If he might make a criticism where there was so much that was good, he would say that when gentlemen wrote reviews in the dull season of early spring, and in so doing mentioned the wages of the agricultural labourer, they should be good enough to inquire what the average earnings of labourers were, rather than the wages of that particular period. Those at Castleacre were put down at 1*l.* a week, when, in point of fact, Mr. Hudson spent 2000*l.* a-year in labour on a farm of 800 acres. In the larger portion of the year men could readily earn 2*s.* 6*d.* per day, and in harvest time often 2*l.* and never less than 30*s.* per week. He hoped the Journal would be issued as early as possible, and he looked forward with a great deal of pleasurable anticipation to the report on Belgian farming, and that not only on account of its agricultural but its political bearing.

Mr. NIELD, as one of the not most inactive members of the Manchester local committee, expressed on its behalf his pleasure at the handsome recognition made in the report of the value of their labours. He was glad to say that his predictions of a successful meeting had been verified to the letter, and he sincerely hoped that a similar successful gathering would be held next year at Oxford. He ventured to say that a large margin of saving had been effected in the fittings of the show-ground, and regretted that their present arrangements precluded them from adopting changes the benefits of which were apparent when they were carried out by the local bodies. He witnessed with pleasure the increase in the number of members, and expressed a

hope that the time would come when every acre of 100 acres would feel it an honour and a privilege to belong to the Royal Agricultural Society. He had been educated for the last two or three years, both privately and publicly, the drawing together to the Agricultural Society of every leading agricultural association in the kingdom; and, though he admitted that they had taken a step in the right direction by dividing the country into five districts, yet he was not satisfied till he found the principal associations united with them, and a deputy from each presiding at their meetings. They might look with some eyes on the rapid progress of the times in which we lived. He admitted the advantages which agriculture had derived from the services rendered to the country by the great territorial magnates of the country; he believed that the more noblemen were brought into personal contact with sensible and practical farmers, the better it was for themselves and for the country. He agreed with the hon. member who spoke that the Journal was greatly improved, and quite a pleasure to read it.

Mr. BOTLEY expressed the pleasure he felt in hearing the report, and also at the improved appearance of the Journal; the more so as he had been told that it would be better if it were more practical and practical essays inserted which would be more read and quoted. That had been the case, and he was happy to see the result he had predicted followed. He congratulated the Society on the success which had attended the institution of the educational examinations, for no money could be better spent than that which was spent in promoting an industrial and useful education, and the result would be the general benefit of noblemen, the middle classes, farmers, and even the agricultural labourer.

Mr. T. WILLSON complained that some of the exhibitors had been withdrawn from the showyard at Manchester, to form part of a jumping exhibition, and many persons who had come hundreds of miles to see them at all, because they had no chance, and there was no means of getting any. He considered it should not be permitted to remove any animals from the Society's show-ground.

Dr. CRISP expressed an opinion that the Journal might be still further improved, and suggested it should contain a summary of what was passing in various parts of the world. He also referred to the desirability of dissolving their connection with the Veterinary College, and expressed an opinion that no arrangement could be made while such connection existed. He thought the Council should advise the Government to establish a national Veterinary College, also advocated a system of inspection and regulation of minor diseases in cattle, which would, he had no doubt, be eventually carried into effect.

Mr. THOMPSON expressed his gratification at the practical feeling which pervaded the meeting, and his approval which had been expressed in favour of the appointment of the Secretary. That gentleman, now admitted, had shown himself an able Editor, and respect to the blackfoot rot [Quarter-ill?], he had cured was to seton very early. Those who had been early setoning had found it very effectual in curing the disease.

A MEMBER: Combined with good management, Mr. THOMPSON said that the well-kept showyard was not so subject to the disease as those which were kept, but setoning had been found very effectual. Caldwell had expressed some doubt about the wisdom of so many miscellaneous articles, yet their inclusion proved very useful in attracting visitors to the showyard and increasing their receipts. The number of members was now 6000. He thought it very wise to have an invested sum, for the purpose of putting up their prize list, and it was only in this way they could carry on their operations on a footing of security. Their object in investing was to pay by the time the standing expenses of the Society. It was intended to have a large invested sum, but it was not sufficient to conduct its operations in a safe manner. The present attendance showed that the selection for the meeting proved that Thursday was a better day for the general meeting.

Mr. CRISP said that the practice of setoning was cruel, that it ought to be put down by the Society, and the Prevention of Cruelty to Animals.

Professor COLEMAN suggested that it would be expedient to send a gentleman down to the place of show, in order to see the implements and arrange as to their mode of trial, so that when the judges came down they would find the implements prepared for them, and be able to commence their work at once without wasting so much time as they now did in arranging the details of the trials.

Mr. TOBE explained that the exhibition of jumping of horses at Manchester was not the Society's display. In point of fact the Society would have it, and the only condition made as to the horses should come through the Society's showyard. With respect to the miscellaneous articles played, no prizes were given for articles which were not agricultural, and the exhibition in question was very remunerative.

Mr. DUCKHAM thought that members of the Society had a right to see everything sent for exhibition without any extra charge.

Lord VERNON said that the Council would pay attention to any suggestions with regard to economical arrangements of the showyard, and he was obliged to any member of a local committee who would make them.

Mr. JACOB WILSON agreed that people who visited the showyard had a right to see the whole exhibition, but a glance at the catalogue would show that the jumping exhibition was not theirs, and the hon.

it were only withdrawn for a short time from the showyard.

Mr GRAY thought it rather beneath the dignity of the Society to listen to a proposition from the local committee that they should have an exhibition of that kind.

Mr. J. NIELD pointed out that the local committee had expended a large sum, and though they had recouped themselves to the extent of 5000l. by this means they were still a good deal out of pocket.

Mr T. WILSON thought it very objectionable that horses should be taken out of the showyard to be spoilt in jumping over fences which no good sportsman could take without the risk of breaking his neck.

Mr THOMPSON said that due notice was given that there would be such an exhibition, but only those horses left the yard which were entered for it, and none without the express sanction of the owners.

Sir W. STIRLING regretted that the question should have arisen, because it was the only thing calculated to mar their perfect unanimity. He had no doubt that union of commerce and agriculture at Manchester would be productive of the best results. There had been a public spirit manifested at Manchester on the occasion of the meeting most creditable. No misunderstanding whatever had arisen, and he considered it a fortunate circumstance that the Manchester meeting had taken place in what was almost a crisis in the history of the country. Agriculture was now one of the staple topics of the day, and was not only discussed at their meetings, but at those of the Social Science Congress, and the subject was treated not only in an agricultural but in a commercial spirit.

The report was unanimously adopted; and, on the motion of Mr. Arkell, the auditors received a vote of thanks; and subsequently, on the motion of Mr Badham, seconded by Mr Torr, they were re-elected.

A cordial vote of thanks to the noble Duke in the chair was given, on the motion of Mr. Duckham, seconded by Mr. Read, M.P.; and

His Grace, in returning thanks, said it gave him great pleasure to fill the position in which the Council had placed him, and to listen to the discussion which had taken place.

THE SMITHFIELD CLUB CATTLE SHOW.

AGRICULTURAL HALL, ISLINGTON.—The Smithfield Club Show was opened for the eighth time in the Agricultural Hall, Islington, on Monday last, with all its previous prospects of success; and these have been amply realised. If the cattle have slightly fallen off in consequence of a number of animals entered being last week within an "infected district," so declared because of the prevalence of the foot-and-mouth disease, the quality and appearance of the large number sent were generally excellent, while the sheep are as good as, if not better than, they ever were, and the pigs are so uniformly good, that nothing more can be desired in this department. Whether, therefore, this show be intended for a practical lesson to farmers, or a country display for the pleasure of the metropolitan inhabitants, it has been perfectly successful.

The Devons, as has been always customary, have been placed in the first position; and, so far as beauty of form and colour go, the collection of this breed in the Agricultural Hall this week have well earned their place; but as regards the practical, or meat-paying value of the little creatures, with which the younger, and the greater part of the older, classes were filled, there is ample room for discussion. Some of the Devons were heavy and well grown; but taking them as a whole, there was not that thriftiness and hardness of appearance which are now required to make both ends meet when a farmer has to depend on the profit of feeding for his fixed expenses and livelihood, or, in other words, for a good interest on the capital he employs. The steers were very remarkable for their perfect ripeness at their early age. They were as mellow in their touch as most cross breeds are when three times as old. Mr. Buller's and Mr. Nixey's were peculiarly of this description, and Mr. Smith's, of Hooper's, Exeter, was as perfect for form and touch as could well be found. The weights do not correspond with the prizes, for in the next class, the 1st prize steer, shown by Mr. Hambro, M.P., did not weigh so much as the 2d prize by 110 lb. In the next class, too, the 1st weighed 14 cwt. 0 qr. 3 lb.; the 2d, 15 cwt. 0 qr. 13 lb.; and Mr. Smith's great and good, but not very ornamental beast, weighed 19 cwt 2 stones 25 lb or nearly 5 cwt 3 stones over the 1st prize. As the quality of this beast was equal to any shown we do not understand the use of weighing the animals, if it be not taken into account at all in estimating the merits of each. This view, too, is more particularly important when it is observed that the 1st prize is only one month younger than the unnoticed beast, which weighed upwards of 5½ cwt. more. The heifers were as pretty as could be, and the cows full of flesh and remarkably firm, from their natural character and skilful feeding.

The Herefords were a far greater improvement on the Birmingham muster than they usually are, although Mr Heath's ox, with a disfigured back, took the highest honour, as he did at Bingley Hall. Nevertheless, the breed is by no means so well illustrated this year as we have seen it. Her Majesty the Queen was 2d, with a beautifully fed steer, and the 3d, with an equally good heifer. In the oxen the Earl of Darley's beast was remarkable for his fine character of head, horn, and coat, while he had great substance, well and evenly distributed, and his feeding was not surpassed, if equalled, among any animals of this breed. Mr. Bettridge's 3d was very beautiful. The Hereford heifers under four years of age were attractive, from the 1st and 2d prizes having appeared

at Birmingham, and the decision in Bingley Hall having been here, very properly as we think, reversed. Mr Arkwright now takes 1st, and Mr. Garrett the 2d Mr. Baldwin's cow at nine years of age was a wonderful beast for youthfulness of appearance and touch. She deservedly took 1st in her class.

The Shorthorns carried off all the special honours, but the males were particularly honoured with the new premium of a 100 gs. cup. This however did not fall to the younger class, wherein her Majesty the Queen was 1st with a well bred and well proportioned steer, but to the medium-aged animals, the steers under three years and three months. In short the Earl of Aylesford's steer which took upwards of 120l. in prize at Birmingham, here took everything in his class that a breeder and feeder could take, and the greatest honour of the Hall, in the form of the 100 gs. cup, for the best animal in the Hall. The value of these prizes, as will be seen by our prize list, is 170l. Thus in two weeks this animal has been awarded prizes to over the amount of 200l. As the Earl of Aylesford has been so constant a breeder and feeder and patron of agricultural shows, we cordially congratulate him on this signal triumph. The live weight of his beautiful steer was 19 cwt. 2 stones 13 lb. The judges of the Shorthorns had evidently an eye to line character, for Mr. Outhwaite's 1st among the oxen was of a similar stamp to the gold cup steer, while the Marquis of Exeter's had everything good about him, excepting a slack back, which partook more of the character of a malformation than any defect of character or breeding. Mr. D. R. Davies, of the Old Hall, Cheshire, added to this class by sending a very fine animal, but too masculine in appearance. Mr. J. Scales sent an ill-formed ox into this class,—a disfigurement to the Shorthorn classes of fat stock generally. Colonel Towneley's heifer was 1st here, as at Bingley Hall, but the cup went against her in favour of the cow sent by Sir W. C. Trevelyan, Bart., as it did at Birmingham. Mr. Atheron's 2d in the heifers, and the Duke of Devonshire's 3d among the cows, were both fine well-grown and massive white animals. The Messrs. Mitchell's 6 years and 10 months cow was only attractive for her beauty of colour and form, for she was very small for a Shorthorn. She was also 2d at Bingley Hall.

The Sussex animals have made a rapid stride in improvement. The form and general character of this breed clearly indicates that they once belonged to the herds from which the Devons spring. Even now there is not more difference between them and the Devons in general, than there is between the North and South Devons themselves. Indeed, when the younger animals are touched, we are inclined to ask where do the Devons end and the Sussex begin. As a whole, however, there is a far greater size and a more valuable proportion of flesh in the Sussex classes than there is among the Devons. Their quality cannot be described as superfine, although in many cases, and, indeed, in most cases, it is excellent, in fact good enough for anybody who is blessed with fair health and a corresponding digestion. Mr. Lee Steere's 1st prize is a grand steer, fine and mellow under the hand, and massive in his flesh. The oxen are very large, and their quality is good, while the cows are very handsome as well as hardy to look at. The breed furnishes good serviceable beasts for farmers who have their rent to pay, either out of beef or butter, or both.

The Suffolk breed made a very poor show, the only one out of the six which was worthy of notice being a very handsome little 3-year-old cow sent from Sandringham by his Royal Highness the Prince of Wales. The two steers had mean, ridgy backs, and were correspondingly coarse all over.

The Longhorns were four only, the 1st prize ox being the one which we described last year from Bingley Hall, as having as perfect a touch as any in the Hall; and having been kept over for this show he has grown into so remarkably good a beast that he would do credit to any breed.

In the Scotch Horned steers or oxen there is the most extraordinary decision we ever saw. In the first place, the 1st prize is described as "breeder unknown," while his age is set down as "about 4 years and 6 months." This may be a fair guess, but no one could guess what his breeding is. If there was another animal in the Hall of a type at all similar it was the black heifer in the class for the female Irish breed. This, however, would not have mattered had there been nothing in particular shown with him, but there was a really good show of Highlanders, and the 2d was a deep well covered brindle, with a perfect outline set off with fine towering horns, while the ox of Mr. Cueves, of Middleton of Rora, Longside, Aberdeen, was as finely formed, massive, and altogether picturesque a Highlander as any one could desire to see in a day's ride in their native county. The 1st prize certainly had a fine back, but his smooth black coat and degenerated Welsh appearance made him a contemptible object beside the grand "Scotch Horned" animals with which he was classed.

The Welsh Cattle were exactly as they were at Birmingham, and Captain Platt again took both prizes.

The Cross-breeds had some good animals among them, but, as we said last week, unless there is something very striking among them, the honours outside of classes ought to go to the pure breeds. After the remarks we then made we were glad to see that the judges awarded the special honours as they did. The enormous blue and white beast from Anzlesca and Bingley Hall put in his appearance here, but he was more adapted for pleasing the unsophisticated than for attracting the attention of practical men.

In the Extra Classes Mr. Foljambe sent a very much overdone white ox, and for some reason or other he was taken out to be compared with the Earl of Aylesford's steer when the 100 gs. cup was being decided

upon. But why this was done we could not guess. Here, too, as if to set off the fine home-bred beasts, the "Concessionaires from the Argentine Republic and Uruguayan Governments," whatever that may mean, sent a specimen of the animals they contemplate bringing from the River Plate, but unless they can surpass this brute there is not much fear of the breed over there coming into competition here beyond what they have done in the shape of bone and hides.

The following were the Judges and their Awards:—

CATTLE.—DEVONS, Hereford, Sussex, Norfolk or Suffolk Polled, Long Horned, Irish Cross or Mixed.—W. H. Henry, Bridgwater Salop; W. Yeoman, Stratford Court, Hereford; John Ford, 1st Rushton, Islandford, Shorthorn, Scotch and Welsh—H. G. Aylmer, West Dereham, Norfolk; Charles De Witt, Baldenham, Beds; William Sateray, Radcliffe-on-Trent, Notts.

DEVONS

Steers, not exceeding 2 years and 6 months old.—1st, 25l., J. H. Buller, Down, Crediton; 2d, 15l., W. G. Nixey, 1st and 2d Court Farm, Slough; 3d, 10l., Her Majesty the Queen, Prince Consort's Norfolk Farm, Windsor.

Steers, not exceeding 3 years and 3 months old.—1st, 30l., C. Hambro, M.P., Milton Abbey, Blandford; 2d, 20l., C. McNiven, Ferryfield, Goslone; 3d, 10l., W. G. Nixey, Upton Court Farm, Slough. Commended: J. Parthing, Farrington, N. Hants.

Heifers, not exceeding 2 years and 6 months old.—1st, 25l., W. Parthing, Slough; 2d, 15l., R. Burton, Bury, N. Hants.

Heifers, not exceeding 4 years old.—1st, 25l., W. G. Nixey, 1st and 2d Court Farm, Slough; 2d, 15l., W. Parthing, Slough; 3d, 10l., C. McNiven, Ferryfield, Goslone. Commended: W. Smith, Hooper's, Exeter.

Cows, above 4 years old, having had at least one live calf.—1st, 25l., W. Parthing, Slough; 2d, 15l., W. Smith, Hooper's, Exeter; 3d, 10l., J. Hitchcock, Broomhouse, Devon.

HEREFORDS

Steers, not exceeding 2 years and 6 months old.—1st, 20l., P. Turner, The Leen, Pembridge; 2d, 15l., Her Majesty the Queen, Prince Consort's Flemish Farm, Windsor.

Steers, not exceeding 3 years and 3 months old.—1st, 30l., J. Price, Court House, Pembridge; 2d, 20l., the Earl of Harley, Cobham Hall, Gravesend; 3d, 10l., H. Bettridge, East Hanney, Wantage. Commended: A. Pike, Milton, Tewkesbury.

Steers or Oxen, above 3 years and 3 months old.—1st, 30l., W. Heath, Lusham Hall, Norwich; 2d, 20l., the Earl of Darley, 3d, 10l., H. Bettridge, East Hanney, Wantage.

Heifers, not exceeding 4 years old.—1st, 25l., J. H. Arkwright, Hampton Court, Leominster; 2d, 15l., T. Garrett, Compton Scarpion, Shipston-on-Steur; 3d, 10l., R. Coston, Hayton, Stanton Lacy, Salop. Commended: Her Majesty the Queen, Prince Consort's Flemish Farm, Windsor.

Cows, above 4 years old, having had at least one live calf.—1st, 20l., J. Baldwin, 1st Bilton, Warwick; 2d, 15l., A. Benjafield, Stalbridge; 3d, 10l., R. Wortley, Norfolk.

SHORTHORNS

Steers, not exceeding 2 years and 6 months old.—1st, 20l., Her Majesty the Queen, Prince Consort's Slaw Farm, Windsor; 2d, 15l., W. Stagg, Aylesford, Oxford; 3d, 10l., R. L. Carter, 1st Waverley.

Steers, not exceeding 3 years and 3 months old.—1st, 30l., the Earl of Aylesford, Packington Hall, Coventry; 2d, 20l., R. Wood, Clapton, Northampton; 3d, 10l., Lord Fearham, Parry's Castle, Bangor. Highly Commended: T. Fulver, Broughton, Kettering.

Steers or Oxen, above 3 years and 3 months old.—1st, 30l., J. Outhwaite, Bidnese, Catterick; 2d, 20l., the Marquis of Exeter, Burghley Park, Stamford; 3d, 10l., Colonel Loyd-Hinsey, M.P., Lockinge Park, Wantage. Highly Commended: P. Brown, Gwentworth, Ipswich.

Heifers, not exceeding 4 years old.—1st, 25l., Colonel Chas. Towneley, Towneley, Burnley, Lancaster; 2d, 15l., T. Atherton, Speke, Garston; 3d, 10l., J. R. Aylmer, Fincham Hall, Downham. Highly Commended: J. Reid, Grayston, Alford.

Cows, above 4 years old, having had at least one live calf.—1st, 25l., Sir W. Calverley, Burt, Wallington, Newcastle-on-Tyne; 2d, 15l., A. and A. Mitchell, Aliso, Chackmannan; 3d, 10l., the Duke of Devonshire, Holker Hall, Grange, Lancaster. Highly Commended: J. Whyte, Chinterty, Blackburn, Aberdeen. Commended: R. Eastwood, Clitheroe.

SUSSEX

Steers or Oxen, not exceeding 3 years old.—1st, 25l., Lee Steere, Jayes Park, Dorking; 2d, 15l., J. and A. Heasman, Angmering, Sussex; 3d, 10l., G. C. Coote, Torrington, Sussex. Commended: G. Napper, Orford, Sussex, and J. M. Montefiore, Worth Park, Crawley.

Steers or Oxen, above 3 years old.—1st, 25l., Lee Steere, Dorking; 2d, 15l., E. Cane, Berwick Court, Lewes; 3d, 10l., J. M. Montefiore, Worth Park, Crawley, Sussex. Commended class generally.

Heifers, not exceeding 4 years old.—1st, 20l., E. and A. Stanford, Eaton Ashurst, Sussex; 2d, 15l., Lee Steere.

Cows, above 4 years old having had at least one live calf.—1st, 20l., J. and A. Heasman, Angmering; 2d, 15l., J. Shoo Smith, Berwick, Lewes. Highly Commended: W. Botting, Hurstpierpoint, Sussex. Commended class generally.

NORFOLK OR SUFFOLK POLLED

Steers or Oxen of any age.—1st, 15l., R. C. Symonds, Aylmerston, Norfolk; 2d, 10l., W. Harvey, Tinworth, Bury St. Edmunds.

Heifers or Cows of any age.—1st, 15l., H. R. H. the Prince of Wales, Sandringham, Norfolk; 2d, 10l., W. T. Mullen, North Walsham, Norfolk.

LONGHORNS

Steers or Oxen of any age.—1st, 10l., Sir J. Harper Crews, Bart., Calke Abbey, Derby; 2d, W. T. Cox, Spendon Hall, Derby.

Heifers or Cows of any age.—1st, 10l., W. T. Cox, Derby.

SCOTCH HORNS

Steers or Oxen of any age.—1st, 30l., Wihart & Wylie, Galowgate, Aberdeen; 2d, 15l., C. Morrison, Baddon Park, Reading. Highly Commended: T. L. Melville Cartwright, Melville, Ladybank Fife. Commended class generally.

Heifers or Cows of any age.—1st, 15l., Sir W. Calverley, Trevelyan, Bart., Wallington, Newcastle-on-Tyne; 2d, 10l., R. Eastwood, Thorneholme, Lancashire.

SCOTCH POLLED

Steers or Oxen of any age.—1st, 30l., J. Stephen, Conglass, Inverurie, Aberdeen; 2d, 15l., A. Longman, Hursfield, Rattle, Banff.

Heifers or Cows, of any age.—1st, 15l., K. Jardine, Esq., M.P., Castlemilk, Lockerbie, Dumfriesshire; 2d, 10l., J. Reid, Greystone, Alford, Aberdeen.

IRISH (AND BRED IN IRELAND)

Steers or Oxen, of any age.—1st, 10l., R. Wortley, Suffolk Hall, Aylsham, Norfolk; 2d, 5l., W. Nipper, Calfield, Norfolk.

Heifers or Cows, of any age.—1st, 10l., Lord Berners, Keythorpe Hall, Leicester; 2d, 5l., no entry.

WELSH.

Steers or Oxen (runts), of any age.—1st, 20l., H. Williams, Abercothly, Nantgaredig, Carmarthen; 2d, 10l., Capt. H. Platt, Gorrddinog, Bangor.

Heifers or Cows, of any age.—No entry.

CROSS OR MIXED-BRED.

Steers, not exceeding 3 years old.—1st, 25l., J. and W. Martin, Aberdeen; 2d, 5l., W. and J. Lawson, Meikletown, Aberdeen; 3d, 10l., R. Walker, Altyre, Forres. Highly Commended: J. Wortley, Felmingham, Aylsham. Commended: class generally.

Steers or Oxen, above 3 years old.—1st, 25l., J. P. McPherson, Muertan of Kinloss, Forres, Elgin; 2d, 15l., J. and W. Martin, Aberdeen; 3d, 10l., R. H. Harris, Earnhill, Forres, Moray. Commended: class generally.

Heifers, not exceeding 4 years old.—1st, 20l., J. D. Allen, Pyt House Farm, Tisbury; 2d, 10l., H. N. L. Morrison, Blair Guise, Whitehouse, Aberdeen. Commended: G. Mitchell, Foveru, Aberdeen, and H.R.H. the Prince of Wales, Sandringham.

SILVER CUPS.

Silver Cup, value 40l., to the exhibitor, for the best Steer or Ox in any of the classes, the Earl of Aylesford, Packington Hall, Coventry.

Silver Cup, value 40l., to the exhibitor, for the best Heifer or Cow in any of the classes, Sir W. Calverley Trevelyan, Bart., Wellington, Newcastle-on-Tyne.

GOLD MEDALS.

Gold Medal to the breeder of the animal winning the Silver Cup for—

The best Steer or Ox in any of the classes, the Earl of Aylesford, Packington Hall, Coventry.

The best Heifer or Cow in any of the classes, Sir W. Trevelyan, Bart., Wellington, Newcastle-on-Tyne.

EXTRA STOCK.

(That cannot be shown in any of the Classes.)

Silver Medal and 7l. to the exhibitor, for the best Steer or Ox, G. S. Foljambe, Osberton Hall, Worksop. Highly Commended: Her Majesty the Queen. Commended: G. Lawson, H.R.H. the Prince of Wales, Messrs. Wishart & Wylie, T. Bromwich, and J. Overman.

Silver Medal and 5l. to the exhibitor, for the best Heifer or Cow, J. Christy, Boynton Hall, Chelmsford. Highly Commended: R. Jardine, Esq., M.P.

CHAMPION PRIZE.

Piece of Plate, value 100l., for "the best beast in the show," the Earl of Aylesford, Packington Hall, Coventry.

SHEEP.

The Leicesters were placed in the first position, and were a small show of ten pens. Lord Berners took the first prize for shearlings of both heavy and light weights, the former trio weighing 6 cwt. 2 qr. 21 lb., and the latter 5 cwt. 3 qr. 7 lb. These were admirable for their symmetry, fine lustrous fleeces, and general pure traits. Mr. Newman's and Colonel Lowther's were also fine of form and pure as regards character, while Mr. Jordan's, of Driffield, were only a trifle coarse, and weighed 19 lb. more.

The Cotswolds were a poor lot of two pens. The disinclination of Cotswold breeders to exhibit on these occasions is something altogether unintelligible. They have the grandest breed of sheep in the world to show, but the outside public do not know it.

The Lincolns stood just as they did at Birmingham, the same exhibitors taking the same prizes, and only one additional pen being shown, which received no honour.

The Kentish or Romney Marsh were fine pens, and although their backs were not flat and their coats white and staring, there was a considerable improvement in the touch. The hardness of these sheep appears to make them a desirable breed on the bleak marsh from which they take their name.

The Cross-bred Long-woolled sheep were generally very mean; but Mr. T. W. D. Harris sent three Leicester and Lincoln, first cross, which were extraordinary for size, symmetry, and the fineness and lustre of their fleeces.

In the Extra Stock Lord Berners was fairly beaten, the cup going to the executors of the late Mr. Jordan. Lord Berners' wether weighed 1 cwt. 3 qr. 26 lb., and the prize wether 2 cwt. 1 qr. 19 lb., or 41 lb. more. For the cup for ewes there were only two entries. In the Long-woolled sheep (not Leicesters) Mr. Harris was again the winner, with a magnificent Lincoln-Leicester ewe, the weight of which was 2 cwt. 1 qr. 12 lb.

The Southdowns appear to have been put thus far down the list that they might be outside the gallery pillars, so that their beautiful symmetry might be towards the light, and thereby be more plainly seen by the spectators. If this be so, it was good judgment on the part of the stewards, for a finer lot of beauties were never seen together. Lord Walsingham almost surpassed himself on this occasion, and it must have been highly gratifying to his agent, Mr. Henry Woods, and his clever shepherd, Day, to see that, even in such good company, the Merton sheep carried everything so easily before them. The Merton 1st prize in the class not restricted to weight, took, in addition, the 20l. cup, as the best pen of Hants, Wilts, or Southdowns. Their weight was 6 cwt. 1 qr. 7 lb. Lord Sondes' 2d prize weighed 6 cwt. 0 qr. 3 lb. In the class not to exceed 200 lb., the Merton sheep were marvellously pretty, and their touch was equal to their beauty. Mr. Foljambe was 2d here with a very pretty trio, their weight being 4 lb. less in the three. The Merton 1st prize two-shears were the most perfect in form for sheep of this age that we ever saw. Sir W. Throckmorton, Bart., was a good second, and the Earl of Radnor a corresponding third.

The Hants and Wilts Downs were a great improvement on last collection; in fact, these sheep come better and better every year. Messrs. R. & J. Russell's were extraordinary for size and quality, their backs being equal to most of the neater Southdowns. Their weight was 7 cwt. 1 qr. 11 lb. Mr. Walter's were but little inferior as regards form and quality; but they were lighter by 31 lb. the three. As an indication of

the suitability for early forcing, and the great size this breed will come to at an early age, there were no entries of two-shears.

The Shropshires were few, and, as far as they could do so, the prizes stood the same as they did at Birmingham. In the absence of Lord Chesham's 2d shearling pen, Mr. Nock took 2d prize, and three entries having failed to appear, Lord Wenlock took the 3d. In the two-shears, Lord Wenlock was 1st and Mrs. Beach 2d, in a very weak class.

The Oxfordshires were anything but a fine show, and it seems to be the fashion to besmear the coats of these sheep with oil and dust. This, we presume, arises from the habit of cutting their coats flat on the back, and, indeed, something of the kind is necessary to disguise this deep cutting into the fleece. The backs of the 2d prize sheep were awfully disfigured, the whole of them being in but little better form. The prizes for fat wethers had only one pen shown for them.

The Mountain Breeds were of the whitefaced and blackfaced tribes, the former being Dartmoor, and the latter the bold, wild, and wiry Scotch.

Ryeland, Cheviot, and Dorset were represented by a pen of each, the former taking 1st, the latter the 2d and the Cheviot 3d. This and the previous class are more ornamental than useful as competitors.

In the second edition of Extra Stock there were some remarkable sheep. Mr. Rigden sent a wether, weighing, however, only 1 cwt. 2 qr. 15 lb., and Lord Walsingham took this cup also very easily. Sir W. Throckmorton, however, took the cup for ewes with a very handsome and heavy sheep. In the class for Short-woolled, not Southdown, Mr. Nock took the cup for a splendid Shropshire wether; and in the ewes Mr. J. Rawlence won the cup with as grand a sheep as any in the Hall. This was of the Hampshire breed, the weight being 2 cwt. 2 qr. 26 lb.

The Cross-bred Long and Short Woolled Sheep were remarkable for their variety, and also for the pen with which Mr. Overman took the medal as well as cup for his Long-wool and Southdown cross. Mr. Rook's second prize were Lincoln-Herts, their weight being 7 cwt. 2 qr. 18 lb.; Mr. Overman's weighing 7 cwt. 1 qr. 3 lb. Mr. Overman was again first for a single fat wether, and he also took the medal for the best Long and Short-woolled cross; and a more beautiful sheep we have never seen.

The following were the Judges and their Awards:—

SHEEP.—Leicesters, Cotswolds, Lincoln, Kentish or Romney Marsh, and other distinct Long-wools, Oxfordshire, Mountain, and Cross—Charles Clark, Scopwick, near Lincoln. Ralph Newton, Campsfield, Woodstock; John Davis, Webton Court, Hereford. Southdowns, Hampshire or Wiltshire, Shropshire, Ryland, Cheviot, and Dorset—Henry Masfen, Pendeford, Wolverhampton; Henry Lugar, Ingham, Bury St. Edmunds; Henry Hart, Beddingham, Lewes, Sussex.

LEICESTERS.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., Lord Berners, Keythorpe Hall, Leicester; 2d, 15l., W. Brown, Holme-on-Spalding Moor, York; 3d, 5l., B. Painter, Burley-on-the-Hill, Oakham, Rutland.

Fat Wethers, 1 year old (under 23 months), each sheep not to exceed 220 lb. live weight.—1st, 20l., Lord Berners, 2d, 15l., J. Newman, Harrowden, Bedford; 3d, 5l., Colonel Lowther, Oakham, Rutland.

COTSWOLDS.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., Right Hon. Sir J. Rolt, Wotton-under-Edge, Gloucester; 2d, 15l., J. Baldwin, Luddington, Warwick.

LINCOLNS.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., J. Byron, Kirkby Green, Sleaford; 2d, 15l., J. R. Caswell, Quadding, near Spalding; 3d, 5l., R. N. Morley, Leadenham, near Grantham.

KENTISH OR ROMNEY MARSH.

Fat Wethers, 1 year old (under 23 months).—1st, 15l., W. Burch, Rhode Court, Faversham, Kent; 2d, 10l., J. Newport, Ashford, Kent.

CROSS-BRED LONG WOOLS.

Fat Wethers, 1 year old (under 23 months).—1st, 15l., T. W. D. Harris, Wooton, Northampton; 2d, 10l., Sir W. De Capel Brooke, Bart., Kettering, Northampton.

SOUTH-DOWNS.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., Lord Walsingham, Thetford, Norfolk; 2d, 10l., Lord Sondes, Thetford, Norfolk; 3d, 5l., Sir W. Throckmorton, Bart., Buckland, Berks. Highly Commended: Duke of Richmond, Goodwood. Commended: Earl Radnor, Coleshill, High Wycombe.

Fat Wethers, 1 year old (under 23 months), each sheep not to exceed 200 lb. live weight.—1st, 15l., Lord Walsingham; 2d, 10l., G. S. Foljambe, Worksop, Nottingham; 3d, 5l., Lord Sondes. Commended: Lord Brybrooke, Audley End, Essex, the Duke of Richmond, Goodwood.

Fat Wethers, 2 years old (above 23 and under 35 months).—1st, 20l., Lord Walsingham, Thetford, Norfolk; 2d, 10l., Sir W. Throckmorton, Bart.; 3d, 5l., Earl Radnor. Highly Commended: Duke of Richmond, Goodwood. Commended: class generally.

HAMPSHIRE OR WILTSHIRE DOWNS.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., R. and J. Russell, Horton Kirby, Kent; 2d, 15l., J. Walter, Bearwood, Berks; 3d, 5l., L. Loyd, Monk's Orchard, Addington, Surrey. Highly Commended: J. Russell, St. John's, Sutton-at-Hove, Kent. Commended: class generally.

Fat Wethers, 2 years old (above 23 and under 35 months).—No entry.

SHROPSHIRE.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., Lord Chesham, Chesham, Bucks; 2d, 10l., T. Nock, Sutton Maddock, Shropshire; 3d, 5l., Lord Wenlock, Escrik Park, York.

Fat Wethers, 2 years old (above 23 and under 35 months).—1st, 15l., Lord Wenlock; 2d, 5l., S. Beach, Brewood, Pookridge, Stafford. Commended: Earl of Aylesford, Coventry.

OXFORDSHIRE.

Fat Wethers, 1 year old (under 23 months).—1st, 20l., A. Rogers, Bromham, Bedford; 2d, 15l., F. Street, Harrowden, Bedford; 3d, 5l., S. Druce, Eynsham, Oxford.

Fat Wethers, 2 years old (above 23 and under 35 months).—1st, 15l., A. Rogers, Bromham, Bedford; 2d, no entry.

MOUNTAIN BREEDS.

Fat Wethers (of any Whitefaced Mountain breed, of any age).—1st, 15l., W. Smith, Hoopern, Exeter; 2d, 10l., J. Tapp, Twitchea, Devon.

Fat Wethers (of any Blackfaced or Speckledfaced Mountain breed, of any age).—1st, 15l., J. M'Gill, Rotchell, Dumfries; 2d, 10l., Marquis of Aylesbury, Marlborough, Wiltshire.

RYELANDS, CHEVIOTS, DORSETS, &c. Fat Wethers.—1st, 15l., J. B. Downing, Hallowell, Bedford; 2d, 10l., H. Farthing, Nether Stowey, Somerset; 3d, 5l., J. M'Gill, Rotchell, Dumfries.

CROSS-BRED LONG AND SHORT WOOLS.

Fat Wethers, 1 year old (under 23 months).—1st, 15l., J. Overman, Burnham Sutton, Norfolk; 2d, 10l., Watton, Thetford, Norfolk; 3d, 5l., G. Ellis, Bedford.

Fat Wethers, 1 year old (under 23 months), not to exceed 220 lb. live weight.—1st, 15l., Burnham Sutton; 2d, 5l., Colonel Loyd, Wootton Bassett, Berks.

SILVER CUP.

Silver Cup, value 20l., to the exhibitor, for the best Sheep in any of the classes, Lord Berners, Keythorpe Hall, Leicester.

EXTRA STOCK.

(That cannot be shown in any of the Classes.)

Silver Medal to the exhibitor, for the best Wether Sheep, the executors of F. Jordan, Easton, Bedford.

Silver Medal to the exhibitor, for the best Lamb Sheep (not Leicester), T. W. D. Harris, Wootton, Northampton.

Silver Medal to the exhibitor for the best Southdown Sheep, Lord Walsingham, Merton Hall, Bedford. Commended: W. Taylor. Commended: class generally.

Silver Medal to the exhibitor for the best Short-woolled Sheep, Lord Walsingham, Merton Hall, Bedford. Highly Commended: H. Humphrey. Commended: Lord Walsingham.

Silver Medal to the exhibitor for the best Short-woolled Wether (not Southdown), T. Nock, Sutton Maddock.

Silver Medal to the exhibitor for the best Short-woolled Sheep (not Southdown), J. Rawlence, Bulbridge, Wiltshire.

Silver Medal to the exhibitor for the best Cross-bred (Long and Short-woolled Cross), J. Overman, Burnham Sutton.

PIGS.

These creatures become more and more of a general character and quality from feeding every day. At this show there were 55 pens, and not one was done from excessive forcing, while large larders and dowagers were altogether absent. The swinish monstrosities are now considered unworthy a place in a show of agricultural stock. Flabby, patchy cattle which used to appear as a great proof that the shows are at length becoming more instructive, both to the rising generation of farmers and the concourse of town visitors.

In the class for white breeds under 9 months Mr. Cattle's 8 months and 28 days old was extraordinary for substance and fine mellow fat. These are of the greatest possible weight for their kind and age. Mr. Lyon was in next class, as he was at Birmingham, with a pen well as his animals always are. The younger pigs did not present so much uniformity. Chamberlayne's, 1st, had the appearance of a skin of a negro; and Mr. Coate's, 2d, were very "lardified." The Berkshires were unusual there being only three pens over 9 months in pens over 12 months of age. As regards character there was nothing remarkable, excepting the breed, like others, is "sporting," as the gardeners so that we shall soon have Berkshires of the small breed, in the same way as we have the small white breeds.

The following were the Judges and their Awards:—

PROCS.—Joseph Smith, Henley-in-Arden, Warwick; Woodman, Southeast, Lewes; Gilbert Murray, Castle, Derby.

WHITE.

Not exceeding 9 months old.—1st, 10l., C. Cattle Nottingham; 2d, 5l., Captain R. P. Warren, Berks. Highly Commended: Rev. J. O. Stevens, Savernham, Berks. Above 9 and not exceeding 12 months old.—1st, J. Lynn, Stroxtan, Lincoln; 2d, 5l., W. H. Dunn, High Berks. Highly Commended: T. L. M. Cartwright, Berks.

Above 12 and not exceeding 18 months old.—1st, W. H. Dunn, Hungerford, Berks; 2d, 5l., Earl of Radnor. Commended: Her Majesty the Queen, Prince Consort's Farm, Windsor.

BLACK.

Not exceeding 9 months old.—1st, 10l., T. Chamberlayne, Cranbury Park, Winchester; 2d, 5l., J. Coate, High Blandford. Highly Commended: J. Kent, Whyke, Hampshire.

Above 9 and not exceeding 12 months old.—1st, Chamberlayne, Cranbury Park, Winchester; 2d, 5l., J. Coate, High Blandford, Dorset. Highly Commended: J. W. Wuyke, Chichester, Sussex.

Above 12 and not exceeding 18 months old.—1st, J. Coate, Hammoor, Blandford, Dorset; 2d, 5l., Capt. J. Warren, Basingstoke. Commended: C. McNeill, Surrey.

OTHER BREEDS.

Not exceeding 9 months old.—1st, 10l., S. Druce, Oxford; 2d, 5l., J. Biggs, Cublington, Beds. Above 9 and not exceeding 12 months old.—1st, Roberson, Hertford; 2d, 5l., J. Biggs, Cublington. Highly Commended: J. Treadwell, Upper Winchester, Berks.

Above 12 and not exceeding 18 months old.—1st, Clark, Altwood, Berks; 2d, 5l., J. P. King, Berks.

SILVER CUP.

Silver Cup, value 20l., to the exhibitor, for the best Pig in any of the classes, J. Coate, Hammoor, Dorset.

EXTRA STOCK.

(That cannot be shown in any of the Classes.)

Silver Medal to the exhibitor for the best Pig, C. Coate, Porryfield, Godstone, Surrey. Highly Commended: J. Overman, T. Chamberlayne, Berks. Commended: J. Overman, T. Chamberlayne, Berks. Stephens, and J. Coate.

IMPLEMENTS.

The exhibition of implements in the Agricultural Hall this year is not above an average. The number of stands in the main body of the hall exceeds that of last year, there being on the ground floor 31 for 1868; and in the galleries, 177 against 23 for 1868; and in the galleries, 177 against 164. Total this year, 208; last year, 193; increase 15 stands. But the number of stands indicated

the exhibitors, and as the space both years is small—or we may say, the same—it follows that many of the exhibitors have not been able to get the articles entered in the catalogue into the Hall. On the other hand, we never saw the stands more closely packed together, while the selection seen the best ever credited to the exhibitors. In the Avenue of Art, there are some 22 stands, and in the new department opened this year, viz., the Central Hall, Bazaar, &c., total in this department, 72 stands. Grand total on exhibition, 280 stands.

Horizontal Engines form an interesting class. Some of them are coming perhaps rather familiar to our friends, but, upon the whole, we have to report progress. The number is also on the increase. Horizontal engines are on the increase for indoor threshing, especially in our northern and western counties, where the climate is unsuited for outdoor threshing.

Vertical engines continue to merit growing patronage. They have their advantages over the horizontal engines, not only in construction as to the working and extra and unequal wear of the piston and cylinder, but in their adaptation to light work—as grinding, chaff cutting, and root-pulping. The small area of space they occupy is also greatly in their favour. Of late years very great progress has been made in the cattle-feeding department of farm practice, hence the growing demand for engines of this class, but this is not all that must be reported, for they are evidently also entering into competition with their rivals in the threshing barn. They have long been in extensive use by builders for hoisting and pumping, being made locomotive by means of rails, and constructed on this plan they are proving equally effective and advantageous in the brick-field, quarry, wood-yard, large dairies for churning, laundries, for driving washing machines, and the like. Add to this the growing use of a heavier class of engines for steam culture, which necessitates as it were the employment of small vertical ones at the homestead, it is easy accounting for the growing popularity of the latter at all our implement exhibitions. In construction there is a close similarity on the whole, but in details of mechanism they are diversified. Something of course depends upon the special purposes for which they have been made, and whether they are to be used outdoors or indoors, and whether they are to burn coal or coke, and so on.

Portable Engines continue to claim the chief share of the Hall. They are of all sizes, from the small "pony" up to the big "steam horse." They exemplify the highest standard of skilled labour, and in the details of mechanism we have to report progress likewise. The improvements made by Roby & Co., Perseverance Iron Works, Lincoln, merit special notice; they consist chiefly of a "governor," regulating the cut-off of the steam in a very effective manner; it is placed and works horizontally in the crank-shaft, and acts directly upon the eccentric, by which the full boiler pressure of the steam is always got in the cylinder. The admission of full-pressure steam to the cylinder being thus regulated in the most effective manner, the engine always works at its maximum point, effecting thereby a corresponding economy in the consumption of fuel, as compared with the old plan. The cylinder is jacketed and well cased, and from the brackets carrying the crank-shaft and governor being cast in a piece with the saddle, the boiler is thus strengthened where it most requires it. Improvements have also been made in the boiler, both as to the generation of steam and the easy keeping of it in effective working trim. The steel boiler of William Adams & Son, and other improvements of their portable engine, merit special notice.

Traction Engines—This favourite class is not so well represented in numbers as it should have been, several examples not being admitted for the want of room. This restriction in the admission of traction engines gives a prominence to the old portables, which they otherwise would not have enjoyed in the Hall. The limited number on view are, however, a first-rate selection, a flattering but trustworthy sample of the whole class exhibited at Manchester, Leicester, and other summer meetings of the Royal Agricultural Society of England, of different exhibitors showing respective peculiarities of construction. Thus, the engine of Messrs Richard Garrett & Sons differs from the two, a 14-horse and a 12-horse ploughing engine, of John Fowler & Co.; these latter, again, from the Messrs Clayton & Shuttleworth's, Mr. Burrell's, and the Messrs James & Frederick Howard's, and the Bedford engine, again, from the Messrs. Aveling & Porter's. The agricultural public is now familiar with the distinctive characteristics of all these engines, and it is highly interesting to hear how closely farmers scrutinise differences, each from his own point of view, as determined by experience and observation. The grand desideratum generally at issue is the cultivation of land by steam—the absence of the steam-plough this year—the fact, however, which this gives to the cultivators, shows a great diversity of soil and climate; harvest results an increase of from 8 to 20 bushels per acre, when thrown in the scales, so influence the balance of opinion as to baffle any approximation at a general conclusion in favour of this or that peculiarity of construction. At the same time twin-engine hauling and smashing are obviously this year in the ascendency, but a few words more on the head under steam-harvest implements.

Steam Boilers—The Messrs. J. & F. Howard exhibit their "patent safety boiler and superheater," which continues to receive a well-merited patronage in agriculture and all the other arts and branches

of manufacture where steam-power to any considerable extent is used. It is adapted for small works as well as large ones, but in large concerns, where a number of boilers are used, the economy of steam and fuel, taking into account at the same time the greater safety, leaves, perhaps, a balance in its favour. One large house, for example, some time ago, after making the necessary inspection of those in use, had their boilers put up on the Howard plan, as illustrated in the accompanying section, and before two years had expired they were so satisfied with the advantages realised that they gave orders for four more boilers to take the place of those in use on the old plan long before they were worn out. Such facts speak for themselves. With the view of placing the matter of fact argument fairly before them, we give the following description of the illustration. The new boiler, it will be seen, is built up of wrought-iron tubes, the bursting pressure of each of which is fully 2000 lb. per square inch, and the whole of the steam pipes and connections are tested to a cold water pressure of 500 lb. before they leave the Britannia Iron Works. When a common boiler bursts at work, the upshot is generally more easily imagined than described. It is otherwise with the safety boiler, for in the event of the bursting of a single tube, say any of those shown in section, the result would only be equivalent to the forcible opening of the safety-valve and blowing off of steam into the heating chamber, thereby suddenly lowering the temperature and steam pressure, and putting out perhaps the fire, so that no dangerous accident or serious loss of property could be sustained. The simplicity of parts, the facility with which they can be set up and repaired, economy of house room, and the durability of the whole, form together another characteristic of the safety boiler and superheater. Thus, as there are no rivets or seams in their construction, there is not a single bolt or joint exposed to the action of the fire. The tubes being all counterparts of each other, those farthest from and those nearest when the heat is most intense, can be interchanged in suc-

HOWARD'S NEW PATENT SAFETY BOILER AND SUPERHEATER.

cession, so as to increase the durability of the whole to a maximum. The tubes being also so arranged and fitted in sections that each is free to expand and contract reciprocally, as they absorb or give out heat, it follows that the expansion or contraction, as the case may be, produces no harm. Again, as the parts are all made on the interchangeable principle, they are easily set up and repaired, and with regard to house room the new boiler does not require over half the space of a Cornish one of equal horse-power. The circulation of the water is so perfect throughout the boiler that no burning out or fouling of the tubes takes place. Thus, as each tube has within it an internal one rising up through the water space, the water is consequently divided into annular concentric columns. The upper portion of the tubes is divided from the lower by a diaphragm, and the current of heated gases from the fire (the direction of which will be seen in the section by the arrows) impinging upon the tubes, causes the water in the outer space or ring to rise to the top and flow down to the bottom of the inner tube, thereby keeping up a most active circulation in every part of the boiler. The upper part of the tubes form the heating chamber, and from the manner they are exposed to the heat it will readily be seen that the high-pressure process of superheating can easily be carried to the desired degree.

Corrugated Tube Boiler, or more correctly speaking, **Three-lobed Tube Boiler**.—The Messrs. Kinsey, Norton, Hill & Co., Robin Hood Works, Nottingham, exhibit a boiler with three-lobed tubes (Kinsey's patent), which has an awkward resemblance to the Messrs. Howard's safety superheater in more respects than one. Thus the mode of applying heat—i. e., the flue and chimney—and the position of the lower horizontal tube and the diaphragm are identical, and even the vertical outer corrugated tubes, each with three lobes—each lobe opening into the other with a central tube rising up in each lobe—is virtually an imitation of three of Howard's tubes, shown in the above section. The one exhibited is a three-lobed tube. They may be made with any number according to the horse-power required. As to the specific mechanism there is nothing new in that—corrugated tubes having long ago been used; but we do not recollect having seen any in use with three lobes, as in Kinsey's patent.

Gas Engines—The Huzon Gas Engine is in its

place, in the clock gallery—a 1-horse power engine, and is exhibited at work by Mr F. B. Valance, Greenwich and London. In almost all sorts of household work it is freer from objection than steam-power, and wherever it is in use it is giving very great satisfaction. It is well adapted for driving the churn in the dairy, or the washing and wringing machines in the laundry, where a supply of gas can be had, and also for grinding, crushing, &c., &c., as you can start the engine at the gas is turned on, and stop instantly by turning it off, without any loss of time or motive power, while gas is cheaper than steam, and the Huzon Gas Engine more easily kept in working order.

Steam Ploughs—What shall we say to the reader—"that there is not a steam plough in the great hall?" No, not one! Mr Smith, of Wootton, does not require a steam plough, and I memory does not fail us he once told us, perhaps half-joke, half-serious, "the day is not far distant when steam ploughs will not be shown at our general meeting," but we never imagined that that time would be Christmas, 1869! The poet Drayton tells his readers that the Hereford birds sat on the ground and sang curses against the plough, because they had a branch to perch on, every tree having been pulled up, and those who say some up purposely to sow a prejudice against the sowing of the character of the soil, are such up.

Steam Cultivators have of all their own way this year in the Agriculture Hall. The fact, apart from any other argument, goes far to prove that harvest results are in their favour, and we aver that this is likewise the general testimony of experience. It will no doubt be said that had there been room in the Hall, steam ploughs would have been shown. But that is not the question at issue. It is an old and true saying, "Whatever touches the purse-strings eventually tells its own tale," and leaving the reader to apply this we have to report the two cultivators on the stand of John Fowler & Co., and the very high degree of perfection they exemplify in mechanism and manufacture. Being entirely free from all complication the resistance falls equally upon the working parts, so that they are both strong and simple, while the wearing parts, so to speak, are, on the other hand, reduced to a minimum. The main axle that carries the road wheels is cranked, and as the frame carrying the lines is connected to the crank the latter (the lines are lowered or raised and adjusted to any depth required by the tilage or nature of the land. The body or frame fixed to the crank is of a breadth suitable for heavy land, but when crossing or working light lands, lugged sides are put on, adding as many tines as you like, and when hauled by double engine tackle the cultivator may be over 40 ft. in length. The two ropes are from each end—are attached to the free end of the long turning (or lifting) lever, seen in advance of the single wheel in front. This long lever is carried on a stud sufficiently far back to place the lever within the reach of the steersman so as to give him complete command of it. The two ropes become alternately the hauling rope and the tail rope, and at the end when the alternation takes place, in the act of turning, self-acting rope guides receive the tail rope; and in this way one man on y is re-

quired to work the implement. On the other end of the turning lever are two chains, connected with two quadrant pulleys on the crank axle, and as the lever is pulled round the chains turn the axle by means of the quadrant, and thus raise the implement out of the ground. Thus when it comes up to one headland the engine on the opposite headland is thrown into gear, when it pulls the lever round, raises the frame, which is held by a catch, and when up to the proper height the implement is then hauled into fresh ground by the lever coming against a stop. The steersman, who remains seated all the while, then releases the catch, when the implement drops into work and is hauled along the field; the tail rope being laid down in the rear ready to become the hauling rope when the cultivator comes up to the hauling engine; and so on until the field is finished, the turning at the headland occupying less time than is required to describe it.

The Different Systems of Rope Traction in the cultivation of land by steam-power are now familiarly known under various designations, as (1), twin engine and twin implement system; (2), twin engine and single implement system, or double engine and single implement system; (3), single engine and twin implement system; (4), the roundabout system—single engine and implement; (5), the single engine, anchor, and implement system; and (6), the flying rope and twin rigger anchor, or single engine system (Fisken's). Then there are winding drums and clip drums, attached or detached, but they do not necessarily form systems. That shown in the Hall by the Messrs. John Fowler & Co. is included in the two Messrs—a 14-horse and 12-horse—each carrying a winding drum under the boiler: the two engines, of course, representing two 14-horse and two 12-horse, each pair for working a cultivator as described above.

The Messrs. James and Frederick Howard exhibit a traction engine adapted for either the first or fifth systems, and models illustrating how the both systems, and also the fourth, are carried out. The Messrs. Coleman & Martin, of Leeds, show two instances of the third system, with their own, and their own. The Britannia Steam Cultivator Company enter the sixth in the catalogue. Models of Fisken's light rope steam ploughing tackle, but the stand is empty.

The following engraving illustrates the system.

coffee pots, kitchen ranges, and so on, including, of course, sewing machines.

Dairy Utensils as last year, with the exception of Ash's current churn, in which the cream flows against a fixed dasher; and Hunt & Pickering's milk can (Hunt's patent), in which the neck and lid of the ordinary cans in use about Leicester is replaced by true and faced. A conical wooden cover, seated with cork, is fitted and secured inside the neck by a compound lever, which is made to act with considerable pressure on the milk, while it at the same time keeps down the cover and makes the can air-tight, and the levers are secured by a lock. The cans are made in all sizes, of the best charcoal tinned sheet-iron, and fitted with wood bottoms.

Carpeting Tools, grindstones, saw-benches, endless saws or feeders, leather and vulcanized india-rubber boots, and many other articles.

Artificial Manures, oilcakes, and feeding stuffs, are well represented by C. F. Stofell's concentrated fish manure below stairs in the arcade, and by Raynbird & Co. Davis's compressed fodders, &c., and others in the galleries.

Henry Allnatt, Esq., of the Estate Office, has the most interesting stand in the Agricultural Hall. His diagrams are drawn with surprising fidelity of purpose and effect.

SEEDS AND ROOTS.

Messrs. Hooper & Co., seed merchants, Covent Garden, exhibit a finely arranged selection of seed Potatoes, consisting of small samples of the most noted varieties of the day. Paterson's Bovinia, or cattle-feeder, occupies a prominent central position. The roots, although exceedingly large, are perfectly healthy, which indicates a vigorous constitution.

Messrs. Thomas Gibbs & Co., corner of Half Moon Street, Piccadilly, London, W., the seedsman to the Royal Agricultural Society of England, exhibit splendid collections—1st, of dried specimens of selected natural Grasses; 2d, of all the most approved kinds of Wheat, Barley, Oats, &c.; 3d, seeds of the above two specimens; 4th, growing specimens in pots. Their collection of roots is of first-rate quality and finely arranged:—Drumhead Cabbage (Robinson's), each weighing upwards of 50lb.; Yellow Globe, Orange Globe, and Red Globe Mangel are superior, and so is the Long Red variety; Swedes, excellent; and this also applies to their purple and green Kohl Rabi, their yellow and white-fleshed Turnips, and to their Parsnips and Belgian Carrots.

Messrs. J. C. Wheeler & Son, Gloucester, exhibit a fine collection of roots and seeds. The different varieties of Mangels are both large and superior in quality.

Messrs. George Gibbs & Co., 24, 25, and 26, Down Street, Piccadilly, London, W., have, as usual, a large stand, tastefully laid out with magnificent roots of the finest quality, surmounted ornamentally with dried specimens of all the best Grasses, thus illustrating the produce of their mixtures for laying down land to permanent meadow and pasture, and also for renovating worn-out grass-land. Their Drumhead Cabbages (Robinson's) are of enormous size, one weighing 59 lb., and another 60 lb., when newly pulled. A Gourd weighs 84 lb., Long Red Mangel about 46. Their Yellow Oval Mangels are also unusually large and fine. The Globe varieties are also splendid; Swedes and Kohl Rabi very fine; and the same may be said of yellow and white-fleshed Turnips, and of Belgian and Long Surrey Carrots.

Messrs. Raynbird, Caldecott, Bawtree, Dowling & Co., Basingstoke and Mark Lane, London, exhibit finely selected samples of agricultural seeds, including seed corn and the Grasses, also of roots, oilcakes, feeding stuffs, and manures, all of the very best quality.

Messrs. Isaac Wright & Son, Great Bentley, Essex, exhibit fine Cabbages, Swedes, and the different varieties of Globe and Long Mangel Wurzel, with samples of agricultural seeds and specimens of the Grasses.

Messrs. Thomas Harrison & Son, Midland Seed Warehouse, Leicester, have a splendid stand. The numerous articles exhibited are judiciously selected, and of the very best quality, and this applies equally to seed roots and dried specimens.

Messrs. James Carter & Co., High Holborn, London, have a most magnificent collection, very skillfully selected from their own farms and those of their customers. The splendid show of roots are from the latter, and the seeds and growing specimens in garden pans and pots from the former. The gigantic Brussels Sprouts, which are without a rival in the Hall, are most attractive objects, and so are the enormous Drumhead Cabbages and Drumhead Savoys, produced by Mr Robinson this year. The Warden Mangels, Mammoth Long Reds, and sewage produce from Barking, at the rate of 50 tons per acre, are all wonderful specimens of vegetable growth. So are the splendid Swedes, grown by B Allan, Esq., Wexford. The Kohl Rabi are fine; the yellow and white-fleshed Turnips are very excellent, and the same may be said of Belgian Carrots and Jersey Parsnips. The Sugar-Beet and the "Perfection Salad Beet" merit the highest commendation. There is a fine show of seed Potatoes, including Paterson's Bovinia and Victoria, and some other varieties more interesting to gardeners than farmers.

The growing specimens show the germinating powers of the seed and the constitutional health of the specimens themselves.

Mr. John K. King, Great Coggeshall, Essex, has a fine collection of his pedigree prize stocks of Mangel Wurzel, Swedes, and other roots, whose superior quality is attracting the attention of good judges, practically acquainted with the growth of the seed. His roots are but of medium size, finely formed, and remarkably free from abnormal growth or

unhealthy development; and this applies to the Mangels as much as to the Swedes and Turnips.

Messrs. Sutton & Sons, Royal Berks Seed Establishment, Reading, Berks, show a splendid collection of dried Grasses, and also of Grasses in growth, showing their germinating powers. The roots are super-excellent and finely arranged. The Mammoth Long Red Mangels in the centre, and the intermediate or oblong orange and yellow varieties on either side are magnificent, and universally admired both for size and quality. Their Champion Swedes are also very superior, and so is their Kohl Rabi, more especially the green variety. The yellow and white-fleshed Turnips are also very fine, and so are the different kinds of Sugar-Beet, Carrots, and Parsnips. The Drumhead Cabbages are remarkable productions of vegetable growth. Their Early Racehorse and Walker's Regents are superior specimens of seed Potatoes, and so are Drummond's Prolific and the King of the Potatoes. A fine sample of Paterson's Bovinia is shown. The Reading Onions are also excellent.

Mr. Alfred Hall, Westbury Farm, Westbury Wilts, has a most attractive exhibition of his Westbury Swedes, all growing as it were. He also shows his Long Red and Yellow Globe Mangels, Green Kohl Rabi and Belgian Carrots.

The almost incredible size of roots shown this year and the enormous produce per acre call for a general remark in conclusion. When Cabbages weigh 60 lb. and upwards each, Mangels 48 lb., and Potatoes are grown as big as dumb-bells, and when 50 tons of the former (Mangels) are grown per acre, and 40 tons of Potatoes, does it not augur well for the future?

At the annual dinner of the Smithfield Club, held on Monday evening, in the new dining hall, a larger number than has been known for some years assembled. The Duke of Marlborough was in the chair, and in giving "Success to the Smithfield Club," his Grace reminded his hearers how the society, from a small beginning, had developed itself, increasing more and more in usefulness, in public estimation, and in prosperity, until at last it had become the most important agricultural association in the country. He then drew a comparison between the Royal Agricultural Society and the Smithfield Club, speaking of the former as a society which fostered the breeding of cattle, while the Club promoted the feeding of the animals for the use of man. Lord Walsingham returned thanks for the prize winners, expressing his gratification that he had obtained prizes for every pen of sheep (three in number) which he had exhibited. The noble lord expressed his opinion that the show was, on the whole, a fair average one. Mr. Keary, for the judges, said that the show was a good average one, no doubt, but he had known better animals take the gold medals; still he was much surprised at seeing so large an amount of food produced at such early maturity as the show of 1869 in a most remarkable degree exhibited.

HIGHLAND AND AGRICULTURAL.

At the monthly meeting of the directors of this Society, held last week, it was resolved that the anniversary general meeting of the Society should be held on Wednesday, January 19, 1870.

Dumfries Show.—The following are the principal points noticed in the report with reference to the show to be held at Dumfries in July next year—1st. It was resolved to add a section for Ayrshire cows in-calf, of any age. 2d. That the premiums for stock should be the same as at the Edinburgh show, with the exception of those for Ayrshire cows, extra horses, and Leicester sheep, in regard to which a modification is proposed. 3d. That the premiums for extra sheep and for dairy produce should be the medium gold and silver medals. 4th. That a silver medal should be given to the commended animals in all classes of stock, and as a 2d prize for poultry in place of the Bronze Medal. The following additions to the regulations were recommended:—1. No animal to be allowed to compete in more than one section. 2. With reference to regulations 6 and 8, birth of at least a seven months' calf must be certified; and in regard to regulation 9, birth of at least a nine months' foal. 3. A veterinary surgeon will attend each set of judges of horses. He shall examine those selected for premiums, and shall declare as to their soundness before the judges finally decide, but the veterinary surgeon shall in no way interfere with the judging. 4. In the class of horses, all breeding stock selected for premiums shall be examined by a veterinary surgeon, but shall only be cast by him on the ground of unsoundness which may be likely to affect their progeny. 5. No protests on veterinary grounds will be received. The board approved of the various suggestions contained in the minute in regard to the Dumfries show; and the secretary was instructed to submit the revised list and regulations to a meeting of members to be held at Dumfries on Wednesday the 15th current. In regard to the implement department, the board resolved that the judges at Dumfries should be authorized to award medals or commendations, as was done at the Edinburgh show, for general collections, and for new inventions or improvements, where a trial is not practicable.

Proposed Show at Perth in 1871.—The classes of stock for the proposed show at Perth in 1871, as suggested by the committee on general shows on Nov. 17, was approved of by the board, and the secretary was instructed to bring the list before the members in the next meeting to be held at Perth on Friday the 17th current.

Premiums for Essays and Reports.—The following new subjects were added—On the operation of the Contagious Diseases (Animals) Act, 1869, on the different modes of shoeing horses, with special reference to those recently introduced; on lambing and the diseases incident thereto, particularly whether some of

these diseases are of an infectious or contagious nature, with statistics (competition for this premium to be limited to shepherds); on the methods of management of woods and forests in the schools of Germany, Hanover, France, and other parts of the Continent, on the current prices realized for forest produce in different districts throughout Scotland; on the effects of the very dry summer of 1869 on trees and shrubs generally in different soils, situations and exposures; on the comparative advantage of ploughing-in manure immediately after it is spread on the land or of allowing it to remain on the ground for some weeks before it is covered; on the causes of the failure of winter Wheat sown after early Potatoes lifted in July or August.

Farmers' Clubs.

LONDON.

On Farm Agreements: Monday, Dec. 6.—Mr. MASFEN read a paper on this subject, in which, after some very discursive remarks on the general relations of landlord, tenant, and labourer, he discussed Mr. Cadle's form of farm agreement, to which the Royal Agricultural Society of England had awarded their premium.

MR. CADLE'S FORM OF FARM AGREEMENT.

In the year 1868 the Royal Agricultural Society offered a premium for the best form of agricultural agreement, or an essay upon the same, and in awarding this prize to Mr. Cadle they recognise the existing necessity for more liberal covenants. I do not know how far my views may be endorsed by the members of this Club, but if the motive power of the Royal Agricultural Society will assist in carrying out the revolution proposed in Mr. Cadle's agreement, I think we have grounds for hope that a point is gained, and we shall soon find a better system than the present unsatisfactory mode of making out justice to quitting tenants.

This agreement sets forth that the hay, straw, &c., all belong to the landlord, and that the hay, straw, fodder and roots of every description be consumed on the farm, except that certain quantities of hay, straw, and roots be sold, the full value being returned to the farm in the shape of cake or artificial manure. Now, this is a boon not generally given to farmers, and the great waste you frequently see of straw, where a tenant is compelled to consume it all, is such as to render it little better than rotted straw, returning nothing fertilizing to the land for succeeding crops. Another clause not generally found is, that a tenant may sow two white straw crops in succession. Now this, I think, will be advantageous in many localities, and not injurious to the land; it has been so in my case, having frequently found a great difficulty in the growth of Clover, and in each case, when I have adopted the second white straw crop, preceded by a liberal application of manure, the result has been a satisfactory root of red Clover. Mr. Cadle proposes compensation for artificial food and manure used on a liberal scale, and I think it will meet with many supporters; as far as the food is concerned I will go with him, but I am not disposed to sanction his views as regards superphosphate, except as regards that used in the last year of the occupation. For draining and all permanent improvements in building, &c., on the tenant's own grass land, a planting fences and fruit trees, a section of the landlord for all improvements being given, I fully endorse his proposals, and coincide with his general mode of compensation for the various appliances referred to as the productive elements which a tenant, farming highly, must leave for the benefit of his successor. In clause 9 stipulation is made for all land sowed to be paid for if clean, 5s. to 30s. per acre, at the discretion of the valuer, in addition to the Clover or Grass seeds sown, &c., returning to the tenant an equivalent for good manure, &c., which he would receive no more than 10s. per acre, &c.

In a discussion at the Midland Farmers' Club, Mr. Russell, of Cheshire, directed the attention of the meeting to all agreements of a stipulation for clean land. He proposes that, at the expiration of Michaelmas of any year, 1/4 of the arable land shall be left to plant with white straw crops, one fourth shall have been followed with green crops during the previous summer, the other moiety shall have been wholly under Clover or mixed Grass seeds or part in Clover, the rest Beans and Peas; after being manured, some of the Clover or Grass seeds being allowed to stand for seed. He requires that no more than one-fourth of the arable land should be fallow in the year after the termination of the tenancy, nor require an outlay of more than 10s. per acre, &c. if it does not exceed that sum the landlord or tenant should pay the difference, if more the outgoing tenant should pay. To follow the compensation clause. Not less than one-fourth of the Clover or mixed Grass seeds shall be in own for hay during the last year, for the use of and to be paid for by the incoming tenant, for the remainder of the land, whereon Clover or other Grasses have been grown, the whole standing by sheep, the incoming tenant shall pay after the rate of 40s. per acre, provided such land be clean and that only one crop of corn has been taken since the previous fallow. There are other covenants that relate to the purchase of manures, which are dealt with in the manner proposed by Mr. Cadle. With one exception, Mr. Randall proposes that one half the proceeds of the hay, straw, &c., sold be returned to the tenant.

TIME OF ENTRY TO FARMS.

Much diversity of opinion exists on the time of quitting and entry on farms; it is contended in some localities that Michaelmas is a more desirable time for change than Lady Day.

It is not general in my locality; but on several occasions I have valued on farms where a change has taken place at Michaelmas, and in those cases I have found it has given satisfaction. In the Michaelmas change one thing is apparent—that the off-going tenant can clear away, and that the incoming tenant, by paying for the produce, which is then secured, is at liberty to proceed in all matters without hindrance, and carry on the various operations of the farm, which are often very unsatisfactory performed by an off-goer who leaves at Lady Day. I should here observe that, although I oppose any set rule of cropping, I should require the farm to be given up in a certain course, although the valuer would never consider a farm up to the required standard of good husbandry when a proposition of any one crop prevailed. I have always contended in agreement should be made to suit the localities. It is said, "No three-course system for the off-going tenant." It is said, "The off-going tenant should have a good tenant for six or eight years, &c." Mr. Cadle's reply is, "Give liberal agreements, and the off-going tenant will have been benefited by the change." Ad practical men know much land in 1869, &c., that all of artificial food and manure, &c., which is consumed from a liberal diet of the best animals. The off-going tenant's capital is not expected to be made by the animals who consume the food, but from the fertilizing properties of the manure.

you see, the want of recognition in all farming customs of ancient date. In some instances the manure upon the farm belongs to the tenant; he pays on entry, and, as a matter of course, receives for it on leaving. In that case there is no object gained by lowering the condition of the farm. If he has a limited quantity of manure on entry, and leaving a larger proportion at the expiration of his tenancy, he receives for all additional, and is thus recompensed for the expense to which he has been put by that increase. This is considered by many farmers the best form of occupation, and as one of the best of all old agreements has certainly much to recommend it. In other counties there are various customs in general use, called compensation for dressings and acts of husbandry, that find favour as tending to a good state of husbandry. The off-going tenant receives compensation for the last year's artificial manure bill, deducting certain sums for the roots, as per the mode of consuming them.

THE LABOURER.

Another most important consideration for the tenant is to see that he stipulates for the provision of good cottage accommodation:—

We are often told we provide our cattle with comfortable and warm shelter, but the lodgings of our agricultural labourer is not taken into consideration. This is a thing that requires attention, proper accommodation within a reasonable distance from his labour should be provided. The Urban Chargeability Act has in some measure removed an obstacle in the way of this great good; but there is much still to be done to make the matter as satisfactory as I could wish. Lord Leicester expressed a good opinion upon this subject a few years ago. He told us that in improving the dwellings of the labourer we were not to expect a return for our capital direct, but must charge the additional convenience we receive with some share of the expense incurred, which should be borne by both landowner and tenant, and in that view I think he would find many of these best able to form an opinion join him. The labourer must be better educated, and with that increased education you fit him for a more elevated position in the social scale, and in no way so well reward him, as in increasing the happiness of his own fireside. Education enlightens him, and should make him a better labourer, and that same information makes him more alive to the position in which he has been too much of a reproach to our class and of a mis-erisation by another. I believe the agricultural labourer of this kingdom will bear favourable comparison with the operative classes generally, still I consider there is necessity for his condition being improved, the requirements of the age make the service he has to perform more intricate than formerly. The education of the labourers' children will occupy the attention of Parliament during the next session, and I trust that in dealing with it provision will be made to educate them to the position they are expected to fill, and if in addition to their book knowledge some scheme can be devised for their technical education, an additional object will be achieved. The steam engine, plough, reaping machine, in fact every new appliance for the general cultivation of the farm, is rendered more valuable, the amount of property in the shape of machinery more costly than formerly, hence you require a better man, a more intelligence must be brought to bear in nearly every branch of labour in which he is engaged.

GAME.

The next is one of the most difficult questions to deal with in connection with landlord and tenant—I allude to game.

Mr. Cadle, in his agreement, provides for the destruction of rabbits all the year, and for no dog during the breeding season, which is quite right, and with the general stipulation. With regard to compensation for damage done by game I cannot coincide with the proposal, knowing from practical experience the evil attending the clause, viz., "To all what all damage done by game, exceeding 5s. per acre for each and every acre so injured." I have frequently been called in to assess damages done by game, and all who have been similarly placed will agree with me that it is surrounded by a variety of disagreeable circumstances. You must first as per this agreement, submit to an amount of damage, receiving no compensation; you then have to make a claim of a nature not the most agreeable, and no claim is viewed either by a landowner or his advisers with a more jealous eye than the one alluded to. I will ask you as practical men, in how many cases of this kind have you not found that a notice to quit has followed on almost the very next opportunity after such a claim has been made? If, gentlemen, you have not, I have. When consulted upon matters of this kind, my first question is, Do you value your occupation? If so, do not do anything likely to irritate your landlord, or those in his employ, for it must be well known there are besides the owner those who are fully as difficult to deal with in things of this kind. I believe a greater evil exists than this over-preservation of game. Another most objectionable practice on some estates is to introduce a second tenant by setting the game. This should never be done without first offering it to the tenant, and if he refuses to have it at the value placed upon it when he takes the farm (which should always be a fair one) the landlord should then be considered at liberty to deal with it as he thinks well. I look for the whole question to be more set at rest by public opinion being brought to bear upon it than anything else. Men and things are more influenced by that than by any other power. The law now gives the tenant the game, but by a voluntary act he resigns his right to the owner, feeling at the same time he has little option in the matter. There is one remark I wish to make upon the rabbit clause in Mr. Cadle's agreement; it provides for the destruction of them at any time, but there are hundreds of farms where rabbits never remain on the land during the day, although at night they visit you by hundreds, to the utter destruction of your crop. Now, in cases of this sort, the stipulation affords no remedy, you have no power to enter the coverts where these pests of the farm take shelter during the day, and to attempt to interfere there would be considered sacrilege.

THE LEASE.

One word upon Scotch farming and leases. As you are aware, in Scotland the general system of tenure is by lease of 19 or 21 years, renewable at a certain period, prior to the expiration of the term specified.

The system of farming there has much to recommend it to our notice—land well farmed, masters and labourers happy and prosperous, the amount of capital there invested contrasting very favourably with that of England. No complaint can there be heard of the uncertainty of tenure, and the want of security for invested capital. The tenant immediately makes a liberal investment with an assurance that there is no opportunity during his term to reap the reward of the same—and it is as applicable to the case of a yearly tenant, if the security which Mr. Cadle sets forth in his essay be not upon. We were told by the late Mr. G. of Dunston, a lease will bring a barren heath to the productivity of a garden, and that a yearly tenancy will return the garden to its original desert state.

POSSIBILITIES OF ENGLISH AGRICULTURE.

I feel persuaded that if either of the systems here

proposed were generally adopted, it would tend more than anything else to increase the value of the land of this kingdom, and would double the available food for the people.

Mr. Allison has recorded an opinion that the husbandry of Flanders in our plains, and of Tuscany on our hill sides, would easily raise food enough for double our population. Mr. Smith, of Dunston, whose name will everywhere command respect, has expressed his conviction that by leaving and subsiding alone, leaving the question of manure out of sight, Great Britain in 25 years will become a corn exporting country; while Professor Johnston, in his lectures upon agricultural chemistry, expresses his deliberate conviction that, as a whole, this island does not produce one half the food for man which it might be made to bear with profit to the farmer, and which by the time our population is doubled he believes will be found readily to yield. The late Prince Consort, who took so deep an interest in the progress of agriculture, in one of his speeches said—"Agriculture, which was once the main pursuit of this as of every other nation, holds even now, notwithstanding the development of commerce and manufactures, a fundamental position in the realm, and, although time has changed the position which the owner of the land with his feudal dependents held in the empire, the country gentleman, with his wife and children, the country clergyman, the tenant or the labourer, still form a great and, I hope, a happy family, in which we gradually recognise the foundation of our social state. Science and mechanical improvement have in these days changed the mere practice of cultivating the soil into an industrial pursuit, requiring capital, machinery, industry, skill, and perseverance in the struggle of competition. This is another great change, but we must consider it a great progress, as it demands higher efforts and a higher intelligence." His Grace the Duke of Marlborough so aptly said "Whatever the material prosperity of the country may be, it must be based on that which supplies the resources of natural life and vigour to the nation." Sir John Pakington also "repudiates the idea of a man placing confidence in his landlord, let him treat it commercially, and place his trust in a written document." If then, we are to credit these assertions—and I fully believe to a great extent in their correctness—I ask my brother farmers if we should not be "Up and doing." The name of Earl Ducie is familiar to most in this room; his views upon the question before us are clear and concise. At an agricultural dinner he thus addressed those present—"Those farmers who look with dislike upon the progress of improvement, under the impression that it operates against themselves, could not entertain a greater mistake; for go through the length and breadth of England, it would be seen that where the landlord was found the most enlightened, the tenant was found in the most flourishing circumstances; the tenant knew his duty to his landlord, and the landlord to his tenant. No question could affect more the relative position of both parties than that of leases, and his opinion was, that till that question was fairly and clearly understood, all their efforts after improvement would fall short of what they ought to be. He (Lord Ducie) would give every tenant a lease, but in return he must have intelligence. He considered a man a fool who invested his capital without security. Mr. Randall says, that by sensible and business men a lease was considered most desirable. But we are fettered by landlords, what we know to be a fact, that in very extensive and highly cultivated parts of the country (he alluded to Yorkshire and Lincolnshire) land was occupied from year to year. The farms in the neighbourhood alluded to remained from generation to generation in the hands of the same family of tenants, who considered if they had leases their farms would be re-valued, and might be called upon to pay an increase of rent, which increased value was mainly due to their own industry and outlay.

CONCLUSION.

In the first place I feel bound to express my opinion in favour of a lease, considering it the best security for the investment of capital tending to the independence of the occupier, and an increase of value to the landlord, with a largely increased production for the benefit of the nation at large. Secondly, in cases where an objection is made to granting a lease a liberal tenant-right should be given, extending a scale of compensation for unexhausted improvements, or for clean farming to such an extent, or in an equal ratio to that proposed in the agreement selected by the Royal Agricultural Society, and with at least twelve months' notice to quit.

During the subsequent discussion (after some explanatory remarks by Mr. CADLE)—

Mr. Brown, of Tring, said as a landlord he could declare there were bad tenants as well as bad landlords. An agreement cuts both ways. And that was true also of one clause in his agreements that was worth all the rest. "The landlord agrees to a valuation, at the end of the tenancy, of all permanent improvements made by the tenant, for which full compensation has not been received." As to excessive rental, he had valued a farm and the rent was objected to by a member of this Club. He then "put it on the market, as it was called, and the result was an increase of 5s. per acre over his valuation. It was the farmers who did this. The farmers raised the rents, and not the land agents. He was opposed to Michaelmas outgoings. It was a great inconvenience for one to begin before the other had left, but at Lady Day one could walk in and the other out. There ought to be protection against bad tenants as well as bad landlords. With regard to game, he would annihilate it if he could, but the gentlemen of the county loved sport, and he would give them encouragement.

Mr. Mizen asked if we were at all agreed as to who should do the improvement to the land? He found that if he spent 6l. for dung and 6l. for chalk, and should die at the end of 12 months, his widow would not be able to claim one farthing for the outlay. He had drained land 26 years ago, and every drain was now perfect. That certainly ought to be equal a permanent improvement, and the willow or family of a man who made such an investment ought to have compensation. He did not believe in acts done for no price. As wealth increased property would become more valuable, and surely we could not imagine land to be the only property which remains stationary as regards value. He knew a farmer who spent 3/ an acre in oilcake, which he brought and consumed on the farm. Now, will you tie a man like this not to sell his hay and straw? He expended 3000l. a year for extraneous food, because he found it more profitable than it was to consume straw and depend on roots; and he ought to have some security.

Mr. TRETHERY said the tenant ought to do his own chalking. If this were not so, it would soon be expected that landlords should be the ploughing. But he would not compensate for this or any other permanent improvement by valuation, but before ploughing or chalking, or anything else was done, he would have a written agreement defining the quality of the land. As regards improvements, tenants and landlords are not right and all landlords are wrong. He offered a compensation clause to leases. As to selling hay and straw, his experience was, that the farmer who consumed his hay, straw, and roots was the best farmer. Who was to check the quantity of hay sold, and the manure brought back in return?

Mr. COLESMAKER, too, did not approve of long leases. He

rather believed in arrangements for compensation. He might be a good fellow and a bad farmer, or a bad fellow and a good farmer, and a disagreeable fellow. The tenant might not "hit it off," and if a long lease were given the term might be disagreeable to both.

Mr. READ said—W. Loozer makes an improvement, and ought to be compensated. He differed from Mr. Trettery in the question whether a tenant ought to be compensated for improvements for every improvement. He thought that it was in Lincolnshire, &c. that the tenant ought to be compensated for every improvement. He was in favour of long leases, but he thought the time had come when the tenant ought to be compensated for general improvements.

Mr. STURTEVANT said there were too many run-down farms in towns wanted to have a farm, though young to teach farmers how to farm the land there to spend a fortune. This was no doubt the case, but it was very detrimental to the interests of this country. He thought that such run-down farms ought to be reduced to words and figures. "Unexhausted improvements" "tenant-right" "unexhausted improvements" Write them down, tenant right, a farm ought to be viewed in the mill, a manufactory, or any other place of business.

Farm Memoranda.

WEST GLOUCESTERSHIRE. December 1881. has come upon us unusually early, and with severity, for on October 27 our hills were covered with snow, and several rather sharp frosts followed. This somewhat aroused our anxiety for the securing of the root crops, which had been a very favourable time for the ears of wheat. It is now pretty well completed hereabouts, and is day too soon, for we had another heavy frost on the morning of the 1st inst., accompanied with rain which has very nearly put a stop to the growth of fallows. Fortunately the Wheat was advanced in this neighbourhood; all the Wheat and Clover leys are sown, and in most cases the plant appearing strong, except upon some of the clay soils, which by the way were sown in a rough state, and not wet enough for the seed to germinate properly; therefore it has not done otherwise would have done had the rain come as it was sown. But upon the whole a favourable seed-time could scarcely be desired. It has been taken as much as possible of the weather for the carting out of the dung for the roots next year. We are now ploughing and subsoiling the land, a plan which we are likely to see more practised than it is, for it is worthy of greater patronage, inasmuch as it assists the drainage of the soil, as well as the production of heavier crops of roots.

Stock of every description is selling well. Cows are more sought after than common at this time of year, owing probably to an abundant supply of food; they range from 12l. to 18l. per cow, 16l. to 22l.; beef, 75s. to 80s. per cwt. Store lambs are high at 8d. to 8½d. per lb. Store lambs are high at 21s. to 11s. 9d., porkers, 12s. to 12s. 3d. per score.

Much anxiety is felt hereabouts at the time of the foot-and-mouth disease in four or five herds, and at a distance of several miles apart a month ago, in a village near here, some of the herds were attacked with the disease, which first was confined to the one homestead; but within a fortnight or so, two other herds became infected, but not seriously, at two or three miles apart, and neither of the owners could give any cause for the outbreak, as they have not any fresh stock into their respective herds since time past. It behoves us all to be very careful going to inspect another stock (especially herds) out of curiosity, as this disease is the most contagious character, and as carried in clothes from one herd to another, as certain beast will give it to another. Authorised inspectors, too, should be most careful in visiting diseased herds, or they, instead of preventing the spread of the disease, will be the conveyors of it from herd to herd, so long as one's cattle are free from disease, do not tax themselves with anxiety about the matter, but do all in their power to suppress the disease, but we trust they will not be too desirous of it, but we trust they will not be too desirous of their interference. Every farmer having a herd infected will be but too careful to try to restore them as soon as possible, and perhaps the best able to manage his own herd, a restriction as to driving our cattle about the place, suffering from the disease, should be imposed upon us, is perfectly right and just. Some time ago we were asked by a neighbouring farmer to leave a fat heifer in our cowhouse on its way to the slaughter-house, which was granted. Upon her arrival she was put in a box, and was fetched away on the following day. As soon as she was gone the cowman swept the dung, and littered down the box again, in one of our cows, whose time was up to a few days the cow became very unwell, and her food. Having no suspicion that it was the matter, beyond expecting her to be done; but, as no calf came within a reasonable time, suspicions were soon aroused, and we were sorry that she had the foot-and-mouth disease, immediately shut off all communication with the infected shed, in which were 19 cows and a whole of which had it except one. If she had it was in the mildest possible form. The attacked calved when in the very worst stage.

and was down for some time; indeed, we hardly expected she could recover; but she did, and so did all the others. We did not give any medicine whatever, simply kept them very clean, and nursed them throughly. Not one of the cattle at the home- stead, although it is situated only a few hundred yards from the cow-house; neither did either of our neighbours have it amongst their cattle; thus showing the disease can, with proper care on the part of the owners of stock, be stamped out, or its ravages greatly alleviated. The fat heifer above referred to showed no sign whatever of being infected, but it was proved that she had been taken to market in a cattle pen, which had had in it a beast suffering with foot-and-mouth disease only a few days before. F. W.

NEW HALL FARM, PENDLETON, MANCHESTER.—Farm, 201½ acres—Pasture, 61 acres; meadow not covered with dung-water, 63 acres; meadow covered with dung-water, 20 acres; Wheat after Potatoes, 21 acres. Oats, 17 acres, Rye, 2 acres, Potatoes, 16 acres, Swedes, 7 acres, Mangel Wurzel, 2 acres; orchard and gardens, 2 acres, plantations and roads, 12½ acres. Customary rotations 1st, green crops, 2d, Wheat; 3d, Oats—with seeds for two years and upwards. Live stock—seven horses, seven colts, 30 dairy cows, 17 stirks and heifers, 51 sheep and lambs, 5 pigs, 10 rearing calves, and 3 bulls. Total, 112. Have top-dressed over 100 acres of grass-land since this year came in, with town's manure, lime compost, and other manures. Also used 550 tons for Potatoes, Swedes, and Mangels, and five tons of superphosphate. No drainage. Since last gained the prize I have put up at my own expense a strong wood shedding, slated and tiled. Have subsoiled 16 acres from 18 to 20 inches deep, and trenched ploughed 10 acres. Hugh Higson, August 6.

Mr Higson's farm lies on the banks of the Irwell, a little above Manchester, and is well sheltered from the E.N.E. and N.W. by high ground and plantations. The climate good for the district. Not at a great altitude, being very few feet above the river. The surface is nearly level. The soil a good deep sandy loam and alluvial. Good public roads through it, and close to a good market for anything, and for procuring fertilisers of every description without railway or water carriage. The Potatoes, Swedes, and Mangels very vigorous crops and perfectly clean, with the headridges well followed. The 2 acres of Rye had been cut for soiling, and the land sown with common Turnips, which were turned, very clean, and looking well. A 9-acre field of Wheat the heaviest crop we have seen. The remainder, 12 acres, also a heavy clean crop. A 7-acre field of Oats, after Potatoes, a heavy clean crop. A 10-acre field after seeds, not so good or so clean—had failed in places. The meadow and pasture lands produce good herbage, free from coarse Grass or weeds, a considerable portion lying on the banks of the river. All the fences, gates and posts in good order. Roads, all public ones and in good keeping. The farm buildings not in uniform order, built no doubt at different periods but very clean, and in good repair. Sufficiently commodious, three neat fancy cottages in the yard. Mr Higson does not live in the farmhouse, which is neat and in good repair. He has other callings more profitable than farming. He has a good and useful assortment of implements, and 21 stock frames, all round ones. The cattle mostly of improved Short-horn, but long pedigrees, and many real good animals, but perhaps not the deepest milkers. The bulls are well bred animals. The entire farm is in first-class order, and we cannot see where much improvement can be made.—Inspected August 6th, 1869.

We have never had a greater difficulty in deciding on our awards than in this case. Had the cases been parallel we might have had an easy task, but we have had to consider point by point. The circumstances in every respect so different. The position of the parties, the soil, the climate, and locality all different. Mr Higson's opponent's farm is 300 acres, a mossy soil, and in a worse climate, and 10 miles from Manchester. Gets a living solely by farming, and has expended a great amount of money in draining, new fences, and roads, but, with the exception of the Oats, the crops are not quite so heavy. Two points only brought us to our conclusion, but whether right or wrong we cannot say. His opponent's Potatoes are in butts, and he had not finished his hay making on the 7th of this month. Inspector of Manchester Agricultural Society.

Miscellaneous.

Returns showing the Average Annual Price of Wheat for each of the 21 years from 1826 to 1846, both inclusive; and also for 21 years, from 1847 to 1867, both inclusive; and the maximum and minimum prices distinctively in each of those series of years, together with the average price, on the whole, of each series:—

Table with columns for Per Qr, d, and years (1826-1867). It shows price fluctuations for wheat over two 21-year periods, including average, maximum, and minimum prices.

A. W. Fonblanque, Comptroller of Corn Returns.

Glue which will unite Polished Steel.—The following is a Turkish recipe for a cement used to fasten diamonds and other precious stones to metallic surfaces, and which is said to be capable of strongly uniting surfaces of polished steel, even when exposed to moisture. It is as follows:—Dissolve five or six bits of gum mastic, each the size of a large pea, in as much spirits of wine as will suffice to render it liquid. In another vessel dissolve in brandy as much isinglass, previously softened in water, as will make a 2-ounce phial of strong glue, adding two small bits of gum ammoniac, which must be rubbed until dissolved. Then mix the whole with heat. Keep in a phial closely stopped. When it is to be used, set the phial in boiling water. The Stationer.

Calendar of Operations.

DECEMBER.—Carting: Keep in advance. The days are now short, but that is no reason why steam work of any kind should be allowed to fall behind, but the contrary, for the lengthening days of spring invariably bring with them enough to do. If field work is concluded for the time being, or if the teams are driven out of the field by frost or bad weather, all sorts of carting that can be done should be set about without delay.

Clay Fen Land is done at this time without horses, the clay or clayey marl being found under the peat earth, sometimes only 2 or 3 feet below the surface. Trenches are opened, the clay dug out and spread across between the trenches with the spade or spade and barrow at the rate of from 50 to 200 cubic yards per acre. The trenches are then filled with the peat earth dug out above the clay. The work is heavy, but remunerating, and much land is clayed annually in our fen districts.

Chalking or marling.—In those places where drifted chalk is covered by a bed of clay only a few feet in depth, by opening trenches it is brought up and spread upon the surface with the spade. In other places greensand and gravelly marl lie below 3 or 4 feet of clay, when each is dug up and applied in the same way, at this season, wholly by manual labour.

Trenching.—Reclaiming waste land, and deepening what is already under the plough, by trenching, are works which are prosecuted this month, as in November. In some places hands are more easily got in the present state of the labour market during December and January, than earlier, and when such is the case the work of trenching proceeds accordingly. Shallow, rocky soils are deepened, either by trenching out the rock or by carting on fresh soil, and not unfrequently partly by both these operations; trenching being necessary to remove portions of the rock which crop out in some places nearly to the surface, and in others to the surface altogether.

Fences.—Steam culture is causing the removal of many old fences with the view of enlarging fields. In stubbing out old ones it is better to trench the ground well under the hedge, as the roots are smaller and more easily cut than at the surface. If there is no ditch, begin at one end by opening a trench 2 or 3 feet deep, according to the nature of the subsoil and the depth to which the roots have gone. But if there is a ditch or two ditches, one on each side, put a drain-pipe in one ditch, and then undermine the hedge on one or both sides, as the case may be. In this way an experienced hand will soon stub out an old hedge and fill the ditches without any botheration from the roots. Before planting a new hedge on the flat the ground should be trenched 2 feet deep, well manured with compost, and limed. Lime compost makes excellent manure for a young Thorn hedge. If planted on a bank between two open ditches, trenching will be unnecessary, unless in the case of moorland; but the young hedge will stand more in need of manure. Some farmers plant two rows vertically on the top, others form two horizontal banks, on which the plants are laid. The former is the more natural, as the roots will not grow horizontally, but the latter is best adapted for many soils, as the roots strike downwards, and thus spread over a wider surface.

Early Lamb.—On many farms in Sussex, Hants, and Dorset, this is the height of the lambing season. The month is unusually trying for the health of cattle, as may be judged by the rapid fluctuations of the thermometer, and the peculiar natural physical condition of live stock at this season of the year. Ewes, therefore, require careful attention both before and after lambing. Wet coats must be avoided. It follows that there should be a lambing shed or hovel sufficiently large to hold the ewe flock with their followers in wet and stormy weather, and such the most successful flockmasters endeavour to have. In open weather those that are able have a run of the pastures during the day, but are housed over-night. Ewes about the lamb should have a small paddock close by, as they will thus do better during the day than in the hovel, particularly if we have the very mild weather sometimes experienced at this season in our southern counties. The Belgian Carrot is one of the best roots for milk ewes, while it is equally well adapted for indoor feeding in stormy weather, and for the lambs when they begin to feed. They should be given pulped along with a little meal and Clover hay chaff. W. B.

Notices to Correspondents.

LAND AGENTS I suppose possibly Mr H Allnutt, of the Antigua Gazette, 20, Fleet Street may be able to help you. MENDERS ON GRASSES AND FENCIBLES.—I would refer you to P. L. G., the proprietor per acre in roads and trusses for plant was, by a transposition, rendered "31 1/2", instead of "2 1/2". ROYAL AGRICULTURAL COLLEGE M.—The annual fees more than the usual name. An earnest student will get first rate knowledge of chemistry as well as of agriculture there.

F. T. ARCHER'S "FRIGI DOMO"—Patronised by Her Majesty the Queen for Windsor Castle and Frogmore Gardens, the Duke of Northumberland, Duke of Devonshire, late Sir J. Paxton for the Crystal Palace, Koyal Gardens, Kew; Professor Lindley for the Horticultural Society, &c.

The best Shading is "Frigi Domo" Netting. Write for List, unprepared Hair and Wool, a perfect non-conductor of heat or cold, keeping a fixed temperature where it is applied. It is adapted for all Horticultural and Floricultural purposes, for PROTECTION from the COLD WINDS and MORNING FROSTS "FRIGI DOMO" NETTING, 3 yards wide, 1s. 6d. per yard run. "FRIGI DOMO" CANVAS. JAMES PHILLIPS AND CO.

beg to submit their prices as follows:—GLASS for ORCHARD HOUSES, As supplied by them to Mr. Rivers, to the Royal Horticultural Society, and to most of the Nobility, Clergy, and Gentlemen of the United Kingdom.

Table listing prices for Horticultural Glass in various sizes (e.g., 11 by 8, 12 by 9, 13 by 10) and quantities (e.g., 100 feet boxes).

These prices only apply to the sizes stated.

Table listing prices for Small Sheet Squares in various sizes (e.g., 4 by 4, 6 by 6, 8 by 8) and quantities (e.g., 100 feet boxes).

SMALL SHEET SQUARES.

Table listing prices for Small Sheet Squares in various sizes (e.g., 4 by 4, 6 by 6, 8 by 8) and quantities (e.g., 100 feet boxes).

ORCHARD-HOUSE SIZES.

Table listing prices for Orchard-House Sizes in various dimensions (e.g., 10 by 12, 12 by 14, 14 by 16) and quantities (e.g., 100 feet).

SMALL SHEET SQUARES, 15 oz., per 100 feet.

Table listing prices for Small Sheet Squares, 15 oz., per 100 feet in various sizes (e.g., 6 by 4, 8 by 4, 10 by 4).

LARGE SHEET SQUARES, 15 oz., per 100 feet.

Table listing prices for Large Sheet Squares, 15 oz., per 100 feet in various sizes (e.g., 10 by 8, 12 by 9, 14 by 10).

SHEET GLASS.

In Sheets for Cutting up, averaging from 6 to 9 feet super. 15 oz.

Table listing prices for Sheet Glass in various qualities (e.g., 4ths quality, 3ds, 2ds, Best) and quantities (e.g., per 200 feet case).

SHET GLASS is made only in the following substances, 15 oz.

Table listing prices for Shet Glass in various substances (e.g., 21 oz., 20 oz., 32 oz., 30 oz., and 42 oz.).

HARTLEY'S IMPROVED ROLLED ROUGH PLATE IN

1-8th in., 3-16th in., 1-4th in., and 3-8th in. substances. BRITISH PLATE GLASS for Windows and Silvered for Looking Glasses, Coloured Glass, Glass Shades, Striking Glasses, &c. &c.

PAINTS, COLOURS, VARNISHES, &c. STUCCO PAINT, 2s. per cwt. This Paint adheres firmly to the walls, resists the weather, and is free from the glossy appearance of Oil Paint, resembling a stone surface, and can be made any required shade. It is mixed with rain or pure river water.

WHITE ZINC PAINT, 3s. per cwt. One hundredweight of pure Zinc Paint, with three gallons of Linseed Oil, will cover as much as one hundredweight and a-half of White Lead and six gallons of Linseed Oil. Special Dryers for this Paint.

IMPROVED ANTI-CORROSION PAINT, 3s. to 3s. 6d. per cwt. Anti-corrosion Paint is extensively used for all kinds of work in exposed situations, on Brick, Stone, Compo, Iron, Iron Bridges, Conservatories, Greenhouses, &c., and is easily laid on by any ordinary workman. Prepared Oil for ditto, 4s. per gallon.

It is with great gratification that we announce our permission to refer upon any occasion to the various

HEATING APPARATUSES at the above, where our "ONE BOILER SYSTEM"

HAS FOR YEARS BEEN SUBJECTED TO THE MOST CRITICAL TESTS WITH EVERY SATISFACTORY RESULT. IT IS MATCHLESS FOR EFFICIENCY, AND IS WORKING THE LARGEST APPARATUS ON RECORD.

These are no theoretical statements, but positive facts, and it is not too much to add, that no boiler can boast a parallel.

For List of Details, see "ILLUSTRATED BOOK of DESIGNS" (12th Edition), which can be obtained by addressing a note to **JOHN WEEKS AND COMPANY, HORTICULTURAL ENGINEERS, &c., KING'S ROAD, CHELSEA.**

GREEN'S PATENT IMPROVED TUBULAR HOT-WATER BOILERS.

OBLONG BOILER.

SQUARE BOILER.

THE ABOVE BOILERS ARE

THE MOST EFFECTIVE AND DURABLE EVER INVENTED.

They can be set to work at a nominal cost, inasmuch as no brickwork is required; as will be seen from the above drawing, they are placed upon a Cast-iron base which answers the purpose of Foundation and Ashpit.

From the peculiar and substantial manner in which these Boilers are made, they are warranted to last for years without getting out of order; in fact, we guarantee ten years, but feel convinced that they will serve all the purposes for which they are intended for a much longer period.

They are specially adapted for Heating Greenhouses, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c.

THE FOLLOWING ARE THE ADVANTAGES OF THESE BOILERS:—

- 1st, They require no setting in brickwork.
- 2d, They are complete in themselves, having perfect means of regulation.
- 3d, They take up little room, and can be put in places inaccessible to other Boilers.
- 4th, They are economisers of fuel, owing to the great amount of heating surface upon which the fire acts in a direct manner, and the consumption of smoke.
- 5th, The fire can be made to last from 12 to 24 hours without attention.
- 6th, Any number of Flows and Returns can be annexed to the Boilers by means of mud doors.
- 7th, By means of mud doors, they can be readily cleaned out when required.
- 8th, The Chimney is made of cast-iron, which can either be taken through the wall or turned into a flue, to meet the convenience of the situation that it may be in.

GARDENERS' CHRONICLE PRIZE

At the GREAT PROVINCIAL SHOW of the ROYAL...

The Gardeners' Chronicle. SATURDAY, DECEMBER 18, 1869.

MEETINGS FOR THE ENSUING WEEK.

Table with 2 columns: Date and Meeting Name. Includes Royal Horticultural (Fruit and Floral) and Scientific Committee.

We have now before us the ROYAL HORTICULTURAL SOCIETY'S PROGRAMME for 1870. The proposed arrangements differ from those of preceding years...

We are glad to find, in what may be called the Great Show of June 15, and which is to include leading features of Orchids, stove and greenhouse plants...

more familiar plants already grown up, and with which visitors have become so well acquainted. It may be hoped, on account of the variety they impart...

Among the novel features of this schedule, as compared with former years, we find that provision is made for a somewhat important show of Gladioli, with a premier prize of 10l., offered by the Duke of Buccleuch...

So much relates to South Kensington. We get, moreover, this year, a vast improvement upon last, in the early announcement of the Society's own portion of the schedule for the Oxford meeting...

We mentioned the Dublin Hyacinth show last week, and we may now add that the Royal Caledonian Horticultural Society will hold a Hyacinth show on the 29th and 30th of March.

so that exhibitors and censors have their work before them, and we cannot close the year 1869 better than by wishing both, in the campaign of 1870, all the good fortune and satisfaction which may fully attend upon right and just decisions.

LAST week we inserted an extract from the Echo, headed the TYRANNY OF GALLIENERS. In that letter there was much truth mixed with some error. This week it is our painful province to publish the record of some transactions of quite another character.

"Label.—Barnes v Lady Rolle.—This was an action for libel in the Queen's Bench, in which the defendant, Lady LOUISA ROLLE, had allowed judgment to go by default...

"The plaintiff had been head gardener to Lord and Lady ROLLE for nearly 30 years, at Bilton, Devonshire, and, according to his testimony, and that of other witnesses, he had bestowed great care on the management of the gardens, and they were represented as the finest in England.

"The letters were put in as evidence, and the passages containing the libel read to the jury, and were set forth in the proceedings. The first letter was addressed to a lady named CATLIGH, who had purchased some of Lady ROLLE'S surplus Pines.

"The second letter was dated the 18th of June, 1869, and addressed to a gentleman named MAULLIERS who had applied to see the gardens at Bilton, in which her ladyship made the following statement—

"The plaintiff was now 64 years of age. He said when he left Bilton a service of plate was presented to him, and when he resigned the gardens were in a perfect state. He had nothing to do with Mrs. CATLIGH'S refusal to take any more of the surplus Pines.

"No evidence was given on the part of Lady ROLLE. Mr. Serjeant ROBINSON, in his opening address and in summing up, asked the jury to award fair and temperate damages.

"In the course of the case it was proved that Mr. Flood, attorney for the plaintiff, residing at Exeter, had obtained the letter written to Mr. MAULLIERS. Mr. LOPES invited the jury to arrive at the conclusion that the justice of the case would be satisfied by an assessment of one farthing in damages.

ROLLE was advanced in years, and felt irritated at the plaintiff leaving her service so soon as he did. The learned Counsel commented in strong language on the conduct of the attorney, and said that if BARNES had been left to himself the action would not have been brought, but it was an attorney's action, and he trusted the jury would express their opinion by the nominal amount they awarded.

"Mr. Under-Sheriff BURCHELL told the jury that the libel was admitted. The only question for them was the loss the plaintiff had sustained by the letters. There was no pretence for special damage. The letters were written to two persons only, and it was not because the plaintiff was poor in comparison with Lady ROLLE, nor that her ladyship was rich, that they should give considerable damages. It was their province to say whether mere nominal or substantial damages would satisfy the justice of the case.

"The jury retired, and on their return, after a brief consultation, assessed the damages at 100*l.*, the full amount claimed in the declaration."

— THE following letter has been sent us for publication:—The Council of the Workmen's International Exhibition, to be opened on July 7, 1870, at the Agricultural Hall, Islington, has determined to hold a conference of delegates from the towns of the United Kingdom, and of other countries, on the 10th January next, at the rooms of the Society of Arts (in John Street, Adelphi), which have kindly been lent for that occasion. The day's business will begin at 10 A.M., and will be distributed as follows:—

1. Statement and discussion of the proposed method of arrangement of exhibition
2. Statement and discussion of the proposed system of prizes, and appointment of jurors
3. Discussion on the opening of workshops in the exhibition
4. Reports, statements, and suggestions from local committees
5. Statement and discussion as to the means to be adopted to make the exhibition promote the interests of technical education.

Mr. MUNDELLA, M.P., and Mr. S. MORLEY, M.P., will successively occupy the chair, during the day's sitting. The conference will be brought to a close at 4 P.M., and all the delegates are invited to meet the Council at dinner (Mr. T. HUGHES, M.P., to preside) at 5.30. In the evening a public meeting will be held at 8 P.M. at Exeter Hall, at which Professor HUXLEY will preside, if it should be impossible for the president (the Rt. Hon. W. E. GLADSTONE, M.P.) to be present. The following resolutions will be moved:—

1. That the principles laid down in the prospectus of the Workmen's International Exhibition of 1870, which require the worker's name to be attached to the article produced, are both just and useful; as tending to give workmen their share in the credit of production, and to increase the pride and interest which attaches to skilled labour.
2. That it is of the highest importance to develop amongst all the people a true perception of what is beautiful in colour and form, and a scientific knowledge of the machinery and material employed in existing industries, and this meeting pledges its best exertions to promote the success of the Workmen's International Exhibition of 1870, as a valuable instrument to this end.
3. That the true knowledge and aptitude for combination shown by workmen who can produce for a Workmen's Exhibition an article requiring many different kinds of labour, deserve the encouragement of every class, as the first step towards greater and more important kinds of co-operation.
4. That it is in the interest of all nations that each should stimulate the other in the development of their higher productive powers, the prosperity of every people requiring continual progress in the cultivation of human faculties and that perfection of machinery which yields the largest return to the day-labourer.

We ought to add that the Council strongly hopes that all towns in this and other countries will lose no time in calling together a public meeting, and appointing delegates to attend the conference. Such delegates must be appointed by public meeting, and we shall be extremely glad to receive as early as possible the names of those who will attend. The Council are especially desirous that co-operative, trade, benefit, and other societies, and workmen's clubs and institutes, and large workshops will also send delegates on this occasion. We are directed to request that all such societies should put themselves in communication with us, and to assure them that their representatives will be gladly welcomed. The Council will provide accommodation for the night of January 10 for those delegates who wish them to do so, and will otherwise do all in their power to facilitate the attendance of their visitors, on receiving communications on the subject. We would therefore urge, not only our own local committees, but all those who are interested in the carrying out of a workmen's international exhibition, to take immediate steps for calling together a meeting of their fellow townsmen for the purpose of making better known the character of the undertaking, to appoint committees where they are not already in existence, to multiply the number of intending exhibitors, and to appoint delegates to the conference. AUBERON HEBBERT, THOMAS PARLSON, J. W. PROBYN, Hon. Secs., 150, Strand, London, Nov. 30, 1869. Several noblemen and gentlemen of high position and great influence, but whose names we are obliged to omit, have promised to take part in the meeting.

— M. VICTOR CHATEL has raised the alarm cry of "War with the grubs of the May-bug" (*vers blancs des hannetons*), and predicts an immense invasion of these insects in the spring of 1870 or 1871, and which he believes will take the proportions of a great plague. Hence he urges that it is necessary to act without delay, and daily. The grubs must be picked up by school children, or eaten by poultry, as soon as the ground is ploughed or dug, while ravens, magpies, starlings, wood-pigeons, sparrows, and hedgehogs, the great enemies of May-bugs, must be preserved and encouraged.

— A correspondent has sent us a sample of the seeds of the two Conifers called THUJA GIGANTEA—the true and the false—for the purpose of again direct-

ing attention to the confusion existing in gardens, and perpetuated in many nursery catalogues and advertisements, as to the proper application of the name. The seeds, like the plants, are most dissimilar. It may be, therefore, useful to repeat that the plant usually called Thuja gigantea in gardens, is not Thuja gigantea at all, properly so called, but the LIBOCEDRUS DEUCEBENS of Torrey, which bears the synonyms of Thuja Craigiana, Murray, and Thuja gigantea, Carrière and Gordon; while the plant called Thuja Lobbii in gardens is the true THUJA GIGANTEA of Nuttall, the original describer—Thuja Menziesii, Douglas, Carrière, and Gordon, and Thuja Lobbii, Hort., being synonyms. Cultivators will please make a note of this, and correct their lists accordingly.

— M. ERNEST FAIVRE gives the subjoined resumé of his experience as to the effects of ANNULAR WOUNDS in the BARK of TREES. In the Mulberry trees, as in all trees deprived of latex, annular incisions generally produce the following manifestations:—1, formation at the upper lip of the wound of a swelling or tissue restorer; 2, diametrical growth of the parts above the zone of bark taken off; 3, hardening of the wood in that region; 4, stationary condition of the parts below, if they are deprived of leaves and of buds; or, if not, vigorous shoots from below the lower lip of the wound; 5, more easy, more early, and more abundant flowering and fructification, 6, destruction, after a variable time, of all the parts above the annulation.

— A good deal of interest has lately been excited in India, especially about the NEILGHERRIES, as to the possibility of raising MUSHROOMS artificially. It was known that an esculent Fungus is occasionally developed on white ant's nests, and experiments have been made at Bangalore with white ant's nest soil. We have just received a quantity of Agaric, preserved in alcohol, which have appeared on it, but we have no information as to whether they have proved to be useful esculents or not. The species is certainly undescribed, but approaching in some respects one of which we have a drawing transmitted from Ceylon by the late Dr. GARDNER, with strongly twisted gregarious stems, arising from a common base. It does not, however, appear amongst the numerous figures which have been sent us by Mr. THWAITES, so that Dr. GARDNER'S Agaric is probably not a common species in Ceylon. The species before us probably belongs to the subgenus Armillaria, and may be called Agaricus termitigena—the characters of which, so far as they can be elicited without dried specimens, for those before us may have lost their colour, may be given as follows:—

- Pileus 1–2 inches across, strongly and obtusely umbonate, smooth centre, or notched at the margin, which is thin and even, or slightly striate, edge at first slightly indented.
- Stem 8 inches high, 3/4 inch thick, solid, cartilaginous, not twisted, darker than the pileus, especially towards the base, slightly tomentose or fibrillose; ring ascending, permanent, situated near the top of the stem, with a more or less lacerated margin.
- Gills rather narrow, $\frac{1}{2}$ inch wide, $\frac{1}{2}$ inch apart, $\frac{1}{2}$ inch behind; edge entire. M. J. B.

— We have on more than one occasion had before us samples of Mr. STEVENSON'S ABYSSINIAN MIXTURE, a compound prepared for the destruction of insects, such as mealy-bug, scale, thrips, red spider, &c, which infest plants; and our experience of its action upon these pests is very satisfactory. When used at the strength indicated by the vendor, namely, 4 oz. to the gallon, a single application when the parts are well wetted is sufficient to kill the greater number, while the few stragglers such as may have escaped the first application are cleared off by a second. The mixture has to be dissolved in hot water, and used after cooling. The experimental trial we have made of it warrants us in stating that it will be a very useful help towards keeping a collection of plants clean.

— From some recent experiments by M. E. PRILLIEUX on the GREENING OF ETIOLATED PLANTS, communicated to the French Academy of Sciences, he concludes that in order to acquire the maximum of chlorophyll, that is to say a healthy green colour, such plants should at first be submitted to moderate light (*peu intense*), and afterwards, in order that assimilation may be carried on under the best possible conditions, to a more energetic light. M. PRILLIEUX deduces from his studies the following general law:—In order that the action of light may be utilized by plants, it must, like that of heat, be kept within certain limits, beyond which it remains without effect. These limits do not appear to be the same for different functions, thus a quantity of light which is excessive for the production of green matter is utilisable for the decomposition of carbonic acid by the green matter already formed. The maximum is not the same for both these phenomena, much less light being required for the greening than for the reduction of the carbonic acid.

— The proprietors of the "Journal of Horticulture" offer the following PRIZE for COMPETITION at the show of the ROYAL HORTICULTURAL SOCIETY at OXFORD in July next, viz.:—Dessert of Fruits, unlimited as to quantity and kind, fit for the table, and combining excellence of quality with taste in arrangement, 10*l.* Open to amateurs and gentlemen's gardeners only.

PLANT PORTRAITS.

BEONIA SEDESI.—*Flor. and Pomol* 1869, 169, with tab. Begoniaceae. This is one of the finest hybrid Begonias in cultivation, being of good habit, a free flowerer, and bright coloured. It is the result of a cross, B. boliviana being one of the parents, and it requires cool stove treatment. The purplish red fleshy stems, grow erect, and bear obliquely ovate-lanceolate, dull green, red-haired leaves, from the axils of which spring the 3-flowered cymes, bearing flowers of a rich carmine crimson, the central one male, larger than the lateral smaller five-petaled females, and composed of two ovate sepals and two oblong ovate spreading petals. Messrs. Veitch & Sons were the fortunate raisers of this fine novelty.

CALOCHORTUS UNIFLORUS.—*Bol. Mag.* t. 1868, p. 10. A lovely dwarf habit half hardy herb, with small, round, and a slender leafy scape supporting from 1 to 2 of a pale pink colour, and measure 1/4 inch across. The most lovely little liliaceous plant the Botanical Garden of San Francisco has seen. It is a native of C. Ilacinas. It is a native of the high mountains of Cruz. "Though called uniflorus the flowers are more than two."

CHRYSA TERNATA.—*Rev. Hort.* 1869, 499, with tab. This ornamental and little-known greenhouse plant, which comes from the temperate parts of Mexico, with long stalked trifoliate leaves, simple, elliptic-oblong leaflets, and bears an umbeliferous sweet-scented flowers, which bear some resemblance of the Orange tree. The plant introduced from Peru is now very rarely met with.

COTONEASTER FLORENTINA.—*Leafy Bot.* t. 1869, p. 10. A neat, very pretty, hardy evergreen shrub, with a foot in height, with congested, crowded branches, clothed with small obovate-oblong leaves, not 1/2 inch long, but are of a shining dark green, silvery white beneath; the flowers are small, succeeded by depressed, globose, crimson berries, the smallest of the Cotoneasters, and was raised by Messrs. Saunders, Esq., from North Indian seeds, obtained by late Dr. Royle.

COTONEASTER CONGESTA.—*Refug. Bot.* t. 1869, p. 10. A neat hardy evergreen shrub, resembling C. florentina in aspect, and forming a compact rounded bush, with recurved, remarkably congested branches, the leaves are obovate-oblong, of a palish green, and the flowers are silvery beneath; the flowers are white, succeeded by globose, crimson berries. This was also raised from seeds, communicated to Mr. Wilson Saunders, Esq. It is a plant of slow growth, and scarcely attains a height of 1 foot.

COTONEASTER PROSTRATA.—*Refug. Bot.* t. 1869, p. 10. A prostrate habit half hardy evergreen shrub, with branches, having English nodes, and rounded, reddish obovate leaves, dark green above, and silvery beneath, the white flowers are globose turbinate berries. A native of the mountains of the Himalayas, introduced by W. Wilson Saunders, Esq. It is least effective as a decorative plant of any of the Cotoneasters.

COTONEASTER SIMONI.—*Refug. Bot.* t. 1869, p. 10. An excellent representation of a tolerably well-known evergreen shrub, one of the most ornamental Cotoneasters, and hitherto undescribed botanical specimens are larger than in the allied species, oblong-ovate green above, with the berries turbinate, and dark. It is a native of Khasya.

CUPRESSUS MACROCARPA VARIEGATA.—*L. Hort.* t. 1869, p. 10. In this variety of the well-known C. macrocarpa, the branches appear irregularly blotched with a sequence of some of the twigs being without chlorophyll, is similar in character to that of Thujaopsis delavrayana variegata. It is a variety of Cupressus macrocarpa.

DENDROBIUM BASSINAE.—*Bol. Mag.* t. 1869, p. 10. A remarkable and beautiful stove epiphyte, of which will be found at p. 164, has the pendulous stem, feet long, and densely knotted, these bear either solitary or in pairs, the large white parts of which are prettily tipped with rose colour. The lip is marked with a broad yellow line, and by Col. Hanson from the Aracan Mountains, in 1860, and was also found by the Rev. G. S. P. in the mountains of Kiang-koung.

ELAEAGNUS ANGUSTIFOLIA.—*Flor. and Pomol* 1869, p. 10. A very pretty little tufted shrub, with potential grows from 1 to 2 inches in height, and soil or position in which it occurs, and the leaves are 1 inch long, linear, entire, pointed, slightly petioled, the flowers, 1 to 2 on each stem, measure a line or across, and are of the palest and brightest rose colour. It is a native of the mountains of the Pyrenees.

HELLEBORUS LANCEOLATUS.—*Re. Hort.* 1869, p. 10. A remarkably showy stove plant, with stems of about 2 feet in height, bearing long, ovate lanceolate acuminate leaves of a bright green, and an inflorescence consisting of clusters of bracts, of which the outer ones are longer and more deeply coloured, orange red towards the base, which is from the centre of the bracts, and the plant is a native of the mountains of the Pyrenees, and was introduced to the Jardin des Plantes at Paris.

LEUCODENDRON TULIPIFERUM.—*L. Hort.* t. 1869, p. 10. A very pretty little ornamental shrub, with robust, erect succulent stems, which are of a reddish purple colour, and bear thick, obovate lanceolate leaves, of a dark green on the upper surface, and bright green beneath. The small, inconspicuous, whitish flowers are in long, drooping, axillary racemes. The name of Leucodendron tulipiferum was introduced from the country of the Upper States of the United States.

LILIU MAXIMOWICHI.—*Gard. Mag.* t. 1869, p. 10. A very pretty little ornamental shrub, with slender stems from 2 to 3 feet high, clothed with small, lanceolate leaves, and bearing comparatively large, brilliant orange, ring flowers, with lanceolate recurved segments, marked with small elliptic black purple spots, where is found a distinct net-like pattern, which is twisted at the point. It appears to have been introduced from the country of the Upper States of the St. Petersburg Botanic Garden from Japan.

LEUCODENDRON TULIPIFERUM.—*L. Hort.* t. 1869, p. 10. A well marked tree, with finest hardy deciduous trees, the young shoots are covered with which are freely blotched with yellow, in a manner over the central portions of the disc. It is a native of the Belgian Gardens.

MESEMBRYANTHEMUM POLYCHROMUM.—*L. Hort.* t. 1869, p. 10. A very pretty little ornamental shrub, with succulent herb, the close matted growth of which is well suited for another summer bedding culture. The fleshy stems are thickly clothed with fleshy, heart-shaped leaves, which are densely covered with cream colour, so that the plant forms a mass, entirely covering the surface, the flowers are of a rosy purple. It is a garden variety, and is a native of the Cape of Good Hope.

ONCHOCLEA MEXICANA.—*Flor. and Pomol* 1869, p. 10. One of the most charming of stove epiphytes, with congested compressed peduncles, and bearing racemes of large and beautifully coloured flowers, and petals oblong lanceolate, obtuse, wavy, purple, and white, and the sepals, oblong lanceolate, and white in the front half, and marked at the base with a blotch of purple, which passes in a kind of broad patch of rich orange colour. It is a native of the mountains of the Pyrenees, and has been introduced by M. Lindau.

ONIDIUM SPLENDIDUM.—*Flora des Serres*, t. 1835. Orchidaceae. A grand and extremely rare epiphyte has short roundish subcompressed pseudobulbs, bearing each a single oblong leaf, and an erect raceme of large showy flowers, the sepals and petals of which are oblong-ligulate, nearly covered with chestnut-coloured blotches on a dull greenish ground, and the lip is very large, obovate, with a broad claw like base, and a clear bright yellow colour. It comes from Guatemala, and appears to be in the hands of Messrs. Thibaut and Kettler.

POEQUERIA MULTIFLORA.—*L'Hist. Hort.* t. 597. Cistaceae. This magnificent evergreen stove shrub is furnished with broad oval-oblong subcoriaceous leaves, which are velvety beneath. The inflorescence consists of terminal cymes of numerous large white fragrant flowers, which have a slender tube, 4 inches long, and a spreading star shaped limb, measuring some 2½ inches across, and consisting of five unequal long-oblong segments. It was introduced to the establishment of M. A. Verschaffelt, from St. Catherine's, near the Mauritius in 1866.

SALICAZURATA DESCHAMPSIANA.—*Rev. Hort.* 1869, 134. Cistaceae. A warm greenhouse sub-shrubby plant, of great beauty, growing 3 feet or more in height, and furnished with cordiform acuminate leaves, the stems being terminated by ovate-oblong terminal spike-like collections of flowers, which are of a lively rose colour, with the tube of the corolla very much inflated, and the ovate caducous bracts and spreading calyx both of a deep red colour. It is cultivated in the French gardens.

VELLOZIA ELEGANS.—*Bot. Mag.* t. 5803. Hamodoraceae. An interesting warm greenhouse or stove perennial, with a slender erect, flexuous stem, clothed above with the tristichous, serrated, ensiform leaves, which are sharply keeled, and become flattening at the base. The terminal peduncles become divided into three to five long slender pedicels, supporting the flowers, which are pale lilac in bud, then pure white, enlarging and turning green after flowering. "Our first knowledge of this plant," writes Dr. Hooker, "was derived from a specimen brought from his garden by the Hon. H. Fox Talbot, Esq., to the Kew Herbarium, in 1866, and which was raised from seed procured either from the Cape or Madagascar." This specimen Prof. Oliver proposed the name of *Vellozia*. Subsequently, when a plant which had been pro-

rotted manure, and protect them well from slugs. They are likewise gems when bedded out for early spring. The best time to plant out both the double and single varieties for a spring display is early in October, that their roots may have strength to flower early in spring, they delight in rather a strong rich soil, but will grow in almost any soil in a shady situation.

After they have done flowering divide the roots, and remove them into a shady border, composed of rich strong soil, and carefully attend to watering until they have taken root, after which they will require no further care beside keeping them free from weed until the following autumn, when they should be taken up and planted as before recommended. New varieties may be raised from seed if carefully selected. I have this autumn planted out several thousands of the single varieties of various colours in my arrangements of spring bedding plants. *Edward Bennett, Osberton.*

CHURCH DECORATION.—No. III.

Drawing and Making Designs (continued).—We started with asserting how important it is to base almost every design upon a circle; and we have already gone even further, and been obliged to avail ourselves of the use of two circles, one within the other. Let us now proceed to draw some stars, in doing which we again find two circles indispensable. Describe two circles from the same centre, one with a radius of 12 inches, the other with a radius of 5 inches. Divide the outer one into six parts, by six points at equal distances apart. Do the same on the smaller circle, but place the points just half-way between the points of the larger circle, as shown on figure 4. By ruling lines from the points on one circle to the points

for keeping flowers alive or for replenishing with fresh ones as they fade, it is quite in good taste, and in every way commendable to use well-made artificial flowers, at least, such is our opinion. We studiously select our finest flowers for church decoration, as the Jews of old obeyed the command, "the first of the first fruits of thy land thou shalt bring into the house of the Lord thy God." And who shall say that there is not more art in making a plant bloom well just when its flowers are wanted, than in any artificial flower that ever was made?

The great dangers to be apprehended from permitting the use of artificial flowers for church decoration are, first, that a wrong flower may be introduced, say a white Japan Lily instead of a common Lily, when the one blooms in autumn and the other in early summer, and, secondly, that they are liable to be placed in impossible positions. All this, however, may be obviated by obtaining the assistance of some experienced head gardener or amateur, who is familiar with the flowers which it is proposed to be used. *W. T.*

[Here for the present we take leave of this portion of the subject, with the intention of reverting to it about Easter. In the meantime we shall from time to time allude to certain plants of special interest or value for church decoration, and to the readiest mode of growing them. *Eds.*]

CALCAREOUS SOILS FOR VINES.

THE discussion respecting the influence of calcareous soils on Vines which has appeared in your columns has afforded some interesting information, and will bear still further illustration. The recorded experience of a practical and observant man always deserves consideration, and although Mr. Cramb's conclusions do not accord with the opinion largely entertained by

FIG. 4.

FIG. 5.

FIG. 6.

duced to the Edinburgh Botanic Gardens bore flowers, the name was named by Prof. Balfour, *Vellozia Talboti*, which was afterwards changed to *Talbotia elegans*. Dr. Hooker, however, regards it as not separable from *Vellozia*.

THE PRIMROSE.

THE Primrose family is eminently distinguished amongst flowers as being one of the earliest harbingers of the spring, and is no less conspicuous for the simplicity and beauty of its flowers, and the delightful odour which they impart. Several of the species now wild in Britain, forming the most pleasing ornaments of our woods and valleys. *Primula vulgaris*, the common species of our woods, which in its wild state, has been sung by poets, admired by lovers, and known to almost every one as one of the most charming flowers of early spring, needs no comment, being the supposed parent of all our innumerable varieties of beautiful Primroses it would be hardly worth to omit to mention it in this short notice.

The whole of this beautiful spring-flowering genus of late years been much neglected, but the rage in the present day for spring gardening is now calling to our aid those old early favourites of our youth. Nothing can look more cheerful in the early spring months, every variety is full of interest, and the heart of a child seems to leap with joy at the first sight of a Primrose. Most of the varieties are of the most easy culture, and their free flowering properties make them valuable either for beds, pots, or borders.

The most highly-prized cultivated varieties of this flower are the double ones, yet how scarce (judging by the high prices asked for them) they appear to have become. In my boyhood's days they could have been purchased for much less money, but then I have no doubt they were much more extensively grown. I fear these high prices will deter people from planting them so extensively as they deserve to be, and thus prevent their being distributed through the country as plentifully as in bygone days. The double varieties, which there are several colours, can be grown and potted in pots, 32's being the most suitable size for the purpose, they should be grown out in the open air during the summer season, and lifted and potted out about the end of September, in a mixture of leaf-mould, sand, and peat, and either plunged in ashes and covered with a shaly situation, or put into a cool frame, where they may remain until they come into flower, and then removed into the greenhouse.

After the flowering season is over, turn the plants out of the pots, and divide them into as many parts as you are eyes, plant them out in a shady situation, in a bed composed of leaf-mould, loam, sand, and well

on the other, a six-rayed star is obtained of correct proportions.

Illustrations of five-rayed and seven-rayed stars will be found in figures 5 and 6. With reference to these, as well as to other stars having an odd number of rays, it is worth while to notice, that when you have fixed the points upon the outer circle, you can most easily determine the points on the inner circle by ruling lines from the points on the outer circle through the centre and beyond it, until you come to the inner circle. In each of these last two figures such a line is indicated by dots.

On comparing these two stars, it will doubtless be noticed that one is a sharp or long-pointed, and the other a blunt or short-pointed star; and, on farther examination, it will be seen that this difference is entirely dependent upon the relative sizes of the circles; for in the blunt-pointed star the diameter of the smaller circle is half that of the larger one, while in the sharp-pointed star the inner circle has a diameter of only one-fourth of that of the outer circle.

In determining the position of the points upon the outer circle for the formation of five and seven-rayed stars, it will be useful to remember that they are most readily drawn upon a circle with a radius of 20, in which case the points of a five-rayed star will be 23 from each other, and the points of a seven-rayed star will be 17 from each other.

Reverting to the subject of hanging designs, such as up upon such walls we may find that to be it is practicable to suspend such designs on a screw nail, it is advisable to hang them up temporarily upon a nail in some place within easy reach, and thus to test whether or not they will, with their existing arrangements for suspension, hang "square" when they reach the nail for which they are intended. This trial will afford ready means of making any necessary corrections, and thus much valuable time will be saved at the final hanging.

Artificial Flowers—Many are accustomed to condemn the use of artificial flowers in churches, for reasons which we need not discuss. Our views on this matter depend upon the quality of the flowers, upon the amount of art, or of ignorance, displayed in their manufacture, upon the extent to which they resemble and might be mistaken for, the truly natural ones. A badly-made artificial flower ought never to be allowed to come into a church—it were better to have faded or dead flowers—and better still to have none at all. But there are now such beautifully-made flowers to be had, that there is no excuse for using inferior and bad imitations. And where decorations are required to last for some days, and there are no conveniences either

Vine growers, his arguments are not the less instructive, and have the recommendation of being suggestive of inquiry into a subject that has not, as far as I am aware, been fully investigated, viz., the peculiar character and qualities of the various limestones in relation to horticulture. Experience is the best teacher, and information coming from persons who have practically tested the value of the different limestones on their natural beds will materially advance the inquiry. Your correspondent "B." has brought forward many arguments and illustrations in favour of lime in its various conditions in the cultivation of Vines, and there can be no doubt that soils which, from contiguity to chalk, and similar aggregations of lime, have been largely intermixed with such substances, are amongst those that are highly favourable for fruit and Vine culture.

Limestone formations are extensively developed in this country, and their partial disruption and degradation during the drift period caused the matters composing them to be widely distributed, and our best soils have been strengthened and fortified by the admixture of calcareous elements; but it must be remembered that lime, when thus amalgamated with soil, is no longer caustic in its action, but by the loss of its more active properties it has become more identified with the soil of which it forms a part, and more available for the support of vegetation.

The great limestone formations as they now exist, and where their surfaces are not obscured by accumulations of drift, are of a very characteristic of such formations, in such soil, derived immediately from the rock on which it rests, does not contain all the fertile qualities which are found in the alluvial soil of the valleys. The magnesian limestone in Yorkshire and Nottinghamshire, without adventitious aid from other formations, does not present any very encouraging basis to work upon; and, independently of any peculiarities it may possess obnoxious to the Vine, it would certainly fail to afford those elements of nutrition required by that plant in the artificial and forcing culture it is subjected to in our hot-houses. Limestone will certainly exercise a chemical influence on matters exposed to it, and certain kinds of magnesian limestone are said to possess noxious properties so as to make their use objectionable for agricultural purposes. This stone examined chemically has been found to contain the same component parts—about three of lime and two of magnesia. The magnesian lime in a certain time imbibed only 42-both parts of fixed air, while common lime had imbibed 45ths of its quantity, and to this non-absorption and the consequent remaining of the magnesian lime for a longer time in a state of causticity, the names

quality has been attributed. But, however objectionable may be the lime and the exposed surfaces of magnesian rock sparsely covered with soil, there are many places situated on the magnesian limestone formation which are exceptionally favourable for Vine culture; but it is where considerable deposits of drift of a light loamy character have been made, or where the soft shaly argillaceous beds have been exposed and broken up during the glacial drift period, and rendered more friable and mouldy by the subsequent action of the weather and artificial management. I need only instance Bury Hill, near Mansfield, where Grapes of great excellence have been grown.

If we turn to another great lime-producing formation—the carboniferous or mountain limestone—I question if instances can be found of soils resting immediately upon that rock, and derived directly from its decomposition, being in themselves rich enough, and affording all that is required in a soil, to produce Grapes of superior quality. Although it is highly fossiliferous, the true limestone of this formation is excessively hard, and sub-crystalline in character—so much so, that in Derbyshire it is worked up as marble. In some localities, when freshly broken, it smells offensively, and in the neighbourhood of trap dykes it is bituminous in character. This description relates only to the limestone beds. Leaving them, as being most unlikely to form Vine soils, we reach a series of stratified beds associated with the mountain limestone, and derived from the degradation of all preceding rocks, exhibiting great variety of composition. There are examples of sandstones, shales, slaty flags, and grits. The waste of these matters, washed down the precipitous Derbyshire hills, added to limestone detritus, forms a soil that possesses, with but little artificial aid, every constituent of fertility, and has doubtless greatly assisted the cultural efforts of the great gardeners who have rendered Chatsworth famous.

The extensive and important oolite limestone formation stretches across the country, from Lyme Regis in Dorsetshire to Yorkshire. It appears in hill ranges and elevations of the excellent altitude for climatic advantages of from 400 to 600 feet above the sea; it is throughout strongly calcareous, and varies in composition, being in some instances soft and friable, and in others hard and siliceous. In some cases the upper beds have been swept away, and deposits of marly clay left. The lime soil resting immediately on the oolitic rock is thinly spread upon the surface, and it is only within the last half century that its capabilities, in an agricultural point of view, have been appreciated. With the aid of artificial manure and stock, good cereal crops are obtained, but I cannot regard it as being likely to afford a congenial or sufficient soil for Vine culture. The rock is cold, retentive of moisture, and not broken up sufficiently to allow the penetration of roots or the passage of air; and again I am unable to instance any remarkable cases of success in Vine cultivation pursued upon this limestone, and on the soil afforded by it. But descending to the valleys which everywhere intersect the hill ranges, an accumulation of soil, partly derived from the calcareous hills, and from the clay beds of the lias and marlstone is found, which has the character and some of the qualities of rich alluvium or loam; with this natural compost at command, a good cultivator may justly calculate on satisfactory results in Vine culture. The vineries at Belton, near Grantham, situated in one of the valleys near the limestone hills, for many years afforded the finest Grapes grown in the district.

I think it will be found that very many more instances of successful Vine cultivation will be found in the valleys adjoining the chalk, than on the chalk itself. I am not indisposed to believe that chalk being softer than ordinary limestone, under cultivation may decompose more rapidly, its silicates may be more readily available, and its causticity less than the magnesian lime; still I am persuaded that the Vine will be found to thrive best in the composts nature has spread on our hillsides and on the plains and valleys, composts that contain all the varied mineral riches of calcareous hills, contributions wrenched from the primitive rocks by the devastating floods of the drift period, matters yielded up by the old sea-beds of the lias, or borrowed from the gypseous beds of the red sandstone. These loamy deposits, some the gifts of great floods, others of rivers that year by year pursue their work of mixing, amalgamating, and depositing earthy and other matters on the soils that give us the best corn, the best vegetables, the best fruits, and finally the best Grapes—when we most closely imitate these in preparing matters for our Vine borders, our success is the most assured. *William Ingram, Belvoir Castle Gardens.*

POTATO GRAFTING.

"HEY, Giles" Potato! In what a garb you are likely to become dressed? Blended with your fine Latin titled relations, how caressed you will be? I wish you much joy. *Solanum tuberosum*—ahem! Giles Potato, my boy! why, you have got—let me see—nearly a thousand of your fine family connections, most of whom, let me tell you, would snub, ay, even poison you, poor Giles! Therefore be careful how you make your selection; take the Editors' advice: some half dozen or so out of the whole lot might prove congenial, not caring to notice the "hair on your hocks," and submit to marry you into their families, where your fine robust constitution might work such wonders, by producing a generation to wear "such coats" that "e'en their own fathers wouldn't know 'em."

I must say I felt rather famous, as I arose one fine morning lately to find my patronymic placed in much honour amongst those of other and better men. But fate is driving, otherwise I would give a good pull at the reins, in so far as the cross-fertilisation of the Potato is concerned. I cannot, however, see the slightest chance

of my getting out of these "ruts" for the next seven years; and I do hope and believe, if I am permitted to live so long, that I shall be able to show you a fine smooth surface, with a good sound bottom by that time. I have got, I am happy to say, after long and weary years of trials, my Dukes of Oxford, viz., good male Potato sires, which merely want "licking into form," and this must be done by cross-fertilisation again, kidneys with kidneys, and rounds with rounds. I assure you that those kaleidoscopic "fellows," which you so pleasurably animadverted upon, could be placed in a line of beauty and symmetry. I have not arrived at their creation for nothing, and I could give you a correct pedigree of each "coloured piece," though I own I fear Dame Nature will ever play her pranks in the Potato, as in most other things, by occasionally in her most precocious moods "advancing backwards" as well as forwards. But she will never recede farther than natural origin, let it be human, animal, or vegetable. No art in the world could induce that wild-looking seedling of mine to enter into any other than Potato existence. Was there ever a perpetuated cross between the pheasant and the fowl? Then I must beg with yourself to remain very sceptical indeed about uniting the distinct genera *Helianthus* and *Solanum*. I stick to species, and the varieties of species, in my attempts at improvement, dismissing for ever from my mind considerations how men, once monkeys, happened to lose their tails through an acquired habit of sitting down! This Potato-grafting affair has certainly laid those who have hitherto practised, or recommended its continuance, under ridicule; but there is much more reasonableness and hopefulness in it than there would be in grafting the Artichoke on to the Potato. It is possible to cause results in the one case, impossible in the other; and if any good is to be the result of my persistence in grafting the Potato, I do propose to follow it up; and if it should take me about as long as the cross-breeding process, why the year 1900 will strike before I could gain the "brush," and Nature would, in my regards, have "advanced backwards" into Shakespeare's second stage of childhood! I am sure I ought not to advise any one to enter on the improvement of the esculent, as a hobby. Let me rather advise others to take to Pelargoniums, Roses, or Pomology: one successful effort in those ways will bring them more credit and acknowledgement, in every probability, in a tithe of the time than a hundred masterful summersaults in the other.

Great satisfaction, however, remains in the consideration that we cannot all produce Yorkshire Heros, nor are we all born to be Kings! But there are two names in connection with this Potato grafting, now that it has met with the prominence you have been good enough to bestow upon it, which you have left out, and which should be remembered, viz., the Rev. W. F. Radcliffe, as being the first to unearth the process, and Mr. Thomas Almond, of Bedale, Yorkshire, for producing his hybrid, the Yorkshire Hero—certainly not the least prominent of its class yet in the field. I still retain Mr. Taylor's notes by me, carefully guarded as the apple of my eye, but I feel it due to him for me ere long to return them to their rightful owner: their honest open faces first proved to me that in them there could be no guile, and so it has proved, and will prove more and more for many years to come, or I am very much mistaken.

One sentence more:—I think my friend Mr. A. Dean has hardly treated this subject with his usual acumen. If he would allow himself some opportunity to conceive of the graft-tuber, as he will call it—seeing that he objects to its being named a "stock"—and the graft, in the light of cotyledons, as merely supplying *pabulum* for the subsistence of the young germ or shoot till such time as the latter has formed roots, it can by a very slight stretch of the imagination become understood how the act of hybridisation will have already commenced in the cases of healthy action during the process of the cicatrization of the skins and the combining of the cellular tissue; in fact, the cross is and must be so completed: the roots afterwards formed upon the shoot merely cater for the support of the life of the foliage and the crop.

Another correspondent proposes to graft by approach of two distinct young shoots. Here we get minglings of constituents from above, and the plant supported through life from below by nourishment from Mother Earth through the roots, which have nothing to do with actual hybridisation; for if they had, how could individual products remain true from year to year, and for the ever of their existence? *Robt. Fenn, the Rectory Woodstock, Oxon, December 9.*

Home Correspondence.

Mildew on Roots of Trees.—In further reference to this subject, permit me to observe that though Mr. Miller has in his last paper laboured hard to show that the diseased state of the *Picea*—recently alluded to by me in your columns—originated rather from the influence of some deleterious constituent in the substrata over which the tree is growing, than from the effects of Fungi alone, he has unfortunately done so partly under false premises, inasmuch as he has (perhaps unwittingly) confounded my description of the strata pertaining to the Tulip tree with those belonging to the *Picea*, thereby invalidating his supposition that the roots of the latter were not enabled to penetrate the obdurate formation, which exists only under the Tulip tree, whereas that underlying the *Picea* differs considerably in its composition from the former. Secondly, this invalidity is rendered still more apparent by the fact that the tree is supported in position by means of the stout poles, arranged so as to resist, even the force of a tornado, hence the "ever restless winds" can have no appreciable effect on the root process, as Mr. Miller seems to

imagine. Thirdly, Mr. Miller, again, seems to have been away, whereas every visibly infected tree is subjected to excision when the tree first begins to decay on Mother Earth, hence my remark, "the *Picea* now apparently in a state of non-vitality," no longer exists. Recurring to the substratum over which the *Picea* is growing, allow me to remark that in the *Picea* there are several Spruce, Fir, and Shrub, planted several years ago, the existence of the tree in question, of which, as far as I am cognizant, I have not seen any evidence aught pernicious in the soil, but that the decay of the roots arose from the Fungi alone. This assumption is strengthened by the fact that recently I have ascertained that the old roots of pre-existing trees and shrubs, when the latter were cut down, that these old roots were the progenitors of the present *Picea*. I will however grant that my exploration in the soil under the tree in support of the above assumption, may deny that the old roots in question are present somewhere in the soil under the tree, would involve much labour to instance search, from the fact that the old roots are at a considerable depth below the surface, by the adding of other soil for leveling purposes, the cause of the decay of some trees may be in accordance with the ideas of some authorities, no reason to doubt; but to affirm that the soil alone is not capable of affecting the trees, is, I conceive, unwarranted by observation of facts. In proof of this, to adduce an example that has recently come to my notice, it is that of a *Wellingtonia*, about 13 feet high, on a nobleman's pleasure grounds in this country, and which during the past summer has been sickly hue, which was attributed to the drought. Scrutiny, however, proved a severe attack of Fungi, arising in contact with bits of decayed old roots, which generated fungous spawn, these old roots having been inadvertently conveyed in the soil on a plateau on which the *Wellingtonia* were planted, some five or six years ago. In addition to the many proofs already adduced, in addition to which I may advert to those of some *Deodars* at Bickon, lately mentioned by Barnes in your columns (see p. 1257), I would merely observe that, notwithstanding the fact that the soil is not capable of affecting the tissues of trees, it is really surprising that practitioners should yet affect to suppose the presence of such as old roots and bits of wood in their Vine borders. Such persons are materially impressed with what happens in the roots at Rabley Gardens some few years ago, as attested by Mr. J. Munro, the then editor of the *Gardeners' Chronicle* of April 30, 1863, in the case the disease arose from fungous contact with the Elm boughs, old roots, and fragments of the artificial drainage of the Vine borders at *Gardiner, Eaton Park*.

Tricks of the Trade.—Is your correspondent aware that there are three different varieties of English nurseries under the name of *Picea*? he in the first instance make it plain, as he wanted? If botanists are agreed to be true one, horticulturists are not, and after man might be willing to sell, but not to buy the one he considered the true one. One of the three forms exists with me as a seedling, but not appear identical with any other *Picea*, but in the opinion of some of my friends to be magnificent, and I certainly would not to "warrant" that it will not. It is on my "B. M.'s" own account, that his own conscientious enough not to take advantage of a did not sell him one thing for another, of also acute enough not to "warrant" the identity of which (horticulturally) is established. In all friendship I would advise "B. M." whether he was not disappointed or deceived? *An Old Nurseryman.*

Garden Ivies.—Not having seen your "Revision of Hederacea," and hearing of it in the first time, it was simply impossible for me in my paper on "Garden Ivies," to be indebtedness to him. If, however, I was honoured because I have taken a leaf out of Nature, and have had more regard to the truth than for authority in my reading of the subject, have no objection at all. It is perhaps to ask whether Dr Seemann has proposed to me in any way, for in a paper in which I contributed to the "Gardeners' Chronicle," Dec. 12, 1863, I described a lot of *Hedera* and flung them aside as distant relatives of the Ivies of the garden. It is evident that he has not yet mastered the purport of my paper, perhaps is more my fault than his, but I will wait for his perception of my paper, and approval which must necessarily be found my selected 50 varieties were arranged upwards of 200 names, and the majority were of extravagant in length, hideous in shape, and deceptive in meaning, there was left, and that was to do as I have done, all afresh, and after a strictly

What am I to understand by "Hedera helix minor" or "Hedera helix major"? Is it the elegant marbled variety called British Ivy? It cannot be, because it does not mean variegated or coloured like the ivy which I could like marble. I could not go on mentioning such names as these, so I have given the most distinctive characteristic of each, and the new name thereupon. Thus, the "Hedera helix major" above cited bears now the name of which conveys the idea of something more than the usual unattractive colouring, as in the case of the Ivy. For garden purposes it is a better name for botanical purposes it is Hedera helix major. As to the determination of Ivies as Ivies, it is not necessary to look after hairs and scales at all. It is not necessary to feel the botanical eye, much less the microscope, to enable me to distinguish my three species of Hedera from other species of Hedera of the books. I admit authority in these matters, which fully accounts for the "starchiness" and forbidding eccentricities of botanical nomenclature. As Dr. Seemann asks for information on a few practical points, I have great pleasure in supplying to his request.—First, as to determining the place of an Ivy in my classification. It is easily done without the aid of fruit, and I will undertake to tell Dr. Seemann in an instant to what part of my classification my Ivy he can show me should be assigned. If we were to adopt the colour of the fruit as the principal character, we should never attain to a classification as I could easily explain, could I dare to trespass on your space. Dr. Seemann says, "I have never been able to find out whether Ivies with white blotched leaves have white fruit, and those with yellow blotched leaves have yellow fruit." This confession ought to make an end of the discussion, for it proves that the writer has had a very limited experience with Ivies, and therefore should not be in haste to stultify me out because I do not bow my neck to the Basil of Authority. My aurea Hedera helix aurea maculata and my aurea Hedera helix aurea maculata has golden leaves and black berries. My pallida Hedera canariensis and my pallida Hedera canariensis has white blotched leaves and black berries. This, however, is a climbing Ivy, which I had to grow in a fruiting state in order to determine its place in my classification. In altering its form the variegation was banished, which was a matter of no consequence, seeing that the object was accomplished. I do not expect that my classification will endure for all time, but I maintain first that it is my own, and the result of much observation and some little hard work, second, that it is calculated to be useful to cultivators, and perhaps suggestive to the botanists, who appear to be too often preoccupied with the idea that plants were made for their names, whereas in truth their names must be made for the plants. Any who wish to see the 50 species enumerated in my paper may do so by applying to Mr. Turner's nursery, South as I have written, or to a gentleman upwards of 200 specimens, and examples of all the 50 kinds. Shirley.

Speckled Apples.—In reference to your note on "Speckled Apples," in the Notices to Correspondents in the *Chronicle*, at p. 1068, I wish to inform you that I have had an opportunity to compare another thermometer (with that of Negretti's) which my gardener had been using, I was sorry to find that it had escaped his notice that the column of spirit had been separated, so that his observations had for some time been recorded at least below the true temperature. I have no doubt the specks on the Apples were caused by the same action. W. C. Trevelyan, Wallington.

Vine Budding.—For the benefit of the uninitiated, perhaps you will have the goodness to clear up a little difficulty which has occurred in my endeavour to interpret your directions (p. 1209) for inserting the buds "exactly as in budding the Peach tree; and differs from Rose budding only in the non-removal of the wood cut with the bark." The non-removal of the wood I can understand, as a manipulatory necessity, owing to the extreme tenuity of the bark of the Vine, little or nothing that could be handled would remain if the wood were removed; its office, I imagine, being merely that of a vehicle for the bud. It is not so difficult to understand that the bark of the stock is to be raised for the reception of the bud, in the manner of Rose budding? Neither my gardener (who is a skilful hand) nor myself can conceive such a mode of the attempt. Instead of raising the bark, we are to cut a clean slice out of the stock, and then to burnum exactly to the shape and size of the bud, applying the latter to the stock in the usual manner, and sealing with plastic. This method, I hope, differs in no essential particular from the method you have described; and it is, in fact, the nearest approach we were able to make to it. We found the sap in a liquid state; and in a very protected from frost and rain I know of no natural law that would forbid "a happy union," even at the end of the year. As Uninitiated Amateur, Clapham Park.

Mr. Stevens will be good enough to explain to me the mode of budding adopted, about which there seems to be some apprehension. E. D.

The Maiden-hair tree alluded to by Mr. Stevens, at p. 1258, is still in existence and in full vigour. Its height is now 61 feet, and the circumference at 1 feet from the ground is 5 feet 7 inches. The case of the Tump trees is 98 feet high, and the circumference at 1 feet from the ground. The Maiden-hair tree is now 114 feet high. *Chronicle*, Dec. 14.

Holland Vines.—In a leading article (p. 1229), signed "P.," it is made to the failure of the Bishop's Vine, and a conclusion drawn from it which hardly think logical. "P." says "these Vines have

been kept to the single rod, restrictive and close pruning systems, and have failed as thousands of Vines have done before them." Now this might be quite true—and strictly logical if the object were to grow a Vine as a handsome plant to look at and to preserve it like the Hampton Court Vine to a vigorous old age. But it seems to me that the real object in this country is to grow Vines to produce the greatest quantity of fine fruit in a limited space. Glass-houses are expensive, and if by one system we can grow every year 1000 lb of Grapes in a house which, by another system will only produce 250 lb, what does it signify if the Vines live in a few years and have to be replaced? Respecting the system of close pruning Vines, I say, do not give it up if it pays. If anyone will calculate the amount of Grapes which may be grown in a given space by means of "whip pruning" of Vines as compared to the ordinary system it will astonish him. In an ordinary viney 1 lb to each 2 square feet of surface covered by the glass is considered a great crop. Mr. Thomson says, in a house 15 feet wide allow the rods to run up at distances of 30 inches, and upon each rod allow eight bunches of 1½ lb. each, or 12 lb. to a rod, occupying a space of 37½ square feet. Let us however, take it at 1 lb. from each 2 square feet of house room, or 1 lb. to each foot. Now I mention that by the whip system of pruning we can grow four times that weight of Grapes. By the usual system we grow 1 lb. from each square foot of house room, but by the whip system we can grow 2 lb. from each square foot. No doubt our Vines may die in a few years, but what then? The replanting of Vines is a very trifling matter. Supposing we had to replant our Vines every two years we should still be gainers by the system, because the cost of young Vines is very trifling, and we can always get a half crop the first year after planting, if we plant proper sized Vines, and a full crop the second year. Rather sharp work, if meant to be taken as the rule. E. D.

In saying this I speak from actual experience. I have Vines planted as standards under glass pruned on the whip system, and I know that each rod can be made to produce 10 lb of Grapes. The Vines are planted in rows 4 feet apart, running north and south, and are 15 inches apart in the row, consequently each Vine occupies a space of 5 square feet, and if each rod produces 10 lb of Grapes, it follows that each square foot of house room produces 2 lb of Grapes. Now, I freely admit that the ground must be highly manured to do this, but after all what is the cost of manure? It is a mere bagatelle compared with the cost of the glasshouse and the artificial heat. No doubt some of your readers will say the thing is impossible. All I can say is that I know it to be quite possible, and I think a very little reflection will show them that there is really nothing wonderful in it. Suppose we have a Vine in a 16-inch pot. That Vine has just 1 square foot of surface to root into, whereas each of my Vines has 5 square feet to root into. But 5 lb. of Grapes from a Vine in a 16-inch pot would not be considered anything very wonderful. If thus a single square foot of surface in a pot will, with careful culture, produce 5 lb. of Grapes, why should it be thought unreasonable to expect 10 lb from 5 square feet of the soil, which forms the floor of the hothouse itself? No doubt pot Vines are usually worn out in a single year, but then if a pot Vine has been grown in a 16-inch pot, and is meant to be thrown away after one crop, it will be made to produce considerably more than 5 lb of Grapes; in fact, it will produce 8 lb or 10 lb, or five times as much from the same extent of soil as I speak of. I doubt very much whether a Vine in a 16-inch pot, restricted to 2 lb. of Grapes yearly (which would be the proportionate quantity), would ever wear out, or at all events it would last with careful treatment for many years. Whether my Vines will wear out or not experience only will show, for I have not had them long enough yet, I shall not, however, be greatly disappointed if they do. To replace a few Vines every year is not a very great outlay. But in reality I see no reason whatever why they should wear out. Some of the vineyards in Burgundy are said to be several hundred years old, and the Vines in them have not been replanted in the memory of man, yet these Vines are every year cut down to a "stump" that has only some half dozen eyes left upon it. Surely these Vines are as "closely pruned" as those which in this country are treated on the single-rod whip system. How comes it, then, that they are not "used up" or "pumped out"? There is an expression in France, *les yeux de la vigne*, which means literally "the eyes of the Vine," and which is synonymous with "good wine," implying that the older the Vine the better the wine, yet we know that in all the large vineyards of France the Vines are every year pruned down to a stump, from 6 to 15 inches high, and from this stump starts forth every year 6 or 8 shoots, each of which is allowed to bear one or two bunches, and is rigidly stopped when it is about 3 or 3½ feet long. Indeed, the rough pruning that Vines get in the Vine countries would astonish many a Grape grower in England. Can "P." then explain why these Vines do not die off, or get used up just at the very time when they ought to be in their prime? G. A. H.—Our leader upon this subject demands the attention of every Grape grower. The fact is most gardeners are in constant danger of sacrificing freedom for trimness. To cut close is a more common practice than to cut skilfully or wisely. The fishing-rod or waking-stick is too often the model that the close-spurrier tries to follow. Smoothness, too, must be had at any price—even though the whole of the strongest eyes on the Vine must be paid for it. Many show much more anxiety to cut homewards than fruitwards. All the noble spurs, though burdened with embryo fruit, fall victims to the knife, chisel, or saw, simply because

they are ugly looking things. No matter through the branch becomes barren, so long as the barbarous maker can rejoice in the spectacle of a strictly stuck on rafter or wall. The winter facelings on the vine often followed by spring stoppage and subsequent bursting leaves are looked as on things unworthy of space, and are treated as if they were not wanted, the fruit. The plant is over-crowded with the after and thus with the loss of strength, the back of its strength. No! the Vine does not want to give up the contest. Its vital power is strong, and it will carry with the resistance and punishment of a plant. Halted in its attempts to grow at the expense of its fruit, it then turns its energy to the roots, and makes a rush homewards. The leading shoots can get our rafters like rain-courses. But the use of the savage pruner is to cut down the leading shoots, and thus the Vine is given a powerful shock in the entire system. For a time the furthest end joints are paralysed, a state of collapse ensues. Life trembles in the balance with death, it, however, conquers. But the effect of the shock endures for a time. The plant gradually regains strength, but proceeds generally more slowly—cautiously. There is a new distribution of force. It seldom again ventures to risk all its energy in one direction. It seeks safety and various outlets for its growing power. Thus having better chance of escaping observation than the strong, staked leader. But the pruner's eye is upon them. He no longer measures inches, but cuts in any one, punch, two, cut, three, save back to one, and so on, throughout the season. And yet many affect to wonder at pollarded Vines wearing out prematurely, and fading in their prime. What, the pollards in our hedgerows have a natural and pleasant time of it compared to the barbarous cruelties perpetrated upon Grape Vines under glass. The former are permitted to make at least one summer's growth in peace, and sometimes as many as four or five, but the poor Vines are under the thumb or knife of the operator from January to December. They die if they can to counteract the evils of such cruel treatment, they hoard up clandestine shoots behind leaves, and grow away rapidly in every hidden nook or corner, that they may preserve that healthy root action upon which the maturation of the crop and the preparation for the succeeding one depends. Could our close spurriers and pinchers only see the checks which the practice gives to the roots, and how they resent the cramping of the top, this might possibly lead them to abandon it. I am not forgetful of the fact that excessive root action may favour sterility, while the moderate activity of the roots induces fertility. But where root action is excessive it is much safer to deal with it directly by root pruning, than indirectly by top cramping, or close pruning. In the former case, we perform a surgical operation where it is needed, in the latter we bring about a state of general weakness of the entire plant, which often ends in death, in our attempts to cure a well understood and easily managed malady. But as, doubtless, those who have spurred Vines all their lives will continue to do so, and as many are only beginning to spur who will also become enamoured of the system, and as, moreover, the spurring system is simple, and has the merit possibly of packing the utmost amount of fruit-bearing wood into the smallest possible area, it may be well to notice an excellent means of neutralising to a great extent the evils resulting from the practice. The greatest evil possible is the big franco which it offers to the formation of roots. This evil might be neutralised or remedied by allowing the leading shoot of the Vines to run on without stopping each year. Mr. Ward, Mr. Miller's successful Grape grower at Bishop Stortford, also allows shoots to proceed from the base of his Muscat Vines near the wall plates. Both top and bottom shoots get powerfully to form roots, while doubtless the top one, by drawing up a full supply of fluids through the entire length of the canes, brings the raw supplies of food needed within easy reach of the bunches. At the autumn pruning both shoots are cut back, to be succeeded by others the following season. Possibly no better means could be adopted in combination with a system of close spurring. But I greatly doubt the wisdom of adopting the system of close spurring for a permanency. It is all very well to mix it with the long or short rod systems. By such means no rod, nor portion of a rod, need be spurred for a longer period than three years. It could then be cut out to make way for another, and so on in succession. On long rafters three or four rods could be standing them together, and portions of them spurred or not as desired. On shorter ones two rods would be enough. When once furnished a rod could be cut out and another started every year, and thus the roots as well as the top be made to renew their youth annually. Vines so treated could hardly ever wear out, provided the borders were properly formed and kept well nourished. Though I believe "P." is substantially right in regard to the cause of failure of Mr. Nash's Vines, yet it ought to be stated that the chief symbol of their weakness, consists in the shanking of their fruit. For close spurred Vines of their age, the leaves developed are respectable, and the show of fruit promising, but the fruit becomes wrecked in the last stage by shanking off fruit in bunches of berries and bunches. The border is in battalions of berries and bunches. The border is wide, and mostly raised above the surrounding ground. I agree with "P." that the roots would not be likely to take much harm, even if they had run out of the borders into the kitchen garden, that run out in front of them. What is certain is, that they cannot be the surface of the border. As these Vines are historical, perhaps you could send a trustworthy reporter to see them taken up, and give a full and particular account where they were found, and in what condition. I do not consider the extraordinary prosperity that delighted the late Dr. Landley

as a good quality in a Vine border. This quality in excess is a great deal more likely to foster the development of gross and short-lived roots and wood than of healthy and long-lived plants. Possibly the Vines burst through the borders, as described by "B." (p. 1331). Most practical men can confirm his description, that Vine roots will often hasten away through the best soils and the richest dressings, and bury themselves in gravel walks or hard roadways. They choose to endure hardness, and I have long learned that firmness, amounting to obstinacy, is one of the best physical conditions of a Vine border. Has the want of it caused the wreck, by shanking, of the famous Vines of Jones Nash, Esq., at Bishop Stortford? *David Tell Fact.*

Soil for Ferns.—Although most Ferns thrive in the usual compost of peat and sand, sometimes with, and sometimes without the addition of a little loam, my experience tells me that, generally speaking, they do not get enough of what they require out of it in time to ensure a full development before the season of growth is over. This is owing to the insoluble nature of ordinary peat. By adding a plentiful proportion of thoroughly decayed wood to my compost of peat, sand and loam, I find that my plants exhibit a very superior luxuriance to that of the collection from which they were taken. *J. H. Maw, Broseley.*

Chilian Beet.—I venture to send you my experience of the above Beet this summer, in the belief that it may prove of some little interest to those of your readers who may have tried the plant or who contemplate giving it a trial for bedding purposes. I got some of the seed with my general supply of flower seeds in the beginning of May, and had it sown in a well-prepared border, composed of good loamy soil. The seed germinated well enough, the plants grew vigorously, and were soon ready for removing to the position that I had assigned for them in the flower garden. I must tell you that I sowed it for the express purpose of introducing it into the composition of my summer bedding, having heard so much said in favour of it by the party sending it out (which, as a matter of course, I could not escape), and it having otherwise been recommended to me. I was much astonished, on close examination of the plants at the stage of growth at which they were fit for transplanting, to be unable to perceive any points in them approaching to anything of a superior character to other Beets used for a like purpose. I thought, however, that it would improve as it saw more days. On that assumption I transferred to the centre of each of the various beds one of the most promising plants, and promised to myself a treat in witnessing its expected fine, dark, rich colour blend admirably with the other plants composing the beds. But lo! what was my annoyance and disappointment to observe, when too late, that instead of improving, as I had so sanguinely predicted, a retrograde movement had set in; and from thenceforward it daily became worse and worse—coarser and coarser every moment of its wretched life, until it reached the climax of its monstrosities, and displayed to my disappointment a rough, coarse, dirty, half-green Beet, approaching to the size and coarseness of a Mangel used for agricultural purposes, and, of course, completely spoiling the look of my beds, and proving an eyesore to all who had the misfortune to see it. Thus have I recounted to you my first, and, I dare say, my last, experience of the Chilian Beet, which from the very bottom of my heart I wish God-speed out of the horticultural world. In the ever-interesting columns of the *Gardeners' Chronicle* might I ask some of your readers to let appear their experiences in the cultivation of this so-called acquisition in bedding? *Tap, Dublin, December 7.*

Low Border Pear Trees.—I have a row of these trees grafted on the Quince stock, and now about six years old. They are on a border sloping to the south and sheltered behind. They are in fine health, and every season delight me with the abundance of blossoms they annually produce. But alas! they do not give me any fruit worthy of notice. In 1866 there was a total failure; in 1867 I was gratified with two or three dozen—a poor crop, but it made me hope on; in 1868, three Pears; and this season, 1869, one poor solitary fruit made me almost despair. I have tried tiffany and hushes of evergreens as protectors, without avail. The question I now wish to ask is, can Mr. Robinson, who is a great advocate for this French mode of training, suggest any safe protector, or can any of your contributors? I think I have read in your columns a suggestion from some one that ridges of thin boards would answer well the purpose. It is just possible that some one of your numerous readers may have tried this method; if so, I hope to see it reported on, for I fear that without some efficient mode of protecting the blossoms, fruit from such trees must be a myth in our English climate. *Inquirer.*

Potting Lilliums.—I would not have troubled you further on this matter but for the fact that your correspondent "M." now that he finds some of his arguments untenable, wishes, by shifting them off his own shoulders, to encumber me with them. Thus, at p. 1138, "M." writes: "The stem is kept alive sometimes by roots emitted from itself, independently of the bulb. These roots sustain it after the bulb has stopped its supply, consequently the bulb is at rest previously, and when the stem is dead the advent of the resting period is long past." I disputed this theory, i. e., that "the bulb had been long gone to rest previously to the stems dying." And here is "M.'s" rejoinder (see p. 1232):—"W. E. has not turned out Lilliums yet, or he would not write such nonsense as dead roots supporting dead stems, &c." Now, what I did was to write of "dead roots," quoting "M." fairly by saying, "living roots existing but to support dead stems, &c." It is not necessary that I should further notice this, though I reassert, that to say a bulb has long gone to rest whilst the stem with roots,

and it may be leaves attached, is active, is somewhat strange reasoning, and cannot, I think, rightly explain the real meaning of so acute an observer as your correspondent seems to be. Why it is the bulb which receives support from the stem at this juncture, and not that the former "refuses further support" to the latter! I freely endorse "M.'s" inference that the bulbs are "never really at rest." But I cannot see how this aids his argument, unless, indeed, he would hasten them off to a state of semi-rest in October, and then immediately force upon them some four months of unobservable underground activity ere any sign of superficial growth exhibits itself. Rather let him with me give them that well-timed annual ebb and flow of a bulb's, or other deciduous plant's mode of growth, as regularly as each tide moves to and from our shores, and as Nature so beautifully illustrates in all her doings. Take the time of the plant's decadence aboveground in the autumn, to that of its surface activity in the spring, and by draining a line at or about mid-winter, not November, may we not naturally infer that a change is developing itself, and that greater vitality is becoming co-existent with the equally remarkable change of the season? Again, "M." is beside the mark when with characteristic ability he calls upon your readers to observe my recent bit of tuition from "Dame Nature." I said, as did "M." himself, that long ago I received this lesson at her august hands. Mr. Tanton's remarks, to which he refers me, afford valuable information, as do "M.'s" also. They are nevertheless combatable upon sound principles, but I do not intend to enter further into the question, as sufficient has already been advanced on this subject by *W. E.*—I fear, in my hurried reply to Mr. Smith's letter, I left unnoticed an important point, which is this: in speaking of "potting," a distinction ought to be drawn between "potting" and "shifting" plants. One would come to the conclusion on reading Mr. Smith's letter that he must have shifted his Lillium so late as February 1, because he dreads the disturbance of his bulbs at any time, and of course much more so just at the time they start into growth. If such is not the case, he has succeeded in stretching out his late Lilliums as far from the usual habit of the plants as he has pushed his early ones. I never had occasion to pot before October; and November I consider is as late as I can safely leave them, this being about the middle of the time Mr. Smith takes to get through his potting. It is, no doubt, a safe time to recommend to those who have a few bulbs only. I must thank Mr. Smith for his letter. It shows there is more to be done with Lilliums than many of us imagined. Although Mr. Smith endeavours to find fault with me, he has, nevertheless, although indirectly, fully endorsed the most important points I raised; and I hope he may live to see Lilliums in flower all the year round. Your correspondent "A.," who lately treated on Nerines, lays himself open to the same charge; at least, he was not sufficiently explicit when speaking of potting. The flowering of that class of plants almost entirely depends on their management in this respect. Autumnal floral display, to which this class of plants lends no unimportant aid, may suddenly be a blank, by pulling to pieces the pots of bulbs, and separating them one from another, in order, it may be, to increase the supply. The best plan would be to divide the batch into smaller batches without more disturbance than is actually necessary. I have known some varieties of these plants flower successively for nearly 20 years, with no more attention paid to them than a little additional soil at the surface; and other varieties, by being potted as above described, have refused to flower for several years after. *M.*

Dry Rot.—Attentive readers of your Journal cannot fail to have noticed with satisfaction an increasing interest in Fungological matters. Upon the subject of dry rot there is still much to be discovered, and if I am correctly informed we are without any knowledge at present of the form of the fructification of this most mischievous mycelium. Having occasion just now to order the re-binning of the whole of a cellar, containing many thousand pounds worth of wine, I send you this note of all the information that I have been able to obtain, in the hope of eliciting further knowledge from yourself and others. Deal laths, soaked for three weeks in a solution of sulphate of copper, are said to be impervious to dry rot. Lime-washing the bin before using it again, is said by others to be all that is necessary, provided that all affected laths have been removed and destroyed. But for the recent notices about mildew at the roots of Fir trees, I should have thought seriously of using pitch-Pine laths. Now I am assured that dry rot will not attack either East Indian Teak or Demerara Greenheart. Do you know of any chemical principle in these woods antagonistic to Fungoid growth? Sulphur or creasote would be apt to affect the flavour of the wine through the corks. *W. T.* [The fructification of dry rot (*Merulius lachrymans*) is well known, and consists of myriads of snuff-coloured spores. Many other Fungi, however, occur in cellars, which must not be confounded with true dry rot. We have never seen true dry rot on Teak or Greenheart, but they are subject, especially where they come in contact with other wood, to that form of decomposition which is known under the name of Eremcausis. No one can tell why particular Fungi affect particular kinds of wood, while others affect almost all wood equally. A solution of corrosive sublimate is a certain cure, but its effect wears out after a few years. Perhaps the best substitute for laths is strong felt, which must be previously steeped in creasote or the above-mentioned solution. True dry rot, however, seldom originates in the laths. *M. J. B.*]

Continuity of Growth.—I notice at p. 1279 of your impression for December 11, an able article by Mr. D. T. Fish upon this subject. In that article he

makes reference to my letter upon Vine p. 1161, and therein repeatedly misrepresents I said. Will you, therefore, have the goodness to allow me a little space to rectify the matter. I, and most of the others who have written on the subject, says, only tends to strengthen my position in the matter. If Mr. Fish will have the goodness to read the first ten lines of my article, he will find the conclusion to which he has come at the end of the last paragraph of his article is just the same as contained in the little word, "No," which answers two opposite questions of Mr. Gill and Mr. Fish, viz., "that root and top action proceed simultaneously" when plants are grown in a natural condition. The case brought forward by Mr. Fish to prove that leaves could be produced without roots, has no bearing upon the subject, and yet have the cases cited by Mr. Fish to reverse, for both are extraordinary circumstances having any bearing whatever upon what is not, the result of root and leaf formation, and healthy tree in a natural condition, must be remembered that this is the case which I took my stand. From beginning to end of my article there is no reference made to roots or roots might do if placed in a condition other than their natural state. Every one knows that ordinary things are accomplished by the means of the vegetable kingdom in their struggle for existence. Roots in some cases will form shoots, and shoots in almost every case will form roots, and this has no bearing upon the subject of the first understood it, and wrote accordingly who have written upon the subject had been in mind, there would have been less said upon the and far sounder conclusions would have been by them. Again, Mr. Fish misrepresents me that I said "spongioles cannot be formed without aid of leaves;" and by denying this he misrepresents himself; for does he not adopt the language of Owen at the top of his third paragraph, that "the leaf falls not because an old leaf is because a new leaf is born," clearly showing that tree is never without leaves the whole of its life. It was looking at it in this light that what Mr. Fish attributes to me, he looked towards the end of my article to find these words, when referring to this point that there may be no misconception upon it, let me say that buds are leaves, flower buds in embryo, and consequently act as spongioles until such time as the leaves begin to develop. Mr. Fish taken this sentence, in conjunction with what he attributes to me, he would have done justice; but, by taking the one without the other, entirely misrepresents my meaning. I ought to be put right when I am wrong, but I can't misrepresent. Regarding my reference to a pump, the simile was used for simplicity, not to be literally understood; and a man of intelligence as Mr. Fish cannot fail to perceive what I meant by it. If, however, as Mr. Fish says, of a pump does not draw water at all, will he be so good as enlighten us by stating how it can accomplish this without it, unless he uses a James McMillan. [We believe that the buds act rather as consumers than as producers as our correspondent states. *Eos.*]

Vine Soils.—I know the authors of your article are so competent to put controversialists to rest, that I so highly approve of your liberal admission of opinions into the *Chronicle*, that I could not but question the action of calcareous soils. In common parlance, a soil may be calcareous, but, strictly speaking, the surface soil is calcareous, exclusively formed of carbonate of lime. The calcareous soil of this place is composed of numbers, of 45 parts carbonate of lime, 10 parts aluminous earth, and 10 siliceous, and is very sandy. In it the Vines grow vigorously and abundantly. I have two Vines, planted 20 years ago, the roots of one run under a carriage, the other under a grass plat; they are never more than 10 feet apart. Last winter, I sawed off one of them close to the ground, and the other grew 2 to 3 inches in length daily in July, and about 16 feet in length, strong red roots. Such calcareous soil is good for Vines. As to success on soils of pure siliceous, but I know a part of a shire that was black sand, and almost barren, and a view to improve it, was first dressed with small results, then chalk was added, and it became fertile. My recommendation, therefore, designate no soil as unfruitful until you have obtained its component parts; and I am sure it will be a great advantage if writers treating on horticulture or agriculture would let us know the position of the soil they write about. *Farther Barton, Cirencester.*

Yellow Bedding Plants.—Your correspondent "T. P. T." (p. 1284) is in error when he says "The Pansy has been tried over and over again as a summer bedding plant but has always failed." At the end of July it is used up. If "T. P. T." here next August, September, or October, convince him otherwise, and take him masses of Yellow Pansies as well persuade him, and thus prove by ocular demonstration that he not use it up by the end of July. I have a good lot of latea, in the middle of October, one perfect flower, with my friend Mr. Willis, when at the success in the cultivation of the Pansy depends upon its proper management. *Osberton.*

entirely free from the greenfly, which is sometimes very troublesome to this plant. Dieffenbachia maculata stands next, a remarkable plant, and all the more creditable by reason of the small pot it was grown in. How seldom we see this plant shown to perfection: generally speaking, as the leaves attain age they turn a dingy brown colour, which entirely destroys its character and usefulness for exhibition. But such is not the case with Mr. Bennett's plant, it retains its pretty green leaves, freely blotched with white throughout. This plant should always be cut down in the winter, and must be shaded from the scorching sun, to grow it to perfection.

Alocasias of sorts, and Dracaenas of sorts, have also a place here, as also have the Sansevieria zeylanica—an immense plant, Boehmeria argentea, Pavetta borbonica, Cyanophyllum magnificum, Marantas of sorts, and last, but not least, that seldom-seen plant, Campylobotrys refulgens. In days gone by, Mr. Bennett has shown this plant probably better than any other man in the country. Abundant drainage, a light, porous soil, with plenty of silver sand, and close shading, give the clue to success.

I find I have accidentally omitted to mention a good specimen of Cyperus alternifolius variegatus, which is the largest of the kind and the best coloured I have ever seen, not an entirely green leaf being seen on the plant. To colour this plant to perfection requires some amount of skill; but if the following simple rules are adopted, the desired object may invariably be secured. 1st. Don't have a plant that has been obtained from seed, as that cannot be relied on to produce variegation. 2d. Rest the plant every winter, and cut it down, keeping it in a warm house. 3d. Pot in a compost containing equal quantities of peat, leaf-mould, silver sand, and brick or mortar rubbish, and only pot once a-year. This plant is especially valuable for the trimming of vases, &c., and should have a place in every collection.

Before taking my leave of the house containing the above remarkable specimens, I would just state that I noticed several young plants of recent introduction, including some of the new Crotons, but as their characters are not sufficiently developed in their young state to enable one to form an accurate opinion of their respective merits, I refrain from making any comment upon them at present. In another house devoted to flowering plants I noticed the following as being remarkably fine and well-flowered, but as I did not take any notes, I am unable to give particulars as to size and the number of flowers each plant carried:—Bougainvillea glabra, Allamandas—cathartica, Schottii, grandiflora (very beautiful), Hendersoni, and peritofolia (good); Ixoras—salicifolia, javanica, and coccinea; Dipladenias—splendens (good), crassinoda, and the lovely amabilis (the latter unusually fine); Clerodendron Kämpferi and Thomsonæ, good; Rondeletia speciosa and Stephanotis floribunda were alike good. I cannot conclude this incomplete account of the plants without stating that there are many good specimen greenhouse plants in another house; and further, that the place looked remarkably well at the time of my visit (middle of September) throughout. The Vanilla has also abundance of fruit pods this season. Thos. Simpson, Broomfield, Chelmsford.

Garden Operations.

(For the ensuing week.)

PLANT HOUSES.

THE ornamental and useful Francisceas will now generally be more or less enlivening stoves with their variably tinted blue, or mauve and white flowers. Whilst at this stage no moisture should be allowed to settle upon the plants, neither should any great amount of humidity be permitted in the structure containing them. The flowers being somewhat delicate, they readily damp off before their usual time if any excess is permitted in either way. Kalosanthes should now be kept as dry as they conveniently can be without allowing them to become at all shrivelled in the leaf. They do not require much heat; a moderately cool, but dry corner, in any intermediate house which is kept up to a mean of from 45° to 50°, will suit them well. Bulbs, such as Hyacinths, Crocuses, Narcissus, &c., will now become an attractive feature in gardens generally. A constant successional supply should therefore be maintained. There is one point in the culture of these favourites to which all growers do not seem to attach the proper amount of attention, and concerning which a few words may not be out of place here. I refer to the fact, that instead of removing them from beneath the material which was placed over them during the process of root-making, as soon as they have fairly established themselves, many let them remain, one batch after another, until they are wanted for forcing, when, in many instances, the later lot has made some inches of growth. The leaves and flower-spikes so produced are thoroughly blanched, and as ill adapted as anything can well be to carry forward those necessary offices in connection with roots which are necessary to produce fine individual flowers, and in the absence of which no cultural merit is attainable. As soon as the bulbs have made roots, and become properly attached to the soil, let them be removed to the full light, where both sun and air may freely reach them; the cooler the situation the better, provided always that frost is not permitted to reach them. The nearer they are placed to the glass the better, and it may be said in regard to waterings that the more frequently the soil needs a fresh supply the better, provided at all times that the balls dry kindly, and nothing in the way of stagnant soil exists, as the roots delight in a fresh supply. There may be some few instances in which certain cultivators wish to make a good show of blooming plants at a very early date, and who, in order to do so, are not

averse to forcing their plants out of season. To furnish such a display as this, there are some few rather unusual subjects which will respond with tolerable freedom to a little extra pushing, especially Clerodendrons—the varieties C. Thomsonæ and C. Balfourii in particular; Impatiens flaccida and I. flaccida alba; most of the Gardenias, excepting G. Stanleyana; such varieties of evergreen shrubs, like Hibiscus, as may be grown; Bougainvilleas and Libonias; which may all be turned to very useful account.

FORCING HOUSES.

I have little to add in regard to Early Fineries. Be particular not to enforce too much artificial warmth at any stage, as far more injury will accrue therefrom than is to be seen at the moment by the superficial observer. Attend constantly to the state of heat of the fermenting materials upon the outer borders. The fluctuating weather we have experienced of late in this wise—sometimes sharp and frosty, at others a densely surcharged humid atmosphere—will necessitate constant watchfulness to keep the heat at a uniform mean. See that the Vines in the Late Fineries do not suffer at any time during severe weather from frost, but afford protection therefrom in some shape or form. I need add little in regard to Pines, excepting it be to recommend in those instances where an uninterrupted supply of Pine-apples is necessary, that a few of the forwardest successional be sorted out, and means be assured to cause them to show as soon as possible. This to follow those now showing fruit. Should very severe weather ensue—and it often happens about this time—let me suggest that the utmost caution be exercised, not to exceed by a single degree the maximum of artificial heat which is absolutely necessary; for depend upon it the dry, heated atmosphere, even at a minimum, will prove a sufficient tax upon all well cultivated plants. Especially is this to be enforced if the cold is of some duration, when a slight reduction of the mean heat may be advisable. Keep well above the temperate point at all times, but hug it as closely as is possible during such periods as these, of course according to the requirements of each separate batch of plants. Keep up a successional supply of such things as Seakale, Mushrooms, Asparagus, &c, by the continued introduction of the necessary material at properly regulated intervals, in order that no scarcity of a proper supply may show a faulty place in past arrangements.

HARDY FRUIT GARDEN.

Those who may not yet have placed the necessary protective material against Fig trees attached to walls out-of-doors, should now do so at once. Straw hurdles neatly hung up against them, so as to represent a thatch, do as well as anything; as, while they ward off any really severe frosts that occur, they nevertheless admit more air amongst the branches behind them than is possible when they are tightly bound up with straw or hay. I lately referred to the necessity of running white cotton athwart Gooseberry or Currant trees, for the purpose of keeping small birds from destroying the fruit-buds. I find that the best material for this purpose is the best white hempen or flax string used by shoemakers. It is procurable in balls, costing about 2½d. These balls contain many yards, and the material is very strong.

HARDY FLOWER GARDEN.

When I last wrote, and, indeed, but a day or two since, everything seemed to indicate a frosty period. The change in the moon's quarter on the forenoon of the 10th inst. has, however, changed the aspect of affairs, though there can be no certainty of a mild period for many days together. It will be necessary, therefore, to provide proper protection for all subjects likely to require it, should a frosty period ensue. This will be the more imperative after so mild a period. Young plants of Cynerium argenteum (the Pampas Grass) should have some sort of protection placed around their base. Outdoor beds of Hyacinths and Tulips should have some protecting material for a like purpose. Should there be a mild period, push forward all planting, or any form of alterations which may be in hand, &c, with the utmost despatch; this especially in regard to the removal of turf and the necessary occasional rolling of grass plots. Give Neapolitan Violets all the air possible during mild periods, keeping them clear of everything in the form of decay. Protect Pot Roses which are intended for forcing shortly, and keep them moderately dry. During unusually wet periods, even on light soils, the Bellis perennis aucubafolia (both white and red flowered varieties) will scarcely exist; they should therefore be potted up and receive the protection of a frame; the same remarks will also apply equally to the best double varieties of Pyrethrum.

KITCHEN GARDEN.

It will be advisable to look over those crops which were lately protected by the use of litter, whether dried Fern or straw, and, by removing all such from them, to allow the air, with what drying tendency it may have, full play. In those instances, where the rows of Celery have not been so protected—and it was not needful, it will be seen that the sides of the somewhat abrupt and upright mounds have crumbled or wasted by the influence of the frost. These it will be advisable to go over and to replace the soil to its former position, or should a sharper period ensue the crop will be liable to suffer, so attenuated have the sides of the mounds become. Look through all frames or pits containing Lettuces or Endive, and remove such as are at all decayed, which some are certain to be at this time, even with every attention. In the case of good stock frames it will be advisable to fill up all vacancies with other suitable plants taken up from the outer borders. Look out for the necessary materials for making hotbeds; for the time will now soon come round when they must be turned to account. W. E.

TOWN GARDENING.

A VERY useful subject for hiding blank walls in gardens is the Grape Vine. Now is the best time for pruning and nailing it, an operation which should be done as follows:—Considering that the fruit has more importance (for the purposes above mentioned) than the fruit, the plants must be so pruned as to favour the production of the leaves. The main leading shoots may be trained either horizontally or perpendicularly about 12 inches apart from each other. These shoots should be cut back to a plane which may be nailed straight towards the extremity of the buds. The young wood of the past season should be pruned to one or more eyes, according to the strength of the shoot and the space to be filled. Sufficient quantity of last year's wood should be secured, to fill up spaces caused by the removal of older branches. When the pruning is finished, all in neatly and regularly. A good dressing of dung, forked in a few feet round the stem, will do great service to them. Should the weather be dry and fine, roll the Grass well, sweep and rake, and clear the borders of everything in the way of rubbish, so that the garden may be in a happy state at Christmas. J. D.

STATE OF THE WEATHER AT CHRISWICK, FROM THE 1st OF DECEMBER 1862 TO THE 15th INST.

Table with columns: Dec, Moon's Age, Barometer (Max, Min), Temperature of the Air (Max, Min, Mean), and other weather-related data for the week ending Dec 15, 1863.

Summary of weather conditions for the week, including observations on temperature, wind, and precipitation.

STATE OF THE WEATHER AT CHRISWICK DURING THE LAST 43 YEARS.

Table showing long-term weather statistics for Chriswick, including average highest and lowest temperatures, mean temperature, and frequency of rain.

Additional weather notes and observations for the period covered by the table.

Notices to Correspondents.

A collection of notices and responses to readers, including information about books, garden products, and local events.

outstripped us in agricultural economy and production? For ourselves, although aware of the industrious and indefatigable character of the Chinese, we have full confidence that English agriculturists might overtake and even surpass them. It is surprising that questions affecting the welfare of agriculture excite so little public interest. Yet we are persuaded that no very important steps will be taken in the improvement of farming until popular intelligence has cleared away certain obstacles which we have often pointed out, and which, as they are social, or political, can only be removed by the pressure of public opinion.

No one can seriously compare the agricultural skill and contrivance of any other European nation with that of England; our farming is that of a thickly populated and enterprising nation. It is deficient only where it wants a fair field for enterprise and materials for the exercise of skill.

— THE grain trade in London has been in a slow and almost unaltered condition throughout the week. A trifling exception may, however, be made to Wheat, both English and foreign, which has declined 1s. per quarter, and to Oats, which are lower in value by 6d. per quarter. Barley, Beans, Peas, and feeding stuff generally have been a dull sale at previous rates. The highest quotation for this year's Wheat of English growth is 43s., and red samples are quoted as low as 36s. per quarter. Country markets have corresponded.

— The Metropolitan great Christmas stock market has confirmed the remarks we made on the Bingley Hall animals in regard to the want of firmness in their fat. There were some of the more corn fed stock which were firm and good, but the great bulk of the animals were in the worst condition which has been seen at the Christmas market for several years. This created a large amount of surprise in some quarters, but if it be looked at from the light in which we viewed it, it will at once become intelligible. The question, therefore, may be again asked—Would it not be better for us if circumstances should discourage the importation of live stock, which is so often diseased, and thereby increase the encouragement to import foreign corn for producing a largely increased amount of animal food at home? It was further remarked in many places that in-and-in-breeding is proving yearly to be more and more unremunerative. Does this apply to the small-boned pedigree Shorthorns? the diminutive pedigree Devons? or to the less fleshy and more uniform pedigree Herefords? Does it also apply to sheep? As to pigs, we may at once say we know it does. While this is the result of home breeding too, it is equally clear that foreign animals are greatly improved in their form and character. This was particularly noticeable on Monday last in the Dutch and French beasts. The Scotch beasts, again, took the lead as regards form and condition from feeding. This was not anticipated, for the animals of late, where they have come off grass and turnips, have been soft and flabby, the result no doubt of an excess of moisture in their green food and roots. The following is the return of the numbers at the "great market" during the last 28 years:—

Year.	Beasts shown.	Price.	Year.	Beasts shown.	Price.
1841	4700	3 8 to 5 0	1856	6749	3 4 to 5 0
1842	4711	3 4 to 4 8	1857	6556	3 4 to 4 8
1843	4511	3 8 to 4 4	1858	6174	3 4 to 5 0
1844	5773	4 0 to 4 6	1859	7560	3 6 to 5 4
1845	5276	3 6 to 4 8	1860	7866	3 4 to 5 4
1846	4570	4 0 to 5 8	1861	8841	3 4 to 5 0
1847	4382	3 4 to 4 8	1862	8430	3 4 to 5 0
1848	5042	3 4 to 4 8	1863	10370	3 6 to 5 2
1849	5767	3 4 to 4 6	1864	7131	3 8 to 5 8
1850	6341	3 0 to 3 10	1865	7530	3 4 to 5 4
1851	6103	2 8 to 4 2	1866	7349	3 8 to 5 6
1852	6071	2 8 to 4 0	1867	8110	3 4 to 5 1
1853	7077	3 2 to 4 10	1868	7921	3 4 to 5 8
1854	6171	3 6 to 5 4	1869	6728	3 4 to 5 10
1855	7000	3 8 to 5 2			

The trade was not in a very animated state, in consequence of the length of time there was before the coming festival. It was besides anticipated that an unusually large supply would arrive for the Thursday's market. This, however, did not transpire, for there were only 1812 beasts in the market, including those left over from Monday. Previous prices were therefore maintained for both choice and middling qualities, 5s. 8d. per sub being the highest quotations. In such provincial markets as Wakefield, Manchester, Liverpool, Birmingham, Bristol, and so on, the numbers are reported as larger, and the condition of most of them as good. Of sheep, but few of the show class were present either on Monday or Thursday. The large supply of 24,790 on the two days made all but the show sheep and ripe handlers slow of sale.

— On Saturday morning last an outbreak of foot-and-mouth disease was discovered among the few cattle which remained in the Agricultural Hall after the close of the Smithfield Club exhibition on the previous day. Under the provisions of the special order for holding the exhibition, arrangements had been made for removing cattle out of the metropolis with a police order, which was granted only on the production of a certificate of health, signed by one of the veterinary surgeons, and in pursuance of this provision Professors SIMONDS and BROWN examined all the cattle in the Hall on Friday, and signed the required certificates, all the animals being free from disease. During Friday night the greater part of the stock was

removed. On Saturday morning, however, one of the remaining cattle, a Devon ox, was discovered to be ill, and was immediately taken from the Hall and put in the hospital, as it is termed,—a distant part of the building, which is appropriated to the reception of animals which may be taken ill during the show. An examination was made of the ox by the veterinary inspectors, and he was found to be suffering from the incipient stage of foot-and-mouth disease. Pending the issue of instructions from the Privy Council respecting the disposal of the animals, directions were given to prevent any of the 45 which were left in the Hall being taken away. The police licenses for the removal of cattle out of the metropolis were revoked in the course of the afternoon. On Monday the cattle were again inspected, and several of them indicated the existence of the disease; the total number of attacks amounted to seven. Police licences were issued on Monday for the slaughter of the cattle within the metropolis, and they were all removed from the Hall during Monday and Tuesday. Disinfection of the manure was commenced immediately under the supervision of the inspector to the local authority. It is somewhat remarkable that this is the first instance of the appearance of a contagious disease among cattle at the Smithfield Show since the outbreak of cattle plague in this country led to the holding of exhibitions under the restrictions of the Privy Council licence. Respecting the cause of the outbreak the professional opinion is, that the infection was in some way conveyed to the cattle, probably by persons coming from diseased animals, two or three days before the discovery of the disease. This opinion is based on the well-known fact of the limited duration of the incubative stage of foot-and-mouth disease; not more than 48 hours intervening between the time of infection and the declaration of symptoms in the majority of instances.

— The West Herts fat stock show at Watford on Tuesday last was a most successful local exhibition. Seven cups were awarded, in addition to money prizes. W. H. SWITH, Esq., M.P., offered two 10-guinea cups, one for the best bred ox or steer in any of the classes, and the other for the best bred cow or heifer, both to have been bred by a tenant-farmer. These were judicious premiums, as in each case the selected animal had not taken a prize in its class. Mr. LEACH LONGROFT, Hemel Hempstead, took the 1st for a very handsome steer, and Mr. JOHN WHITE the 2nd for a good 2-year-old heifer. The 1st class prize in the oxen was taken by Mrs. MORTEN, Lea Farm, Watford, and also the cup given by the Earl of ESSEX for the best ox or steer, without any conditions as to breeding. The Earl of CLARENDON, K.G., was 2d with a good steer of 2 years and 8 months. In the heifers the Earl of CLARENDON was 1st, and W. JONES LOYD, Esq., 2d. In this class, however, there was the best animal bred by a tenant-farmer, and for her was awarded the handsome prize of a 20-guinea cup, subscribed for by the unkeepers and tradesmen of Watford. Mr. G. STONE, Cassio Bridge Farm, Watford, was the possessor of this fine blood-red cow. Lord CHESHAM was also a winner in the heifer class, with a very pretty West Highlander. Two cups were offered for sheep, one by W. JONES LOYD, Esq., and the other by H. R. BRAND, Esq., M.P. These were both to be competed for by tenant-farmers only. Lord CHESHAM took the 5-guinea prize offered by the Old Berkley Hunt for the best sheep (ewe or wether) of any age or breed. This was with one of five 2-shear Shrops. The pigs were excellent, W. JONES LOYD, Esq., taking three 1st prizes with excellently bred and fed pens. The Earl of Essex was also a successful exhibitor. Poultry, pigeons, and dead poultry, to the number of 142 prizes, made up a very attractive show, and the number of visitors indicated that it was well appreciated. This show was arranged in tents; but it is anticipated that by next year a public hall for this show and public meetings generally will be completed.

OUR LIVE STOCK.

BUFFON long ago remarked that domestic animals breed oftener in the year, and produce more young at a birth than wild animals of the same species; they also sometimes breed at an earlier age. Mr. Darwin in discussing this interesting point tells us that some authors have lately attempted to show that fertility increases and decreases in an inverse ratio with the amount of food. This strange doctrine has apparently arisen from individual animals when supplied with an inordinate quantity of food, and from plants of many kinds when grown on excessively rich soils, as on a dunghill, becoming sterile. With hardly an exception, our domesticated animals which have long been habituated to a regular and copious supply of food without the labour of searching for it are more fertile than the corresponding wild animals. It is notorious how frequently cats and dogs breed, and how many young they produce at a birth. The wild rabbit is said generally to breed four times yearly, and to produce from four to eight young; the tame rabbit breeds six to seven times yearly, and produces from four to eleven young. The ferret, though generally so closely confined, is more prolific than its supposed wild prototype. The wild sow is remarkably prolific, for she often breeds twice in the year, and produces from four to eight, and sometimes even twelve young at a birth; but the domestic sow regularly breeds twice a-year, and would breed oftener if permitted; and a sow that produces less than eight pigs at a birth "is worth little, and the sooner she is fattened for the butcher the better." The amount of food affects the fertility even of the same individual: thus sheep, which on mountains never produce more than one lamb at a birth, when brought down to lowland pastures frequently bear twins. This difference is apparently not due to the cold of the higher land, for sheep and other
