
English Mechanic and World of Science

[Supplement to the ENGLISH MECHANIC, Oct. 4, 1872.]

THE

ENGLISH MECHANIC

AND

World of Science.

WITH WHICH ARE INCORPORATED

"The Mechanic," "Scientific Opinion," and "The British and Foreign Mechanic."

ILLUSTRATED WITH NUMEROUS PRACTICAL ENGRAVINGS.

VOLUME XV.

LONDON:

OFFICE, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

SOLD BY ALL BOOKSELLERS AND NEWSAGENTS IN THE KINGDOM.

1872.

LONDON: PRINTED BY W. SULLY, PLOUGH-COURT, FETTER-LANE.

INDEX TO VOL. XV., ENGLISH MECHANIC.

A 1 CLOCK, the, 40
Aberration (of intellect), 9
Abolition of steamer funnels, 368
Absorbent quality of printing paper, 104
Abyssinian gold, 133
Acarus Crossii, 571
Accessories of the lathe, 72
Acetic acid, testing, 183, 208, 234, 284
Acid: acetic, testing, 183, 208, 234, 284; bulb thermometer, 35; stearic and palmitic, 608; sulphuric, 18, 43, 545; tartaric, testing, 547
Acoustic illustrations of the method by which stellar motions are determined by spectroscope, 458
Acoustics, 623
Action: of gravity, 616; of oil on waves, 623
Actions: pianoforte, 149; practical instructions for making piano, 173
Activity, solar: 7; influence of the planets upon, 33
Address of the president of the British Association, 584
Adjustable spanners and wrenches, 243
Adjusting balances and mainsprings, 209, 641
Adjustment of an equatorial, 116, 129, 154, 180
Adulteration: detection of in food, 525; of aniline colours, 126; of food, 347; of wax, 144
Advanced chemists, to, 340, 388
Æolian harp: improved, 540; tuning, 598
Aërated: bread-making machine, 625; drinks, 21, machine for making, 380, 546, 622, 670; ginger beer, 571; waters, 261, 309
Aëronautics, 191
Aërostatics, 569
Age of trees, 598, 646
Agricultural: chemistry, value of, 57; manures, 219
Agriculture, 156, 391
Aims and instruments of scientific thought, 634
Air: and rain, 239, 818; and warmth, 105, 130; coal-cutting by compressed, 531; compressed, 649; as a motive power, 28, 384; compressing, 548, 596, 622, 646, 670; pressure, resistance of steel plates to, 645
Air-bladder in fishes, 13, 73
Air-chambers, bursting of, 126, 154
Air-guns, modern catapult and, 434
Air-pumps, 78
Air-vessel: for pump, 518; on suction pipe, 673
Albumen paper, preventing blisters in, 144
Alcohol: 530, 624; question, 109, 171, 198, 225, 256, 276
Alcor, 434
Ale: effect of temperature upon, 235, 284; sour, 547
Alexandra palace organ, 43
Algebra, 130, 180, 232, 365, 391
Algol, 636
Allen's patent governor, 372
Alliance, piano, 40, 333
Allingham's propeller, 39, 62, 92, 148, 173
Alloys, atomic proportioned, 590, 669
Almanac, the *Nautical*, 9, 116
Aloes, Socotrine, 339
Alphabets, origin of, 638
Alt-azimuth: an improved, 249; stand for refractors, 614
Alum, test for in bread, 454
Aluminium coinage, 482
Amalgamated zinc, 21, 38
Amateur: organ building, 302, 354, 409; science, government and, 253, 334, 437; turners' society, 97, 150
Amateurs: motive power for, 105, 129, 154, 206, 258, 283, 336
Amber: 113; bending, 156
American: and Scotch inventions, 119; chucks, 495; drill chuck, 516; lathe chuck, 284; paper car-wheels, 222; science, 276
Ammonia: domestic uses of, 140; test, Nessler's, 48, 78, 101
Ammoniac chloride, 46, 76
Ammoniacal liquor, 673
Analyses from Geo. E. Davis, 305
Analysis: 339; food, 467; of ores, 18; qualitative, 207; spectrum, 171; sugar, 18; water, 181
Analysing ash of cane-sugar, 182
Ancient: constellations, 380, 411, 431; musical instruments, 324, 384, 568; wrought iron, 518
Aneroid: barometer, pocket, 44, 101; bell, 425
Angle of reflection and incidence, 17, 100, 152, 204, 231, 283, 307, 360, 440
Aniline: black, 417, 545; colours, adulteration of, 126; violet, a new, 299
Animal life, influence of light on, 605, 669
Animals and plants, 356
Annealing steel, 146, 181, 308, 547
Animals, 48, 101
Antares, or α Scorpionis, 485
Ant-hill earth, 544
Anthracene, 430
Anti-mildew grain protector, 278
Antipodes, time at, 208, 233, 259, 284, 308, 337, 361
Antiquity of man, 514
Ants: 201, 310, 496, 621; are they pirates? 72, 121, 147, 357; in the Isle of May, 359
Aphides, destroying, 133
Apparatus: blowing, 519, 570; for determining specific gravity, 220; novel, 325; self-acting blowing, 124
Apparent local time, 38
Aquarium: 491, 516, 546, 572; fresh-water, 156, 206; gravel for, 625; marine, 589, 644; water for, 673; zinc for, 362
Aquilæ: 263; P XVIII., 536; stars in, 614
Arches, brick-vaulted, 468
Architecture, naval, 23
Arcs, semi-diurnal, 9
Area: of boat, 156; of chimney, 260; of segment of circular ring, 22, 76, 128, 153
Argento pictures, 58
Argostoli, phenomena of, 410, 436
Arithmetical, 61, 130
Arrangement and preservation of insects, 265
Arsenic: in wall-papers, 236, 261, 309; test for, 442
Art: disappearance of, 469, 518, 545; schools of in potteries, 445
Artesian well in Boston, U.S., 61
Article in *Nature*, on an, 144
Artificial: butter, 180; gum, 209; legs, 71, 75; manures, 209, 381, 438, 465, 512; oils, 443, 468; so-called organic concretions, 503; stone, 334
Artillery, works on, 625
Ascension, right, 490
Ash timber, 286
Assay, wet and dry copper, 99
Assayer's duties, 234, 259, 309
Asthma: hay, 571, 622, 646, 670; on the treatment of, 55
Astronomical: 61, 102, 154; catastrophe, 196; notes, 27, 136, 265, 370, 475, 605; refraction, 637
Astronomy: and the ENGLISH MECHANIC in New Zealand, 11; Mr. Proctor's Essays on, 291; natural observatories for the study of the physics of, 317
Atmosphere: carbonic acid and the, 286, 338; compressibility of the, 151, 204, 358; lunar, 662; our coal-stores and the, 334, 385, 411, 437
Atmospheric: burner, 567; dust, 5, 66, 92, 124, 147; elastic force, 279, 326; geology, 530; pressures, 648, 571; waves, the Meteorological Office and, 37
Atomic: proportioned alloys, 590, 669; theory, 300
Atomicities: 11, 68, 230, 280; valencies and, 10, 41, 99, 122, 123, 200
Auburn hair, 625
Augers, improved, 481
August meteors, 542, 614, 640, 662
Aurora: 147, 331, 383, 537; borealis, 11, 566
Auroræ boreales and gales, 644
Australia, trip to, 364
Australian meat: 38, 62, 126; preserving 178
Austria, metric system in, 179
Automatic gaslighting, 325, 556
Automaton chess-player, 546
Axes of the planets, 379, 406, 460, 482, 594
Axis: moon's, 9, 40; of Venus, 430, 460

B. A. C. stars, 508
B. Sc. of London, 441
Back of teeth, cleaning, 442, 492
Background, photographic, 183
Bacon curing, 21, 75
Bad: sleeper, 338, 387; water, 590
Bait, salmon spawn as, 79, 104, 129
Baker's ovens, 180
Baliste, washing, 364
Balance-wheel, fixing on verge, 285
Balloon: dimensions of, 313; fire, 154
Balsamed object-glass, 353, 383, 411
Bands: driving, 365; worn waterproof, 365
Banjoists, to, 257
Barges, iron, 111
Barlow lens, 223
Barm, yeast or, 625
Barometer: pocket aneroid, 44, 101; tube, vacuum in, 157
Barometers at sea, 385
Barrel organ, pocket, 105
Barrister, 156
Barron steel process, 454
Barrow-in-Furness, 310
Basket-making, 129
Bass, thorough, 183
Bass's beer, 131
Bat-making, 621
Bath: removing organic matter from, 144; silver, 21, 105, 130; swimming, making, 21, 45
Batteries: 593; secondary, 189
Bat-making, 595
Battery: 46, 340; coil, 391; continuous, 360; defective, 182, 206; diminished action of, 417, 467; Himmer's galvanic, 113, 275; manganese, 496; powerful galvanic, 490
Battle of the gauges continued, 654
Bearing rein, 384, 430, 462, 484, 514
Bearings, glass axle, 638
Beating gold, 262
Bedding-out, 292
Beds, spring, 106, 130
Bee cabinet, Myborg, 354, 433
Beech, varnishing, 107
Beefsteak, vegetable, 425
Beef-tea, worthlessness of, 191
Beehive: 19, 105, 154, 519, 643; improved, 251, 305, 510, 567; wooden, 156
Bee-keeping, 14, 17, 158, 547, 597, 672
Beer: and spirits, testing, 570; Bass's, 131; ginger, 648; spruce, 78; treacle, 153
Bees: 339, 363, 492, 546, 571, 596, 643, 646, 648; and beekeeping, 14, 27, 66; chloroforming, to remove honey, 281, 284; English black *v.* Ligurian, 666; how to get a swarm of, 496; Ligurian, 232, 511; management of, 32, 158, 182, 224, 335, 470, 494, 590, 642; stings of, &c., 79, 103, 129, 154, 180, 206, 231, 360
Beetles, killing, 79, 102, 129, 180
Bell: aneroid, 425; electric, 48, 182, 207, 361, 466, 569; electric, anticipated, 253, 280; pianette, 182, 226, 275, 333, 483
Bellows: organ, 333, 413; water, 410
Bell's patent feed-water heater, 55
Belts, fixing on tires, 102
Bench, carpenter's tool-chest and, 311
Bending: amber, 156; laths, 519; tires, 44, 101
Berlin black, 79, 102
Bible, bug, 153
Bicycle, brake for, 596
Bicycles: simple way of fitting handles to, 177; speed of, 73
Billiard cloths, grease in, 368
Billiards, 331
Binary stars, 143
Birch, 45
Birds: economy of small, 203, 252; eggs, cabinet for, 517; eggs, preserving, 428; flight of, 121; stuffing, 152
Birmingham, science in, 613
Bisulphide of carbon: engine, 140; fragrant, 656
Bitumen as a photographic material, 299
Black: aniline, 417, 545; Berlin, 79, 102; Brunswick, 130, 155; cloth coats, reviving, 156, 232; dye for leather, 599, 624, 670; lacquer, 387; varnish, flexible, 572, 596; varnish for microscope objects, 440
Blackbeetles, London, 209, 235, 260
Blackberry and strawberry, 307, 360, 386, 413
Blackening transparencies, 18
Blacking gun-barrels, 179
Blacklead, manufacture of, 569
Bleaching: agent, sulphur as a, 281; oil, 168; tanned goods, 621
Bleaching-powder: 18; testing, 235, 261, 285, 309, 361
Blind, deaf and: 23, 47; writing-machine for, 164
Blindness, colour, 179
Blind-roller, self-acting, 295
Blinds, Venetian, 340, 388
Blinkers, removable, 538, 591
Blistering, preventing albumen paper from, 144
Blood: action of quinine on white corpuscles of, 8; circulation of, 18, 74, 127, 179, 205; white corpuscles of, 8
Bloom of scarlet runners, fixing the, 599, 646
Blowing: apparatus, 519, 570; novel, 325; small birds' eggs, 490
Blowpipe, improved, 247
Blue: billy, 131; cochineal, 674
Bluecoat school, 625
Boat, area of, 156
Boat-building, 415, 494, 518, 543, 623
Boats: anti-nauseating, 433; caulking, 209; new sliding seat for racing, 372
Bodies, embalming by injection, 497
Boiled oil, 468, 492
Boiler: 180; charcoal furnace for model, 442; construction and management, 13, 68; duration of, 236; electricity from steam, 23; explosions, spheroidal state of water and, 632; for small engine, 19; for small steamboat, 258, 308, 361, 386, 645; high-pressure firebox, 417, 467, 517; hot-house, 364, 388, 467; incrustation, 645; tannate of soda in, 439; power of, 310; preventing incrustation of, 493; query, 414; small steam, 414; soda-ash in, 20, 232; strength of, 128
Boilers: 44, 148; incrustation of steam, 481, 546; pressure in steam, 91; protection for steam, 596; recent improvements in English and American, 113, 138; removing scale in, 346
Boiling: by steam, 157, 181; under pressure, 545
Bone-cave in Yorkshire, 324
Bones: as manure, 306; dissolving, 491
Book, using a, without hands, 19, 44, 62, 74, 127, 224, 253, 280
Bookbinder's press, 623, 646
Book-keeping, 625, 647
Books: curving edges of, 571; lettering backs of, 102; marbling edges of, by transfer, 416; on Ceylon, 23, 46
Bootmaking, 105, 129, 234, 309, 335, 385, 571, 623, 672
Boots, machine for cleaning, 520, 547
Boring: and cutting indiarubber, 676; and mortising machine, 216; for water-jet, 672
Botanical names, 408, 443
Botany: of Cornwall, 285, 309; treasury of, 156
Bottle, pressure on cork of, 183
Bottle-caps, siphon, 231
Bottone, batch from Mr., 145, 305
Boundary line, drawing, 47, 77, 101
Bow: 105, 130, 155; golail or Indian pellet, 255, 386, 434
Box: levels, circular brass, 78; musical, 44
Boxes, plant, 625, 647
Braces, gauge for bit, 325
Bracing and bellying pianofortes, 325, 358
Brake for bicycle, 596, 623
Brandy from sawdust, 439
Brass: blackening, 288, 312; blocks, stereotyping, 625, 647; casting solid, 102, 129, 180, 231; moulding, 645; punching holes in sheet, 650; screws, 416, 467; separating iron from, 127; springs, 288, 312; wire, restoring, 389
Brasswork: burnishers for, 313, 339; lacquering, 43, 547
Brazil, industrial classes in, 88
Brazing: ferrules of fishing-rods, 101 fine saws, 469
Bread: fermenting with starch, 621; Nevill's, 646; test for alum in, 454
Breadth of stair-steps, 417
Breaking strain of hollow iron columns, 78, 102
Breath, shortness of, 28
Breech-loaders, 649
Breeding, rabbit, 17.
Brewing: query, 362; water, rust in, 363
Brick: and tile glazing, 571; vaulted arches, 468
Brick-kiln, heat of, 75
Bricks: microscopic deposits on, 128; new material for, 372
Bridge: connecting England and France, proposed, 62, 201, 230, 278; skew, 495
Brilliant experiments, 84
Britannia metal, solder for, 183, 207

British Association: and the mechanical equivalent of heat, 664; gleanings, 613, 637; President's address, 584
British manufactures and scientific research, 345
Bronze: Florentine or brown, 155; imitation, 362, 493, 518; paint for iron, 248
Bronzing, 168
Brown: hat, 180; ink, 183; vandyke, 466; varnish for baskets, 517
Brunswick black, 130, 155
Brush, to bind a, 168
Brushes, revolving, 465
Bryant and May's matches, 387, 466
Buckmaster, Smith, &c., 41
Budding or grafting, 491
Buffalo pickers, 571
Bug bible, the, 153
Bugs, lice, and parasites, 235
Building: Brannan's system of monolithic, 360, 488; on sand, 519; trade, novelty in, 445
Buildings: concrete, 92, 477; monolithic, 461, 483, 542, 663
Bullet: fall of, 493, 541, 567, 619; upward deflection of, 279, 306, 353, 412, 510
Bumps, heat, 599
Bunions, 209, 235, 260
Burner, handy atmospheric, 567
Burners, gas, 183, 208
Burnishers for brasswork, 313, 339
Burnt in photographs, 143
Bursting of air-chambers, 126, 129, 154
'Bus, new steam, 161
Busts, marble, 102
Butter: artificial, 180; flavour of, 350; preserving tub, 181
Butterflies: and caterpillars, 659; and moths, setting out, 434
Buttons, cleaning metal, 156

CABBAGE plants and planting, 158, 182, 339, 364
Cabinet for birds' eggs, 517
Cabinets, microscopical, 218, 307
Cables, submarine telegraph, 169
Calculating wages, 595, 644
Calculus: 548, 596; integral and differential, 520, 547, 570
Calendar, compendious perpetual, 308
Caliper compasses, 16, 38, 97
Camera: lucida, 521; obscura, 646
Canada: piano in, 488; printing in, 568
Canadian watercourses, &c., 357
Canaries, 491
Canary's song, 207
Cancri, zeta, 183
Cane-sugar, analysing ash of, 182
Canine, 103, 129, 154
Canoe: 628, 671; voyage, 209, 598
Capillarity, 136
Capturing moths, 182
Carat, 45
Carbolic acid: as a hair-dye, 599; for preserving hides, 348; medicinal use of, 507
Carbon: coppering, 494, 518; fragrant bisulphide of, 656; preparation of, 672; pipes, 493
Carbonic: acid in atmosphere, 338, 413; acid in charcoal, 288; ink paper, 105
Cards, Ashworth's fine-pointed flattened wire, 250
Carmine staining, 258, 350
Carpenter, Dr.: and geometry, 664; and perspective, 89, 119, 152, 175, 200, 251, 306, 328, 383, 439; on chalk, 607; on oceanic circulation, 553
Carpenter's bench and tool-chest, 310
Carpet stretcher, 324
Carriage: lamp, economic, 565; wheels, improvements in, 226, 346; wheels, turning spokes of, 673
Cartoons, Raphael's, 289
Cart-wheels, tireing, 338, 363
Carving, 182
Case, violin, 569
Cask-stand, new, 349
Casting: brass solid, 102, 129, 180, 231; largest, 17; metal in airtight mould, 124; sand for, 102, 180
Castings: 148, 179; iron, 569, 599; microscope, 354, 411; small malleable, 470, 570
Cast-iron: column, sustaining power of, 287; properties of, 534; welding, 155
Castor, orbit of the double star, 377
Cast-steel chisels, tempering, 262, 287, 310, 387
Cataclysmo-mythology, "E. L. G." and, 171
Catalogues, 91
Catalytic action of spongy platinum, 439
Catarrh, relief for, 280
Catastrophe, an astronomical, 196
Caterpillars, preserving, 340, 364, 441
Cattle, weight of, 105
Caulking boats, 209
Caustic soda, 430
Caution about potatoes, 211
Cave explorations, 609
Cayenne: 389; pepper, adulteration of, 526
Cell, Leclanché, 388
Cells: pattern lead, 349; varnish, 598
Cement: for fixing glass letters, 181, 183; for Stourbridge clay fire-bricks, 77; for water, 23, 48; from sewage, 241; meerschaum, 156, 206, 281; on postage stamps, 649, 671
Cemented object-glasses, 300, 379
Cementing iron in wood, 235, 259
Cements, useful, 325
Centre: drill-chuck, 74; making, 23
Centre-points, 21
Centrifugal: force, 514, 536, 563, 621; pump, 470, 518, 569, 621
Certificate, chemists', 48, 77
Ceylon, books on, 23, 46
Chalk: Dr. Carpenter on, 607; for microscope, 521
Champagne stains, 19, 44
Changes of level in land and sea, 620, 663
Chapman, death of Mr. E. T., 439
Character of curve, 156
Charcoal: 286; carbonic acid in, 288; furnace for model boiler, 442, 467; pipes, 493
Charred manuscript, restoring, 89
Charts, weather, 27
Cheap farming, 415
Checkering tool, 495
Cheese, cream, 415
Chemical: 18, 19, 45, 78, 101, 131, 258, 288, 310, 339, 364, 387, 417, 469, 470, 493, 544, 569, 645; action, drying by, 269; compounds, definition of, 334; influence of solar light, 144; moisture-absorbing, 414; nomenclature, 632; new system of, 319; notes, 273, 430; physiology, 421; products, utilising, 365
Chemistry: 311, 339, 388; degrees in, 79; inorganic, 520, 547; lessons on, 2, 29, 84, 111, 214, 241, 396, 448, 578, 658; value of agricultural, 57
Chemists' certificate, 48, 77
Chemists: advanced, to, 340, 388; task for, 17, 157, 232; to, 673
Chess: 315, 546, 569; problems, 315, 342, 367, 393, 419, 445, 472, 497, 522, 550, 575, 601, 627, 652, 676
Chess-player: 443, 469, 492, 545; automaton, 546
Chest-expander, 389, 414
Chiding-stone, 312
Chignon, pathology of, 645
Child, provision for, 495
Children, photographing, 144
Children's concert, 19
Chimney: area of, 260; smoky, 261
Chimney-piece, repolishing, 517
Chinese white copper, 572, 596, 646
Chloride of lime, 336
Chlorine: 287; production of, 296, 404
Chloroforming bees to remove honey, 281, 284
Cholera, the, 482
Chromo-lithography, 570
Chronometer balance spring, 129, 206
Chuck: a traversing screw, 150; American lathe, 284; grip, 287, 338; oval, 206
Chucks, American, 495
Church, model of, 44, 179
Cider in wine, detecting, 185
Circular saw: driving, 259, 442, 467; spindle, 93
Circulation: of the blood, 18, 74, 127, 179, 205; influence of respiration on, 425; oceanic, 473, 499, 553, 567, 588, 603
Cistern, contents of, 287, 310, 362
Claret, 20
Clavicle, humerus, and new cranium, 255
Clean: pipe, 333; plates chemically, 236, 262, 309
Cleaning: feathers, 495; greasy wool, 482; jewellery, 340, 364, 516; oil-paintings, 233, 259, 548, 573; old engravings, 23; organ, 233; plain blue silk, 440; silk, 491; violoncello, 258
Climaxodus and new reptile tooth, 203
Clock: A 1, 40; cheap observatory, 40, 124, 641; first, who made the, 363, 387, 414, 441; rate, 638; sidereal, 171
Clock-line, turret, 410
Clocks: electric, 5; keeping dust from, 491
Cloth: cleaning scarlet, 131; pasting to maps, 572; restoring worn black, 23, 155, 180
Clothes, paper, 597
Clothes-horse, suspended, 13
Clouds, colours of, 383
Coaches, painting, 88
Coal: and domestic economy, 530; dear, how it may prove a benefit, 564, 620; economy in using, 463, 537, 565, 589; experimental borings for, 231; fossil plants, 565; getting, 648; in Ireland, 565, 645; stone, 408, 438; stores, and the atmosphere, 334, 385, 411, 437; supplies, 454, 619; waste of, 609; zinc v., 286
Coal cutting: by compressed air, 531; machinery, 140, 197
Coal-measures and coal supply, 167, 192
Coals, science in search of, 557
Cochineal: blue, 674; insects, 61, 413
Cocoa, 530
Coffee: 416, 467, 517, 530; syrup of, 61; testing, 482
Coil: battery, 391; construction, 361; defective, 157; induction, 339, 364, 488; medical, 597, 671; Rhumkorff's, 79
Coinage: aluminium, 482; decimal, 68
Coins, 46
Cold: deafness from, 387, 413; influence of on vegetable grains, 94, 126, 147, 178; wave of, 51
Colds in head, 235, 261, 285
Colliery: explosions, 14, 38, 65, 124, 177, 224; and weather, 276; pump for, 517
Collodio-bromide, 621
Collodion filter, Maynard's, 144
Colonies, the ENGLISH MECHANIC in the, 463
Colorado, 650, 672
Colour: 97, 149; blindness, 179; optical power as affecting perception of, 7; restoring to marble mantel-piece, 235
Coloured: ink, 391, 544; printing inks, 260; suns, 296, 358, 383, 436
Colouring: for outside work, 43; matter, extracting vegetable, 671; photos, 49, 79, 272; walls, 157
Colours: of the clouds, 383, 437; spectrum, 262, 286, 338, 362, 387
Column: our mathematical, 645; sustaining power of cast-iron, 440
Combs, steel, 441, 491
Combined tool, another, 99
Combustion, spontaneous, 70, 74, 98, 111, 127
Cometary: deluge, 326; orbits, 116
Cometic, 61
Comet: 536; "E. L. G.'s," 252, 303, 327; Noah's, who invented, 350; Roscoe's "hatful" of, 331
Comets, contact of, with the earth, 68, 91, 117
Coming struggle, the, 512
Commercial geography, 387
Compasses, caliper, 16, 38, 97
Competitive examinations, 38, 73, 121, 256
Complaint: spinal, 128; students' 200, 228
Composition for moulding, 208, 234
Compound: engine, 260, 361, 466; horse-power of marine, 258; eyepieces, 456
Compressed air: 649; as a motive power, 28, 384
Compressibility of the atmosphere, 151, 204, 358
Compressing: air, 548, 596, 646, 670; water, 157, 232, 258, 284, 308, 336
Concert, children's, 19
Concertina: English, 622; German, 493; repairing, 128
Concertinas, 153
Concrete: 467; building, 477; description of a, 617; engine beds, 467; moulds, coating wooden, 155; multiplication, 144, 199, 223, 282; proper manipulation of, 666; walls and buildings, 23, 47, 92, 277
Concretions, artificial so-called organic, 503
Condensation of steam in pipes, 410, 461, 513
Condensed milk, 633
Conductivity of copper wire, 133
Conductors: lightning, 14, 39, 69, 93, 120, 568, 620; gas and water-pipes as, 6
Cone pulleys, unequal sizes of, 468, 492
Confectionery: improved means of manufacturing, 199; sugar-boiling, &c., 13
Confusion in the head, 340, 388
Congratulatory, 61
Conic sections, 236, 262
Conjuring, magic and, 103
Connecting-rod, stub end for, 454
Conservatories, glazing, 147
Constellations, the ancient, 380, 411, 431
Constipation, 365, 390, 441, 467, 491, 517, 544
Constitution of nature, 429, 457, 478
Consumption, cause of, 371
Contact-breaker, defective, 208
Contact of liquids, 164
Contamination of water-supply, 141
Contents of cistern, 287, 310, 362
Contents of cylinders, calculating, 19, 75, 153
Continent, tour on the, 565
Continuous battery, 360
Cooking: by gas, 492; apparatus, economical, 613
Cool air in hot climates, 235, 261, 337
Co-operation, "E. L. G." and, 666
Co-operative: and other crudities, 667; societies and stores, 39, 96, 148, 178, 198, 357, 412, 465, 511, 540
Copper: assay, wet and dry, 99; gas-pipes, 51; mending, 182; precipitation of silver by, 613; Wallaroo, 258; wire, conductivity of, 133
Coppering carbon, 494, 518
Coppers, tin boxes to hold, 332
Corals: growth of, 676; "P. Santalinus" and his, 330
Core box, 624
Cork lock, 352
Cork-cutting machine, 309, 363
Corks, locking, 312
Cornet, four-valved, 670
Corn-screen, 310
Cornopean, cleaning, 157
Cornwall, botany of, 285, 309
Corpulence, 598, 623
Corpuscles of blood, white, 8
Corona, solar, 614, 639
Cosmical, 61
Cosmopolitan move, 51
Costless ventilation, 68
Co-stores, 617
Cottage hives, cheap super for, 462
Cotton-spinning, 234
Cough, whooping, 236, 262, 285
Counting envelopes, 597
Coupler, octave, 387
Covered: strings in pianos, 538; wire, 23, 45
Cover-plates, 365, 414
Crackers, detonating, 339
Crank, death of, 561, 642
Crater, wonderful, 359
Cream: cheese, 414; of tartar, 43
Creams, ice, 624
Creation, connecting links in natural history of, 14
Cricket: bats, 516, 571; cap, dye for, 365
Cricket-bat making, 622
Critical, 61
Critics, concerning certain (or uncertain), 380
Crossbow, 336
Cryolite, 23
Crystallised iron, 372
Crystals in gas tar, 129, 180, 231, 283, 307
Ctenodus, 488
Cube, duplication of the, 333
Cucumber culture, 434
Cultivation of grapes under glass, 399
Culture: cucumber, 434; fish, 596; of the grape, 547; potato, 66
Curing: bacon, 21, 75; skins, 20; sprats, 310
Curious: case of double refraction, 251; phenomenon, 62
Curl in peach, 441
Currency 21
Curry: 286; and rice, 183
Curve: character of, 156; of mirror, 672; sunrise and other, 98
Curving book edges, 573
Cut-nail works at Middlesbrough, 531
Cutler's wheels, 47
Cutter-bar, 668
Cutting: cylindrical glass, 626, 647; mounts, 45; press for paper, 442; screw 100, 104, 127, 224, 589, 644; tools, tempering, 155
Cyanide of potassium, 209, 234
Cylinder, double oscillating, 105
Cylindrical vessels, calculating contents of, 19, 75, 153
Cyrillus, Theophilus and, 147

DAISY extractor, 105, 180
Damp walls, 18, 74, 127, 312
Dandelion roots, 288, 312, 338, 340, 388
Danks's puddling machine, 110
Dark tent, portable, 365, 389
Darkening: graduations on scales, 625, 647; walnut, 206, 231, 283, 386
Darkness, life in, 15, 68
Darwin, "J. C." and, 385, 461
Darwinism, the "fallacies" of, 527, 591
Dates, table of, 44
Davis, analyses from Mr., 305
Day: and night telescope, 519, 546, 570, 645; length of sidereal, 23, 76
Deadening sound, 157, 182, 206
Deaf: and blind, 23; dog, 336, 413
Deafness arising from cold, 387, 413
Dear coal, how it may prove a benefit, 564, 620
Death: of an inventor, 166; of the crank, 561, 642; putrefaction after, 121
Debility, 182, 207, 233, 258, 284, 308, 336, 361, 466, 516
Decaying ivory carving, 208
Decimal: coinage, 68; system, 148
Decimalism, save us from, 36, 67
Decimalist, Herschel no, 96
Decimals and the decimal system, 113
Declination: of the sun, 70, 125; reduction of, 490
Decomposition of water: 638; by zinc, 32
Deep-sea: sounding lines, 606; water of, 289
Defaulting sovereigns, 57
Defective: battery, 182, 206; coil, 157; contact breaker, 208; feed pump, 183; organ, 40; plating solution, 44, 128; sewing-machine, 155, 516
Defects in harmoniums, some thoughts on, 359
Definition of chemical compounds, 334
Degrees in chemistry, 79
Deluge: 198, 229, 256, 304, 327; after "E. L. G." the, 223; cometary, 326; "E. L. G." and his pet, 277, 303; existing evidence of, 352; more proofs of, 304; one proof of, 175, 255; "Un Irlandais" and the, 276
Demerara, Georgetown, 19
Deliquescents, 625, 648
Dentistry, surgical, 364
Depths, star, 109, 140, 166, 190, 248
Dermestes, 336
Description of a concrete building, 617
Desert of Sahara, 182
Desiccation of wood, 1
Destroying aphides, 133
Detection of adulteration of articles of food, 525
Determining longitude, 224
Detonating crackers, 339
Diameter of screw, 516
Diamond: fields, 101; polishing, 387
Diamonds, recent discoveries of, 355
Diastase, 206
Dictionary of scientific terms, 624, 647
Diet, pork, 231, 283, 307, 360, 413, 466
Dimensions of mail-boats, 598, 623
Diminished action of battery, 417, 467
Directing posts, improved, 123, 173
Dirty mercury, 470, 493
Disappearance of art, 469, 518, 545
Disc, dividing metal, 48, 77, 101, 154, 180, 231
Discharge of water over weirs, 183, 208, 234
Discoveries of diamonds, recent, 355
Discovery: important, 60; of minor planet, 99, 143
Disease: rabbit, 286; silkworm, 157, 182; the potato, 653, 666; tobacco and, 9; wall papers and, 374
Diseases: lung, how produced, 427; zymotic, 130, 180
Disinfectant, new, 365
Disinfectants, 555
Disinfecting houses, 21, 75
Dispersion of seeds by the wind, 540
Disregard of theory in constructing opera-glasses, 595, 643
Dissolving bones, 491
Distances: judging, 515; of the stars, 300
Distant: objects, how we see, 16, 36, 94, 120, 174, 227; signals on Midland railway, alteration of, 541, 621, 667
Distillation: improvement in fractional, 377; of wood, 360
Distilled water, 79, 102
Distribution of animals and plants, 356
Divi-divi, nacascolo or, 124
Dividing metal disc, 48, 77, 101, 154, 180, 231
Doctors' Commons, 311
Dog: deaf, 336, 413; with weak sight 312
Dogs, fleas in, 600, 646
Domestic uses of ammonia, 140
Door handles of railway carriages, 150, 225
Dormoy's revolving rabble for puddling 213

Double: flowers, how to obtain from seed, 281; rockets, 415, 517; stars, new, 148, 201, 230, 274, 328, 355, 462, 485, 542, 567, 594, 614
Doubling frames, 44
Draconis (a): as the Pole-star, 171; recession and, 379
Draft holes in fireplaces, 362
Draining mines of water, 410, 515
Drains, house, 480
Drawing: boundary line, 47, 77, 101; from the microscope, 506; geometrical, 21
Drawings: copying, by electricity, 61; transferring pencil, 495, 599, 621
Dresser-top, 469
Dressing: jack line, 625, 647; kid, 155; dried yeast, 599
Drill, new rock, 588
Drill-chuck: American, 516; centre, 74
Drilling machine: 76, 151, 198; universal angular, 57
Drinking fountains, 445
Drinks, aerated: 21; machine for making, 546, 622, 670
Driving and transferring bees, 590
Driving-bands, 365
Drowning, 179, 206
Drunkards, tea, 209
Dry: soap, 544; steam, 157, 181, 232, 258, 284, 306, 360, 386, 413, 440, 466, 491, 544, 595
Dryer, a new, 482
Drying: by chemical action, 269; by steam, 598, 623; plants for herbarium, 281
Dubroni's photographic apparatus, 468
Duckweed, 47
Dugong oil, 465
Dumpy level, 103
Duodecimal: arithmetic, 118; system, 152
Duplication of the cube, 333
Durability: of framed timbers, 231; of textile fabrics, 220
Duration of boiler, 236
Durer's, Albert, engravings, 339
Dust: atmospheric, 5, 66, 92, 124, 147; in the spectroscope, 9, 66, 69, 97, 117; keeping from clocks, 491; Vesuvian, 637; workshop, 49
Duties: of assayer, 234, 259, 309; of farm estate agent, 153
Duty, succession, 183, 208, 233
Dwelling-houses, healthiest sites for, 51
Dye: black for leather, 599, 624; for cricket cap, 365; hair, 287, 310, 338, 595; scarlet, for silk and wool, 430
Dyeing: 544; parchment, 155; pulp for sugar paper, 443, 469; raw cotton, 390
Dynamic refrigerator, 428
Dynamite, experiments with in Italy, 522

E. and O. E., 105
"E. L. G.": 663; and cataclysmo-mythology, 171; and co-operation, 666; and geology, 119, 229, 254; and his pet deluge, 277, 303; after the deluge, 228; comet of, 252, 303, 327
Ears, sounds of the muscles and the, 485
Earth: ant-hill, 544; contact of comets with, 68, 91, 117; interior of, 638, 647, 662; lightning from the, 568, 620; weight of at creation and now, 200
Earthquakes and volcanoes, 193, 220, 271, 348, 374, 464
Earwig in ear, 178, 231
Ebdy's patent gas stove, 402, 483
Ebonising wood, 157, 181
Echo: 339, 363, 466; of sound on water, 468
Eclipse, the late solar, 7, 143, 249
Eclipses of sun as seen from Jupiter, 176
Economic carriage lamp, 565
Economical: cooking apparatus, 613; use of steam, 2
Economy: in using coals, 463, 530, 537, 565, 589, 643; of fuel and prevention of smoke, 59, 234; of fuel in steam navigation, 556; of small birds, 203, 252
Edible mushrooms of Italy, 510
Education: 357, 470, 493; and science, 356 in Saxony, 99; musical, 539; Science Department and scientific, 266; scientific, 67, 266; scientific report of the commission on, 343
Eels in paste, 23, 46
Effects: magic lantern, 418; of faults in visionon painting, 162; of increasing the superficies of soundboards in pianos, 382; of lightning, recent disastrous, 38
Eggs: blowing small birds', 490; hens', 417; number of, from a hen, 676; preserving, 156; preserving birds', 428; soft, 492
Elastic force, atmospheric, 279, 326
Elder flower: water, 548; wine, 493
Electric: bell, 48, 182, 207, 569; bell, anticipated, 258, 280; clocks, 5; kite, 364, 466; light, action of magnet on, 272; sparks, 17, 42, 62, 157, 199, 228, 256, 566
Electrical: 70, 74, 79, 126, 157, 182, 206, 235, 670: bells, anticipated, 253; machine, Holtz's, 90, 398; phenomenon, remarkable, 13, 68; signal bell, 361, 466
Electricity: 35, 389, 412, 414; applied to engraving, 65, 389, 441; atmospheric, 313; copying drawings by, 61; from steam boiler, 23; household, 148; influence of on liquids, 502; lamplighting by, 7; measuring temperatures by, 533, 558; surface, 32; vitality and, 391; what is it, 240, 279, 293, 302, 344
Electro-deposition: of iron, 180; of nickel, 216
Electrolysis, 230, 80
Electro-magnetic gaslighting apparatus, 385
Electro-metallurgy, 321, 395, 423, 501
Electro-motive force: 23; comparing, 543, 640; measurement of, 490; voltaic standard of, 404
Electro-plating, 262, 287
Electrotype: casting, 547; iron as an, 54
Electrotyping, 492, 519, 545, 569, 571, 621
Ellipsograph, 593
Embalming bodies by injection, 497
Emigration to San Francisco, 312
Employment for retired tradesman, 519, 546
Enamelling, 391
Encyclopædia, London, 441
Endorsing ink, 313
Energy: force and, 300; origin of volcanic, 404
Engine: 363; beds, concrete, 467; bisulphide of carbon, 140; compound, 258, 260, 361, 466; fuel for, 519; gun-cotton, 199, 223; horizontal, 45; horse-power of compound, 258; jacketed cylinder, 47; magnetic, 413, 466; non-packing and valveless, 593; power, foreign calculation of, 258; power of high pressure, 14; power of, 548, 596; pumps of portable, 23, 45, 76; query, 74, 127; rotary 462, 514, rotating valve for, 320; trunk, 207; varnish paint for, 364; waste of coal in the steam, 610; water pressure, 6
Engineer, marine, 153
Engineering inquiry, 519
Engineers, London Association of Foremen, 482
Engines, good and bad, 611
England: and New Zealand, time in, 74; history of, 102; in relation to music, 427
English: and American boilers, improvements in, 113, 138, 168; black v. Ligurian bees, 666; concertina, 622
ENGLISH MECHANIC: in the colonies, 463; in New Zealand, astronomy and, 11; lifeboat, 394; turners' society, 589, 641
Engraving: 182; by graphotype, 417, 442; electricity applied to, 365, 389, 441
Engravings: Albert Durer's, 339; cleaning old, 23; mildew in old, 127
Enlarging photographs, 496, 624
Entomological, 276, 305, 333, 354, 411, 496, 519
Entomologist's holiday, 187
Envelopes, counting, 597
"Eos," news from, 354
Equation: 49, 79, 102, 340, 364; of time, 490
Equations for formation of hydric sulphate, 22
Equatorial: adjustment of an, 116, 129, 154, 180; use and adjustments of, 551, 629
Equisetum, 156, 206, 232
Ermine fur, 45
Erratic meteor, 121
Errors in popular works professing to describe musical instruments, 176
Eruption of Vesuvius, recent, 272
Escape wheel, fastening in lever watch, 100, 152, 205, 283
Essays on Astronomy: 291; Proctor's 326
Essence: of phosphorus, 442; of wood smoke, 649
Etching: on glass, 287; on stone, 671; steel, 102
Euplectella, 541
Evaporation of water, 625, 647
Evidence: of star systems and drift, new, 369; of the deluge, existing, 352
Evolution and the human arm, 638
Examination: military, 262; question, 21, 76
Examinations: competitive, 38, 73, 121, 256; technological, 526
Excessive perspiration, 599, 646
Excitement, nervous, 650
Exhibited inventions, 670
Exhibition: this year's International, 255; Vienna universal, 659
Expander, chest, 389, 414
Expansion joints in steam pipes, 310
Expeditions to the North Pole, 194
Experimental borings for coal, 231
Experiments: brilliant, 34; with dynamite in Italy, 522
Explorations, cave, 609
Explosions: colliery, 14, 38, 124, 177, 224, 276; hydraulic, 596
Explosive: agents applied to industrial purposes, 249; strongest liquid, 19
Explosives, igniting point of, 481, 566
Extinct volcanoes, 66, 174
Extinction of fires, 598, 623
Extract of meat, 283
Extracting: glass stopper, 48, 77, 129; iodine from seaweed, 209, 234, 569; opium from poppies, 673; wax from old comb, 494
Extractor, daisy, 105, 180
Extracts of meat, 633
Eye query, 469
Eyebrows falling off, 208
Eyepiece, microscope as an, 430
Eyepieces: 513, 536, 562; compound, 546; solar, 328

"F. R. A. S.": geo-mythology and, 146; Jupiter's satellites and, 62
Fabric, making gold and silver leaf adhere to, 258
Faces, spirit, 33
Faculæ, solar, 302
Fairbairn's ventilating bucket, 234, 259
Fairlie locomotive, 41, 96, 151, 199
Faith, sight, and mythology, 200
Fall of a bullet, 493, 541, 567, 619
Fallacies of Darwinism, 527, 591
False hair, 194
Fanlight, staining, 673
Faraday: lecture, 378; Michael, 452
Farm estate agent's duties, 153
Farmer, want of observation in the, 59
Farming, cheap, 415
Fastenings for watchchains, 530
Feathered tribes, our summer visitors of, 196
Feathers, cleaning, 495
Feed-pump, defective, 183
Feed-water heater, Bell's, 55
Feeders, organ, 16, 40
Feeding: bees, 642; pig, 442, 492
Felspar, 23, 46
Felt hats, 340, 364
Fenugreek, 541
Fermenting bread with starch, 621
Fern printing on white wood, 127
Ferns, 79, 104
Ferrules, brazing fishing-rod, 101
Fettling materials, 517
Fever tree, 157
Fiddle, the "Harmonious Blacksmith's" new, 274, 302
Fiddler's violin reflector, 465
Fiddles: and Fiddlers, 672; on, 354, 409, 463, 487, 650
Field glasses, 536
Fields, diamond, 101
Fifteen schoolgirls, problem of, 13
Filter: cheap water, 87, 235, 309; Maynard's collodion, 144
Filtering water, 311
Finding the meridian, 430
Fire-balloons, 154
Firebars, 389
Firedamp, prevention of, 268
Fire-engine: a new, 31; steam, 156
Fire-engines, 313, 387
Fire-marks on silver goods, 625
Fireplaces, draft holes in, 362
Fireproof deed boxes, sheet-iron, 569
Fires, extinction of, 598, 623
First: railway, 416; watch and clock made, 363, 387, 414, 441
Fish: 387; culture, 596
Fishes: air-bladder in, 13, 73; colour of, 613
Fishing: socks, waterproof, 441; worms for, 311
Fishing-rod ferrules, brazing, 101
Fishponds, puddling, 672
Five-octave pianofortes, 382
Fixative for down of Lepidoptera, 462
Fixing: bloom of scarlet runners, 599; dyeing and, 312; photo. prints, 673
Flame, hydrogen, 365, 391, 441
Flame, sensitive, 217
Flatting, 571
Flavour of butter, 350
Fleas in dogs, 600, 646
Fleming's locking corks, 312
Flexible: marble, 211; oil-painting 231; rendering new rope, 415; varnish for leather, 572, 596
Flight of birds, 121
Floats: water-level, 156; water-wheel, 598
Floor of Plato, 661
Florentine bronze, 155
Florida, productions of, 51
Flour, tests for, 597
Flow of water, 16
Flowers: double, how to obtain from seed, 281; odour of, 676; skeleton, 599
Flues, greenhouse, 562
Fluid: cosmic, Dr. Le Plongeon on, 281; lens for photography, 521, 571; meat, 299
Fluoresence, 165
Fly: green, 183, 208, 233, 259; house, 572, 646
Flywheel: 254; radius and weight of, 45
Focal length, and magnifying power of object-glasses, 453; of lenses, 338, 362
Focus of a lens, 300
Fogging, 91
Food: adulteration of, 347; analysis, 467; for rabbits, 43; supply, our, 90; supply, and the sewage question, 397
Footwalks, improved method of laying, 379
Force: and energy, 300; centrifugal, 514, 536, 563, 621; electromotive, 23, 543, 640; measurement of electromotive, 490; new mode of converting mechanical into its heat equivalent, 280; of gravity at surface of earth, 514; storing and transmitting by compressed air, 384
Force-pump, portable, 516
Forces, parallelogram of, 515, 536, 561, 641
Forcing-pan, lamp for, 128
Foreign woods, 262
Forests: and rainfall, 339, 363; submerged, 598
Fork and wedge motion, 100
Formation of ozone, 133
Formula, 493
"Fossil": man, 478, 638; plants, coal, 565
Fountains, drinking, 445
Four-valved cornet, 670
Four-wheeled vehicles, 153
Fowling punt, 46
Foxes, scaring, 21
Fragrant bisulphide of carbon, 656
Frame, tambour, 516
Frames, doubling, 44
Framing, picture, 572, 596
France, insanity in, 51
Freemasonry, 442
Freezing, how a man feels when, 59
French: magazine, 391; polishing, 75
Fresh-water aquarium, 156, 206
Fret-saw, 645; fastening, 338
Fruit: and grape wine, 211; puddings, 465; syrups, 195, 516
Fuchsias: 648, 671; geraniums and, 415, 467
Fuel: economy of, 59, 234, 556; for steam-engine, 519; for the winter, 594; in Italy, 588
Full moons in advance, a few, 638, 673
Fumes from gasworks, 262
Funnels, abolition of, 368
Fur: ermine, 45; moth v., 19, 44
Furnace: for heating wheel-tires, 541; spring, 571
Furnace-shaft, removing bodily, 143
Furnaces, revolving, 151, 174, 305
Furniture polish, 157
Fused chloride of silver, 649, 671
Fusion of arsenic, 613

GALES, auroræ boreales and, 644
Galvanic: battery, powerful, 490; cell, new form of, 170
Galvanometer, 49, 78
Gamboge, 386
Garden: gate, 46; models, 623; produce, preserving, 442; stuff, 121
Gas: 79, 103, 157, 520, 548, 571, 672; and water pipes as lightning-conductors, 6; burners, 183, 208; cheap, 547; cooking by, 492; detecting sulphur in, 107; heating by, 349; purification, 404; sewer, 41; stove, Ebdy's patent, 402, 483; tank, 47; tar, crystals in, 129, 180, 231, 283, 307; warming greenhouses with, 387, 441
Gaslighting: automatic, 325, 556; electro-magnetic apparatus for, 385
Gas-pipe, threads in, 519
Gas-pipes, copper, 51
Gassendi, 177, 277, 406, 437, 540; central hills in, 485
Gasworks: fumes from, 262; scrubber for, 235
Gate, garden, 46
Gauge for bit braces, 325
Gauges, battle of the, 654
Gearing waggon-wheels, 43, 469, 518
Gelatine: 195; moulds for plaster ornaments, 286
Geocentric longitude, 48, 101
Geography, commercial, 387
Geological distribution of goitre, 638
Geology: atmospheric, 580; "E. L. G." and, 119, 229, 254; in relation to plant life, 142; progress of, 114, 141, 167, 192
Geometrical: 443, 648, 649, 671; approximation, 359; drawing, 21; question, 79, 103
Geometry: 546, 570, 622, 645, 670; Dr. Carpenter and, 664; geometry of, 113; 355, pure, 306
Geo-mythology, "F.R.A.S." and, 146
Georgetown, Demerara, 19
Geraniums and fuchsias, 415, 467
Germ theory, the, 350
German: concertina, 493; North Pole expedition, 111
Giant planet, a, 244, 283, 384, 405, 431, 482, 508, 542, 595, 614, 640
Gig apron, indiarubber, 362
Gilding: 168; on glass, 74; strips of wood, 146, 283; thin steel, 19
Ginger: adulterations of, 525; beer, 648; aerated, 671
Glass: action of sunlight on, 613; blowing, 364, 387; cutting cylindrical, 623, 647; etching on, 287; fastening vulcanite cells to, 21; gilding on, 74; granite, 248; lettering on, 248; letters, cement for fixing, 181, 183; ornamental designs on, 248; polishing edges of, 516; refractive index of, 105; sun-screens, 273; water, 207
Glazing: brick and tile, 572; conservatories, 147; improved method of, 38, 98, 124
Gleanings, British Association, 613, 677
Globe: is the interior a vacuum, 635, 638, 647; size and speed rate of, 649
Glorious metric system, 12
Glove cleaning, 286
Gloves: spotted kid, 20, 548; sting-proof, 258
Glowworms, 517
Glue: liquid, 51; another, 489
Glues, 597
Glycerine, lime-juice and, 157, 181, 261, 309
Glycogen, formation of in liver, 278
Gnats, 622
Goitre, geological distribution of, 638
Golail or Indian pellet bow, 254, 386, 434
Gold: fixing leaf to fabrics, 158, 258; leaf, laying, 168; making malleable, 258; polishing on stone, 156; quartz, 361, 388
Gold-beating, 262
Goldfish, 156
Goods traffic, separate railways for, 541
Gooseberries, preserving, 496
Gosse's "Omphalos," 255, 274
Government: and amateur science, 252, 334; schools, 670; scientific expedition, 8
Governor: Allen's patent, 373; Simmonds', 33; Trotman's hydraulic, 581
Grafting, budding or, 491
Grailing, spiral, 34, 94
Grain: protector, anti-mildew, 273; storing 439
Granite: glass, 248; polishing, 19, 74
Granulated gold, 222
Grape culture, 547
Grapes: cultivation of under glass, packing, 596, 623
Graphite batteries, 667
Graphotype, engraving by, 417, 442
Gravel for aquarium, 623

Gravitation: 48, 78, 116; and repulsion, 197; "T. A." and, 197, 250: terrestrial, 17, 18, 36, 74, 97, 119, 144, 172, 201, 205, 228
Gravity, action of, 616
Gravity, force of at and near surface of earth, 514
Grease: in billiard cloths, 368; on leather bands, 645
Greasy strapping, 517
Greek upsilon, 21, 75, 128, 153
Green: fly, 183, 208, 233, 259; peas, preserving, 496
Greenheart timber, 312, 339
Greenhouse: "English Mechanic," 620; flues, 562; hints on the construction of, 538, 592, 620
Greenhouses: warming, 206, 232, 592, 644; with gas, 387, 441
Grinding turning tools, 332
Grip chuck, 287, 338
Grove's cell, 623
Growth of corals, 676
Guano, what is it? 5
Gulf stream: 537, 558; and map projections, 662; map, Mr. Proctor's, 566, 588
Gum, artificial, 209
Gums, 182
Gun: another disabled, 676; barrel, wonderful, 33, 856; barrels, blacking, 179; communicating rotary motion to ball fired from smooth-bore, 123, 148, 171, 196, 227, 231, 253, 283
Gun-cotton engine, 199, 223
Gunpowder, making, 22
Guns: greatly elongated projectiles for rifled, 515, 565; on the rifling of great, 331, 385
Gut: lines, 183; speeding pulleys for, 415, 467
Guttapercha, a new, 14
Gyro pigeon, 222
Gyroscope: 563, 616; properties of the, 582, 642
Gyroscopes, spinning tops and, 326, 353, 381, 412, 460, 484, 486, 509, 542, 642
Gyroscopic mysteries, 664

HADDOCKS, rizart, 107
Hair: 392, 417, 442, 467, 517; auburn, 623; dye, 287, 310, 338, 595; false, 194; turning white, 491
Hairsprings, 569, 621, 667
Hair-wash, 209, 234, 259, 284, 337
Hammer, tilt, 128, 179, 231
Hams, spoiled, 631
Hand pad, 649
Hand-railing, 671
Handles for sash tools, 105
Hands, using book without, 19, 44, 74, 127, 224, 253, 280
Harbour scheme for Calais, 231
Hard: water, 365, 389, 414; woods, mortices in, 74, 205
Hardening: iron plates, 231; lead or zinc type, 517; spiral springs, 495, 519; steel shafts, 517; teeth, 547
Haricots verts en salade, 107
Hark back, 508
Harmonicon: metallic, 79, 103, 154, 206, 258; pianos, 125
"Harmonious Blacksmith's": funny first fiddle, 274, 302; to, 152
Harmonium: 105, 154, 434; holes in valve-board of, 545; keys, 672; pedal, 262, 310; reeds, 324; stops, 311
Harmoniums, thoughts on defects in, 359
Harp: 354, 409, 463, 489, 510, 566, 625, 668; improved Æolian, 540
Harvest moon, 536
Hat, brown, 180
Hats, felt, 340, 364
Hay asthma, 571, 622, 646, 670
Hayti, island of, 571, 622
Head: colds in, 235, 261, 285; confusion in the, 340, 388
Healing wounds, simple method of, 302
Health, labour and, 393
Healthiest sites for dwelling-houses, 51
Healthy and comfortable houses, 577
Heart disease, increase of, 33
Heat: action of on primitive forms of life, 33; bumps, 599; equivalent, new mode of converting mechanical force into its, 280; generated by meteors, 352; mechanical equivalent of, British Association and the, 664; of brick-kilns, 75; of Mars, 430
Heating: apparatus, hot-water, 632; bar iron, 258; by gas, 349; by hot air, 513, 619; greenhouse, 644; house, 261; of railway carriages, 87; steel, 376
Hebrews, the semi-barbarous, 352
Hedgehog, 287
Height: of mountain, finding, 688, 648, 671; of sea-waves, 171, 183; of Swiss mountains, 21
Hen, number of eggs from a, 676
Hens' eggs, 417
Herbarium, drying plants for, 261
Herbs, 389
Herodotus, Aristarchus and, 406
Herschel: no decimalist, 96; Sir J., on the metric system, 36
Hides, carbolic acid for preserving, 348
High-pressure firebox boiler, 417, 467, 517
Hills, turret-shaped, 19
Himmer's galvanic battery, 118, 175
Hints: on colouring photographs, 272; on metricalism, 37; on painting, 66, 168, 248; on the construction of greenhouses, 538, 592, 620; on using blasting powder, 393
Historical notes on poisoning, 458, 504
History: of England, 102; of the pianoforte, brief contribution to the early,
Hives, cheap super for cottage, 488, 540
Hoist, light shifting, 572, 622
Holiday, entomologist's, 187
Hollis observing seat, 146, 225
Holly: walking-sticks, 47; wood, 19, 261, 387
Holtz's induction machine, 48, 90, 398, 646
Honey, chloroforming bees to remove, 281, 284
Honeydew, production of, 114, 178
Hoofs, horses, 625
Hops and slops, 484
Horizontal engine, 45
Horn, 621
Horns, polishing bullocks', 207, 259
Horsehair, 235
Horse-power 332; nominal, 188, 195
Horses' hoofs, 625
Horticultural jottings, 148
Hot: air, heating by, 513, 619; climates, cool air in, 235, 261, 285, 337; peas, 313, 339; soldering iron, 312; water heating apparatus, 632; water tanks, zinc for, 547
Hothouse boiler, 364, 388, 467
House: disinfecting, 21, 76; drains, 490; fly, 572, 646; heating, 261; painting, 494, 621; plants, a plea for, 42; wooden, at North Tawton, 568
Household electricity, 148
Houses: Canadian, 357; healthy and comfortable, 577; timber, 389, 441, 568
How we see distant objects, 16, 94, 120, 227, 278
Howe sewing-machine, 329
Human relics, 236, 285
Humea elegans, 337, 387
Hundredweight, theory of, "Philo's," 94
Hyacinth bulbs, 443, 469
Hydraulic: 443, 492, 518, 569, 645; explosions, 598; governor, Trotman's, 581; machine for blowing organs, 648; press, 286, 310; rams, 207
Hydric sulphate, equations for forming, 22
Hydrofluoric acid, manufacture of, 430
Hydrogen: flame, 365, 391, 441; certain phenomena associated with, 247; lamp, 365
Hydrophobia, 540
Hygrometer: 573, 596; motive power, 362
Hypochlorites, production of, 296

ICE: 600; and water, temperature of, 209; creams, 624, 647, 670
Iceland spar, 569
Ice-making, 441
Igniting point of explosives, 481, 566
Illuminated sign, 47
Imitation: bronze, 362, 493, 518; marbles, 100
Immersed substances, friction of, 613
Improvements: in omnibuses, 616; in photography, 582
Incidence, angle of reflection and, 17, 100, 152, 204, 231, 283, 307, 440
Incombustible, rendering wood, 207, 233, 259
Income-tax, 157
Increase of heart disease, 33
Incrustation: boiler, 481, 493, 645; tannate of soda in boiler, 439
Incubator, 101, 153, 229, 281, 355, 404, 436
Indian method of boiling rice, 107
Indiarubber: boring and cutting, 676; bottle, leaking, 671; gig apron, 362, overcoat, 130, 155; stretched, 308
Indicator, level and angle, 61
Indigestion, 519
Indigo, recovering, 470
Indigotine, pure, 430
Induction: coil, 339, 364, 488; machine, Holtz's, 48
Industrial: classes in Brazil, 88; uses of magnesia, 32
Inflammable oils, 445
Influence: of cold on vegetable grains, 94, 126, 147, 178; of light on plant and animal life, 577, 605, 669; of planets on solar activity, 33
Injury to vacuum tubes, 157
Ink: 208; brown, 183; endorsing, 313; marking, 625; powders, 183; printers' 130, 154, 390
Inks, coloured, 544
Inland navigation, 252
Inorganic chemistry, 520, 547
Insanity in France, 51
Inscriptions, rock, 44, 157, 182, 233
Insect: beds, lias, 45; metamorphosis, 659
Insects: arrangement and preservation of, 265; cochineal, 61; in tables and chairs, 312, 362, 387
Instinct, 397, 608
Instrument for measuring light for photography, 312
Instruments: ancient musical, 324, 384, 568; strange and rare musical, 223, 257, 274; tuning keyed, 618, 643; tuning musical, 567
Integral and differential calculus, 520, 547, 570
Interior of the earth a vacuum? 638, 647, 662, 671
Internal resistance, 301, 359, 412, 566
International Exhibition, this year's, 255
Intonation, on, 667
Inventions: American and Scotch, 119; exhibited, 670; of Stephenson, the alleged, 225
Inventor, death of an, 166
Iodine, extracting from seaweed, 209, 234, 569
Ireland: coal in, 565, 645; raised beach in, 638; trip to, 339, 363
Iris or rainbow, the, 573, 596
Iron: ancient wrought, 518; and steel, metallurgy of, 28, 54, 85, 110, 135, 163; as an electrotype, 54; barges, 111; castings, 569, 599; cementing in wood, 235; columns, breaking strain of, 78, 102; crystallised, 372; electro-deposition of, 180; meteoric, 613; ores, removing phosphorus from, 220; painting bedstead, 386, 440; phosphorus in, 8; plates, hardening, 231; purification of, 441; separating from brass, 127; sheet, protecting from rust, 349; soldering, 75; stains in oak, 23, 47; tool, size of, 414, 467; vat, rust in, 18, 100; vats leaking with one liquid and not with another, 545
Irradiation: 528; photographic, 377
Is: light invisible? 280, 303; the moon spherical? 513
Island of Hayti, 571, 622
Isochronism, watchmaking and, 17, 179
Italy: edible mushrooms of, 510; fuel in, 588
Ivory: carving decaying, 208; turning, 416

"J. K. P.," to, 209
"Jack of all Trades," to, 263, 281, 310, 513, 650
Jacket, steam, the, 59
Jacketed cylinder engine, 47
Jamaica, 99
Japan, 613
Jewellery: cleaning, 340, 364, 516; soldering, 337
Joints, expansion, in steam-pipes, 310
Jottings, horticultural, 148
Judging distances, 515
Jupiter: 411, 664; eclipses of sun as seen from, 176; something wrong with, 223; temperature of, 274
Jupiter's satellites: 9, 40, 76, 116, 249, 377; and "F.R.A.S," 62; something wrong with, 223

KEROSENE, 418
Key, pianoforte tuning, 540
Keyed instruments, tuning, 618, 643
Keys, harmonium, 672
Kid, dressing, 155
Kid gloves, spotted, 20
Killing: beetles, 79, 102, 129, 180; roots of trees, 157, 182, 568
Kind-chandron system of shaft-sinking, 7
King-numbers, 65, 123, 173
King's Cliffe, turners and turnery of, 402
Kitchen chairs, red stain and polish for, 128
Kite, electric, 364, 466
Kites, 624, 647
Knight's tour, 546
Knitting and sewing machine, combined, 269
Knives, tempering, 258
Knott, to Mr., 208
Koumiss, 250

LABORATORIES, photographic, 477
Laboratory purification, 648, 671
Labour and health, 393
Lacquer: 646; black, 387; optician's, 208
Lacquering brasswork, 43, 547
Lakes, boiling, 42
Lamp: for forcing-pan, 128; hydrogen, 365
Lampblack, 624
Lamplighting by electricity, 7
Lamps, paraffin-oil, 350
Land: and sea, changes of level in, 620, 663; surveying, 547
Language: Portuguese, 441, 492; Spanish, 673
Lantern pinions, 21, 44, 101, 125, 205
Lapidary's wheel, 597
Largest casting, 17
Larvæ, 305
Lathe: and its accessories, 72; chuck, 130; chuck, American, 284; construction, 619; four-in. centre, 48; head mandril, 288; queries, 130, 235, 260, 285; setting, 48, 129, 154, 180, 670; tools, steel for, 102; Whitworth, 204
Laths, bending, 519
Launch, steam, 17
Law of vibration and attraction throughout the universe, 382
Lead: in sulphuric acid, 392, 416; pipes, 183
Leaking indiarubber bottle, 671
Leaky: tap, 311, 362; tubes, 389, 414
Leather: bands, grease on, 645; black dye for, 599, 624, 670; flexible varnish for, 572; machine, 649; marking for ornamental stitching, 231; staining, 545; waterproof, 133
Leaves: machine to cut, 362; nature printed, 569, 595
Leclanché cell, 288
Left-hand screw, cutting a, 224
Legs, artificial, 71, 75
Lemon marmalade, 129, 180
Lemonade syrup, 183, 207
Length of sidereal day, 23, 45, 76
Lens: Barlow, 223; fluid for photography, 521; focus of, 300; photo., 206, 338
Lenses: 120; focal length of, 338, 362; liquid, 377; silvering the surfaces of field, 204
Leroy's non-conducting composition, 568
Lessons on chemistry, 2, 29, 84, 111, 214, 241, 396, 448, 578, 658
Lettering backs of books, 102
Level: and angle indicator, 61; dumpy, 105; of railway curve, 312
Levels, circular brass box, 78
Levelling, 415
Lever escapement, 649
Lias insect beds, 45
Libraries, 650, 673
Libration, moon's, 661
Liebreich, Dr., and Turner, 203
Life: action of heat and various chemical agents on the primitive forms of, 33; development of protoplasmic and fungus, 89; in darkness, 15, 68; influence of light on animal and plant, 577, 605; protoplasmic, 72
Lifeboat, ENGLISH MECHANIC, 394, 461
Life-cycle of a false wasp, 660
Lifting water, 47, 77
Light: 391, 416, 470, 498; and animal life, 605, 669; for middle of room, 77; influence of on plant life, 577; is it invisible? 280, 303; measuring amount of, 362; oxyhydric, 126, 588, 657; science, 379; smoke and, 573, 638; undulatory theory of, 300; velocity of rays of, 23; wanted, more, 496
Lighthouses, 517
Lightning, 147, 466, 568; and thunder, 598, 650, 673; disastrous effects of, 358; from the earth, 568, 620; speed of, 364; thunderbolts and, 271
Lightning-conductors: 14, 39, 69, 93, 120, 568, 620; gas and water-pipes as, 6
Lights, magnesium, 79
Ligurian bees, 232, 511; English black v., 666
Lime, chloride of, 386
Lime-juice and glycerine, 157, 181, 261, 309
Lime or electric-light for magic lantern, 365, 390
Limits of resistance of telegraph wires, 48, 93
Line: dressing jack, 647; shaft, 103
Lines, gut, 183
Link-motion, 176
Linseed, 48, 77
Lint, 146, 181
Liquid: explosive, strongest, 19; glue, 51, 489; lenses, 377; solid and, 389
Liquids: contact of, 164; influence of electricity on, 502
Liquor, ammoniacal, 673
Lithography, chromo, 570
Liver, formation of glycogen in, 273
Lock: cork, 352; needle, 441, 491, 516, 568; nuts and washers, 454; Samels' patent standard, 195; secret spring or, 416
Locking-corks, Fleming's, 312
Locomotive: performance of, 195; the Fairlie, 41, 96, 151, 199; tubes, old, 340, 388, 517
Locomotives: 443; road, 133; washing out boilers of, 377
Locust, remarkable, 209
Logarithms: 78, 468; reductions by *Nautical Almanac* method and by proportional, 508; Vlacq's tables of, 249
London: association of Foremen Engineers, 482; B. Sc. of, 441; blackbeetles, 209, 260; Encyclopædia, 441; museums of, 475, 553, 630; ordnance map of, 313, 339
Long and short rifles, 157
Longitude: 274; chronographic determination of, 7; determining, 224; discovering at sea by the moon and fixed stars, 119; geocentric, 48, 101; of the sun, mean, 258; solar, 171
Losses, national, 494
Loudness of pianoforte trebles, practical methods of increasing the, 301
Lowdon, Mr., at sea, 171
Lubricating oils, testing, 18, 100
Lunar: atmosphere, 662; maps, 91; meteorology, 53, 120, 632, 640; motions 638; objects for observation, 40, 119 253, 381, 436, 563, 662
Lung diseases, how produced, 427
Lyra, ring-nebula in, 614
Lyræ: 57 M., 638

"M. R. C. S.," on ventilating, 196
Machine: aërated breadmaking, 25; aërated drinks making, 380, 546, 622, 670; boot cleaning, 520, 547; boring and mortising, 216; cork cutting, 309; Danks' puddling, 110; drilling, 2, 151, 198; Holtz electrical, 90, 398, 646; leather, 649; magneto-electric 303; monster magnetic, 49, 262; moulding, Scott's patent, 156; mowing, 48, 571, 622; punching, improved, 371; punching and shearing, 23, 261; sad papering, 246; saw-sharpening and gulleting, 127; tenoning, 476; to cut leaves, 32; universal angular drilling, 57; wheel-cutting, small, 131, 16
Machinery: coal-cutting, 140, 197; speeding, 183, 207, 233, 284
Machines: puddling, 83; mathematical, 520, 571, 622; wire-covering, 268, 381, 407, 433
Mackenzie's torch lightener, 40
Madeira, 18, 74
Madnip and wood laurel, 45
Magazine, French, 391
Magic and conjuring, 103
Magic-lantern: effects, 413; japanning 387; lime-light or electric light for 365, 390; sheet, 44; slides, painting 248
Magnesia, industrial uses of, 32
Magnesium: 674; lights, 9
Magnet: action of an electric light, 272
Magnetic: 70, 209, 260; engine, Paine, 306; machine, monster, 49, 262; movement, 339, 387, 414, 49
Magnetine, or improved skeuasma, 59
Magnetism: 229, 235, 299; atmospheric electricity and, 313
Magneto-electric machine, 303
Magnitudes, star, 116

Mahogany, polishing, 75
Mail boats, dimensions of, 598, 628
Maine power, 543
Mainsprings, adjusting, 209, 641
Maize, potash from, 273
Malleable: castings, small, 470, 570; making gold, 231
Mamertus and French volcanoes, 279
Man: antiquity of, 514; primitive condition of, 666; the "fossil," 478, 638
Management: and construction of boilers, 13; of bees, 32, 158, 224, 335, 494, 590, 642
Mance's method of measuring internal resistance of cell, 276, 301
Manchester Steam Users' Association, 530
Mandril, lathe head, 288
Manganese battery, 496
Mangle, 390
Manifestations, more "psychic," 58, 175
Manipulation of concrete, the proper, 666
Manufacture: of blacklead, 569; of textile fabrics at Pompeii, 506
Manufactures, and scientific research, British, 345
Manure, bones as, 306
Manures: agricultural, 218; and their values, 130, 155; artificial, 209, 381, 438, 465, 512
Manuscript, restoring charred, 88
Map: Mr. Proctor's Gulf-stream, 566, 588, 662; projections, 662
Maple veneers, 648
Maps: lunar, 91; star, 9; weather, 450; pasting cloth to, 572
Marble: busts, 102; flexible, 211; inlaid table, design for, 673; mantelpiece, restoring colour to, 235; paper, transferring to book edges, 416
Marbled edges, varnish for, 573
Marbles, imitation, 100
Marine: aquarium, 589, 644; engineer, 153
Marking-ink, 625
Markings, planetary, 377
Marmalade: lemon, 129, 180; orange, 107
Mars, heat of, 430
Marseilles soap, 79
Marsh mallow for hardening plaster of Paris, 281
Martini rifle, 650
Mastery system, the, 11
Matches, Bryant & May's, 387, 466
Material: for bricks, 372; for roads, 45
Mathematical: 152, 307, 548, 571; column, our, 645, 669; machines and tables, 520, 571, 622; problems, 566
Matter and force, 586
May, ants in Isle of, 359
Measurement of waves, 606
Measuring temperatures by electricity, 533, 558
Meat: Australian, 38, 62, 126, 178; extract, of, 283, 633; fluid, 299; preserved, 79, 633
Mechanical: equivalent of heat, the British Association and, 664; force, new mode of converting into its heat equivalent, 280
Mechanics, practical, 469, 518
Mechanism, 375, 401, 428, 455, 479, 507, 532, 554, 583, 609, 633, 660
Medical: 131, 157; coil, 597, 648, 671; discovery, Whitlaw's, 45
Medicinal use of carbolic acid, 507
Medicine, positive philosophy and, 139
Meerschaum: 301; pipes, 156, 206, 281, 284; pipes, silver tubes for, 102
Memoirs of R. A. S., 480
Memory, improving, 208
Mercurial vapour, 40, 119
Mercury: 545; dirty, 470, 493; purifying, 469
Meridian, finding the, 430, 442
Metal: casting in air-tight mould, 124; leaf printing on silk and cotton, 672; mines regulation bill, 68
Metallic: harmonicon, 79, 103, 154, 206, 258; stain for wood, 493
Metallurgy of iron and steel, 28, 54, 85, 135, 163
Metals: coating oxidisable, 61; of New South Wales, 589; photo. engraving on, 217; railway, 597; tests for, 18; weight of per foot, 44; working in, 230
Metamorphosis, insect, 659
Meteor: 408; an erratic, 121
Meteoric iron, 612
Meteorites: 137
Meteorological: conferences, 35; office, and atmospheric waves, 37
Meteorology: lunar, 53, 120, 632, 640; progress of, 320
Meteors: August, 542, 614, 640, 662; comets, &c., 79, 377; heat generated by, 352
Method: of making a left screw with a right screw plate, 172; of obtaining stearic and palmitic acids, new, 608
Metric system: 69, 117, 118; glorious, 12; in Austria, 179; Sir J. Herschel on, 36; the pound and the, 144
Metricalism, some hints on, 87
Metropolitan crater of the moon, 91
Mice eating peas, 390, 441, 491
Micrometer: double image, 7; eyepiece, proposed universal, 543
Microscope, 263, 282, 310; as an eyepiece, 430; castings, 354, 411, 437; chalk for, 521; drawing from the, 506
Microscopes, proposed universal standard micrometer eyepiece, for, 543
Microscopic: deposit on bricks, 128; objects, black varnish for, 440; objects, cabinets for, 307
Microscopical: 203, 224; cabinets, 218; notes, 8, 56, 162, 349
Microscopists, prizes for amateur, 8
Mildew: in boat sails, 207; in old engravings, 127
Military examination, 262
Milk: condensed, 633; correct weight of, 393, 406
Mill, tidal, 183
Millers, to, 310, 362
Miners, new safety-lamp for, 217, 275, 333, 658
Mines: draining water from, 410, 515; waste of coal in, 610
Mira Ceti, 638
Mirage, a lecture experiment on, 613
Mirror: curve of, 672; for telescope, silvering, 388
Mistletoe berries, 42
Mode of washing, new, 143
Model: of church, 44, 179; steamboat, 105, 208
Models, garden, 625
Moisture: chemicals that absorb, 414; on tin surface, 624
Moment, magnetic, 339, 387, 414, 491
Momentum, 416
Monkey nut, 414
Monolithic building, and Brannon's system of, 360, 408, 409, 461, 483, 542, 663
Monochord with soundboard, and other musical string testing machines, 618
Months, republican, 571, 640
Moon: 156, 614, 661; axis of, 9, 40; full, 673; harvest, 536; in pictures, &c., 560; is it spherical? 513, 540, 566; libration of, 661; metropolitan crater of, 91; rising and setting of, 44, 74
Moons, a few full, 638, 673
Moonlight nights, telescopic work for, 73, 291
Moonrise, 633
More light wanted, 496
Morning sunset, a, 436, 465, 486
Morse, Prof., 143
Mortices in hard woods, 74, 128, 205
Moth: in piano, 598; v. fur, 19, 44; wax 547, 570
Moths: 469, 493, 519; capturing, 182; preserving, 235, 260; setting-out butterflies and, 434, 589
Motion, fork and wedge, 100; new method of changing reciprocating into rotary, 484, 537, 593; of sailing boat, 649, 671
Motion, lunar, 638
Motive power: compressed air as, 28; for amateurs, 105, 129, 154, 206, 258, 283, 336; for hygrometers, 362
Movement, vital, 638
Moulding: brass, 645; composition for, 208, 234; machine, Scott's patent, 156
Mountains: finding height of, 638, 648, 671; volcanic, 42
Mounting small objects in balsam, 411
Mounts, cutting, 45
Mowing machine, 548, 571, 622
Much experience in few words, 250
Multiplication: concrete, 145, 199, 223, 282; method of, 62
Muscles and ears, sounds of, 485
Musette and voix celeste stops, 17
Museums of London, 475, 553, 630
Mushrooms, edible, of Italy, 510
Music: copying, 364; England in relation to, 427; examinations, Society of Arts', 404
Musical: box, 44; boxes on soundboards, 357; education, 539; instruments, 257; ancient, 324, 384, 568; instruments, errors in popular works professing to describe, 176; strange and rare, 223, 274; rotation, 39; tuning, 567
Mustard, adulterations of, 525
Myborg bee-cabinet, 354, 433
Mysteries, gyroscopic, 664
Mythology, faith, sight and, 200

NACASCOLO or divi-divi, 124
Names: botanical, 416, 443; stellar and astronomical, 12
Naphtha, turpentine and wood, 569
National: losses, 494; observatories for the study of the physics of astronomy, 317; observatories, insufficiency of, 143
Natural: history subjects, waterglass as a preservative of, 466; phenomena and productions of the polar regions, 164
Nature: constitution of, 429, 457, 478; man as the interpreter of, 585; on an article in, 144; scientific interpretation of, 585; sketching from, 520, 547, 670, 696, 622, 646, 670
Nature-printed leaves, 560, 595
Nature-prints by photography, 298
Nautical Almanac, the, 9, 116
Naval architecture, 23
Navigation: 313, 363; aërial, 613; inland, 252
Nebulæ, constitution and distribution of, 377
Needle: lock, 441, 491, 516, 568; tempering, 673
Negro, 353, 407, 438, 439, 460, 484
Nephilim in Yorkshire, 483
Nerve of a tooth, 165
Nervous excitement, 650
Nessler's ammonia test, 48, 78, 101
Nevill's bread, 646
New: South Wales, and its metals, 589; testament, textual revision of, 100; Zealand time again, 171; Zealand wool, 74
News from "Eos," 354
Newspaper science, 434
Newtonian reflectors, centreing the flat of, 150
Nickel: electro-deposition of, 216; plating with platinum and, 325; silver, 578, 628, 670
Night and day: telescope, 519, 546, 570; temperature, 79, 104
Nightingale, 332, 442
Nitrogen in plants, 314, 350, 356
Noah's comet, who invented, 350
Nomenclature: 66, 117, 225; chemical, 632; new, 319; scientific, 92
Nominal horse-power, 188, 195
North London railway, 354
North Pole, expeditions to, 194
Noses of stairs, 130
Notation, musical, 39
Notes: astronomical, 27, 136, 265, 370, 475, 605; chemical, 273, 430; microscopical, 8, 56, 162, 349; of communications to the Academy of Sciences, Paris, 424, 506, 604, 655; of French science, 371, 422; photographic, 144
Novel: blowing apparatus, 325; method of sawing timber, 407; railway signal, 430; telescope, 257
Novelty in the building trade, 445
Number of eggs from a hen, 676
Numismatical, 157
Nut, monkey, 415

OAK: iron stains in, 23, 47; polishing floors of, 78, 129; stains in, 545
Oatcake-making, 537
Object-glass: 339; balsamed, 353, 383, 411, 437; purchase of, 638; radius of surface of, 22, 43, 100, 176, 204, 235, 355, 412, 437, 543, 545, 643
Object-glasses: 616, 667; cemented, 300, 379; focal length and magnifying power of, 453
Objects: lunar, 40, 119, 331, 436, 563, 662; mounting small in balsam, 411
Observation, self-deception in, 447
Observatories: insufficiency of national, 143; national, for study of physics of astronomy, 317
Observatory clock, cheap, 40, 124, 641
Observing: astronomical society, 230; seat, Hollis, 225
Occultations of Uranus, 40
Oceanic circulation: 473, 499, 567, 588, 603; and the Gulf Stream, 553; Carpenter v. Mühry, 567, 588
Octave coupler, 387
Odour of flowers, 676
Oil: action of on waves, 596, 623; animal, refining, 155; bleaching, 168; boiled, 492; Dugong, 465; paint, flexible, 231; peppermint, 673
Oil-can, improved pattern, 299
Oil-painting, cleaning, 183, 233, 259, 548, 573
Oils: artificial, 443, 468; testing inflammable, 445; testing vegetable lubricating, 18, 100
Oil-stains, removing, 155
Old wives' science, 105, 129, 154, 180, 232
Oleate of soda, 43
Omnibuses, improvements in, 615
"Omphalos" Gosse's, 255, 274
Onions, 493, 621, 648
Ontario, 621
Opera-glass: 103; disregard of theory frequently shown in the construction of the, 595, 643
Opium, extracting from poppies, 678
Optical: 61; power as affecting the perception of colours, 7
Optician's lacquer, 208, 259
Optics, 600
Orange marmalade, 107
Orange-coloured spectacles, 612
Orbit of double star Castor, 377
Orbits, cometary, 116
Ordnance map of London, 318, 339
Ores: analysis of, 18
Ores, tests for, 17
Organ: 74, 75, 155, 312, 365, 382, 387, 388, 414, 417, 442, 546, 598, 671; Alexandra Palace, 43; bellows, 338, 418; built, the, 70, 541, 563, 615, 669; cleaning, 233; defective, 40; expression à la main on the, 514, 589; feeders, 16, 40; hydraulic machine for blowing, 648; new material for pipes of, 484, 513, 539; pallets, 75; pipes, 181, 417; pipes, voicing, 262; pneumatic levers for, 328; pocket barrel, 105; stops, 78; weights of wind in, 44
Organ-building: amateur, 302, 354, 489, 546; new material in, 513, 539, 591
Organic: concretions, artificial so-called, 503; matter, removing from bath, 144
Origin: of alphabets, 638; of primary beliefs, 586; of volcanic energy, 404
Ornament, pretty parlour, 360
Ornamental: designs on glass, 248; stitching, marking leather for, 231; sliderest, 665; turning, 69, 98, 124, 146, 196, 255, 332, 567, 641, 647
Ornamentation of silver-plate, 60
Ornaments, transferring, 246
Oscillating cylinder: double, 105; reversing gear for, 309
Osseine, gelatine, and osmazone, 195
Our coal supplies, 619
Outside work, colouring for, 43
Oval: chuck, 206; turning, 493
Oven, cracked, 206
Ovens, bakers', 180
Overcoat, indiarubber, 130, 155
Overgraining, 547
Oxford frames, varnish for, 74
Oxyhydric light, the, 126, 588, 657
Ozone: 386; formation of, 133

PACKFONG or Chinese white copper, 572, 596, 646
Packing: grapes, 593, 623; rings of piston, 390, 414, 493
Packman's (Dr.) steam-engine, 354, 439
Pad, hand, 649
Paine's magnetic engine, 306
Paint: for portable engine boiler, 364; refuse, 158, 181; removing old, 163; rubber graphite, 425; smell of, 365, 390, 491
Painters' Company, prizes of, 185
Painting: coaches, 88; effects of faults in vision on, 162; hints on, 88, 168, 248; house, 494, 621; iron bedsteads, 386, 440; the spectrum, 273
Paisley shawls, scouring, 74
Palæolithic age and primitive man, 333
Palæontology, vegetable, 267
Pallets of organ, 75
Panama canal, the, 535
Pansies, 415, 467
Pantograph, 311
Paper: carbonic ink, 105; car-wheels, 222; clothes, 597; from wood, 372; utilising old, 624
Paperhanging, 261
Papermaking: reminiscences of, 379; wood pulp for, 409
Papier-mâché, 625
Parallax, sun's mean, 436
Parallelogram of forces, 515, 536, 561, 641
Parasites, bugs, lice, and, 235
Parchment, dyeing, 130, 155
Parlour ornament, pretty, 360
Parrot, 79, 102, 129, 494
Paste: 443, 469, 493; eels in, 23, 46; steel-hardening, 130
Pasting cloth to maps, 572
Patent: how to procure a, 390; laws, report of the committee on the, 244; rights, 338
Pathology of the chignon, 645
Patriarchal writing, 385
Pattern-making, 155
Patterns: tool for describing, 98; varnish (red) for, 416
Pattern-lead cells, 349
Pavement, tar, 468, 517, 594
Peach, curl in, 441
Pear-wood, seasoning, 415, 517
Pearls, 51
Peas: hot, 313, 339; mice eating, 390, 441, 491; preserving green, 496, 621
Peat fuel in Canada, 187
Pedal: harmonium, 262, 310; playing, 339
Pedals: for piano, 79; radiating, 43
Pedestrian tour, 181, 232, 336, 360, 413, 466, 490, 516
Pendulum: 489; "Veritas" and the, 543
Pens, quill, 495, 570, 598, 621
Pepper, adulterations of, 526
Peppermint, oil of, 673
Performance: of a locomotive, 195; of telescope, 357
Permanent polish, 74
Perpendicular shaft, turning, 21, 75, 153, 258, 307
Perpetual calendar, compendious, 308
Perspective: 251, 353, 439, 465, 489, 509, 536, 560, 594, 617, 664; Dr. Carpenter and, 39, 119, 152, 175, 200, 251, 306, 353, 439
Perspiration, excessive, 599, 646
Phenomena: associated with hydrogen flame, certain, 247; solar, 151
Phenomenon: curious, 62; of Argostoli, 410, 436; remarkable electrical, 13, 68
"Philo:" and ventilation, 9; hundred-weight theory of, 94
Phonometers, 619
Phosphorescence of the sea, 116
Phosphorus: essence of, 442; in iron, 8; removing from iron ores, 220
Photo.-engraving on metals, 217
Photographic: 130, 229, 339, 442, 573, 624; apparatus, Dubroni's, 468; background, 183; irradiation, 377; laboratories, 477; lens, 206, 312, 338; prints, fixing, 673; preserving, 399; process, 312, new, 137, 260
Photographing the sun, 171, 261
Photographs: burnt-in, 143; enlarging, 496, 624; hints on colouring, 272
Photography: 23, 46, 79, 104, 157, 207, 209, 233, 235, 287, 288, 310, 311, 390, 495, 624, 673; fluid lens for, 521, 571; for uninitiated, 90, 191, 246; improvements in, 582; nature-prints by, 298; submarine, 543
Photometer, new, 215
Photos, colouring, 49, 79
Phrenology, 21, 38, 75, 418, 442, 468, 492, 545
Physical geology, "E. L. G." and, 229
Physiology, chemical, 421
Pi multiplication, Screw's, 97, 119
Planette, bell, 182, 226, 275, 332, 383
Piano: 645; actions, instructions for making, 149, 173; alliance, 40, 333; construction, 16, 65, 95, 204, 250, 382, 463, 518, 591; effect of increasing the superficies of soundboards of, 382; five octave, 382; how to improve the trebles of cottage, 431; in Canada, 433; increasing the loudness of trebles in, 301; moth in, 598; pedals for, 79; quator, or tetrachord, 177, 225, 275; rewiring old, 547, 645; strings, improved scale for lengths of, 202, 223
Pianoforte: actions, 149, 173; bracing and bellying, 335, 368; brief contribution to early history of, 435; soundboards of, 487; tuning-key, 540, 568, 591; unsound, 645
Pianofortes: primitive, alias dulcimers, with and without strings, 275, 518; tuning, 463, 486
Pianos: covered strings in, where and how to commence using, 538; harmonicon, 125
Piano-violin, the, 412
Picture-framing, 572, 596, 622, 670
Pictures: "argento," 58; moon in, 560; transferring, 168
Pie-heater, 670
Pig-feeding, 442, 492
Pigeon, gyro, 222
Pigeons, vermin and, 105
Pigment, new green, 536

Pigs: and pig-feeding, 20; rabbits, and shell-fish, 512
Pinholes: in lead pipes, stopping, 160; spots and, 91
Pinions, lantern, 20, 44, 101, 125, 205
Pipe: a clean, 333; meerschaum, 284, 390
Pipes: carbon or charcoal, 493; condensation of steam in, 410, 461, 513; lead, 183; organ, 181; voicing, 262; proportions of, 25
Pirates, are ants? 72, 121, 147, 357
Piston, packing rings of, 390, 414, 493
Pitch of roof, 130, 156, 181, 206
Pitches of screws, 262
Pith, reducing to pulp, 569
Pivots, 493
Plaister, sticking, 19
Plane surfaces: testing, 567; working, 519, 546
Planes, sash, 673
Planet: discovery of minor, 99, 143; giant, a, 244, 283, 384, 405, 431, 482, 508, 542, 595, 614, 640; Vulcan, the, 274
Planetary: and cometary orbits, 116; markings, 377
Planets: axes of, 379, 406, 460, 482, 594; elongation of inferior and oppositions of superior, 638; temperature of, 390
Plant: boxes, 625, 647
Plant life, geology in relation to, 142
Plants, nitrogen in, 314, 350, 356
Plaster: casts, preserving, 59; of paris, 105, 130, 180; of paris, marsh mallow for hardening, 281; ornaments, gelatine moulds for, 286
Plates: chemically clean, 236, 262, 309; preserving, 206
Plating: solution, defective, 44, 128; with nickel and platinum, 325
Platinic chloride, 76
Platinum, catalytic action of spongy, 439
Plato: 198, 384, 411, 433, 485; the floor of, 661
Plea for house plants, 42
Plums, 491, 517
Pneumatic levers for organs, 328
Poisoning: historical notes on, 458, 504
Polar regions, natural phenomena of, 164
Polariscope, 365
Pole-star, α Draconis as, 171
Polish: furniture, 157; permanent, 74; white, 104
Polishing: 88; bullocks' horns, 207, 259; diamond, 387; edges of glass, 516; French, 75; granite, 19, 74; mahogany, 75; oak floors, 78, 129; slate, 516
Polyzoa, 87
Pompeii, manufacture of textile fabrics at, 506
Pony, worms in, 600, 624, 646
Poor man's provender, 453
Pork diet, 231, 283, 307, 360, 413, 466
Porous substances, determining specific gravity of, 306
Portable dark tent, 365, 389
Portuguese language, 441, 492
Positive philosophy and medicine, 139
Postage stamps: 235, 260; cement on, 649, 671
Postal authorities, suggestions for, 94
Posts: improved directing, 123; telegraph, 206
Potassium: cyanide of, 209, 234; new method of obtaining, 273
Potash, red prussiate of, 443, 468
Potato: culture, 66; disease, 653, 666; another remedy for, 593; stains, 671
Potatoes: 310; caution about, 211; diseased, 621; preserving, 17
Potteries, schools of art in the, 445
Poultry, 572, 624, 647, 671
Pouncing pattern on printing blocks, 621
Pound, the, and the metric system, 144
Powder: hints on the employment of blasting, 395; water, 493
Powders, ink, 183
Power: 101, 127; Maine, 543; of boiler, 287, 310; of engine, 548, 596; of high pressure engine, 14; of water-wheel, 209, 285, 259, 284, 287, 309, 311; steam, 259, 361, 645; to drive crown printing machine, 183; tidal, 257; water, 17, 312, 363, 413, 442, 467
Powerful galvanic battery, 490
Power-loom weaving, 235
Practical: man, the so-called, 612; mechanics, 469, 518
Practice makes perfect, 143
Precipitation of silver by copper, 613
Prehistoric: races, 179; trees, 393
Preparation: of carbon, 672; of chlorine, 404; of telegraph poles, 245
Preservation: and desiccation of wood, 1; of insects, 265; of wood, 189
Preserve, vegetable marrow, 231
Preserved: meat, 79, 633; peas (green) and gooseberries, 496
Press: bookbinder's, 598, 623, 646; for cutting paper, 442; hydraulic, 286, 310
Pressure: boiling under, 545; in steam-boilers, 91; of water, 79, 102; of wind, 339; on cork of bottle, 183; under water, 17
Pressures, atmospheric, 648, 671
Preventing paper sticking to silk after being printed with metal leaf, 312
Primitive: condition of man, 666; man, palæolithic age and, 333
Printers': ink, 130, 154; ink, coloured, 260; ink, varnish for, 390; rollers, 520, 546
Printing: in Canada, 568; machine, power to drive crown, 183; metal leaf on silk and cotton, 673; paper, absorbent quality of, 104
Prints: photographic, preserving, 399; transferring to wood, 128
Prizes: for amateur microscopists, 8; for art workmen, 195; of the Painters' Company, 185; of the Turners' Company, 581
Problem: 155; of fifteen school-girls, 13
Problems, mathematical, 566
Proctor, Mr.: and Noah's comet, 351; on spinning tops and gyroscopes, 353
Proctor's: "Essays on Astronomy," 291, 326; Gulf Stream Map, 566, 588; smaller Star Atlas, 662; Star Atlas, 560
Production of honeydew, 114
Professors, 468
Progress: of geology, 114, 141, 167, 192; of meteorology, 320
Projectiles for rifled guns, greatly elongated, 515, 561
Projections, map, 662
Pronunciation: 274; Spanish, 443, 470, 518, 545, 621, 645
Proofs of the deluge, 175, 255, 304
Propeller, Allingham's, 39, 62, 92, 148, 173
Properties: of cast iron, 534; of the gyroscope, 582, 642
Proportions of pipes, 35
Protection for steam-boiler, 572, 596
Protoplasmic life, 72
Provender, poor man's, 453
Provision for child, 495
Psychic: force, 33; force people, what has become of the, 69; manifestations, 175; more, 58
Puddings, fruit, 465
Puddling: Dormoy's revolving rabble for, 213; fishponds, 672; furnaces, revolving, 174, 229, 280, 305; machines, 83, 110
Pulleys, unequal sizes of cone, 468, 492
Pulp, dyeing for sugar paper, 443
Pulse-beats, variation of, 613
Pump: air-vessel for, 519; centrifugal, 470, 518, 569, 621; colliery, 517; portable force, 516; wooden, 105, 130, 155
Pumps of portable engine, 23, 45, 76
Punches, machine, 390
Punching: and shearing machine, 22; holes in sheet brass, 650; machine, improved, 321; machines, 261
Punt, fowling, 46
Purchase: of object-glass, 638; of a reflector, 379; of a spectroscope, 272
Pure geometry of 113: 355, 306
Purification: laboratory, 648, 671; of gas, 404; of iron, 441
Purifying mercury, 469
Putrefaction: after death, 121; prevention of, 89
Putty powder, preparation of, 98
Pyro-plating, 557
Pyrethrum parthenium, 364, 388
Pythagoras's theorem: 257; new proof of, 203, 282

QUALITATIVE analysis, 207
Quarry, bringing slate to surface of, 671
Queries, unanswered, 176
Question: alcohol, 171, 198, 225, 256, 278; arithmetical, 130; examination, 21, 76; geometrical, 79, 103; in trigonometry, 413; mathematical, 152; of sight, 20, 44, 75, 103, 128, 153, 205, 231, 283, 336; slide valve (Cameron's pump), 287, 310; trigonometrical, 260, 309, 316
Quill pens, 495, 570, 598, 621
Quinine: 288, 310; action of, on white corpuscles of blood, 8
Quoits, game of, 441

RABBIT: breeding, 17; disease, 286
Rabbits: food for, 43; pigs, and shellfish, 512
Rabble for puddling, Dormoy's revolving, 213
Races: prehistoric, 179; training for bicycle, 625
Radius: and weight of flywheel, 45; of sector, 313, 363; of surface of object-glass, 22, 43, 100, 176, 204, 225, 355, 412, 437, 543, 545, 643
Railway: carriages, door-handles of, 150, 225; carriages, heating, 87, 542, 620, 666; curve, level of, 312; first, 416; metals, 597; signal, novel, 430; submarine, 377; tarpaulins for, in tropics, 154
Railways: or no railways, the battle of the gauges continued, 654; separate for goods traffic, 541
Rain, air and, 239, 318
Rainbow, iris or, 573, 596
Rain-fall, forests and, 338, 363, 637
Rain-water tanks, 283
Raised beach in Ireland, 638
Raising water by tidal power, 198
Rams, hydraulic, 207
Raphael's cartoons, 289
Rate, clock, 638
Rats, 183, 208, 233
Reason wanted, 152, 204, 283
Recession, α Draconis and, 379
Recovering indigo, 470
Recurrent vision, 190, 282, 332, 412
Reducing-valve, self-acting, 399
Reduction: in the size of musical instruments, 567; of declination, 490
Reductions by *Nautical Almanac* method, and by proportional logarithms, 508
Reeds, harmonium, 324
Refining animal oil, 155
Reflection, 488, 514
Reflections, secondary, 273
Reflector: purchase of, 379; tests for 4½in., 116; violin, "Fiddler's," 465
Reflectors: Newtonian, centreing flat of, 150; astronomical, 637
Refraction: curious case of double, 251; star altitudes and, 508
Refractive index of glass, 105
Refractor: alt-azimuth stand for, 614; tests for a 3¼in., 430
Refrigerator, dynamic, 428
Refuse paint, 156, 181
Regelation, 314
Regulator, water, 466
Rein, the bearing, 384, 430, 462, 484, 514
Relics, human, 285
Relief for catarrh, 280
Remedy for potato disease, another, 593
Reminiscences of paper-making, 377
Removal of the standards, 107, 123
Repairing: concertina, 128; the watch, 421, 448, 489, 503, 529, 537, 564, 580, 657
Replies, &c., from Sigma, 618
Report of the commission on scientific education, 343
Reptiles, stuffing, 599
Republican months, 571, 646
Repulsion: gravitation and, 197; "T. A." and, 228
Re-'scaping old verge wheel, 180
Resistance of voltaic cell: Mance's method of measuring internal, 276, 301; finding internal, 412, 490
Respirators, 156
Rest, the Washington spherical, 644
Retrievers, 127, 179
Reversing gear for oscillating cylinders, 309

Reviews of Books:—
Air and Rain, by R. Angus Smith, 239, 318
British Rainfall, by J. G. Symons, 426
Catalogue of Model Steam-engines and Castings, 270
Cause of Consumption, by Dr. MacCormac, 371
Chemical Physiology, by Dr. Thudichum, 421
Conversations on Natural Philosophy, by Mrs. Marcet, 426
Deviation of the Compass in Iron Ships, by W. H. Rosser, 4
Healthy and Comfortable Houses, by Dr. Drysdale and Dr. Hayward, 577
Dictionary of Chemistry, by H. Watts, 56
Electrical Tables and Formulæ, by L. Clark and R. Sabine, 270
Elementary Treatise on Curve Tracing, by Percival Frost, 57
Essays on Astronomy, by R. A. Proctor, 291
Elements of Chemistry, by W. A. Miller, 270
Fallacies of Darwinism, by Dr. Bree, 527
Geological Survey of Ohio, by J. S. Newberry, 270
Geometrical Conic Sections, by J. Stuart Jackson, 270
Handbook of Chemical Technology, by R. Wagner, 579
Healthy Houses, by W. Eassie, 426
Iron as a Material of Construction, 426
Michael Faraday, by J. H. Gladstone, 452
Miscellaneous, 57, 270, 427, 580
Natural Philosophy for General Readers and Young Persons, by E. Atkinson, 270
Nautical Surveying, Introduction to, by J. K. Laughton, 579
Noxious, Beneficial, and other Insects of the State of Missouri, by C. V. Riley, 579
Observations of Comets from B.C. 611, to A.D. 1640, by John Williams, 4
Perspective, by Lieut. W. H. Collins, 527
Pocket-book of Mechanics and Engineering, by J. W. Nystrom, 270
Pocket Dictionary of Technical Terms used in Arts and Manufactures, 427
Practical Plane Geometry, by J. F. Heather, 426
Railways or no Railways, by R. F. Fairlie, 654
Scales for the Ready Comparison of British and Metric Weights and Measures, by A. L. Newdigate, 56
Science and Commerce, by P. L. Simmonds, 580
Science Primers, Chemistry by Prof. Roscoe, Physics by Prof. Balfour Stewart, 56
Solid Geometry and Conic Sections, by J. M. Wilson, 270
Spon's Dictionary of Engineering, 56
Sun, the, Ruler, Fire Light and Life of the Planetary System, by R. A. Proctor, 270
Treatise on the Theory of Friction, by J. H. Jellett, 56
Treatise on the Metallurgy of Iron, by H. Bauerman, 270

Revision of New Testament, textual, 100
Reviving black cloth coat, 155, 232
Revolving: brushes, 465; furnaces, 151, 229, 280, 305
Rewards of science, 60
Rewiring old piano, 547, 645
Rheumatism, kerosene as a cure for, 241
Rhumkorff's coil, 79
Rice: boiled, 336; curry and, 183
Rifle: targets, 619; Martini, 650
Rifles, long and short, 157
Rifling of great guns, 331, 385
Rigging model yacht, 156
Right ascension, 490
Ring-nebula in Lyra, 614
Rising and setting of moon, 44, 74
Rivets, tool for punching out from watch-chains, 412
Road: crusher, inexpensive steam, 543; locomotives, 133; material, 45
Roasting jacks, 650
Robin Hood sewing-machine, 355, 461
Rock: drill, new, 588; insciptions, 44, 157, 182, 233
Rockets, double, 415, 517
Rods, wood, 22, 45, 76, 101, 205
Roller, self-acting blind, 295
Rollers: of wringing machines, 23, 47; printers', 520, 546
Rolling of ships, 613
Roof, pitch of, 130, 156, 181
Room, light for middle of, 77
Rooms, ventilating, 19
Root, vine, 443
Roots: dandelion, 288, 312, 333, 340, 388; hyacinth, 469; of trees, killing, 568
Rope, rendering new flexible, 415
Roscoe's "hatful" of comet, 331
Roses, 391, 415, 441, 492
Rose-trees, 18, 21, 100
Rotary: engine, 462, 514; motion, changing reciprocating into, 484, 537, 593
Rotating: shot, 148, 171, 198, 227, 253, 282; valve for steam-engine, 320
Rotation rate of globe, 649
Rotten silk, 519
Rouge, 494
Rough skin, 573
Round shoulders and curved spines, 514
Roundabout theory, 638
Rowing, 674
Royal: Astronomical Society, memoirs of, 430; Society, soirée of, 185
Rubber: graphite paint, 425; stretching vulcanised, 470; tires, 130, 155
Rust: in brewing water, 363; in iron vat, 18, 100; preventing, 105, 130, 156; protecting sheet-iron from, 349
Rusty iron castings, 599

SAFETY-LAMP for miners, new, 116, 217, 275, 333, 658
Safety-valve, weight on, 105, 129, 154
Sahara, desert of, 182
Sailing boat, motion of, 649, 671
Sails, mildew in boat, 207
Salads, fresh vegetables and sweet, 263
Salmon spawn for bait, 79, 104, 129
Salt damp in walls, 78, 180, 258
Salts produced from kelp, separating, 20
Samels' patent standard lock, 195
San Francisco, emigration to, 312
Sand: building on, 519; for casting, 102, 180
Sand-papering machine, 246
Sash planes, 673
Sash fastener, new, 537
Sashes, fastening loose window, 152
Sash-tool handles, 105
Satellites: Jupiter's, 8, 40, 76, 116; of Jupiter and Saturn, 249
Saturn, semi-diameter of, 116
Save us from decimalism! 36, 67
Saw, circular, driving, 259, 442, 467
Saw-bench, water power to work, 103
Sawdust, brandy from, 439
Saw-sharpening machine, 129
Sawing timber, novel method of, 407
Saws: brazing fine, 469; improved spindle for circular, 13; spindle for circular, 93, 259
Saxony, education in, 99
Scale: 468; in boilers, removing, 346
Scales, darkening graduations of, 625, 647
Scarecrows, 443, 469
Scaring foxes, 21
Scarlet: cloth, cleaning, 131; dye for wool and silk, 430; runners, 104, 154, 339, 364, 388; fixing bloom of, 599, 646; tunic, stained, 547, 596
Scent from violets, &c., 129
Scholarships, Whitworth, 543
School: bluecoat, 625; government, 670
Schools of art in the potteries, 445
Science: and education, 356; American, 276; and art department, 515; department and scientific education, 266; examinations, 312; Government and amateur, 253, 334, 437; in Birmingham, 613; in search of coals, 557; light, 379; newspaper, 434; notes of French, 371, 422; old wives', 105, 129, 154, 180, 232; rewards of, 60; study of natural, 99
Sciences, notes of communications to the Paris Academy of, 424, 506, 604, 655

Scientific Societies:—
Bristol Naturalists, 8
Chemical, 300, 378, 404
Engineers', 429
Hackney, 60
Institution of Civil Engineers, 7, 249
Iron and Steel Institute, 35
Meteorological, 35, 379
Royal, 221, 404
Royal Astronomical, 7, 148, 249, 377

Scientific: are conventional terms, 334; education, 67, 266; education, report of the commission on, 343; expedition, government, 8; nomenclature, 92; research, British manufactures and, 345; terms, dictionary of, 624, 647; thought, aims and instruments of, 634
Scorpii, new double star 11, 462
Scorpionis, alpha, 485
Scraper, sharpening steel, 45
Screen, corn, 310
Screw: cutting, 100, 104, 197, 589, 644; cutting left hand, 224; cutting left with right screw-plate, 172
Screws: 650; brass, 416, 467; improved for woodwork, 377; pitches of, 262
Scroll-saw, improved, 347
Scrolls, 248
Scrubber for gasworks, 235
Sea: barometers at, 385; mouse, 416; Mr. Lowdon at, 171; phosphorescence of, 116; serpents, 550; sickness, 55, 323, 625, 647; story of the, 489; wave motion of, 189; waves, height of, 171, 183
Seals, engine-turned, 625
Sealskin, 44
Searcher after truth: 380; "Sigma" as a, 352

Seas, inland, temperature and physical conditions of, 656
Seasoning pear-wood, 415, 517
Seat: Hollis observing, 146; sliding, for racing boats, 372
Sea-water at home, 336
Seaweed, extracting iodine from ashes of, 209, 234, 569
Seaweeds, 572, 646
Secondary: batteries, 189; reflections, 273
Secret spring or lock, 416
Sector, radius of, 313, 339, 363
Seedbox, 19
Seeds: 469; dispersion of by winds, 540; how to obtain double flowers from, 281; influence of cold on, 94, 126, 147; unripe, 104, 178
Selenographical, 172, 277, 540
Selenography, 256, 384
Self-deception in observation, 447
Semi-barbarous Hebrews, 352
Semi-diurnal arcs, 9
Sensitive flames, 217
Separating lenses, 674
Serpents, venomous, 198, 340
Setting: lathe, 48, 129, 154, 180, 670; moths, 589
Seven-keyed tuning-fork, 569
Sewage: cement from, 241; question, our food supply and the, 397
Sewer gas, 41
Sewing-machine, 103, 410, 417, 465; combined knitting and, 269; defective, 155, 516; difficulty, 311, 338; extras, 258; Howe, 329; Robin Hood, 355, 461; Singer new family, 172; Weir's, 649
Shaft: kind-chaudron system of sinking, 7; line, 103; turning perpendicular, 21, 75, 153, 258, 307
Shafts: hardening steel, 517; strength of, 442, 467; velocity of wheels and, 179
Sheepskins, cleaning white, 208
Shellfish, pigs, rabbits and, 512
Shifting hoist, light, 572, 622
Shilling, suspended, 365, 390, 414, 439, 517
Shipbuilding, woods used in, 400
Ships: rolling of, 613; suggestions for making half worn-out iron seaworthy, 58
Shoe, thick-soled, 287, 338
Shoemaking, boot and, 309, 335, 385, 573, 623, 672
Shorthand, 234
Shortness of breath, 28
Shot, rotating, 148, 171, 198, 227, 253, 282
Show stand, 547
Shower of stones, 51
Sidereal: clock, 171; day, length of, 23, 76
Sight: 236, 261; a question of, 20, 44, 75, 101, 128, 153, 205, 231, 283, 336; dog with weak, 312
"Sigma" as a "searcher after truth," 352
Sign, illuminated, 47
Signals, distant on Midland, 541, 621, 667
Silician steel, 140
Silk: cleaning plain blue, 387, 440, 491; printing metal leaf on, 672; rotten, 519; solvents, 597; spontaneous combustion of, 482; working, 547
Silkworm: disease, 157, 182; eggs, regulating the hatching of, 586
Silver: and gilt articles, 595; bath, 21, 105, 130; chloride, fused, 649, 671; film for sunscreens, 333; goods, fire marks on, 625; nickel, 573, 625, 670; plate, ornamentation of, 60; precipitation of, by copper, 613
Silvered glass sun-screens, 224
Silvering: field lenses, 204; mirror for telescope, 388; solution (photo.), 191
Silver-plating, 340, 364, 398
Simmonds' governor, 33
Singer new family sewing-machine, 172
Single v. double cylinder engines, 619
Siphon bottle-caps, 231
Skeleton flowers, 599
Skeletons, 182
Sketching from nature, 520, 547, 570, 596, 622, 646, 670
Sketching-board, steadying, 470, 494
Skew bridge, 495
Skin, rough, 573
Skins, curing, 20
Slate: bringing to surface of quarry, 671; clocks, polishing, 516
Sleeper, a bad, 311, 338, 387
Slide, new microscope, 656
Slide-rest, ornamental, 665
Slide-rests, re, 469, 492
Slide-valve question (Cameron's pump), 287, 310
Slops, hops and, 484
Small-pox, prevention and cure of, 102
Smee's battery, 38, 46
Smell: 294, 344; of paint, 365, 390, 491
Smoke: and light, 573, 623; economy of fuel and prevention of, 59; essence of wood, 650
Smoky chimney, 261
Snatchblock, improved, 346
Soap: boiling, 77; dry, 544; Marseilles, 79
Societies, co-operative, 39, 96, 148, 178, 198
Society, amateur turners', 97, 150, 589, 641
Socket handles, 671
Socotrine aloes, 339
Soda: nitrate of, 312, 338, 363, 570; oleate of, 43; silicate of, 46, 47, 77, 258; tannate of, for preventing incrustation, 439
Soda-ash in boilers, 20, 232
Soda-water, 573
Sofa, stuffing for, 74
Soft eggs, 492
Softening spring water, 470
Soirée of Royal Society, 185
Solar: activity, 7; influence of planets upon, 33; corona, the, 614, 639; eclipse, late, 7; eyepieces, 328; faculæ, 302; heat, source of, 7; light, chemical influence of, 144; longitude, 171; phenomena, 151
Solariological, 61
Solder: for Britannia metal, 183, 207; yellow, 195
Soldering: flux, 627; iron, 75; iron, hot, 312; jewellery, 337; tinning and, 236, 261, 285, 309, 361
Solid, liquid and, 389, 414
Soluble glass, 46, 590
Solvents, silk, 597
Something wrong: with Jupiter, 223; with the sun, 558
Song of canary, 207
Soper rifle, 93
Sound: deadening, 157, 182, 206; echo of on water, 648; (or unsound) theory, 430, 489, 508, 665; waves, 30
Soundboards: directions of motions of, 539; effects of increasing superficies of, 382; musical boxes on, 357, 391; new, 667; of pianofortes, 487
Sounding-lines, deep-sea, Sir W. Thomson on, 606
Sounds of muscles and the ears 485
Sour ale, 547
Sovereigns, defaulting, 57
Spanish: language, 673; pronunciation, 443, 470, 518, 545, 621, 645
Spanners and wrenches, adjustable, 243
Spar, Iceland, 569
Sparks, electrical, 42, 62, 157, , 228, 256, 566
Specific gravity: apparatus for determining, 220; of porous substances, determining, 306
Spectacles: orange coloured, 612; suitable, 310
Spectroscope: 310; adjustable for dispersive power, 7; dust in the, 9, 66, 69, 97, 117; purchase of a, 273
Spectrum: colours, 262, 286, 338, 361, 387; painting the, 273
Specula, 638
Speculum: 673; working, 257, 279
Speed of bicycles, 73
Speeding: machinery, 183, 207, 233, 284; pulleys for gut, 415, 467
Spherical rest, the Washington, 644
Spheroidal state of water and boiler explosions, 632
Spicules of sponge, 8
Spinal complaint, 128
Spindle for circular saws, 13, 93
Spines, round shoulders and curved, 514
Spinning, 495
Spinning tops: 252, 307, 353, 412; and gyroscopes, 326, 353, 381, 412, 435, 460, 484, 542, 642; support of, 279, 306
Spiral: grailing, 34, 94; turning, 157
Spirit faces, 33
Spirits, testing beer and, 519, 570
Spiritualistic, 126
Spirometer, 492
Spoiled hams, 621
Sponge spicules, 8
Sponges, 559
Spontaneous combustion: 18, 70, 98, 111, 127; of silk, 482
Spots on Whitechapel, 571
Sprats, curing, 310
Spring: beds, 105, 130; furnace, 571
Springs: 261; brass, 288, 312; hardening spiral, 495
Spruce beer, 78
Spur-wheels, teeth of, 209
Squinting, 49, 79, 102
Stain: and polish, red, for kitchen chairs, 128; metallic for wood, 493; violin, 232
Stains: champagne, 19, 44; in oak plank, 545; in wood, 673; potato, 671
Staining: carmine, 258; fanlight, 673; glass, 491, 517, 544; leather, 546; tissues, 349
Stair-noses, 130
Stair-steps, breadth of, 417
Stamps, postage: 235, 260; cement on, 649, 671
Standards, removal of the, 107, 123
Star: altitudes and refraction, 508; Atlas, Proctor's, 560, 662; depths, 109, 140, 166, 190, 248; drift, new evidence about, 369; gazing, telescope for, 430; magnitudes, 116; maps, 9; systems and star drift, no evidence about, 369
Starch, fermenting bread with, 621
Starlings, 181
Stars: 11; B. A. C., 508; distances of the, 300; double, 148, 274, 328, 462, 485, 542, 614; in Aquilæ, 614; new double, 148, 201, 230, 280, 355, 462, 567, 594; triple 485
Steam: 77; boiling by, 157, 181; 'bus, new, 161; carriages on common roads, 434; condensation of in pipes, 410, 461, 513; dry, 157, 181, 232, 258, 284, 308, 360, 386, 413, 440, 466, 490, 544, 595; drying by, 598, 623; economical use of, 2; fire-engine, 156; jacket, the, 59; launch, 17; pipes, expansion joints in, 310; road-crusher, inexpensive and simple, 543; tricycle, Yorkshire, 255; Users' Association, Manchester, 530
Steamboat: model, 105, 258; boiler for, 258, 308, 361, 386, 645
Steam-guns, 433
Steam-power, 207, 259, 361, 645; want of, 18, 101
Steamship, proposed large, 482
Stearic and palmitic acids, new method of obtaining, 608
Stearine, 101
Steel: 163; annealing, 146, 181, 308; combs, 441, 491; etching, 102; for lathe tools, 102, 129; gilding thin, 19; hardening paste, 130; heating, 376; modes of making, 163; plates, resistance of to air-pressure, 645; preserving the polish of, 377; process, Barron, 454; shafts, hardening, 517; Silician, 140; spring, annealing, 547
Stellar: and astronomical names, 12; motions, 377; method of determining with spectroscope, 458
Stencilling, 248
Stephenson and his alleged inventions, 225
Stereotyping: 153, 206, 231, 258; brass blocks, 625, 647
Sticking-plaister, 19
Sticks, bending, 573
Stinging of bees, &c., 79, 103, 129, 154, 180, 206, 231, 360
Sting-proof gloves, 258
Stone: artificial, 334; coal, 408, 438; chiding, 312; etching on, 671; gold polishing on, 156
Stones, shower of, 51
Stopper, extracting glass, 48
Stopping: pinholes in lead pipes, 160; teeth, 44
Stops, telescope, 638
Stores, co-operative, 412, 463, 511, 540
Stove, Ebdy's gas, 483
Stoves, 643
Strange and rare musical instruments, 223
Strapping, recipe for greasy, 517
Strawberries, 383, 441
Strawberry, blackberry and, 307, 360, 386, 413
Strength: of boiler, 128; of shafts, 442, 467
Stretched indiarubber, 308
Stretcher, carpet, 324
Stretching vulcanised rubber, 470
Striping, 88
Stroke, 470, 518, 569
Struggle, the coming, 512
Stub-end for connecting-rod, 454
Student's complaint, a, 200, 228
Study of natural science, 99
Stuffing: birds, 152; for sofa, 74; reptiles, 599
Submarine: photography, 543; railway, 377; structures, 347; telegraph cables, 169
Submerged forests, 598
Succession duty, 183, 208, 233
Suction pipe, air-vessel on, 673
Sugar: analysis, 18; boiling, 13, 78; paper, dyeing pulp for, 443, 469; test for, 183
Suggestion for postal authorities, 94
Suggestions for making half-worn-out iron ships seaworthy at small cost, 58
Sulphur: and oil cement, 156; as a bleaching agent, 281; in gas, detecting, 105; in wall-papers, 470, 493
Sulphuric acid: 18, 43, 545; lead in, 392, 416
Sulphurous smell after thunderstorms, 645
Summer visitors of the feathered tribes, our, 196, 332
Sun: 250, 358; and terrestrial magnetism, 188; declination of, 70, 125; disc of, value of one second on, 77; mean parallax of, 436; photographing the, 171, 258, 261; something wrong with the, 558; temperature of the, 465; viewing the, 201
Sundials, 79, 103, 154, 672
Sundries, 144, 352
Sunlight, action of on glass, 613
Sunrise: curve, 98; sunset and, 536, 573, 647
Suns, coloured, 296, 358, 383, 436
Sunscreen: 303; for all telescopes, 150; silvered glass, 224, 273; silver films for, 333
Sunset: a morning, 436, 465, 486; sunrise and, 536, 573
Sunspots, 358, 406, 430, 436, 463, 485, 562, 614, 640, 668
Sunstroke, 529
Super: for cottage hives, cheap, 433, 462, 540; removing, 648
Superheater, 569
Supply, our food, 90
Surface, electricity, 32
Surfaces: testing plane and convex, 567; working plane, 519, 546
Surgery: 104, 154, 180, 206, 307; abroad, 595
Surgical dentistry, 364
Surveying, land, 547
Suspended: clothes-horse, 13; shilling, 365, 390, 414, 439, 517
Sustaining power of cast-iron columns, 287, 442
Swimming-bath, making, 21, 45
Swiss mountains, height of, 21
Sycosis, 381
Syrup: lemonade, 183, 207; of coffee, 61
Syrups, fruit, 195, 516
Systems: decimal, 148; duodecimal, 152; mastery, 11; metric, 12, 69, 117

"T. A.": and gravitation, 197, 250; and repulsion, 228
Table: design for marble inlaid, 673; of dates, 44
Tables: and chairs, insects in, 312, 338, 362; mathematical machines and, 520; of Uranus, 377
Talmi-gold, 133
Tambour frame, 516
Tame wasp, 613
Tanks: hot water, zinc for, 547; rain-water, 283
Tanned goods, bleaching, 621
Tap, leaky, 311, 362
Tar: pavement, 468, 517, 594; separating from wool, 286, 387
Taraxacum, 572
Targets, rifle, 619
Tarpaulins for railway carriages in the tropics, 154
Tartar, cream of, 43
Tartaric acid, testing, 547
Task for chemists, 17, 157, 232
Tasmania, 337
Tea: coffee, cocoa, alcohol, and, 583; drunkards, 269; testing, 441, 491
Technological examinations, 526
Teeth: 182, 233, 284; cleaning back of, 442, 492; hardening, 547; of spur wheels, 209; of wheels, 564
Telegraph: posts, 206; preparation of, 245; wire, limits of resistance in, 48, 93; wires in cities, underground, 470, 518
Telegraphy: hydro-electric, 336; improvement in, 107; in United States, 466
Telescope: 18; day and night, 519, 546, 570, 645; diffraction phenomena in, 7; for star-gazing, 430; novel, 257; performance of, 357, 412; silvering mirror for, 388; stops, 638; testing, 379; valuable, 459
Telescopes: sun-screen for all, 150; tests for, 591
Telescopic: walking-sticks, 613; work for moonlight nights, 73, 291
Temperature; and physical conditions of inland seas, 656; effect of upon ale, 235, 284; measuring by electricity, 533, 558; night and day, 79, 104; of ice and water, 209; of Jupiter, 273; of the planets, 390; of the sun, 465
Tempering: cast-steel chisels, 262, 287, 310, 387; cutting-tools, 155; knives and trowels, 258; needle, 673
Tenoning machine, 476
Tent, portable dark, 365, 389
Terra-cotta, 43, 100
Terra-metallic tiles, 469
Terrestrial gravitation, 17, 36, 74, 97, 119, 144, 172, 201, 205, 228
Test: for alum in bread, 454; for arsenic, 442; for sugar, 183
Testing: acetic acid, 183, 208, 234, 284; beer and spirits, 519, 570; bleaching-powder, 261, 285, 309, 361; coffee, 482; inflammable oils, 445; plane and convex surfaces, 567; tartaric acid, 547; tea, 441, 491; telescopes, 379; vegetable lubricating oils, 18, 100
Tests: for flour, 597; ores, 17; reflector, 4½in., 116; refractor, 3¾in., 430; telescopes, 591
Tetrachordon, 177, 225, 275
Textile fabrics: durability of, 220; manufacture of at Pompeii, 506
Theophilus and Cyrillus, 147
Theorem, Pythagoras's: 257; new proof of, 203, 282
Theory: of vision, 171, 278; roundabout, 638; sound (or unsound), 430, 489, 508, 665
Thermometer: 236, 261; acid bulb, 35
Thermopile, 440
Thick-soled shoe, 287, 338
Thistles, how to destroy, 379
Thorough bass, 183
Thought, aims and instruments of scientific, 634
Threads in gas-pipes, 519
Thunder, lightning and, 597, 650, 673
Thunderbolts and lightning, 271
Thunder-storms: 35, 381; sulphurous smell after, 645
Tidal: mill, 183; power, 257
Tide, utilisation of power of, 609
Tile, glazing brick and, 573
Tiles, terra-metallic, 469
Tilt-hammer, 128, 179, 231, 283
Timber: ash, 286; greenheart, 312, 339; houses, 389, 441, 568
Timbers, durability of framed, 231
Time: apparent local, 38; at the antipodes, 208, 233, 259, 284, 308, 337, 361; equation of, 490; in England and New Zealand, 74; measures, 332
Tin: boxes to hold coppers, 332; preparation of oxide of, 98; surface, moisture on, 624
Tinned water-bottles, 104
Tinning and soldering, 236, 261, 285, 309, 361
Tireing cart-wheels, 338, 363
Tires: bending, 44, 100; fixing belts on, 102; furnace for heating wheel, 541; rubber, 130, 155; wheel, 46
Tissues, staining, 349
Tobacco and disease, 9
Tones, of violin, how they may be increased, 253
Tonkes, Mr.: letters by, 38, 70, 93, 126; to 71, 129
Tool: another combined, 99; checkering, 495; for describing patterns, 98; for punching out rivets of watch-chains, 412; size of iron, 415, 467
Tool-chest, carpenter's bench and, 311
Tools: improved turning, 523; wood-engraving, 416
Tooth, nerve of a, 165
Tooth-stopping, 44, 127
Top, spinning: 252, 279, 306, 307, 326, 353
Tortoise, 18
Touch-lightener, Mackenzie's, 40
Tour: on the Continent, 565; pedestrian, 181, 232, 336, 360, 413, 466, 490, 516
Tradesman, employment for retired, 519, 546
Training for bicycle races, 625
Transferring: pencil drawings to boxwood, 495, 621, to paper, 599; marble-paper to book edges, 416; prints to wood, 128, 168
Transit: instrument, wall, 640; lines, construction of, 121; of Venus, 9; of Zodiacal constellations, 223
Transits of Venus, past, 43
Transparencies, blackening, 18
Traversing screw chuck, 150
Treacle beer, 153
Treasury of botany, 156

Treatment of asthma, 55
Trebles: increasing the loudness of pianoforte, 301; of ordinary cottage pianos, improving, 431
Trees: age of, 598, 646; killing roots of, 157, 182, 568; pre-historic, 393; rainfall and, 637
Tremolo: 417; on violin, 487, 519
Tricycle: "Turret," 150; Yorkshire steam, 255
Trigonometrical, 263, 309, 494, 547
Trigonometry, question in, 260, 309, 361, 413
Trip: to Australia, 364; to Ireland, 339, 363
Triple stars, 485
Trunk engine, 207
Truss, 493, 546
Truth, searcher after, 380; "Sigma" as, 352
Tub butter, preserving, 181
Tubes: for meerschaum pipes, silver, 102; leaky, 389, 414; luminous, 596; old locomotive, 340, 388, 517
Tunic, stained scarlet, 547, 596
Tuning: 567; Æolian harp, 598; keyed instruments, 618, 643; pianofortes, and other stringed instruments, 463, 486; violin, 391, 416, 467, 487, 492, 517
Tuning-fork, seven-keyed, 569
Tuning-key, pianoforte, 540, 568, 591
Turbine, 157
Turin, university of, 313, 339
Turkey stone cutting, 75
Turner, Dr. Liebreich and, 203
Turners': Company, prizes of the, 581; society, amateur, 97, 150, 589, 641
Turners and turnery of King's Cliffe, 402
Turning: 338; ivory, 416; ornamental, 69, 98, 121, 146, 198, 255, 332, 567, 641, 647; oval, 493; spiral, 157; spokes of carriage wheels, 673; tools for metals, 516; tools, grinding, 332; tools, improved, 528
Turpentine and wood naphtha, 569
Turret: clock-line, 410; tricycle, 150
Turret-shaped hills, 19
Type, hardening lead or zinc, 517

UNANSWERED QUERIES, 176
Uncoiling new wire rope, 260
Underground telegraph wires in cities, 470, 518
Undulatory theory of light, 300
Unequal sizes of cone pulleys, 468, 492
University of Turin, 313, 339
Uninitiated, photography for the, 90, 191, 246
United States, telegraphy in, 466
Unripe seeds, 104
Unsound pianoforte, 645
Upsilon, Greek, 19, 75, 128, 153
Uranus: occultations of, 40; tables of, 379
Use and adjustments of the equatoreal, 551, 629
Useful cements, 325
Utilisation: of the power of the tide, 609; of waste material, 482
Utilising: chemical products, 365; old paper, 624

"V. C. A.," 133
Vacuum: in barometer tube, 157; is the interior of the globe a, 647; tubes, injury to, 157
Valencies and atomicities, 10, 41, 99, 123, 200
Valuable telescope, 459
Value of: agricultural chemistry, 57; manures, 130, 155; one second on sun's disc, 77
Valve, rotating, 320
Valveless and non-packing engine, 593
Vandyke brown, 466
Vapour, mercurial, 40, 119
Variation of pulse-beats, 613
Varnish: black for microscope objects, 440; cells, 598; flexible black for leather, 572, 596; for marble edges, 573; for Oxford frames, 74; for patterns, red, 416; for printing inks, 390
Varnishes, 88
Varnishing: 88; wall-paper, 75
Vats, iron, leaking, 545
Vegetable: beefsteak, 425; colouring matter, extracting, 671; marrow, preserved, 231; palæontology, 267
Vegetables, fresh, and sweet salads, 268
Vehicle, four-wheeled, 153
Velocipedes, 43, 98, 340, 364
Velocity: of rays of light, 23; of wheels and shafts, 179
Veneering, 155, 181
Veneers: 569; for covering walls, 298; maple, 648
Venetian blinds, 340, 388
Venomous serpents, 198, 340
Ventilating: bucket, Fairbairn's, 234, 259; "M.R.C.S." on, 196; rooms, 19; warming and, 40, 72, 93, 151
Ventilation: costless, 68; "Philo" and, 9
Venus: axis of, 430, 460; past transits of, 43; transit of, 9
Verde antico, 120, 178, 230
Verge, fixing balance wheel on, 285
Verge wheel, re-scaping old, 180
Veritas and the pendulum, 543
Vermin: 648; and pigeons, 105; novel method of destroying, 477
Vesuvian dust, 637
Vesuvius, recent eruption of, 272
Vibration and attraction, law of, 382
Vienna universal exhibition, 659
Viewing the sun, 201
Vine root, 443, 469
Vinegar: adulterations of, 525; detection of vitriol in, 273
Violet, a new aniline, 299
Violets and roses, scent from, 129
Violin: 21, 45, 104, 131, 180, 233, 467, 488, 516; case, 569; constructing, 516; how the tones of may be increased, 253, 207; new form of, 254, 274, 382; old, 517; reflector, "Fiddler's," 465; stain for, 232; tremolo on, 487; tuning, 391, 416, 467, 487, 492, 517; worm-eaten, 495, 621
Violoncello, cleaning, 182, 258
Virginia, its climate and soil, 181, 206
Vision: 520, 546; effects of faults in on painting, 162; recurrent, 190, 282, 332, 412; theory of and spectrum analysis, 171, 273
Visitors, summer, 332
Vital movement, 638
Vitality and electricity, 391
Vitriol, detection of in vinegar, 273
Vlacq's tables of logarithms, 249
Voice, weak, 105, 155, 340, 365, 389
Voicing organ pipes, 262
Volcanic mountains, 42
Volcanoes: earthquakes and, 193, 220, 271, 348, 374, 464; extinct, 66, 174; Mamertus and French, 279
Voltaic standard of electro-motive force, 404
Voyage, canoe, 209
Vulcan, the planet, 273
Vulcanite cells, fasteningto glass, 21

WAGES, calculating, 595, 644
Walking-sticks, telescopic, 613
Wall transit instrument, 640
Wallaroo copper, 258
Wall-papers: 621; arsenic in, 236, 261, 309; sulphur in, 470, 493; varnishing, 75
Walls: colouring, 157; concrete, 23; damp, 18, 74, 312; salt damp in, 78, 180, 258; wiring garden, 333; wood veneers for covering, 298
Walnut, darkening, 206, 233, 283, 386
Want of steam-power, 18, 101
Wanted, more light, 496
Warming: and ventilating, 40, 93, 151; greenhouses, 206, 232, 387, 441, 592; railway carriages, 542, 620, 666
Warmth, air and, 105, 130
Washers, locknuts and, 454
Washing: ballste, 364; new mode of, 143
Washing-machine, new, 190
Washington spherical rest, 644
Wasp, tame, 613
Waste: material, utilisation of a, 482; of coal, the, 609
Watch: fastening escape-wheel in lever, 100, 152, 205, 283; first made, 368, 387, 414, 441; repairing, 489, 564; the, and how to repair it, 421, 448, 503, 529, 580, 657
Watch-chains, fastenings for, 530
Watch-drills, 648
Watchmaking: 44, 205, 388, 596; and isochronism, 17, 179
Watch-plate, restoring colour of, 491
Water: aërated, 261, 309; analysis of, 181; bad, 599; bellows, 410; boring for jet of, 672; cement for, 23, 48; compressing, 157, 232, 258, 284, 308, 336; decomposition of, 638, by zinc, 32; distilled, 79, 102; elder-flower, 548; evaporation of, 625, 647; filter, cheap, 87, 309; filtering water, 311; flow of, 16; flow over weirs, 183, 208, 234; for aquarium, 673; hard, 365, 414; lifting, 47, 77; of deep-sea, 289; powder, 493; power, 17, 99, 103, 413; pressure of, 79, 102, 625; pressure under, 17; raising by tidal power, 198; regulator, 466; softening spring, 470; spheroidal state of and boiler explosions, 632; supply, 622; where is it gone to? 226, 328
Watercourses, Canadian, 357
Watercress, 201
Water-floats, 156
Water-glass: 259, 547; as a preservative of natural history subjects, 466
Water-pressure engine, 6
Water-power, 312, 363, 413, 442, 467
Waterproof: fishing socks, 441; leather, 133; worn, 365
Water-wheel: 20, 75, 156, 206, 258, 336, 337, 413; floats, 598; power of, 209, 235, 259, 284, 287, 309, 311
Wave-motion of the sea, 189
Wave pattern, 649
Waves: action of oil on, 598, 623; measurement of, 606; sound, 30
Wax: adulteration of, 144; extracting from old comb, 494; moth, 547, 570
Weak voice, 105, 155, 340, 365, 389
Weather: charts, 27; colliery explosions and the, 276; glass, 69, 126; maps, 450
Weaving by power-loom, 235
Webb's "Celestial Objects," 560
Weight: for safety-valve, 105, 129, 154; of cattle, 105, 130; metals, 44; milk, correct, 393; the earth at creation and now, 200
Weir's sewing machine, 649
Weirs, discharge of water over, 183, 208, 234
Welding cast iron, 155
Well, the deepest, 379
Well-sinking, 157
Westinghouse atmospheric railway brake 295
What is guano? 5
Wheelbarrow, 392
Wheel-cutters, 100
Wheels: 670; carriage, 346; cutlers', 47, gearing waggon, 43, 469, 518; teeth of, 564; turning spokes of carriage, 673
Wheel-tires: 46; furnace for heating, 541
Where is the water gone to? 226, 328
White: hair turning, 491; hard, 22; polish, 104
Whitechapel, spots on, 571
Whitewash, removing, 520
Whitlaw's new medical discovery, 45
Whitworth: lathe, 204; scholarships, 543
Whooping-cough, 236, 262, 285
Wind: 102; pressure of, 339
Window-sashes, fastening loose, 152, 199
Wine, elder-flower, 493
Wine, fruit and grape, 211
Winter, fuel for, 594
Winter's electrical machine, 545
Wire: covered, 23, 45; purifying zinc, 79; restoring brass, 389; rope, uncoiling new, 260
Wire-covering machine, 268, 381, 407, 433
Wiring garden walls, 333
Wonderful crater, 359
Wonderful gun-barrel, 38, 356
Wood: cementing iron in, 235, 259; distillation of, 361; ebonising, 57, 181; engraving tools for, 416, fern printing on white, 127; fireproof, 613; foreign, 258; gilding strips on, 233; laurel, madnip and, 415; metallic stain for, 493; paper from, 372; preservation and desiccation of, 1; preserving, 189; pulp for paper-making, 409; rendering incombustible, 207, 233, 259; rods, 22, 76, 101, 205; screws for, improved, 377; smoke, essence of, 649; stains in, 673
Wooden: concrete moulds, coating, 155; house at North Tawton, the, 568; pump, 105, 130, 155
Woods used in shipbuilding, 400
Wool: cleaning greasy, 482; separating tar from, 286
Woolwich infant, the, 562
Words, much experience in few, 250
Working: in metals, 230; plane surfaces, 519, 546; silk, 547; speculum, 257, 279
Worm-eaten violin, 495, 621
Works on artillery, 625
Worms: for fishing, 311; in pony, 600, 624, 646
Worthlessness of beef tea, 191
Wortley, Colonel Stuart, emulsion process of, 260
Wounds, simple method of healing, 302
Wrenches, improved spanners and, 243
Wringing-machine, rollers for, 23, 47
Writing, patriarchal, 385
Writing-machine for the blind, 164

YACHT: building, 416; rigging model, 156
Yeast: dried, 599; or barm, 625
Yorkshire: bone-cave in, 323; Nephilim in, 483; steam tricycle, 255

ZINC: amalgamated, 21, 38; and coal, 286; for aquarium, 362; wire, purifying, 79
Zodiacal constellations, transit of, 223
Zymotic diseases, 130, 180

ILLUSTRATIONS.

ACCESSORIES, lathe, 72
Æolian harp, improved, 540
Aerated drinks, improved machine for making, 380
Air, compressing, 596, 649
Allen's patent, governor, 373
Allingham's propeller, 39, 173
Amateur's, motive power for, 80
American chucks, 495
Aneroid, bell, 425
Angle of reflection and incidence, 204, 283
Antipodes, time at the, 234, 337
Apparatus for heating by hot water, 632
Aquarium, marine, 589
Arches, skewbacks of camber, 675
Area of segment of circular ring, 128
Aristarchus and Herodotus, 406
Artificial: calcareous formations, 86, 504; legs, 71; so-called organic concretions, 504
Atmosphere, compressibility of, 204
Atmospheric burner, handy, 567
Automatic gaslighting, 325

BANJO and bell attachment, 257
Basket-making, 120
Battery, Himmer's galvanic, 113
Bees, management of, 590
Beehive: improved, 511; Myborg, 251
Bell aneroid, 425
Bell-ringing mechanism for model church, 179
Bellows, water, 410
Bell's patent feed-water heater, 26
Bells, electric, 182
Belts, fixing on tires, 102
Bending tires, 44, 101
Bicycle handle, simple way of fitting, 177
Bleaching-powder, testing, 236
Blind-roller, self-acting, 295
Blowing apparatus; hydraulic, 648; self-acting, 124
Boats, sliding seat for racing, 372
Boiler for model steamboat, 258, 259
Boilers, recent improvements in English and American, 113, 138
Boiling by steam, 181
Book, using without hands, 19, 127, 224
Bookbinder's press, 623
Boot and shoemaking, 573
Boring and mortising machine, 216
Boundary line, drawing, 77
Braces, gauge for bit, 325
Bridge, proposed Channel, 64
Bucket, Fairbairn's ventilating, 259
Buildings, monolithic, 408
Burner, handy atmospheric, 567
Bus, new steam, 161
Butterflies and moths, setting, 266
Buttons, cleaning metal, 156

CABINET for microscope objects, 307
Calcareous formations, artificial, 86, 504
Calculus, 548
Caliper compasses, 16
Carpenter's bench and tool-chest, 311
Carpet stretcher, 324
Carriage wheels, improvements in, 225
Cask stand, new, 349
Casting metal in air-tight moulds, 124
Centrifugal pump, 419, 470
Channel bridge, proposed, 64
Chemistry, lessons on, 3, 30, 112, 242
Chess, 546
Chest expander, 389, 414
Chimney, smoky, 261
Chuck: grip, 338; oval, 130, 206; traversing screw, 150
Chucks, American, 495
Circular saws: improved spindle for, 13; spindle for, 259
Clavicle, humerus, and new cranium, 255
Cleaning metal buttons, 156
Clothes-horse, suspended, 13
Coffee, 416, 517
Coil, medical, 597
Colliery explosions and the weather, connection between, 222
Combined knitting and sewing machine, 269; tool, another, 99
Compasses, caliper, 16
Complaint, spinal, 128
Compound engines, 361
Compressibility of the atmosphere, 204
Compressing air, 596, 649
Concretions, artificial so-called organic, 504
Confectionery, improved means o manufacturing, 199
Conic sections, 262
Connecting-rod, stub-end for, 454
Cork lock, 352
Corks, Fleming's locking, 312
Cover-plates, 414
Cranium, clavicle, humerus, and new, 255
Cube, duplication of the, 333
Curve, sunrise, 98
Cutter-bar, 668
Cutting screws, 644
Cyrillus, Theophilus and, 147

DAISY extractor, 180
Dark tent, portable, 389
Deluge, one proof of, 175
Disc, avoiding metal, 77, 180
Disease, the potato, 653
Distant signals on Midland, 541
Dormoy's revolving rabble, 213
Double stars, new, 280
Drains, house, 481
Drawing boundary line, 77
Drilling machine: 76; universal angular, 57
Duplication of the cube, 333
Dynamic refrigerator, 428

EBDY'S patent gas-stove, 402
Eccentric, adjustable, 13
Eclipses of sun as seen from Jupiter, 176
Edible mushrooms of Italy, 510
Electric bells, 182
Electrical machine, the Holtz, 90, 398
Electricity, measuring temperatures by, 531, 558
Electro-metallurgy, 502
Ellipsograph, 593

THE ENGLISH MECHANIC

AND WORLD OF SCIENCE.

ARTICLES.

THE PRESERVATION AND DESICCATION OF WOOD.

THE preservation of timber is a subject that has occupied the attention of scientific inquirers for years, and notwithstanding that iron has supplanted it for many purposes, wood is still used to an extent which makes its duration a consideration not to be lightly passed over. On p. 324 of our last volume we gave an account of the results of some experiments tried with various antiseptic preparations on green oak, by Herr Muller, from which it appeared that the best method of preserving wood from the effects of moisture is to force into it two mineral antiseptic salts, which mutually decompose each other in the pores of the wood, and by coagulating the albumen, and excluding the water, prevent decay. The two salts found to give the best results were phosphate of soda and chloride of barium, in solutions of which the timber was steeped; but a combination of soda, soap, and sulphate of copper is probably equally efficient, and this latter process is to be preferred for timber likely to be subjected to the attacks of worms, which under certain circumstances necessitate the exercise of as much precaution as the decay known by the generic name of rot. The best known processes, however, are those which employ creosote, corrosive sublimate (Kyanising), chloride of zinc, and sulphate of copper, all of which have been used with fair success. Kyan's process, patented in 1832 and 1836, was highly thought of at the time of its introduction, but it is now seldom used. Payne's method consisted in first forcing a solution of sulphate of iron into the wood, and subsequently introducing carbonate of soda, an insoluble substance being thus formed in the cellular structure of the wood, the process when properly and effectually carried out having yielded satisfactory results. Chloride of zinc has been used in several of the Government dockyards in preserving wood for the interior fittings of vessels, which are frequently liable to the attacks of insects. But probably the most successful process hitherto adopted is that known as creosoting, in which the wood is completely impregnated with oil of tar, the bituminous portion of which enters the capillary tubes of the material, closing the pores and preventing the access of air and moisture, while the albumen is coagulated and the attacks of worms and insects generally warded off by the noxious properties of the creosote. But even this method fails to preserve timber from the ravages of the *Limnoria terebrans* for any length of time, as piles under water, such as those of jetties, have been found to be eaten through after about four years, although thoroughly creosoted, the preserving process appearing to be effective only so long as the external coating of the oil endured. The process, as patented by Mr. Bethell, consists in drying the wood in a chamber through which the smoke and the products of combustion of the fuel, which also heats the oil, are passed; the wood while still warm is then immersed in a bath of heated creosote, or placed in strong wrought-iron cylinders, and the preserving fluid forced into it at a high pressure. With soft woods, such as pine, but little difficulty is experienced in thoroughly impregnating the timber, but with oak and other woods a pressure of 170lb. or 180lb. on the square inch is not sufficient to creosote more than the outer inch or so.

One of the simplest methods of preserving wood is that introduced by M. Boucherie, which has been found effectual with elm, poplar, alder, beech, birch, and other porous-grained timber when newly felled. He employs a solution of sulphate of copper (1 to 100 of water), and a water-tight cap being fitted on one end of the log to be preserved and connected by a tube with the tank containing the solution, which is elevated about 40ft. from the ground, the sap runs out at one end as the preserving fluid enters at the other, the weight of the liquid in the tank furnishing the very moderate pressure required by this system.

Some interesting particulars of the various plans hitherto adopted for the desiccation of wood, have been recently published by M. Payen in the *Annales de Conservatoire*. From these we find that the methods heretofore employed in the desiccation of wood may be referred to one of the following classes:—1. Coatings applied to the surface of wood in order to prevent the access of air and moisture. 2. Simple immersion in an antiseptic fluid. 3. Vital suction or filtration, of which the Boucherie process mentioned above is the type. 4. Injection of antiseptic fluids, in a closed vessel, by alternation of vacuum and pressure. 5. Artificial desiccation, followed by injection in closed vessels.

The presence of water and air in wood is one of the principal causes of the fermentation of its organic matter, and of its consequent alteration and destruction. These changes often remove an appreciable part of organic matter containing combustible carbon and hydrogen, while the hygroscopic water contained in the wood, in its volatilisation absorbs a part of the heat developed in combustion, thus diminishing its calorific powers.

To give a precise notion of the utility of the desiccation of wood fuel, it is necessary to compare the quantity of useful heat obtained from dried and from green wood. This comparison is easily made by taking for standard the mean elementary composition of some wood, say oak, and the equivalent of carbon given under the two conditions. 100 parts of dry oak contain 50 of carbon, 6·20 of hydrogen, and 43·80 of oxygen. To the calorific power of the carbon (50) should be added, the equivalent representing the excess of hydrogen (somewhat variable in different kinds of wood) above the quantity necessary to unite with the oxygen so as to form water. In oak, this excess is 0·630; equivalent to at least 1·89 of carbon. 100 parts of dry oak are, therefore, equivalent to $50 + 1{\cdot}89 = 51{\cdot}89$ of pure carbon.

But in order to determine the quantity of useful heat, it is proper to deduct that which, in the process of combustion, transforms into vapour the hydrogen and oxygen. This water of composition is fifty-hundredths of the total weight, absorbing in transformation into vapour at the temperature of combustion a quantity of heat equivalent to 5 of carbon, which is to be deducted from 51·89; giving a remainder of 46·89 of useful carbon, which represents the calorific power of 100 parts of dry oak.

Now suppose that moist oak contains 45 per cent. of water: As 100 parts of desiccated wood represent 46·89 of carbon, 55 would give 25·79 of carbon; from which is to be deducted 4·50 used in vaporising the 45 parts of water; giving 21·29. It follows that 225 parts of green wood must be burned to give as much useful heat as 100 of dry. But besides this loss, it happens that in certain cases, as in the melting of glass and of zinc, it is impossible to attain the desired end by the use of green wood. Hence, desiccation, almost always useful, becomes an absolute necessity in the manufacture of glass and in metallurgy where wood is the fuel employed.

In the injection of wood under pressure the elimination of the water of moisture permits the antiseptic liquid to take its place. Hence the more or less complete expulsion of the water would be useful in various ways, and would fulfil one of the conditions most favourable to its conservation.

There are two methods of desiccation: the natural, by long exposure to air, under cover; and the artificial, by means of stoves or ovens. The natural process is insufficient for preservation; for however great the pains and long the exposure, there always remains a residuum of water, amounting to from 10 to 20 per cent., sufficient to cause fermentation, to invite insects, and to favour cryptogamic growths. This sort of drying is suited only to wood for carpentry or furniture; being sufficient to prevent change of dimensions or warping when removed from the action of humidity. The artificial process secures a more complete preservation, since it drives from the wood all the contained moisture; this condition cannot be maintained against the influence of the atmosphere, except by some coating impervious to moisture. On the other hand, the preparation of the wood, or its injection with antiseptic fluids in closed vessels cannot be successful unless the wood has been sufficiently dried, so as to allow the withdrawal of the air from the tissues. When moist wood is subjected to this process, the liquids cannot escape; and of course their place cannot be taken by antiseptic fluids.

Experience has shown that injection in closed vessels is practicable only with woods sufficiently dried, and this explains the invention of so many apparatus for desiccation. It is only within a few years that this preliminary desiccation has become successful; a success mainly due to the apparatus described further on.

Attempts to desiccate wood have been frequently made. Wollaston and Fourcroy recommended the process; and Newmann employed steam for the purpose. Placing the wood in a large wooden box, he admitted steam from a boiler and drew off the condensed vapour charged with albumen and sap. The progress was tested by the colour of the liquid drawn off; when this became colourless the wood was taken out. This method would have given favourable results if superheated steam had been employed so as thoroughly to permeate the wood; but the expense would have been too great. In 1837 M. de Mecquenem invented a process which consisted in subjecting the wood to a current of heated air in a closed vessel; the current being impelled by a blower. The air entered at the bottom and escaped at the top. In 1839 M. Carpentier patented an invention in which he made use of a hermetically closed chamber, in which the wood was exposed to the action of air heated by passing over metallic plates, and introduced through four longitudinal tubes disposed upon the floor of the furnace, from which it was discharged into the heating chamber. The vapours and the moist air escaped by four longitudinal pipes placed in the upper part of the furnace and communicating with the chimney.

In 1848—1853 Bethell, who gave much attention to the preservation of wood and vegetable substances, took out a number of patents in England and France. One of these consisted of a rectangular brick chamber, with hollow walls filled with cinders to prevent radiation; the arched roof being constructed in the same way. One end was left free to admit a carriage on rails, and a double iron door closed this entrance when the chamber was filled. At the other end was a furnace provided with a grate for the burning of coke, oil, wood, or tar, according to the end in view, whether simple desiccation, or *smoking;* that is, impregnating with antiseptic gases proceeding from the incomplete combustion of tarry substances. The products of combustion passed through a central flue at the bottom, which divided near the entrance; the branches carried the smoke to the bottom of the chamber, from which it passed over the wood. The smoke, gases, and moisture escaped at one end by a pipe at the top, and at the other by a sort of ventilating chimney. The temperature was about 210° Fahr., and the time varied from eight to twelve hours. This rapidity was obtained at considerable expense of fuel; for the rapid movement of the heated gases did not permit the complete utilisation of their caloric, and it is doubtful whether large pieces of wood, as railway ties, can be thoroughly desiccated in so short a time. This, indeed, was shown by numerous experiments made at London in 1853 by the "Desiccating Company." The wood was placed in a close chamber of a capacity of about 1,300 cubic yards. The air was heated in Taylor's apparatus, as in the metallurgy of iron, and was driven over the wood by a ventilator; but slowly, and in such quantity that the atmosphere of the chamber was entirely changed in three or four minutes. Nearly twenty-four bushels of coal were consumed in twenty-four hours. It was found that an average of fifteen days was required for complete desiccation at a temperature of from 113° to 140°. This low temperature and protracted time seem to be better for woods that are to be used in carpentry, cabinet work, and the like.

The furnace of M. Guibert, of Tourlaville, invented in 1861, was in essential points similar to that of Bethell, patented in England in 1848. Reuther's invention (1860) was intended for the desiccation of ties and their injection with creosote. The products of combustion are introduced by means of canals at the bottom of either side of the chamber. These are covered with iron plates which heat the air within the chamber. At the extremities near the door are two vertical pipes which enter the hollow space in the walls and the vault. A chimney surmounts the vault at either end. Before the wood is put in, the two orifices at the end of the canals are opened so that the smoke and heated gas may enter the chamber and raise its temperature. At the beginning of the operation, one chimney is closed so that the products of combustion may pass directly to the other chimney by the vertical pipes. When the vault is warm enough, the second chimney, that near the entrance, is closed. The time of desiccation is twenty-four hours, the temperature being gradually raised to 210°.

In all the apparatus described, the gas, smoke, and heat are introduced at the bottom, while the discharge is from the top. This disposition is defective, because the heated air rises directly to the top of the chamber, and escapes without having had time to become saturated with the moisture of the wood.

Peclet in his treatise on "Heat" noticed this defect, and recommended a reversal of the direction of the heated currents. He states that in 1822 M. Ternaux effected this in a vermicelli desiccator at Saint Ouen, and that the operation was much more rapid. He says: "We thus find a condition of great importance; that the issue of vapours should always be effected at the bottom of the drying-chamber. This prevents stagnation, and is at the same time very favourable to the saturation of the heated air; for hot air moves rapidly while rising in a denser medium, but moves slowly and distributes itself uniformly when it circulates downward."

Peclet proposed the following process for drying wood and peat: Two parallel galleries with a furnace at the bottom of each, and horizontal pipes under the bottom, through which the smoke is to pass uniformly and in succession, so as to distribute the heat as uniformly as possible. Each gallery is to be closed at both ends by double doors, and is to be provided with rails for iron waggons, upon which the wood is to be piled so as nearly to fill the chamber. The smoke of the two furnaces passes into a common chimney of large section, having a draught-regulator at its top. The adjacent walls of the galleries form a closed space; in the middle of this is a chimney which communicates below with each of the galleries by means of orifices provided with registers. On each side of the chimney, at the bottom, are the furnaces. This process was applied some years ago at Graffenstaden. The apparatus was of trapezoidal form; there were six chambers heated by seven furnaces, disposed in two sections separated by a passage. The vapours escaped by lateral orifices at the bottom, opening into the chimney. Each furnace was connected with a horizontal brick chamber, hermetically closed at the end, which divided and returned upon itself to open into a vertical chimney near the furnace. The desiccation lasted night and day for from ten to twenty days. Experience fixed the temperature for oak at 100° and for pine at 120°. The action of this apparatus is very slow, and, therefore, not fitted for the desiccation of railroad ties.

In 1851 M. Imbert took out a patent for an oven for drying wood intended as fuel in metal or glass works. The chamber was long, and its bottom was covered with metallic plates forming three longitudinal tubes, which terminated at one end in the chimney of a small furnace set several yards below, in a vault. The carriages entered at one end and were removed at the other, near which the products from the fire entered by orifices in the plates. The gases escaped by an orifice in the lower part of the oven. When the wood on the carriage nearest the discharging door was dry enough, it was shoved out by another introduced at the entrance. The temperature was lower nearer the entrance, so that the wood advanced in a contrary direction to that of the motion of the gases, and passed into successively higher temperatures.

This device of making the wood advance in a direction contrary to the motion of the heated gas was afterwards recommended by Lechatelier in 1853. He proposed for the desiccation of ties which were to be injected, an apparatus like the kiln employed in annealing glass. The wood was to be put in a long gallery, on waggons, and to be slowly moved in a direction contrary to that of the heated gas, towards the maximum point of temperature, the introduction and removal being effected as in the last case.

In 1863 Mr. Blythe, an English manufacturer who was engaged at Bordeaux and Landes in the injection of wood with sulphate of copper, invented the apparatus which has now come into most general use. This is a double oven, composed of two rectangular chambers about 10½ft. wide, 8ft. high, and 10½ft. long. The outer and partition walls are of brick, resting on a foundation of masonry. Two brick vaults roof the chamber. The side and partition walls are hollow, the space being 3in. wide, and extending the entire length and height of the wall. These hollow spaces communicate with the lower part of the chambers by small openings, and with small chimneys at the top. At either end of each chamber is a double gate of iron. In each chamber, at a little distance from the side walls, are set two walls of masonry for the rails. Between and below these walls is a long arched passage, communicating with a furnace. The furnaces are covered by a fire-brick vault, which projects over the fire-grate far enough into the chamber to cover the flame. Along the whole length of the walls of the passage just described, and inside the rails, run two small flues or passages; and between these is another flue, so connected with the furnaces as to form a separate passage for each, so as to prevent the mixture of the products of combustion.

The action of the apparatus is as follows:—Four waggons of wood are introduced, and the doors shut. The products of combustion enter the passages from the furnaces; thence they enter through orifices into the two flues just inside the rails. The heated gases now rise and and pass through the wood, taking up the water that has been converted into vapour. In doing this they cool, and then pass along the walls, which are colder than the middle of the chambers. Arriving at the bottom, they escape by orifices regularly distributed in the hollow wall, and pass out by the chimneys. By this method a constant and uniform circulation is secured, and the temperature is sensibly uniform.

The great advantage of this system is that the process can be completed within twenty-four hours after the tree is felled, and even water-logged timber can be subjected to it and effectually dried.

THE ECONOMICAL USE OF STEAM.

AT the recent meeting of the Manchester Steam-Users' Association, Sir William Fairbairn made some observations concerning the most economical pressure at which it is desirable to employ steam. The subject is one of increasing importance, if not exactly in view of the exhaustion of our coal supplies, at least as an attempt to meet the largely enhanced cost of fuel which is likely to arise. It is a matter of fact that by raising the working pressure from 10lb. or 15lb. to 50lb. a saving of one half the fuel required is effected, while an equal amount of work is accomplished; and assuming that the same law holds good for pressures up to even 1,000lb. it is a subject worthy the earnest consideration of steam-users at what pressure it is safe to work boilers in order to obtain the greatest economy in fuel. From the experiments which Sir W. Fairbairn has made for some years past on the density, force, and temperature of steam, he is convinced that if a large economy in fuel is ever to be attained it must be by employing greatly increased pressure, and a more largely augmented rate of expansion than what is usual at present. The results of his experiments have convinced him that dry steam isolated from water at a high pressure gives double the work at the same expenditure of fuel—an opinion which is indorsed by the most eminent writers on the subject. Regarding the construction of boilers capable of withstanding high pressures as a matter completely under control, and having arrived by actual practice, at a knowledge that steam at 50lb. or 70lb. per square inch can be governed as easily as that at 15, he asks why pressures of 150lb. and 200lb. should not be tried on the presumption that the saving of fuel would be in proportion and follow the same law in the ratio of the increase of pressure—*i.e.*, a more complete utilisation of the heat, and consequently a greater amount of work at the same expenditure of fuel. All attempts to effect changes of this description are, of course, limited by the amount of strength it is found possible to impart to the boiler, and by the conditions essential to the safety of its working. On this, the most important part of the question, however, he has no misgivings, for from experiments he has been making recently, he is convinced that the steam-user would be as safe, if not safer, in working at 150lb. as he is at present with 50lb. per square inch. Sir William did not explain the principle on which these boilers are to be constructed, but mentioned that he had one of 80 horse-power at work, which had been tested by hydraulic pressure to 400lb. on the square inch, this being the limit to which the pumps and gauges employed were capable of working. He is convinced that it would have withstood double that pressure (*i.e.*, 800lb.) if the testing apparatus had been equal to the task. A suitable engine is also undergoing a series of trials, and while all parties are satisfied with the boiler, he hopes that the same may before long be said of the engine. Sir William was very naturally reticent as to the construction of his experimental apparatus, but the introduction of the matter before the Association is an earnest that full particulars will shortly be given. The engineer of the Association points out that no higher charge is made for boilers working at 100lb. than for those at as low as 10lb. per square inch, provided they are constructed in a manner suitable to the higher pressure. Locomotives are worked at from 120lb. to 200lb. on the square inch, and we see no reason why similar pressures should not become the fashion in stationary boilers; for, as Sir William said, "there are no secrets in boiler explosions; they are entirely owing either to neglect on the part of the engineer or on the part of his employer."

LESSONS ON CHEMISTRY.*

BY SELIMO R. BOTTONE.

(*Late of the Istituto Bellino, Novara, Italy.*)

(*Continued from p. 597, Vol. XIV.*)

SECTION 6B. — COMPOUNDS OF OXYGEN WITH CHLORINE.

98.—OXYGEN combines with chlorine in five[1] different proportions, but of the resulting compounds only *three* are known in the free state.

1 Many chemists admit only *three* of these as being definite compounds; but they are not agreed as to which of the five are to come under this designation. While Miller, Roscoe, and most English chemists hold the bodies marked A, B, and C to be the true oxides of chlorine, Millon, and others who have devoted much study to the subject, incline to the belief that A, B, and E are the only ones worthy of that name, and that the others are either mixtures of chlorine gas with one or other of these oxides, or else compounds of these oxides with each other. A brief notice of these doubtfully-constituted bodies will be found at the end of this section (6B).

A. CHLORINE MONOXIDE.[2]—*Synonym: Hypochlorous anhydride. Symbol:* $Cl_2'O''$. *Molecular weight:* 87.

99. PROPERTIES.—At ordinary temperatures this body exists as a pale reddish yellow gas[3] of the specific gravity of 3·01. Its odour is very powerful, resembling that of chlorine. It dissolves freely in water, furnishing a solution of yellow colour, which possesses powerful bleaching properties. At a temperature of about 0° Fahr., chlorine monoxide becomes liquid. In the fluid state it is of a red colour, and is heavier than water. Thrown into water, liquid chlorine monoxide sinks to the bottom, and then, provided there be sufficient water, dissolves. When once reduced to the liquid form chlorine monoxide does not boil, or even appear to volatilise, until the temperature reaches 70° Fahr. It is, however, a very dangerous body to handle, as it sometimes explodes spontaneously even when surrounded with a freezing mixture. The solution of chlorine monoxide in water bleaches with much greater power than the solution of chlorine. We can easily understand the reason of this greater energy when we call to mind that chlorine bleaches by virtue of its power of seizing the hydrogen contained in the water, and liberating its oxygen; for the quantity of oxygen liberated by the chlorine monoxide solution is exactly double that liberated by an equal amount of chlorine solution. This is illustrated by the following equations:—

For Chlorine $\qquad Cl_2' + H_2'O'' = Cl_2'H_2' + O''$

For Chlorine Monoxide $\qquad Cl_2'O'' + H_2'O'' = Cl_2'H_2' + O_2''$

The oxygen thus liberated, being in the *nascent state*,[4] rapidly enters into combination with the elements of the colouring matter, producing thereby colourless compounds.

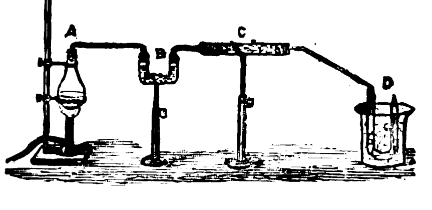
100.—As we shall return to the subject of chlorine monoxide when dealing of the correct application of the word "acid," we would impress on the reader's mind *that the solution of chlorine monoxide in water is yellow.*

101.—PREPARATION.—By passing *dry* chlorine over mercury oxide, when part of the chlorine combines with the mercury to form mercury chloride, and part with the oxygen to form chlorine monoxide. The following equation exemplifies the changes which take place:—

$$Hg''O'' + Cl_4' = Hg''Cl_2' + Cl_2'O''.$$

Fig. 9 represents the apparatus required. A is the flask for generating chlorine, B tube containing calcium chloride, which absorbs[5] any moisture the gas may carry with it; C tube containing mercury oxide, D tube in which the

FIG. 9



chlorine monoxide may be condensed by a freezing mixture.

A (2). HYPOCHLOROUS ACID.—*Synonym: Hydrogen Hypochlorite.*[6] *Symbol:* $H'A'O''$. *Molecular and combining weight:* 52·5.

102.—PROPERTIES. — Hypochlorous acid is a colourless fluid, of a very peculiar smell and powerful bleaching properties. It combines with metals to form a class of bodies called *hypochlorites.* It appears to be formed from chlorine monoxide by the union of one molecule of water with one of chlorine monoxide (hence called hypochlorous anhydride, or hypochlorous acid without water.) By this union a substitution takes place, and two molecules of hypochlorous acid result. The following graphic equation will facilitate comprehension:—

1 Molecule of Chlorine Monoxide. $\quad$ 1 Molecule of Water. $\quad$ 2 Molecules of Hypochlorous Acid.

$$\left.\begin{array}{l}Cl'\\Cl'\end{array}\right\rangle O'' + \left.\begin{array}{l}H'\\H'\end{array}\right\rangle O'' = \overbrace{\left.\begin{array}{l}Cl'\\H'\end{array}\right\rangle O'' + \left.\begin{array}{l}Cl'\\H'\end{array}\right\rangle O''}$$

When hypochlorous acid acts on metallic bodies, the hydrogen contained in the molecule is expelled, and the metal takes its place thus:—

$$M' + H'Cl'O'' = M'Cl'O'' + H.$$

(See paragraph 53.) Acted on by metallic oxides, water is formed, while the metal unites with the oxide of chlorine, thus:—

$$M_2'O'' + 2H'Cl'O'' = 2M'Cl'O'' + H_2'O''.$$

The resulting compound in either case is a hypochlorite of the metal employed. This property of acting on metallic oxides, with the production of water, is common to all acids.[7]

103.—PREPARATION. — When chlorine gas is passed through a cold solution of soda ($Na'H'O''$), a mixture of sodium hypochlorite, along with sodium chloride, is formed, as may be seen below:

$$2Na'H'O'' + Cl_2' = Na'Cl'O'' + Na'Cl' + H_2'O''.$$

If, instead of soda, we use slaked lime ($Ca''H_2'O_2''$), a similar interchange takes place, and we obtain a calcium hypochlorite in mixture with a calcium chloride, thus:—

$$2Ca''H_2'O_2'' + 2Cl_2' = Ca''Cl_2'O_2'' + Ca''Cl_2' + 2H_2'O''.$$

By acting on either of these substances with dilute nitric, or acetic acid, the hypochlorous acid is liberated, and may be obtained by distillation; while the calcium chloride (or sodium chloride, as the case may be) is left unchanged. The following equation elucidates this:—

$$Ca''Cl_2'O_2'', Ca''Cl_2' + 2H'N'''O_3'' = Ca''2N'''O_3'' + Ca''Cl_2 + H_2'Cl_2'O_2''.$$

104.—The hypochlorites are much used in the arts as bleaching and disinfectant agents; the ones most in use are the impure calcium, sodium, and potassium hypochlorites. The first is known commercially under the names of *bleaching powder*, or *chloride of lime;* the second is known as *bleaching liquor*, or *chloride of soda;* and the last goes by the name of *Eau de Javelle.* The use of the hypochlorites of magnesium, aluminium, and zinc, as bleaching agents, has also been proposed. Chloride of lime, for the use of the arts, is prepared on a large scale by the following process:—A chamber, built of lead or Yorkshire flagstone, and containing a number of perforated shelves, is provided. Into this, on the shelves, are placed thin layers of well-slaked lime. Chlorine[8] is then introduced, which, acting on the lime, produces the compound in question. The richness of the resulting substance in hypochlorite depends—(1) on the goodness of the lime; (2) on the amount of water it has absorbed during the slaking; and (3) on not allowing the chlorine to enter the chamber too rapidly, as in this latter case heat is generated, and a new compound, possessing no bleaching properties, is formed. The quantity of chlorine absorbed, even under the most favourable circumstances, always falls short of that indicated by theory. When acted on by hydrochloric acid, hypochlorous acid is resolved into water and chlorine, as the following equation illustrates:—

$$\left.\begin{array}{l}Cl'\\H'\end{array}\right\rangle O'' + H'Cl' = \left.\begin{array}{l}H'\\H'\end{array}\right\rangle O'' + Cl'Cl'.$$

All acids which are sufficiently powerful to set free hydrochloric acid from calcium chloride, produce this effect when added to bleaching powder.

105.—We have seen (paragraph 87) that manganese binoxide facilitates the production of oxygen from potassium chlorate without undergoing any *apparent* change; a somewhat similar effect is produced when the oxide of copper, or of cobalt, is heated with the solution of a hypochlorite. No change is visible in the oxide used, but the oxygen of the hypochlorite is gradually eliminated, and a metallic chloride is formed, thus:—

$$M'Cl'O'' = M'Cl' + O''.$$

"This decomposition depends on the fact, that higher oxides of the metal are at first formed; but these decompose under the influence of heat, and give off oxygen, regenerating the lower oxide, which again attacks another portion of hypochlorite, and thus the process becomes continuous. It is not improbable that the action of manganese binoxide, in facilitating the evolution of oxygen from potassium chlorate, may depend upon a similar action."[9] It is also probable that the effect noticed above (of copper sulphate on air and hydrochloric acid) is due to the same cause. Owing to the above reaction, oxygen may be easily prepared from a hypochlorite.

106.—By attentive examination of the mode in which hypochlorous acid comports itself with regard to metals and metallic oxides, we are led to the conclusion that the rational graphic formula of this body is

$$\begin{array}{l}Cl'\\ \updownarrow\\ O''\leftrightarrow H'\end{array}$$

Here we see that the bivalency of the oxygen enables it to hold the two atoms (each monovalent) of hydrogen and chlorine, and this gives also the key to the interchanges which may be effected by substituting a metal for the hydrogen. Not only can the hydrogen be replaced by another monovalent body, but the chlorine also is capable of being replaced in like manner. Hence, as we have seen (104), by acting on this body with hydrochloric acid, we actually bring about this substitution. It is worthy of remark, that both monoxide of chlorine and hypochlorous anhydride may be conveniently referred to the type, *water.*

Water. Chlorine Monoxide. Hypochlorous Acid.

$$\left.\begin{array}{l}H'\\H'\end{array}\right\rangle O'' \qquad \left.\begin{array}{l}Cl'\\Cl'\end{array}\right\rangle O'' \qquad \left.\begin{array}{l}H'\\Cl'\end{array}\right\rangle O''$$

But water itself may be referred to the type *oxygen*, for the oxygen molecule is built up of two bivalent atoms of oxygen,[10]

Oxygen. $\qquad$ Water.

$$O'' \rightleftarrows O'' \qquad \left.\begin{array}{l}H'\\H'\end{array}\right\rangle O''$$

while in water two monovalent atoms of hydrogen replace one bivalent atom of oxygen.

[2] Owing to the different views held by various chemists as to the molecular constitution of bodies, and the relations which these hold to one another, our chemical nomenclature is in a state of transition and fearful disorder. Hardly two chemists agree as to the most appropriate name for any compound. Hence, at the London University Matriculation Examinations, the name given to the compounds and expected to be used by the candidates varies with each examiner, and at nearly every examination. It would only confuse the reader were we to put in the text *all* the names by which any substance may be designated; but in footnote will be found most of the received names. All theoretical considerations regarding the adaptability, propriety, and scientific accuracy of the names will be deferred until a sufficient number of facts has been placed under the reader's notice to enable him to judge for himself. The synonyms of chlorine monoxide are protoxide of chlorine and hypochlorous acid. This last is the name *now* used (1872) by the examiners.

[3] Of all modern autherities Roscoe is the only one who states this gas to be colourless.

[4] Nascent (from *nascere*, to be born), being born. An element is said to be nascent when just set free from a compound containing it. Elements are found to be gifted with much greater chemical energy when in the nascent state than in their ordinary condition. The reason is obvious. We have seen (17) that elements in their free state consist of an aggregation of molecules, each of which is built up of two or more atoms of the self-same element. Now, in these molecules the valencies of the element are, to a certain extent, satisfied reciprocally. Let us take, for the sake of example, the molecule of ordinary oxygen, consisting, as we have reason to believe, of one atom of oxygen, united to another atom of oxygen, by virtue of the two valencies inherent to each atom, thus:—

$$O'' \rightleftarrows O''$$

But on liberating an element (say oxygen) from its compounds, the individual atoms are, *pro tempore*, free, and hence act with their full power, thus:—

$$\leftarrow O'' \rightarrow$$

But, of course, if no other element be present with which they can combine by preference, these atoms instantly unite to form the molecules of ordinary oxygen.

[5] Many substances are used for drying gases. Pumice stone soaked in oil of vitriol is very useful. Potash, lime, &c., are sometimes employed.

[6] Hydric hypochlorite. Barff., 1871.

[7] We use the term "acid" in preference to "hydrogen salt," for reasons which will be hereafter adduced.

[8] The chlorine for this purpose is prepared by a new and most interesting process. It has been found that by causing a mixture of hydrochloric acid gas and common air to pass over heated copper sulphate, the oxygen contained in the air combines with the hydrogen of the hydrochloric acid, forming water, and liberating the chlorine, thus:—

$$O_2'' + H_4'Cl_4' = H_4'O_2'' + Cl_4'.$$

The copper sulphate *apparently* undergoes no change, hence it may be used an indefinite number of times; but it is probable that a series of rapid oxidations and deoxidations take place in it. We shall return to this point shortly when treating of the action of some metallic oxides on hypochlorites.

[9] Roscoe.

[10] See paragraph 26 in farther elucidation of this view.

B. CHLORINE TRIOXIDE.—*Synonym: Chlorous anhydride.*[11] *Symbol:* $Cl_2'O_3''$. *Combining weight:* 119.

107.—PROPERTIES.—A gas of a deep greenish-yellow colour, with a specific gravity of about 2·745.[12] It has a very strong, pungent smell. In the presence of water it bleaches powerfully. Heated to 135° Fahr. it explodes with moderate force, resolving itself into his constituents.

108.—PREPARATION.—When a mixture of potassium chlorate, nitric acid, and a deoxidising body[13] is heated to a temperature somewhat under 135° Fahr., chlorine trioxide is evolved, and may be collected by downward displacement, as shown at Fig. 3 (see paragraph 51). Care must be taken not to reach 135°, as explosion would ensue.

B (2). CHLOROUS ACID.—*Synonym: Hydrogen Chlorite.*[14] *Symbol:* $H'Cl'O_2''$. *Combining weight:* 68·5.

109.—This body has been but little studied. It is known to be a most active bleaching agent. It is formed by the union of chlorous anhydride with the elements of water, thus:—

$$Cl_2'O_3'' + H_2'O'' = H'Cl'O_2'' + H'Cl'O_2''.$$

In presence of metallic oxides, it gives rise to a *chlorite* of the metal employed with the reproduction of water, thus:—

$$M''O'' + 2H'Cl'O_2'' = M''2Cl'O_2'' + H_2'O''.$$

The graphic formula of this body may be expressed as

$$H' \rightarrow \leftarrow O'' \rightarrow \leftarrow O'' \rightarrow \leftarrow Cl'$$

REVIEWS.

The Deviation of the Compass in Iron Ships considered practically. By W. H. ROSSER. London: J. Imray and Son.

A VERY practical manual on an important subject, and when we consider the immense amount of property afloat and the vast number of lives exposed to danger, if not to death, on our ocean highways, the appearance of a concise series of directions for ascertaining the *deviation* of the compass in iron ships by the ordinary method of swinging, for the construction of steering cards, for the determination of deviation at sea by time azimuths of the sun or a star, for finding the errors of adjusted compasses, and also of the heeling error, with the method of adjusting the standard compass, and other matters appertaining to the general subject, written in an easy style, which we are certain will commend itself to the class for which the work is principally intended, is a sign that no ordinary interest is manifested in the welfare of our sea-going population.

It is to be regretted that undue dependence is often placed on the adjustment of the compasses by professional adjusters, the officers of a ship in many cases being quite satisfied that the compasses are adjusted, and they are furnished with a steering card. On this head the author's prefatory remarks are exceedingly pertinent. Speaking of the treatment of the subject as distinct from its connection with the science of magnetism, and its mathematical investigation, he says:—

"The majority of seamen (fully to the extent of ninety-nine out of every hundred) are unscientific and non-mathematical, yet not so ignorant, but that if told *why* they are to do a thing they will do it better than by blindly following a rule without a reason assigned, as is the case when they add together certain logarithms to obtain particular results in the various problems of navigation.

"An intercourse for upwards of twenty years with the officers of the Merchant Service—as teacher, adjuster of compasses, and author—has given me ample means of making myself acquainted with their weak points; and to appreciate how weak they are in the matter of the deviation of the compass one has only to attend an inquiry into the loss of an iron ship, when the crude questions asked, and equally crude answers given fully testify that nautical assessors, masters, mates, and pilots are all in the same category."

On the extent of deviation and the importance of having the steering compass adjusted, especially for short voyages, the author says:—

"It can well be supposed that when the maximum deviation of the steering compass in vessels employed on short voyages exceeds a point, it would be preferable to adjust it by the use of magnets, for if left uncorrected the man at the wheel could not but be perfectly bewildered."

We were somewhat surprised to find from the author's twenty years' experience, that "it must be said with regret that in the Merchant Service comparatively few iron ships and steamers carry a standard compass; at least, an instrument entitled to that name. In the large majority of instances all the compasses are, as regards the cardinal points, adjusted by the use of bar magnets, while the quadrantal deviation, which ought to be compensated by chain boxes or by cylindrical iron is too generally neglected, so that after all such compasses are but *partially* adjusted." If this really be the case we, as members of the press, and feeling the importance of the public safety, must say *emphatically* "such things ought not to be."

The sections on "heeling error" are written with much judgment. Bearing in mind that an iron ship is itself a magnet affected differently in every position she may be in by the earth's magnetism, and that her compasses are adjusted on an even beam, a competent knowledge on the part of the master of the error of deviation produced by heeling is indispensable, especially as this error is perpetually changing with the latitude, and is more or less dependent upon the lay of the ship when building. It is during this process she takes up her magnetism, but not permanently so. The author's observations on this head are important:

"It is useless to offer any remarks on the direction in which an iron ship should be built; it must be built in the builder's yard, be the lay of it what it may; but it would be well if there were a better understanding between builder, owner, optician, and adjuster than there seems to be at present. Vessels would then be better equipped as regards compasses than they are now. Further, no vessel should be turned off the stocks and immediately afterwards adjusted or swung for the errors of the compasses, subsequently loaded, and then sent to sea; such a mode of proceeding is nothing more or less than wicked in the extreme, for by the time the ship is ready for sea the errors have changed and the given deviation cards are of no use. After launching, the vessel while fitting and loading should lie in the opposite direction to that in which it was built, and be swung for the errors of the compasses just before going to sea.

"Vessels lose a large part of their magnetism within a short time of their launching. * * * As a rule they cannot be said to have settled to their normal condition under two to two and a half years; after that no change of any significance occurs except under a considerable change of geographical position, which is equivalent to saying that the deviation changes with a change of the magnetic elements within the range of which they are brought by voyaging from one region to another."

As regards the compasses generally supplied, our author says, "A walk through the portion of any town where these instruments are exposed in the windows is not very encouraging, and the general impression derived from an examination of them, taking one with the other, is that they are far from being instruments of precision." On the idea of cutting off the ship's magnetism from the compass, he says:—

"Never set your wits to work to devise a method of cutting off from the compass the magnetism of the ship, such a thing being an impossibility; it would only show you are witless. None but quacks in science talk of demagnetising and depolarising a ship, of cutting off a ship's magnetism, or of inventing a compass to be unaffected with deviation; but you may, if you have a spare compass, try it in different parts of the ship to find out the spot of least deviation; you thereby show your judgment."

This book, which is illustrated with Napier's diagram of the curve of deviation, is one of which every page contains valuable information. Its rules are concise and its directions so plain that a master could readily ascertain the deviation of the compasses of his own ship and readily adjust them. In a word, it contains all that is necessary to become acquainted with for the safety of his vessel, so far as magnetism is concerned.

Observations of Comets from B.C. 611 to A.D. 1640. Extracted from the Chinese Annals. By JOHN WILLIAMS, F.S.A., Assistant Secretary of the Royal Astronomical Society. London: 1871.

THE award of the Gold Medal of the Royal Astronomical Society to Sig. Schiaparelli has tended to invest Cometary Astronomy with a new interest. Although we have the orbits of but two comets identified with those of meteors it is not improbable that as science advances other indentifications will be made, and catalogues of comets will be in greater request than heretofore. The catalogue now before us of 373 comets recorded by the Chinese, contains 149 instances not included in Biot's "Catalogue of Comets observed in China," published in the supplement to the "Connaissance des Temps" for 1846, and may be regarded as the most complete collection of notices of these phenomena from those ancient annals. The well-known Sinological attainments of the translator, and his perfect acquaintance with the Chinese language, particularly fit him for rendering into English the notices of Cometary phenomena contained in the work. In each case the year and day in our reckoning of the appearance of the comet is given, also the year of the Chinese epoch; the moon and day of the same phenomenon are given with all the astronomical particulars, such as its place amongst the stars, the character and length of its tail, and the direction which this appendage assumed. Accompanying the catalogue is an atlas of 32 maps, including the 28 stellar divisions most in use by the Chinese astronomers, and continually referred to by them in their observations. This atlas is not only curious and interesting as giving an idea of Chinese astronomy so far as regards the stars, but Mr. Williams has, by giving reduced tracings of Flamsteed's figures, furnished the means—by laying down upon them the corresponding Chinese asterisms—of identifying the stars in both systems, the Chinese and European. It is this feature which renders the work so valuable in an astronomical point of view, nor is it less valuable as a guide to Chinese chronology. The mode of reckoning by cycles of 60 years, which has been in use in China since the year 2637 B.C.; the lunar cycle of 19 years; the arrangements of the months, &c., are all fully explained and illustrated by appropriate tables, so that the work, having a much higher value than being a mere catalogue of comets, will greatly assist students of Chinese history. The introductory remarks also contain a very interesting account of the early astronomy of the Chinese. The following extract shows the great care and amount of labour that has been bestowed on the translation of the catalogue.

"From the preceding remarks it must be evident that the production of this work has been attended with no ordinary amount of labour. Many thousands of Chinese characters required to be carefully copied and accurately translated, the whole of the dates ascertained by computation, and numerous works, both Chinese and European, had to be examined or collated. In addition to these, the construction of the tables for computing the dates of their chronology, and of the atlas, both of which have been found not merely useful but indispensable to the carrying on of the work, required a great amount of research and attention. How far the results may be worthy of the time and labour bestowed on them must be left for those who are better qualified than myself to form an opinion on such subjects to determine. Errors may doubtless be found to exist, although every care has been taken to avoid them; and it is hoped that none seriously affecting the character of any part of the work may be found. It must, however, be remembered, that this is strictly a work of reference, and as such may at some future period be of service in investigations respecting the former appearance of any particular comet that may then pay us a visit."

---

11 Chlorous acid, 1820-56; chlorous acid, 1871. Barff, &c.

12 Air 1·00. Its density is, therefore, *anomalous*—that is to say, does not agree with the received view of the constitution of a molecule. We have seen (17) that the weight of a molecule is usually the weight of 2 vols. Now 2 vols. of hydrogen weigh 2; but 2 vols. of chlorine trioxide, instead of weighing 119 (as the formula given above would lead me to infer) weigh only 79·4. This peculiarity points to one of two things:—(1) Either the generally-received formula is incorrect; (2) or contraction has taken place to a lesser extent than indicated by theory. This latter is probably the true cause of the discrepancy in question, for we find that 3 vols. of oxygen and 2 of chlorine have coalesced to form 3 vols. of the compound, instead of 2 only; hence 3 vols. weigh 119, which is the theoretical weight of one molecule of this body.

13 A deoxodising body is one which absorbs oxygen readily, hence takes oxygen from or deoxodises any substance with which it may be placed in contact. Deoxodising bodies are also called reducing agents.

14 Hydric chlorite. Barff, 1871.

ELECTRIC CLOCKS.

AT a recent meeting of the Society of Arts connected with the Technological Institute of Massachusetts, Mr. J. Hamblett read a paper on electric clocks, of which the following is an abstract:—

One of the first attempts to propel clocks by electricity was made by Alexander Bain about 1812. His battery consisted of a plate of copper and a plate of zinc buried in the earth. The pendulum rod was of wood, with a large coil of copper wire for a bob; the ends of the wire were carried up the pendulum rod to its point of suspension, and were there connected with wires from the buried plates; two brackets, about half way up the rod, supported a sliding breakpiece, which was so situated that it would be pushed a little at every vibration of the pendulum, and by this means an electric circuit was made and broken. The operation of these clocks was not satisfactory, as they were liable to error from fluctuations of the battery power.

Batteries have always been a source of trouble to electric clock makers, for upon their constancy the accuracy of the clocks in a great measure depends. Mr. Hamblett uses the Smee battery; the elements are pure zinc and platinum; the solution consists of pure water and chemically pure sulphuric acid. He uses no screw cups, as they are liable to become loose, and are frequently the source of much annoyance. The wires connecting the elements of his battery are soldered together. An electric clock invented by Mr. Charles Shepard has been much used in England. In these clocks the impulse is given to the pendulum by the falling of a lever, which is raised at each vibration of the pendulum by an electro-magnet. As the weight of the lever and the distance which it falls are constant quantities, the impulse imparted to the pendulum will be constant, and the accuracy of the clocks will not be affected by fluctuations of the battery power.

The mechanism of these clocks is such that an electric circuit is established and broken once every second, which operates dials at distant places. Electric contacts are usually made of platinum or of an alloy of platinum and iridium. When the circuit is broken, an electric spark passes between the contact points, which causes a slight oxidation of the platinum, and, where an electric current is established every second, this oxide may accumulate and become a cause of error. In Mr. Hamblett's clocks, this difficulty is obviated to a great extent by establishing the circuit, which moves the dials only once in a minute. The dials are made very simple and tick once in each minute; and all the dials controlled by one clock will move together, indicating exactly the beginning of each minute.

Clocks cannot only be propelled, but may be controlled and corrected by electricity. Clocks controlled by electricity have two small magnets, placed at the lower end of the pendulum, which are so arranged in relation to two stationary coils of wire that at each vibration of the pendulum one of the magnets will pass into the opening in one of the coils. Once each second an electric current is sent through the coils from the controlling clock, and if the controlled clock be inclined to go slow, the current from the controlling clock, acting upon the magnets, will tend to accelerate it, and *vice versa*. Mr. Hamblett believes this to be the best method yet devised for distributing time. One standard clock may control many other clocks at different points, and if an accident happens to the wires the controlled clocks will not stop, but will go on at their own rates. Methods similar to this have been adopted in Edinburgh, Glasgow, and St. Petersburg. A clock, erected by Mr. Hamblett in the observatory at Alleghany City, Pa., controls all the clocks of the Pennsylvania Central Railroad, and those of connecting lines westward to St. Louis. This is the longest line of time distribution in the world. He made brief mention of the various time signals and time balls used in different countries, and explained at length the distribution of time and the operation of time signals in England by the mean time clock in the observatory at Greenwich.

WHAT IS GUANO?

THIS question has recently attracted a good deal of attention from several naturalists, especially from Professor A. M. Edwards, of the Lyceum of Natural History of New York. Professor Edwards says that in California there is a deposit of "Infusoria," improperly so-called, accompanied by bitumen, which bitumen the gentlemen of the State Survey believe has been derived from those "Infusoria," and that contiguous thereto we have guano deposits. At Payta, in Peru, Dr. C. F. Winslow discovered an "Infusorial" deposit, almost identical in character with the Californian one; near by are bitumen springs, and lying off the coast are the guano islands of Lobos, Chincha, Guanape, and others. At Natanai, Japan, we have extensive "Infusorial" strata and bitumen; it is not recorded whether guano occurs in that quarter. In the island of Barbadoes we have "Infusorial" strata, bitumen, and near by the guano islands of the Caribbean Sea; and he is informed guano is abundant on the small islands and rocks nearly throughout the West Indian Archipelago. In the island of Trinidad we have "Infusorial" strata and bitumen, and, of course, adjacent guano. At all of these localities volcanic action is evident, but we have some localities of guano without "Infusorial" strata or bitumen as yet recorded, while we have the celebrated "Infusorial" strata of Virginia, which, by a little stretch of the imagination, may be supposed to be related in some way to the petroleum of West Virginia and Pennsylvania. In Algeria we have "Infusorial" strata and bitumen, but he never heard of guano having been found near by. However, now that attention is called to this fact it is to be hoped that more careful observations will be made connected with the subject, and he hereby calls on all sciencists and travellers to do all they can to assist in the elucidation of this interesting and important matter. From all of these facts, and others that he has collected of no less importance, derived from chemical and microscopical characters, he has come to the conclusion that guano is not the excreta of birds deposited upon the islands and mainland after its upheaval, but that it is the result of the accumulation of the bodies of animals and plants, for the most part minute, and belonging to the group which Haeckel has included in a new kingdom, separate from the animal as well as the vegetable, under the name of Protista, and subsequently upheaved from the bottom of the ocean. Subsequent chemical changes have transformed it into guano, or heat and pressure have so acted upon it that the organic matter has been transformed into bitumen, while the mineral constituents are preserved in the beautiful *atomies* that make up the mass of the extensive "Infusorial" strata found in various parts of the world.—*Monthly Microscopical Journal*.

ATMOSPHERIC DUST.*

(*Concluded from page* 658, Vol. XIV.)

HAVING demonstrated that the ordinary atmosphere is filled with organic dust, it will be necessary to show you that the quantity and quality may vary considerably according to the locality. It is self-evident as regards the quantity, that, in spite of the extreme lightness of these particles, they will gradually subside and settle down, and a pure atmosphere, as regards motes, is attainable. Even in the country, however, we find these motes. There may, besides, be organic particles even too fine for the highest powers of our microscope, or the analysis of a beam of sunlight. It, however, requires the constant regurgitation of the waves of air, from the movements of a busy city or shifting winds, to keep this dust suspended. I have here a flask which has been placed all night in the vaults of St. Michan's Church. The vaults are so dry, and absorb moisture so rapidly, that all the bodies that are placed in them are converted into natural mummies. There are specimens, centuries old, that are as perfect as the day they were placed there, except that the flesh is converted into parchment. In these subterranean vaults there is a long passage, closed by an iron door; and when this passage is closed, there is nothing but the stillness of death. What could be more appropriate for an experiment? This flask which we have here was first exhausted, and then opened in an inverted position in the vaults. After some time it was removed, taking the precaution, however, to close it before it was removed. On placing this across the course of the light, it is found to be optically empty; it contains no dust, although it had been in a place where everything was dry and dusty; but the air was perfectly still, and all the motes had subsided; thus we see that, by merely placing a flask that has been opened in a certain locality across the beam of light, we can optically analyse it. Again, as we ascend, there is less and less of this dust. On the high mountains, such as the Alps, the air is found to be nearly pure.

We now come to a very important part—namely, the composition of this dust. The composition will differ much according to the locality; but large cities interest us most, both from the fact that the dust abounds in such localities, and because it comes in contact with more lungs. In such cities the dust contains larger quantities of matter out of place (dirt) than other localities. It mainly or almost entirely consists of stable manure, in a finely comminuted condition, with germs and other products arising from the fermentation connected therewith. In 1866, the cholera year, I published analyses of the street dusts of Dublin, taken from Grafton and other streets, and drew particular attention to the importance of this subject, as bearing upon sanitary matters. Next year Dr. Letheby wrote upon the same subject, in connection with the mud and dust of London, and also gave analyses of them. I now place before you the results of some analyses recently made for this lecture:—

Grafton-street, dust dried at 212° Fahr. contained organic matter, 31; carbon, 43·7; nitrogen, 1·07; per cent. Cab stand, Nassau-street, contained organic matter, 45; carbon, 57·5; nitrogen, 2·1 per cent., nitrates and ammonia a trace.

These dusts, if left in a damp condition, after some days become alkaline, and evolve ammonia; when first produced, they are faintly acid, and contain little or no ammonia; this, however, does not always apply to cab stands, the mud and dirt of which is generally in a progressing state of composition; they are most mischievous spots, and require a great deal of supervision. This disagreeable matter is all well ground down by the wheels of the cabs on the paving stones. If we take into consideration the fact that, over Carlisle Bridge alone we have a milling power that would grind many barrels of corn *per diem*, we see how well this organic matter is prepared to work mischief, if it is capable of doing so. The street dust becomes the pabulum, or stock in trade, of the atmospheric dust; and when we consider the large amount of animal matter of the worst description that is spread out for the play of the breezes, the quality of the organic matter of our atmosphere can be well appreciated. That the great supply of this organic matter is gotten from the street dust, is borne out by the microscopic and other researches of Dr. Angus Smith. These floating particles may be viewed as the carriers of zymotic diseases, or those started by ferments.

Disease is simply a matter of chemical change produced, in many cases, by the direct action of a ferment. M. Pasteur, proved, many years since, that if a flask of putrescible matter were closed after being filled with air that had passed through red-hot tubes, we get no fermentation. Why? Professor Tyndall's experiments explain this phenomenon; the germs of fermentation contained in the air have been destroyed. M. Pasteur had done to the air entering the flask what was done some short time since to the air entering the tube. The germs were burnt up. Here are specimens of soup and milk some two months old, and yet, when opened to-day, quite fresh and good; but the most curious part of this is the fact that they were simply closed with prepared cotton wool. Each specimen was boiled in its respective flask, to destroy any germs that might be in them, and closed whilst boiling, but now they have been once opened fermentation would set in, for the atmospheric dust would enter with the air.

One of the practical applications of these and similar experiments has been wonderfully developed by Professor Lister, of Edinburgh. To use his own words, it is a system of treatment which consists of such management of surgical cases as shall effectually prevent the occurrence of putrefaction in the parts concerned. Space will not permit me to go into Professor Lister's line of investigation at present; but, in conclusion, I may remark that by a careful and well-considered system of antiseptic treatment, which is based upon the scientific consideration of the germ theory, hospital gangrene, and such like diseases are said to be almost unknown in the institution with which he is connected.

As regards the dust eliminated during the different processes of trades, I have only one or two remarks to make. In most cases they act chemically, but many cases are known where they shorten life merely by the mechanical entrance of particles into the lungs. Where we find coarse and heavy particles, such as iron, and such glutinous particles as flour, passing through the protective passages into the lungs there is nothing wonderful in spores passing, 250,000 of which have been seen in one drop of water, particularly when such motes are found to pass and bubble through vessels containing sulphuric acid without being stopped.

There is a great deal of grinding in the manufacture of edge tools, and polished iron work of every description; and there are two kinds of grinders—the wet and the dry grinders; the first suffer, but not nearly so much as the latter, who "buff" or polish their goods with emery, which you know is a very hard mineral. It is also curious to find that the polishing of cast iron is said to be much more injurious than wrought, or even steel. The sleeves of these men's shirts are a mass of iron mould from wiping the perspiration off their faces.

One intellectual man said that workmen could not afford respirators, which soon became filthy, and were very hot and uncomfortable to wear, and made them feel faint. When told that he did not look so bad, he said that at one time he was very ill, but was much better now (aged 32). His doctor had told him he might live to about 46; his fellow-workers died about 40. He took an emetic every week. Dr. Sigerson also states that scutch mills, from the character of their spiky dust, are human slaughter houses. Dr. Mapother has described an excellent respirator for working men. Although the workman is sometimes an inconsiderate being, what does he not suffer in the cause of commerce? and how careful we should be in legislating justly and considerately for this being who offers up as a sacrifice so many precious days of his life on the altar of mammon.

As regards the difficulty in intercepting this floating matter, Tyndall, in mentioning the subject, gives cotton wool as being the best intercepter; therefore it will be the best mechanical purifier. You must remember that when there are no par-

* By C. R. C. TICHBORNE, F.C.S., &c. An abstract of a lecture delivered before the Royal Dublin Society.

ticles of dust, there is no continuity of the light. The following experiment of Tyndall will illustrate this in another manner. I have here an ordinary glass shade, and I will place it in the track of the beam mouth downwards. The track can be observed passing through the shade; but if I let pure hydrogen gas enter the shade from the top downwards, this gas being much lighter than ordinary air, it gradually displaces it. Hydrogen is a metal in a gaseous state, and is the lightest substance known. As soon as it occupies the space crossed by the beam the luminous space is obliterated. Here we have the same results, or darkness, produced as when we burnt up the motes.

Having thus reminded you of the optical appearance that is produced by placing pure gas or air in the track of the beam, you will understand the experiments which illustrate the effects of cotton-wool as a fitting medium, as detailed by Professor Tyndall:—"I fill my lungs with ordinary air, and breathe through a glass tube across the electric beam. The condensation of the aqueous vapour of the breath is shown by the formation of a luminous white cloud of delicate texture. It is necessary to abolish this cloud by heating the tube: when this is done, the luminous track of the beam is uninterrupted, the dust from the lungs makes good the particles displaced. But after a time an obscure disc appears upon the beam, the darkness of which increases, until finally towards the end of the expiration, the beam is, as it were, pierced by an intense black hole, in which no particles whatever can be discovered. The air, in fact, has so lodged its motes within the passages of the lungs as to render the last portions of the expired air absolutely free from suspended matter. I now empty my lungs as perfectly as possible, and, placing a handful of cotton wool against my mouth and nostrils, inhale through it. On expiring the air through the glass tube, its freedom from floating matter is at once manifested. From the beginning of the expiration the beam is pierced by a black aperture."

Before concluding this rather meagre account of so important a subject, I would wish to add a few words as regards the merit and bearing of the question generally. Because we have had it strikingly placed before us that we are constantly inhaling dust, we are not necessarily to work ourselves into a dust mania; but, on the other hand, we should not be callous to the danger that may arise from such a quarter.

You know, perhaps, Voltaire's remarks when he was told that coffee was a slow poison—"You are right, my friend; it is slow, and horribly slow. I have been drinking it more than seventy years, and it has not killed me yet." Well, Voltaire was a sceptical kind of man, but we must not be too sceptical, for dust may be harmless, very slow poison, and sometimes such a poison that no human efforts could stay its power. I remember a very clever article appearing in one of the papers some years since upon the change of matter, in which the author showed that the number of persons who had existed upon our globe would, on calculation, be five persons to every square foot of earth; so that the earth was one vast cemetery, the whole surface of the globe having been dug over 128 times to bury its dead—that

"There's not a dust that floats on air
But once was living man."

Now, such a notion would not be pleasant; and, however clever such writing may be, it is but the hyperbole of science—simply a poetical license. We are not breathing the dust of our forefathers; it is changed, and is constantly changing. We are consuming oxygen, hydrogen, carbon, and other substances; but the oxygen, when it enters into my system, and combines with the products it already finds there, is no longer oxygen; its entity is destroyed, and it exists as another compound. In fact, our bodily existence on earth may be viewed as typical of the interchange of chemical molecules generally; and, whilst we are tied to these chemical atoms, let us hope that we may use them to our own honour, and to the advantage of our fellow-creatures.

GAS AND WATER PIPES AS LIGHTNING CONDUCTORS.

THE influence of gas and water pipes in determining the direction of a discharge of lightning formed the subject of a paper recently read by Mr. Henry Wilde, before the Manchester Literary and Philosophical Society. The author said:—

Although the utility of the lightning-conductor has been established in all parts of the world by the experience of more than a century, yet a sufficient number of instances are recorded of damage done by lightning to buildings armed with conductors to produce, in the minds of some, an impression that the protective influence of lightning-conductors is of but questionable value. The destruction by fire of the church at Crumpsall during a thunderstorm has induced me to bring before the society some facts connected with the electric discharge, which have guided me for some years in the recommendation of means by which disasters of this kind may be averted.

For the proper consideration of this subject, it is necessary to make a distinction between the mechanical damage, which is the direct effect of the lightning stroke, and the damage caused indirectly by the firing of inflammable materials which happen to be in the line of discharge.

Instances of mechanical injury to buildings not provided with conductors are still sufficiently numerous to illustrate the terrific force of the lightning stroke. Wherever lofty buildings are furnished with conductors from the summit to the base, and thence into the earth, damage of the mechanical kind is now unknown; and even in those cases where lightning conductors have not extended continuously through the whole height of a building, or where the lower extremity of the conductor has terminated abruptly at the base of the building, the severity of the stroke has been greatly mitigated, the damage being limited, in many cases, to the loosening of a few stones or bricks.

The ever extending introduction of gas and water pipes into the interior of buildings armed with lightning-conductors has, however, greatly altered the character of the protection which they formerly afforded, and the conviction has been long forced upon me that while buildings so armed are effectually protected from injury of the mechanical kind, they are more subject to damage by fire. The proximity of lightning-conductors to gas and water mains as an element of danger has not yet, so far as I know, engaged the attention of electricians, and it was first brought under my notice at Oldham, in 1861, by witnessing the effects of a lightning discharge from the end of a length of iron wire rope, which had been fixed near to the top of a tall factory chimney, for the purpose of supporting a long length of telegraph wire. The chimney was provided with a copper lightning-conductor terminating in the ground in the usual manner. In close proximity to the conductor, and parallel with it, the wire rope descended from near the top of the chimney for a distance of 100ft., and was finally secured to an iron bolt inserted in the chimney about 10ft. from the ground. During a thunderstorm which occurred soon after the telegraph wire was fixed the lightning descended the wire rope, and instead of discharging itself upon the neighbouring lightning-conductor, darted through the air for a distance of 16ft. to a gas-meter in the cellar of an adjoining cotton warehouse, where it fused the lead pipe connections and ignited the gas. That the discharge had really passed between the end of the wire rope and the lead pipe connections, was abundantly evident from the marks made on the chimney by the fusion and volatilisation of the end of the wire rope, and by the fusion the lead pipe. As the accident occurred in the day-time, the fire was soon detected and promptly extinguished.

Another and equally instructive instance of the influence of gas-pipes in determining the direction of the lightning discharge occurred in the summer of 1863 at St. Paul's Church, Kersal Moor, during divine service. To the outside of the spire and tower of this church a copper conductor was fixed, the lower extremity of which was extended under the soil for a distance of about 20ft. The lightning descended this conductor, but instead of passing into the earth by the path provided for it, struck through the side of the tower to a small gas-pipe fixed to the inner wall. The point at which the lightning left the conductor was about 5ft. above the level of the ground, and the thickness of the wall pierced was about 4ft.; but beyond the fracture of one of the outer stones of the wall, and the shattering of the plaster near the gas-pipe, the building sustained no injury. That the direction of the electric discharge had, in this case, been determined by the gas-pipes which passed under the floor of the church was evident from the fact that the watches of several members of the congregation who were seated in the vicinity of the gas mains were so strongly magnetised as to be rendered unserviceable.

The church at Crumpsall is about a mile distant from that at Kersal Moor, and the ignition of the gas by lightning, which undoubtedly caused its destruction, is not so distinctly traceable as it is in other cases which have come under my observation, because the evidences of the passage of the electric discharge have been obliterated by the fire. From information, however, communicated to me by the clerk in charge of the building as to the arrangement of the gas-pipes, the most probable course of the electric discharge was ultimately found. The church is provided with a copper conductor, which descends outside the spire and tower as far as the level of the roof. The conductor then enters a large iron down-spout, and from thence is carried into the same drain as that in which the spout discharges itself. Immediately under the roof of the nave, and against the wall, a line of iron gas-pipe extended parallel with the horizontal lead gutter which conveyed the water from the roof to the iron spout in which the conductor was inclosed. This line of gas-piping, though not in use for some time previous to the fire, was in contact with the pipes connected with the meter in the vestry where the fire originated, and was not more than 3ft. distant from the lead gutter on the roof. As no indications of the electric discharge having taken place through the masonry were found, as in the case of the church at Kersal Moor, it seems highly probable that the lightning left the conductor at the point where the latter entered the iron spout, and by traversing the space between the leaden gutter and the line of gas-piping in the roof found a more easy path to the earth by the gas mains than was provided for it in the drain.

In my experiments on the electrical condition of the terrestrial globe, I have already directed attention to the powerful influence which lines of metal, extended in contact with moist ground, exercise in promoting the discharge of electric currents of comparatively low tension into the earth's substance, and also that the amount of the discharge from an electro-motor into the earth increases conjointly with the tension of the current and the length of the conductor extended in contact with the earth. It is not, therefore, surprising that atmospheric electricity, of a tension sufficient to strike through a stratum of air several hundred yards thick, should find a easier path to the earth by leaping from a lightning conductor through a few feet of air or stone to a great system of gas and water mains, extending in large towns for miles, than by the short line of metal extending in the ground which forms the usual termination of a lightning conductor.

It deserves to be noticed that in the cases of lightning discharge which I have cited the lightning conductors acted efficiently in protecting the buildings from damage of a mechanical nature—the trifling injury to the church tower at Kersal Moor being directly attributable to the presence of the gas-pipe in proximity to the conductor. Nor would there have been any danger from fire by the ignition of the gas if all the pipes used in the interior of the buildings had been made of iron or brass instead of lead; for all the cases of the ignition of gas by lightning which have come under my observation have been brought about by the fusion of lead pipes in the line of discharge. The substitution of brass and iron, wherever lead is used in the construction of gas apparatus, would, however, be attended with great inconvenience and expense, and moreover would not avert other dangers incident to the disruptive discharge from the conductor to the gas and water pipes within a building. I have, therefore, recommended that in all cases where lightning conductors are attached to buildings, fitted up with gas and water pipes, the lower extremity of the lightning conductor should be bound in good metallic contact with one or other of such pipes outside the building. By attending to this precaution the disruptive discharge between the lightning conductor and the gas and water pipes is prevented, and the fusible metal pipes in the interior of the building are placed out of the influence of the lightning discharge.

Objections have been raised by some corporations to the establishment of metallic connection between lightning conductors and gas mains, on the ground that damage might arise from ignition and explosion. These objections are most irrational, as gas will not ignite and explode unless mixed with atmospheric air, and the passage of lightning along continuous metallic conductors will not ignite gas, even when mixed with air. Moreover, in every case of the ignition of gas by lightning the discharge is actually transmitted along the mains, such objections notwithstanding. A grave responsibility, therefore, rests upon those who, after introducing a source of danger into a building, raise obstacles to the adoption of measures for averting this danger.

WATER-PRESSURE ENGINE.

ENGRAVINGS of a very simple form of water-pressure engine designed by Mr. A. Schmid, of Zurich, and which is now being manufactured in this country by Messrs. Fielding and Platt, of the Atlas Iron Works, Gloucester, will be found at page 12. The engine shown in our illustration has a 7in. cylinder with 9in. stroke, and is calculated to develop 5 effective horse-power for each 100ft. of head of water with which it is worked. Referring to the engraving, it will be seen that the cylinder is oscillating and that the face to which the passages from each end of the cylinder open, is curved to an arc of a circle struck from the centre line of the trunnions. This face is beneath the cylinder, and bears upon a correspondingly formed concave face, having in it three ports, of which that in the centre communicates with the supply pipe, and the two outer ones with the escape or exhaust. It will be readily understood, from an inspection of the section, how, as the cylinder oscillates, the water is alternately admitted to, and exhausted from, each end of the cylinder.

Referring to Fig. 3 it will be seen that the trunnions on the cylinder work in bearings formed in a pair of levers having their fulcra at one end on the engine frame, and connected at the other end by a cross piece, as shown. A bolt—connected at its lower end to the engine frame—passes up through this cross piece, and exerts a downward pull upon it through the intervention of an indiarubber washer. By means of the nuts on this bolt the pressure can be regulated to just the amount sufficient to keep what we may call the valve faces in water-tight contact. The trunnion bearings are also adjustable for wear, as shown in Figs. 2 and 4.

An air-vessel is provided on the supply pipe to take up any shocks which would otherwise be caused by variations in the speed of flow through that pipe, and it is found that in practice these engines run with great smoothness. An engine of this class, with 5in. stroke, has been run most satisfactorily at 200 revolutions per minute. As regards the duty obtained, we quote the following extract from a report made by Professor Kronauer, of the Polytechnic School at Zurich. He says:—"As a member of the jury charged with the trial of twelve water motors (five cylinder engines and seven turbines) of different constructions, I can state that the engine of Mr. Schmid has surpassed all the others in regard of the percentage of duty and of simplicity of construction, the trials, which have been made with the greatest care and accuracy, having given a useful effect of 89 per cent." The engine is, as the Professor justly remarks, of very simple construction, and the proportions and general design are excellent. No doubt these engines will prove very useful motors in a large number of cases.

LAMPLIGHTING BY ELECTRICITY.

A PLAN for lighting street and other lamps by electricity has been "invented" by a resident of San Francisco. Dr. Van Zandt not only lights the gas, but also turns it on or off by electricity. The lamps are connected by underground wires with a central station, where the apparatus is situated, consisting of a galvanic battery, an induction coil, and a switch to throw the current on or off the wires in any portion of the city, so that all or any part of the lamps may be lighted or extinguished as required. Two independent circuits are necessary, one for operating an automatic apparatus in each lamp by which the gas is turned on and off; the other for conveying the current which lights the gas. The wire for the last circuit passes across the slit in the burner, where it is broken, so that the passage of the electric current produces a spark which ignites the gas. The wire near the burner cannot be insulated by caoutchouc or cloth, as these are destroyed by the heat; it is insulated by winding it around non-conducting trunnions on the burner. Above these insulators, the wires are of German silver tipped with platinum. Trials of this apparatus, using thirty-seven burners and over a mile of wire, have been made in one of the towns of the States, with results which show that the invention is applicable to the purpose for which it is intended.

SCIENTIFIC SOCIETIES.

ROYAL ASTRONOMICAL SOCIETY.

THE monthly meeting of this Society was held on Friday, March 8, Professor Cayley, President, in the chair.

The Late Solar Eclipse.

We were greatly disappointed on finding that only *one* communication had been received by the Society on this subject. We well remember the absorbing interest manifested on the occasion of the return of the members of the different expeditions which went out to observe the eclipse of December, 1870, and we felt it a decided blank when the only communication read was that from Mr. Russell, the Government Astronomer at Sydney, detailing the arrangements that had been made for observing the late eclipse, which were rendered nugatory by the presence of clouds. A question was asked by Captain Noble as to whether any other communications had been received, which he supplemented by another—viz., If not, why not? In reply it was stated that no *original* communications had been made to the Society. The notices contained in the report of the council presented at the annual meeting were obtained from various sources. This introduced some remarks on the proposed publication of the results by the Society (see ENGLISH MECHANIC, No. 357, January 26, 1872, p. 479), among which it was stated that the Government having been applied to to print the results, and having announced that no funds were available for the purpose, the council of the Royal Astronomical Society had volunteered to defray the expenses, an understanding having been entered into with the council of the British Association, through whose instrumentality the funds for the expedition had been obtained, that all observed facts should be published and none suppressed, although some might appear to be irrelevant.

Solar Activity.

Messrs. De La Rue, Stewart, and Lowey, communicated the usual annual summary of photographic solar observations at Kew, from which it appeared that the intensity of the spot-producing energy is diminishing, also that groups of sun-spots have of late been developed in the higher latitudes. In connection with this subject we find from the annual report that 381 photograms of the sun were taken during the past year on 226 days, but we regret to learn that the continuous photographic record of the sun's disk will shortly draw to a close. During the past ten years 2,778 solar photograms have been taken, and about twenty papers communicated to the Royal and Royal Astronomical Societies embodying the results.

Source of Solar Heat.

A communication on this subject by Maxwell Hall was read. The author considered that the slow contraction of the sun contributed to the development of solar heat.

Approaching Transit of Venus.

An interesting communication from Otto Struve on the preparations by the Russian Government for observing the forthcoming transit was read. The number of stations to take part in the observations within the territories of the Russian Empire is twenty-four. They will be fully equipped for the purpose.

Aurora Borealis.

A communication, by Mr. Finlayson, on the Aurora of February 4, 1872, was read. We did not remark any peculiarity in the observations.

Diffraction Phenomena in a Telescope.

Captain Noble having noticed some remarkable phenomena of diffraction while observing was induced to search for the cause, and found it to arise from the labours of a busy spider, having effected an entrance within the tube and constructed a complete network or grating across. These little creatures are often annoying to the astronomer, although he is so greatly indebted to them for the means of measurement. It was mentioned that on one occasion a spider had found its way into a micrometer and had availed itself of the lines already there.

Optical Power as Affecting the Perception of Colours.

Col. Strange communicated a note on certain observations on the effect of optical power in producing a difference in the perception of certain colours. It appeared that the Colonel and some ladies of his family were at the theatre, and that the ladies directed his attention to a dress which they described as *pink*. On using his opera glass he at once pronounced it to be *yellow*, and requested the ladies to view it through the same medium, when they too agreed that it was *yellow*. Subsequently it was ascertained that the dress in question was really white trimmed with yellow. The colonel said that nothing was more untrustworthy than descriptions of colour, and as much attention had of late been given to the colours of heavenly bodies, he considered the fact above narrated worthy of record, and that in observations of colour the effects of various powers should be ascertained and recorded.

Chronographic Determination of Longitude.

A determination of the longitude of Teheran, in Persia, as connected with the Great Indian Survey, was communicated by Col. Walker. We understood that this determination connects the arc between Greenwich and Madras with that previously determined between Greenwich and San Francisco, by the intermediate station Cambridge, Massachusetts. The retardation on the Indian line of 3,870 miles was less than 0·5 second. In the American determination the time of transmission of the galvanic current was 0·8 second. In the determination of the difference of longitude of Neufchâtel and Zurich, the velocity of the galvanic current was found to be about 7,300 miles in a second.

Double Image Micrometer.

Mr. Browning called attention to a double image micrometer which he had constructed by employing a divided Barlow lens. The instrument which was exhibited gave occasion to numerous remarks on the various contrivances that had been adopted for the purpose from Dollond's divided object-glass, 1750, which was mentioned by Captain Noble, to a plan of the Astronomer Royal, which Dr. De La Rue considered to be similar to the one before the meeting. Col. Strange considered that an advantage is gained by dividing an intermediate lens.

Spectroscope Adjustable for Dispersive Power.

Mr. Browning exhibited and explained the construction of a spectroscope, with especial reference to effecting a change in the dispersive power, as readily as altering the magnifying power of a telescope. The instrument, which possesses the ordinary automatic movement, is furnished with an extra prism, to be inserted in the battery of prisms, so as to reduce or vary the dispersion as the observer may desire.

In addition to the above, papers were read by the President on the "Variation of the Position of the Orbit in the Planetary Theory," and on a "Pair of Differential Equations in the Lunar Theory;" by Mr. Knott on the "Measures of the Binary Star ξ Ursa Majoris;" by Captain Noble on "Uniformity in the Measurement of Position Angles with the Telescope;" by Mr. Russell, "An Explanatory Note on η Argûs;" and by M. Stephan "Observations of the Minor Planet (117) Loomia, and Nebulæ discovered and observed at Marseilles."

THE INSTITUTION OF CIVIL ENGINEERS.

AT the last meeting of the Institution of Civil Engineers, held on March 5, 1872, Thomas Hawksley, Esq., President, in the chair, the paper read was "On the Kind-Chaudron System of Sinking Shafts through Water-Bearing Strata, without the use of Pumping Machinery," by Mr. Emerson Bainbridge, Assoc.-Inst. C.E.

Of the total expenditure necessary to open out a coal field, one of the chief items of cost was caused by the heavy expenses incurred in sinking the shafts, and when such sinking happened to pass through water-bearing strata, the proportion due to this head, of the total cost, was much increased. When a shaft exceeded 200 or 300 yards in depth, and when the water occurred near the surface, it was usual to keep the water back by the insertion of cylindrical metal "tubbing," placed upon a hard bed of rock at a point immediately below the lowest feeder. Where pits were less than 100 or 200 yards in depth, the application of tubbing was not of much service, as the movement and dislocation of the strata, consequent upon the removal of the coal, generally caused the water to find its way into the underground workings. The sinkings in which there was the largest quantity of water had been carried in Belgium through the chalk, and in England through the Permian series; these rocks usually being sufficiently porous to contain large volumes of water. Without exception, in England, all such sinkings had been made by the use of pumping machinery of sufficient power to keep the pit, during the process of sinking, comparatively dry.

It was stated that the question of dealing with wet sinkings in the most economical manner would, before long, become of much greater importance than heretofore. In the Report of the Royal Coal Commission an estimate was given of the coal remaining in the British Islands, as follows:—

	Million Tons.
Coal yet remaining which is or will have to be reached by sinkings through the coal-measures	90,527
Coal yet remaining which is or will have to be got by sinkings through the Permian and other formations overlying the coal-measures.. ..	104,418
Total	194,945

It thus appeared that 104,418 millions of tons, or 54 per cent. of the remaining resources of the British coal-fields would have to be reached by pits sunk through the Permian and other formations more recent than the coal-measures; and, as a rule, more likely to be saturated with large volumes of water. With such important evidence bearing on the future of coal-mining, it had been considered that the present was an opportune moment to bring under the notice of the Institution a description of a mode of sinking shafts through water-bearing rocks, which had proved successful in many cases on the Continent.

The plan of sinking pits hitherto practised in this country consisted in dealing with the water by means of large pumping engines, in leaving the bottoms of the pits dry enough to allow the sinkers to block the well, and in keeping back the water in the upper strata by metal rings, cast in segments about 4ft. long, and connected by wooden joints, which were wedged tight, when all the tubbing was fixed. The evils of this system were: 1. The heavy first cost of the plant, when special pumping machinery was used. 2. The expense of the wedging tubs, and the cost of fixing them. 3. The delay caused by the sinkers being compelled to work always in water. 4. The high first cost of the tubbing and of fixing it in the shaft, and the liability of the tubbing leaking in consequence of the numerous joints.

In the application of the Kind-Chaudron system these evils were to a great extent avoided. This system consisted of a combination of Mr. Kind's well-known apparatus for boring wells, with an ingenious device, invented by M. Chaudron, for fixing cylindrical tubbing under water in such a manner as to make it quite secure and water-tight. In the latter part of 1871 the author, accompanied by Mr. W. Cochrane, visited the Maurage pits, near Mons, where two shafts were being sunk by this process. These shafts, though having a depth respectively of 373ft. and 593ft. at the date of that visit, had been bored that depth under water with a diameter of 13ft. 6in., the water having been constantly standing at a depth of 37ft. from the surface. The Chaudron system consisted of the following distinct processes:—1. The erection of the machinery on the surface. 2. The boring of the pits to the lowest part of the water-bearing strata. 3. The placing of the tubbing. 4. The introduction of cement behind the tubbing to complete its solidity. 5. The extraction of the water from the pits, and the erection of wedged cribs to secure the moss-box. The machinery on the surface consisted of a capstan engine, which raised the *débris* from the pits, and a vertical engine, by means of which the boring tools were lifted at each stroke; the speed of the latter engine varying from fifteen to eighteen strokes per minute. The first tool applied was the small trepan, which weighed 8 tons, and bored a hole 4ft. 8⅔in. in diameter, the depth of the boring being increased at the rate of from 6ft. to 10ft. per day. The pit was enlarged by a trepan weighing 16½ tons, which increased the size to 13ft. 6in., and was kept from 10 to 30 yards behind the pit made by the smaller trepan. The larger boring tool had 28 teeth, and the smaller tool 14 teeth, each tooth weighing 72lb. The boring by the larger trepan did not progress faster than about 3ft. per day of 24 hours. The boring was generally carried on in the day, the remaining twelve hours being employed in raising the *débris* from the pits. When the bottom of the water-bearing strata was reached, the tubbing, which consisted of metal cylinders cast in complete rings of an internal diameter of 12ft., and a length of 4ft. 9in., was placed in the shaft, the rings of tubbing being connected by bolts. The tubbing was tested by hydraulic apparatus to one-half more pressure than it was expected to be subjected to. The rings of tubbing were let down into the shaft by means of the capstan; the moss-box at the bottom of the tubbing being placed in the pit first. The moss-box consisted of two cylinders, one sliding inside the other, and each having a flange broad enough to form a chamber to hold a quantity of ordinary moss. When the moss-box reached the bed which was prepared for it at the bottom of the pit, the weight of the super-incumbent tubbing pressed upon the moss, and formed a water-tight barrier. The tubbing being thus fixed, the annular space between it and the sides of the shaft was filled with cement, thus insuring the solidity of the tubbing; after this was finished, the standing water in the shaft was drawn out, and the joint below the moss-box was made permanently safe, by the fixing of several rings of tubbing resting on two strong wedging cribs.

The comparative cost of sinking by the processes referred to was shown by two tables, one of which exhibited the complete cost of sinking, and the time occupied by the ordinary system, at eighteen different collieries, whilst the other gave the same information for ten collieries put down by M. Chaudron's process. The results showed that, whilst with the system of sinking by the aid of pumping machinery, the average cost per foot had amounted to £114·7, and the rate of sinking to 8·9ft. per month, with the Chaudron process the average cost of all the pits was equal to £22·9 per foot, and the speed of sinking to 15·8ft. per month. This striking result, which was so much in favour of the Chaudron system, evinced the importance which this mode of dealing with water-bearing strata was likely to have.

It was remarked that, where a large quantity of water occurred in shallow sinkings, tubbing would be of no avail, and the economy of boring by the "Niveau plein" system would probably be considerable. On the other hand, where the strata were hard, and where the feeders of water were so well separated by beds of rock as to allow them to be dealt with separately, the ordinary system of sinking might prove as economical as the Chaudron process. The boring of the shaft by the Chaudron process could not be said to be advisable below the water-bearing strata, as with an increased depth the time which could be utilised in boring would become less, and further, the small particles into which the rock was broken by the tool hindered the sinking, so that it progressed more slowly than when the shafts were sunk by the ordinary mode.

BRISTOL NATURALISTS' SOCIETY.

THE usual general meeting of this society was held at the New Institute, on Thursday evening last. The president, Mr. W. Sanders, F.R.S., was in the chair, and a paper was read by Mr. W. W. Stoddart, F.G.S., on the Cotswold-hills, especially part of the range near the town of Wotton-under-Edge, or Wotton-under-Ridge, which was visited by the members of the society in one of their general excursions during the past season. During the excursion an observation was made, which gave the height of Tyndal's monument, near Nibley, as 626ft. above the sea level. In time not geologically distant, and during an age when the land stood considerably lower than now, the sea, there is every reason to believe, flowed far up the vale of Tewkesbury, and met the deep inlet projecting southward from the basin of the Ribble. This, which was first pointed out by Sir R. I. Murchison, was called by him the Ancient Straits of Malvern. The early geological history of Great Britain was then sketched, showing how, in very distant days, it consisted of patches of the igneous rocks exposed to the wearing action of the Western Sea, which gradually wore them down and deposited the detritus on the eastern side, forming continually newer and newer beds of sand and clay, &c. The various and distinct populations of those ancient seas were described, and specimens shown, such as the Trilobites of Siluria and the armour-plated fish of the old red sandstone and carboniferous series, with others more minute but not less interesting. The abundant, but perhaps monotonous, vegetation of the coal-measures succeeded, indicating estuarine conditions of growth and deposit. The thick deposit of new red sandstone succeeds, nearly unfossiliferous in this locality, but showing a rich fauna in the Austrian Alps. Next is the Rhætic series, with its rich fossil treasures, of which Aust Cliff and Westbury-on-Severn afford abundant supplies. The various beds of the lias and oolite were dwelt on, and more in detail, as the district in question is mainly composed of these. Particular attention was drawn to the constant occurrence of one particular fossil in many of these beds, not, of course, alone, but in company with others not peculiar to it. Thus, certain beds of the trias are characterised by ammonites peculiar to them, and found neither in the beds above nor in those below. In the same way, some of the beds of the oolite are distinguished by the presence in them of a shell called, from its shape, Terebratula fimbria, and so on. The advantage of this means of readily distinguishing strata was shown, and the alternatives between which geologists have to choose pointed out. They must admit either that these creatures were called into being, endured but a short time, and then became extinct, or that the beds in which their remains occur, though often only a few feet in thickness, required for their deposition a long series of ages. For many reasons which could not be set forth at length, geologists had unanimously chosen the latter alternative, and hence the great age they were compelled to assign to the crust of the earth and the animal and vegetable tribes upon it. The resemblance and difference between the Cotswolds and Dundry-hill were dwelt on, and the variation in thickness of the same bed in different localities explained. A sketch map was exhibited, showing the contour of the country if sunk to a depth of 500ft. The Ancient Straits of Malvern would be restored, and the counties of Gloucester, Worcester, Somerset, and Hereford reduced to an archipelago, consisting of the Cotswold and of Malvern, &c., separated by deep ocean creeks and channels. The speaker concluded by an allusion to the connection of agriculture with the geology of a district, mentioning the single fact that the common damson will not come to perfection off the fuller's earth, and therefore grows nowhere so well as in the districts where the subsoil consists of this formation. Natives of those districts regard damsons grown on other soil as worthless, however good they may appear to those who are not familiar with the fruit in its favourite habitat. Several questions were asked, and some discussion followed the reading of the paper.

USEFUL AND SCIENTIFIC NOTES.

Phosphorus in Iron.—The presence of the least trace of phosphorus and sulphur in iron will destroy it for many purposes, and a correct and easy way of detecting these substances is therefore important. K. Meineke dissolves the finely pulverised iron in chloride of copper, separates the reduced copper by treatment with an excess of chloride of copper and common salt, filters through a layer of asbestos, brings the insoluble portions adhering to the abestos into a beaker-glass, and oxidises by strong nitric acid and chlorate of potash; then he evaporates with hydrochloric acid and determines the sulphur by baryta as sulphate, and the phosphorus by molybdic acid in the usual way.

Government Scientific Expedition.—It is said that the *Challenger* will be commissioned early in the summer for a voyage of exploration and research. Some scientific gentlemen will be accommodated on board the vessel, and it is probable that Captain George S. Nares, now serving in the surveying vessel *Shearwater*, in the Red Sea, will be placed in command. The actual places which will be visited have not yet been determined, but it is anticipated that the groups of islands in the Pacific will have special attention bestowed upon them. This movement on the part of the Admiralty is in encouraging contrast to the fact that Arctic voyages have been abandoned to other nations, and to the late refusal of the Lords of the Treasury to grant any assistance whatever to the Livingstone search expedition.

Sir Roderick I. Murchison.—In the Geological Museum, Jermyn street, have recently been placed some objects of interest in connection with the late Sir R. I. Murchison. In the hall is a marble bust of him, executed by H. Weekes, R.A., and on the principal floor are two objects connected with his labours in the geology of Russia. It will be remembered that by those labours he established the right of the Permian to rank as a separate formation. The Emperor Nicholas I. presented to him a beautiful large vase in avanturine quartz on a square pedestal of gray porphyry from the Kourgon Mountains, in the province of Tomsk, Siberia, and this he bequeathed to the museum. The other object is a fine metal salver, having a worked border of illustrations of various mineralogical and metallurgical arts. There is an inscription in Russian, the translation of which is, "To the geologist Murchison, in testimony of their highest esteem, the Russian Administration of Mines, Zlata, Ust, 1843." Professor Ramsay has been appointed Director-General of the Geological Survey of the United Kingdom, in the room of Sir R. I. Murchison.

MICROSCOPICAL NOTES.

Sponge Spicules. — There are two common sponges which deserve attention as furnishing interesting spicules. The one is the common fresh-water sponge, *Spongilla fluviatilis*, containing spicules of two forms,—one with two discs like serrated wheels united by an axle, the other slightly curved, pointed at each end, and rough on the surface. These are siliceous spicules, and may be obtained by the use of nitric acid. The other is a marine sponge, but the spicules which are also of two forms are calcareous. In this case liquor potassæ must be employed to obtain the spicules. One form is tri-radiate and the other club-shaped at one end and pointed at the other. The sponge is very small and white, and may be found attached to sea-weeds. It is called *Grantia compressa*. These spicules should have a place in every cabinet.

The White Corpuscles of the Blood.—Dr. Rodenstein, in a paper on Tuberculosis in the *New York Medical Journal*, calls attention to the action of the white corpuscles of the blood, as seen under the microscope. He says that in making experiments with blood corpuscles he has lately noticed that if a drop of blood, freshly drawn, be placed in an alkaline solution of carmine, the red corpuscles lose their power of forming rouleaux, and the white corpuscles absorb the carmine, seek each other, congregate in little masses, and seem to become agglutinated to each other. In a drop of blood prepared for microscopic inspection, by careful focussing there can be seen the whole field covered by fine little rings, which seem to form a delicate network, looking somewhat like the cornea of a fly seen with a low power; this is nothing but the red corpuscles of the blood which touch each other by their edges. Scattered over this delicate, pale network, there can be seen, here and there, little, bright red, cellular masses; these are the white corpuscles of the blood tinged with carmine.

Action of Quinine on the White Corpuscles of the Blood.—This subject, in which Binz and Stricker held somewhat different views, has recently, says the *Lancet*, been taken up by Herr Kerner, who contributes a paper on this subject to the last part of Pflüger's "Archiv," being incited by the observations of Mosler on the cure of certain cases of leucæmia by the administration of quinine. Kerner remarks that it is quite possible to obtain a neutral salt of quinine, and in his experiments he used the chloride and the carbonate. He drew small quantities of blood from cats and dogs, and applied a one-tenth solution of this salt in proportion to the blood of 1 part to 4000, upon a microscopic stage maintained at blood heat. The result was striking. The white corpuscles became round and darkly granular, and the movements were very speedily completely arrested. It of course became interesting to compare these effects with those produced by other neutral salts, and in pursuing this investigation to some extent he found that salicin, caffein, atropine, and arseniate of potash were all either wholly indifferent or possessed only the slightest influence. Quinine, therefore, exerts a remarkable action on the white corpuscles of the blood, independent of its antiseptic properties.

Prizes for Amateur Microscopists.—We wish to remind our microscopical readers of the prizes offered by the Countess of Ducie through the Early Closing Association, viz.:—(1) Two Prizes for the best lists of the ponds and other aquatic resorts for collecting purposes, within 20 miles of Charing-cross. 1st Prize, Three guineas: 2nd, Two guineas. Rules:—1. The exact locality of the pond must be given, in order that it may be identified, and the name of the railway station nearest to it. 2. Each competitor to send in his lists sealed in a cover bearing a motto, and accompanied by an envelope sealed, in which is inclosed the real name, address, and occupation of the competitor. (2) A Prize for the best list of the ponds and other aquatic resorts for collecting purposes, within 20 miles of Charing-cross, with a list of the microscopical animals and plants found in them during each month of the year, commencing March 1, 1872. Five guineas. Rules:—1. The exact locality of the pond must be given, and the name of the nearest railway station. 2. The date of the visit must be specified. 3. When any rare or supposed new objects are found, specimens should be immediately forwarded to Walter W. Reeves, Esq., Royal Microscopical Society, King's College, Strand (Somerset House), for examination. 4. Each competitor to send in his lists and other information sealed in a cover bearing a motto, and accompanied by an envelope sealed, in which is inclosed the real name, address, and occupation of the competitor. The lists are to be delivered not later than March 31, 1873, addressed Secretary, Natural History Prizes, 100, Fleet-street, E.C. The adjudicators are Mr. H. J. Slack and Mr. W. W. Reeves, the Secretary and Assistant-Secretary of the Royal Microscopical Society, and they will attach importance to notes and records of pond life made in each month with reference to the local distribution, development, or hybernation of the species

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor of the ENGLISH MECHANIC, *81, Tavistock-street, Covent Garden, W.C.*

All Cheques and Post Office Orders to be made payable to J. PASSMORE EDWARDS.

"I would have every one write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

**** In order to facilitate reference, Correspondents when speaking of any Letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

THE *NAUTICAL ALMANAC*—STAR MAPS—THE MOON'S AXIS—THE TRANSIT OF VENUS—JUPITER'S SATELLITES — SEMIDIURNAL ARCS—AND ABERRATION (OF INTELLECT).

[3795.]—PERHAPS the most immediate answer to Mr. John Andrews (query 11186, p. 649) is that the *Nautical Almanac* takes no cognisance whatever of the wants and requirements of amateur observers (as such), but is wholly given up to data having navigational value. I would, however, further remind my querist that a long series of observations of a system of satellites is requisite before trustworthy tables can be computed from them; and that as the Uranian and Neptunean moons are only discernible in our largest instruments, we can scarcely expect such observations to accumulate very rapidly. The little difficulty attendant on the employment of an 11in. or 12in. achromatic on board of a ship lurching through an angle of some 35° is scarcely worth alluding to.

"M. D. D." (query 11182, p. 650), will find some difficulty in obtaining "*a* chart of the stars, with the figures of the constellations marked on." Perhaps the index plates of Proctor's "Gnomonic Atlas" would be the likeliest thing to suit him. In answer to his second question, I may say that Hannay's "Almanack" is *not* to be had; and that probably the "Illustrated London Almanack" contains as much popular astronomy as any of them.

Will Mr. Birt (letter 3753, p. 660) forgive me for pointing out that it is the inclination of the moon's axis to the plane of the orbit which she describes *about the earth* which determines the amount of libration in latitude, as visible to us? The inclination of that axis to the ecliptic is very ancillary to this; for it must be borne in mind that it is from the earth, and not from the sun, that we view her.

Now that I know that it is the transit of Venus in 1761 with reference to which Mr. Lowdon put query 10871, page 572, I may tell him that it was observed at Greenwich by the Savilian Professor of Geometry, Mr. Bliss (Dr. Bradley, the Astronomer Royal, whom he succeeded, being unfortunately ill at the time), and by a Mr. Green, the then first assistant. Bliss employed an old 15-ft. (non-achromatic) refractor; Green, a 2ft. Gregorian reflector by Short, with a divided convex lens before its aperture, as a micrometer. The weather was very indifferent, though, and they only had glimpses of the transit by fits and starts for a short time, until towards the end of it, when the sky cleared, and they, in company with Bird the optician, observed the egress. Internal contact took place on June 5, 20h. 19m. (*i.e.*, 8h. 19m. a.m. on June 6th, mean civil time), and the final egress at 20h. 37m. 9s. A Mr. Hornsby and a Mr. Phelps also seem to have made some indifferent observations at Shirburn Castle, Lord Macclesfield's seat. There was a grand party, too, assembled at Saville House (in those days standing in the fields, but now a blackened ruin in Leicester-square). The gazers here were the Duke of York, Princes William, Henry, and Frederick, and the Princess Augusta; the observers, Short, the famous optician, Dr. Blair, and Dr. Bevis. The last internal contact, as determined at this station, occurred at 8h. 18m. 21½s. a.m., as seen by Short; while the final egress seemed to Dr. Blair to happen at 8h. 36m 12½s.; and to Short at 8h. 37m. 5½s. The fact of the latter observing with a larger telescope will probably account for part of this discrepancy; and the masterly researches of the present Astronomer-Royal at the Cape of Good Hope, Mr. E. J. Stone, afford an easy solution of the rest of it. I may add that the transit was also observed in London, or its neighbourhood, by Mr. Canton and Mr. Dunn; at St. Helena, by Dr. Maskelyne (the successor to Bliss as Astronomer Royal); in Sweden, in Paris, in Constantinople, in Siberia, in Madras, and in other localities, by various observers. It only remains to add that at the time of transit the geocentric longitude of the sun and Venus was 75° 36′ 31″; that the duration of the transit was about 6h. 16m., and that was the second transit ever witnessed by the human eye.

I have no idea that any such photometrical experiments as those inquired for by "E. T. S." in query 11310, p. 676, have ever been made. The late Sir John Herschel did investigate the relative brightness of some of the heavenly bodies, while he was at the Cape; but I never heard of any comparison having been made, mediately, or immediately, of the difference in the amount of light emitted by the sun here and in the tropics.

In reply to "Vega" (query 11225, p. 676), I can only say that the time given on p. 576, as that of the reappearance of Jupiter's first satellite on January 12, 1871, is quite correctly printed; and that it rests on the authority of Mr. W. M. Christie, the first-assistant at the Royal Observatory. My querist says nothing, by the way, about his own longitude. His recorded observation would place him a long way to the west of Greenwich.

I have, on a former occasion, given somewhere in these columns the method of calculating semi-diurnal arcs; but, in the interest of Mr. Cramer (query 11232, p. 676), will once more repeat it. "The simplest known formula," then, may be thus expressed:—To the log. tan. of the latitude add the log. tan. of the declination of the star. The result, suppressing 10, will be the log. sin. of an arc, which, turned into time, must be added to, or subtracted from, six hours (according as the declination has the same name as, or a different name from, the latitude). The result will be the semi-diurnal arc required. A single example must suffice, by way of illustration. What is the semi-diurnal arc of Fomalhaut, at Melbourne?

Lat. of Melbourne, S.—37° 50′; log. tan.—9·8902040.
Fomalhaut, Dec. S.—30° 18′; log. tan.—9·7666751.

Log. sin. of 26° 59′ 19″. 9·6568791.

Then 26° 59′ 19″ = 1h. 47m. 57s., and *adding* this to six hours (because the declination and latitude are both *south*, we finally get 7h. 47m. 57s. as the semi-diurnal arc of Fomalhaut, at Melbourne. Of course, had it been a star with north declination, the quantity whose log. sin. we obtained must have been subtracted. Mr. Cramer must, though, see that we proceed on the assumption that the body whose apparition above the horizon we are investigating retains its declination invariable from its rising to its setting. It is just because the moon changes hers so rapidly that a table of semi-diurnal arcs is to a great extent useless with her. My querist will of course observe that the formula given above takes no account of refraction.

I think that some one must have been poking fun at Mr. Clements (query 11248, p. 677), as it is almost impossible to conceive that any such paper as he inquires for can ever have been published. I have not the pleasure of knowing "Captain William Noble, of Uckfield," and must most emphatically disclaim the smallest intention of saying anything personally discourteous or offensive to that gentleman; but I cannot refrain from observing that if he really does fancy that he observed "187 occultations of Uranus . . . . in the years 1867-68." I would suggest to his friends that Dr. Forbes Winslow would be a proper and likely man to deal with *his* Constant of Aberration; and that a temporary change of air from Uckfield to, say, Hanwell—or perhaps Colney Hatch—might ultimately result in the suppression or destruction of such astounding observations and calculations as Mr. Clements mentions, altogether.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

DUST IN THE SPECTROSCOPE.

[3796.]—MAY I be allowed to suggest to that eminent optician, Mr. John Browning, F.R.A.S., who appears as an occasional contributor to our MECHANIC, that he would be adding one more to the very numerous favours he has already conferred on the scientific world if he would publish in these columns his method of freeing the jaws of the slit of a spectroscope from those minute and impalpable particles of dust which, when the slit is very much narrowed, annoy the observer by striping the spectrum with longitudinal lines? I have tried a clean camel's-hair pencil and a freshly cut splinter of dogwood as means of removing them, but with by no means absolute success.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

"PHILO" AND VENTILATION.

[3797.]—"PHILO" (letter 3725, p. 637) disclaims the notion I imputed to him (because it was a common one at present), that constructing self-ventilative buildings was a matter of refined science; and he shows, in a column of the most misleading and mischievous fallacies that he has not the faintest idea of what self-ventilation (the only thing I deemed it worth while to write about) means! He describes how he admits fresh air to a murderously misconstructed room as a slight palliative to its non-ventilation—a very slight one, if there be no exit of foul air, and he describes none—and then asks me whether I consider such palliative "very elaborately scientific." He would appear to suppose that by this miserable shift he has "cured" his room, or made a murderous structure an innocent one. He may well object to my bird test, because he must be aware its trial in his room would kill any number of birds before half the minimum of fuel could be burnt, however "quickly," or however "slowly."

But there is not a single sentence in his letter that is not a mischievous fallacy, unless the single clause in which he adopts my dictum that building ventilation is as simple as and "closely similar to the ventilating of lanterns." He has plainly never constructed either a room or a lantern rightly, that is to say, either a lantern that would be saleable in a shop, or a room wherein a bird would live through my experiment. Birds would so live in any lighthouse lantern, or any enlarged model of a saleable lantern of any kind, through the burning of as many tons of fuel as you choose, as quickly or as slowly as you choose. If "Philo" denies this, let him give his name, and let us have a wager like the Hampden-Wallace-Bedford-level wager. It is an incomparably more important question than the flatness or roundness of an earth on which we pass (as the *Pall Mall Gazette* said) so few years. We, or Mr. Hampden, had infinitely better die in the error that the earth is round (or flat) when it is the contrary, than hold "Philo's" views of ventilation. Let me construct a model chamber of one cubic yard, the openings both for inlet and outlet not to exceed two square inches, and hang one or two caged canaries, with food and water to last them, say, a week. "Philo" is to burn therein, at as many points as he will, not directly under their cages, all the gas or other hydrocarbon fuel that he chooses, and kill the birds thereby if he can. If he can kill any before consuming their provisions, I lose the wager; if he cannot kill any (without other combustibles than hydrogen and carbon) I win it.

It is utterly untrue that "the sole difficulty is to change the air of a room often enough to keep it fresh and sweet, without having it uncomfortably cold, &c." A room has no business to require its air "changed," by external act, either often or at all. In a lantern, and in any rightly-designed room, it will change itself by the breathed air instantly leaving and fresh replacing it—the breathed air and no other, whether it be much or little, from one child or a wedged roomful of men—exactly that air, and neither more nor less, leaving and being replaced. "Philo" has not the remotest conception why this is the case in a lantern, and less perfectly in the present House of Commons, but not at all, probably in any other modern room in England. He probably knows (or has the means of knowing if he will use them instead of scribbling about it), that in all these the breathed air, instead of leaving at once, mixes inseparably with all the rest, and though none but fresh air may enter, what manner of air it shall drive out, whether the worst or the best in the room, is all utter chance-medley; or rather the structure is about the best that could be devised for mixing up all foul air with the fresh as rapidly and inextricably as possible! The main problem (it can hardly be called "difficulty") is to prevent this mixture, as every lantern does prevent it, and let out the used and poisoned particles of air instantly—for external (not internal) diffusion—and waste none of their power in moving other air than themselves. But though this is as simple as laying a pavement that shall not be flooded, "Philo" has no more conception of it than of the chemistry of Sirius.

A room that has, as he describes, a "longest period intended" for people to breathe in it, is simply a murderous room; and if it be any architect's theory that rooms are to have this "longest period intended," where is such period marked? or why is it not conspicuously engraved on them? What he says is "simply impossible," is simply the condition of Moorish rooms built ten centuries ago, and still in use, and of the lantern of every lighthouse in England! The reason lies in a difference between every right and every wrong room, that I have often described in three lines. Now let "Philo" describe it.

Mr. Saunders (letter 3726) is more likely to do this, because he does not scribble about "laws of pneumatics," and "the simplest thing conceivable," and so may have time to think a simple thing out, perhaps.

E. L. G.

TOBACCO AND DISEASE.

[3798.]—YOUR correspondent, a "Fellow of the Statistical Society," having finished his argument against the use of tobacco, permit me to reply. I shall not occupy six columns (see lets. 3347, 3448, 3777, pp. 431, 484, 666) in so doing, as there are but few points calling for any extended notice. First, I disclaim all intentional "dogmatic assertion," and all title to speak *ex cathedrâ;* but I think I am as well able to express an opinion on this question as a man who makes a selection of one-sided extracts, and who probably never smoked a pipe in his life. When Mr. Gwilt (let. 3188, p. 331) made the statement that epithelioma had been produced by smoking I knew that he had no authority for it, and coming across "Chambers's Encyclopædia" at the time, I extracted information from it which I thought might be useful, if not interesting (p. 355), and I gave the authorities for the statements made, which were by no means one-sided. Since the advent of the "F.S.S.," however, I have written to an able and well-known physician inquiring if there was any ground for the assertion that epithelioma is caused by tobacco-smoking, and he replied that the one has "no connection, direct or otherwise," with the other.

Now, with regard to M. Bouisson's statistics, what are they worth? Is there no other cause but tobacco to account for epithelioma in—above all persons—"old soldiers, rich idlers, and tavern loungers"? It seems that even M. Bouisson acknowledges the "taint;" but thinks the morbid predisposition would remain latent were it not for the local provocation of the tobacco—a view of the matter which in a modified form I pointed out in my previous letter, when I said that all tobacco could possibly do was to determine the locale of the cancer. What, may I ask, is the local provocation inducing the exhibition of epithelioma in parts where no tobacco smoke is ever applied? Why does not the morbid predisposition rest latent in these cases, and in the cases of non-smokers?

As to the second letter of the "F.S.S." what is there worth attention in it that I did not notice in my communication? I expressly mentioned Dr. Richardson's opinion on the effects of early smoking; but your correspondent makes a ludicrous mixture of tobacco and jam, quite beside the point (as he will see if he "digests" the Dr.'s remarks), and actually asks me which I would give my children, tobacco or jam—as if they were peculiar infants rejoicing in long pipes and strong ale. One does not set strong meat before babes, nor jams and lollipops before men! I cannot attempt to reconcile the statement that, *mirabile dictu*, "snuff is a mere *outward* application" with the assertion that an analytical preparation of the lungs and liver of a man (poisoned, poor fellow, by snuff at the early age of threescore and ten) "exhibited all the reactions of nicotine." Neither can I wade through the long list of statements in the third letter on p. 666 which appear to be written chiefly in the subjunctive mood, and to be utterly unsupported by *proof*. There, is one statement, however, which your correspondent appears to think very highly of, as he asks the "defenders of tobacco" to explain it. It is, that in 1838 the tobacco monopoly produced 28,000,000 francs, and there were 8,000 insane persons, but in 1862 the produce was 180,000,000 and the number of lunatics was 44,000. Of course in the interval there were no extraordinary circumstances occurring in France, but the "constant proportion in this increase" is undoubtedly due to tobacco. It will be seen that in 1838 there was one insane person for every 3,500 francs produced by the tobacco monopoly, but in 1862 there was only one for every 4,272 so obtained. But let us reduce this argument (!) to an absurdity. In 1838 there were 28,000,000 pints of cod-liver oil consumed, and 8,000 persons died of consumption; in 1862 188,000,000 pints were consumed, and 44,000 persons died of consumption; therefore, the cod-liver oil was the cause of this "constant proportion in the increase." If this had gone on without any *increase of population* for many more twenty-four years, Frenchmen would have become curiosities by their scarcity.

Your correspondent quotes from the *Doctor* the opinion of Professor Lefebre as to the influence of tobacco in causing insanity, but he does not quote from the *Doctor* the review of that very article in the *Dublin University Magazine* which appears to have bemuddled him. The *Doctor* said that if the statements contained in the article were true it was singular that the terrible effects of tobacco did not make themselves more apparent. I quote from memory.

But I am occupying space uselessly. The one great argument, and a clincher, against the tobaccophobists is, that men do smoke and yet continue to live, tolerably free from disease, and able to support those "chagrins, reverses, misfortunes," and so on, which Dr. Druhen, with a strange perversion of obstinate facts, thinks they would encounter much better without "the *depressing* action of this plant."

Even granting that tobacco may cause some latent disease to show itself in certain cases, are we all to deny ourselves the enjoyment of the weed for this? Why we should all be chronic alarmists, afraid to do anything—afraid of the rain, of the cold, of the heat, afraid of our very selves, if this argument were carried to its logical conclusion. I know that under certain circumstances I found tobacco a friend: I will place that kindness to its credit when I prove it an enemy.

But what is this I see? "There is no possible standard of 'moderation' in the use of tobacco." The old, worn out, effete argument of the teetotallers, used by a man who pretends to a right to speak on an "intricate pathological question," who has no personal experience of tobacco, and who "*cannot assent*" (*brutum fulmen*) to the opinions of Dr. Richardson, save those which harmonise with his own view of the question. The fact is, I have been speaking of the moderate use of tobacco, your correspondent of the *im*moderate—the abuse of the weed. It is more than possible that tobacco-smoking really does harm to those with whose idiocrasies it does not agree, but plain and palpable *facts* refute every argument your correspondent has brought against its use in moderation—for though he may not be able to see it, there is a distinction as well as a difference between its use and its abuse.

I may appropriately conclude with the statement that tobacco-smoke does *not* contain the bogey Nicotine. "Our" chemists may perhaps analyse it and say if I am right or wrong. The nicotine (if any remains) is in the "oil," and I pity the taste of the man who swallows that. It is pyridine, picoline, or some other *ine* that ruins the "slaves" of tobacco both morally and physically. But *satis verborum*.

Saul Rymea.

[We beg to suggest that this controversy should end with this letter.]—Ed.

VALENCIES AND ATOMICITIES.

[3799.]—"Beacon Lough" (let. 3742, p. 642) somewhat overstrains my remark as to the relative comprehensibility of the constitutional formulæ and the binary formulæ of acids and salts; no one who has read much of my communications in these pages will suppose that I would imply that the mere difficulty of an idea is any objection to its study. What I have said, and what I now repeat with any amount of emphasis required, is that the doctrine of atomicities, as debated among chemists, in the fashion illustrated by the discussion (which as usual, degenerates into a mere squabble) between "Beacon Lough" and Mr. Bottone, is a dispute about what is wholly hypothetical.

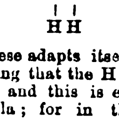
Any examiner who should venture to reject any formula attempting to define the constitution of sulphuric acid, and evidencing the possession of any ideas on the subject, because it did not agree with Frankland's guesses, would commit an act of gross tyranny, unless, of course, it was stipulated that the examination was to be governed by the guesses aforesaid.

The dispute as to whether sulphur is a dyad or a hexad, is one about words and about properties wholly hypothetical. We take up certain conceptions and fit them to a dyad or hexad atom; that is, we say the atom is hexad, *because* such and such a molecule exists, and then we say, such and such a form must be that in which the molecule exists, *because* the atom on which it is based is hexad. Some people may call this science, for my part I think it is very like the old scholastic logic, and bears a strong resemblance to the discussion as to how many thousand angels could dance together on the point of a needle, as to which no man really knew anything. Of course, in science, the great majority of men will be able to grasp only one idea, and will pin their faith to one teacher and system, just as in religion, the majority can see truth only within their own wretched little "ism." Be it so: they may be right to anchor themselves to something which appears to them fixed, and satisfies their needs. But others there are who can and must take wider views, and on their behalf I protest against any attempt to set up any standard of orthodoxy where there is not an absolute and ascertained truth in question, but merely an opinion. That is really the only point on which "Beacon Lough" and I differ.

As to the opinions themselves, sulphur and its products (both because of their practical importance and the care with which they have been examined), furnish the best illustration. "Beacon Lough" has given us the hexad formula of Frankland, and asks me to contrast it with Mr. Bottone's dyad formula of sulphuric acid, as to their adaptability to the act of electrolysis. On that head they are exactly alike, for each presents the hydrogen as forming part of two atoms of hydroxyl. Let me say here that I always use the word atom for a compound radical which cannot exist by itself, and plays the part of an elementary atom in combination. But the point I urged before was, that neither formula was so satisfactory as the simple H_2SO_4, meaning by this not the mere rational formula giving the number of elementary atoms in a lump, but the binary formula, treating the acid as composed of the chlorous radical SO_4, and the hydrogen satisfying that radical and replaceable directly by monad or dyad metals.

Here then, I contend for the broad view that each and every one of these formulæ and conceptions is one aspect of a many-sided truth, and that it is a true chemist's duty to study each of them, and recognise its value; not to sit himself down in front of one side and deny the existence of the others.

Now, I hold that if there is any such thing in reality as atomicity or valency of atoms, and if what we speak of under those names is anything more than a convenient mode of expressing ideas as to the grouping of the atoms within a molecule, then sulphur is a dyad only, and that Mr. Bottone's formula is the most probable; for in what does the difference consist? We know that S takes up two atoms of O, forming sulphurous anhydride, a closed molecule $S<\begin{matrix}O\\|\\O\end{matrix}$; again, this is converted into sulphuric acid by opening the bond between the oxygen atoms, and satisfying each of their free valencies by a monad atom of hydroxyl $-O-H$. This gives us $S<\begin{matrix}O-O-H\\O-O-H\end{matrix}$. Treating sulphur as a hexad we must suppose (it being all supposition) that two oxygen atoms fixed themselves each to two of the sulphur attractions, leaving two undeveloped, $\underset{\smile}{O=S=O}$; then the addition to these of the hydroxyl atoms gives us:—



Now, either of these adapts itself to the electrolytic reaction by assuming that the H is torn away and replaced by a metal, and this is equally explained by the binary formula; for in this the radical is $S<\begin{matrix}O-O-\\O-O-\end{matrix}$ possessing two free valencies.

But the doctrine of atomicity fails to tell us why that radical either does not exist or cannot be isolated; for if these bonds or valencies do exist and act as supposed, I, at all events, fail to see why the two free oxygen valencies do not satisfy themselves, as they are assumed to do in other cases. If "Beacon Lough" wishes me to accept his diagram (after Frankland) as an explanation, and to assume that it is a reality, and that the two hydroxyl atoms are stuck upon opposite sides of the sulphur atom, and that if the hydrogen atoms are removed the valencies set free are out of each others' range; then all I can say is, that I fail to see how a dyad atom, such as zinc, can ever manage to hook itself on to those valencies and displace the hydrogen.

This serious failure of the existing atomicity notions (for they have scarcely arrived at the dignity of a theory, let their disciples affirm them ever so vehemently) is of the same nature as "Beacon Lough's" explanations of the silico-fluorides and compound chlorides. It is nothing but a pure assertion, and not an explanation, to say that some bodies (say, binary salts) are formed in consequence of laws of valency by which satisfied molecules are formed, and that other bodies (say, compound salts) are formed by junctions of such molecules on other principles as yet unknown; for these latter bodies are just as truly built upon chemical affinities, and are as absolutely definite structures, as the others. The only true and honest course is to regard the doctrines of valency as speculations and guesses at truth; not to attempt to place the opinion of a Frankland or a Wurtz upon the footing of a decree of the ancient kings of the Medes and Persians, which altereth not; because in these revolutionary days that sort of despotism only excites rebellion.

I have hitherto used the two words valency and atomicity as synonymous, because this is commonly done; there is, however, an important distinction capable of being made if consented to. Valency may represent the power of substitution or combination as to monad atoms, hydrogen or chlorine. Here we have tangible facts alone to deal with, and in this sense the doctrines of valency are simple and important; they, however, derive their value from, and are connected to the "new notation:" thus oxygen is bivalent, so is sulphur, because in the new notation, for very sound reasons, we have doubled their own equivalent number, or ratio to hydrogen. The term valency, therefore, connects the new atomic notation with the old equivalent notation and represents facts.

Atomicity, on the other hand, represents hypothesis; it assumes a definite property of the atoms themselves, something in the actual constitution of the oxygen or sulphur atom which gives it a power of attaching to itself 2, 4, or 6 similar powers exerted either by separate monad atoms or radicals; or by 1 or more atoms possessing several similar powers themselves. Here we leave real facts, and enter upon a wilderness of guesses which may be true, but may also be false. It is in this connection we begin to dispute whether sulphur is dyad or hexad, for we know that sulphur unites to 2 atoms of hydrogen or chlorine, and calling its valency 2 expresses, therefore, this fact. We range the atoms according to our fancy, and we can develop 2, 4, or 6 imaginary links to the sulphur atom, but in calling its atomicity dyad or hexad, we only express our guess at the explanation of the facts. Sigma.

VALENCY.—To "Beacon Lough."

[3800.]—A very instructive dialogue, and one which, by the way, bears greatly on this subject, took place between two Frenchmen who were desirous of airing their English in Regent-street. A began by asking the lucid question "Did it rain to-morrow?" "Yes, it was!" was B's prompt and logical rejoinder. The pertinence and coherence of the queries and replies with which my good friend "Beacon Lough" favours me from time to time bear so strong a resemblance of qualities displayed in the above dialogue, that a suspicion has arisen in my mind that "Beacon Lough" is the identical B who framed the response to that difficult and portentous question. To render my meaning clearer I shall quote several passages in my amiable correspondent's letters, which will also serve to show the profound veneration which he has for truth, and the great care he displays in not contradicting himself. In letter 3420, page 460, "Beacon Lough" says: "Right or wrong, Dr. Frankland system of chemistry, with his atomicities, is taught in these (Government) classes. . . . . The text-book is necessarily somewhat meagre and skeleton-like, thus leaving ample room for the Mechanic to come in and fill it up, so to speak." Now I put it to the intelligent reader: What inference can be drawn from this juxtaposition of Dr. Frankland's name with "the text-book? If "Beacon Lough" constructs his sentences so as to leave the sense ambiguous (or rather that they mean the contrary to what he intends) surely I am not to be taxed with a want of verity. Acting on the self evident signification (and not the hidden meaning) of these words, I sought everywhere for a text-book emanating from Dr. Frankland, but I was assured by all to whom I applied that no such text-book existed. Consequently I denied, and still deny, that any of Dr. Frankland's works are at present text-books for the Government classes. Finding that I had taken the trouble to sift this matter, "Beacon Lough" now comes forward (letter 3742) to tell me that I am quite correct this time, and that Dr. Frankland's works are not the accepted text-books; but in order to qualify this he says my inference is quite the reverse, &c. What inference? Did it rain to-morrow, &c.? I must also call attention to the evident regard for real advancement contained in the opening words of the sentence "Right or wrong," &c. (letter 3420). In the same letter another very strong assertion is made—viz.: "these (atomicities) form the very life blood of modern chemistry," &c. But this assertion is only made to be contradicted, for at letter 3742, page 641, "Beacon Lough," with remarkable sang froid, tells me that "I must surely know" that the compounds I quoted—viz., K_2SiF_6, KBF_4, K_2PtCl_6, &c., are "all instances of molecular combination." Pray, how comes it, if "atomicities form the very life blood of modern chemistry," how comes it, I repeat, that above one thousand definite crystalline compounds exist, whose constitution is incompatible with, and inexplicable by the theory of "atomicities" (to use "Beacon Lough's" antiquated, loose, and ambiguous expression), and which require a new and distinct, though co-existent theory of "molecular combination"? I have already stated on various occasions that I placed very little reliance on the theory of valencies as it at present stands; but I must say that consequent upon thinking over the examples adduced by "Beacon Lough" I feel that the theory has even less basis than I was previously disposed to admit.

At letter 3742 we have a beautiful chain of reasoning, made, however, only to be immediately destroyed by the substance of the following sentence. I quote the passages, as it is important to keep them well in mind:—"It seems to me that if an element A combined with a monad atoms $x\ x\ x\ x$ and y, its atomicity must be equal to n, and that therefore when we find nitrogen combined with four monad atoms of H, and one monad atom of Cl, the only reasonable conclusion to which we can come is that N is a pentad." Immediately following upon this we are told that the compounds, K_2SiF_6, KBF_4, K_2PtCl_6, &c., are "all instances of molecular combination," or, in other words, not amenable to the same process of reasoning. This example alone is sufficient to show us what a tendency there is in the human mind to reject or lose sight of all that does not agree with its peculiar bent. Now, applying exactly the same reasoning as ... that my logical friend has applied to nitrogen, I also I should arrive at the conclusion that platinum is octavalent, for I might say, "It seems to me that if an element A combine with n monad atoms $x\ x\ x\ x\ x$ and $y\ y$, its atomicity must be equal to n, and that, therefore, when we find platinum combined with six monad atoms of Cl, and two monad atoms of K, the only reasonable conclusion to which we can come is that platinum is an octad."

A little farther on, another statement is made which has no foundation on fact. ... that when a chemist ... at the beginning of a series of ... adheres to them throughout. To confute this, I must give the names of a few books (I am loth to do so, for "Beacon Lough" says there are few errors that cannot be sustained by some book or other, though he quotes freely) in which exceptions are taken to the tables, &c., in the works. Beginning at W. Gregory's "Outlines of Chemistry," published 1848, where, in the table, the equivalents of phosphorus, arsenic, &c., are stated to be respectively 15·7, and 37·5, while in the body of the work the reader is requested to make the change to 31·4 and 75, &c.; coming on to Fownes, &c., until we arrive at such modern works as Odling's "Manual," Roscoe's "Elementary Chemistry," and Barff's "Chemistry," we find numerous examples of this, which is simply an acknowledgment of a recently-discovered fact, instead of a blind following of a theory. I will just point out the cases in the three last mentioned works, as they may interest the general reader. Professor Odling, in his "Manual," speaking of the elements of the chlorine group, points out their varying valency, while in the table of valency he classes them as monads.

Roscoe, in the table, puts tantalum and niobium as trivalent and pentavalent, while in the body of the work they are specified as pentavalent only. See pp. 279 and 253, edition 1871. Again, at p. 168, the elements of the nitrogen group are specially stated to be all *trivalent*, but at p. 174 their pentavalency is admitted. Barff, at pp. 210 and 211, states that oxygen, and other elements like it, are divalent; nitrogen, &c., trivalent, &c. At p. 260, he shows that nitrogen and phosphorus may be considered as pentavalent, and oxygen as tetravalent (see third edition of the above work, 1872). But the fact is, that in all these cases no contradiction is involved; it is simply a case of honestly stating the truth, whenever, or wherever found. Were I to find that a compound existed of the formula HCl_3, I should immediately call my readers' attention to the fact (even though I might have reached the middle of my lessons), and warn him not to consider hydrogen as constantly monovalent. Although, at p. 538, "Beacon Lough" says, "there are few errors which might not be accounted for by reference to some author or another," yet, at p. 641, he quotes "somebody" (not quite sure who) to prove something I have never denied; and taxes me with assigning bivalency to chloride, &c., when I have simply pointed out that the chlorine group is certainly monovalent as compared to hydrogen, although in the compounds I mentioned that such valency will not account for their existence, and would lead us to infer that they can act as triads, dyads, or pentads. This is a fact; and I truly sympathise with "Beacon Lough" when I find his pet theories must yield to facts. And now I think I am entitled to know what "Beacon Lough" requires me to do. At letter 3420 he states his object in writing to be, "not to get up an argument," &c., but to prevent that "lessons in the science which must tend to confuse the subject should be set forth in our pages." To meet this amiable proposal, as our kind Editor has not thought fit to take the hint, I would suggest that "Beacon Lough" should get up a series of lessons to replace mine. I am quite willing to withdraw, and shall much enjoy the examples of "molecular combination" to which we shall be treated. With regard to bringing my papers into conformity with the "legal system," I have already refused to do so, as I see no point of agreement betwixt legality and chemistry, except that they both terminate in y. Relative to the valencies assigned to the elements, I have distinctly stated (paragraph 21) that they *do* vary, and that my table of valencies, &c., was made out with reference to hydrogen only (see 34 at foot-note). I repeat, I have never even inferred that nitrogen, &c., does not sometimes act as a pentad. But I shall defer giving this group, pentavalency compared to hydrogen, until "Beacon Lough" or some one else has demonstrated the existence of NH_5, PH_5, AsH_5, &c. I note with pleasure that my lessons have been of some benefit to "Beacon Lough," and that he has adopted one of my ideas—viz.: that the valency of the molecule is independent of the valency of the component atoms (see 21) for his "molecular combinations" mean nothing, if not this.

In obedience to his wish, in conformity with the table given at 34 and the views held out at 21, I can represent the formula of ammonium chloride as being $\frac{1}{N'''H'_4}\ \frac{1}{H'Cl'}$, an instance, "as my learned friend must surely know of molecular combination."

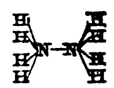
I avail myself of this occasion of correcting an erroneous statement which I made, regarding the valency assigned to sulphur by Dr. Frankland. As "Beacon Lough" did not specify which work he alluded to, I looked into a list of "atomicities" by Dr. Frankland, and there I found sulphur marked thus, = S''. I am now inclined to believe that this must be a typographic error, for on turning to my copy of the "Lecture Notes" I find that Dr. Frankland certainly does admit three different valencies. But this has no bearing on the point at issue, for, as I said before, the constitution of all known sulphur compounds can be easily explained by regarding sulphur as a dyad. Up to the present time no compounds of sulphur with hydrogen, corresponding to $S^{iv}H'_4$, or $S^{vi}H'_6$ are known to exist, and as I have taken hydrogen as the standard for valency, I feel that to be consistent I must consider it as bivalent only.

I must here take exception at the very unfair manner in which "Beacon Lough" twists "Sigma's" plain phrases into significations never intended. Now our talented friend "Sigma" stated that H_2SO_4 gave us a much better idea of the comportment of sulphuric acid in reactions in general, and electrolysis in particular than any other; but "Beacon Lough" proceeds to question him as if he ("Sigma") wished to institute a comparison between my (?) formula and Dr. Frankland's. Again, "Beacon Lough" does "Sigma" great injustice when he perverts his veritable meaning that "nothing but what is easy is to be admitted into science." "Sigma" indeed states H_2SO_4 to be easier of comprehension than $\left.\begin{matrix}SO_2\\H_2\end{matrix}\right\}O_2$ or $SO_2\left\{\begin{matrix}HO\\HO\end{matrix}\right.$, but he expressly enjoins us "to recognise the use of each, and, above all things, most carefully to avoid pinning our faith exclusively to any one idea or doctrine." Fortunately, for the progress of science, "Beacon Lough" ... he may persistently ignore them; so that until "Beacon Lough" can give us the graphic formula of the following compounds, which shall agree with Dr. Frankland's (or rather "Beacon Lough's") "atomicities," and their vapour densities, I must say that, as he prettily put it, he is "studying the shadow," instead of "getting the substance." The compounds I refer to are these:—Ammonium chloride, phosphorus pentachloride, chloric oxide, bromine pentachloride, iodine pentabromide, &c. As "Beacon Lough" finds himself unable or unwilling to give me the graphic formula of compounds referred to in my last letter, I shall, for the present, withhold them, but shall notice them in the course of my lessons. I take this opportunity of thanking "Beacon Lough" for the "amende honorable" contained in his last letter.

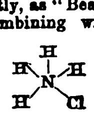
S. BOTTONE.

ATOMICITIES.

[3801.]—ALLOW me, through the medium of your paper, to call Mr. S. Bottone's attention to the atomicity of nitrogen in his letter (3470, p. 488). I cannot see, in the face of reason itself, how he can possibly make nitrogen anything else but a pentatomic element, even in his "terrible poser," Ammonium, which he states as NH_4, which is not exactly correct, the proper formulæ of which is $\left\{\begin{matrix}NH_4\\NH_4\end{matrix}\right.$, and the bonds of the nitrogen atoms consequently engaged, thus:—



four of the bonds of each being held by hydrogen, and the fifth bond of one of the nitrogen atoms is neutralised with the fifth bond of the other nitrogen atom, consequently it is a pentad. I quite agree with him, ammonium chloride is the monatomic radical ammonium united with one atom of chlorine; but he must take into consideration that the other four bonds of the nitrogen atom are engaged by the four atoms of hydrogen; consequently, as "Beacon Lough" says, it is a pentad, by combining with five monatomic elements, thus:—



The same may be said of ammonium carbonate, which is a similar example, thus:—$O = C < \begin{matrix}O - N \equiv H_4\\O - N \equiv H_4\end{matrix}$. Then, with regard to phosphorus pentachloride, I have always been led to believe that the five atoms of chlorine were united directly with the phosphorus, and I think Mr. Bottone's phospho-chloramine is merely a ruse to clear himself of a blunder. Also, allow me to call Mr. Bottone's attention to his last paper on chemistry (February 2nd, page 498), in which he states phosphorus to be a triad in phosphorus acid, when it is a pentad, thus:—P^vOHHo_2, or $H - O - \overset{\overset{O}{\|}}{\underset{\underset{H}{|}}{P^v}} - O - H$, according to Dr. Frankland, whose views Mr. Bottone "holds in the highest respect," yet wanders so much astray from them.

MERCURIC.

AURORA BOREALIS.

[3802.]—APROPOS of Aurora borealis, I observed the last very carefully with spectroscope, and, owing to previous suspicion of the fact, observed it simultaneously with the light of a common candle, and found that the well-known green line almost, if not exactly, corresponds with a likewise green line shown (when you look down or at the end of the wick) by the spectrum of a common wax candle.

I have this moment verified the above statement. Looking at spectrum of lighted wick of common candle, you get five lines:—

180 = D, the yellow or sodium.
229·5 = D – E, one reddish-green line (seen with difficulty).
368·5 = E – b, the green line in question.
557 = F – G, a violet-blue line.
800 = G, a violet line.

In the auroral spectrum I thought I distinguished two lines, one the green, and the other too faint to fix its whereabouts, and this with a Browning's instrument of exquisite definition. The whole sky, irrespective of the auroral colour, shows this green line spectrum, which, however, is brightest on looking at the whitish-green light, and not so bright at the reddish, and is totally absent when there is no aurora.

CIRRS.

STARS.

[3803.]—I HAVE obtained, with my 8in. Alvan Clark refractor, the following observations of stars to which Mr. Burnham has called attention. The magnitude scale is one intermediate between those of Herschel and Struve, and has a light ratio of 2·512. In the case, however, of small stars near large ones, I doubt whether much weight is to be attached to magnitude estimates.

8 MONOCEROTIS.—P = 356·18°, D = 1·797". Small star, about 10 mag., and bluish.

4 MONOCEROTIS.—P = 178·60°, D = 3·385". Small star, about 10½ mag., blue. There is also a second minute companion, 11¼ mag., P = 244·1°, D = 10".

LALANDE 12936.—Near Sirius. P = 169·42°, D = 4·071". Small star, about 9½ mag.

40 ERIDANI.—The small star in the $s\ f$ quadrant mentioned by Mr. Burnham, I estimate of about 12½ mag. The Baron Dembowski mentions a star at a distance of 30" in the $n\ p$ quadrant. I fancied I glimpsed this star on March 4, but could not verify my suspicion on the following evening. There is a small star at a distance of about 100" in the same quadrant, of 12 or 12½ mag.

On March 6, I looked at the star No. 156 of the Pulkowa Catalogue, and thought it certainly oblong in a direction of 135°. I have not as yet come across any measures of it.

GEORGE KNOTT.

ASTRONOMY AND "THE ENGLISH MECHANIC" IN NEW ZEALAND.

[3804.]—YOUR useful and instructive periodical has always afforded us much pleasure and profit. We look for its arrival every month, for to it we are chiefly indebted for all the scientific news from the great centre of science. Astronomy being the principal subject of interest to us, perhaps it may interest some of your readers to hear what we have done out here. As this is but a young colony there are few persons who take much interest in scientific subjects, their time being mostly occupied with business; in fact, we do not know six persons in the province who take any interest in astronomy whatever; the consequence is that there is little demand for scientific instruments, books, &c., and we have great difficulty in getting them.

Our telescope we imported from Sydney; it is of 3in. aperture, and will divide stars 2" apart, as well as perform well on the planets, &c. We have lately been studying Orion, and can very clearly see the four stars in the trapezium, and sometimes when the atmosphere is clear have made out the fifth.

Our observatory is of our own construction, and answers very well; it is square and made of wood; the roof is divided into two parts, one of which is fixed and the other slides up and down on rollers. We find it easy to work, and was more readily constructed than any other shape might have been with our limited means and conveniences. The size of the building is 10ft. square, the highest part of the roof 6ft. 6in. high, and the lowest 6ft.; the movable portion of the roof is about 8ft. × 10ft. As the roof is covered with iron the slope is sufficient to throw off the rain. We have a 7in. transit theodolite which we use for transit purposes. The cost of the building for materials only was about £10. We have also a pretty complete assortment of meteorological instruments, an anemometer with Robinson's cups is fixed on the top of a stout post at one corner of the observatory, and two barometers are inside; the other instruments are in the garden.

In the above building we have spent many pleasant hours, and hope for many more. We hope ere long to be in a position to afford one of Browning's 8½in. reflectors; but, in the mean time, must be contented with the moderate aperture we possess.

Auckland, New Zealand. LAMBERT & TAYLOR.

THE MASTERY SYSTEM.

[3805.]—IF any one wishes to learn German, French, Spanish, or even Hebrew conversationally, let them by all means go to Longmans and procure "The Handbook to the Mastery System," price 2s. When convinced, as he will be, of the effectual way in which, by this method, languages are to be learnt, he will procure the particular volume he needs at the same price as the "Handbook." The epithet "mastery" is given to it because the language will thus be mastered in an incredibly short time.

THE GLORIOUS METRIC SYSTEM.

[3806.]—IT may not look well, Mr. Editor, that one who occupies so much of your space as your kindness allows me to do, should complain of another taking rather more than his share, but really it was scarcely reasonable for "E. L. G." to fill three columns in proving what nobody can think of denying, that more numbers may be divided without remainder by 6 and its multiples than by 10 and its multiplies, and that many fractions cannot be exactly expressed decimally. That is all well known, and is acknowledged to be a drawback to the metric system; but its advocates believe, notwithstanding those blemishes and the evident and serious inconveniences of change, that the advantages of the system when introduced will much preponderate, and it will need a far more forcible reasoner than "E. L. G." to shake that conviction.

It is a rule, with very few exceptions, that those who insist strongly upon a bad argument do so from conscious want of a good one, and it is another, nearly as invariable, that those who hope to conquer by argument will not descend to abuse; thus, when "E. L. G." tries to prejudice the case by talking of French Atheists and the pitiful bubble of their blowing, and asks the decimalists if it is yet quite certain that nothing but folly governed the metrical systems of all known races till the time of Marat and his Goddess of Reason, whether they were all fools to invent units divisible by 3, 4, &c., he must be very simple, or must rely very much upon the ignorance of his expected readers. To such arguments (to say nothing of their bad taste) there are two strong objections—first, the assertion is not true that no known races adopted the decimal system of coins and measures till the time of Marat; and, secondly, if true, it is nothing to the purpose. The Chinese, as everybody knows, do now use, and probably, from a time far before history, have adhered to and experienced the great advantages of, the decimal system; and, if it were a new system, that would be no more an argument against its use than it would have been against using logarithms when they were first invented.

"E. L. G." asserts (which is easier than proving) that if we decide to divide our measures of length, surface, capacity, weight, and money-value decimally, we must in consistency divide time and angles in like manner. He might as well say that those who decide to go to Uxbridge-road must, in consistency, go on to Uxbridge. I believe that the great ease with which decimally divided measures of length, surface, capacity, weight, and value may be learnt, the certainty with which they may be remembered, and the convenience with which they can be used, estimated, and compared with each other, will greatly counterbalance the trouble, cost, and inconvenience of the change, and therefore support the change; but, as I am not convinced that a decimal division of hours, and days, and years will be better than that now in use, I do not support that change, and deny that there is any inconsistency in declining to do so. We cannot divide the year of 365¼ days into equal periods of 10 days, but it can with a remainder of 1¼ day be divided into 52 weeks of 7 days each; there would, therefore, be no gain, but loss of convenience, in having 10 instead of 7 days, even if it were not the general feeling that it is right as well as expedient to leave every seventh day for rest. There is also no great advantage to be gained by dividing the day, as might be done, into 10 instead of 24 equal periods; it is not therefore worth while making the change.

The case is, however, very different with arbitrary measures for which any unit may be chosen or selected according to convenience; and it would palpably be very convenient if all nations with much intercommunication would use the same units and divisions, or, if not exactly the same, such as can be easily interchanged. For example, if our ton were made to correspond exactly, instead of very nearly, with the French Millier or million grammes, exactly instead of nearly equal to the weight of a cube metre of water; and if our sovereign were exactly equal in value to 25 francs, instead of being worth about 6 farthings more. It is true, there would be some inconvenience and cost in making the alteration, but the convenience of having our weights and moneys exactly interchangeable is far greater. If such simple changes were made, instead of two or three authorised tables of weight, avoirdupois, troy, and apothecaries, with two pounds of different weights and three systems of division, and others unauthorised, there would be one uniform weight, and one system of division; and that the simplest, most easy to add, subtract, multiply, or divide, to compare with any other, or to perceive at a glance ratios and percentages.

Of course, the full advantage will not be obtained unless all weights and measures of things to be bought or sold, as well as money, are divided decimally; but there is no reason why they should not be; and the only serious difficulty is in finding appropriate names for the new weights and measures which will not be confounded with those now in use, and easily spoken by Englishmen. With respect to money, there is no difficulty, as only one new coin, for which an old name may be revived, will be needed. If, by charging the cost of coining the sovereign, we reduce its value by 6 farthings to that of 25 francs, or divide it, as now, into 10 florins, 100 chequers, and enact that the pound shall be worth 1000 instead of 960 farthings, no other change will be needed than issuing coins (chequers) each worth 10 of those farthings, or twopence halfpenny, or one-tenth of a florin, or one-hundredth of a sovereign. The threepenny and fourpenny pieces should be called in, and no more half-crowns or sixpences coined. Shillings or half florins would be worth twelvepence halfpenny—that is, the value of the pennies would be reduced 4 per cent., and penny buns and penny newspapers would perhaps need to be made a little smaller. The cost of low-priced articles would soon be adjusted to the slightest change in the value of copper coins, and that is about all the inconvenience that would be left.

PHILO.

STELLAR AND ASTRONOMICAL NAMES.

[3807.]—WITH much humility I would ask why we should not name the stars as we do the craters in the moon? Why not deify our most distinguished lights of science after their departure to join the now sufficiently large number on the roll of fame and give each a bright particular star? Constellations might as far as possible keep together the names of those distinguished in one branch of science. Let us take Orion for example; the seven principal stars would be not α, β, γ, &c., but Ampère, Weber, Volta, Galvani, Oersted, Sturgeon, and Faraday—magnitude having no reference to eminence. By this means we should perpetuate the fame of the truly great men of the earth. Comets might be named after ballet-dancers and statesmen.

M. PARIS.

REMARKABLE ELECTRICAL PHENOMENON.

[3808.]—IN carrying out a series of experiments for the purpose of making uninsulated, or imperfectly insulated, wires available for telegraphy, I have met with a remarkable phenomenon which I do not know has been before observed.

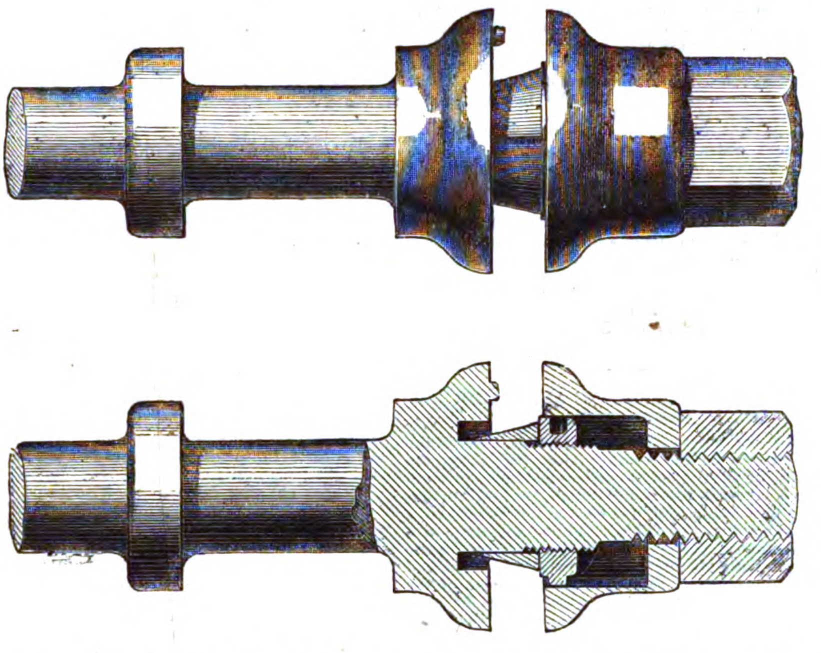
By the kind permission of the owners, I submerged a mile or two of naked wire in Wimbledon Lake, for experimental purposes; and I found that charging it with electricity of either name it retained the charge obstinately for many minutes. For instance, after attempting to discharge it at intervals of five seconds for three minutes, I found it still retained a very considerable portion of the charge, so that I have no doubt it would still have retained some portion after five or six minutes.

This may be due partly to polarisation (so called) of the wires, but I can scarcely think that this would continue for so long a time. I am inclined myself to attribute it to the electrisation of the strata of water surrounding the wires which, like the glass in a Leyden phial, require a considerable time to lose their polarity entirely. In salt water I find that the phenomenon almost disappears.

2, The Cedars, Putney. H. HIGHTON.

IMPROVED SPINDLE FOR CIRCULAR SAWS.

[3809.]—I FORWARD an illustration of Otley's patent saw spindle, which may interest those of your readers who employ circular saws. It is a simple device intended to avoid the difficulty experienced in adjusting circular saws on the ordinary spindle. A conical washer or ring, it will be seen, enters the hole in the saw to a greater or lesser depth, according to the size of the



hole. By means of the nut at the back this conical piece is forced home and makes the saw properly firm and truly centred. The illustrations explain themselves. I think the invention deserves the attention of saw-mill engineers. F. T. E.

AIR BLADDER IN FISHES.

[3810.]—I REGRET to find that the old Borellian theory relative to the use of the air-bladder in fishes still finds advocates in your valuable paper. It is upwards of twenty years ago since a paper was read at the Royal Society here on the subject, in which it was clearly shown that the air-bladder could have no influence in raising or lowering the fish in the water; in fact, no muscles exist in the fish adequate to compress the air-bladder so as to diminish its bulk, and should the fish be 34ft. below the surface, there are no muscles which could by any possibility expand it so as to take off the pressure of 15lb. on the square inch of this organ; in the latter case the air-bladder would be compressed to half its bulk. The primary use of the air-bladder would seem to be to keep the centre of gravity in the proper position, so that the whole effect of the force of the tail should operate in the progression of the fish. As the profile of the fish varies, the centre of resistance varies also, and if the centre of gravity were too high or too low, the force of the tail would cause the fish to rotate round its centre of gravity, but by having the direction of the tail force passing through these two centres, no rotation takes place. The air-bladder, then, is for regulating the position of the centre of gravity in the varying condition of the fish. In many fishes it is elongated so that the air can be located before or behind, as to produce the best effects; in the gurnard tribe and others it has lateral divisions, so that the fish can swim on its side, &c. There are other uses ascribed to the air-bladder of fishes, but the above I believe to be the most important.

Dublin. LATRATOR.

PROBLEM OF FIFTEEN SCHOOL GIRLS.

[3811.]—THE method of fulfilling the original conditions by transposing Mr. Proctor's letters occurred to me almost immediately after I had written my last letter, and I carried it still further, so as to get a more regular arrangement of the tables. I am even hoping to be able to deduce a *rule* from the tables thus transposed, which I will send if I succeed in my attempt.

L. C. E.

CONFECTIONERY, SUGAR BOILING, &c.—VI.

[3812.]—COMFITS AND PAN GOODS.—Have a comfit pan of any convenient size, suspend it from the ceiling at a convenient height to work it easy, have a charcoal fire or a stove to work it over to keep it warm, but not too hot. Have some dissolved gum not too thick. Boil some loaf sugar to 230° by the thermometer, keep it near the pan, and keep it warm; then take some coriander seed, carraway seed, or almonds, or anything you want to coat with the sugar. Put them in your pan, wet them slightly with the dissolved gum, then dust a little flour to just coat them, then add your sugar by degrees, keeping the pan well shaken all the time. To finish them boil the sugar rather less, leave what you want to colour in the pan, give them the colour in liquid, and shake them until dry, then colour the remainder separately.

I shall only give a few remarks on crystallizing, as it takes a great deal of time and trouble to crystallise goods, besides a warm room to keep the syrups in their proper degrees of heat while crystallising.

TO CRYSTALLISE COCOANUT CHIPS.—Take any quantity of cocoanuts, slice them up in thin slices, dry them in a warm stove, not so hot as to brown or shrivel them, and then place them in a tin box. Boil some sugar to 225°, pour it over the chips in the tin box so as to cover them, place them in a warm place, from 95 to 100° for 10 hours; then drain off the syrup from the chips, and place them again in the stove or warm room to dry. You can colour some red with a little colouring, but you must leave the syrup until a sort of skin forms on top before putting it on the chips.

SUGAR CANDIES.—Have tin or copper pans, with small holes opposite each other in each end of your shapes; put some twine across your boxes lengthways; then boil some loaf sugar to 230°, stand it aside until a skin forms on the top, then pour it in your pans, put it in a warm place, at about 100°, for a week; when well crystallised on the twine take it from the pans, wash it in just lukewarm water, then dry it again in the stove. You may colour it with any of the previous colours when boiling the sugar. You may make brown candies with the best raw sugar the same way as refined chocolate sweets.

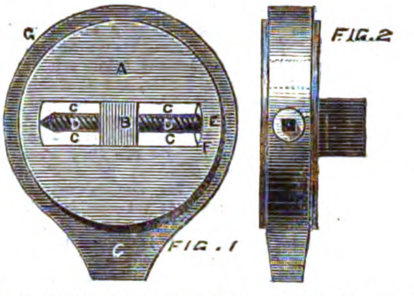
Get some pure chocolate powder, not that which is sold as prepared, but the powder without sugar being mixed with it. Boil some good raw sugar to 235°. Stand it aside to dispel the heat, then work it against the sides of the pan until it begins to grain or get creamy; then work in your chocolate powder; the quantity can be best judged by the strength of your sugar and chocolate powder.

I think by practice and perseverance in the recipes I have sent, any one having a little knowledge before will be able to make any of the plain or fancy sweets which I have named, and any difficulty the novice finds in making them I shall be most happy to clear up for him. I would give the directions for lozenges, &c.; but it would take a good space, and there must be separate rooms for making up, as it takes great cleanliness and care, but any recipes for mixing lozenges I will at any time send to subscribers through "our" journal.

L. W. D.

BOILER CONSTRUCTION AND MANAGEMENT.

[3813.]—I HAVE a great desire to arrive at a convenient two-horse motive power for my workshop. I am an amateur, and have no water-power or suitable place for windmill; have no gas for a gas-engine, and would not use one if I had; so I fancy I must look to steam. I cannot afford to keep a man to look after my steam, and so I write this hoping that some kind reader will give me his advice as to how to set to work, and his opinion on some crude ideas I shall set forth of my own. I have an engine just now, but from the bother

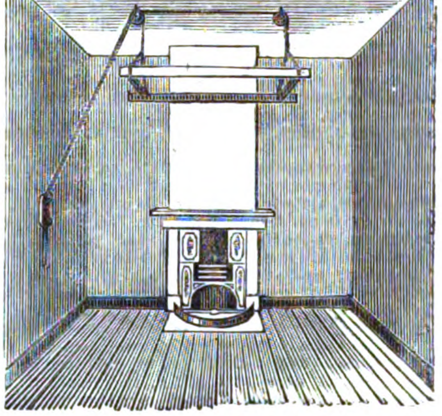


I have—first in firing, second in watching water, third in constantly regulating steam by opening or closing partially the steam-cock, and now and then blowing off some—the whole thing is almost useless. The greatest trouble is the water, and I have an idea of an adjustable eccentric which shall regulate the stroke of my pump in such a manner that after a few trials I may get the pump to throw enough to keep the water safe for at least an hour or an hour and a half. I should like an opinion on it. A is the eccentric wheel, with a slot in it, C C C. B is the end of shaft, squared to fit slot, and D D is a screw passing through B, having a collar at F, and a squared head at E. Fig. 2 shows a hole through ring G, showing square head of screw D D underneath. Now, by bringing the hole to coincide with E, and a key being applied, any amount of eccentricity can be given to A, and I imagine it might be adjusted to give the exact throw to keep the water pretty constant.

As to the boiler itself, I fancy a copper one, if the expense would not be too great. Perhaps some reader could give me an idea what a multitubular copper boiler for a two-horse engine would cost, or say how long an iron one would last with the fitful work it would have to do in the hands of an amateur (with pretty good water, however), say, four days in one week, one in the next, and perhaps nothing for the next six weeks. I fancy a damper in the flue, workable by an attachment near the lathe, would regulate the steam generation near enough, but I would like some hints; and, finally, could any of your readers do me the greatest kindness of all, by giving me good practical dimensions for a moderate running engine to suit? I fancy there is enough data given above for any one to see what I want. T. L. F.

A SUSPENDED CLOTHES HORSE.

[3814.]—I SEND you a rough sketch of what may be called "a suspended clothes horse." Its construction is both simple and cheap,—certainly no slight recommendations, though not the greatest. Everybody knows (of course I am speaking now of the working classes) how annoying and dangerous to health it is to have to dry clothes on a washing day in a house where children and grown-up people are alike exposed to the steamy atmosphere, and colds, coughs, &c., can scarcely be avoided where the old plan of drying clothes is adopted—viz., placing them on horses near the fire. The next better plan is to throw a line across the room, but even this is very inconvenient. The one I suggest



is made in the following manner:—Two scantlings of timber $1\frac{1}{2}$in. + $\frac{3}{4}$in., of such lengths as may be convenient and suitable to requirements, are fastened by two shorter pieces, say 18in. long, placed near each end as shown on sketch. A single and a double pulley are then fixed in the ceiling, the same distance from each other as the cross pieces are, and as near to the fire-place as may be convenient. A length of sash cord is then taken, the two ends of which are passed through the double pulley, one going to the single pulley through which it is passed; both ends are then secured to short loops of cord fastened to the cross pieces. The contrivance can then be raised and lowered at pleasure, and by means of a hook on the wall and knots tied in the cord, can be fixed at any height. This is no new thing, but I think it is not so generally adopted as it would be were it brought before the washing public, hence my apology for troubling you.

J. W. (Bradford.)

BEES, AND BEE-KEEPING.

[3815.]—BEES are now collecting pollen in large quantities, and, as they show great comparative activity, many bee keepers will be cheated into the belief that the dangers of wintering are over, and that this early activity denotes early swarming and a good honey crop. The Ides of March are come! Ay, Cæsar; but not gone! replied the soothsayer, who knew what was likely to happen, and ere they were gone Cæsar was no more: and although no soothsayer, I should like to warn amateur bee-keepers that although early spring has come, there is yet considerable cause for apprehension. Doubtless many bee-keepers will be glad to know what is likely to happen, but there are also many who will not heed warning or advice, and will not believe either until after the catastrophe. What is true of bees at one time is true of them at all times under similar conditions, and what has happened once will happen again when predisposing causes are similar, and as those causes vary, so will their results, and accordingly, as those predisposing causes are known and understood, so may they be governed and turned to good or evil. "Coming events cast their shadows before," and he is wise who is willing to pierce through them by the light of other people's experience. Prophesying after the event is easy enough, and hence it is not difficult for speculative bee prophets to give apparently good reasons for all sorts of failures after they have happened.

When bees are kept in straw skips, and have been deprived of their supers of honey in autumn, their ability to stand the ensuing winter could only have been judged by the weight of the hive and its contents, and taking into account the age of the comb; and although it may be ascertained whether the lower parts of the combs contain brood or not, it is almost impossible to determine what the comb actually contains, and a strong stock of bees which have stored their honey in the super, will, as they discontinue breeding, store pollen largely in the breeding cells, and consequently there may be more weight of pollen than honey in the hive, but of which fact the bee-keeper is, of course, blissfully ignorant. When early spring arrives, the hive is again judged by weight, and the bee-keeper congratulates himself on the fact of his bees having consumed so little honey. There may be plenty of bees in the hive at this time, but no brood, for the bees would be unable to commence breeding until they could gather honey; for the owner, judging by their weight, would think feeding quite uncalled for, and when the first season arrives, as it has done during the present month, the bees all go to work gathering little honey and much pollen, until they choke nearly all the cells with the latter, so that the poor queen has nowhere to deposit her eggs, and the stock dwindles during the summer from repletion of pollen, and to the surprise of its owner, perishes during the ensuing winter. This is the fate of hundreds of stocks of bees, good, sound, healthy stocks, which, if they could have begun breeding early, say in January, before pollen could be gathered, would by March be so charged with brood, which would have consumed so much of the old pollen, as to render repletion impossible. This argument is, in my opinion, one of the strongest against the use of hives with fixed combs, for if the bees were in movable comb hives, their autumn state could be correctly ascertained, and their condition in spring, as described, rendered impossible. I therefore strongly advise all persons who keep bees in hives in which the combs are fixed not to trust to weight alone as a guide to their condition, but to feed gently and continuously during all spring months.

Weak stock, such as those described by "Sixty Two," query 11046, p. 623, No. 362, should be treated in a similar way, and stimulated to their utmost. This cannot be done by giving them large quantities of food at once, but may be accomplished by patience and perseverance. To induce bees to commence breeding, it is necessary that a constant and regular supply of food should be given them, so as to induce them to think summer has come, when they will act accordingly, and when summer has come they will be fit for anything. Some writers on bees recommend honey as the best food for bees, and perhaps it is when absolutely pure, but I cannot too strongly advise bee-keepers against the practice of giving honey to bees, for it is in honey that the germs of foul brood are most likely to be contained, and to the use of it as bee-food the destruction of large apiaries is due. The mess which is sold by grocers and others as honey often contains both animal and vegetable matter—to wit, smashed brood and pollen, the result of the system which culminates in the brimstone pit, which finds a defender in Mr. Pettigrew,—and this said mess containing, as it does, all the elements of fermentation, is considered by eminent German apiarians to be the cause of that fearful disease which, in my opinion, is the only one thing which is a real obstacle in successful apiculture, and I fear nothing else, for all else is preventible.

Stimulative feeding should be performed as follows:—First, give the bees half a pint of syrup in such a way as they can get it easily; a bottle on top is best, so that they can suck it through perforated zinc, this will give them a sort of fillip and put them in good heart, then without removing the perforated zinc, procure a piece of plain zinc or tin, and punch three or four small pin holes in it, on which place your feeding bottle, and set the whole on the perforated zinc. By this means the bees will only be able to take the syrup very slowly, but the supply should continue for a long time, care being taken that the bees do not take in more than half a pint per day for the first two or three weeks, which may, of course, be regulated by the size and number of the holes in the plain zinc. There is very little trouble in this mode, and the bees do not get so excited by day after a short time, as they do when food is given them by fits and starts.

Stocks that are known to be strong and healthy require little attention at present, as they will be ready with their thousands at the right time, but the chief present difficulty lies with those above described, and it is curious to witness the apathy of bee-keepers in the matter. The chief value of a stock of bees is in having it strong in numbers when honey abounds, and to insure that, is one of the greatest arts in bee-culture, yet many never think of their bees until the fruit trees are in blossom, and it is often only then that many stocks are enabled to commence breeding at all.

The past few days have set all stocks breeding in a greater or less degree, as is evidenced by their carrying so much pollen, but it must be evident to the most superficial observer that very little honey is obtainable, and as there is a very probable chance that a spell of March weather will shortly come roaring among us, when the bees will not be able to go out at all, I wish to caution amateurs and novices against the impression which prevails, that bees have been storing honey which will help them through a spell of rough weather. Really, the very opposite is the case, for the bees have been deluded into the belief that summer is at hand, and that mild bright weather will continue, and have acted accordingly, impoverishing themselves by their instinctive desire to propagate their own species, so that if a spell of weather should imprison them, many stocks will be in considerable danger for want of continued supplies.

The same course should be adopted with them as with stocks which have been artificially induced to commence breeding; they should be fed liberally and continuously until the weather breaks and they can get abroad again.

The best food for bees is made of 5lb. of best loaf-sugar boiled in two pints of water. The addition of a wineglassful of vinegar will prevent the sugar re-crystallising.

Moist sugar or beer should not be used, as they both contain fermentative principles, and when mixed with pollen might act as the honey aforesaid.

C. N. ABBOTT.

COLLIERY EXPLOSIONS AND THEIR PREVENTION.

[3816.]—IN my last letter I said that most of the letters written on the above subject had shown the ignorance of the subject the writers had taken in hand. I did not say so as regarded "Philo's," as hitherto that was the only letter that had treated the subject in a practical manner, and I think "Philo" will agree with me that most of the suggestions put forward for the better ventilation of mines, &c., were rather absurd, and quite justified what I said as to the ignorance of the writers on the subject, and I am sorry that he calls my politeness in question, as nothing was further from my mind than any thought of being personal in the letter. In the three cases of loss of life mentioned in my last letter, I omitted to mention their cause; not one of them was caused by gas; two of the deaths were caused by falls of coal through insufficient propping when holeing, the remaining one by a corf running over a man.

Now I agree with "Philo" that where wilful neglect on the part of a mine owner for the safety of his workmen causes the death of a man, he is morally guilty of causing that death, but in an accident in the literal sense of the word he is not guilty, and yet I understand "Philo" would make him responsible for these also. As to "Philo's" project for insurance of collieries, I very much doubt if the known recklessness of colliers in fiery districts (where carelessness of colliers could be cause of explosions), would not have the effect of raising the rate of insurance to much more than he says. On my remarks as to the recklessness of colliers, he does not reply, so presume he agrees with me on that point. In my last I admitted that the small collieries did require much improvement. If "Philo" will examine the different inspectors' reports, he will find that it is the small collieries that swell the large total of deaths each year, and where the men in authority are often badly paid, and of little experience, and where the owners cannot go to a great expense in laying out their colliery, and providing the best machinery, &c. KING COAL.

A NEW GUTTAPERCHA.

[3817.]—I BEG to call the attention of the readers of the ENGLISH MECHANIC interested in the question, to a tree of Queensland which deserves an investigation, viz., the Mimusops parviflora, of the Sapodilla order or Sapotaceæ. This tree has a thick milky sap, in taste resembling fresh cream; the same peculiarity with the massaranduba (Mimusops elata) and the balata (Mimusops balata), on which I gave notes in an earlier number of this paper. The balata seems to be, for several purposes, an excellent addition to caoutchouc and guttapercha. Of the use of the massaranduba in Europe I cannot find any mention; perhaps it is confounded with balata by the trade.

I will try to give, in a future number, a list of all the caoutchouc and guttapercha yielding trees. I am for the moment arranging a classification of about 800 tanning materials, with notes on the principal of them.

Melle, near Ghent. BERNARDIN, Museum Curator.

POWER OF HIGH PRESSURE ENGINE.

[3818.]—A PORTABLE engine near me, with two 8in. cylinders, is driving two pairs of 4ft. millstones and a flour-dressing mill (bolter) with about 1cwt. of coals per hour. There has been an iron chimney with two bends erected about 40ft. high; the result was a good draught to raise the steam in less time than before, but with a larger consumption of coals they could with difficulty drive one pair of stones. It was tried in various ways, with and without the exhaust turned into the chimney, but it would not do, and the tall chimney is standing disused, and the chimney on the engine was again replaced.

With the tall chimney this engine is almost identical with "Inquirer's," and leads me to suppose that the 50ft. iron chimney has more to do with his unsatisfactory position than anything else, and I believe the erection of a good brick shaft will yield a more satisfactory result than the same sum spent in law.

Many years since a friend erected an iron chimney which was not satisfactory, and a brick shaft was substituted with very great advantage; this was a high pressure engine, driving two or three pairs of stones. I am working a 7½in. cylinder at 50lb. pressure on a portable engine, or more properly a stationary engine, on multitubular boiler, with rather under ½cwt. of coals per hour, driving one pair of 4ft. 4in. millstones, grinding from three to four bushels of wheat per hour, with which I am very well satisfied. I believe the unpleasant humming of the portable engine is caused by the vibration of the ash-pan. When my engine was used as a portable the noise was deafening; now it is fixed on a brick ash-pit there is no sound but the beat of the exhaust. R. R. SMITH.

LIGHTNING CONDUCTORS.

[3819.]—HAVING had a small bone to pick with "Philo" on my own account, I may as well point out to him his own errors, seeing his facility in providing errors for others. (N.B.—Fault-finding is exhibited thus in two distinct modes.)

Professor Henry is *not* mistaken in recommending rods as lightning conductors, but "Philo" (let. 3733, p. 638) most certainly *is* mistaken, for he asserts "that it is the surface that carries the electricity," whereas it is the mass of metal, and the surface has not the very smallest concern in the matter. Copper is best even if very much smaller, not because it is less liable to rust, but because it is a better conductor. All metallic portions of the exteriors of buildings, gutters, down-pipes, and so on should be connected to the conductor, and that to gas and water pipes, but gutter pipes are not reliable in themselves because of the breach of conducting continuity at the joints.

Without entering into the point debated between "Philo" and "F. R. A. S.," and without adjusting the relative weight to be given to the opinions of Sir John Herschel and "our" "F.R.A.S.," I beg to protest against the definition of the latter by "Philo" (let. 3730, p. 637), as one "whom we do not know." We do actually know "F. R. A. S." a great deal better than we know Sir John Herschel. The name in such cases is simply an indicator to the mind whose expression of opinion we are listening to. The name Sir John Herschel merely tells us that an opinion comes from a mind whose judgment has been ascertained and valued by others. The name "F. R. A. S." *in these pages* does exactly the same; it tells us that an opinion he expresses comes from a mind whose powers have been very fully shown and tested, and which we are, therefore, able to value for ourselves; his own actual name at the most could only tell us whether it was recognised outside of "our" pages, but as we, at all events, well know the man, *i.e.* the mind, the mere possession of his personal name could add in our judgment, no more weight to his statements than would the information that he stands six feet high, or wears a moustache. People who judge by names rarely have much judgment of their own. SIGMA.

CONNECTING LINKS IN THE NATURAL HISTORY OF CREATION.

[3820.]—I HOPE "A Lover of Truth" (letter 3471, p. 640), will not be very angry with me for telling him that he has been sold. The "monkey-fish of Japan," (Barnum's mermaid under a new name), instead of being "a connecting link in the natural history of creation," is simply a manufactured monstrosity.

In an article, "De Monstris," in this month's *Dark Blue* magazine, the Rev. .. G. Wood (whose authority I hope will be enough for 'A Lover of Truth") says the following apropos of this subject:—

"I cannot leave the subject of monsters without a short reference to the Japanese mermaids, which are now and then brought before the public. These are nearly all made to represent the conventional idea of mermaids, except that the upper half is formed in semblance of a monkey and not of a human being. They are quite common, and are manufactured by dozens, most of the makers adhering to the same type, but one or two striking out original ideas of their own. They are well made, but not so well as is generally thought. The late Mr. Waterton, whose skill in taxidermy was supreme, had an entire contempt for

Japanese mermaids, which he stigmatised as clumsy fabrications, saying that he could make better work with his left hand. Certainly the amusing monstrosities which he made, and with which he delighted to delude visitors to his collection, were much superior to the best Japanese mermaid that I have seen. Some years ago a fishmonger in the old Hungerford Market showed me one of these mermaids, and was quite angry with me when I praised the excellence of its manufacture. He really believed that it was a genuine inhabitant of the water, framing his belief on the fact that there was no junction between the fish and the maid. Neither was there. The Japanese taxidermist knew his business too well to have any junction at all, the seeming skin being nothing but the papier-mâché worked over a model, and having fins, scales, teeth, and nails inserted in the proper places."

Will this satisfy "A Lover of Truth"? WILSON.

LIFE IN DARKNESS.

[3821.]—I THINK Professor Thomson must have been misunderstood, for the dictum that "life cannot exist in darkness" is totally opposed to known facts. I send an extract from Hartwig's "Subterranean World," which, although, possibly not conclusive on the point in question, cannot fail, I imagine, to interest many of your readers:—

"While subterranean vegetation is exclusively confined to mushrooms, animal life of almost every class has far more abundant representatives, for plants are in general much more dependent on the vivifying influence of light. The various animals which are found dwelling in caves may be subdivided into two groups; one, which, though preferring darkness, and spending a great part of its existence under the earth, yet often voluntarily seeks the light of day, or at least wanders forth at night; while the other is exclusively subterranean, and is never seen above the surface of the earth, unless by chance or when driven up by violence.

To the first group belong most of the insectivorous and rodent quadrupeds that dwell in self-made burrows, or pursue a subterranean prey, such as the armadilloes and the moles. The large family of the bats likewise love to sleep by day, or to hibernate in warm and solitary caves, where they are sometimes found in numbers as countless as the sea-birds which flock round some rocky island of the north. When Professor Silliman visited the Mammoth Cave (October 16, 1822), he everywhere saw them suspended in dense clusters from the roofs, though a large number had not yet retired into winter-quarters. In a small space, scarcely four or five inches square, he counted no less than forty bats, and convinced himself that at least one hundred and twenty find room on a square foot, as they held not only by the surface of the walls of their retreat, but by each other, one closely crowding over another. Such clusters are found in the interior of the cavern, which branches out in many directions as far as two miles from the entrance, so that a very superficial survey allows them to be counted by millions. Who, in these dismal regions, where no change of temperature or of light announces the various seasons, tells them that the reign of winter is past? who awakes them at the proper time out of the deep sleep in which they remain plunged for months? The same mysterious voice of instinct which regulates the migrations of the birds and the wanderings of the fishes, and which in this case, as in every other, is equally wonderful and incomprehensible.

In the class of birds we find many cave-haunting species. The pigeons like to nestle in grottoes, which also serve as welcome retreats to the moping owl; and various swallows and swifts breed chiefly in the darkness of caverns. One of the most remarkable of these troglodytic birds is the guacharo, which inhabits a large cave in the valley of Caripe, near the town of Cumana, and of which an interesting account has been given by Humboldt, who first introduced it to the notice of Europe.

The *Cueva del Guacharo* is pierced in the vertical profile of a rock, and the entrance is towards the south, forming a noble vault 80ft. broad and 72ft. high. The rock surmounting the cavern is covered with trees of gigantic growth, and all the luxuriant profusion of an inter-tropical vegetation. Plantain-leaved heliconias, and wondrous orchids, the Praga palm, and tree arums, grow along the banks of a river that flows out of the cave, while lianas, and a variety of creeping plants, rocked to and fro by the wind, form elegant festoons before its entrance. What a contrast between this magnificently decorated portal and the gloomy mouth of the Surtshellir, imbedded in the lava wildernesses of Iceland! As the cave at first penetrates into the mountain in a straight direction, the light of day does not disappear for a considerable distance from the entrance, so that visitors are able to go forward for about 430ft. without being obliged to light their torches; and here, where light begins to fail, the hoarse cries of the nocturnal birds are heard from afar.

The guacharo is of the size of the common fowl. Its hooked bill is wide, like that of the goat-sucker, and furnished at the base with stiff hairs directed forwards. The plumage, like that of most nocturnal birds, is sombre brownish gray, mixed with black stripes and large white spots. The eyes are incapable of bearing the light of day, and the wings are disproportionately large, measuring not less than 4½ft. from tip to tip. It quits the cavern only at nightfall, especially when there is moonlight; and Humboldt remarks that it is almost the only frugivorous nocturnal bird yet known, for it does not prey upon insects like the goat-sucker, but feeds on very hard fruits, which its strong-hooked beak is well fitted to crack. The horrible noise made by thousands of these birds in the dark recesses of the cavern can be compared only to the wild shrieks of the sea-mews round a solitary bird mountain, or to the deafening uproar of the crows when assembled in vast flocks in the dark fir-forests of the North. The clamour increases on advancing deeper into the cave, the birds being disturbed by the torch-light; and as those nestling in the side avenues of the cave begin to utter their mournful cries when the first sink into silence, it seems as if their troops were alternately complaining to each other of the intruders. By fixing torches to the end of long poles, the Indians, who serve as guides in the cavern, show the nests of these birds, 50ft. or 60ft. above the heads of the explorers, in funnel-shaped holes with which the cavern roof is pierced like a sieve.

Once a year, about midsummer, the guacharo cavern is entered by the Indians. Armed with poles they ransack the greater part of the nests, while the old birds, uttering lamentable cries, hover over the heads of the robbers. The young which fall down are opened on the spot. The peritoneum is found loaded with fat, and a layer of the same substance reaches from the abdomen to the vent, forming a kind of cushion between the birds' legs. The European nocturnal birds are meagre, as, instead of feasting on fruits and oily kernels, they live upon the scanty produce of the chase; while in the guacharo, as in our fattened geese, the accumulation of fat is promoted by darkness and abundant food. At the period above mentioned, which is known at Caripe as the "oil harvest," huts are erected by the Indians with palm leaves near the entrance, and even in the very porch of the cavern. There the fat of the young birds just killed is melted in clay pots over a brushwood fire, and is said to be very pure and of a good taste. Its small quantity, however, is quite out of proportion to the numbers killed, as not more than 150 or 160 jars of perfectly clear oil are collected from the massacre of thousands.

The way into the interior of the cavern leads along the banks of the small river which flows through its dark recesses; but sometimes large masses of stalactites obstruct the passage, and force the visitor to wade through the water, which is, however, not more than 2ft. deep. As far as 1,458ft. from the entrance the cave maintains the same direction, width, and height of sixty or seventy feet, so that it would be difficult to find another mountain cavern of so regular a formation. Humboldt had great difficulty in persuading the natives to pass beyond the part of the cave which they usually visit to collect the oil, as they believed its deeper penetralia to be the abode of their ancestors' spirits; but since the great naturalist's visit, they seem to have abandoned their ancient superstitions, or to have acquired a greater courage in facing the mysteries of the grotto, for, while they would only accompany Humboldt as far as 236 fathoms into the interior of the cave, later travellers, such as Codazzi and Beaupertuis, have advanced with their guides to double the distance, though without reaching its end. They found that beyond the furthest point explored by Humboldt the cave loses its regularity, and has its walls covered with stalactites. In the embranchments of the grotto Codazzi found innumerable birds. It was formerly supposed that the guacharo was exclusively confined to this cave; latterly, however, it has also been found in the province of Bogota.

The discovery of animals adapted for perpetual darkness is but of modern date, and as the vast majority of caves have not yet been thoroughly explored by zoologists, the number of genera and species already known gives us reason to believe that future investigations will add considerably to their number. In the Adelsberg, Lueg, and Magdalena grottoes, which form but an inconsiderable part of the extensive cavernous regions of Carniola, seven exclusively subterranean insects, one spider, two scorpionides, one millepede, two crustaceans, one snail, and one reptile—in all fifteen different species of animals, belonging to no less than six different classes—have been found.

Among these dwellers of the dark, warfare is as rife as in the regions of light. Thus, in the recesses of the grotto of Adelsberg, the cavern beetle (*Leptodirus Hochenwartii*) is persecuted and devoured by the scorpioniform *Blothrus spelæus*, and by the eyeless spider (*Stalita tænaria*). The black and brown Leptodirus discovered in the grotto of Adelsberg in 1831, by Count Hochenwart, is distinguished by long and delicate antennæ and legs, and comparatively small translucent and smooth elytra. The unique specimen found at the time was unfortunately lost, and although twenty-five florins were offered to the cavern guides for one of these beetles, fourteen years passed before it was re-discovered in the same cave. Since then other collectors have been more fortunate, particularly Prince Robert Khevenhüller, who, during his repeated visits to the cave of Adelsberg, captured no less than twenty specimens of the Leptodirus.

Cautiously feeling its way with its long antennæ, the beetle slowly ascends the damp stalactital columns, and accelerates its movements at the approach of a light. The greater number were found in the evening, thus giving reason for supposing that the leptodirus is a nocturnal beetle, although it is hardly possible to conceive how the alternating influence of night and day can still be felt in these regions of darkness. The manner in which it is pursued by the eyeless blothrus (discovered in 1833, by Mr. F. Schmidt), has been several times observed by Prince Khevenhüller. He once saw one of these cavern scorpions slowly crawling along, stretching out its palpi in all directions, and evidently on the search. He immediately guessed that the animal was engaged in a hunting expedition, and soon found that he was not mistaken, for a fine Leptodirus was crawling about 4ft. higher on the opposite wall. For a long time the Prince left the two insects undisturbed, until he had thoroughly convinced himself that the movements of the Blothrus were evidently regulated by those of the Leptodirus, and that the former was, beyond all doubt, in pursuit of the beetle. A Leptodirus having been thrown along with a Blothrus into a phial, was immediately cut to pieces and devoured.

The eyeless cavern spider (*Stalita tænaria*), with brownish palpæ and a snow-white abdomen, is not seldom found in the hollows of the stalactites, lying in wait for the unfortunate Leptodirus. On the surface of the earth spiders are frequently obliged to fast for a very long time; but in caverns where life is so sparingly distributed, the patience of the Stalita must be exemplary, even among spiders. Her appearance on the snow-white stalactital columns, where she only becomes visible when illumined by the full light of a taper, is very striking. Like a vision, she sweeps away in her ivory robe, accompanied by her increasing shadow, until she finally disappears in the darkness. Torches are not allowed to be carried in the grotto of Adelsberg, that the whiteness of the stalactites may not be tarnished by the smoke.

But the largest and most interesting of all the European cave animals is undoubtedly the Olm (*Proteus anguinus*; *Hypochthon*). This enigmatic reptile was first found in the famous lake of Cirknitz, which, communicating with numerous subterranean caves, alternately receives and loses its waters through openings in the rock. After long and heavy rains the floods, which the hidden vaults are no longer able to contain, gush forth in foaming cataracts, and the lake, which generally forms but a long and narrow channel, then swells to at least three times its ordinary width. Sometimes, after a long drought, the contrary takes place, and the whole lake disappears under ground. Thus, from December, 1833, to October, 1834, not a trace of it was visible, so thoroughly had it concealed itself in its subterranean reservoirs, where its fishes, secure from the persecutions of man, multiplied in a remarkable manner. The olm, which only casually comes to the light of day, along with the overflowing waters of the Cirknitz Lake, was first discovered in 1814, in one of its permanent subterranean abodes. The Magdalena or "Black Grotto" situated about a league to the north of Adelsberg, slants abruptly into the bowels of the mountain. After a long and difficult passage over blocks of stone or through soft mud, a tranquil pool is at length reached, which rises or falls simultaneously with the waters of the Poik, and proves, by this reciprocal action, that in all probability, all the numerous grottoes and subterranean river channels of this so strangely undermined country form but one vast and intricate network. It was in this pool, which no light illumines and no wind ever stirs, that numerous Protei were first discovered; but as hundreds of specimens have since found their way to the cabinets of naturalists, to be observed, dissected, or bottled up in spirits, their number has very much decreased, and the time is perhaps not far distant when they will be entirely extirpated in the grotto, where from time immemorial they had enjoyed an undisturbed security. The Proteus is one of those remarkable reptiles which breathe at the same time through lungs and gills, having on each side of the neck three rose-red branchiæ, which it retains through life, as its lungs are but imperfectly developed. It has a long eel-like body, with an elongated head, a compressed tail, and four very short and thin legs. The skin is flesh-coloured, and so translucent that the liver and the heart, which beats about fifty times in a minute, can be distinctly seen underneath. In spite of its apparent weakness, it is able to glide rapidly through the water. Its four little legs remain immovable while swimming; they are only used for creeping, and then in a very imperfect manner. During rapid movements the gills swell and assume a lively scarlet colour; when quiet, they collapse and become white like the rest of the body. Sometimes the animal raises its head above the water to breathe, but pulmonary respiration evidently plays but a secondary part in its economy, as it can only live a very short time out of the water. The skeleton consists almost entirely of cartilage. The eyes, two little black spots, lie buried under the skin, and, as may well be imagined, are very imperfectly developed. Although more than a thousand specimens have been observed, yet but little is known about its mode of life, nor has it been ascertained whether it is oviparous or brings forth live young. In a captive state the Proteus is able to live for several years without any apparent food; but on fastening a small worm to the extremity of a thin stick, and holding it under the water close to the head of the reptile, it shoots rapidly towards it, swallows it with the same velocity, then ejects it again, and repeats this manœuvre several times, until it finally retains the morsel. The untiring zeal of the German naturalists has discovered the Proteus in thirty-one different caverns, and ascertained seven distinct species, varying by their size, the form of the head, the position of the eyes, and the colour of the skin. Six of these species belong to the caverns of Carniola, and the seventh to those of Dalmatia. Two different species never inhabit the same cavern.

During the visit which the Archduke Ferdinand paid, in 1819, to the Magdalena Grotto, the most remarkable parts of the cave were brilliantly illuminated, so as to produce a magical effect. Charon's boat, issuing from a dark recess, came gliding along over the black surface of the pool. The grim ferryman drew up his net before the august visitors, and presented them with six Protei that had been entangled in its meshes. Dr. Schmidl mentions part of the subterranean river in the Planina cave, 1,715 fathoms from the entrance, as the spot where the Protei are most abundant. Near to a small cascade which the rivulet here forms over a reef, the waters absolutely swarm with them, and the light-coloured animals, darting about in all directions in the dark stream, afford a strange and picturesque spectacle. As the cavern is of most difficult access, they here enjoy a tranquility rarely disturbed, and no doubt they have many other still more hidden retreats, to which man is incapable of penetrating. The best method for transporting the Proteus is now perfectly understood, and living specimens have been conveyed as far as Russia, Hungary, and Scotland. All that they need is a frequent supply of fresh water, and a careful removal of all light. Their food need cause no trouble, as the water contains all they require. It is recommended to lay a piece of stalactite from their native grotto in the vase in which they are transported. When resting or sleeping, they then coil themselves round the stone, as if tenderly embracing it. In this manner they have already been kept above five years out of their caverns. The guides to the Grotto of Adelsberg have always got a supply on hand, and sell them for about two florins each.

On turning our attention from the grottoes of Carniola to those of the New World, we find, in the vast Mammoth Cave in Kentucky, a no less interesting animal creation, which, though different from that of the Austrian caverns, still shows a certain family resemblance, and affords another proof that a similarity of external circumstances always produces analogous forms of organic life. Thus, the two blind beetles which are found in the Mammoth Cave belong to the same genera (*Anophthalmus* and *Adelops*) that have also their representatives in the grotto of Adelsberg. The largest insect is here a species of cricket, with enormously long antennæ; there are also two small white eyeless spiders and a few crustaceans. The Mammoth Cave has no preteiform reptile to boast of, but a peculiar blind rat and a peculiar blind fish.

The cavern rat, which is tolerably numerous, but which, on account of its remarkable timidity, seldom shows itself, differs from the common or Norway rat, by its bluish colour, its white abdomen, neck, and feet, and its soft hair. It has large black eyes, like those of a rabbit, but entirely destitute of an iris, and uncommonly long whiskers, as if Nature had wished to indemnify it for the loss of sight by a more perfect development of the sense of touch. Although the eyes of this rat are large and brilliant, yet Professor Silliman convinced himself of their perfect insensibility to light. All proof is wanting that it ever visits the upper world.

The blind fish (*Amblyopsis spelæus*) is now become tolerably rare from its having been so frequently fished out of the Lethe stream, as the subterranean river of the Mammoth Cave is called. Many physiologists have already made it the subject of their observations, and are generally of opinion that the Amblyopsis was not originally blind, but that, having found its way into the cave, it gradually lost its powers of vision. The celebrated naturalist Agassiz, however, being perfectly convinced that all animals existing in a wild state have been created within their actual bounds with all the peculiarities of structure which distinguished them at the present day, is of opinion that the blind fish and all the other blind animals of the Mammoth Cave are the aboriginal children of darkness, and have at no time been connected with the world of light."

SAUL RYMEA.

ORGAN FEEDERS.

[3822.]—THE arrangement given by "A Young Organist" (letter 3746, p. 642) was described to me by an organ builder two years ago. He called it the French double feeder, and I have a drawing of it, which corresponds almost exactly with that given in the ENGLISH MECHANIC. I have not seen it used, but was given to understand that it was very useful where much wind was required from a small bellows space.

A MERE NOVICE.

HOW WE SEE DISTANT OBJECTS.

[3823.]—ON the 2nd ult. you were so kind as to insert my letter (3493, No. 358), asking Mr. Proctor to explain how the mirror became visible to the spectator under the conditions mentioned. Not having up to the present seen his reply in your pages, I conclude that my letter has either escaped his notice or that press of business has prevented him from sending you the necessary explanation. I will now take the liberty of drawing the attention of your very clever correspondent "F. R. A. S." to the problem, and hope he will kindly supply the explanation thereof. There is a theory called the microscopical, which states that the most polished surface is microscopically rough, and that from the atomic prisms certain rays are reflected in every direction, thus enabling the spectator to see the illuminated object. But it seems to me that the light would be so dispersed, that in the case of a mirror we could not expect to see an object distinctly reflected. But suppose the mirror be removed, and the dark screen transferred to the opposite side of the room so as to prevent the tiny ray of light from being reflected from the opposite wall, we shall see the ray as it passes across the room, but there is nothing to reflect any part of it to the eye of the observer or the camera. Will it be asserted that the atmosphere of the room reflects a portion? if so, it must be again and again reflected, so that in a short distance it would be lost. An old theory, I believe, was at one time held —supposing that the eye had the power of directing the electricity (which is everywhere) on a distant object (illuminated), and receiving back the correct image thereof, the convex lens having the same power. I hope the gentlemen I have asked to explain this will kindly do so, as I think it is deserving of their attention.

E. J. D.

FLOW OF WATER.

[3824.]—I BELIEVE "our" correspondent J. T. Holehouse (letter 3745, page 641) has mistaken the formula. The one that he gives is applicable to "pipes" and conduits when flowing full; but for open channels he will, I doubt not, find that given by me more applicable. Now, using his formula, $V = 140 \sqrt{rs} - 11 \sqrt[3]{rs}$, as given. Thus:—

H = 5ft. per mile.

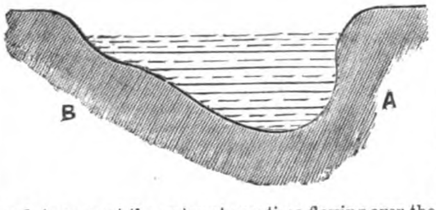
$WP = 5{\cdot}33 + 1{\cdot}0 + 1{\cdot}0 = 7{\cdot}33$, the wetted perimeter in feet.

$A = 5{\cdot}33 \times 1{\cdot}0 = 5{\cdot}33$, the area in feet.

$$r = \frac{A}{WP} = \frac{5{\cdot}33}{7{\cdot}33} = {\cdot}727.$$

$$\text{Then } V = 140 \times \sqrt{{\cdot}727 \times \frac{5}{5280}} - 11 \times \sqrt[3]{{\cdot}727 \times \frac{5}{5280}}$$

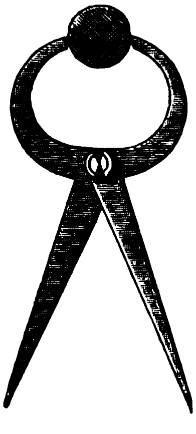
$= 2{\cdot}6875$ft. per second velocity, $= 161{\cdot}25$ft. per minute, velocity × 5·33, area = 860 cubic feet per minute, will give 5,375 gallons per minute, being considerably over the requirement. Besides, in cutting the channel, there would be a much larger excavation than necessary, as the surface of the flowing water should be some inches below the surface or ground



level, to prevent the water at any time flowing over the banks from accidental causes. By his dimensions, the sectional area of the cutting would be about 8 superficial feet. By mine, about 5 superficial feet; on a considerable length, this would materially differ in the cost. The question, as I understand it, resolves itself into this. An engineer (by the bye, we are all engineers now) has to devise the best, simplest, and cheapest scheme to carry a certain quantity of water a definite distance, whereon only a certain fall in feet per mile can be obtained. What form and size of channel will best serve the purpose? I believe, from my own knowledge and practice, the sizes I have given will meet these views. If I take J. T. Holehouse's sizes, and use the formulæ I gave for an open channel, I find the velocity will be 148·5ft. per minute, and the quantity 792 cubic feet per minute = 4,950 gallons. If J. T. Holehouse will kindly refer to "Neville," he will see that he is very precise on the conditions. I omitted in my last to mention that care must be exercised where bends or curves occur in the channel: at these places I would recommend an increased width, so as to somewhat reduce the velocity of the flow, and prevent the scouring of the sides (see Fig.). Wherever there is a bend and the more acute the angle, so will the outside at A deepen, and the inside or side B "silt" up. Every-day experience, by observation, will prove this.

TUBAL-KAIN.

CALIPER COMPASSES.



[3825.]—I HAVE not seen any mention in "ours" of a little tool which is likely to be found useful under certain contingencies, and I send an illustration of it. The compass is so proportioned that the distance of the points of the long legs is 3·1416 times that of the short ones. Your readers will, therefore see, that the upper points being adjusted to the diameter of a bar, as shown in the illustration, the distance covered by the lower ones will give the circumference without farther calculation. I saw it in an American journal; but it is possible that it may be an old idea rejuvenated. What does "J. K. P." think of it?

K. T. L.

PIANO CONSTRUCTION.

[3826.]—THERE are one or two things in the engraving of the improved design for a cheap cottage piano (p. 613, Vol. XIV.) which might possibly mislead an amateur if not a professional pianoforte-maker; the latter I am not presumptuous enough to attempt to instruct. *Imprimis*, the strings of C above the lines ought not to have been represented as if they were not parallel, which they are, to those of C, its octave above. The effect is to show them nearer the strings of pitch C, measured horizontally from where they rest on the belly bridge, instead of slightly divergent.

I ought to have mentioned that in Fig. 1 the horizontal string-plate along its bottom is not shown, because doing this would have hidden the screws which fix the lower edge of the soundboard, that being only a quarter of an inch above the upper surface of the horizontal portion of the string-plate. See section of these parts shown in Fig. 2, which shows the string-plate *in situ*, also one of the cast-iron "lumps," as the pianoforte-makers call them. These lumps are simply cast-iron cranked bars, the T heads of which should be as wide as each wooden brace, and about five-eighths of an inch thick; they ought to be let into the braces to a depth equal to the thickness of their T heads, which should be bedded accurately against the end grain of the wood. Perhaps the easiest method of making this joint perfect is to give the surfaces a thick coating of a mixture of whitelead, ground in oil, whiting, and gold size, which speedily becomes much harder than even the end grain of spruce fir. These lumps must, of course, be fixed and adjusted to the top edge of the string-plate before the soundboard is fixed, because they pass through holes made in the latter.

It has occurred to me that when a cranked brace on Kohlman's system is made in cast iron, it would be a cheap but valuable improvement to carry up a taper feather, projecting in front of that upper portion of the brace which is behind the strings. This would greatly stiffen the flat portion of the brace, which must, unless the belly-bridge be made considerably higher than usual, necessarily be rather thin, say from three-eighths to half of an inch thick, and, therefore, deficient in rigidity. As this projecting part, or feather, as a pattern-maker would call it, must needs be in the space between the strings of two successive notes, and project above the plane of those strings, and as that space diminishes until, at the hammer line, they approach within from a quarter to five-sixteenths of an inch, it will be needful not only to gradually diminish its projection towards its upper end, but also to taper it sideways until reduced to about three-sixteenths of an inch thick, so that there shall be no danger of the strings touching it when they are vibrating; also not to carry it up so high as the hammer line. For causing this feather to leave the sand easily, its top edge should be rounded, and a very small fillet be on each of its sides where it commences to project from the flat surface of the brace. If the edges of the latter, which are moulded downwards, also be rounded, the casting will be at once cleaner, because easier for the founder to mould and run, and require less dressing to prepare it for painting or japanning.

As some of my amateur readers who do not intend to make many pianos, or who might wish to strengthen those they possess, by introducing two or three Kohlman bracings into them, would hardly desire to make two or three wooden patterns for cast-iron bracing-bars, I subjoin a few practical instructions for making Kohlman bracing-bars on the plan of that shown by Figs. 6 and 7.

Instead of spreading out the head of the brace as shown in Fig. 6 for the purpose of causing it to abut against a wider portion of the lower edge of the wrest-pin-plate (a thing, by the way, most pianos are not provided with), I think it preferable to let into the wrest-plank a piece of bar-iron, whose thickness is the same as that of the upper portion of the brace. This iron may be from ⅞in. to 1¼in. wide, and secured in its place by about five No. 14 1½in. screws. It should be pretty long, say, 8in. to 12in., so that it may abut against a considerable length of wood, and distribute the pressure sufficiently to prevent it from being concentrated on a small surface of wood. When a pin-plate is used, it need not be more than half the length required when it abuts against wood, but it is essential the pin-plate be well fitted to the edge of this bar. It will be found very desirable to let the top of the brace extend about 1¼in. above the bottom of the wrest-plank, and secure it to the latter by a 1¼in. No. 16 screw.

The easiest method I can think of for an amateur to form the mortices in the bars N and L, which receive the steel plate O, is to remove most of the metal with a drill about one-sixty-fourth of an inch smaller than the thickness of the steel plate. Having chipped out the metal between the holes, and filed the mortices true to the lines, you can proceed to fit the steel plate into both. It should be what workmen call "a driving fit," not a very easy thing to be effected by an unpractised amateur, even when the said mortices are formed by the slotting machine, or accurately drifted, with their ends and sides perfectly parallel. A steady fit sideways is sufficient, but the steel plate ought to be fitted to bear accurately throughout the whole depths of the ends of the mortices. Fortunately, the absolute parallelism of the latter is quite unimportant, so I prefer to file them taper about one sixty-fourth of an inch, and to taper the steel plate to fit their ends, driving it in with the hammer, and relieving those portions of its surfaces which abut against the ends of the mortices until it bears throughout their depth, and projects, say, one-sixteenth of an inch for forming the rivet. Probably the quickest and easiest way would be to heat the mortices red and drive in the steel plate. Then, having slightly countersunk the external ends and sides of each mortice, rivet the plate and file off any projections. The job is completed so strongly that, in the workshop phraseology of the English mechanic, "you can't pull it apart with your teeth."

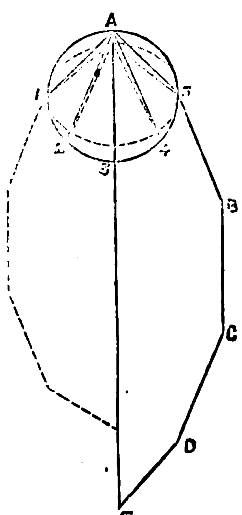
The lower portion of this brace must be morticed into the string plate below the hitch-pins, provided the strings of two successive notes be disposed nearer to each other than the thickness of the bar L, which they certainly would be in pianos not originally designed to receive this kind of front bracing. The only evil which results is that the hitch-pins of those notes must be nearer the bridge than their near fellows, the former necessarily being between the back of the brace L and the plate. There is, however, not the least need to insert all the other hitch-pins equally near the bridge, unless, indeed, we prefer uniformity to utility. Probably it might look prettier, but "handsome is whot handsome does;" and, after all, it is the reverse of good taste to ornament any construction at the cost of its utility.

The tie and strut, combined in one (K), is, by the way, represented in Fig. 3, with the nut, which abuts against the front of the wooden brace A, projecting beyond the front of that brace. Now, as I have designed only about three-eighths of an inch of space between the back of the soundboard and the front of the brace—in fact, the strings may be within 1⅜in. of the braceing —there would be some danger of the belly sinking under the pressure of the strings until it became sufficiently depressed to rest on this nut. The effects on the tone would be, in newspaper reporters' phraseology, "more easily conceived than described," so I designed this nut to be let into the brace to an amount equal to about two-thirds its thickness, leaving only about one-eighth of an inch projecting to turn it by when regulating the position of the Kohlman brace. Probably, although rather more complex, it might be preferable in practice to use a strut formed of a piece of ⅜in. rod iron, having a coarse and shallow-threaded screw (say about ten threads to one inch) formed on it,and screwed through the wooden brace A to receive any back thrust to which the Kohlman brace could be subjected by the tension of the strings in front of it. If it be thought worth while to tie the Kohlman brace—which I think it is, because, with the strut, this would enable its position in relation to the strings and the soundboard to be adjusted,should doing so be found needful, after the instrument has been tuned—I think a piece of 5-16in. or ⅜in. rod iron tapped into the Kohlman brace, passing through a hole bored through the wooden brace A, and having a nut and washer at the back of the latter, would be found to be at once the cheapest and best way of doing it; for,after all, it is difficult to apply a spanner to turn the nut, which is partly sunk in the front of the brace A, the space between the back of the soundboard and the front of the brace being so small that there is hardly room to turn the nut, were it made six or even eight-sided. Facility of adjustment, or regulation, as pianoforte-makers call it, is a *sine quâ non* in their profession.

There is an advantage to be obtained by the employment of Kohlman's or any other efficient system of front metal bracing in cottage pianos which is of considerable value when saving room is important, for it enables the depth of the back and case to be reduced from 1½in. to 3in. There can be no necessity to make the wooden bracings A equally deep when they are no longer subjected to any considerable pressure tending to arch them. Now, efficient front metal bracing relieves them from this pressure almost perfectly, consequently it cannot be necessary to make the wooden back braces more than 2in. or 3in. deep; in fact, only sufficiently rigid to become efficient stays for the metal bracing in front. The late Mr. Mott used, indeed, to say no back bracing at all was needful if the front metal bracing was efficiently tied and strutted in the manner shown in his patent (No. 11180, price 6d.) to the key bottom. He had much experience, and I think he was not far wrong; but this might be a reform far too radical for our conservative feelings (query, prejudices). THE HARMONIOUS BLACKSMITH.

TERRESTRIAL GRAVITATION.

[3827.]—THE method of finding the amount of force exerted by a globe on an attracted particle, described by Mr. Proctor in letter 3711, is too intricate for my comprehension, neither can I show that the amount of attraction is the same as though its mass were condensed into its centre. But I think it can be shown that although the amount of attraction is as the mass, the power is not inversely as the radius.



The circle in the diagram is intended for the outline of a truly spherical metal ball. Divide the circumference from the point A into eight equal spaces, and draw the lines 1 2 3 4 5; now draw the construction B C D E, and the resultant line E A will give in units of length the amount of force exerted at A. The dotted ellipse within the circle is the same ball when flattened in the lathe, the inferior length of its resultant showing the lessened force at the pole of an oblate spheroid. I consider this method gives accurate results; perhaps Mr. Proctor will kindly pass his eye over the diagram. T. A.

ERRATUM.—In letter 3721, page 635, Vol. XIV., line 32, for "defy" read "deify the powers, operations, and objects of Nature."

Preserving Potatoes.—To preserve potatoes in a proper state for food for many years, says the *Stamford Mercury*, it is only necessary to scald them, or subject them to a heated oven for a few minutes. By doing this they will never sprout, and the farinaceous substance will keep good for many years, provided the cortical part (the skin) be entire. They should be well dried after being scalded.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustration on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Commercial letters, or queries, or replies, are not inserted. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded; and the names of correspondents are not given to inquirers.

[10479.]—**Steam Launch (U.Q.).**—Engine: 4in. cylinder, 7in. stroke, downward vertical, bolted to two stringers running length of boat; shaft to have not less than three bearings, and to have a slight dip towards the stern, in order to raise boat's head when running; fix as large a drum on end of shaft as space will allow, from which your pump may be driven; link motion reversing gear is the best to have. Boiler: two horse-power vertical, five-sixteenths of an inch plates, except top, which is three-eighths of an inch; two cross water tubes are quite enough, 4½in. diameter, pressure 50lb. Screw: four bladed 20in. diameter, 3ft. 6in. pitch, running at 270 per minute, gives in mine a speed of 7¾ miles per hour. Boiler to be set on a ⅝in. plate to keep boat's bottom from fire. Boat, 29ft. over all, beam 5ft. 3in., depth (aft) 3ft. 6in., draft (aft) 2ft. 9in., forward 1ft., engine 6ft. 6in. from stern, boiler 10ft., leaving 19ft. clear space for passengers; mine is so arranged that I can work her single handed. Bare particulars are only given as space is so valuable in the ENGLISH MECHANIC.—G. D.

[10488.]—**Tests for Ores.**—I fully indorse the opinion of our worthy assayer, "Un Irlandais," on page 566. It is impossible for any one to perform a qualitative analysis correctly without they have been through a regular course of study. I have seen students who have been engaged for a year in their scientific pursuits detect sodium and calcium in every mixture given them, when those metals were not present at all, and if this happened after one year's reading, what might be expected from one whose science is only to be "rough and ready"? However, Scheerer & Blandford on "The Blowpipe" is the work I would advise him to procure; published by Williams & Norgate, London.—GEORGE E. DAVIS.

[10501.]—**Water Power (U.Q.).**—Try the water-power engine, but before proceeding see if the pressure is steady at 50lb. per square inch or 110ft. The power required may be obtained with less pressure, but at too great expense, as in such cases the water must go through a meter. A newspaper in this town is printed with a water-power engine fed by 1in. pipe. The writer has three in daily use; one for driving a lathe, and the other for business purposes. He tried a small turbine, and found it a humbug—this remark refers only to small turbines. The water-power engine is most useful where there is a very high pressure, and only small service pipes. If I had the reliable pressure (by a gauge), the time per day it will be used, I could give a fair estimate of the cost, also the rate per thousand gallons for the water.—K. K.

[10510.]—**A Task for Chemists (U.Q.).**—Seeing that no reply has appeared to this query, I suggest that wood may be made pliable for soles of boots,by dissolving out the resinous and siliceous matter. Many methods may be adopted to accomplish this. Some simple ones would be to (1) boil for three or four hours in a solution of caustic soda of specific gravity, say, 1·09; (2) boil for one hour in water; (3) soak for eight or ten hours in a chlorine solution of specific gravity, about 1·02. By making one or two experiments you will find if the doses of caustic soda and chlorine should be increased or diminished. Perhaps the above may be improved by giving it a soaking in dilute hydrochloric or sulphuric acid, previous to the chlorine solution.—BUSY BEE.

[10512.]—**Musette and Voix Celeste Stops (U.Q.).**—The voix celeste stop is simply two dulcianas, one tuned a shade sharper than the other. In putting them in they are made with separate slides, so that one can be used without the other. I believe that it is possible to produce a similar effect with a Viol da Gamba or kerolophaun, with a dulciana tuned to beat to the aforesaid. I cannot exactly describe the musette, but I believe it to be an 8ft. wooden pipe containing a reed.—ORGANIST.

[10565.]—**Pressure under Water, &c. (U.Q.).** —(1) The pressure of 100ft. of water may be reckoned three atmospheres, or 44lb. per square inch. Hence at one mile deep it will about 2320lb; at two miles, 4640lb.; and at three miles, 6960lb. per square inch. (2) Caustic alkalies, as potash, soda, barytes, or lime, greedily attract and absorb carbonic acid; the last the most slowly. The hardening of mortar depends on this absorption, and is not complete for years. (3) The third question must be explained. What is meant by raising "steam to work an engine with hydrogen gas"? Which is to work the engine? The battery to decompose water, in any way, to yield a horse-power, must oxidise 28lb. of iron or 32lb. of zinc, for every 6lb. of coke that would yield the same power by combustion, supposing in both cases no waste, but perfect economy of the forces.—E. L. G.

[10608.]—**Bee-Keeping.**—If "H. H. H.'s" bees swarm twice, which they are not certain to do, it will be better for him to return the second swarm to the parent hive on the evening of the day on which it issued forth. Why? Because the mother queen leaves the hive with the first swarm, and the queen which will lead out the second will be a young unfertile one. If they are added to the first swarm, both the queens and numerous workers may be killed, and the tender new combs in the hive injured in manipulation; but, anyhow, one of the queens will surely be destroyed, and it may be the fertile one. Whereas, if the second swarm be returned to the hive on the evening of the first day, only one queen will be injured, and all other queen cells destroyed (as a rule), and all the power and strength of that swarm will be expended in honey gathering for their owner instead of comb-building for their new home.—C. N. ABBOTT.

[10617.]—**Watchmaking and Isochronism (U.Q.).**—The ability to apply an isochronous hair-spring to a watch must be considered as one of the highest attainments of the art. The literature on the subject of watchmaking is extremely scanty, and with regard to isochronism, I am not aware that there is any work in existence which treats fully on the subject, though I would recommend our correspondent to read a very interesting paper "On the Laws of Isochronism of the Balance Spring," by Charles Frodsham, in the *Horological Journal*, Nos. 159 and 160, also a variety of information on hair-springs in Vol. VI. of the MECHANIC, commencing in No. 139. He should also read Scotchford's essay on the detached lever escapement, in which the existence of such a property as isochronism in the balance spring is disputed. The prize of £50 offered by the Baroness Burdett Coutts, will doubtless produce an exhaustive essay on the subject, and which, like the prize essay on the lever escapement, I should not be surprised to find carried off by a foreigner.—WEST CORNWALL.

[10641.]—**Rabbit Breeding.**—The first thing to be looked to in breeding rabbits is to see that they have a proper hutch, and above all keep them dry, for dampness causes many fatal diseases. The strongest and most prolific are generally gray, black,or black and white. In pairing them I would recommend the female to be gray, and either a black and white or black male. As the males are, as a rule, very much given to devouring the young ones, remove them about a week before the female's time of bringing forth, and about the same time thoroughly clean out the hutch and put in a bed of clean sweet hay or straw. I generally gave my female rabbits a little warm milk shortly after the young ones were brought forth, which they seemed to relish, and which did them much good. —BED OF STONE.

[10660.]—**The Largest Casting (U.Q.).**—Whichever of the iron castings referred to may be the heavier, they must yield the palm to some of the church bells of Moscow. The largest, that which, in 1787, three years after being successfully recast and used, was broken by cold water thrown on it during the conflagration of its belfry, but may, for aught I know, have been lately recast, weighs, according to the dimensions, 220 English tons.—E. L. G.

[10664.]—**Angle of Reflection and Incidence.** —The fact noticed by "A. P. S." that the angles of incidence and reflection made by a billiard ball on striking the cushion are not equal is one well known to all billiard players. It is seen very plainly when the ball is struck hard enough to rebound several times from side to side of the table; each time the angle of reflection becomes less, and the ball comes off the cushion more nearly perpendicular to the side of the table. M. Paris is quite right in saying that the elasticity of the cushion is the cause of this. Making use of the diagram on p. 591, the force of the stroke compresses the cushion not only in the direction E C, but also in the direction A B, and the elasticity of the cushion drives the ball off it again in the directions C E and B A. The latter being small compared to the other, the course of the ball after impact is but slightly changed; and if the ball be moving slowly, so slightly as to be imperceptible; though I believe the change of direction does exist in every case. Let "A. P. S." consider what would happen if the cushion were made of soft clay: the ball, on striking it, would bury itself in a cylindrical hole, the axis of which would not be at right angles to the cushion, but more in the direction of the course of the ball before impact. If the clay were harder, the ball would make a dent in it, and raise a ripple of clay in front of itself, something like the bit of steel raised on a rasp by the punch. This latter is what does happen in the case of an elastic cushion, and it is the force of this lump or ripple recovering its form that slightly tends to drive the ball directly back on its course, and thus lessens the angle of reflection.—LICHFIELD.

[10685.]—**The Electric Spark.**—What is the cause of its luminosity? The querist might as well ask what is the cause of any other luminosity, or of any sound; sound is vibratory movement propagated through air, and if things vibrate in air, the natural thing to expect is sound. A case of silent vibration may call for inquiry as remarkable. Light is also some vibratory movement, propagated through universal ether or matter in its atoms or molecules; and electrical discharges (as well as chemical combustion) are atomic or molecular actions; and it is natural to expect the propagation of their disturbance in the form of radiant heat, which, within certain limits of pitch, affects our eyes as light; just as air vibrations between 16 and about 8,000 per second are sounds to us, but below 16 or above 8,000 they are not sounds *to us*, though they may be to any non-human ear. And the limits of pitch in the rays that are light to us are much narrower, indeed, less than an octave; so that it is quite probable there may be animal eyes seeing by none of the light that is light to us, but wholly by rays that are dark and unknown to us. And the skies may contain galaxies of suns conspicuous to our cat or dog, but eternally unknowable to astronomers, merely because their light may all be of pitches an octave higher or lower than that of sodium!—E. L. G.

[10696.]—**Testing Vegetable Lubricating Oils (U.Q.).**—I presume "W. M." knows the old method of testing by lubricating the axes of a wheel with the oil to be tried, making it revolve with an equal force and counting the number of its revolutions by means of a counting wheel turned by an endless screw on the axis. "W. M." of course knows also that some oils get thick and sticky by exposure to air. I do not know that the plan has been tried, but think it worth trying, whether the lubricating quality of oils might not be correctly tested by oiling a smooth surface of iron and trying which is the angle of rest on it of a smooth piece of brass lying upon it. As the friction or adhesion between similar surfaces is proportionate to the pressure, any convenient thickness of metal may be used, and the angle of inclination may be fixed very accurately by using a fine-threaded screw, or a graduated wedge to raise the iron surface at one end to any desired degree.—PHILO.

[10702.]—**Terrestrial Gravitation.**—I am not sure that I quite understand "T. A.'s" difficulty, but will try again to remove what I suppose it to be. It is easy to prove, though tedious to explain, that the joint attractive force of all the particles of a homogeneous sphere is the same as it would be if the attraction of all of them were exerted at the centre, and therefore that in calculating that joint force it is quite correct and very convenient to assume that point to be the centre of attraction to all other bodies at or beyond the surface of the sphere. The same is nearly true of any ellipsoid, which is nearly a sphere, such as the earth, and a body at the equator being 13¼ miles, or 1 part in 299, further from the centre than one at the pole is attracted less than it is nearly, as the square of 298^2 is less than 299^2—*i.e.*, $89401 - 88804 = \frac{1}{597}$ (more exactly $\frac{1}{590}$) for the centre of a spheroid is not precisely its centre of attraction. The effect would be precisely the same whether the particles of which the spheroid consists be connected or not, so long as they remain in the same position. Perhaps, if instead of considering the case of spheroids, we imagine what would be the effect upon the weight of a body on the surface of a spherical earth, and 13¼ miles above it, the explanation may seem more simple. Supposing the weight at the surface to be 590, it would be 13¼ miles, or $\frac{1}{299}$ more distant from the centre, only 598, for in that case the centre of the sphere would correspond with the centre of attraction. The attraction is not proportional to the diameter, but nearly inversely proportional to the square of the distance from the centre of a spheroid, and exactly so of a sphere.—PHILO.

[10716.]—**Telescope.**—I would from experience warn those who do not know the real qualities of an astronomical and terrestrial telescope from purchasing those at £5. I bought one with (as I was told) graduated powers up to 250. I took it to India, and in three months it was useless; altogether it cost me £8, and I was glad to get ten shillings for it at an auction. Soft French object-glasses imperfectly curved, and badly cemented, for sale only, are utterly worthless. My advice from experience is—go to a thoroughly reliable maker, tell him what you want, and you won't be taken in. A novice who wants to learn something of the hidden lore of the heavens only requires a 2in. or 2½in. object-glass, with eyepieces for 60, 80, and 120, on a firm stand. Most respectable opticians will supply this for £5, and it will be both satisfactory and instructive. Of course a terrestrial eyepiece will accompany as well as a dark glass for sun views. I have had far more pleasure in studying the heavens through such a glass on a calm clear night than in looking through an 8in. refractor.—MASTER OF NONE.

[10718.]—**Sugar Analysis.**—Let "Cornubia" proceed thus:—The copper solution: Dissolve 34·64grm. pure copper sulphate in 200 cubic centimetres water, in another vessel 173grm. of sodium potassium tartrate (Rochelle salt) are to be dissolved in 480 cubic centimetres of 10 per cent. caustic soda, mix the two solutions together, and dilute the clear blue fluid to a litre. Then 10 cubic centimetres of this solution requires for its decomposition 0·05grm. glucose. All sugars are converted into glucose before being estimated, and as 0·0475grm. of cane or milk sugar, and 0·045grm. of starch or dextrine corresponds to 0·05grm. of grape sugar or glucose, 10 cubic centimetres must be equivalent to the weight of the different sugars. As an illustration I give the process I employ in the analysis of flours; I have six or seven samples at once before me, and a rapid and accurate method is everything with me, the only drawback is the long heating it requires, but this I leave to my laboratory youth, who fills up the flasks as they boil away. I take 1grm. of the flour, mix it with 20 cubic centimetres of water to a smooth paste, transfer it to flask and heat until thick. I then add 8 cubic centimetres of dilute sulphuric acid (1 to 4) and heat for eight hours on a sand bath, replacing the water as it boils away. The free acid is then neutralised with caustic soda, and the whole diluted to 250 cubic centimetres; 10 cubic centimetres of the copper solution is then placed in a flask with 40 cubic centimetres of distilled water and boiled, the burette is filled from the 250 cubic centimetres flask, and the solution dropped into the boiling flask until the blue colour of the copper has gone. An indicator of an acetic acid solution of potassium ferrocyanide may be used, the liquor being allowed to settle, and a drop of the clear fluid being taken from the top of the liquid. Whilst copper remains in excess, a drop taken out produces the well-known brown colour. The number of cubic centimetres used divided into 1,125 will give the percentage of starch, thus, in one of my experiments 17 cubic centimetres were taken, which would give 66·17 per cent. of starch. I may as well add, that until the operator has had considerable experience in the method duplicate analyses should be made upon the same sample to insure accurate results.—GEORGE E. DAVIS.

[10728.]—**Blackening Transparencies.**—Try twenty drops of a saturated solution. I expect that is what is intended.—E. H.

[10798.]—**Tortoise.**—The toy called a "lively turtle" is nothing more than an imitation, on a small scale, of a tortoise, inclosed in a wooden box with a glass cover. Its liveliness consists in a perpetual shaking of the legs—"lively," but not lifelike. What the construction is I do not know, but some of "our" readers will possibly be able to explain. I suppose the legs are connected by a spring. I am in the dark as to whether this is what "Willie Scorer" means, but I have seen one of these in a box 1½in. in diameter, and presume it is the "toy" referred to.—SAUL RYMEA.

[10819.]—**Bleaching Powder.**—If "Omega" will turn to p. 135, No. 344, of "our" journal, he will find the most accurate method for estimating the amount of chlorine in bleaching powder there described. It is Bunsen's method, and is given on that page as an illustration of quantitative analysis.—GEORGE E. DAVIS.

[10834.]—**Analysis of Ores.**—To "JANUARY."—Read the answer to "Far West," by "Un Irlandais" on p. 566, and also my reply in this present number, 10488. The only work I would recommend is Sutton's "Volumetric Analysis," 12s. 6d. I believe this last edition. It is a splendid work.—GEORGE E. DAVIS.

[10863.]—**Sulphuric Acid.**—To make 1 ton of sulphuric acid at 150° Tw. per day, or 7 tons a week, 20 tons of sulphur must be burnt, requiring two chambers, each containing 7,000 cubic feet, and these two chambers would have to be supplemented by a column 3ft. square, and about 25ft. high, otherwise there would be a large escape of sulphur into the flues. If 47 per cent. pyrites are used, 5 tons per week must be burnt in order to make 7 tons of vitriol per week. Between 5cwt. and 6cwt. of nitre will be required weekly, but of course, all these calculations depend upon good management. I should advise him not to commence on too small a scale, and could give him further advice if he requires it.—GEORGE E. DAVIS.

[10882.]—**Damp Walls.**—I am obliged to, not offended with, T. H. Saunders; he may be right, and I will consider his suggestion. I submit to him that if vertical percolation is the cause, why is there no internal damp in the south-eastern gable? The filleting behind stone coping of that gable is more exposed to south-western rainstorms than is that of south-western gable. The coping projects some 2in., and the gable is steep to throw off wet; an equilateral triangle. Another correspondent suggested gas tar, surely not an ornamental article to apply to a red brick house with stone dressings. Thanks all the same.—R. J.

[10883.]—**Rust in Iron Vat.**—If "R. J." will say what salts he crystallizes in his vats, perhaps I can help him. Also whether the liquors inserted are alkaline, neutral, or acid.—GEORGE E. DAVIS.

[10889.]—**Rose Trees.**—No one having authority seems to have replied to Mr. Abbott's query. Allow me to say that so far as I have ever heard his definition is perfectly correct. A dwarf rose is one on its own bottom; a standard one budded on a stock, the height of the latter being perfectly immaterial. I will undertake to affirm that no nurseryman would send roses budded on short stocks when dwarfs were ordered.—SAUL RYMEA.

[10919.]—**Chemical.**—Take a mixture of nitric acid and water, which is made of a strength of 74° on Twaddell's hydrometer. Six drachms of this acid is to be placed in a flask and forty grains of silver added, heat being applied until all is dissolved. Two fluid ounces of alcohol are then added, and the flask heated in a sand-bath, or what is better, a water-bath, until a lively reaction is commenced; the flask is allowed to cool after the reaction has proceeded, when the silver fulminate will mostly be found at the bottom. Water dissolves this salt to a certain extent, so silver would always be found in the filtrate. I cannot spare the time to write out a table to show the quantity of water required to reduce the gravity of nitric acid, but "Singlestick" can get the result by adding water to the acid until when quite cold it will show 100°Tw. = 1·5, 80°Tw. = 1·4, 75°Tw. = 1.37, and 60°Tw. = 1·3 specific gravity.—GEORGE E. DAVIS.

[10930.]—**Want of Steam Power.**—Many thanks to those who have noticed my query. The exhaust pipe is a two-inch bore. Would "F. T. S. S. D." recommend a smaller one? And could this be done by cutting the pipe and screwing a smaller one in? This would reduce the size to a one and a half inch bore. To me it seems that the steam is thrown off faster than it can be generated while at work. While the steam is at 30lb. or 40lb. pressure it is quite able to do the work, and does it well; but the difficulty is to maintain that pressure with a speed of 180 or 140 revolutions per minute. Would it be any advantage to direct steam-pipe into the chimney and cause more draught? At present the steam is blown off into the open air. The thrashing machine I use is one of Richmond and Chandler's two horse, with 24in. drum; formerly I worked it with a two-horse gear, my two horses working it with comparative ease. Next autumn I shall have a larger machine, a double blast with 42in. drum; but I want to get my engine right before going to that expense. The engine can be worked continually at 50lb., 60lb., or 70lb. pressure, providing it does not exceed sixty or seventy revolutions per minute. I thought a larger fly-wheel would increase the speed of thrashing machine drum, for it is off the fly-wheel I drive, not having a drum for the strap; the fly-wheel weighs upwards of 8cwt.—is this too heavy? I am confident the engine is strong enough to do the work if I can maintain the speed. When I start, say at 40lb. pressure, for the first five minutes it is all that I could wish, but after that time the speed decreases. The boiler has been tested to 120lb.; to what pressure may I work it with safety?—AGRI.

[10941.]—**Spontaneous Combustion.**—Mr. Tonkes will perhaps excuse me for saying that oily waste will take fire from spontaneous combustion. I knew a case at the Poonah Arsenal, when a man, who had been oiling the paint work of a gun carriage, having put the oily waste he had been using on the wheel nave whilst he went to dinner, found it on fire on his return. The waste was fully exposed to the hot sun. Besides this instance, I have known the same action arise from linseed oil being spilled on sawdust; and to further confirm this, I may say that I gave the man £3 for giving the alarm of fire.—MANUS.

[10950.]—**Madeira.**—Does "E. L. G." mean that the Portuguese of Madeira is so hard? Surely Portuguese to a person knowing Latin is as easy as any of the other Romanesque tongues. I have heard that there is no particular dialectic variation.—M. PARIS.

[10954.]—**Circulation of the Blood.**—Mr. Guthrie, in his very excellent reply to this query, states that death "produced through obstruction of the respiratory system is twofold, by excess of carbon in the air, or by oxygen starvation," but I am inclined to imagine that they both result from the same cause—oxygen starvation. Excess of carbon in the air indicates an insufficiency of oxygen, and consequently is identical with oxygen starvation. The food which we take may be divided into two parts. Building material, to repair and build up the system, and fuel to sustain a constant supply of heat through the body; the former consists of that class of food in which the elements are the same as those employed in the constitution of the human body, the latter consists of those articles of diet only which contain the elements which are acknowledged as those of combustion—viz., carbon and hydrogen, the oxygen to effect the combustion being introduced by respiration. Respiration is on the same principle as combustion, and, therefore, the chemical process of respiration is similar to the process of combustion, in exchanging carbonic acid for oxygen. The oxygen inhaled unites with the carbon of the blood, and forms carbonic acid, and with the hydrogen to form vapour of water, both of which are expired. I wish to identify myself with the opinions that others have expressed in objecting to the assertion that "respiration aids circulation."—C. W. H.

[10954.]—**Circulation of the Blood.**—This question has received several answers, but they are all defective, for though it is true that respiration, so far as it means the taking in and expulsion of gaseous matters by or for the lungs, may not actually aid the circulation, yet the act of respiration plays a very important part in it. The forces which circulate the blood are many and various, and we have a *vis a tergo*, or force acting from behind to propel the blood forward, as does the heart, for instance, and a *vis a fronte* or force from before, or in front of the stream, to encourage the flow back into the chest; such is the effect of inspiration. When we draw in our breath, the cavity of the chest is expanded by the ascent of the ribs and the descent of the diaphragm, and consequently a partial vacuum is produced, and this is immediately filled by a rush of air down the windpipe; but any other body which could obtain access to the chest would act in the same manner. If there be an opening between the ribs, the air or any fluid with which the opening is in connection would find its way in to the exclusion of the air by the windpipe. Now, the impetus given by the heart barely extends beyond the smallest vessels, called capillaries, so that other forces have now to come into operation; of these it is only needful here to speak of the last—viz., the expansion of the chest. The blood has arrived in the ascending and descending *venæ cavæ*, which have become united, when the expansion of the chest acts as a suction pump, finally delivering the blood to the right side of the heart. The contrary action of the chest (expiration), causes a slight regurgitation in the veins; but, at the same time, accelerates the current in the *aorta*. There is here no reflux, excepting in the case of disease, the opening being protected by a valve.—FELLOW OF THE ROYAL COLLEGE OF SURGEONS.

[10964.]—**Tests for Metals.**—To "J. B." AND "CHEMICAL STUDENT."—"J. B." has committed a *lapsus calami* in his answer to "Chemical Student." The filtrate from the barium carbonate precipitate should be acidified with HCl, boiled, neutralised with ammonia, and the zinc and manganese precipitated with ammonium sulphide. This is then to be filtered, and the filtrate freed from barium and calcium with sulphate and oxalate of ammonium, filter and test for magnesium in the filtrate with sodium phosphate. The mixed ZnS and MnS is then to be treated with acetic acid, which dissolves out the MnS and leaves the ZnS. If followed out, as "J. B." states, the precipitate will contain $BaSo_4$, CaC_2O_4, ZnO, MnO, and Mn_2O_3, and upon adding acetic acid these three latter would be dissolved, and the zinc would not be left behind as stated; besides, zinc oxide is dissolved by excess of ammonia, so zinc would probably be found in the filtrate, where magnesium is to be looked for.—GEORGE E. DAVIS.

[10974.] — **Polishing Granite.** — "Buz-Fuz" thanks correspondents for their replies, but cannot think that either have practised what they recommend. The recipes given appear to apply to marble and not to granite. "Buz-Fuz" will send a present worth half a guinea to any one who will forward a recipe that will answer effectively.

[10994.]—**Holly Wood.**—I have cut large quantities of it for cog-teeth and other millright work; it is considered far superior to beech or hornbeam for such purposes.—SAWYER.

[10996.]—**How to Use a Book Without Hands.**—I submit the following very simple expedient. Let the armless man get some one to strap a broad leather band, to which is fastened a tin plate, with a socket on to his forehead round his head; into the tin socket, let him fix a piece of stick, say, 8in. long, upright as sketch; at the end that is free let him tie a ball or knob of cotton, wool, or sponge, the whole ball about an inch diameter, covered over with wash leather, and this slightly damped with clean water (not to stain the book), will prove, or I am very much mistaken, the best and handiest substitute for a wet finger, and who ever saw the page that resisted turning by a wet finger.—CIRED.

[10996.] — **How to Use a Book without Hands.**—I think the following will suit the unfortunate engine driver. Let "T. M. W." get a disc of smooth sheet indiarubber about the size of a half-crown. Make a small hole in the centre of the disc, into which insert the end of a bit of glass or gutta-percha tube (about 6in. long), so that it fits tightly, wrapping it, if necessary, with thread. To use this little instrument, let the sufferer put one end of the tube into his mouth and apply the disc of indiarubber at the other end to the leaf of the book, seeing that it fits closely; then, by sucking through the tube, the air is exhausted and the leaf sticks to the disc, and can be turned over with ease.—CAROLUS.

[10996.] — **How to Use a Book without Hands.**—I feel very much for the engine driver, and will endeavour to invent a revolving desk, whereby he could read the ENGLISH MECHANIC every week. I will send him it free of any expense if he will advertise his address.—M. O.

[10999.]—**Gilding Thin Steel.**—Steel may be gilt by using an ethereal solution of gold. The more usual method is to gild by the electrotype, the steel being first covered with a coating of copper; this is done by using the battery, and a neutral solution of cyanide of copper; not an acid solution of sulphate of copper. Copper will precipitate upon steel or iron from the sulphate, but the deposit is worthless on account of the acid attacking the steel, and disintegrating the surface under the copper.—A BARRISTER.

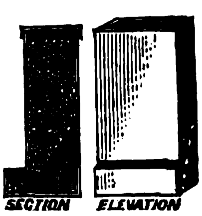
[11023.]—**The Strongest Liquid Explosive.**—Without doubt, the liquid called chloride or quadrochloride of nitrogen is as yet the most powerfully explosive liquid that chemistry can produce. It is prepared by bringing chlorine gas in contact with a tepid solution of hydrochlorate of ammonia, or nitrate of ammonia, but the operation is so fearfully dangerous to life and limb that none but experienced chemists should attempt to make even five grains or drops of it. Its specific gravity is 1·653. The actual cost per gallon is a matter of calculation. Supposing a gallon of this substance to be by any means successfully manufactured without explosion I certainly would not like to be within three miles of it, and I should require a fee of two or three guineas, and pre-payment, to make the smallest sample of it.—EXPLOSIVE.

[11038.]—**Chemical.**—When catechu is boiled with caustic alkali, a deep brown fluid is obtained which contains tannate and japonate of sodium, or potassium, which ever alkali is used. When it is boiled with sodium carbonate, sodium rubiate is formed, together with sodium tannate. The acids are formed by the oxidation of the catechin which is contained in the catechu. The tannic acid may be extracted with cold water—hot water must not be used, as it would extract the catechin. When soda is combined with charcoal (carbon) sodium carbonate is formed, and the inquirer must indeed be a very "Young Chemist" if he is unaware of its properties being in any way affected. In making oxalic acid by Dale's process 80 parts of caustic soda and 56 parts of caustic potash are taken and a solution made which stands 70°Tw. Sawdust is then added to make a thick paste, which is spread in thin layers upon iron plates, and heated to a temperature of 400° Fahr., being kept constantly stirred.—GEORGE E. DAVIS.

[11040.]—**Boiler for Small Engine.**—The small engine referred to has as yet no boiler of its own, but was tried from a large one. The engraver has scarcely done the engine justice (owing to the photograph being rather indistinct), as he has omitted the mouldings that run all round the frame, and has shown one or two details incorrectly. The model is really very handsome—the cylinder covers, steam, and adjusting bosses, and the bearings being all of bright brass, as is also the feed pump.—L. C. E.

[11041.]—**Children's Concert.**—Mozart's melody, "Ah! vous dirai-je, maman." It is the *tema* of one of his airs with variations for piano.—C. J. R.

[11049.] — **Seedbox.** — I once wanted a seedbox which should prevent the waste of seed, and I made one from a cigar box, as per sketch. I think it will sufficiently explain itself. It answers very well.—HARRY WEBB.



SECTION ELEVATION

[11054.] — **Calculating Contents of Cylindrical Vessels.** — Multiply height by half diameter, and this by half circumference; or multiply height by square of diameter and by $\frac{1}{4}\pi$. To multiply any sum by $\frac{1}{4}\pi$ correct to nine figures, you may deduct its quarter and 100th and 100,000th of the same quarter. Then add two-tenths of the second deduction and three-tenths of the third, and to the resulting sum add its twentieth. To take the example mis-wrought by A. J. Shaw (p. 648), 1ft. 8in. is 1·75ft. (not 1·72), and its square is

$1^2 + \cdot7^2 + \cdot05^2$	=	1·4925
2 (1 × ·7)	=	1·4
2 (1·7 × ·05)	=	·17
		3·0625
Multiply by		4·5
		1·53125
		12·25
Contents in cylindrical feet	=	13·78125
Deduct a quarter		3·4453125
And a 100th of it		34453125
And a 100,000th		34453
		10·301449922
Add ·2 of 100th		6890625
And ·3 of 100,000th		10336
		10·308350883
Add 5 per cent.		·515417544
Cubic feet	=	10·823768427

This is exact to the ninth figure. We owe this curiously easy way of bringing round into square units, or cylindric into cubic ones, to Mr. Drach.—E. L. G.

[11054.]—**Calculating Contents of Cylindrical Vessels.**—"Excelsior" has made a terrible blunder in his statement that "the solid contents of a cylinder is equal to the square of the diameter × the height × 3·14159." The solid contents of a cylinder are equal to the square of the diameter × the height × ·7854. Thus his example of a cylinder, 2ft. high and 2ft. in diameter, would come out $2^2 \times 2 \times \cdot7854 =$ 6·2832, and not 25·13272, as given by him.—A BARRISTER.

[11054.]—**Calculating the Contents of Cylindrical Vessels.**—This cannot be done with absolute accuracy, because the proportion of the circumference to the diameter of a circle cannot be expressed precisely; it is very nearly 22 to 7, rather more than 3 to 1, more exactly 3·1416 to 1. As a circle may be conceived to consist of an infinite number of triangles, with the circumference for the bases, with their apices meeting at the centre, and as the area of any triangle is equal to its height, multiplied by half its base, and as the supposed triangles have the circumference for their joint bases, their joint area is equal to half the circumference (*i.e.*, half the diameter multiplied by 3·1416) by half the diameter, or a quarter of the square of the diameter by 3·1416, or the square of the diameter by $\frac{3\cdot1416}{4} = \cdot7854$. It is easier to remember $\frac{22}{7} = 3\cdot14$, which may often be used instead of 3·1416, as near enough. If an approximate estimate be sufficient, it may be convenient to know that the square of the diameter in inches is very little more than the contents of a pipe full of water a yard long in pounds, or with the unit cut off by a decimal point in gallons.—PHILO.

[11060.]—**The Bee Hive.**—F. J. Godden is informed that he will find the way of applying guides to frames described in let. 3269, p. 384, No. 353, and he will only have to vary from the sketch of knife-gauge by making the notch in it so as to come in the centre of his frames. The frames should hang from front to rear of him, and the back should be raised at least an inch, so as to throw both front and back out of perpendicular. "Carr's Hive," described in Neighbour's catalogue, has three thicknesses of glass in rear, and no cover to them, so that the whole of the back is open, and a statement is there made that covering for glass is not necessary, as bees will work as well in daylight as darkness. I have read that daylight acts on honey chemically and induces crystallisation, but have not pursued that branch of the subject. I should recommend Mr. Godden to keep his glass hives under cover, except when under observation, as otherwise they are dangerous things in a house. I know bees will work in daylight, as I have seen combs formed by outlying clusters under the bee stance, but they have always been deserted and emptied in autumn.—C. N. ABBOTT.

[11063.]—**Moth v. Fur.**—In storing woollen goods I use camphor as a preventative against moths. The camphor is laid between the folds of the goods, and some fresh added every two or three weeks.—BUSY BEE.

[11064.]—**Sticking Plaister.**—Ordinary sticking plaister is made by boiling oxide of lead (litharge), olive oil, and water together to a proper consistence, and then spread on calico. Court plaister is made by brushing a solution of isinglass over silk.—J. KING HARRIS.

[11065.]—**Ventilating Rooms.**—"Philo" has described a lucky expedient for inlet that our English windows happen to afford—namely, by either raising the lower sash, or lowering the upper a few inches, and filling up the top or bottom opening thus formed, leaving air to enter only by an upward detour between the two "meeting-bars" (as they are called), which, in short, ought never to meet at all. Every sash ought to be two inches longer (*i. e.*, higher) than they are now made, and they would be all right (only needing, of course, a different fastening). But windows to open are a barbarism that ought nowhere to be required. No dwelling rightly constructed ever did, or ever will, have its ventilation aided by opening windows; but, on the contrary, interrupted and spoilt, if it have any self-ventilative capability at all. Of course, it is "a self-evident truth" that you must have outlet for foul air if any fresh is to take its place; but not a bit more evident or necessary than another that "Philo" utterly ignores—namely, that an outlet is no outlet for foul air if the room contains one cubic barleycorn of space higher than the top of the said "outlet." His Arnott valve "hidden behind a picture," or any of those sold with top borders to come between them and the ceiling, or any that are below a cornice, are "enough to make a cat laugh" at human Victorian-age superstition (see also letter).—E. L. G.

[11086.]—**Georgetown, Demerara.**—I hardly know why my former communication on this subject had "No Name" appended; I suppose, however, I had forgotten to attach my usual signature, and the editor thought that appended the most appropriate. In reply to "Young Man" I beg to say that sailing vessels go from London, Liverpool, Bristol, and Glasgow to Demerara regularly. Inquiry made at the docks of any of these ports will elicit the necessary information, or a letter addressed to Messrs. James Ewing & Co., Glasgow, will do the same thing. The West Indies Packet Companies' steamers leave Southampton on the 2nd and 17th of each month. The passage for sailing vessel averages forty days, and costs about £22, per steamer twenty-one days, and costs £30. There is no season better than another for starting, or at least the difference is so slight that it is not worth thinking about. As to whether a "Young Man" should secure an engagement before going out, or go out on chance, there are certain advantages and disadvantages in both ways. If he can get an engagement made here he would get his passage paid out, and probably an advance for an outfit as well; but then he would not make nearly so good terms as if he went on his own charges and made his bargain on the spot. On the whole I think if a "Young Man" can secure an engagement for three years before starting it would be better. That is, however, a matter of some difficulty, unless he knows, or is known by, some one who is in the habit of sending assistants out, as for obvious reasons we should not think of sending a stranger, or, indeed, any young man that we did not thoroughly know. Demerara is not subject to earthquakes, and is quite out of the hurricane latitude. Trollop's "West Indies," if a superficial knowledge only is required, and may be got at almost any ordinary circulating library; but if more exact and extensive information is desiderated, "Dalton's History of British Guiana" is the best.—AULD REEKIE.

[11091.]—**Turret-shaped Hills.**—There are two ways in which turrets or pillars of that form may have originated. If entirely of hard igneous rock, as "Manus" states the Indian ones to be (p. 674), they are dykes that were thrust up through clay, marl, or soft material, which material the diluvial wash has since carried away, leaving the basaltic turret, like that remarkable square one in St. Helena, called the Chimney, figured in Lyell's "Elements," p. 610 (sixth edition). But "Sansjoy's" drawing (p. 624) seems rather to resemble, in some parts, as the three peaks to the right of Fig. 1, hills of soft material that has been protected by stony caps, like glacier-tables, or the pillars of salt near the Dead Sea. In either case there has been a vast removal of soft material by denudation, and this not gradual, or such as "causes now in action" (as Lyell would say) could effect. The downfall of rain that swept away and moulded in smooth rounded sweeps what it left of the softer strata, everywhere on the present surface, was no downpour of inches per hour, as the greatest tropical monsoon rains, but rather of feet or fathoms per minute, and did all its conspicuous work in a single day. "The day that Noah entered the ark, the flood came and destroyed them all."—E. L. G.

[11092.] — **Champagne Stains.** — Unless the colour of the dress is destroyed, a "Vexed Man" may use the following old-fashioned recipe for cleaning silk. Take of gin, honey, and soft soap equal parts, and twice as much water as any one of the other ingredients. Dissolve thoroughly, and when cold brush the stains thoroughly with a hard, clean nail brush dipped in this mixture; have three large basins or tubs full of cold rain water, and dip the silk three or four times into each (this thoroughly removes all stickiness), pass your hand once or twice lengthwise down the silk in order to remove some of the water, but on no account wring it; then hang it over a clothes' screen near a fire, and when damp—*i.e.*, before the silk begins to wrinkle with heat—iron it quickly with a hot iron. Of course the stained width must be removed from the rest of the dress, and it is best to lay it on a deal table and scrub hard. This recipe has been found efficacious in cleaning the most delicate coloured silks, making them look quite new.—CHAMPAGNE CHARLIE.

[11108.]—**Soda Ash in Boilers.**—I have been using it in a 40 horse-power boiler for ten weeks, and have to-day been in and examined the boiler, and find no injurious result, but the quantity I have used has not been sufficient to entirely remove the scale which had previously been allowed to form.—BUSY BEE.

[11111.]—**Curing Skins.**—"Trapper" will find the following recipe everything that could be desired for large or small skins. I have cured many tiger and leopard skins with it in India. The degree of flexibility attainable depends upon the amount of time bestowed in hand rubbing: with plenty of elbow grease a skin can be made as soft as kid. I regret I can furnish no information as to dyeing skins. To prepare skins for fur: Mix bran and soft water sufficient to cover the skins; let this stand four hours covered before being used; then immerse the skins, keeping them well covered for twenty-four hours (less in India); then take out, wash clean, and carefully scrape off all the flesh. To one gallon of water (hot) add one pound of alum and a quarter pound of salt. When dissolved and cool enough to bear the hand, immerse the skins for twenty-four hours, take out and dry in the shade, and well rub with the hand. Stir the liquor, and again immerse for twenty-four hours, dry, and hand rub as before, and then put the skins for twenty-four hours into warm oatmeal and water, stirring occasionally. Dry in the shade, and when the skin is nearly dry, hand rub till quite dry. Theskin is now white leaher, and fit for use. (Tried with great success.)—ILEX.

[11114.]—**Claret.**—I believe claret to be a very healthy drink, in fact, all the doctors with whom I am acquainted recommend it. It affects particularly the liver and stomach, on which it acts as a tonic. It also renders the blood healthy and pure. It is generally adulterated with logwood.—SCH. Q.C.

[11115]—**Pigs and Pig Feeding.**—If the object be to increase income, I cannot help your correspondent. If he have land, and requires manure for it, fat pigs on barley meal; if with the addition of potatoes, offal, wheat flour, ground peas, or beans—a mixture, but price of article must be his guide as to which. After fifty years' experience, during which I have fattened hundreds of pigs, I find on an average the value of the bacon amounts to the cost of the pig and the food on which it is fattened, sometimes a shilling a score profit is made, sometimes the same amount of loss is incurred. My object in feeding pigs was to dispose of offal food, and to increase my manure heap.—A RETIRED FARMER.

[11115.]—**Pigs and Pig Feeding.**—"Corkeran's" income can be increased by keeping pigs if he has facilities for so doing, but it is a mistaken notion to suppose that any profit can be derived if all the food has to be purchased. From experience, I can say that pigs seldom pay for the expense and trouble in such a case; however, let me strongly advise him to take in as many as he can afford to keep, if he has or can obtain the refuse of a large house, mill, or butcher's stall. They will eat almost anything, roots of all kinds, turnips, carrots, mangold-wurtzel, potatoes, good or bad, and green food, including cabbage, greens, and all kinds of garden produce—the most worthless parts need only be given them—some weeds, such as the sow-thistle, occasionally given for its medicinal property, and which they eat with an extraordinary relish, nettles, docks, rape, and chick-weed. But these must be alternated with more substantial food, as they have very little fattening properties when used unmixed. The same may also be said of roots and vegetables. Coarse meal, such as bran, cracked oats, Indian meal, grains, damaged rice-meal, and mill refuse are the best food for fattening, though seldom given alone, but mixed with boiled roots or vegetables chopped fine, or kitchen refuse. There are many articles of pig feeding omitted here which will occur to "Corkeran" when he begins with his pigs. He need not be afraid of trying them with any kind of eatables. The appetite of large pigs is voracious, and they are by no means epicurean or dainty as to what they eat. Let everything given them as food be cooked; raw food is of little or no use. This does not apply to sow-thistles, chick-weed, and other weeds, which are usually given in their natural state. As to "Corkeran's" second question, as to the time of the year he ought to begin, any time or season will do to take in a stock of pigs. Young pigs are best to buy at this season, if he has a small field or bit of sward over which they can run, as exercise is very beneficial to sucklings or very young pigs. Confinement, however, even in a small space, if proper ventilation is afforded, does not retard the growth of small or large swine. Strict cleanliness must be attended to in all cases, as dirt or moisture is sometimes the cause of disease in the feet and legs, and distemper in other parts of the body, which is their principal malady. Pigs are liable to few disorders, and these are amenable to careful treatment and variation of diet. There is very little experience required in rearing them. Disease seldom appears, and is easily warded off or ultimately cured with little trouble on the part of the owner.—RAT-TAT.

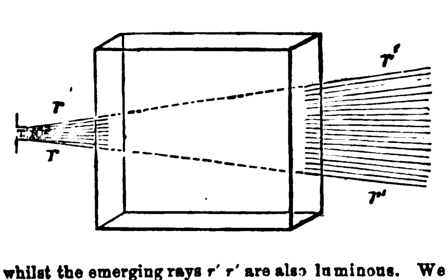
[11116.]—**Spotted Kid Gloves.**—Do not wear the gloves in moist or rainy weather. Keep them under cover as much as possible, and do not allow them to lie for any length of time in damp places. They must also be kept free from greasy or unctuous matter. When touched with oil or grease it shows through them in spots. This also happens if they (the gloves) are a tight fit and the hands perspire. Rub the spots, if white kid gloves, with pipe-clay or powdered French chalk.—RAT-TAT.

[11117.]—**Water-Wheel.**—The form of the buckets, and the angle of the point of the buckets with the ring, will vary with the diameter of the wheel, the depth and number of the buckets, and the velocity of the wheel in feet per second, also with the head of water over the orifice of the fender or sluice which admits the water into the buckets of the wheel. If "Youngster" will furnish sizes I can no doubt give him particulars.—TUBAL-KAIN.

[11120.]—**A Question of Sight.**—I think this is nearly the simplest question we have had, and there have been a few queer ones too. The supposed inhabitants of "Fiddler's" orange would truly see the light of the candle reflected from the walls; he wants to know why we on the dark side of the earth do not see the sun's light in the same way. Well, because the universe happens not to have any walls.—SIGMA.

[11120.]—**A Question of Sight.**—Both "Fiddler" and "A. J. V. G." may be assured "there is more in this," and most other things, than appears to their "first sight." The latter is "agape with speculative wonder" that "a luminous point" produces not exactly the same kind of shadow as the sun. But if his luminous "point" could illuminate "one-half of a globe's surface," he had more reason to be agape. Perhaps he thinks that from a "point"—from one eye—he can see "half of a globe's surface" larger than that eye. Let him note, however, that the sun, even without refraction, illuminates at any moment not merely a half, but about 201 four-hundredths of the earth's surface. He must expose his globe to a luminary that will thus light more than half of it. The sun himself will do exactly the right thing, and cast exactly the kind of shadow from his globe that it does from the globe he dwells on.—E. L. G.

[11120.]—**A Question of Sight.**—May a young student venture to reply to this question, which indeed "has more in it than appears at first sight"? When rays of light proceed from an electric light through the ordinary atmosphere of a room rendered perfectly dark, millions of particles of dust are seen to be floating about in the rays. If, however, these rays of light be directed through a glass case containing ordinary atmosphere, whence all these particles have been absolutely burnt, by passing an electric current through a platinum wire stretched upon points within the case, then luminous rays will be observed on either side of the case, but within it absolute darkness prevails. In diagram let X be the point whence the rays proceed. The rays r r are luminous; the rays within the case indicated by dotted lines are absolutely dark,



whilst the emerging rays r' r' are also luminous. We thus have direct experimental proof that in the absence of the particles of dust, we should perceive no light, unless we look directly towards its source; or in other words light is but reflected by these particles. Therefore, in "Fiddler's" room, strong light from the candle falls upon the day-side of the orange, whilst on the night-side light is not altogether absent, owing to a small amount being diffused by reflection from the small particles of dust existing in the whole room. For like reasons we are not able to see the rays of the sun which are not intercepted by the earth, on account of there being no sufficient amount of matter (if any) in space to render them luminous. On the other hand we can see the stars because we look at them in the direction of their rays of light; and, therefore, even at night time, when, without a moon, we are never absolutely without light, since a small amount is always diffused by our atmosphere, both of rays of the sun and of the stars.—UNDERGRADUATE.

[11120.]—**A Question of Sight.**—"Fiddler" will see that light is conveyed in direct rays and in reflected rays; but some bodies absorb some or all of the rays, and so reflect none, and thus missing direct rays we may miss reflected ones. Tyndall states "the luminiferous ether fills stellar space." So much closer together are the ether atoms than are the atoms of the elements known to chemistry that light travels at the rate of 192,500 miles per second, according to Herschel, while sound travels through air at the rate of but about one-eighteenth of as many feet only—viz., 11,090ft. per second. When "Fiddler" looked at the shadow of his suspended orange, did he cut off from himself all direct or reflected rays from his source of light? No. Now, so excessively minute are the ethereal atoms that (though minuter than the finest needle's point) they have not weight enough in their reflected motion to destroy the eye; and it is only in their reflected motion we receive their impulse in seeing and in observing and looking. If we receive direct rays we destroy the texture of our eyes and lose our sight-power. Evidently the most powerful reflected ray is weak contrasted with a direct ray. Transparency results from the absence of bodies that stop the motion of the light-giving ether: but a transparent atmosphere reflects no portion of the rays of the spectroscope, but the blue ones and the invisible ones—those reflected by clouds are less luminous. Light can hardly be deemed vibration, but force in one direction, light ceasing instantly that combustion stops; so that to a person cut off from direct or reflected rays stellar space is one huge dark expanse lighted only by the distant stars we see of other systems, and not by the sun of our own. As for an earth's shadow, what size is it when cast by the moon on the sun in an eclipse? But its shadow can but be cast on a planet (which reflects Sol's rays) when that planet is not beyond the focus of the shadow. I cannot state just now the limits of the earth's shadow, though it were absurd to suppose it extended to the planet Neptune. Its constant shadow is, nevertheless, easily calculated: it extends an extremely short distance when cast by the sun (so distant is it), than when cast by its own contiguous satellite, the moon.—J. BARWICK.

[11120.]—**A Question of Sight.**—Why should "A. J. V. G." consider the sun as a luminous point? He has only to look at it to see that it is at least more than a point even at our distance of ninety odd millions of miles. The sun being many times larger than the earth, and "A. J. V. G." having reversed this in his experiment, it is not extraordinary that the result of his experiment is the reverse of the known fact. Let him take a moderator lamp for his sun and a marble for his earth, and he will scarcely fail to convince himself of the true nature of the earth's shadow.—V. B.

[11120.]—**A Question of Sight.**—If there is "more in connection with this question than appears at first sight," I should very much like to have it exhibited. To see a shadow of anything anywhere, two things are required—light and a reflecting surface or medium. If "Fiddler" thinks a moment he will see that the only reflectors in the space which Mr. Barwick fills with "attenuated hydrogen" are the stars, the planets, and "our" satellite, the latter of which is obviously the only looking-glass near enough for us to see ourselves in. We don't see those rays of the sun which illuminate the moon until they are reflected from the face of Selene; and I imagine that a man midway between Sirius and the sun would be in darkness, or at least semi-darkness.—SAUL RYMEA.

[11120.]—**A Question of Sight.**—The dark side of the orange in "Fiddler's" supposed case is illuminated by light from the candle after being reflected from the walls of the room. If it were possible to remove the candle and the orange to a place where there is nothing external to the orange from which the light could be reflected to it, a pigmy inhabitant of the dark side would not see the "majority of rays" from the candle any more than we see the "majority of the rays" of the sun at night. Without entering upon the theory of light, I think I am justified in saying that rays of light, in order to be appreciable by the eye, must be directed straight to the eye, whether they come from a self-luminous object or from an object reflecting them. We see the objects of a landscape on account of the rays of the sun being reflected by each object straight to our eyes, the graduated effects between bright sunshine and deep shade being dependent on the number of reflections undergone by the rays between the sun and our eyes. If, therefore, the sun is concealed from us, and is so placed that his rays do not fall on anything in our field of view to reflect or refract them to us, the result is darkness. In looking at a distant star on a clear but dark night we no doubt look athwart the sun's rays streaming in all their glory through space, but as they fall on nothing to reflect them to our eye we see them not. But let the moon or a planet rise across the path of these rays and we immediately become cognisant of light at a spot at which a few moments before we could only discern the vast vault of heaven. The moon is not as described by Demetrius in the "Midsummer Night's Dream," a lantern, with a man, a thornbush, and a dog in it, but a solid body, which in passing through the sun's rays becomes a means of reflecting, and, therefore, revealing to us light which is ever radiating through space, but which without her intervention is often to us as if it were not. Some time ago a slight circumstance showed to me how close the brightest sunshine can be streaming past the eye without producing any impression as such on the retina. I was sitting in an arbour with a narrowish entrance opposite to a bank of laurel bushes. The sunshine was pouring through the boughs of a tree on my right down to the ground on my left, but from where I was sitting the walls of the arbour prevented my seeing either the tree on my right or the illuminated ground on my left. I was accordingly looking at right angles across the rays of sunshine without there being any object in their path to reflect them to the eye. Consequently I perceived no effect of sunshine. All the light apparent to me was what is ordinarily expected from daylight alone. But on blowing a puff of tobacco smoke from my pipe outside the arbour, I became suddenly and unexpectedly alive to the sunshine lying across the line of sight. On perceiving this I increased the volume of smoke, and I saw from where I sat, reflected by the particles of smoke, a sort of map of the rays of sunlight and of the shadows of the boughs through which the sunlight came. On the smoke clearing away the sunlight and the shadows again vanished, and nothing brighter than common daylight was visible between where I sat and the laurel bushes opposite.—V. B.

[11123.]—**Lantern Pinions.**—The pitch or distances of the centres of the pins or trussles should be the same as that of the wheel into which they have to gear.—TUBAL KAIN.

[11125.]—**Silver Bath.**—If the bath has evaporated to about one-third of its former bulk, it must have been very much too weak when last used, or it is much too strong now. Nitrate of silver does not evaporate. Testing the strength is very simple if Charles Lock has the proper instrument for the purpose; if he has not, he had better get one, as it only costs about three shillings, and is always useful. If the bath works well except the clearing of the plate with the cyanide, it must be the cyanide which is at fault; it is either too weak, or perhaps it has been often used and saturated with the iodide of silver, so that it will not dissolve more of it. It is possible, however, that the yellow coating of iodide of silver is readily enough cleared off the plate, but that a dull, white coating remains, which the cyanide will not remove. If this is the case, either the bath is out of order, or light gets at the plate while developing, or going and coming from the camera.—OCCASIONAL PHOTO.

[11125.]—**Silver Bath.**—The silver in Charles Lock's bath all remains behind, but the solution has increased in strength by the evaporation of the water. If he dilutes it down to about the original bulk, neutralises with carbonate of soda, and puts in the sun for a day, then filters and adds a drop or two of dilute nitric acid, it will work well again. (2) Let him try a fresh solution of cyanide, perhaps that he has been using is either very old or has been used until it is saturated with iodide of silver, and has no further solvent action; or it may be that the bath, after standing so long, is very impure and fogs, so that he cannot tell whether it clears or not. (3) There is no simple way of finding the strength.—DÆDALUS.

[11126.]—**Turning Perpendicular Shaft.**—A steam-engine will turn a shaft in any angle of the 360° either approximately horizontal or vertical; proper requirements being attended to.—TUBAL KAIN.

[11128.]—**Making Swimming Bath.**—Build your brickwork in compo, and line the inside with the same (Roman cement), and you will have a waterproof tank. Provide a waste and plug to drain. This is the way I have built the cisterns in malt kilns, and they have always answered well.—M. O.

[11128.]—**Making Swimming Bath.**—If the bath is to be dug out of clay, I would advise "Park Lane" to coat the bottom and sides with a mixture of gas-tar, fine gravel, and sifted ashes, which will render it completely waterproof; or, if the sides are to be of brickwork, he might coat them with Roman cement, and lay the above composition over the bottom.—SCH. Q.C.

[11128.]—**Making Swimming Bath.**—Form the sides and bottom of Portland cement concrete 6in. thick, and afterwards render in Portland cement and sand. This will make a perfectly waterproof bath. Arrangements should be made for supplying and carrying off the water before the concrete is put in.—G. DENOARLGBE.

[11129.]—**Greek Upsilon.**—Seyffarth has investigated the ancient pronunciation of Greek by comparing the proper names in the Septuagint with the same in numerous Oriental versions. He shows most conclusively that the Greek *u* was like the French *u* or German *ü* (something like the Scotch *ui* in guid). The Romans, finding that their *u* was not the equivalent, transferred the Greek letter to their alphabet and called it *y*, which soon lost its true pronunciation, and could not be distinguished from *i*. *Vice versâ*, the Greeks represented the Latin *u* by their diphthong *ou*, which sounded like *oo* in fool.—ARGENT SABLE.

[11129.]—**Greek Upsilon.**—The English *u* gives the only sound of the Greek upsilon. "Pneuma" is not a good example, as in that word there are two letters, *eu*, in Greek, as well as in our manner of spelling it in Roman letters. "Tupto" is a good example; but in English words derived from Greek words beginning with upsilon, the Greek *u* is turned into *y*, as "hydropathy," "hyacinth." There are no such Greek words as "kyklos" and "dryas." If I wanted to write the Greek words in English character that are intended to be represented by the above, it would be thus—"kuklos" and "drus," hence dryads; but a "circle" is more directly from the Latin "circulus."—A HARROW FELLOW.

[11131.]—**Fastening Vulcanite Cells to Glass.**—"Yoiza" must have a bad sample of marine glue; that I am using, which I purchased at a tool-shop in London, adheres to glass most tenaciously.—DÆDALUS.

[11131.]—**Fastening Vulcanite Cells to Glass.**—I have found the cement sold at the Royal Polytechnic Institution, in Regent-street, very effective in fixing vulcanite cells upon glass slides. It is clean to use, dries in twenty-four hours, and holds firmly. Sold as Polytechnic cement.—ILEX.

[11133.]—**Curing Bacon.**—"An Agricultural Labourer" will find the following an excellent method of curing bacon or ham:—To every fourteen pounds of bacon, or ham, use the ordinary quantity of salt, and in addition one ounce and a half each of saltpetre and common soda. The soda prevents that hardness in the lean of the bacon which is so often found, and keeps it mellow all through.—G. DENOARLGBE.

[11133.]—**Curing Bacon.**—The following recipe is copied from the *London Journal* (February 21, 1857):—To 1 gallon of water add 1¼lb. of salt, ¾lb. of sugar, ¼oz. of saltpetre, ¾oz. of potash. Boil the whole together until all the dirt rises to the top, skim off, and when cold pour over your meat. One month is sufficient for it to lay in the pickle. This pickle may be used again several times. It is well to boil and skim when you think it requires it. To smoke bacon, if you have a wide, old-fashioned chimney, and burn wood, you may hang it up in the chimney and dry as I do, or send it to the bakehouse. It will dry if hung up there.—NORTH DEVON.

[11138.]—**Violin.**—I have no doubt that "J. W. L.," being "well acquainted with the Tonic Sol-fa system," will readily acknowledge its superiority over the old notation for singing. Having had some practical experience of its adaptability to stringed instruments, I can confidently recommend "J. W. L." to obtain the "String-Band Book," edited by Rev. Jno. Curwen, and published at the agency, and if he will apply himself assiduously to the instructions and exercises it contains, he will be astonished at the progress he will have made in a short time. For, as he already knows the notation, he can devote all his care and attention to learning the best styles of bowing and fingering; whereas, if he had to learn the clefs, signatures, flats, sharps, and other crotchets of the old notation, the time left to master the bowing and fingering of the instrument would be small indeed. As I am speaking on stringed instruments, I may perhaps be allowed to refer to query 10945, and recommend "R. W. T." to adopt the Tonic Sol-fa system for his violoncello, and he will find the same book replete with excellent advice and exercises for learning that instrument.—J. G.

[11138.]—**Violin.**—It will be necessary for "J. W. L." to learn the old notation, on account of all music for this instrument being written in it. He should buy an instruction book, which would assist him materially, but it would require the aid of a master to give him the "finishing touch."—J. KING HARRIS.

[11139.]—**Geometrical Drawing.**—The best books on descriptive geometry (orthographic and isometric) are E. A. Davidson's "Orthographic and Isometrical Projection" and Bradley's "Elements of Practical Geometry" (Chapman & Hall). For problems and exercises see the "Science and Art Examination Papers" on the above subject.—SCH. Q.C.

[11139.] — **Geometrical Drawing.** — Binns' "Orthographic Projection."—EXCELSIOR.

[11141.]—**Phrenology.**—I should think the best way of studying phrenology would be by observation; at least, I have found it so. For instance, select a certain class of men who have all a certain clearly defined taste for some one subject in particular—as for mathematics, say; observe the way in which their foreheads, &c., are formed, and lay down the rule that all other men who have their heads formed in the same manner have similar tastes. Then set to to find out the exceptions to this rule, and ascertain the reason for those exceptions, and so proceed for every other form of head that may come under your notice. By proceeding thus, you lay down a certain set of rules which you can use when occasion requires.—SCH. Q.C.

[11142.]—**Centre Points.**—Use a wrought-iron crank of 1⅜in. or 1¼in. diameter, with steeled ends hardened, and the radius of the cranks 2½in. to 3in., depending upon the size of the lathe and work to be done.—TUBAL KAIN.

[11143.]—**Height of Swiss Mountains.**—Mont Blanc, 15,732ft.—EXCELSIOR.

[11145.]—**Rose Trees.**—I have found plenty of pure water and a syringe as good for rose-trees as tobacco water. Cabbage, French, and moss roses require all the same treatment; and in order to have fine flowers it is necessary to remove them every three or four years, as they, like potatoes, cast an abundance of slime. Pruning is the most important feature in their cultivation. Until I used my clippers about them most liberally I had poor and degenerated flowers. The shoots must not be uniformly shortened to within a certain distance of the stem; the strong and vigorous shoots should be annually shortened to within six inches of their base, while the weak and slender may be reduced to three or four. Standard roses require still more closely pruning, and all old wood cut from the centre of the head. It is very necessary for standards to be supported firmly to strong stakes.—SARAH.

[11145.]—**Rose Trees.**—"Katrine" will find bitter aloes very good to syringe the trees with. One pennyworth will make three or four gallons. It is very good, also, for any flowers. The trees ought to be cut the beginning of March, and I advise that they be cut at once. Should not pluck any of the buds off unless they seem pretty thick. Water every other day this cool dry weather, and in summer every day, the water being put to the roots and not over the tree.—HARRY W. WEBB.

[11145.]—**Rose Trees.**—"Katrine" need not use either tobacco or lime-water for her roses. If they are well painted with a solution of soft soap before they start, they will not require more than syringing with clear water afterwards. Cut them now: dwarfs as short as you like; standards should have the heads trimmed into shape and weak branches removed; then cut back to the fourth bud, if that is suitable—*i.e.*, if it points downwards or outwards. Roses cannot well have too much manure; watering depends entirely on the season: they did not require much last year. An old gardening friend of mine always digs all round his rose-trees on purpose to cut off the tap-roots, which only assist in forming wood—a method of pruning quite applicable to fruit trees also.—SAUL RYMEA.

[11148.]—**How to Disinfect a House.**—Have all the paper stripped off the walls, and have all the floors, ceilings, and walls washed with lime and water. Any defect in the drainage should be made good, or it may cause a fresh outbreak.—G. DENOARLGBE.

[11148.]—**How to Disinfect a House.**—There are two methods which are believed to be superior to all others. 1. Chlorine gas. 2. Sulphurous acid gas. Both of these plans are noticed in the ENGLISH MECHANIC last week, but hardly in a practical manner "E. L. G." directs the use of a mixture of black oxide of manganese, salt, and sulphuric acid, which will give the chlorine gas, but he directs that one pound of the mixed salts and an equal weight of sulphuric acid be used to each cubic yard of the contents of a house. This is absurd, and shows "E. L. G." has not written from any practical knowledge of the subject. A room 12ft. square and 9ft. high, would require 48lb. salts, and as much acid; a house 24ft. × 15ft. and 30ft. high would take 400lb. of each—a nice joke to capsize 400lb. of sulphuric acid by pulling a string outside the house. The most practical plan I know is that used by the New York officials: it is to place a pan containing one pound of sulphur in each room to be disinfected; this should stand in a larger pan containing sand or earth to avoid risk from fire. Doors and windows are shut, chimneys stopped with a handful of shavings, the sulphur lighted after some strong methylated spirits of wine has been poured over it, and the house abandoned for 24 hours. The sulphur does not light readily without the above preparation.—A BARRISTER.

[11148.]—**How to Disinfect a House.**—Mix well together 1lb. of Calvert's No. 5 carbolic acid with 5 gallons of water, and sprinkle well over the house. Take also the concentrated liquid acid, and vaporise it on hot iron plates in the various rooms, keeping the windows and doors shut to keep in the vapour for two days; then allow a good current of air through the place, and after having whitewashed with ordinary whitewash and carbolic acid, the house may be said to be perfectly safe. Infected clothing should be steeped in carbolic acid solution (1 to 80). Bedding, &c., should be placed in a disinfecting oven and exposed to a temperature of 220° Fahr.,and a large flat jar,of equal parts of carbolic acid and water, should be placed in the oven with the beds. Under the influence of the aqueous vapour and heat, the carbolic acid is volatilised, and the vapour is absorbed by the goods. I have seen zymotic diseases return when a chloride of lime disinfection was relied on, but never with carbolic acid, if enough was used.—GEORGE E. DAVIS.

[11149.]—**Examination Question.**—I agree with the querist that such a question should not have been put, unless opportunity of reference was afforded, or it was put to a very advanced chemical class, and one which had been specially studying subjects of this order. I could not answer it offhand, or without reference to tables and authorities, as it relates to subjects I have never had occasion to deal with, and, therefore, cannot charge my memory with the requisite figures; and being away from home I leave the reply to others.—SIGMA.

[11150.]—**Scaring Foxes.**—I am sorry to inform "A. B. C." that the above subject is not my forte. If it was my difficulty I should try a few shot.—GEORGE E. DAVIS.

[11155.]—**Amalgamated Zinc.**—I always do this in Bunsen's battery by putting some mercury at the bottom of the zinc cell, filling the cell a little fuller than I intend to keep it while working. The mercury then covers the zinc as high as it is wet with the diluted sulphuric acid. After a short time I lower the acid to the proper height. This effectually amalgamates the zinc.—W. BROWNE.

[11155.]—**Amalgamated Zinc.**—I am surprised at "Yakew's" failure, as I have always tried the plan he speaks of and have found it to succeed. Perhaps the dilute acid in which he dipped the plates or cylinders previous to rubbing on the mercury was not strong enough.—SCH. Q. C.

[11162.]—**Aerated Drinks.**—Seltzer water should be a correct imitation of the celebrated German spring. The following is a recipe which I have not tried, but give it as I have it written. Muriate of lime and muriate of magnesia, of each 32grs.; dissolve these in a small quantity of water and add it to a similar solution of 64grs. of bi-carbonate of soda, and 160grs. muriate of soda, and 16grs. phosphate of soda, and add a solution of ½gr. sulphate of iron; put the above together, filter carefully, and add to a gallon of water, then charge with carbonic acid gas to a pressure of 120lb. Potass water:—Dissolve a quantity of bi-carbonate of potass in your water, then charge your water with gas. About 1dr. carbonate of potass to 1 gallon of water. Lithia: Use the carbonate of lithia. Carrara:—Put a quantity of Carrara marble in a crucible, and when calcined add to your water and charge up to 160lb. or 180lb. of pressure—about 10grs. to each bottle. For magnesia use carbonate of magnesia.—SODA-WATER.

[11162.]—**Aerated Drinks.**—"L. W. D." will find the following a good recipe for seltzer water:—Carbonate of soda, 10dr.; carbonate of magnesia, 6dr.; sulphate of potash, ½dr.; common salt, 13dr.; chlorate of potash, ½dr. Of course the gas will have to be forced into it as in soda-water. This quantity is sufficient for two gross of the water.—J. KING HARRIS.

[11163.]—**Currency.**—Here is an account of the new German coinage:—The *Borsen Zeitung* of Berlin gives details of a bill, to be introduced into the German Parliament during the present session, for the regulation of the coinage of the empire, a measure the necessity of which is obvious to any one who has ever been perplexed with the multifarious currencies of the many German States. According to this sketch, the new bill establishes the mark of 100 pennies as the unit of account, and the following will be the small coins:—1. A tenpenny piece, 1,035 of which will contain a pound of fine silver, and 227·7 of which will weigh a pound. 2. A fivepenny piece, with half the value in silver and half in copper. 3. A twopenny piece in copper. 4. A onepenny piece in copper. Higher silver coins: 5. A quarter-mark piece, value twenty-five pennies. 6. A half-mark piece, value fifty pennies. 7. A mark piece. 8. A three-mark piece, corresponding to the present thaler. As the gold money established by the last bill was to consist of twenty and ten mark pieces, the whole new coinage system, if this bill is carried out, will consist of ten coins—the gold pieces corresponding to the English sovereign and half-sovereign, but worth respectively fivepence and twopence halfpenny less; the higher silver coins (quarter-mark, half-mark, mark, and three-mark) corresponding to the threepenny piece, sixpence, shilling, and what would be a three shilling piece, if there were such a coin, but all of fractionally less value, corresponding to the less value of the gold coins; and the smaller silver and copper pieces (ten, five, two, and one pennies) corresponding to the penny and halfpenny, and what would be the fifth and tenth of the English penny, but all of fractionally greater value—the German tenpenny piece being the 200th part of 19s. 7d., whereas the said penny is only the 240th part of 20s. I presume if this is adopted in Germany, Austria will follow suit.—Saul Rymea.

[11164.]—**Making Gunpowder.**—Gunpowder is a compound of saltpetre, sulphur, and charcoal; its quality depends more upon the intimate combination of the ingredients than their absolute purity. The following are the proportions used by the English, French, United States, Russian, and Chinese Governments:—The Royal Mills, Waltham Abbey: Nitre, 75lb.; charcoal, 15lb.; sulphur, 10lb. The French National Establishment: Nitre, 75lb.; charcoal, 12·5lb.; sulphur, 12·5lb. The United States: Nitre, 75lb.; charcoal, 12lb.; sulphur, 13lb. Russian powder: Nitre, 73·78lb.; charcoal, 13·59lb.; sulphur, 12·63lb. Chinese powder: Nitre, 75·0lb.; charcoal, 14·4lb.; sulphur, 9·9lb. The charcoal (which is generally willow, birch, alder, or dogwood) is examined, and all brands and imperfectly burnt coal are removed; it is then sifted and placed in the mill, and reduced to a very fine powder, and passed through a bolting sieve of fine brass wire. It is necessary to reduce the charcoal to as fine a powder as the nitre and sulphur in order to effect an intimate mixture. The sulphur is broken in small pieces, and all extraneous matters picked out, then ground in a mill and passed through a bolting sieve the same as the charcoal. The saltpetre (previously refined) is melted and cast into cakes, which before being broken are carefully brushed, in order to remove any particles of dust or grit which may have got on the surface during the exposure to the air (this precaution is necessary to prevent any accident by explosion during the manufacture of the powder). Having been cleansed, they are broken up with a boxwood mallet, placed in the saltpetre mill, and ground small enough to pass through a fine wire sieve, which is worked in a covered hopper, and received in a tub placed under the hopper, and so connected with it by a cushion that by the weight of the former it presses closely upon the tub and prevents the finer particles of saltpetre flying off. This mode of operating is necessary, because the velocity of the bolting machine would otherwise occasion the saltpetre to form itself into lumps, which would clog the wires of the sieve, and prevent the separation of the powder from that which is imperfectly ground. The saltpetre, sulphur, and charcoal having been prepared as above, are put into separate bins, and when the charges are to be got in readiness for the powder-mill, a quantity of each ingredient for the surface of one bed-stone at a time is to be weighed out according to the proportions required. The three ingredients are put into a charge tub, in the following manner, so as to make the most intimate mixture possible:—(1) A layer of charcoal, then a layer of sulphur; a second layer of charcoal, and a layer of saltpetre. Great care must be taken that these layers bear exactly the same proportion to each other as did the three quantities when weighed off. The charge is then put in the tub and a cover put on; to which is affixed a wooden instrument with eight prongs for stirring the charge, so constructed as to be worked by a handle outside. After the charge is thoroughly incorporated it is taken out and passed through a fine brass wire sieve into another tub placed under the bottom of a covered hopper (similar to the one used for the nitre). The charges having been prepared at the mixing house are deposited in the charge magazines. When wanted the mill-man takes out a charge and places it on the bed stone as equally as possible. The dust which may fly off from the charge in loading the mill is carefully swept down from the stones, wheels, and curb, as soon as possible; for if left till the charge is nearly wrought, and then swept in, it would make the powder foul. After two or three revolutions of the stones to level the charge, it is sprinkled with pure cold water from a copper watering pot, the exact quantity must depend upon the experience of the mill-man and the wet or dry state of the stones. The charge is ground from three to five hours and then taken back to the charge magazine. The next day the charge is carried to the hydraulic press and carefully laid so as to form a mass as equally dense as possible, and it remains under pressure as long as the state of atmosphere requires. The quantity mostly pressed at one time is about 400lb. The mass having stood long enough, it is taken out and broken with a large wooden maul, the pieces being carried to the breaking trough, and further broken by wooden mallets to pieces about the size of peas; 7lb. weight of this is put into the corning sieve; 32 sieves being contained in the corning engine. When the corning man observes that the dust from the pieces of composition has passed through the corning sieve, he puts in a piece of lignum vitæ, called a roller, circular, with ends convex, which granulates the press cake, and makes it pass through the holes of the sieve into another sieve called a hair duster, which allows the dust to separate from the grains by passing into a trough for its reception. The grained powder is now put into a reel lined with canvass, of such a texture as to allow the fine grain and dust to pass through it, while the large and small grains remain in it, and are glazed by friction. The time required for this process is from 30 to 35 minutes. Gunpowder thus glazed is found to keep longer and travel better than when not glazed. The different sorts of powder are then dried in a stove specially constructed. After drying it is removed from the stove and passed through a screen, composed of two inclined planes, covered with fine brass wire sieves. This operation is necessary to cool the powder and remove any dust formed in the drying. From the screens it is removed into wooden barrels which generally contain about 90lb., but which would hold 100lb., room being left for the powder to move about when the barrels are rolled. The barrels are then removed to the magazine—a sample being previously taken from each barrel for proof.—William H. Hey.

[11164.]—**Making Gunpowder.**—In practice the manufacture of 100lb. of gunpowder takes 77½lb. of nitre or saltpetre, 10½lb. of sulphur, and 16lb. charcoal; in all 104lb., the 4lb. being allowed for waste. After the several ingredients have been ground to an impalpable powder, they are well incorporated and worked into a stiff paste. The particles are then separated by mechanical means into small pieces, these again are granulated by being passed through hair sieves. After being pressed and glazed in order to impart to it the property of resisting moisture, the powder is last of all dried thoroughly in what is called a gloom-stove at a temperature of from 140° to 150° Fahrenheit.—Excelsior.

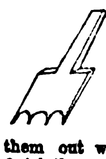
[11165.]—**Radius of Surface of Object-Glass.**—The curves of object-glasses for astro-telescopes require to be calculated very correctly, according to the dispersive and refractive powers which the formula is calculated or based on. The curves given by Mr. W. H. Cash are altogether wrong for a good object-glass. The refractive power of plate, specific gravity 240, is 1·503, and flint, specific gravity 3·230, is 1·652, and the dispersive power of flint is 00·462, and plate 00·290; and if W. H. Cash would make his flint-glass in the proportion of 1 to 2, and crown or plate, specific gravity 24·7, to the proportion of 3 to 5, and calculate the radius of the flints and plate so as their ratios will be as 1·660, he will have an object-glass that will be correct. And when the plates and flints are of the kind stated above, the focus will be to the radius of the flint lens as 1 to 2, or supposing the radius of the flint lens to be, say 24·00, then the focus will come out 48in., with the ratio of radii at 1·660. These proportions I know to be correct, by the formula I have used, and proved over and over again; though I have not used them myself for a long time, I know they are good, and may be useful to many. W. H. Cash might well say he was on the blue rays: with a power of 100 he would have found himself in the midst of it. My advice to him will be to alter the form of his object-glass to these proportions, for his object-glass is now what is called over-corrected, and when he has corrected it for chromatic aberration he will find it is not corrected for spherical aberration.—W. Oldfield.

[11165.]—**Radius of Surface of Object-Glass.**—As Mr. Cash has given me the refractive indices and dispersive ratio of his glass, I can answer his query. Let us take his radii, and let us see what focal length they will produce. Now, we have for the crown glass, $\frac{23{\cdot}422 \times 93{\cdot}786}{46{\cdot}893 + 23{\cdot}422} = 30$in., the geometrical focus of the convex, and $\frac{30}{10{\cdot}58} = 28{\cdot}35$, the refracted focus of the crown. In the same way, $\frac{175{\cdot}91 \times 23{\cdot}422}{87{\cdot}955 - 23{\cdot}422} = 63{\cdot}86$, the geometrical focus of the flint, and $\frac{63{\cdot}86}{12{\cdot}76} = 50$, the refracted focus of concave and $\frac{28{\cdot}35 \times 50}{50 - 28{\cdot}35} = 65$in., the refracted focus of the compound object-glass; and, as Mr. Cash says that his compound focal length is 63·85in., my calculation and his results are very nearly the same, allowing probably for slight errors in workmanship, and I do not think that my severe critic, Mr. Vivian, can work this out more simply than I have done. And now we can see why Mr. Cash's object-glass has a shorter focal length than he intended. The reason is that he has worked his glasses to a higher dispersive power than what he gives me, for $\frac{28{\cdot}35}{50} = 56{\cdot}7$. Consequently, if his dispersive power is correct, his flint lens has too long a focal length, which accounts for his focal length coming out too short. Now let us take the refracted focal length of the convex, 28·35, and we have 28·35 : x : : 636 : 1000, and the refracted focal length of the flint must be 44·57in., and then we have $\frac{44{\cdot}57 \times 28{\cdot}35}{16{\cdot}17} = 70{\cdot}8$in., exactly what his object-glass ought to be, instead of 63·85in., or 65in. Now let us apply the proper correction to the flint lens, and we have—taking 23·422 as the interior curve—44·57 × 12·76 = 56·871, the geometrical focus of the concave lens. Then $\frac{46{\cdot}844\ r}{r - 23{\cdot}422} = 56{\cdot}871$, and consequently the back curve of the flint lens, instead of being 87·955in., ought to be 105in., and then the compound focal length of the object-glass will be 70in. very nearly, exactly as it ought to be, according to Mr. Cash's refractive indices and dispersive ratio, and he will observe that this correction of the flint lens makes the curves far more nearly approaching to Sir J. Herschel's formulæ than his own do. As regards eye-pieces, I strongly advise him to go to the expense of purchasing them, as they are now very reasonable. I have procured mine from Browning of the Minories, and very good they are.—Orion.

[11166.]—**Area of Segment of Circular Ring.**—Observing the discrepancy of "V. B.'s" solution with mine, I searched for the cause, and found, what I had perceived at first, that the given data are incompatible: since, when the centre angle is 60°, 70 is the side of the inscribed hexagon, and 50 must be its apothegm; now, the apothegm side × 0·866, which is not equal to 50, as is given for the side of the inner hexagon or radius of the smaller circle: hence problem not possible with those data.—Bernardin.

[11166.]—**Area of Segment of Circular Ring.**—I see I made an error (p. 675) in saying the segment is one-third of a complete ring—I should have said one-sixth. "E. L. G." has dismissed the question as an incomplete one, and I was very near doing so at first. "Bernardin" has misunderstood it somehow, for the number that he has put down as 85° should be 9,600, which is the square of 97·97. "V. B.'s" solution is correct.—J. K. P.

[11168.]—**Wood Rods.**—"Joiner" will find a bead plane very useful to make wooden rods, the "iron" is somewhat as per sketch, but of course the number and size of the "teeth" must be in accordance with his desire and his strength. His timber should be of the diameter of his rods in thickness, and the plane should have stops screwed on to the sides to prevent it going more than half through it; when, by working on both sides of his stuff, he will be able to turn them out wholesale, and a bit of glass paper will finish them off. I have used this kind of tool to make bird-cage rods for blackbird cages with success, but do not recommend that the plane should be made for more than three rods at once.—C. N. Abbott.



[11168.]—**Wood Rods.**—I should make them with a five-sixteenth bead plane; stick one side; turn the wood and stick the other; the quirk will cut off the bead. When I was in the building line the carpenters made them so.—M. O.

[11168.]—**Wood Rods.**—Plane up a piece of hard wood to the exact thickness, put it in the vice with another piece to back it, and cut a bead on the upper edge with the beading plane held horizontally; then reverse the board and cut a bead on the other side, till the rod comes off. A slight feather is sometimes left which can be planed off, and the rods may be "papered" in the lathe.—Argent Sable.

[11171.]—**Equations for the Formation of Hydric Sulphate.**—"W. N. Oswad" perhaps knows that the heat of the sulphur kilns is employed to heat the pots which contain the nitrate of soda and sulphuric acid, consequently we have varying temperatures, and, I think, varying results. All the text-books are right, and they are all wrong, for they do not mention any variation in the process. If the heat is too low, nitric acid is simply distilled, and is washed down the flues into the acid. If the heat is too high, and in the presence of sulphur dioxide, the nitrogen trioxide and tetroxide are reduced to simple nitrogen. If the happy medium is obtained it is a question whether the trioxide or tetroxide of nitrogen is obtained. I believe the former, for when reducing substances are heated with nitric acid, nitrogen trioxide is the result, and a conclusive proof of this lies in the fact that, when the nitrous fumes are absorbed in the column at the end of the chambers, no other nitrogen compound but the trioxide and a little nitric acid is found in the issuing acid, therefore the reaction would probably be:—$N_2O_3 + SO_2 = SO_3 + N_2O_2$, then $2N_2O_2 + O_2 = 2N_2O_3$, the SO_3 becoming H_2SO_4 by the action of the steam. The chamber crystals, for which so many formulæ have been devised, have been supposed by some to play an important part in the manufacture of sulphuric acid but this is thought by some to be erroneous, and the practical result is thought better if these crystals are never allowed to form.—George E. Davis.

[11172.]—**Punching and Shearing Machine.**—"F. T. S. S. D." will not be able to punch ½in. hole in ⅝in. plate; practically the size of the hole to be punched must not be less than the thickness of the plate. But you can easily punch a ⅝in. hole in ½in. plate, the machine being sufficiently strong for the purpose.—Tubal-Kain.

[11176.]—**White Hard.**—This was an omission of mine or the compositor's: it should have been pasted on and varnished with white hard. The only objection to paste is the swelling the veneer, thin glue is better, if you put a little treacle in it to keep it adhesive

longer. If "R. C. K." is in the country I will send him some veneer if he requires it, and advertises his address.—M. O.

[11179.]—**Covered Wire.** — Copper carefully selected and tested for conductivity should be used; but many makers know nothing or care nothing about such a "theoretical" detail; as "practical" men they want to make money. The number of the wire, of course, varies from 10 to 40, according to the purpose it is required for, and the colour of silk is usually green, but for very delicate instruments white is best, as the dyes often contain iron which produces some very slight disturbance.—SIGMA.

[11181.]—**Centre-Making.**—"Don Pedro" had better square the half width, and the rise or height. Add these squares together, and divide by double the height, thus :—

The height 20in. squared	=	400
The half width 34in. squared	=	1156
Divide by double weight = 40)		1556
		38·9

The radius will be 38in. 9-tenths exactly.—E. L. G.

[11181.]—**Centre-Making.** — First divide the square of half the span by the rise of the arch. Secondly, add the rise of the arch to the first-named quotient, when one-half of the sum so found will give the radius required.—S. J.

[11184.]—**Shortness of Breath.**—John Smith had better be careful how he gets "out of breath." So far from his heart not supplying sufficient blood it supplies him with too much—*i.e.*, sends more to the lungs than they can take, and the best thing he can do is take the advice of a medical man. Dr. Haughton attributes the death of Master M'Grath to the fact that the lungs were diseased and were incapable of preserving that *balance* between the respiration and the circulation which is the true measure of health. It is quite a mistake, he points out, to suppose that an hypertrophied heart is necessarily a sign of disease, for given a corresponding development of lung, a large heart is a positive benefit; the heart of Eclipse is said to have weighed 14lb. But with a large heart and even slight lung disease, congestion of the venous system is apt to occur. Pedestrians and athletes are often afflicted with tubercle. I don't mean that J. Smith is "in a consumption," but he had better take advice if he persists in "getting out of breath."—SAUL RYMEA.

[11186.]—**Length of Sidereal Day.**—I am sorry that by a mistake, either of mine or the printer's, the length of the sidereal day was stated to be 3m. 55·11s. instead of 3m. 55·91s. less than that of the mean solar day, being the difference between 23h. 56m. 4·09s. of mean solar time and 24h. I shall be glad to learn the easiest mode of setting a clock after it is rated, when neither the true time or the meridian is accurately determined without instruments of precision. Is there a better mode than by observing from what point south of the edge of a board fixed vertically the pole star is just visible when on the meridian? As this time may be known very nearly, the meridian may be thus known without sensible error. A point precisely opposite to the north of the vertical board will, of course, be due north, and from that point the exact instant of southing of a star may be observed as it passes the vertical edge.—PHILO.

[11186.]—**Length of Sidereal Day.**—According to the *Nautical Almanac* for 1872 neither "Philo" nor "T. H. M." is right as to the exact length of a sidereal day. Twenty-four hours of mean time are equivalent to 24h. 3m. 56·5554s. of sidereal time, consequently a clock to go correctly should apparently lose 3m. 56·5554s. between each return of a fixed star to the meridian.—T. M.

[11187.]—**Cryolite.**—Can supply cryolite. Is quantity ultimately required? Let "Associate" advertise his address.—R. S. WARLEY.

[11188.] — **Arithmetic.**—£19 19s. 11¾d. × £19 19s. 11¾d. Let "J. Lewis" multiply £20 by £20, and subtract 20 farthings.—J. KING HARRIS.

[11188.]—**Arithmetic.**—I am sorry "E. L. G." can only give a Yankee's answer to my question—namely, another question; but since this is the only reply, I suppose that there is no way to work out the sum in the way I require. As, however, in the second part of "E. L. G.'s" answer he seems to infer that it cannot be worked by any method, I have inclosed for his and the other readers' benefit O'Gorman's method, which, however, is more to show that such a sum can be worked out than for any practical purposes, as the decimal method—viz., reducing the shillings and pence to decimal parts of a pound is by far the simplest and easiest.—Rule: Pounds × pounds, produce pounds; pounds × shillings, produce shillings; pounds × pence, produce pence. Shillings × shillings: every 20 is a shilling, every 5 is threepence, each 1 is 2 farthings and four-tenths. Shillings × pence: every 5 is a farthing, every 1 is two-tenths of a farthing Pence × pence: every 60 is a farthing, every 6 is one-tenth farthing.—J. LEWIS.

[11188.]—**Arithmetic.**—Multiply by £20 and subtract the 19,200th (one farthing the difference between £19 19s. 11¾d. and £20 being the 19,200th part of £20) part of the product; the difference will be the answer required.—G. DENOARLGBE.

[11193.]—**Pumps of Portable Engine.**—The pressure, in the case of the two-valve pump, being alternately above and below the centre of effort of the valve, it will obviously be unable to overcome the barometric resistance to initial suction. When three valves are used one surface is always at a maximum, and the pumps will start, as your correspondent suggests, of their own accord. I had an unpleasant instance of this on one occasion: having left the pump and hose near a pond on my grounds one evening, a mischievous boy inserted it, and in the morning the pond was dry.—MENDEX.

[11194.]—**Restoring Worn Black Cloth.**—I should advise the use of a strongish solution of sesquicarbonate of ammonia to sponge the cloth.—W. F. TRINDER.

[11224.]—**Books on Ceylon.**—The "Catalogue of the Indigenous and Exotic Plants of Ceylon," by Alex. Moon, Colombo, 1824, might, I think, among many others, be useful to the querist; it gives the vulgar names with their scientific translations.—BERNARDIN.

[11235.]—**Eels in Paste.**—"Microscope" must not buy his paste at the shops but make it himself, from flour and water only. It should be made thick, and of course boiled; when cold it should be well stirred with a wooden spoon, this should be done daily to prevent the growth of mould. In warm weather a few days will generally produce a plentiful supply; in cold weather a longer time is necessary. To exhibit the animalcula in the microscope, a little of the paste should be put in some water on a glass slip. They will keep for years if a little fresh paste is occasionally added.—J. KING HARRIS.

[11239.]—**Photography.**—I cannot see the possibility of giving "Caswallon-ap-Davies" sufficient information for him to set up as a photographer (he being ignorant of the art) in the small space which it would be necessary to devote to him in this journal. I am afraid he will find photography not such a simple thing as he, perhaps, imagines. At all events, he had better acquire a knowledge of it before he thinks of setting up in business in that line. He can obtain works on the subject and all information where he purchases his apparatus.—J. KING HARRIS.

[11240.]—**Electromotive Force.**—The force of the Leclanché is so very variable that it is quite possible 100 cells after use may only equal 70 that of a standard cell in good order. But if each cell be tested separately and then in series the result of the last should be the sum of all the cells alone. If not it is most probable that the resistance measures are erroneous. I consider Poggendorf's method a troublesome one, for which reason I did not give it among those I selected as the best. Has "O." got his other resistances, the galvanometer, &c., correct.—SIGMA.

[11243.]—**Deaf and Blind.**—At the Deaf and Dumb Institute of the late Canon Carton, at Bruges, Belgium, a deaf and blind girl has been educated. I think the querist applying there, by letter or otherwise, might receive every information desired.—Y. Y.

[11245.]—**Felspar.**—The analyses differed because the felspar was of different kinds. Felspars are anhydrous double silicates, consisting of a silicate of alumina, combined with a silicate of a protoxide of either potash, soda, lithia, or lime. These oxides being capable of mutually replacing each other, it commonly happens that two or more of them co-exist in the same species. Felspars are generally classified into five groups. Potash felspar, soda felspar, soda-lime felspar, lime felspar, and lithia felspar. Orthoclase or common felspar belongs to the first group, and is the most common. An analysis of one variety is given in Ure's Dictionary as silica, 65·72; alumina, 18·57; potash, 14·02; soda, 1·25; lime, 0·34; magnesia, 0·10—KAPPA.

[11249.]—**Concrete Walls and Buildings.**—Has "W. W." read "Kho Bux's" letters, p. 407, Vol. XIII.? See also pp. 445 and 456, same volume. If in London, "W. W." should inspect a concrete warehouse erected some three or four years since in Great Guildford-street, Southwark, for a Mr. H. Goodwin. See also a capital series of articles describing the different systems of building in concrete on pp. 461, 548, 564, and 579, Vol. XV., of the *Building News*. I visited the building referred to in Great Guildford-street at different stages of its progress, and I think the owner had good reason to be satisfied with it as regards cost of construction and stability. It was built with Tall's apparatus.—KAPPA.

[11251.]—**Iron Stains in Oak.**—A solution of oxalic acid will completely remove the stains, but care should be taken to thoroughly remove all traces of the acid by copious washing with water immediately the stains have disappeared, or it might damage the oak.—KYNCKER.

[11258.]—**Rollers of Wringing Machine.**—I have seen a wringing machine with lignum vitæ rollers that have been in wear for years, and are now equal to new.—WILLIAM H. HEY.

[11262.]—**Electricity from Steam Boiler.**—Vide, in works of Natural Philosophy, the description of Armstrong's hydro-electric machine.—Y. Y.

[11271.]—**Naval Architecture.**—Water-lines or lines of flotation: These are horizontal lines supposed to be described by the surface of the water on the bottom of a ship, and which are exhibited at certain depths upon the sheer draught. Of these, the most particular are the light water-line and the load water-line, the former showing the depression of the ship's body in the water when light or unladen, and the latter the depression when loaded. Water-ways: The edge of the deck next the timbers, which is wrought thicker than the rest of the deck, and so hollowed to the thickness of the deck as to form a gutter or channel for the water to run through the scuppers. Dead water: The eddy which the ship draws after her at her seat or line of flotation in the water, particularly close aft. To this great attention should be paid in the construction of the vessel, especially those with square tucks, for such being carried too low in the water will be attended with great eddies and much dead water. Vessels with a round buttock have but little or no dead water, because by the arching of those vessels the water more easily recovers its state of rest. Bulkheads: The various partitions which seperate one part of a ship from another. Those in the hold are mostly built with rabbeted or ciphered plank. Run: The narrowing of the ship abaft, as for the floor towards the sternpost, where it becomes no broader than the sternpost itself. The term is also used to signify the running or drawing of a line on the ship or mould loft floor, as to run the wale-line, the deck-line, &c.—W. H. HEY.

[11273.]—**Cement for Water.**—Line with (½in. thick) neat Portland cement—that is, without the admixture of sand. Let the cement be exposed to the air in a dry place for a week before used, to avoid shrinkage while setting, and to increase the strength of the cement; use a moderate amount of water with it when mixing, and lay it on quickly, having previously well saturated the stone with water. Do not be sparing of labour in well trowelling the material till it is set moderately hard. The tank can be filled with water in about forty-eight hours after.—T. F.

[11273.]—**Cement for Water.**—Let "Geethe" take his stone cistern to pieces, and use some fresh "Roman cement" (to be obtained at any builder's yard), screwing the cistern together again before it is set.—J. KING HARRIS.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "G. D." has answered 10479; "K. K.," 10501; "Busy Bee," 10510; "Organist," 10512; "E. L. G.," 10565, 10660; "West Cornwall," 10617; "Philo," 10696.

Cleaning Old Engravings.—Instead of carbonate of soda, use the bicarbonate, in slight excess, for decomposing chloride of lime. The reaction is very violent, and Javelle water is easily separated from the precipitate produced. Old engravings, woodcuts, and all kinds of printed matter that have turned yellow, are completely restored by being immersed in it for only one minute, without the least injury to the paper, if the precaution is taken to thoroughly wash the article in water containing a little hyposulphite of soda. Undyed linen and cotton goods of all kinds, however soiled or dirty, are rendered snowy white in a very short time by merely placing them in the liquid mentioned. For the preparation of Javelle water, take four pounds of bicarbonate of soda, one pound of chloride of lime, put the soda into a kettle over the fire, add one gallon of boiling water, let it boil from ten to fifteen minutes, then stir in the chloride of lime, avoiding lumps. When cold, the liquid can be kept in a jug ready for use.

Velocity of Rays of Light.—A prize of 1,000 dollars has been offered by Mr. Uriah A. Boyden, of Boston, Massachussetts, to "any resident of North America who shall determine, by experiment, whether all rays of light, and other physical rays, are or are not transmitted with the same velocity." Any resident of Mexico, the West Indian Islands, or of what is more generally known as North America, may compete. Competitors must forward their memoirs, which must describe every detail and particular of the apparatus employed, and of the method of experimenting, to the Secretary of the Franklin Institute, Philadelphia, before January 1, 1873. Three judges will be appointed, selected from citizens of the United States of known scientific ability, who will examine and report as to which (if any) of the memoirs is of sufficient importance to receive the premium. The memoirs sent in are to become the property of the Franklin Institute, with whom the money is deposited.

QUERIES.

[11274.]—**Cement for Stourbridge Clay Fire Backs.**—I have in my house two of Pierce's patent firegrates with air chambers behind, for warming fresh air and admission into the room (Great Exhibition, 1851). The front of the chamber is the back of the fire-grate, formed in four pieces. Two of these (smaller) pieces describing a curve are at the back of the grate, and the two larger ones rest on the smaller ones. The fire by time has burnt away the smaller pieces at point of junction with each other, and so the smoke gets into the air chamber. Will iron cement or any other prove a good stopping and stand the fire? The Stourbridge clay formed into a cement crumbles away under the action of the fire.—R. J.

[11275.]—**Darkening Walnut.**—Would any subscriber tell me how to darken solid walnut, not veneer? I want to darken it in the raw state from the bench. It must leave the wood clear, but darker than before.—S. Paine.

[11276.]—**Extracting Glass Stopper.**—Can any brother reader inform me if a stopper that has the head broken off can be got out of an empty scent bottle?—A.H.

[11277.]—**Soap Boiling.**—Of what ingredients is soap made? In what proportion are they mixed, and how long are they to boil? Of what are the moulds made for moulding the bars?—Bell.

[11278.]—**Steam.**—Will some of the correspondents of "ours" be good enough to inform me what quantity of steam per minute will pass through straight cast-iron steam pipes, of the following dimensions:—1. 1in. diameter and 10ft. long; 2. 2in. diameter and 20ft. long; 3. 3in. diameter and 60ft. long; the pressure of the steam at the boiler being 30lb., 40lb., 50lb., and 100lb. per square inch?—Vulcan.

[11279.]—**Fire-Damp.**—A friend of mine, whilst searching for dead bodies in the working places of a colliery after an explosion, observed a great many drops of a liquid substance upon the floor of the mine, and along the roof indications similar to those left by the burning of oil on the ground in a zig-zag line. Is it possible that the drops could be the product of an explosion of fire-damp, or of a mixture of fire-damp and sulphuretted hydrogen?—Vulcan.

[11280.]—**Light for the Middle of a Room.**—Will any of your correspondents kindly inform me if there are any means of throwing light into the middle of a room, 20 yards wide and 100 yards long, which is lighted on both sides by windows, so that the middle of the room may have nearly as much light as the sides?—One in the Dark.

[11281.]—**Value of One Second on the Sun's Disc.**—Will one of your readers inform me of the value of one second of arc on the sun's disc? Chambers in his "Astronomy," says: "The lineal value of one second of arc at the mean distance of the sun is 448 miles." Is this a correct estimation? I have seen it questioned in your columns.—A Young Astronomer.

[11282.]—**Preserving Plates.**—Will some of our experienced photo. friends give the formulæ and manipulations necessary for preserving plates wet with golden syrup or honey, and how much longer exposure is required?—Aremac.

[11283.]—**Photo. Lens.**—What is the most generally useful lens for a photo. amateur to get?—Aremac.

[11284.]—**Holtz's Induction Machine.**—Would "Sigma" or any electrical correspondent give me any practical hints about constructing Holtz's induction machine? Would thin window glass do for the discs, or would vulcanite be an improvement? What kind of paper is best for the armatures? and whether, if using glass, would it require to be coated with shellac varnish or otherwise? I have made such a machine from the description in Ganot's "Physics," but have failed. I made my discs of thin window glass with an ebonite spindle running in metallic centres. Perhaps some one would be kind enough to point out my mistake.—New Subscriber.

[11285.]—**Chemist's Certificate.**—Having served part time as a druggist, and having nearly 20 years' practice with drugs prior to the passing of the Act in 1868, and being well acquainted with the nature and properties of drugs commonly used in medicine, and qualified to read Latin prescriptions, and having a knowledge of dispensing, I have lost a great deal of trade in not being a certified chemist, thereby being prohibited from selling medicines containing opium, such as laudanum, syrup of poppies, etc., and I wish to know if any correspondent can inform me how to get a certificate, and what examination is necessary to be passed.—Phœnix.

[11286.]—**Blacking the Barrels of Breech-loading Sporting Fire-arms.**—A recipe for the plan now usually adopted for producing the beautiful black (not brown) on the barrels of breech-loading sporting guns, with particulars how the process is done, would much oblige. Does any book treat on the subject?—B. & J.

[11287.]—**Annuals.**—I should be glad if any gardening correspondent would name a few of the best annuals that remain in bloom at least three or four months in the year.—Aster.

[11288.]—**Hardening Iron Plates.**—Would some kind reader inform me the best and simplest plan to harden and toughen iron plate as much like steel as possible?—John Hogg.

[11289.]—**Flexible Oil Painting.**—I wish to prepare an oil painting on canvas or calico, which will fold up like a map, without cracking at the folds. I shall be obliged, therefore, by some of your scientific and chemical readers informing me how to prepare the calico for this purpose. It should be free as possible from smell, and the colour should not show on the unpainted side.—Verdant.

[11290.]—**Cut-throats or Coral-throats.**—Will some reader of the English Mechanic, learned in birds and their ways, kindly give me some information concerning "cut-throats" or "coral-throats." (1) What is the classical name? (2) What are their food and habits? (3) Where do they come from? and (4) will they breed in confinement? and if so what sort of nest will they build? Any information on the subject will oblige.—Sansjoy.

[11291.]—**Common Sense.**—Can Dr. W. B. Carpenter (p. 632, Vol. XIV.) or any mathematical reader of "ours," kindly give me a key to the discoveries of Professor Sylvester, in relation to "Formula for the Solution of Equations"?—S. J.

[11292.]—**Linseed.**—Would any one inform me what are the medicinal properties and uses to which linseed is applied, and whether its frequent use would prove injurious to the system, especially to infants and young persons?—O. W. Greenhalgh.

[11293.]—**Colour Blindness.**—I wish to know if there is any remedy for the above, also if there is any mode of learning colours. Any information on the above subjects will be thankfully received by—Anxious.

[11294.]—**Dividing Metal Disc.**—A disc of metal 12in. (say) in diameter, of equal density and thickness, and which weighs 12lb., is required to be divided into diameters, so that when cut into three rings and one disc, each should weigh 3lb. A geometrical method for finding the above (as also any other division) with mathematical proofs, will much oblige—Disc.

[11295.]—**Electrical.**—Thanks to Mr. Tonkes for replying to my query. I think, however, he misunderstands the purpose for which I want the machine. I am not just commencing to study electricity as a science, but want it for general experiments, instruction, and amusement. Probably perfect insulation is impossible, but I think it possible to "insulate the prime conductor so as to prevent the spark from flying off;" the lac varnish would prevent the spark passing into the spindle itself, but not the other parts of the machine; supposing a large secondary conductor connected with the prime conductor, capable, if it could be fully charged, of giving a 12in. spark, but this is impossible. A few revolutions of the machine, and before it is half charged, flash goes the spark to the spindle or handle. Stop this by interposing a piece of glass, it actually runs down the disc itself to the rubbers, which are, of course, connected with the earth. How to prevent this is what I want to know? I have heard of a small Winter (I think) machine, giving 12in. to 18in. sparks. If this can be accomplished in a small, why not in a large machine? As I make my own instruments, a description of this machine, with an engraving, if possible, would be more like the thing.—Forked Lightning.

[11296.]—**Chemical.**—Can any one inform me of a cheap substance that will form a powerful fulminate with chlorate of potass? Phosphorus explodes too easily, sulphur not easily enough.—Forked Lightning.

[11297.]—**Spruce Beer.**—Will any one kindly inform me how to make spruce beer?—A Constant Reader.

[11298.]—**Four-inch Centre Lathe.**—I lately purchased a 4in. centre lathe (second-hand). I find that a hole about five-sixteenths of a inch in diameter, is bored up the centre of the mandril some 4in. Can any of your correspondents inform me for what purpose this is intended, as I have never seen it in any new lathes I have inspected with a view to purchase?—G. Thompson.

[11299.]—**Tarpaulings for Railway Carriages in the Tropics.**—Would some of the very obliging correspondents of the English Mechanic kindly afford any information that may be in their power, as to whether these coverings can be made waterproof and fireproof by immersion in any kind of aqueous solution? and whether, if paint, oil, varnish, wax, or similar substances are indispensably requisite, and which are the best methods of preparing and applying them? It is understood that plain tarpaulings, like tent-cloths, are preferable in the topics, on account of not intensifying heat by radiation, and that the lightest fabric is the best. Hence also the question, which is the lightest cloth that can safely be used for all weathers? and can it be made to answer all purposes without composition, or at all events with one of not too compact a nature?—J.G.

[11300.]—**Air Pumps.**—Will H. Turton (letter 3591, p. 560, Vol. XIV.), explain the stuffing boxes, the leather packing, and the piston of his air-pump; and if there is any oil silk valve at either end of the pipe that connects the barrels? A drawing will be of great service.—Last.

[11301.]—**Limits of Resistance in Telegraph Wire.**—How many B. A. units of resistance are there in a mile of ordinary overhead telegraph wire?—W. F. G.

[11302.]—**Circular Brass Box Levels.**—Will some practical reader kindly inform me what liquid is used in circular brass box levels, and what material is employed to fix the flat glass top?—W. F. G.

[11303.]—**Transferring Fluid.**—Can any one inform me of the composition of transferring fluid for taking copies of engravings, and method of use?—J. King Harris.

[11304.]—**Nessler's Ammonia Test.** — In Mr. Tichborne's lecture on "Atmospheric Dust" mention is made of this test. Can a brother reader give me particulars of it?—Kyncker.

[11305.]—**Bakers' Ovens.**—Is there any better way of heating bakers' ovens than the furnace to burn coal placed in the front side of the oven, and can any instrument be got to place in the oven when heated to ascertain the heat?—A Subscriber.

[11306.]—**Glass House.**—I am desirous of having a good glass house for amateur photographic purposes. Will some one of our brotherhood tell me the best and cheapest way to go to work?—W. F. Trinder.

[11307.]—**Design for Garden.**—Will some brother subscriber kindly suggest an artistic design for re-arranging a garden 120ft. long by 11ft. wide (out of which room must be left for a photographic glass house 30ft. long), without having the unsightly straight gravel path and long flower bed all down the side?—W. F. Trinder.

[11308.]—**Geocentric Longitude and Latitude.**—Would any of your correspondents—Mr. Proctor, "F.R.A.S.," or "E. L. G."—explain to me the manner in which I can get the geocentric places of the planets (longitude and latitude) from those of the heliocentric? I am astonished that our "Nautical Almanac" does not furnish us with such information, and that it should be so much behind the "Spanish Almanack" in this respect. I have been told that the geocentric longitude and latitude could be computed from the geocentric right ascension and declination; but why should the savants of the "Nautical Almanac" keep such valuable information from the public?—H. Ellis.

[11309.]—**Breaking Strain of Hollow Iron Columns.**—Will some one give a rule for calculating the breaking strain of long cast-iron hollow columns up to, say, 60ft. in length, when standing plumb, and also when standing at an angle?—A Young Builder.

[11310.]—**Logarithms.**—I would feel exceedingly obliged if Mr. Proctor or any other able correspondent would explain the use of logarithms, and the difference between the common logarithms and hyperbolic logarithms, and the best method of finding their natural numbers. Also, which is considered the best book of logarithms up to, say, 20,000?—A Young Builder.

[11311.]—**Electric Bell.**—Will any kind friend tell me the following? 1. Will one cell of Leclanche's battery, as described on pp. 568 and 596, Vol. XII., be sufficient to work a bell, distance about twelve yards indoors? 2. Would not a cylinder of zinc be as efficient as a wedge? 3. What number cotton-covered wire should I want, or would galvanised iron wire do as well? 4. Shall I want an earth wire? if so, would a piece of galvanised iron wire sunk in the ground, fastened to a piece of iron or lead, answer the purpose, or would a return wire from the bell be best?—An Electrical Beginner.

[11312.]—**Boiler.** — Will "Jack of All Trades," "Liverpool," or any other reader of the Mechanic tell me what kind of steam boiler is now considered the best, the boiler to be stationary, and about 30ft. long × 7ft. diameter? What thickness should the plates be for a boiler of these dimensions, and where steam will be got up to 50lb. per square inch? Would two small boilers be preferable and more economical to a large one as above 30ft. × 7ft.?—One in Trouble.

[11313.]—**Setting Lathe.**—Would "J. K. P." inform me as to the best and sharpest method of setting lathe-head parallel after using for conical turning, as I am given to understand there is a method of obtaining the lathe's dead centre without putting it to the test to see if it is so?—F. Hume.

[11314.]—**Polishing Oak Floors.**—Can any one inform me how oak floors are polished?—H. C.

[11315.]—**Cart Wheel.**—Would some reader kindly inform me how to make a cart wheel, and to put the bush in, with illustrations?—C. Carpenter.

[11316.]—**Oxalate of Chromium, &c.**—Will any chemical correspondent kindly inform me how to make the following salts on a small scale for experimental purposes—viz., oxalate of chromium, oxalate of chromium and potassium, chrome alum, and nitro-prusside of sodium?—Dædalus.

[11317.]—**Sugar Boiling.**—Would "L. W. D." kindly oblige by giving information, through our valuable journal, of the reason why either lump or raw sugar, after being boiled and poured upon the slab, crumbles before there is time to work it? Also, what causes the white stripes in mint lozenges?—X. Y. Z.

[11318.]—**Gravitation.**—If a small thermometer be inverted, the mercury will remain suspended from the glass bulb, not in the least affected by gravity. I have heard, also, that if a sovereign and a feather be simultaneously dropped in an air-pump, they will reach the bottom precisely together, while, according to the attraction of gravitation, bodies should fall with velocities proportioned to their masses, and I cannot understand what contrary effect a vacuum could produce. If any one will kindly explain the cause of this I shall deem it a great favour.—O. W. H.

[11319.]—**Small Copper Coin.**—I have a small copper coin: on one side is an impression of one of the kings of Rome, surrounded with the words "Urbs Romæ;" on the other side is a she-wolf suckling Romulus and Remus. It is in excellent preservation, weighing 37½grs. Will any of your readers be good enough to give me some information respecting the coin, and its probable value?—E. F. M.

[11320.]—**Marking Leather for Ornamental Stitching by Machine.**—Can any of your talented readers help me out of a difficulty? I want to transfer to hogskin various patterns for stitching. I have tried black transferring paper between the pattern and the hogskin, which makes a very black mark; but it comes off too easily, making the leather very dirty. I want some plan to make a clear mark, which will not come off as easily as that mentioned above, and yet come off when the leather is cleaned with indiarubber. Can any one help me?—Seedsman.

[11321.]—**Galvanometer.**—To "Sigma." An answer to the following examination question will oblige:—You are required to describe some system of calibration by which the higher degrees of the galvanometer may be expressed in terms of the lower ones. (Sci. Exam. Honours Paper, 70).—Honours.

[11322.]—**Concrete Building.**—I ask some of your readers to give me a better idea than I possess of concrete building; the moulds I understand and can manage perfectly, but being almost out of the civilised world, I cannot get Portland cement. I have good gravel of different sizes, good sand, good stone lime, white clay, &c. The question is can I build a durable house with the said materials? if so, the quantities, how to mix them, &c.? I have heard that burnt clay and lime makes a kind of hydraulic cement—would they answer the purpose? If any one would make me acquainted with the process, they would greatly oblige—A Man on the Steppes.

[11323.]—**Retardation of Moon.**—Would any of your correspondents inform me the meaning of the term "Retardation of the Moon"? I have looked in several astronomical works, but I cannot get any correct idea of how the moon's motion is retarded when she arrives at the meridian later every day.—John Taylor.

[11324.]—**Salt Damp in Walls.**—Would any one kindly advise the best way of curing dampness of this description. The walls, 14in. thick, are built with 2½in. cavity, and are cemented outside. A breadth of the plaster inside and near the fireplace is covered with a kind of crystalline fur, which is salt to the taste; it rots the wall-paper and throws it off. I have had the wall replastered without any better effect, and therefore suppose that sea sand must have been used in the brickwork.—W. M.

[11825.]—**Moulded Carbon Filter.**—I have one of the above filters, but have rendered it useless through washing the cylinder of carbon in hot water. Will a correspondent kindly inform me how to restore the property of filtration to the carbon, or how to make a new cylinder of carbon?—FILTER.

[11826.]—**Japanning.**—Will the "Welsh Shepherd," "Jack of All Trades," or some other reader kindly tell me how to mix a good japan that will stove well in black, red, green, and yellow?—JAPANNER.

[11827.]—**Monster Magnetic Machine.**—I wish to know Mr. Sprague's opinion about the possibility of constructing a magnetic machine of very large size, with which I could generate 50,000 cubic feet of oxygen from water, within 10 hours. I have seen one of Browning's small magnetic machines, which I think is capable of producing 10 cubic feet of oxygen per minute. Now the principle of doing the same on a small scale being established, I wonder that several instrument makers ridiculed the idea of making such a grand machine, although I told them that the price, if thousands of pounds, would be no objection as long as the above query could satisfactorily be solved, and its result be guaranteed by the maker. I should have even accepted 20 or 30 such machines, if all of them would be required to effect my purpose. But the people I applied to could not say anything positive about it, although such an order with a large sum offered should have induced them to consider my offer.—SIEGM. RAUDNITZ, Asch, Bohemia.

[11328.]—**Organ Stops.**—Can any reader give me a description and scale of Lieblich Gedact and salicional stops, likewise of the Cremona stop.—A SUBSCRIBER WHO APPRECIATES THE MECHANIC.

[11329.]—**Electro Deposition of Iron.**—Can any one give me information on the above? What are the solutions, strength, the best battery and material for moulds, and the best method of making moulds to make solid articles in copper, as I have failed in getting anything but two deposits, one from each face of the mould, and the middle empty?—PUCK IN HOLLOW.

[11330.]—**Vacuum Gauge.**—Will "Jack of All Trades" or some brother reader, be kind enough to favour me with what be thinks is the best vacuum gauge, with a barometer attached to it?—J. W.

[11331.]—**Smallpox.**—Can any of our readers inform me of any way to take away the effects of smallpox? I am slightly marked on my face, but on no other part of body.—INKESFALL.

[11332.]—**Hydraulic Jack.**—Could any reader give a description of an hydraulic jack? I have seen a small one lift enormous weights in a mechanic's shop. They put about a pint of water in at the top, and one man worked a lever.—ZOO ANDRA.

[11333.]—**Motive Power for Amateurs.**—Perhaps some correspondents could publish some of their experiences upon the above subject, as proposed by "W. H. N.," p. 632. Has any correspondent ever tried weights as a motive power? if so, a description would be useful to others besides myself.—ZOO. ANDRA.

[11334.]—**Squinting.**—Can anything be done with a little boy about four years of age to cure him of squinting?—G. W. F.

[11335.]—**Eccentricity of the Earth's Orbit.**—Would some of your correspondents inform me if, with the exception of Grant's "Physical Astronomy," there is any treatise or encyclopædia article on astronomy, published in this country before 1864, when the superior limit of the eccentricity of the earth's orbit, as determined by Lagrange or by Leverrier is given, or even any reference made to the researches of these geometricians on the subject?—JAMES ELLIS.

[11336.]—**To Mr. Tonkes.**—Will Mr. Wm. Tonkes inform me whether, in his answer to query 10758, that it is his real opinion that $\frac{1}{0} = \infty$? If so, will not $\frac{1+1}{0} = \infty + \infty = 2\,\infty$? Again, if $\frac{1}{0} = \infty$, am I justified in writing $\frac{1}{0} = \frac{\infty}{1}$, so $\therefore 1 : 0 :: \infty : 1$, and $1 : \infty :: 0 : 1$? or shall I write $\frac{1}{0} = \frac{\infty}{0}$, so $\therefore 1 : 0 :: \infty : 0$, and $1 : \infty :: 0 : 0$? or otherwise, $\frac{1}{0} = \frac{\infty}{\infty}$, so $\therefore 1 : 0 :: \infty : \infty$, and $1 : \infty :: 0 : \infty$? all of which appear to me most truly absurd.—S. J.

[11337.]—**Equation.**—I should be obliged if any of your correspondents would solve the following equation:—

$$l = a + (n - 1)\,d$$
$$S = \frac{(a + l)\,n}{2}$$

Required to find the value of l and S, a and d and S being known.—SMOOTIUNG PLANE.

[11338.]—**Marseilles Soap.**—In Herschel's "Familiar Lectures," he gives Marseilles soap as one of the ingredients for making the soap bubble fluid. I cannot get hold of any of this soap, however, none of the chemists of a large northern manufacturing town knowing what it is, or where it may be had. Can any of our obliging contributors assist?—TOUCHSTONE.

[11339.]—**Astronomical.**—In a solar year of 365 days, there are 366 sidereal days, and to my reading there is no compensation from the latter as there is of leap year, compensating for fractions of a solar day, in four solar years, the consequence is, that in $\frac{366}{2}$ solar years, Orion, which now souths at midnight of Dec. 21, will south at midnight of June 21. Is this correct, as I can see no notice of it in my authority? Again, why does the polar star always occupy the same place when the earth's axis, by reason of its orbit, changes position?—W. J. PORTER.

[11340.]—**Bread Barrow.**—As I am about having a new bread barrow, I should like to consult my brother subscribers about the best plan to make it, the best wood to make it of, and any other useful hint. I should like to make the body myself. Could not make the wheels, springs, or axle.—BAKER.

[11341.]—**Colouring Photos.**—Will any brother reader inform me how I can colour these? I mean what size is used to take off the greasy nature of them so that they will take the colour well; likewise, whether ordinary water-colours will do. Any practical hints on the above will be much esteemed by—AMATEUR ARTIST.

[11342.]—**Analysing Cast Iron.**—Will some kind reader inform me of a book on analysing cast iron, or kindly help me through the medium of the ENGLISH MECHANIC?—J. W.

[11343.]—**Catechu.**—How can the catechu extracted from Areca catechu be distinguished from the catechu coming from Mimosa catechu? From which tree is obtained the catechu or cutch of commerce?—THANKFUL.

[11344.]—**Australian Trees.**—What Australian trees are called jamwood and manna bark? Scientific names will oblige.—THANKFUL.

[11345.]—**Camping Stoves and Necessaries.**—I should be glad if any of your numerous correspondents would give their experience of the best sort of camping stove and necessaries. Several of us generally take some aquatic excursions, and are generally in a difficulty as to cooking. I saw last year at Henley a capital affair of the sort, in which spirit was used, and when not in use could be packed together in a very compact manner; it comprised gridiron, kettle with spout, and handle to screw on, a frying pan, canisters, &c. I think if any of our friends would furnish a diagram of same it would interest others as well as myself, as the rage seems to be camping now.—W. T. GOULD.

[11346.]—**Induction Coil.**—Will Mr. Wm. Tonkes kindly send details and drawings of the induction coil he mentions in his reply to query 10959, p. 640? I think many correspondents are in the same difficulty as "A. E. T." and myself, and have only a vague idea of the use and position of the ebonite discs of which he speaks.—T. H.

[11347.]—**Velocities of Air and Steam.**—Bourne, in his book on "The Steam-Engine," gives as the rule for the area of steam pipes: "Multiply the square of the diameter of the cylinder in inches by the speed of the piston in feet per minute, and by the decimal ·02, and divide the product by 170." An area thus found gives a velocity to the steam, when it is cut off at two-thirds the stroke, of about 80lb. a second, or 55 miles an hour, or the velocity of the wind in a great storm. Now, in Molesworth's "Pocket-Book of Engineering Formulæ," it is laid down that the velocity of air in the pipes of a blowing engine should not exceed 35lb. a second, or about 25 miles an hour, or the velocity of a brisk gale. Is there any sufficient reason why the velocity of air should be so much less than that of steam? It is true the pressure of the air in a blowing machine rarely exceeds 3lb. on the square inch. But Bourne does not seem to regard the pressure of the steam as a necessary element in the calculation. Can any of your readers refer me to any reliable data as to what the speed of air in pipes may be without extravagant loss from friction, or inform me what was the speed of the air in the pipes which worked the drills in the Mont Cenis tunnel, or any other well-tried cases?—AMATEUR.

[11348.]—**Meteors, Comets, &c.**—M. Paris (3728), in your issue March 8, p. 637, under this heading, states: "The celebrated Whiston was (he believes) the first to start the comet origin of the solar system." Many of your readers would, with myself, no doubt be much obliged if your correspondent would cite his authority for such belief. If I have read your interesting journal correctly, cometic systems is a discovery of a very recent date. Schiaparelli has just had awarded to him the gold medal of the Royal Astronomical Society for verifying the correctness of these theories, which, I learn from the ENGLISH MECHANIC, were propounded in 1854.—JOSEPH A. SONGEST.

[11349.]—**Heating Bar Iron.**—Will some of "our" kind practical readers inform me the best, quickest, and cheapest method of heating bar iron for crank bending purposes, in lengths of 10 to 12 inches heat, and 1¼ inches diameter and upwards?—CRANK ARM.

[11350.]—**Dairy Farming and Pig-keeping.**—Will some one be good enough to inform me what is the smallest scale on which dairy farming, combined with pig-keeping, can be carried on in order to yield a profit of £100 per annum, without allowing for rent and house-keeping expenses—viz., number of acres and cows required, probable yield of milk of each cow per annum, the labour required, cost of food for each cow per annum, number of pigs to begin with, number of pigs to be annually killed, and probable weight of each, and cost of pig-food.—W. M.

[11351.]—**Homœopathic Medicines.**—I have to thank "Jack of All Trades," and Dr. Ussher, for their notices of my last query. Will either of these gentlemen be good enough to state the most economical way to get the mother tinctures, and if they can be got from an ordinary chemist who does not profess to deal in the homœopathic preparations? Also whether these tinctures will keep good for a length of time? How are the sugar pillules treated to give them their homœopathic value? With regard to the tinctures, do I understand aright when I read the answers formerly given as meaning that: 1 drop of mother tincture to 99 of spirit, equal No. 1; 1 drop of No. 1 tincture to 99 of spirit, equal No. 2; 1 drop of No. 2 tincture to 99 of spirit, equal No. 3; and so on. If I am right, then, as one small phial of No. 1 tincture will make thousands of No. 3, would it be worth while to try and get the mother tinctures at all?—A MERE NOVICE.

Holland.—An Old Indian Officer.—Three Years' Subscriber.—B. B.—F. W. Clarke.—Cheeswring.—Would-be M.P.—C. D. Campbell.—John Kitchen.—J. G. Bergman.—A. Oates.—John Wilkes.—W. H. Hollis.—Col. D. G. Anderson.—Horton Corbett.—C. R. T.—A Barrister.—J. F. T.—W. Airey.—Philo.—W. R. Birt.—Housekeeper.—Scotch Tom.—Sigma.—L. S.—Saul Rymea.—Barley Bree.—R. Meekham.—H. G. W.—Tyro.—E. F. Courath.—Busy Bee.—Robert Smith.—Cuprum.—M. O.—John Pescod.—M. B.—An Architect.—A. O. F.—Whitley Partners.—J. Knowles.—E. Barrett.—A Novice in the Art.—Blacking.—E. Nayler.—Labour.—E. Wheldon.—Practical Farrier.

F. I. M. E., E. L. M., see "Hints to Correspondents," No. 4.

H. HENDLEY.—Please ask for the desired information through our columns, as we do not answer by post.

THOS. AMOS, J. J. LEWIS.—Your queries are advertisements.

ELFIN.—Read the last half-score impressions of this publication, and you will find what you are in search of in more than one form. You will also be repaid for your labour in other useful hints you are sure to pick up.

A SUBSCRIBER TO EIGHT VOLS.—Some numbers in each list you mention are out of print. The "Practical Treatise on the Harmonium" ended—or rather was discontinued—on page 198, Vol. XII.

W. P. C. D.—We don't know what queries you refer to.

J. W. LEWIS.—Designs to hand.

MARCH.—Thinks there is room for a practical amateur turner's society in London, and we think so too; and if he or any other person think well to establish such a society, we would encourage it. We never looked approvingly on the suggestion for an English Mechanics' Scientific Society for London, because London abounds in scientific societies of almost every description. We know of no society similar to that indicated by "March," and we therefore say go on and prosper.

J. K. HARRIS.—Thanks for the answers to queries. A discussion on the best form of government would be out of place in our pages.

E. D. J. (Chuckfield.)—These who believe in perpetual motion, are perpetual fools.

E. W. HARRIS.—You deal too much in generalities in your letter on colliery accidents. You write as any educated man might write who may have read a few articles in the newspapers on the subject. What our readers want, and what the scientific world wants, is specific practical information, being the result of your own certain knowledge or experience.

95, VOL. IV.—You can do nothing with such floors but renew them. You can at all times get back numbers by sending stamps.

F. BRIGHTON.—See indices to back vols.

Communications which can only appear as advertisements to hand from Alpha.

A. OAKES.—See recent back numbers, pp. 192, 525, 600, and 343, Vol. XIII., for information on incubators; also previous volumes.

DE T.—Apply to the Secretary of the Manchester School of Art.

AITCH AITCH.—Stained and varnished.

F. PRATT.—We cannot allow the promulgation of such views on smallpox in these pages. You, like all self-commissioned teachers, accuse your fellowmen of "blind fatalism," &c., &c. We think their indisposition to receive your teaching a strong proof of their common sense.

The following correspondents are referred to "Hints to Correspondents," for reasons for the non-appearance of their communications:—G. Ross.—C. H. Gibbins.—Bell.—Amateur Photographer.—W. H. March.—Tyro.—R. E. A.

Frederick Hume.—2s. 1d. post free. See book advertisements.

Griffin.—For recipes for relief of tender feet, &c., see pp. 421, 470, 522, and 546, Vol. XIII.

G. Denoarlgbe.—For directions to remove stains from and whiten ivory, see pp. 167, 241, 95, and 141, Vol. XIII.

R. H. Garth.—If the information cannot be given through our pages it cannot be given at all.

W. J. H.—See back numbers.

Last.—Trübner and Co., Paternoster-row.

J. E. Davis.—We cannot advise in such matters.

E. G.—Yes.

Zoo Andra.—Putty powder is oxide of tin. See p. 509, Vol. XIV., and subsequent numbers.

A Subscriber who Appreciates the English Mechanic.—Unobtainable new in any form.

Thomas W.—Take her to an Ophthalmic Institution—that in Moorfields, if you live in London.

Woodstock.—We are not barbers.

"E.L.G." as a Correspondent.—Besides the communications in answer to "E. L. G." on the metric system, we have received others which we cannot well insert, but from which we may make one or two extracts. "Kappa" says he "looks upon 'E. L. G.' something in the light of a roaring lion, who goes through the columns of the English Mechanic seeking whom he may devour." "1872" in a longer letter, says:—"'E. L. G.' is certainly to be admired and feared. I have often thought who he can be; sometimes I have imagined him Prof. Beesley, at other times Mr. Gladstone, and at other times Felix Pyat; but whoever he may be he is a remarkable man. But, unfortunately, he materially diminishes his influence for good by extravagance in thought and language. Instead of carrying his heart in his head, he carries his head in his heart, and the consequence is he gets in a rage. Take for instance his tempestuous letters on "Co-operative Societies," and the "Glorious Metric System." He vindicates the one with more than Communistic zeal, and attacks the other with more than Lutheran energy. This zeal and this energy may be all very well, but it so happens that the writer expends his power outside the questions respectively in erratic wanderings, and says but little on the questions themselves. It would, in my opinion, be much better if he would moderate his enthusiasm; give us reason instead of passion, which he is well capable of doing, and so turn his great acquirements and abilities to better account."

Ascertaining Apparent Time.—N. S. Heineken says: "Will you be so good as to state that the drawings of my instrument for ascertaining apparent time have been reduced by your engraver to a scale of a little more than one-third. My plate is six inches in diameter."

F. Burling.—Read motto preceding correspondence and write in future about what you understand. No doubt you know many things, but you are at sea on "ship building."

E. J. Thomas.—You are mistaken as to the number of queries inserted. You say yours "is as important as either of the eleven thousand and odd queries which have been privileged with insertion since the English Mechanic commenced its useful career." About thirty thousand queries have been inserted. We commenced to number them for reference purposes about two years and a half since, and began with No. 1. All the queries which appeared in the preceding volumes were unnumbered. We commenced numbering the letters some time after.

Phœbus.—You ride too fast. You have mounted Pegasus with a vengeance. You should at least have a base of operations for your theories to rest on. It may do very well in poetry to separate yourself from everything and everybody; but in science it is essentially different. In art the artist, whoever he may be, is the standard of excellence; but in science, Nature is the groundwork and standard of truth. If you wish to harness electricity to the car of industry, you cannot do it by a flight of imagination, but must enter into the labours of others, and possibly begin where they have left off. By strict observance of the scientific method, you may, by accurate observation, careful experiment, and inexhaustible patience, secure a portion of what you think you are justified in expecting; and even if a very small portion be thus obtained beyond the reach of dispute, a substantial gain will be achieved for man.

Errata.—In letter 8723, "42,000½ metres," and "31,000 metres," should respectively be 42½ thousand metres, and 31¼ thousand.

S. Bottone.—Postscript too late.

THE INVENTOR.

APPLICATIONS FOR LETTERS PATENT DURING THE WEEK ENDING MARCH 12, 1872.

669 T. Broughton, Albert-villas, Dalston, for improvements in the construction of foundations of buildings and in apparatus employed therein.

670 F. G. Underhay, Crawford-passage, Clerkenwell, for improvements in apparatus for controlling the supply of water to dwelling-houses and other buildings.

671 R. Blackburn, Exeter, for improvements in apparatus and in means for treating sewage for agricultural purposes.

672 W. Exall, Reading, for improvements in tube expanders.

673 R. Sutcliffe, Idle, Leeds, for an improvement in steam engine lubricators.

674 J. H. Johnson, Lincoln's Inn-fields, for improvements in apparatus for night signalling. A communication.

675 W. E. Newton, Chancery-lane, for improvements in breech-loading ordnance. A communication.

676 W. E. Newton, Chancery-lane, for improvements in hoisting apparatus, parts of which improvements are also applicable to other purposes. A communication.

677 S. H. Stephens, Breage, Cornwall, for improved machinery for reducing tin stuff and other partially pulverised ores to extract the metal therefrom, and also for grinding paint, cement, and other hard substances, together with feed apparatus therefor, which is also applicable to other pulverisers.

678 C. Bradley, W. Waring, and F. Waring, Bradford, for improvements in apparatus for the combing of wool, silk, and other fibres.

679 W. R. Lake, Southampton-buildings, for improvements in railway rails. A communication.

680 W. R. Lake, Southampton-buildings, for improvements in the manufacture of refined sugar, part of which improvements relate to the production of currents of heated air for the same and for other purposes. A communication.

681 W. E. Carrington, Stockport, for improvements in the construction of felt hats.

682 J. W. Melling, Birkett Bank, Wigan, for improvements in engines actuated by steam or other elastic fluid.

683 W. Lancaster and J. Bullough, Accrington, Lancashire, for improvements in machinery for sizing and dressing yarns.

684 W. Dalgliesh, Kilmarnock, Ayrshire, for improvements in the manufacture of Scotch bonnets, and in the machinery or apparatus employed therefor.

685 C. D. Abel, Southampton-buildings, for improvements in the manufacture of Bessemer steel and iron, and in the production of iron castings, and in apparatus therefore. A communication.

686 J. G. Frei, King-street, City, and G. Kember, Northampton-street, Clerkenwell, for improvements in the construction of pumps for raising and forcing beer and other liquids.

687 T. Taylor, Glasgow, for improvements in turning bowling-green bowls, and in the machinery or apparatus employed therefor.

688 H. Perry, Fetter-lane, City, for improvements in the manufacture of bottles for containing liquids.

689 J. Drevet, Paris, for an improved hydraulic beton.

690 C. Sargent and C. Temple, New Cross, for improvements in steering apparatus.

691 W. O. Palmer, Clapham-road, for improved machinery or apparatus for working the brakes of railway and other carriages.

692 W. H. Cope, Old Gravel-lane, St. George's-in-the-East, for improvements in machinery for boring, cutting, and working rock and other hard substances, chiefly designed for mining, tunnelling, and other like operations.

693 H. J. Griswold, Oxford-street, for improvements in knitting machines.

694 J. C. Lee, Littleborough, Lancashire, for improvements in processes for recovering oil and other useful matters from soap-suds or scourings, and from other waste waters resulting from manufacturing processes.

695 S. Elson, Oldham, for improvements in and relating to fuel economisers and steam generators.

696 J. Roberts, Seaford, Sussex, for improvements in the construction of tramways, and in apparatus to be used in connection therewith.

697 J. W. Carden, Camden-grove North, Peckham, for facilitating linen marking.

698 H. Glover, Brooklyn, U.S., for improvements in local magnetic attraction indicators.

699 J. Arnold, West Smithfield, for a new or improved instrument or appliance for administering balls and other medicines to horses and other animals.

700 B. Smith, J. Stake, R. Tolson, M. Firth, and C. Bradley, Bradford, for improvements in apparatus employed in the combing of wool and other fibres.

701 A. M. Clark, Chancery-lane, for improvements in horse-shoes. A communication.

702 A. M. Clark, Chancery-lane, for improvements in covering top rolls of carding, spinning, and twisting machines. A communication.

703 G. White, Queen-street, Cheapside, for improvements in the manufacture of shuttles for weaving. A communication.

704 E. W. Elmslie, Parliament-street, Westminster, for improvements in the manufacture of hermetically-closed cases and the opening thereof.

705 A. F. Andrews, New Haven, U.S., for improvements in the process of making malleable cast iron, and in apparatus therefor.

706 W. R. Lake, Southampton-buildings, for an improved type-setting machine. A communication.

707 E. Ozanne, Guernsey, for improvements in apparatus for opening and shutting gas valves, and in lighting and extinguishing gas lamps.

708 T. H. Blamires, H. Blamires, and H. Marsden, Huddersfield, for improvements in or applicable to carding engines.

709 M. Brierley and F. L. Stott, Rochdale, for improvements in the manufacture of yarns or threads formed of mixed cotton and animal wool.

710 G. T. Bousfield, Loughborough-park, Brixton, for improvements in sewing machines. A communication.

711 M. A. Wier, Great Winchester-street, City, for improvements in pneumatic apparatus for the transmission and indication of signals.

712 J. Smith, Bishopsgate-street, for improvements in steam boilers and their appendages.

713 S. Littlejohns, North-street, Edgware-road, for improvements in that part of harness called the pad, to effect the instantaneous release of the horse when fallen from accident.

714 C. Avery, Little Cross-street, Islington, for improvements in rotary steam engines and pumps.

715 J. Garneri, Gracechurch-street, City, for a new process for the production and decomposition of anhydrous chlorides and apparatus for those purposes.

716 J. Holden, Hanover Quay, Dublin, for a new or improved compound for use as pavement.

717 W. R. Lake, Southampton-buildings, for improvements in machines for cleaning cotton. A communication.

718 C. W. Lancaster, New Bond-street, for improvements in shot, shell, and other similar missiles.

719 J. G. Harrison, Birmingham, for improvements in the manufacture of gridiron steps for carriages.

720 F. Trotman, Zoological Gardens, W. Turner, Augusta-street, Regent's-park, and W. H. Ryves, Maitland-park-road, St Pancras, for improvements in the closing and opening of necked vessels or bottles.

721 W. Gray, Hendon, for improvements in rotary engines and pumps.

722 W. R. Lake, Southampton-buildings, for improvements in governors for steam engines. A communication.

723 T. D. T. Sparrow and C. G. Spencer, Piccadilly, for a new or improved boomerang and mechanical apparatus for propelling or projecting the same.

724 J. J. Grinlinton, Storey's-gate, Westminster, for further utilising and giving additional value to the products of the coffee bush. A communication.

725 R. Edwards, Deal, for improvements in portable and self-propelling engines, and in adapting them for the purpose of steam ploughing.

726 T. Brearley, Batley, Yorkshire, for an improved finish of woollen textile fabrics and means or apparatus for producing the same.

727 J. F. C. Farquhar, Long-acre, for improvements in light-house and other lamps.

728 T. Perkins, Hitchin, Herts, E. Faux, Yaxley, Huntingdonshire, and S. W. Campain, Deeping Saint Nicholas, Lincolnshire, for improvements in implements for cultivating land, and for actuating the same by steam power.

729 J. A. Anderson, Grosvenor Hotel, Pimlico, for improvements in preserving the cargoes of ships, and in the extinction of fire in ships' holds.

730 R. H. Patterson, Hammersmith, for improvements in the purification of coal gas.

731 S. Corbett, Wellington, Salop, for improvements in ploughs and cultivators.

732 A. Johnson, New York, for improvements in machines for rolling metal.

733 A. H. Hodges, Boston, U.S., for improvements in machinery for trimming or burnishing the soles or both soles and heels of boots or shoes.

734 W. R. Lake, Southampton-buildings, for an improved apparatus for producing and utilising artificial waterfalls for propelling vessels and operating machinery. A communication.

735 C. W. Harrison and A. H. Harrison, Brook-street, Holborn, for improvements in apparatus for heating and cooking by gas.

736 C. de Negri and G. Herrmann, Hornsey-road, and W. Guest, Great Saffron-hill, Middlesex, for improvements in machinery for the manufacture of hat bodies, sacks, bags, hose pipe, and various other articles.

737 F. H. Oclee, New Bailey-street, Salford, for improvements in dentists' busts employed in the display of artificial teeth.

738 G. W. Wigner, Great Tower-street, City, and J. Williamson, Stockport, for improved mechanism applicable to dry closets and commodes.

739 J. Dove, Whitcomb-street, Pall Mall East, for a new or improved metallic heel for boots and shoes.

740 S. Moorhouse, Cheadle Bulkeley, Cheshire, W. J. Kendall, Heaton Norris, Lancashire, for improvements in apparatus for communicating between guard and driver and passengers on railways.

741 F. Cooper, Manchester, for improvements in finishing velvets and velveteens.

742 J. B. Denton, Whitehall-place, and R. Field, Cannon-row, Westminster, for improvements in the method of regulating intermittent filtration of sewage and irrigation, and in apparatus for that purpose.

743 W. H. May, Birmingham, for improvements in stoppers for bottles and jars.

744 W. Gray, Hendon, for improvements in boilers.

745 A. Strauss, Basinghall-street, for improvements in apparatus for indicating the height of bilge water in ships and vessels. A communication.

746 W. J. Curtis, Holloway, for improvements in the construction of the permanent way of railways and tramways, and of the carriages to run thereon.

747 R. F. R. Lucas, Pennfield, Wolverhampton, for improvements in the coking of pitch, and in the manufacture of solid hydrocarbons therefrom.

748 F D. Sargent, Lower Tottenham, for improvements in the construction of cornice poles and roller window blinds to be used either in combination therewith or separately.

749 A. Broune, Gracechurch-street, City, for an improved machine for sewing gloves. A communication.

PATENTS SEALED.

2383 J. Fletcher, for improvements in packing rings for steam engine piston rods, stuffing boxes, pumps, and other similar articles.

2385 J. Livesey, for improvements in asphalte or similar composition, and in the application thereof to various useful purposes.

2394 M. Mirfield and J. Scott, for improvements in extracting or recovering grease and oil from soap-suds and "seak" or saponaceous liquor.

2396 J. Hall, for improvements in breech-loading fire-arms.

2398 R. Long, for improvements in latches or fastenings for gates, doors, and other similar purposes.

2405 R. F. Miller, for improvements in omnibuses and other public vehicles.

2429 J. Gillespie, for improvements in the modes and means or apparatus for preparing fire-clay, and in the moulding and manufacture of articles thereby and therefrom, applicable also to other loams and wares.

2431 J. Gillingham, for improvements in invalid couches.

2434 T. Sampson, for improvements in apparatus for piece-dyeing or dyeing woollen and other fabrics in the piece.

2437 H. D. Furness, for an improved method of lubricating the cylinders and valves of locomotive and other engines.

2443 C. Naylor, for improvements in commodes or closets for sanitary purposes.

2447 W. Brooke, for an improved method of forming or making in the neck of bottles a groove or socket for the reception of washers, and in machinery or apparatus employed therefor.

2452 W. Pawson, for improvements in taps or valves for hot and cold water apparatus.

2556 J. F. Cooke, for an improvement in the manufacture of pocket pencils.

2598 A. V. Newton, for an improved construction of sad iron.

2955 A. E. Samels, for improvements for adjusting and fastening door knobs or handles to lock spindles, and for preventing lateral play or tendency to bind in the woodwork of the door.

3044 R. Douglas and L. Grant, for improvements in utilising the husks or shellings of grain as fuel, and in furnaces employed therefor.

3139 J. Betteley and G. W. Bremner, for improvements in ships or vessels and in the arrangements of apparatus for steering them.

3219 W. Austin and H. D. Ellis, for improved constructions of blocks suitable for paving roads, streets, and other places.

3266 H. Witzenmann, for improvements in the manufacture of linked chains and in means or apparatus employed therein.

3383 G. H. Ellis, for improvements in asphalte roads, ways, and floors.

3419 J. Wood, for improvements in bedsteads, spring mattresses, and other articles for sitting or reclining upon, and in the seats of omnibuses, railway carriages, and other vehicles.

3449 J. E. A. Gwynne and B. Beale, for improvements in the construction of rotary engines, which said improvements are applicable for lifting, forcing, and exhausting.

6 W. S. Fish, for improvements in the construction of packing for piston rods, pipe joints, and other similar purposes.

7 W. S. Fish and J. Wotherspoon, for improvements in yarns, threads, twines, cordage, or ropes, and in the employment or application thereof.

157 W. R. Lake, for improvements in bronzing machines.

181 W. S. Luscom, for improvements in applying power to the wheels of traction engines, portable engines, excavators, and other self-moving machines.

2418 J. L. Clark and J. Muirhead, jun., for improvements in telegraph instruments.

2421 J. E. Wood, for a new paint or varnish for preserving the bottoms of ships and other submerged structures from fouling and decay, also for preserving iron, wood, and other substances (not submerged) requiring protection by paint or varnish.

2425 W. E. Newton, for improvements in furnaces or fireplaces and boilers for the generation of steam.

2441 J. Gowans, for improvements in tramways.

2446 D. B. Peebles, for improvements in gas regulators.

2448 F. A. A. Manier, for improvements in pneumatic telegraphy.

2460 M. Pedley and D. Pedley, for improvements in looms for weaving.

2487 J. W. McCarter, for improvements in sawing machinery.

2605 W. H. Kent, for an improved machine for plaiting textile and other materials.

2671 W. R. Lake, for an improved fastening for boots and shoes.

2759 A. V. Newton, for improvements in electric batteries, and in the means for exciting the same.

2818 L. Perkins, for improvements in locomotive and traction engines.

2819 L. Perkins, for improvements in marine and stationary engines.

2959 J. A. B. Williams, for improvements in machinery for mixing materials for artificial fuel and moulding them into blocks, part of which machinery is applicable for moulding bricks and other analogous articles.

3454 A. Hugentobler, for improvements in the preservation of fresh meat and vegetables, and in the preparation of extract of meat.

91 G. Price, for improvements in muffs or finger protectors.

111 J. Sullivan, for improvements in apparatus for administering pills.

169 W. R. Lake, for improvements in printing presses.

188 J. Booth, for improvements in the manufacture of fabrics in twist lace machines.

264 W. R. Lake, for improvements in machinery for nailing or pegging the soles of boots and shoes to their vamps or uppers.

The English Mechanic

AND

WORLD OF SCIENCE AND ART.

FRIDAY, MARCH 29, 1872.

ARTICLES.

ASTRONOMICAL NOTES FOR APRIL.

BY A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

THE right ascension of the Sun at Greenwich mean noon on April the 1st is 0h. 44m. 23·5s., and his declination 4° 46′ 27·5″ north. He may therefore be said, roughly, to form an isosceles triangle with δ and ε Piscium, ε being at the apex of it. He rises in London on the 1st at 5h. 36m. a.m., and sets at 6h. 31m. p.m.—his rising and setting on the 30th taking place, in the same locality, at 4h. 35m. a.m., and 7h. 19m. p.m., respectively. The equation of time is additive, but diminishing, up to the 14th instant, after which date it becomes subtractive. On the 1st 3m. 47·2s. must be added to the time indicated by a sundial to obtain true clock time, and this quantity decreases to 9·26s. on the 14th. Subsequently, on the 15th, 5·59s. must be subtracted from the time shown by a meridian instrument; and, by the 30th, 2m. 58·49s. must be taken away from apparent time to get mean time. The semi-diameter of the Sun at his Greenwich transit is, on the 1st, 16′ 1·7″, and this occupies 1m. 4·5s. of sidereal time (convertible into mean time by the subtraction of 0·18s.) in its passage over the meridian. The semi-diameter will have diminished to 15′ 54·1″ on the 30th, and this will occupy 1m. 6·01s. of sidereal time (convertible as before) in its transit. The sidereal time at mean noon on April 1st is 0h. 40m. 36·24s., while on the 30th it is 2h. 34m. 56·31s. The mean time at sidereal noon, or mean time of transit of the first point of Aries, is 23h. 15m. 34·5s. on the 1st, and 21h. 21m. 33·16s. on the 30th. Solar activity is now perceptibly diminishing, and spots are becoming both smaller and less frequent than they have been.

The Moon will be New at 31·7m. after midnight on the 7th, will enter her first quarter at 10h. 11·3m. on the night of the 15th, be Full at 1h. 37·2m. in the afternoon of the 23rd, and enter her last quarter at 8h. 20·9m. a.m. on the 30th. She is exactly 23 days old at noon on the 1st, and, of course, 29 days old at the same hour on the 7th. At noon on the 8th her age is 0·5 days, and so on to the 30th, when it is evidently 22·5 days. At 7h. in the evening on April 8th libration will render an additional part of her south-west limb visible, while at 8h. a.m. on the 21st more of her south-east quadrant will come into view from the same cause. The Moon will be in conjunction with Saturn at 4h. 50m. in the afternoon of the 1st, with Venus at 7h. 23m. in the evening of the 5th, with Mars at 4h. 21m. p.m. on the 8th, with Mercury at 8h. 1m. the next morning, with Jupiter 36m. before noon on the 15th, with Uranus at 11 o'clock the same night, and lastly with Saturn again at 11h. 18m. on the night of the 28th.

There will be only three occultations of fixed stars by the Moon, and one close approach to a star by her during this month. First, on April 13, 5 Geminorum will disappear at the Moon's dark limb at 6h. 55m., to reappear at her bright limb at 8h. 6m. Then, at 11h. 48m. on the night of the 14th, she will pass quite close to 48 Geminorum. On the 18th, at 7h. 59m. p.m., B.A.C. 3579 will disappear at the dark limb, reappearing at the bright limb at 9h. 16m.; while, later on the same night, *i* Leonis will be occulted by the dark limb at 10h. 14m., and emerge from behind the bright one at 11h. 10m.

Mercury is now an evening star, and attaining, as he does, his greatest eastern elongation (19° 7′) at 3h. 11m. a.m. on the 5th, and, moreover, having now considerable north declination, is very favourably situated for observation during the early part of April. His apparent diameter increases from some 7″ at the beginning of the month to something like 12″ at the end of it. As he does not set until nearly two hours after the Sun during the first part of April, he may be looked for in the evening sky after sunset, a little to the north of west. He travels from Pisces into Aries, but does not pass near any sufficiently conspicuous star for it to be taken as a mark. His conjunction with the Moon at 8h. 1m. a.m. on the 9th has been noticed above, and he will also be in conjunction with Mars at 1h. 20m. after midnight on the 19th. Our remarks as to his visibility apply only to the earlier part of April, as during the latter half of it he is travelling rapidly towards the west, and is, as a matter of fact, in inferior conjunction with the Sun at 8h. 54m. in the evening of the 24th.

Venus is a morning star, but is indifferently situated for observation, as she only rises between half and three-quarters of an hour before the Sun, in strong twilight; souths between ten and eleven in the morning, and sets, of course, in bright sunshine. Her diameter, too, is now only about 11″, and is diminishing; her disc is approaching a circular form; and she is, altogether, a poor telescopic object. Her conjunction with the Moon at 7h. 23m. on the evening of the 5th has been previously adverted to.

Mars, with his minute disc of only some 5″ in diameter, is too close to the Sun to be visible. His conjunctions with the Moon at 4h. 21m. in the afternoon of the 8th, and with Mercury at 1h. 20m. a.m. on the 20th, have been before referred to.

Jupiter, although rapidly approaching the west, still continues to be the chief and most conspicuous object in the sky, up to, and for a little while after, midnight. He is travelling slowly eastward, through the barren region to the south of Castor and Pollux. He rises on the 1st at 10h. 39m. a.m., souths at 6h. 46·5m. p.m., and sets at 2h. 55m. the next morning—his rising, southing, and setting, on the 30th, taking place at 8h. 58m. a.m., 5h. 3·9m. p.m., and 1h. 10m. a.m. the next day, respectively. 43m. before noon, on the 10th, Jupiter will be in quadrature with the Sun. The effect of this on the interval elapsing between the entry on, or departure from, the disc of Jupiter, of his satellites, and of the shadows which they respectively cast, will be noticed in the list of the phenomena of the Jovian system for this month which we give below. His apparent diameter continues steadily to decrease, from about 40″ at the beginning of April, to 36″ at the end of it. We have previously spoken of his conjunction with the Moon at 11h. 24m. a.m. on the 15th.

Owing to his position with reference to the Earth, the phenomena exhibited by Jupiter's satellites now are decreasing both in number and frequency. During the month of April the following will be exhibited:—Firstly, on the night of the 1st, at 7h. 40m., the transit of satellite 1 will begin. It will be followed by its shadow at 8h. 57m. The egress of the satellite will occur at 10 o'clock, that of the shadow at 11h. 17m. On the 2nd, satellite 1 will reappear from eclipse at 8h. 24m. 6s. A reappearance from eclipse of satellite 3 will also take place at 8h. 3m. 55s. on the evening of the 4th; and it is possible that afterwards, at 1h. 42m. after midnight, the occultation of the 2nd satellite may be perceptible. On the evening of the 6th, satellite 2 will begin its transit at 7h. 59m., its shadow not entering on to the planet's limb until 10h. 32m. At 10h. 54m. the satellite will leave Jupiter's opposite limb, as will the shadow at 1h. 28m. the next morning. 16m. after midnight, on the 7th, satellite 1 will be occulted; while the transit of satellite 3 will commence somewhat later, at 1h. 21m. On the evening of the 8th, at 7h. 43m., satellite 4 will enter on to the face of the planet, satellite 2 will reappear from eclipse at 8h. 25m. 49s., the transit of satellite 1 begin at 9h. 35m., that of its shadow at 10h. 52m., the egress of the satellite at 11h. 54m., that of satellite 4 two minutes later, while the shadow of satellite 1 will not quit Jupiter's limb until 1h. 12m. the next morning. On the night of the 9th, satellite 1 will reappear from eclipse at 10h. 19m. 35s. The egress of the shadow of this same satellite will take place at 7h. 41m. the next evening, the 10th. Perhaps satellite 3 may be perceived to reappear from occultation at 6h. 52m. p.m. on the 11th. It will afterwards disappear in eclipse at 8h. 38m. 19s., reappearing from it at 4m. 54s. after midnight. The transit of satellite 2 will begin at 10h. 37m. on the night of the 13th. Perhaps, under very favourable circumstances, the ingress of its shadow at 1h. 10m., and the egress of the satellite itself at 1h. 32m. the next morning, may be discerned. On the night of the 15th, satellite 2 will reappear from eclipse at 11h. 1m. 6s.; the transit of satellite 1 will commence at 11h. 30m., its shadow come on 47m. after midnight, while it is conceivable that the egress of the satellite may be caught at 1h. 49m. At 8h. 40m. on the night of the 16th satellite 1 will be occulted, to reappear from eclipse at 12h. 15m. 5s. The shadow of this same satellite may perchance be detected in its entry on to the planet, at 7h. 16m. in the evening of the 17th; the egress of the satellite casting it occurring at 8h. 18m.; and the shadow itself passing off at 9h. 35m. Later, satellite 4 will reappear from eclipse at 10h. 22m. 33s. On the 18th it may happen that the occultation of satellite 3, at 7h. 25m., may be discernible. It will reappear from occultation at 10h. 55m., only, however, to suffer eclipse at 12h. 38m. 11s. It may happen that the ingress of satellite 2 may be detected at 1h. 16m. a.m. on the 21st. Satellite 2 will be occulted at 8h. 13m. on the 22nd. The transit of satellite 1 will begin at 1h. 26m., and satellite 2 reappear from eclipse at 1h. 36m. 16s. the next morning, but the observation of these phenomena is problematical. On the night of the 23rd, satellite 1 will be occulted at 10h. 37m. The beginning of the transit of satellite 1, at 7h. 55m., and the egress of the shadow of satellite 2, at 8h. 2m., on the evening of the 24th, may possibly be caught. Afterwards, the ingress of the shadow of satellite 1 will commence at 9h. 10m., the satellite leave the planet's face at 10h. 14m., and the shadow at 11h. 30m. Satellite 1 will reappear from eclipse at 8h. 39m. 31s. on the night of the 25th, and satellite 3 be afterwards occulted at 11h. 30m. The egress of the shadow of satellite 3 will happen at 10h. 7m. on the night of the 29th; satellite 2 will subsequently be occulted at 10h. 52m. Lastly, it is just possible that the occultation of satellite 1 may be perceptible 34m. after midnight on the 30th.

Saturn, in his old quarters in Sagittarius, continues in a deplorable position for the telescopic observer. He rises on the 1st at about a quarter to 3 a.m., souths at 6h. 49·1m. a.m., and sets at 10h. 53m. a.m. On the 30th his rising, southing, and setting take place at 54m. after midnight, at 4h. 58m. a.m., and at 9h. 2m. a.m., respectively. He will be in quadrature with the Sun 35m. after noon on the 10th. Reference has previously been made to his conjunctions with the Moon, at 4h. 50m. p.m., and 11h. 18m. p.m., on the 1st and 28th, respectively.

Uranus, like Jupiter, is travelling towards the west, but is still observable during a good deal of the working part of the night. The directions given for finding him last month (Vol. XIV., p. 576) are equally available for the present one, as his movement is so extremely slow. His diameter remains stationary at 4″. He is in quadrature with the Sun at 10h. 41m. on the night of the 16th. We have spoken, under the proper heading, of his conjunction with the Moon at 11h. p.m. on the 15th.

When we have said that Neptune is in conjunction with the Sun at 9h. 5m. a.m. on the 13th, it will scarcely be necessary to add that he is wholly invisible during April.

Shooting stars would appear to be tolerably common in the month of April. Suspicion exists of a periodical shower at some period between the 4th and the 11th, while a pretty well ascertained one is referred to in the B.A. report for 1870 as occurring between the 19th and 21st of the month.

WEATHER CHARTS.

THE first four weather charts of the Meteorological Office, March 16 to 19, 1872, at 8 a.m., are now before us. The arrangement is good, the land being shaded and the water white. On the left hand we have the weather reports, and on the right the chart for the day, which consists of four maps; one for depicting the isobars, one the isotherms, a third for the general direction of the wind and state of the sea, and a fourth for giving a statement of cloud, rain, &c.

So far the general description. A word on the utility of the charts may not be out of place. Confining our attention to the barometer and temperature, a glance at the four charts will convince us that the area embraced by the maps is but small, the *isobars* and *isotherms* being mere fragments. The directions and values of these lines are the only elements of pressure and temperature attainable from the charts. The relation of the meteorology of the British Islands and France to the Continental area on the east and the oceanic area on the west is unattainable, and these relations are of the first importance in judging of the *progression* of weather. On the 16th we had the barometer ranging from 30· to 29·57, being a gradient N.N.W. of about ·

On the 17th the directions of the lines were altered, running S.W.—N.E. instead of W.S.W.—E.N.E. We are, however, entirely ignorant of the barometric state of the countries in advance of these lines, and quite as ignorant of the nature of the isobars likely to succeed them. This is particularly illustrated in the isobaric chart of March 18, a new system being manifested over the whole of the area. This great and decided alteration in the direction and value of the isobars shows that a single telegram daily is insufficient, according to our views, for the requirements of meteorology.

The most valuable feature of the charts is the connection between barometric pressure and wind. In this notice we cannot enter into a description of the relation existing between the two, further than saying that the wind maps show unmistakably that the general course of the wind is parallel to the direction of the isobars.

COMPRESSED AIR AS A MOTIVE POWER.

WE have had occasion within the last twelve months or so to call the attention of our readers to the progress which is being made in the application of compressed air as a means of obtaining motive power. In this country machines have been constructed, and we believe with satisfactory results, which are put into motion by the expansive force of air compressed by means of water or suitable steam-engines, the power being conveyed to the scene of its operations in pipes, the length of which is practically unlimited. So far as we know, however, compressed air has not been employed in this country for obtaining motion, except in those cases where it is almost impossible to use steam—for instance, in coal-mines; and an account of its successful application to colliery working will be found at p. 2, Vol. XIII. In the United States, on the contrary, compressed air as a motive power has received more than usual attention, especially since its value was proved beyond doubt by the operations at the Mont Cenis tunnel, and American engineers and inventors have been both experimenting and theorising on its capabilities and the best methods for its utilisation—its application to locomotion being the principal object sought by our cousins.

It is actually more than 60 years ago since Medhurst proposed to drive carriages through a brick tunnel by means of an air-blast, and various projects for accomplishing a similar object have been introduced, but have invariably failed, either from mechanical difficulties or from the absence of any economy—perhaps we should say from the great expense incurred in keeping the apparatus in working order. Probably the most notable of all these attempts was the Atmospheric System tried on the South Devon Railway, in 1847, by Brunel, which although successful as far as the mere propulsion of the trains was concerned, was yet so hampered by constantly recurring difficulties that it was finally abandoned by the directors, for "prudential" reasons. The principle of this atmospheric system, which was patented by Clegg and Samuda, consisted in a tube containing a close-fitting piston, which was driven along by the pressure of the air behind it, a vaccuum being created in front of it by means of powerful steam-engines. The tube had a slit in its upper surface which was covered by a valve of leather, and through this slit the bar connecting the piston with the carriages passed. It is obvious that the construction of a valve which should fit with the requisite closeness, and yet open readily, to allow the passage of the connecting bar, must necessarily be a work of great difficulty, requiring much ingenuity and skill for its accomplishment; and it is no wonder, therefore, that in the early life of the system, before experience had been gained by extended trials, many failures should have occurred, and that even Brunel should have recommended no further persistence in the attempt. It was, however, the opinion of many persons at the time that, given the requisite funds, the atmospheric system might eventually have triumphed, and the defects in the original apparatus have been successfully remedied.

A resuscitation of the old system has been frequently proposed of late in the United States for the motive-power of trains in tunnels to be constructed underneath the crowded and busy streets of the principal cities; for although ...ys are there as common as lampposts, ...nd incapable of accommodating the ...onsequence chiefly of the slowness with which the cars are drawn by horse-power. It is in the direction of applying compressed air as a motive-power for tramway cars, however, that experiments have been carried out which bid fair to lead ultimately to success. In several instances cars have been propelled by compressed air, but as the apparatus employed is only regarded as tentative, the details of the mechanism and the characteristic action of the air have not been published with sufficient minuteness to enable an accurate estimate to be made of the power obtained and of its cost. The necessity of some improved means of transit in cities is acknowledged on all hands, and as we know that "Necessity is the mother of Invention," it will probably not be long before some economical, easily-controlled force is applied to the propulsion of street cars, at all events in America. We have already illustrated the American ammonia engine, and we recently described a steam car in course of construction in this country; but we think that compressed air will ultimately be the chosen means of propulsion. Mr. J. A. Whitney, in a paper read before the New York Society of Practical Engineering, after alluding to the objections against the employment of steam in carriages traversing public thoroughfares, and protesting against its use for underground railways in tunnels without openings, declared that horse power is acknowledged to be inadequate to the wants of New York street railways; the transmission of power by ropes, as illustrated in the elevated railway on Greenwich-street, has proved a "mediocre and insufficient method of propulsion," and it is only in pneumatic power that he considers sufficient promise of success appears to justify the outlay required to thoroughly test the principle. The plan, which has hitherto given the best results, consists in compressing the air to a very high degree, and storing it in tanks or cylindrical chambers arranged about the body of the car in the most convenient manner; from these the air is led to a receiver supplying the cylinders, which are constructed in much the same manner as those of steam-engines. In all this there is, of course, but little difficulty; if air is compressed to, say, 200lb. on the square inch, and is then allowed to exercise its elastic force on a piston fitting closely in a cylinder, we can calculate approximately the amount of power the piston should exert, but if we omit to take into consideration the surrounding conditions and the peculiar characteristics of expanding air we shall, without doubt, make a grievous mistake in our calculation. Most of our readers are aware that when compressed air is allowed to expand it robs the surrounding matter of all the heat it can, and, indeed, by virtue of that property has been used for refrigerating purposes. It will be evident, therefore, that unless the air is considerably raised in temperature, or the cylinder heated by means of water or hot air circulating in a jacket, that whatever moisture may be contained in the compressed air will be converted into ice, which will speedily block up the exhaust port and the pipes connected with it, as well as lower the temperature of the air in the reservoir. To obviate this difficulty one inventor proposes to construct the main reservoir of a material which will prevent the loss of heat, and consequently of power, by radiation—the air in the process of compression becoming, of course, considerably raised in temperature—heat which it is desirable to retain; another proposes to pass the pipe conveying the air to the cylinders through the warming apparatus of the car; while a third suggests an arrangement whereby the air from the stove used for warming the car should be made to circulate in annular jackets round the cylinders. Independently of the fact that the stove is not always in requisition to "warm the car," *e.q.*, in the summer, these plans are open to objection on several grounds; and it appears to us that the proposal to heat the cylinders by means of jackets containing hot water is to be preferred, as the water could be changed at the end of each journey, and facilities would be also afforded for warming the air of the main reservoir, in which the refrigerating effect would be experienced during the early part of the piston stroke. Another proposal has for its principal feature the heating of the air by burning hydrogen or carburetted hydrogen in a vessel near the cylinders. The hydrogen is compressed to the same degree as the air, and burns in jets in the air which passes through the above-mentioned vessel on its way to the cylinders. The gas is to be set alight by means of electricity: so that the apparatus for working the car would become a trifle too complicated and expensive, we think.

It will be apparent, then, to our readers that there is nothing impossible in the proposal to run street cars by means of compressed air—in fact, it has been done, and an account of a trial of one at Chicago will be found on p. 345, Vol. XII., in which it is stated that the only fault was the noise made by the exhaust of the engines. This latter can be easily remedied, and the escaping air used to cool the atmosphere of the car in summer and urge the fire in winter. The next question, then, is in reality the main point. What is the cost? There is, first of all, the construction of the reservoirs, which for the sake of lightness must be of steel or copper; and then there is the requisite apparatus for compressing the air, which must be supplied in duplicate, one for each end of the road, for the weight of the car would scarcely be increased for the sake of storing sufficient air for a double journey. The other expenses would be much the same as now, so that it is a matter of comparatively easy calculation to approximately ascertain the first outlay, and whether the increased comfort and speed of travelling could not be obtained for the same amount as is now paid for horseflesh. The system would doubtless be more expensive than steam; but there are "obstructions" to the introduction of the latter which could not well be thrown in the way of compressed air. Mr. Whitney, who is perhaps rather enthusiastic in the matter, believes that passengers may be cheaply carried at a speed of from 20 to 40 miles an hour "with all the comfort of ordinary railways, and none of the dangers or inconveniences incident to the employment of locomotives." His proposal for a pneumatic railway will show how far in this direction the ideas of the Americans are advanced. "An elevated pneumatic tube is to be carried over the buildings and cross-streets, sustained on iron supports constructed on the principle of a suspension bridge over each block; this tube is to be of wrought iron for strength and lightness; lined with wood for moderate warmth and for reduction of friction to the air blast; glazed throughout its length with panes sufficient in size and number to light it well; furnished with switches, to enable a car to be stopped at a station without interference with the others; furnished with electric signals automatically actuated by the cars themselves, to indicate their approach to the stations; the working of the line to be placed, from the lowest duty to the highest, in the hands of educated, careful and properly remunerated engineers, and the question of quick transit, in one of its phases at least, will be solved with greater satisfaction to the public and credit to the engineering profession than the most ardent advocates of speedy passenger travel now dare hope for."

Whether the system will be adopted in this country for propelling street-cars will probably depend in a great measure on the success of the attempt in America; but as a means of obtaining coal that is otherwise out of reach there can be no doubt of the great utility of the compressed-air apparatus. Machines for getting coal are capable of working in a temperature where muscular exertion is almost impossible; and the air having done its work in actuating the apparatus will cool the underground passages, and enable human beings to penetrate much deeper into the crust of the earth than they have hitherto succeeded in doing.

THE METALLURGY OF IRON AND STEEL.

THE following is an abstract report of a course of lectures on the above subject delivered by Dr. Percy, F.R.S., in the lecture theatre of the Geological Museum:—

We have heard of precious metals, noble metals, and base metals: but if a metal is to be judged noble in respect of its utility to mankind, iron holds the highest rank. It is extremely widely diffused, is, in fact, everywhere; however deep we go iron is to be found, and it is a large constituent of many rocks. It exists even in our blood, and without it we could not live. I have seen sufficient iron taken from out of a man's blood to make a medal.

Iron ores contain always the metal in a state of combination, the only case in which we are acquainted with the native metallic iron is that of meteoric iron. This comes probably from some interplanetary spaces—we know not where—and occasionally masses of it have dropped down on our earth, varying in weight from ounces to tons.

Red oxide of iron, or red iron ore, is one of the most important ores in this country; it is now largely in demand for making the metal suitable for the Bessemer steel process, and on this account has lately risen to double its former value. It occurs in large nodular, sometimes "kidney-shaped" masses, and occasionally crystallised, and presenting a bright metallic lustre, when it is known as "specular iron ore." In all these cases it contains the same proportion of chemical elements, and these are iron and oxygen. Oxygen forms about one-fifth of the atmosphere; without it no combustion could occur, no human being could live. The metals have a strong affinity (or liking) for oxygen. A steel spring burns in it with vivid scintillations. Placed in a jet of flame, from a mixture of coal gas and oxygen, the combustion is very striking. If we take a piece of metallic iron and leave it exposed to the air it soon becomes covered with rust. This rust is the oxide of iron, being nothing more than a combination of the metal with the oxygen of the air; in most cases a certain proportion of water is added.

If we take a piece of iron, heat it, and keep it for a long time, it undergoes a change. It increases considerably in weight; and if the heat be continued, especially if the metal be finely divided, as in the state of filings, it becomes converted into an oxide just like the above ore. There is still another way of producing this oxide, —namely, by dissolving the metal in an acid (as muriatic), and then precipitating it by the addition of another substance (as potash or ammonia). If this oxide of iron be rubbed on a piece of paper it will always give a distinct red mark, and never a brown or black one, and in this way we can distinguish between one kind of iron ore and another. This ore, when perfectly pure, contains 70 per cent. of metallic iron. Some of it is used for a very important purpose—viz., burnishing, and when you get hold of a good bit it is worth a good deal of money. It is also used as a pigment, the so-called Indian red and Venetian red are oxides of iron. Also for polishing plate glass, for which purpose the oxide is ground and washed in water, and after the coarser particles have settled the liquid is poured off, and the finer particles for use allowed to subside, and thus they are obtained in a state of great tenuity. Rouge, used for polishing silver, is also an oxide of iron, and the oxide is also frequently used for adulterating "red lead." It is found in Cumberland and Lancashire, and is very much in request on account of its purity; large quantities are now imported from Spain.

Another kind of iron ore is called brown iron ore; it is nothing more than the red ore combined with water, and may be called a natural rust. There is a great deal of it in various parts of the world; much in the Forest of Dean, where it has been worked since the time of the Romans. When perfectly pure it contains 59·89 per cent. metallic iron and 14·5 water. Ochres are an artificial sort of it. It forms the bases of the so-called "Northampton Ore."

The third kind of ore is magnetite or magnetic oxide of iron, and of this kind we have not much in this country. It is a combination of the protoxide and the red or peroxide—viz., $FeO + Fe_2O_3$. It is the natural loadstone, and attracts the magnetic needle, hence its name. It contains 24 parts oxygen to 56 parts iron. It forms one of the most important ores of Sweden, Canada, and the United States, and is one of the purest ores of iron, being in great request for iron adapted for steel manufacture. It contains 72·4 per cent. iron. The next kind is sparry or spathic iron ore. We have not much of it in this country. It is found in Somersetshire, Germany, Austria, and other parts of the world. It is the carbonate of iron, and contains, when pure, 48·25 per cent. of the metal. In addition to its elementary constituents it frequently contains another metal which plays an important part in the manufacture of iron—manganese. When heated it loses all its carbonic acid, and you get not the protoxide of iron remaining, but a mixture of the two oxides. All the important ores of iron from the coal-measures are of this kind; not pure carbonate however, but mixed with more or less clay; a little carbonate of lime, carbonate of magnesia, and always more or less phosphorus, the latter being an inveterate enemy in iron and steel manufacture. From the fact of these clay iron ores containing phosphorus they are unsuitable for many purposes—*e.g.*, the Bessemer process; thence the great demand for the red oxide. Sometimes these ores contain other impurities, as zinc; occasionally lead in form of lead ore; copper in form of copper ore; nickel; and sometimes, but rarely, silver. There is also more or less coaly matter, and when that reaches eight or ten per cent. it gives a dark colour to the ore, which is thence called "black band." They are called "clay" iron ores because the nodules resemble clay; they are found in many parts of the world. They are not confined to the coal-measures, but are also found in the Weald of Sussex—the iron railings round St. Paul's are made from Weald iron ores. The Cleveland iron stone is mainly a carbonate of iron.

Iron varies notably with the kind of ore from which it is made, but this depends not on any difference in the metal itself, but in the presence of certain impurities varying in nature and proportion.

In the extraction of iron the ore is in every case treated as an oxide. If we take the red oxide there is nothing more to do in that respect; the brown variety must be heated to drive off the water; the magnetic ore requires no further treatment; the clay and sparry ores must be previously raised to a red heat to drive off the carbonic acid. Thus in every case we find, without exception, that the material treated for the purpose of obtaining iron and steel is the *oxide of iron.*

If we take the oxide and reduce it to powder, and mix with it a small quantity of charcoal, and then heat it in a closed vessel for a short time, the charcoal will remove the whole of the oxygen. This process requires a very high temperature. If we take a lump of oxide and simply imbed it in red hot charcoal, and keep it so for a few hours, we shall find that every particle of the oxygen will be perfectly removed from it, and there will remain a mass of workable, metallic iron. It is not even essential that there should be extensive contact between the ore and the charcoal, it is sufficient to imbed the former in the latter.

We have heard of the stone age, the bronze age, and the iron age, and are told that they occur, in this sequence. Now bronze is an alloy of copper and tin, usually 10 per cent. of tin, and the production of bronze would imply a considerable degree of advance in the art of metallurgy, as both copper and tin had to be extracted from their ores. They require to be melted together in proper proportions, and then to be melted again and cast. Metallurgically speaking, one would expect to find, other circumstances being clear, that the iron age would be next after the stone age. Iron is so very readily destroyed by corroding, while bronze endures well, that it is no wonder if iron was used by these early people, that it has not come down to us. In the Assyrian collection in the British Museum are some very interesting objects of iron and steel, which show that these people were well acquainted with the use of iron, and that it was plentiful and cheap we may infer from the fact that they used it for hammer heads.

In other instances, in ancient times and at the present day, in countries where it is commonly said that civilisation is not advanced, the process for extracting iron from its ores is essentially a reduction of the oxide by means of charcoal. They take a small furnace, often not larger than an ordinary chimney-pot (cost about three halfpence); this is lined at the bottom with fire-clay, or the best substitute they can get, and has a hole by which to admit the air. These are sometimes circular in section, sometimes rectangular, and frequently the bottom is made to take out. They next reduce the ore to coarse gravel, and place it in the furnace in layers, alternating with layers of charcoal. To keep up a continuous blast, if they have not a double acting bellows, two or three pairs of bellows are worked in alternation. The oxygen is removed, and with the charcoal forms carbonic oxide, which burns at the top of the furnace. After working hard at the bellows for some hours, the ore is reduced, and the iron forms a metallic mass at the bottom of the furnace.

The lecturer then described a kind of bellows used by the Hindoos, who have, no doubt, bellows properly so called, but use a kind of which one man can work two alternately, and so keep up the blast. It consists of a rude piece of wood with a cavity hollowed out, and covered over by a piece of supple buffalo hide. In the hide over the centre of the cavity is a hole through which a string passes, and is fastened to a small peg to prevent it drawing through. The other end of the string is fastened to a long bamboo spring, which thus keeps the hide stretched. A bamboo tube leads the air from the side of the bellows to the furnace. They are worked by a man covering the hole with his heel, at the same time pressing down the hide, and he can work one with each foot. Another example of Indian bellows was shown, consisting of the skin of an animal sewn up, excepting a tubular portion (for the nozzle) at one end and a longitudinal slit at the other. The edges of this slit were fastened to two sticks; and the bellows were worked by setting one end of the sticks firmly together on the ground as a fulcrum for the leverage, and working the other backwards and forwards, closing the sticks as you advance it to force out the air, and opening them on withdrawal. If the hide be supple a good blast can be thus obtained.

A third kind of bellows—double acting—was exhibited, as used in China and Japan, the one in question having been used by an itinerant tinker in China. It consists of a rectangular box, closed at bottom, but with a movable lid, and a hanging valve at each end, opening inwards. Inside is a piston worked by a handle outside, and having a packing of cocks' feathers. On the bottom is a canal running the whole length, with an opening on the top into the box at each end. The exterior opening (in reality two) is about halfway of the length of this canal, inside of which valves are placed to regulate the passage of the air during the working of the piston. This apparatus works remarkably well, giving a good, practically continuous blast.

(To be continued.)

LESSONS ON CHEMISTRY.*

BY SELIMO R. BOTTONE.

(Late of the Istituto Bellino, Novara, Italy.)

(Continued from p. 4.)

c. CHLORINE TETROXIDE.—*Synonym: Chloric Oxide.*[1] *Symbol:* $Cl'O_2''$, or $Cl_2'O_4''$? *Molecular weight:* 67·5.

110.—PROPERTIES.—A gas of a deep yellow colour, with a smell resembling that of chlorine, though not so pungent and suffocating. Its specific gravity is 2·3365, or, what amounts to the same, it is about thirty-four times as heavy as hydrogen, hence we are led to conclude that its molecule contains only one atom of chlorine, united to two of oxygen, and not two of chlorine to four of oxygen (see foot-note referring to chlorine trioxide). In common with the compounds just examined, it possesses great bleaching powers. It may be condensed to a red liquid at a temperature of about—4° Fahr. It is a most dangerous body to operate upon, as it is liable to explode with a very slight rise of temperature, sometimes fracturing the containing vessel, and thereby endangering the experimenter. It dissolves freely in water, but does not appear to unite with it to form an acid,[2] though the solution formerly went by the name of hypochloric acid. This solution, when placed in contact with metallic oxides, gives rise to a mixture of a *chlorite* and a *chlorate*[3] of the metal employed. Up to the present time chloric oxide has received no practical application.

111.—PREPARATION. — A small quantity of potassium chlorate is made into a paste with sulphuric acid. The mixture assumes a deep yellow tint, and is then to be introduced into a retort, which must be carefully heated with *warm water* (bain marie). Chlorine tetroxide is evolved, and may be collected by downward displacement, as water decomposes it, and mercury is attacked by it. The interchanges which take place during the action of sulphuric acid on potassium chlorate occur in two phases—viz., 1st. The production of chloric acid and sulphate of potassium; 2nd. The splitting of chloric acid into water, perchloric acid, and chloric oxide. The following equations may serve to illustrate these changes:—

1st Phase.

$$3K'\overline{\overset{\prime}{Cl}O_3} + 3H_2'\overline{\overset{\prime\prime}{S}O_4} = K'H'\overline{\overset{\prime\prime}{S}O_4} + 3H'\overline{\overset{\prime}{Cl}O_3}$$

2nd Phase.

$$3H'Cl'O_3'' = H_2'O'' + H'Cl'O_4'' + 2Cl'O_2''.$$

112.—The formula of chlorine tetroxide may be represented in two modes, according to the view taken of its constitution. If we take the view, with some, that an open chain (see 26) cannot exist in the free state for an appreciable

1 Peroxide of chlorine.

2 According to some, water decomposes the gas, splitting it up into chlorous and chloric acids.

3 See paragraph 114 in explanation of the term "chlorate."

space of time, we must represent its molecular constitution as being—

But, as we have already seen, this does not agree with its vapour density, hence many chemists hold its constitution to be—

Attention has already been called to the fact (78) that chlorine appears in certain cases to act as if bivalent; this being the case, no difficulty would arise from stating its graphic formula to be—

a formula which would bring its molecular constitution into direct agreement with its vapour density, for $Cl = 35{\cdot}5 + O_2 = 32 = 67{\cdot}5$, which is, as theory leads us to expect, twice its vapour density 33·75 (see 17).

D. CHLORINE PENTOXIDE.—*Synonym: Chloric anhydride.*[4] *Symbol:* $Cl_2'O_5''$ (?). *Molecular weight:* 151 (?).

113.—This body is as yet unknown in the separate state. In combination with the elements of water it exists in chloric acid, to which it bears the same relation as the hypochlorous and chlorous anhydrides bear to hypochlorous and chlorous acids.

D (2). CHLORIC ACID. — *Synonym: Hydrogen Chlorate.*[5] *Symbol:* $H'Cl'O_3''$. *Combining weight:* 84·5.

114.—PROPERTIES.—An oily, colourless fluid, of a strongly sour taste. It reddens vegetable blues, but does not possess bleaching powers. It has never been obtained entirely free from water, for on reaching a certain point of concentration it is decomposed with evolution of oxygen. Heat also effects this decomposition, resolving chloric acid into a higher oxide of chlorine, viz., perchloric acid and oxygen. In fact, its most marked property is the facility with which it parts with its oxygen. For this reason it is a most powerful oxidising agent. A few drops allowed to fall on a piece of paper cause it to ignite, owing to the rapidity with which oxidation takes place (see paragraph 80). In contact with metallic oxides, chloric acid gives rise to a metallic chlorate and water; thus:—

$$M_2'O'' + 2\,H'Cl'O_3'' = 2M'Cl'O_3'' + H_2O.$$

The chlorates are all soluble in water; and on heated split up, as we have already seen (87), into oxygen and a chloride, thus:—

$$M'Cl'O_3'' = M'Cl' + 3O''.$$

Hence potassium chlorate is a most convenient source of oxygen.

115.—PREPARATION.—On passing a current of chlorine through a solution of potash or soda, or through a stratum of slaked lime, *if the temperature be kept low*, a mixture of a chloride and a hypochlorite is produced (see 103), but if the temperature is high, or the resulting compounds be afterwards heated, no hypochlorite is formed (as the hypochlorites are all decomposed by heat) but a chlorate of sodium, potassium, or calcium, as the case may be, mixed with a corresponding chloride. The resulting chlorides, being much more soluble in water than the chlorates, remain in the mother liquor[6] on allowing the solution to crystallise.

From the potassium chlorate $K'Cl'O_3''$, chloric acid may be easily obtained, by dissolving it in water and allowing a body called hydrofluosilicic acid $H_2Si''''F_6'$ to act upon it; when a substitution of the potassium in the chlorate for the hydrogen in the acid takes place, and chloric acid, together with potassium silico-fluoride, are the results, thus:—

$$2K'Cl'O_3'' + H_2'Si''''F_6' = K_2'Si''''F_6' + 2H'Cl'O_3''.$$

The silico-fluoride is insoluble in the resulting chloric acid, hence it may be separated from it by filtration through asbestos, or by decantation.

By treating barium chlorate with sulphuric acid this latter seizes on the barium and liberates the chloric acid. The chlorate must be dissolved in water, and the sulphuric acid (previously diluted and cooled) added gradually as long as a precipitate of barium sulphate is formed: this is separated as in the previous case. The interchanges which take place may be expressed as follows:—

$$Ba''2Cl'O_3'' + H_2'S''O_4'' = Ba''S''O_4'' + 2H'Cl'O_3''.$$

In both these processes, the resulting chloric acid contains a quantity of water, which may be *partially* removed by careful evaporation under the receiver of an air pump, under which sulphuric acid is also placed to absorb moisture. The molecular constitution of chloric acid may be represented graphically thus:—

However, as chloric acid has never been obtained in the state of vapour, this must not be taken as certain: all we know is, that for every atom of chlorine in this compound there are three atoms of oxygen and one of hydrogen. Hydrogen chlorate, or chloric acid, was first isolated by Gay-Lussac.

E. CHLORINE HEPTOXIDE.—*Synonym: Perchloric Anhydride.*[7] *Symbol:* $Cl_2'O_7''$ (?). *Molecular weight:* 183 (?)

116.—This body has not been obtained in the free state. Combined with the elements of water, it forms the compound known as perchloric acid, or hydrogen perchlorate, to which it is related in the same manner as the other anhydrides are to their respective acids.

E (2). PERCHLORIC ACID. *Synonym: Hydrogen Perchlorate.*[8] *Symbol:* $H'Cl'O_4''$. *Combining weight:* 100·5.

117.—PROPERTIES.—Perchloric acid, the most stable of the oxy-acids of chlorine, is, when pure a syrupy, transparent, and colourless fluid, which has been cooled to − 31° Fahr., without solidifying. It is very volatile, and fumes when exposed to the air, owing to its powerful affinity for water. Its specific gravity at the ordinary temperature is 1·782. The readiness with which it parts with its oxygen when in presence of oxidisable bodies causes it to be one of the most powerful oxidising agents known. A drop allowed to fall on any combustible, such as wood, paper, charcoal, &c., produces combustion with explosive violence. Like most acids, it reddens litmus[9] paper; but it possesses no bleaching properties. It combines with water to form a white solid crystalline hydrate, which melts at 122° Fahr. The composition of this hydrate is $H'Cl'O_4'' + H_2'O''$. This hydrate is almost as powerful an oxidising agent as perchloric acid itself. If these crystals be dissolved in water, they form a solution which resembles very much the pure acid, being like it of an oily aspect; it boils at the constant temperature of 392° Fahr. This solution contains 72·3 per cent. of real acid, which corresponds to the formula, $9H'Cl'O_4'' + 19H_2'O''$.[10] In combination with metals, perchloric acid forms a series of compounds called perchlorates, the general formula of which is $M'Cl'O_4''$. As in all other cases where an acid acts on a metal, hydrogen is evolved, and replaced by the metal, thus—

$$H'Cl'O_4'' + M' = M'Cl'O_4'' + H'.$$

The valency of an acid can always be measured by the amount of replaceable hydrogen contained in its molecule. Hence perchloric acid is monovalent, as its molecule contains but one atom of replaceable hydrogen; it can, however, combine with a bivalent metal, but in this case two molecules are required to saturate the bivalency of the metal, thus—

$$M'' + 2H'Cl'O_4 = M''{<}^{Cl'O_4''}_{Cl'O_4''} = 2H'.$$

When perchloric anhydride unites with water to form perchloric acid, the following interchanges are supposed to ensue—

$$Cl_2'O_7'' + H_2'O'' = H'Cl'O_4' + H'Cl'O_4',$$

or, in words, one molecule of water, and one of perchloric anhydride, give rise to two molecules of perchloric acid, or hydrogen perchlorate.

118.—PREPARATION.—Three processes will be described:—1st. By boiling a solution of chloric acid it is converted into water, chloric oxide gas (which escapes), and perchloric acid, thus:—

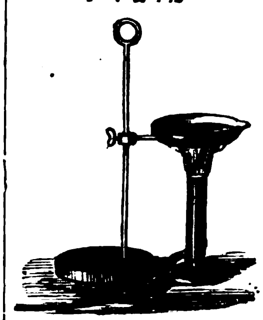
$$3H'Cl'O_3'' = H_2'O'' + Cl_2'O_4'' + H'Cl'O_4''.$$

2nd. On heating potassium chlorate it melts, and if kept in gentle ebullition, without raising the temperature, it gives off oxygen. After some time the fluid mass begins to thicken, and at last assumes a dough-like consistence. If the heat be withdrawn at this point, the mass is found to be a mixture of chloride, chlorate, and *perchlorate* of potassium. On treating this mixture with hydrochloric acid, the chlorate is decomposed, while the perchlorate remains unchanged; washing with a small quantity of water removes the chloride, which is very soluble in water, while the almost insoluble perchlorate remains behind. From potassium percholate perchloric acid may be obtained by distilling it with sulphuric acid, which seizes on the potassium, setting free the perchloric anhydride, which instantly unites with the liberated hydrogen of the sulphuric acid to form perchloric acid, thus:—

$$2K'Cl'O'' + H_2'S''O_4'' = K_2'S''O_4'' + 2H'Cl'O_4''.$$

3rd. Potassium perchlorate may also be prepared by adding well-dried and finely-powdered potassium chlorate, in small portions at a time, to an equal weight of sulphuric acid, and gently warming in an evaporating dish (Fig. 10). The sulphuric acid first liberates the chloric acid from the chlorate; but this is immediately decomposed by heat, and converted into hydrogen, chloride tetroxide, and perchloric acid, which combines with part of the potassium, thus:—

FIG. 10



$$6K'Cl'O_3'' + H_2'S''O_4'' = 3K_2'S''O_4'' + 6H'Cl'O_3'',$$

and then

$$3K_2'S''O_4'' + 6H'Cl'O_3'' = 3H'K'S''O_4'' + 3H' + 3Cl'O_2'' + 3K'Cl'O_4.$$

The compound of sulphuric acid with potassium is readily soluble in water, which is, therefore, used to remove it, leaving undissolved the perchlorate. From this the acid may be obtained as above, or the potassium may be removed by hydrofluosilicic acid, as recommended for chloric acid (115). The molecular constitution of perchloric acid is presumed to be

while that of chlorine heptoxide may be represented by

SOUND WAVES.

M. A. M. MAYER, in a note communicated to the Académie des Sciences, gives an account of certain experiments made by him with reference to alteration in wave length produced from a motion of translation in the sounding body:—Having procured, he says, four tuning forks, fixed to sounding cases, and giving the note $Ut^3 = 256$ complete vibrations per second, I numbered them 1, 2, 3, and 4. I brought Nos. 1 and 2 to perfect unison, by a method to be described. No. 1 was placed before a magic lantern; a little ball of good cork, 6mm. in diameter, was suspended by a silk thread against one of its prongs; the images of fork and ball were projected on a screen. No. 3 had a little wax attached to one of its prongs, so that it gave two beats in a second with No. 1 or No. 2. No. 4 had its extremities filed, and also gave two beats per second with No. 1 or No. 2. Thus No. 4 gave 2 vibrations per second *more* than No. 1, while No. 3 gave 2 vibrations *less*. The following were the experiments:—

EXPERIMENT 1.—Fork No. 2, attached to its case, and held in the hand, is put in vibration at a distance of 30ft. to 60ft. from No. 1 (projected on the screen as above mentioned.) The ball is driven from the prong of No. 1, which vibrates in unison with No. 2.

EXPERIMENT 2.—I placed myself at a distance of 30ft. from No. 1, holding fork No. 2 in one hand and its case in the other. I then set the fork vibrating and moved rapidly towards No. 1. When my movement had become uniform I placed the fork on its case, and did not remove it till just before stopping. Although I came to about a foot distance from No. 1, the ball continued in contact with the prong.

[4] Chloric acid. Barff., 1871.

[5] Hydric chlorate. 1871.

[6] Mother liquor, a term used to denote a solution which has furnished crystals.

[7] Perchloric acid. 1871.

[8] Hydric perchlorate. 1871.

[9] Litmus, a vegetable blue, prepared from a lichen, commonly called orchil.

[10] Roscoe doubts the truth of this being a definite compound.

Experiment 3.—I again approach fork No. 1, as in Experiment 2, but without removing the fork from its case after having attached it. The ball did not move till I stopped. At that moment my assistant, who held his ear near the case, while he watched the screen, noticed No. 1 fork vibrate and the cork leap from it.

Experiments 4 and 5.—I moved away from No. 1 instead of towards it. Results the same as in Experiments 2 and 3.

Experiment 6.—I set No. 3 vibrating as in Experiment 1, this fork making 254 vibrations per second. The ball did not move. Then I removed the fork from its case, and placing myself 30ft. from No. 1, I swung the case in my hand towards No. 1 at a quickness of 8ft. to 9ft. per second, and, while making this forward motion, I put No. 3 above the case. The ball was suddenly thrown from No. 1. When the motion of the case was increased or diminished the vibrations of No. 3 did not affect No. 1.

Experiment 7.—Fork No. 4, which made two vibrations per second more than No. 1, was substituted for that employed in Experiment 6, but placed on the case in its backward movement from No. 1. The results were the same as in Experiment 6.

Experiment 8.—I placed No. 3 before the lantern, and swung No. 1 as in Experiment 7, with the same result.

Experiment 9.—I placed No. 4 before the lantern, and swung No. 1 as in Experiment 6, with the same result as in Experiment 6.

By these simple experiments I have been able to prove the change in wave-length produced by the translation of the vibrating body. By analogy they perfectly explain the modern method of determining the motions of a celestial body by variations in the refrangibilities of its ray's motions, which it is often impossible to ascertain by any other means. It may be useful to offer some remarks on the details of these experiments, which must be attended to in order to succeed.

The forks 1 and 2 must be really in unison. It may happen that two forks vibrating together give no appreciable beats, and are constrained into giving the same number of vibrations per second; while, by making them vibrate separately, the equality is destroyed. I adopt the following method. Having taken three forks, warranted to make the same number of vibrations in a given time, I load one of them so that it gives two or three beats per second with one of the other two which I wish to bring into complete unison. I determine the interval of time between twenty or thirty of these beats by a chronograph. I then determine the interval between the same number of beats with the second fork; and if it is different from that obtained with the first, I attach wax to the more rapidly vibrating fork till it makes the same number of beats as the slower. Having thus adjusted the forks, I have had no difficulty in Experiment 1 at 60ft., and believe the effects would be the same at 100ft. The cork ball should be spherical, and should not do more than touch the fork. It is advisable to varnish the ball. A machine has been invented by which one can communicate a uniform motion of translation to the forks. A small mirror held between two vertical threads may be substituted for the cork ball, giving very delicate indications by the motion of a reflected ray.

The fork No. 1 makes 256 complete vibrations per second; while No. 3 makes 254, thus giving for wave lengths, 4·367ft. and 4·401ft. respectively, reckoning the velocity of sound at 1,118ft. per second.

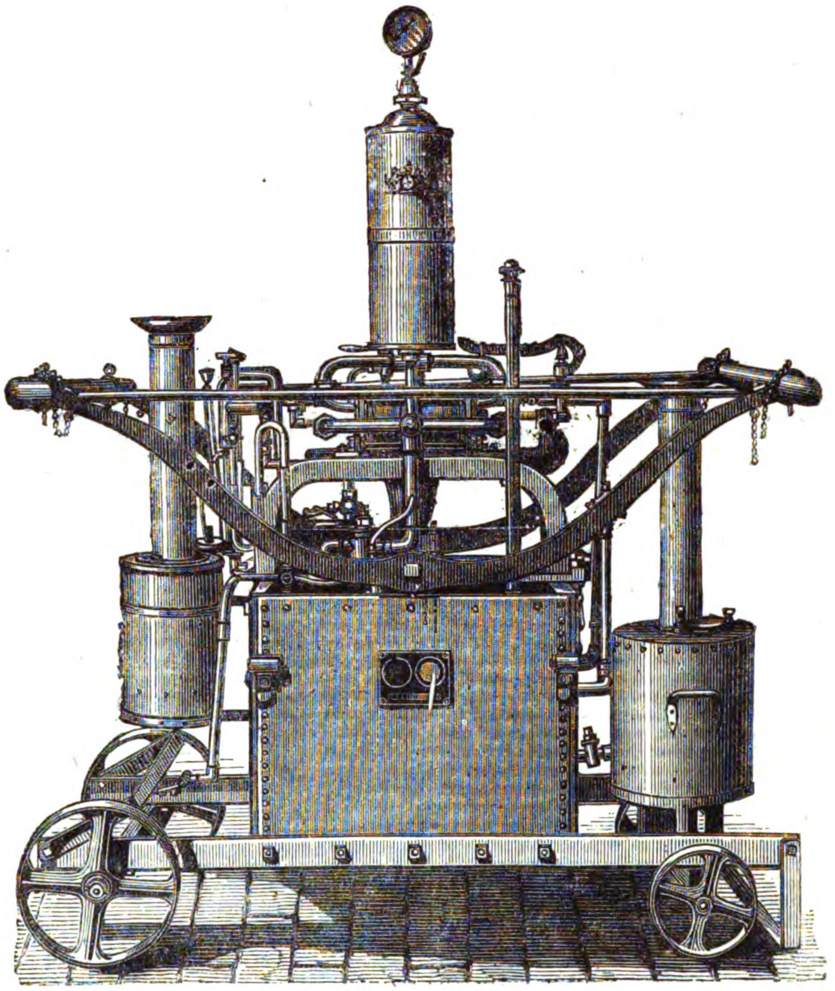
M. Mayer then proves that 256 vibrations of a fixed body will produce the same effect on a distant surface as 254 vibrations of a body which approaches the surface with a speed of 2λ, or twice the wave length of the No. 1 fork—*i.e.*, 8·734ft. per second, which was the speed given to the fork in Experiment 6.

Take next the case of light. Suppose that the fork No. 1, which makes 256 vibrations per second, made 595 millions of millions of vibrations, the number belonging to ray D in the spectrum. Then the fork No. 3 will represent 590 millions of millions of vibrations per second, which will give us a wave length ·0000042 mm., greater than that of D, and which nearly corresponds to a line of iron situated 43 divisions above D, in Angström's map.

We have seen that the fork No. 3, giving 254 vibrations per second, must approach the ear with a speed of 8·734 feet to produce the note belonging to 256 vibrations per second from a fixed point; in the same way the light of a star whose ray vibrates 590 millions of millions of times should reach the eye with a velocity of 28470 per second to give the colour produced when the ray D comes from a stationary flame. A. M. B.

A NEW FIRE-ENGINE.

THE annexed diagram is an illustration of a fire-engine on an entirely new principle patented by Mr. Thomas Atkins, the main features of which will be gathered from the following description. In the trials made recently at Welwyn very satisfactory results were obtained, a fire made of faggots smothered with tar being brought completely under control for an hour, and finally extinguished when its purpose was served, at an expenditure of two and a half gallons of water. The principle of the invention consists in charging the water used with carbonic acid and nitrogen, but its chief novelty lies in the remarkably cheap method of obtaining the carbonic acid, which is made by drawing the atmospheric air through a charcoal fire and forcing it into a tank containing



water. This tank is 2ft. 6in. long by 2ft. wide, and 2ft. deep. The vacuum chamber, which connects the pump with the water to be used in the tank is 1ft. in diameter and 2ft. deep. The pump is 4in. in diameter, double action, 10-in. stroke. On the left hand side is a small stove, with a pierced ring in its interior; this stove is 9in. in diameter and 14in. deep, with a ventilator in the bottom for admitting air to the stove, and a door and frame fitted air-tight to the top, 3in. in the clear, to admit fuel. A small pipe runs from the stove about 18in. high. Half way up the pipe is a small pulse-valve for preventing back action from the pumps in case of leakage, and so adjusted as to work in harmony with a foot-valve in the vacuum chamber that supplies the water to the pump. Between the pulse-valve and the vacuum chamber are two adjusting cocks for regulating in exact proportions the supply of gas and water. A combination of mineral, animal, and vegetable charcoal is used, and when the pump is set in motion and a light applied, in one minute the stove is in full action. The gases being blown through the air vessel on the top are wasted for a minute or two, the apparatus connecting the water and gas cocks is then adjusted, and the machine is ready for use, two minutes being ample for bringing it into full operation. The three-way cock on the delivery nozzle is shut off, and the pressure in the air or gas chamber, shown by the gauge on the top or on the tank, is brought up to 150lb. on the square inch. A pipe of any convenient length, and about 1in. in diameter, is then connected with the machine, and on the end of the pipe a discharging nozzle is attached capable of furnishing a single jet, a spray, or a fine mist. On the inside of the discharging nozzle a pressure gauge is fixed, so that the fireman may keep the point of discharge at 150lb. pressure on the square inch.

According to the inventor, the gases generated and poured into a glass 6in. long, at the pressure before-mentioned, are retained in the water for several minutes, and when thrown upon the fire sink to a temperature of from 40° to 50° Fahr. One cubic foot of this fluid discharged upon any burning pile is capable of doing as much execution in extinguishing fire as 50 cubic feet of water from an ordinary fire-engine, and in one-twentieth part of the time now occupied, while the results are said to be unfailing.

Under the arrangements proposed by the inventor, fire-engines will, he thinks, be of little use, as new conditions will be submitted entirely altering our present notions of dealing with fire. A large skeleton map of London is being prepared, indicating 2,500 receivers or store vessels. These may be fixed in cellars, under pavements, or in warehouses. The contents of such vessels will vary from 150 to 1,000 gallons of water charged with carbonic acid. Pipes, valves, and all necessary apparatus will be attached to these stores, which may be instantly brought into operation, and a fire extinguished by merely turning on a tap and allowing the water to fill the building in the form of spray.

Another important point is the capability of the invention to instantly depolarise vast quantities of sulphurous vapours, carbonic acid gas, carburetted hydrogen, and sulphuretted carburetted hydrogen. A delivery jet of ½in. in diameter is said to be capable of instantly extinguishing and depolarising carburetted hydrogen from a 2ft. main, working at 3in. pressure from the gasometer. Arrangements may be made in coal-pits, mines, caverns, cellars, tunnels, ships, and subterranean railways, for instantly rendering the air pure and healthy. Numerous uses are claimed for this invention. For instance, it may be utilised for softening water, for brewing and dyeing, and particularly for preventing incrustations in steam-boilers.

The inventor also points out that in buildings containing a store-vessel or receiver the whole of the gas-fittings may be used to distribute the charged water, by simply fitting on a pulse-valve here and there which would yield to a pressure greater than that of the coal-gas, and a connection being made between the gas-pipes and the receiver about one or two feet from the meter tap, the "spray" would be conveyed into every room in the building, and the fire extinguished by the carbonic acid gas liberated. The trials hitherto have given encouraging results, and as a company is formed to construct the engines, which will be worked by the London Volunteer Fire Brigade, the invention will be judged by its performance in an actual fire. Those of our readers who have witnessed the powerlessness of plain water in the fierce heat of a raging fire will readily appreciate the utility of carbonic acid cheaply and conveniently thrown upon the flames. Further information on the subject may be obtained of Mr. E. W. Allen, of Ave Maria-lane, E.C., who, we believe, will be happy to explain the invention and give particulars as to the steps which are being taken to introduce it.

INDUSTRIAL USES OF MAGNESIA.

THE oxide of magnesium is a native dark green, glassy, hard, anhydrous oxide, found in rocks under the name of periclase, but is rarely of sufficiently pure water to be of use as a precious stone; a hydrated oxide occurs as the mineral brucite, from which is prepared a valuable cement, and the pure oxide for other purposes. A common way to prepare the oxide is also to heat the carbonate. The uses of the oxide of magnesium have latterly been considerably extended, and it is well to make note of them. Professor Henry St. Claire Deville, of Paris, exposed a piece of caustic magnesia to the influence of a stream of running water, and after the lapse of a few months found that it had become hard like alabaster; he left it in the same position and re-examined it after seven years, and found that it had not in the least deteriorated, but, if anything, had become still harder. An analysis showed it to be nearly pure hydrate of magnesia, similar to the mineral brucite. Deville then stirred up pure caustic magnesia into a paste with water, and sealed it in a glass tube. In a few weeks this also became transparent, and proved, after analysis, to be a pure hydrate, containing 69·3 per cent. magnesia and 30·7 per cent. water. These results instigated Deville to pursue the subject further, and also to hand the matter over to manufacturers of cements. He found that a mixture of magnesia and sulphate of lime did not harden under water, but that magnesia and pulverised chalk or marble dust, when exposed for some time to the action of water, form a hard stone, similar to artificial marble. The magnesia which yielded the hardest mass was that prepared by heating the chloride of magnesium obtained from the bittern of salt water. The heat must not be raised to redness, as the hydraulic properties of the magnesia are diminished by too high a temperature. An important result was obtained from dolomite or magnesian limestone. This is a double carbonate of lime and magnesia, and when heated to below redness, pulverised and mixed with water, yields under water a mass of extraordinary hardness. If magnesian limestone be heated to whiteness, so as to expel all of the carbonic acid, it will no longer set under water; in other words, it loses its hydraulic property when both constituents are deprived of their carbonic acid. The lime of the mineral must retain its carbonic acid, while the heat is raised sufficiently to expel the carbonic acid from the magnesia. The result is an intimate mixture of caustic magnesia and carbonate of lime (marble), which yields a cement that hardens equally well under fresh and salt water, and appears to be admirably adapted to the manufacture of artificial building-stone. The late M. Sorel modified Deville's process by mixing caustic magnesia with chloride of magnesium; the latter ingredient can be substituted by other chlorides, but as the magnesium chloride is a waste product it is better to employ it. The caustic magnesia is stirred into a concentrated solution of chloride of magnesium, and the more concentrated the solution is, the harder will be the cement. This cement becomes perfectly white and very hard. It can be poured into moulds, the same as plaster of Paris, and as any colour can be mixed with it, it can be used for the repair of different kinds of building-stones, as well as in the imitation of a variety of fancy articles. It serves a good purpose as a coating for soft limestone or plaster casts, and for this purpose may be applied with a brush. The cement made by dissolving calcined magnesia in chloride of magnesium is employed as the basis of the manufacture of artificial stone in Boston: by mixing the prepared cement with sand, a peculiar brick is formed; by employing flint, whetstones and hones are made; with kaolin, ornaments of all kinds, statuettes, imitation porcelain, &c., are produced; with sawdust, it gives a good material for covering floors; with carbonate of lime, imitations of marble. Whether it is preferable to use Sorel's method of caustic magnesia and chloride of magnesium, or to adopt the plan proposed by Deville, and make an intimate mixture of carbonate of lime and caustic magnesia, must largely depend upon the cost of the material.

THE MANAGEMENT OF BEES.

THE method of treating bees adopted by the Americans often affords a hint to bee-masters in the old country; we therefore reproduce the following remarks from the *Rural New Yorker*:—

There is no arrangement of a hive that can compensate for the lack of movable frames, and the more simple in construction the better. We prefer a two-story hive, where the honey extractor is employed to obtain surplus honey. But if the one-story hive be preferred, make the hives large enough to contain two or three extra frames upon each side. Honey can be extracted from the brood combs; but great care must be used, or the unsealed brood will be thrown out of the cells. We deem the honey extractor to be of great value, and every apiarian should have one of his own. Oftentimes the hive will contain too much honey, not giving the queen a chance to lay sufficiently to keep up the strength of the colony. Hence the reason why we so often hear the complaint in the fall of the year, "too few bees and too much honey." The reason why so many bee-keepers find, in the spring, that their bees have died leaving plenty of honey in the hive is attributable to the same cause. Bees, to winter in good condition, must have empty cells to cluster in at the commencement of cold weather; and in very many cases we can accomplish this in no other way than to empty some of the centre combs with the extractor. In fact, we consider the honey extractor to be of equal importance to a successful and profitable prosecution of bee-keeping with the movable comb frame; and we should speedily abandon all hope of making this pursuit a remunerative one were it not for these two all-important aids.

Many bee-keepers have complained that dysentery is destroying their bees, in many instances threatening the total destruction of whole apiaries. In this, as in some other cases, we think a little prevention to be far better than a great deal of cure. There are two principal causes of this disease (if it may be called a disease), the first and most important of which is insufficient ventilation. In some seasons the honey gathered by the bees is of a poor quality, being thin and watery; this is especially true of a very wet season. Now, when a considerable quantity of such honey is stored in the hive at once, it is very liable to ferment and sour, before it thickens sufficiently to be sealed over by the bees, especially during a warm and moist spell of weather, unless the hive has ample facilities for thorough ventilation. Again, if the hive is not properly ventilated in the winter season, frost will accumulate upon its walls and the combs; and when this melts the combs will oftentimes be drenched with moisture.

Should there be any considerable quantity of unsealed honey at such a time it will absorb a part of the moisture, rendering the honey thin and watery. The direct cause of this complaint is the consumption of such honey by the bees; and we believe that ninety-nine cases out of a hundred originate from improper or insufficient ventilation. The bees are compelled, or do at least, consume greater quantities of honey than they ought, and are compelled to discharge their fæces in their hives. We have seen combs of such stocks that were literally besmeared with this offensive smelling excrement of the bees. Our advice to all would be, ventilate your hives properly and thoroughly, and you will have little or no trouble from this source.

SURFACE ELECTRICITY.

IT is well known that Faraday made numerous experiments upon this subject, and has varied, under different forms, that which Coulomb has realised with the hollow sphere and its two covers. It is still under this form, the least commodious, that this experiment is repeated in the lecture-room. If the loss is considerable on the day when this experiment is performed, it ceases to be sufficiently conclusive; for it requires, first, to electrify the sphere alone; second, to recover it rapidly with its two covers; third, to take them off; fourth, to prove that these covers are electrified; and, fifth, that the sphere is not. The second operation cannot be executed with great rapidity on account of the form of the covers. Amongst other experiments Faraday has made the following:—He took a cylinder made of metallic gauze placed upon an insulated horizontal metallic disc, the design being to afford proof that the exterior is alone electrified. An animal, such as a mouse, placed in the interior, showed no commotion, even when the whole apparatus was electrified so strongly that bright sparks might be obtained from it.

Faraday did more, he constructed a cubical chamber 12ft. on each side, with laths; the walls were of wire gauze and of paper, and the whole chamber was suspended by means of silken ropes. The chamber, even the interior, could be electrified strongly on connecting it with an electric machine. Faraday inclosed himself in this chamber with electroscopes and various other apparatus, but he failed to find the least trace of electricity, whilst the walls were so strongly electrified that vivid sparks were obtained from the outside, and "brushes" escaped spontaneously.

M. Terquem has endeavoured to repeat this experiment in his lectures, on a small scale, in the following manner. He took any form of bird-cage, whether of wood and iron wire, or entirely of metal, and suspended it to some insulated conductor in communication with the electric machine. Inside the cage was placed a gold-leaf electroscope, and also pieces of tinsel, the feather of a quill, and pith balls. Whilst it was possible to obtain vivid sparks from the cage nothing moved in the interior. Within the cage was suspended a bundle of linen yarn, and underneath the cage a similar bundle; the interior bundle remained undisturbed, whilst the exterior was greatly excited and electrified, all the bits of yarn spreading out, and on approaching the hand the peculiar crackling due to electricity was heard.

Bands of paper being stuck along the length of the wires of the cage, the exterior bands would twist strongly, and get displaced, whilst the interior remained vertical and unmoved when the cage was electrified. To complete the experiment, a bird might be placed inside the cage, and by his singing and general demeanour prove that he was not only completely indifferent to the phenomenon of electrical charge and discharge, but that behaving so proved that the interior of the cage was perfectly free from all electrical phenomena, whilst the exterior alone was susceptible to the electrical influences.

We quite agree, says *Engineering*, with M. Terquem, that this experiment is very simple, full of proof, very easy indeed to prove, and, above all, requires neither complicated nor costly apparatus, and is one that might be frequently introduced into the lecture room as a proof of one of the most interesting points in electricity.

THE DECOMPOSITION OF WATER BY ZINC.

THE decomposition of water by zinc in conjunction with a more negative metal was the subject of a paper presented to the Royal Society, by Dr. J. H. Gladstone and Mr. A. Tribe, F.C.S. According to the authors, pure zinc is incapable of decomposing pure water, even at 100° C., but at a considerably higher temperature it is known to combine with its oxygen. Davy exposed pure water for two days to the action of a pile of silver and zinc plates, separated only by pasteboard, without obtaining any hydrogen; Buff, however, had shown that a very minute trace of gas can be formed at the ordinary temperature by a pair of zinc and platinum plates. By bringing the metals closer together, and thus increasing the electrical tension of the liquid, the authors could effect the same combination of zinc with oxygen at the ordinary temperature which takes place without the second metal at a very high temperature. On thin sheets of zinc and copper being hammered together, and placed in a bottle filled with distilled water, small bubbles of gas were formed; the same result obtained when the experiment was tried in a more perfect form. Under the microscope the bubbles of gas are seen to form, not on the zinc, but among the copper crystals, and sometimes to make their appearance on the glass at some distance off. Lest it might be contended that the free oxygen usually present in distilled water had been the means of starting this action, the experiment was repeated with water as free from oxygen as could be obtained by boiling. Iron and lead, under similar circumstances, also decomposed pure water, and the action of magnesium was greatly increased by conjunction with copper. The effect of the more negative metal was the same as would have been produced by an increase of heat. From a practical point of view this experiment may serve as a ready means of preparing pure hydrogen; from a theoretical point of view its interest seems to lie in the fact that the dissociation of a binary compound by means of two metals may take place at infinitesimally short distances, when it would not take place were the layer of liquid enough to offer resistance to the current, and also in the correlation between this force and heat.

PSYCHIC FORCE—SPIRIT FACES.

THE following is clipped from the last number of the *Scientific American*:—One of the marvels of spirit jugglery, or "psychic force" as the learned Dr. Crookes denominates it, is the production of images of human forms, hands, arms, faces, &c., which are seen by the observers to float around in the air. In some cases, the faces have been recognised as those of departed friends by sitters in spiritual circles. Quite a thriving business is done in this city by professors of the art; but some queer revelations have lately been made. One Gordon carried on a spirit establishment and was doing a profitable business, at 50 cents. a head, until his partner, the business manager, in a quarrel peached on him, and revealed to the public how the thing was done. Professor Gordon, it appears, dressed in the paraphernalia of a high priest, appears before his audience, turns down the lights, and then by means of strings and bands manipulates a series of large lithographic coloured pictures of faces, causing the pictures to rise from behind an altar, float and sway in the air. These pictures represent females, children, and men, and in the dim twilight are from time to time pronounced, by this or that person in the audience, to be the spirit faces of their departed friends. Only a small stock of pictures is required to produce these supernatural effects.

A higher priced professor of this mystic art is one Slade, who until recently has confined his spirits to the more commonplace dodges of spirit-writing on slates, rapping, table lifting, accordeon playing, knife throwing, &c. His circles are more select, generally only two admitted at a time to the performance; tickets 3 dols. each. Lately he has added the spirit face business and raised the price to 5 dols. An intelligent friend of ours, who visited the show, pronounces the faces to be those of genuine spirits, and regards the whole performance as most astonishing. He came away completely converted to the doctrine of the bodily presence and power of the spirits. *Per contra*, the New York *Sun* recently published an *exposé* of Slade's manipulations, as derived from a member of his own household. The faces are produced behind a black curtain, and make their appearance before a small opening in the same. Slade employs a stock of masks and pictures, which he works by means of threads, making them rise and appear before the opening, the gas being turned down so as give a dim sepulchral effect. How it is that any intelligent person can be brought to attribute these tricks to spiritual agency passes comprehension.

THE INFLUENCE OF THE PLANETS UPON SOLAR ACTIVITY.

AT a recent meeting of the Royal Society Messrs. De La Rue, Balfour Stewart, and Loewy presented a memoir containing the results of further investigations into this matter. In previous memoirs they pointed out that the behaviour of sun-spots with regard to increase and diminution, as they pass across the sun's visible disc, is not altogether of an arbitrary nature. It has been supposed that during a period of several months sun-spots will, on the whole, attain their minimum of size at the centre of the disc. They will then alter their behaviour so as, on the whole, to diminish during the whole time of their passage across the disc: thirdly, their behaviour will be such that they reach a maximum at the centre; and lastly, they will be found to increase in size during their whole passage across the disc. These various types of behaviour appeared to the observers always to follow one another in the above order; and in a paper printed for private circulation in 1866 the authors discussed the matter at considerable length, after having carefully measured the area of each of the groups observed by Carrington, in order to increase the accuracy of their results. In the present instance nineteen or twenty months were obtained as the approximate value of the period of recurrence of the same behaviour. The observations extend from the beginning of 1854 to the end of 1860, forming the series of Carrington; the Kew series commenced in 1866. There is, then, nearly a continuous series of observations. The behaviour, with regard to size, of the various groups as each passes from left to right across the sun's visible disc is discussed in this memoir.

The average behaviour of spots, as far as can be judged from the information at present attainable, is not quite symmetrical as regards the centre of the disc. Without attempting at present to enter into an explanation of this remarkable phenomenon, the authors point to it as a confirmation of their view that most spots are accompanied by a wall-shaped surrounding of facula. Observations show that, on the whole, the life-history of the facula begins and ends earlier than that of the spot which it surrounds, and that throughout a gradual subsidence of this elevated mural appendage seems to be taking place. But such a diminution of the wall discloses more of the spot itself, and hence the spot areas, measured on the eastern half of the hemisphere, might be expected, *cæteris paribus*, to be smaller than those observed in the western half. In order to investigate the causes or concomitants of a departure from the average behaviour of spots, the whole mass of observations is divided into four portions, depending upon the position of a planet, and the planets chosen are Venus, Mercury, and Jupiter. If the results are examined it will be found that in the cases of Venus and Mercury there are indications of a behaviour of sun-spots appearing to have reference to the positions of these planets. This behaviour may be characterised as follows:—The average size of a spot would appear to attain its maximum on that side of the sun which is turned away from Venus or from Mercury, and to have its minimum in the neighbourhood of Venus or of Mercury.

The authors leave it for others to remark upon the nature and strength of the evidence now deduced as to a connection of some sort between the behaviour of sun-spots and the positions of the planets Venus and Mercury. They think, however, it must be allowed that the investigation is one of interest and importance; and they trust that arrangements may be made for the systematic continuance of solar observations in such localities as will insure a daily picture of the sun's disc. The influence of blank days in diminishing the value of a series of sun observations is very manifest. The behaviour across the sun's disc of 421 groups of Carrington's series out of a total number of 885 groups has been recorded; the same for 373 out of 544 groups observed at Kew. Thus, out of a total of 1,429 groups, the record only contains the behaviour of 794. Blank days necessitate interpolations. It is, therefore, of much importance for the future of such researches that there should be several observing stations so placed as to insure the daily record. These are not experiments that can be multiplied *ad libitum*; for in this case Nature gives us in a year or in ten years a certain amount of information, and no more, while it depends upon ourselves to make a good use of the information which she affords. It is already universally acknowledged that we ought to make the best possible use of the few precious moments of a total eclipse; but such observations must necessarily be incomplete unless they are followed up by the equally important if more laborious task of recording the sun's surface from day to day.

ACTION OF HEAT AND VARIOUS CHEMICAL AGENTS ON THE PRIMITIVE FORMS OF LIFE.*

DR. CALVERT said that his experiments led him to disbelieve in spontaneous generation; that he had found great difficulty in securing pure water free from germs; but at last he succeeded in preparing it so that it would keep for months without life appearing. He introduced some of this water into small tubes, and placed them near putrid meat; and on opening the tubes from time to time life was observed after twenty days, whereas in the pure distilled water in the flask no life appeared. If the production was spontaneous, why, he asked, did not life appear in the liquid contained in the inclosed flask, as well as in the tubes which had been exposed to the atmosphere? Speaking of the effects of heat, he proceeded to say that he had found that the greater portion of all microscopic life was destroyed by a temperature of 200° Fahr., but that there was one form which survived all temperatures below 300°. He dipped calico in a putrescent solution of albumen, and then submitted it to a temperature of 300°. The calico was softened, but a black opaque vibrio was afterwards found to be as lively as ever. To test the action of various chemical agents, mostly disinfectants, he added the one-thousandth part to one part of a solution of white of egg and four of pure water. In the first series the white of egg solution was quite fresh; in the second it was alive with vibrios. Thirty-eight substances had been experimented on, and special note was made when vibrios, fungi, and odour were first observed:—1. Chloride of lime or bleaching-powder, instead of stopping, actually promoted, the decomposition of the albumen liquid—vibrios were found in great abundance, but no fungi. 2. Sulphate of quinine retarded the production of vibrio life, which appeared on the twenty-sixth day; but even after eighty days there were no fungi. 3. Acids promoted the formation of fungi, particularly the sulphuric and acetic; whilst arsenious acid had no marked effect. 4. Alkalies, on the other hand, promoted the formation of vibrios, and prevented the growth of fungi. Chloride of zinc and bichloride of mercury prevented the formation of vibrios, and fungi were not found before the fifty-third day. 5. Carbolic and chrysolic acids were the only agents which prevented the formation both of vibrios and fungi. 6. Permanganate prevented smell, but had no effect in retarding the production of primitive life. In the second series the albumen solution was putrid and full of life. Sulphuric acid and acetic acid seemed to paralyse the microscopic life, but at the end of twenty-four hours the vibrios recovered, and then fungi began to form rapidly. Soda produced little or no effect. Ammonia and lime promoted the putrescence, and had very little effect on the microscopic life. Chloride of zinc destroyed the greater part of life, and there was no reappearance until after 80 days. Sulpho-carbolate of zinc is nearly as powerful as chloride of zinc, and Dr. Calvert thought it would prove a most convenient and useful disinfectant. Permanganate destroyed the odour, even for eighty days, but life continued most active. Sulphate of quinine did not affect the motion of vibrios. After six days the putrid odour was increased, but no fungi were formed. Picric acid acted in the same way. Charcoal added to the pure albumen prevented the development of smell. Vibrios appeared at the end of six days, fungi at twenty-one days, and putridity at fifty. Added to putrid albumen, the putrid odour was removed, but life was unaffected. Under no circumstances was life entirely destroyed. One part of putrid albumen solution was added to two parts of strong sulphuric acid. There was a great rise of temperature, and yet the black vibrio before noticed was as lively as before.

In the discussion which followed, Dr. Letheby remarked that bleaching-powder acted by supplying oxygen, which was an important agent in the production of life, but it might nevertheless act as a powerful disinfectant. It was most important not to jump to the conclusion that infectious matters were necessarily associated with microscopic life. He could not understand the action of sulphate of quinine, for he had a vivid recollection that decoction of bark was apt to become mouldy.

Dr. Barclay believed that vibrio and fungus life had very little to do with disease. He believed disease arose from putrefactive change in dead animal tissue, and from this, while undergoing a special process of change, being introduced into the living tissue, and superinducing a similar change in the living tissue.

* By Dr. F. Crace Calvert. Delivered before the Association of Medical Officers of Health.

INCREASE OF HEART-DISEASE.

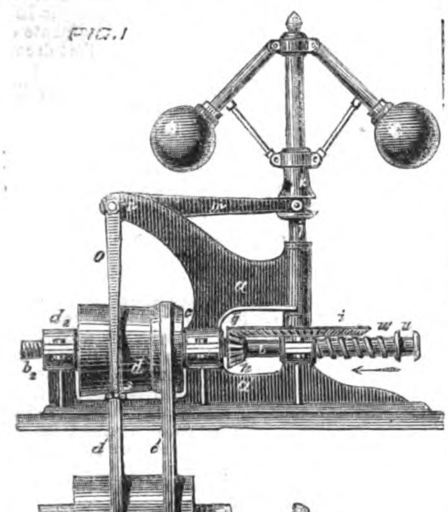
THE tendency of modern investigation into the influence of civilisation on longevity seems to show a twofold series of agencies at work. On the one hand, sanitary improvements and the lessened mortality from epidemics undoubtedly tend to diminish the average death-rates; but, on the other hand, there is practically much less improvement in total death-rates than might be expected if these ameliorating causes were not counterbalanced by the increasing fatality of other classes of disease, such as diseases of the brain and heart. It is important to recognise the precise facts. The excess may, probably, to some extent, be regarded as an unavoidable result of the great mental strain and hurried excitement of these times, in which steam and electricity mark time for us, in an overcrowded community, where competition is carried to the highest point, and where the struggle for existence, not to say for intellectual and other distinction, is carried on with sleepless and exhausting energy. But an evil recognised is sometimes half cured; and the intellectual classes, looking at figures such as those Dr. Quain has displayed at his interesting Lumleian Lectures at the College of Physicians on Diseases of the Walls of the Heart, may well consider the propriety of attending to the hygiene of their lives, as well as of their houses; and to remember that, to enjoy and benefit by even pure air, soil, and water, they must avoid disabling heart and brain by the incessant labours which too often make useful lives joyless, and embitter the harvesting of the crop which has been too diligently shown. These warning figures tell that, during the last 20 years, the total of deaths of males at all ages from heart-disease has increased in number from 5,746 in 1851 to 12,428 in 1870. The percentage of deaths from heart-disease for 1,000 of population living was ·755 between the years 1851 and 1855; it has risen to 1·085 from 1866 to 1870. This increase, it must be observed too, has taken place wholly in connection with the working years of active social life. There is no change in the percentage of deaths from this cause in males under 25 years of age. Between 20 and 45 years of age it has risen from ·553 to ·709, and that almost exclusively in males, for there is almost no increase in the percentage of females dying from heart-disease during the 25 years of life from 21 to 45. These figures convey their own lesson, and warn us to take a little more care not to kill ourselves for the sake of living.—*British Medical Journal.*

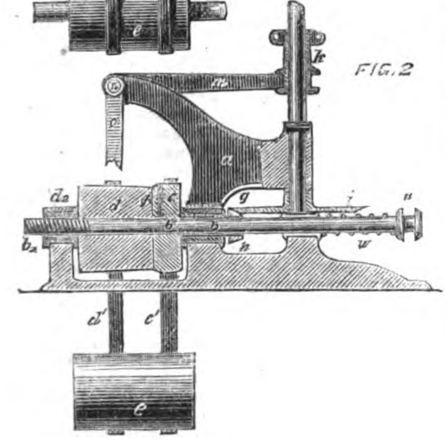
SIMMONDS'S GOVERNOR.

WE subjoin illustrations of an arrangement of governor for steam engines or water wheels, designed by Mr. William Edgar Simmonds, of Hartford, Connecticut. Fig. 1 being a side elevation and Fig. 2 a vertical longitudinal section. In these figures *a* shows the supporting bracket or frame, and *b* the main shaft, on which are two pulleys, *c* and *d*. The latter of these is the frustrum of a cone, whose diameter at the centre of its length is the same as the diameter of the pulley, *c*. Both these pulleys are driven by belts from the drum, ...

is of equal diameter throughout its whole length. These belts are indicated by the letters c^1 d^1. Neither of these pulleys, *c d*, are fast on the shaft, *b*; but the shaft is made to always revolve with the pulley, *c*, by means of a pin, *f*, driven through from the circumference, its inner end projecting into a slot made in one side of the shaft, and extending from the point, b^1, to the end b^*, which, while it serves to make the shaft, *b*, revolve synchronously with the pulley, *c*, yet allows it to move back and forth lengthwise.

From the side of the pulley, *c*, a sleeve, *g*, fitting around the shaft, *b*, and serving as a bearing both for itself and the shaft, extends through the frame, *a*. Upon the side of this sleeve is the small bevel-wheel, *h*, gearing into the horizontal bevel-wheel, *i*, which is fast on the shaft, *j*, to the upper end of which is attached a common ball-governor, actuating the sleeve, *k*. This sleeve moves the arm, *m*, attached to the shaft, *n*, to the opposite end of which is fixed the arm, *o*, attached at its lower end to the fork, *s*, which controls the sidewise movements of the belt, d^1, so that, when the balls of the governor rise, the belt, d^1, will be shifted from the centre of the latter toward that side of the pulley where the diameter is the smallest, and when the balls fall the opposite effect will be produced.





The pulley, *d*, has a sleeve, d^*, upon its side, which serves as a bearing for itself and for the shaft, *b*. Within this sleeve a screw-thread is cut upon the shaft, *b*, which fits in a female screw in the sleeve, d^*. The effect of this arrangement is this:—The ball governor is so adjusted that, at the speed which it is desirable to observe, the sleeve, *k*, will be in the centre of its vertical play, and at this point it should hold the belt, d^1, in the centre of the length of the pulley, *d*, so that it and the pulley, *c*, will revolve synchronously.

Now suppose a greater load to be thrown on the engine, or other motor, the balls will fall, and the belt, d^1, will move toward the large end of the pulley, *d*. This will cause the pulley, *d*, to revolve more slowly than the pulley, *c*, and will cause the shaft, *b*, to move lengthwise in the direction indicated by the arrow, which movement, by means of proper connections, made from the collared groove, *u*, will allow more steam or other motive power to have access to the motor, and this movement will continue till enough of the motive power is admitted to attain the desired speed, when, of course, the belt, d^1, will move back to the centre of the pulley, *d*; but—and this is the important feature of the invention—the shaft, *b*, will not move back toward its first position unless the belt, d^1, moves beyond the centre of the pulley toward the smallest diameter of the latter. When the speed of the governor balls exceeds the desired rate this action will be reversed, and the shaft will move in the opposite direction, and the steam or other motive power will be shut off till the desired speed is again reached; but as before the shaft will not again move toward its first position till the belt, d^1, passes by the centre of the pulley, and toward the large end; so that, however much the power or the load may vary, the governor will immediately adapt itself thereto, and still maintain a uniform rate of speed. The difference between it and the common ball governor is readily explained.

In using the common ball governor no more steam can find access to the cylinder when the load is increased unless the speed slackens, and the balls are thus allowed to drop down, while to give a continuance to extra steam the balls must remain down, and the speed remain decreased; and *vice versa*, when the load is lightened and the speed becomes too much accelerated. In Mr. Simmonds's governor, on the other hand, when the load or the power is varied, the supply of steam is modified until the requisite speed is attained, and the valve is then left at that point till the speed again varies from the desired rate. When the belt, *d*, is running on the centre of the pulley, *d*, which it will do when the balls are running at the desired speed, both the pulleys, *c* and *d*, are running at the same speed, and the shaft, *b*, is stationary so far as its length-wise motion is concerned.

If, by any chance the end, b^*, of the shaft, *b* should move so far out in that direction as to entirely clear the screw from the female thread, then the spiral spring, W, will press the shaft in the opposite direction, so that the screws will again engage when the opportunity is offered. The object of this arrangement is to prevent the valve or gate being operated upon after it is pulled open to its full width, as would be the case if the screw thread on the shaft, *b*, moved continuously. After the valve is open to its full width, to move it further, will of course, be of no use.

Of course, the pulley, *d*, instead of being the frustrum of a cone, might be made of equal diameter throughout, and the drum which drives it might be the frustrum of a cone, and the same purpose would be served.

If, for any reason, it is found desirable to have the difference between the diameters of the cone-pulley anything very considerable, then the same friction—at all times—on the belt can be attained by the use of a small idle pulley. It is not deemed necessary to show how the shaft, *b*, is connected with the valve or gate which controls the inlet of motive power to the engine or wheel, that being a very simple matter to do, the connection being made from the collared groove, *u*. In using this governor on steam-engines it can be connected directly with a stationary cut-off, or be made to control a cut-off which is the steam valve itself, or be made to control the position of the "block" in a "link," or to control any of the valves in use.

According to *Engineering*, one of these governors is at work with most satisfactory results at the Phœnix Works, in Hartford, Connecticut, U.S.A., where the inventor is employed as foreman, and preparations are being made to commence the manufacture on a large scale for the American market.

SPIRAL GRAILING.*

THE operation called "grailing," by which a flat surface of wood or ivory is prepared, previously to being ornamented with the eccentric cutter, drill, or other instrument, is usually performed by cutting a series of fine concentric circles from the circumference to the centre of the work, produced by moving a pointed tool in the slide-rest, say the 150th or 200th of an inch for each cut, until it forms a mere dot in the centre. This is a slow and tedious operation, especially on a piece of work of any size—such, for instance, as the lid of a box four inches in diameter, and unless the greatest care be taken to move the tool the exact distance for each cut, certain circles will catch the eye more than others, and the surface will not have that even, "dead" look, which contrasts so well with the ornamented portions. Moreover, the point of the tool is apt to lose something of its sharpness before the grailing is completed, and thus, again, the surface may lack that evenness of appearance which is its greatest beauty. Many turners are, of course, aware that grailing may be effected by means of a single fine spiral line, running from the circumference to the centre of the work, and some lathes are fitted with the necessary apparatus for doing this; but I think the practice ought to be more generally known than it seems to be, for the trifling addition to the lathe which it requires is within the power of any amateur to make for himself, while there can be no question about the saving of time which it effects, in spite of the minute or two required for putting the bands in position; and the result is in every way satisfactory, the surface presenting a perfectly even, uniform appearance, fully equal, if not superior to ordinary grailing when performed in the most careful manner, and, like it, showing a beautiful play of light as it is moved about in different positions. It is, of course, requisite that the surface should be perfectly flat and even before commencing the cut, and that the tool should be as sharp as possible. This sharpness will be found to be much better maintained during the cutting of one spiral line than when the tool has to cut a considerable number of separate circles. All that is necessary is to connect the screw of the slide-rest with the mandril by a series of bands, in such a manner that the point of the tool will move slowly across the face of the work, while the latter revolves rapidly on the lathe. This may be effected in the following manner.

The usual lathe-band, from the largest groove of the driving wheel of the lathe to the smallest groove of the mandril pulley, gives a rapid motion to the work. A second band passes from the smallest groove of the double-bevelled wheel to the largest on the left-hand pulley of the overhead gear. A third band descends from a *very small* pulley on the overhead spindle to a large one fixed upon one end of the slide-rest screw. This wooden pulley or wheel, as well as the smaller one from which it is driven, any turner may make for himself of box or other wood. It should have a square hole through its centre if it is to be slipped on the square end of the slide-rest screw, which may be done if the overhead gear admits of being pushed sufficiently far back over the bed of the lathe to bring it directly over the right-hand end of the rest as it stands across the lathe-bearers; or, if the slide-rest is adapted for the spiral apparatus, and has a projecting piece at the left-hand end of its screw, the wooden pulley or wheel may be placed on that. In my own case, in consequence of the limited range backwards and forwards of my overhead spindle, which is supported by two uprights rising from either end of the lathe-bed, I was unable to place it directly over either end of my slide-rest, and therefore had to make my large pulley on the larger end of a conical piece of boxwood, hollowed out so as to admit within the hollow about 3in. of the left-hand end of the rest. In this manner I was able to bring the groove of the wooden wheel beneath the overhead spindle. Of course, a simple stout disc of wood with a groove formed on its edge is sufficient, if the end of the rest can be placed immediately below the spindle. Any desired degree of fineness can be given to the grailing by altering the position of the lathe-band. The following are the diameters of the various wheels and pulleys that I use, and find to answer.

Large wheel, about 27in. diameter.
Mandril pulley, about 3¾in. diameter.
"Slow motion" of driving wheel, about 14in. diameter.
Large pulley overhead, about 4in. diameter.
Small pulley, about 1¼in. diameter.
Wooden pulley on slide-rest, about 5¼in. diameter.

These proportions produce grailing as fine as can possibly be required—almost too fine, as it takes good eyes to distinguish the lines at all. By shifting the lathe band to about the centre of the large bevel of the driving wheel and of the mandril pulley, grailing is produced of about the usual degree of fineness. As, from the smallness of the lesser pulley on the overhead spindle, the band might possibly slip upon it should the slide-rest screw work at all stiffly, or the work offer too much resistance to the tool, it is as well, instead of forming its groove of the usual V shape, to leave it of sufficient width to allow of the band, which should be of small catgut, being passed twice round it.

In grailing by the means here described, the tool should be so set as to penetrate no deeper than will suffice just to remove the original surface of the work from between two adjoining coils of the spiral line. If it be set to cut too deeply, the work is apt to be torn by it. The progress of the tool, which must always be from the outer edge or circumference of the work towards the centre, must be carefully watched, and the moment the centre is reached, the tool must be withdrawn quickly. G. C. C.

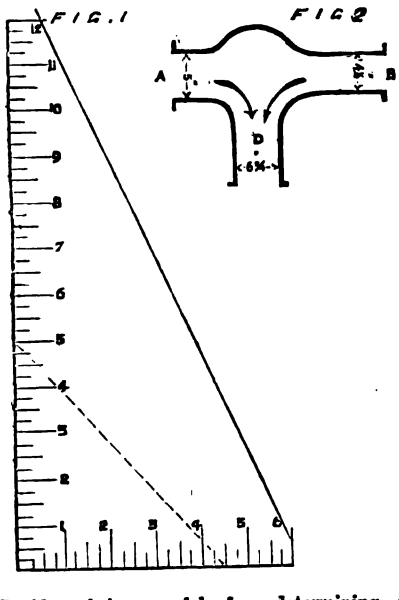
* From *The Quarterly Journal of the Amateur Mechanical Society*.

Brilliant Experiments.—The *American Chemist* reports some lectures on science that appear to have been illustrated with experiments of unexampled brilliancy. President Morton, of the Stevens Institute, in a demonstration of the decomposition of light, produced a rainbow 15ft. in diameter. Professor Barker, of Yale College, in a lecture on the "Chemistry of the Sun," managed by means of the electric light to project upon the screen continuous spectra 20ft. in length, and successfully reversed the sodium line. By some ingenious devices of Professor Morton a representation of a total eclipse of the sun was given, showing the advance of the moon, the crescent sun, Bailey's beads, and, at totality, the outburst of the corona, and the red prominence or solar flames. The formation of the sun flames was further illustrated before the vertical lantern by means of a layer of water, coloured red by carmine, at the bottom of a tank of clear water. The flames were produced by passing electricity through a fine coil of wire in the tank, for on heating the wire the red liquid was carried upward.

THE PROPORTIONS OF PIPES.

ANNEXED is a sketch of a handy little contrivance, designed by Mr. G. Cockburn, of Glasgow, for ascertaining the diameter of a pipe, &c., having a sectional area equal to that of two other pipes, or *vice versa*. The instrument consists simply of a piece of wood or cardboard shaped like a set square, as shown in Fig. 1, or a diagram of the same form drawn on paper, and divided out along the two edges which are at right angles to each other, the divisions being taken to represent inches, feet, or yards, &c., according to the kind of work for which the instrument is used. When employed for determining the equivalent diameters of pipes or bars, inch subdivisions are generally found most convenient.

The mode of using the instrument will be readily understood from an example. Suppose, for instance, that two pipes, A and B (Fig. 2) respectively 5in. and 4½in. in diameter, deliver into a third pipe, D, and it be required to find the proper diameter for the latter pipe. Then from 5 on the scale of one of the divided edges to 4½ on the other draw a line, as shown in Fig. 1, and the length of this line measured with the same scale as that to which the edges are divided will be the diameter of pipe required—in this case 6¾in. On the other hand, if a pipe, D, 6¾in. in diameter, be delivered into a pipe, A, 5in. in diameter, and it was required to know what other size of pipe, B, should also be supplied, all that would be necessary would be to take the division point 5 on one edge as a centre, and with 6¾in. as a radius, describe an arc cutting the other divided edge. The point at which the latter edge was cut by this arc would show the diameter of pipe required.



Besides being useful for determining the diameters of pipes or circles of equivalent areas, the instrument is also available for determining the sides of equivalent squares, while by a little contrivance it can be made available for determining the diameter of a pipe or bar having a sectional area equal to the aggregate sectional areas of any number of other pipes or bars of which the diameters are known. To use it for this purpose it is only necessary, first, to determine by its aid the diameter of pipe or bar equivalent to any two of the whole number, and next to ascertain the equivalent of the diameter thus ascertained, and that of a third pipe or bar, and so on. The arrangement of the instrument is, of course, founded on the fact that the areas of squares and circles increase as the squares of their sides and diameters respectively, and that the square of the hypotheneuse of a right-angled triangle is equal to the sum of the squares of its two sides.

SCIENTIFIC SOCIETIES.

THE METEOROLOGICAL SOCIETY.

AN ordinary meeting of this Society was held on Wednesday, March 20, Dr. J. W. Tripe, President, in the chair.

Thunder Storms.

A paper was read by R. H. Scott, Esq., Director of the Meteorological Office, entitled "Notes on Thunder Storms during the last six years." The author remarked that on the Continent the disastrous effects of thunder and hail storms had given rise to the existence of offices for effecting insurances upon property and stock in the event of the destruction of either by lightning or hail, and while Continental meteorologists were engaged in tracing out the tracks, and ascertaining the principal features of thunder and hail storms, it behoved English meteorologists to be up and doing, so that they might not be left ingloriously behind in the race in which our neighbours were engaged.

The Scottish Meteorological Society had already examined the thunder storms recorded at its stations during twelve years. The storms mentioned in the present paper extended only over half that period, the data having been contributed by fourteen stations connected with the office. The most remarkable results were that London had furnished the greatest number of thunder storms, 84 having been recorded in the metropolis, and that the next large number, 64, had occurred at Valencia, on the west coast of Ireland. The distribution in time of these storms is interesting, the greatest number occurring in July at London, and in January at Valencia. A secondary maximum at Valencia occurred in September. On the contrast between London and Valencia, Mr. Scott remarked that the great winter gales which impinge on Ireland and our western coasts are highly charged with clouds, and he consequently attributes the occurrence of the winter maximum at Valencia to the arrivals of the winter gales.

In the discussion which followed the reading of this paper, Mr. Glaisher said that even as compared with Greenwich, London had the greatest number of thunder storms; a storm coming up over Greenwich is generally deflected either over London or Epping Forest. A speaker alluded to the fact that the maxima of large rain-fall usually occur in the winter, and those of small rain-fall in the summer, and suggested that as Valencia has a large rainfall, the maximum both of its rain and thunder storms would be observed in the winter; while in London, which has a smaller rain-fall, these phenomena would occur in the summer. In reference to a suggestion that London contains numerous spires, Mr. Scott mentioned that having resided some little time in Munich, where spires are both lofty and numerous, he could bear testimony to the frequency of thunder storms, and it is well known that in that city they are more numerous than in many other places on the Continent.

Acid Bulb Thermometer.

Mr. Whitehouse read a paper on "A Modification of the Wet and Dry Bulb Thermometer," in which he proposed to obviate the uncertainty attendant upon the use of the wet bulb in frosty weather by employing a third thermometer, the bulb of which should be kept constantly covered with a film of concentrated sulphuric acid. A drawing of the instrument was exhibited, in which it was shown that the mode of supplying the bulb with acid was by means of a siphon, by which a regular flow was secured. The author explained the action of the acid bulb to be that of absorbing moisture from the air, and the evolution of heat in consequence of the mixture of the moisture with the acid, the result being that the acid bulb reads constantly higher than the dry, and gives directly the amount of vapour in a given space of atmosphere. The sensibility of the acid bulb was described as being ten to one that of the wet bulb. The paper was accompanied by numerous results of observations projected in curves.

An interesting discussion followed the reading of this paper, the President pointing out several difficulties which presented themselves to him as affecting the use of the instrument. Mr. Glaisher considered that the author had broken some important ground, as especially connected with the unreliability of the wet bulb when frozen. There is much, doubtless, to work out as regards the general principle, but it is an endeavour to meet a difficulty which is continually presenting itself at low temperatures. A question was asked relative to the effect of electricity on the regular flow of acid from the siphon on the bulb, and in reply it appeared that the delivery of the acid could be regulated with considerable nicety. Some experiments were made on the evolution of heat by immersing the bulb of a delicate thermometer in sulphuric acid.

At the conclusion of the meeting, Mr. Scott announced the issue, by the Meteorological Office, of daily weather charts.

Meteorological Conference.

Dr. Buys Ballot has issued a pamphlet (in English) entitled "Suggestions on a uniform system of Meteorological Observation," in the preface to which he speaks of a meeting of the General Congress of Meteorologists to be held, probably at Vienna, in the course of the present year. That much remains to be effected in the various branches of meteorological inquiry there can be no doubt, and if a perfect understanding between the leading meteorologists of the world were established, much valuable time would be saved, and much misdirected effort prevented; and it is to be hoped that at the anticipated Congress the important subjects now engaging the attention of theorists and observers will receive the consideration of the distinguished physicists who will doubtless form the members of the Congress. With the view of saving the time of the Congress, and of giving a greater circulation to his own views, Buys Ballot has written the pamphlet, and adopted the English language as being widely known. His principal aim is to draw attention to the *general method of observing*, and of printing records of the facts observed at the least expense, in order that particular investigations may be facilitated. In the establishment of a uniform system of observations throughout the world, we recognise a power far superior to the imperfect and disconnected systems of the past, and while Buys Ballot is devoting all his energies to securing so desirable a result, there is another portion of the work of the Congress which we trust will not be lost sight of. In meteorology, observation is an advance of theory. Millions of observations are accumulating, and we may ask the question, when and how will they be used? Investigations, some of which are mentioned by Buys Ballot, for example, the progress of storms, the origin of depression, systems and the laws of winds prevailing in all parts of the globe need a *theory* to connect them, and to show their dependence on certain physical and thermal conditions. The Congress will do but half its work if amongst its members it lacks those, who, with enlarged views of the physics of the globe are capable of setting forth a theory which—by its unbending mathematical relations, its cognisance of forces which produce those disturbances so useful, and at times so disastrous, to man and its power of grasping facts of various complexions—can be employed in solving the great problems of the meteorology of extra tropical regions. It is the theory of meteorology that needs advancing, and we hope that this great object will receive its due attention from the Congress.

THE IRON AND STEEL INSTITUTE.

A PAPER entitled "On Dormoy's Process of Mechanical Puddling," by Frederick A. Paget, C.E., was read at this Institute recently:—

The plan about to be described has been applied to forty puddling furnaces in different parts of Austria and France. The nearest of these works are at Rimancourt in the Department of the Haute-Marne, France. Three of M. Dormoy's apparatus are now there at work, and the plan is being adapted to all the remaining puddling furnaces. Its leading feature consists in placing a rabble, rapidly rotated by steam power, in the hands of the puddler. The ordinary furnace itself is left unchanged, except that the sides of the beds are set at an angle instead of being vertical.

To adapt the plan to any common existing puddling furnace, a shaft conveying power from any prime mover is carried about six feet above the furnace. A belt from a pulley transmits the rotation of the shaft to another pulley or sheave below, which rests on the belt a little in front of the furnace door. One end of the boss of the pulley is so jointed to a handle held by the puddler that the pulley can rotate without carrying round the handle. The other end embraces the outer end of the rabble, to which it is held by a cross-pin. The belt is thus made to rotate the rabble in any required position, in a somewhat similar way to the well-known rotating hairbrush. The number of revolutions employed is from three to five hundred per minute for white pig iron, and from eight hundred to one thousand for gray pig iron. The belt, while carrying and rotating the rabble, endows it with mechanical energy, and allows the stirring and puddling action to be directed to any portion of the molten metal. The rapidity with which the tool can be worked round gives the metal such an impulse that it turns horizontally on the bed, continually renewing the surfaces in contact with the atmosphere.

The point of the rotating rabble, instead of being hooked, carries a disc. When the iron has come to nature, this is replaced by a rabble having a short twisted point.

The following are figures giving the work done at Rimancourt by one of these furnaces during the first two weeks of last December:—

Working day of 24 hours—1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15; number of charges—23, 23, 23, 24, 24, 24, 25, 28, 26, 25, 26, 26, 25, 24, 23.

Total—369 charges, during which the furnace was fettled only nine times, or an average of one fettling per 40 charges.

The charges of pig and of hammerslag for the furnace bed amounted to 97,060 kilogrammes. The amount produced 81,921 kilogrammes, with an expenditure of coals of 45,240 kilogrammes, which gives 1,185 kilogrammes of pig per 1,000 kilogrammes of wrought-iron, with an expenditure of only 552 kilogrammes of coal per metric tonne.

Briefly, the result of different trials shows an increase of at least 30 per cent. in the yield, with a proportionate diminution in the consumption of fuel. In spite of the greater number of charges, the puddler is very little fatigued.

This process, both in Austria and France, is found to eliminate phosphorus and sulphur to such an extent that inferior brands of pig produce iron equal to charcoal iron.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the Editor of the ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

All Cheques and Post Office Orders to be made payable to J. PASSMORE EDWARDS.

"I would have every one write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

*** *In order to facilitate reference, Correspondents when speaking of any Letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

TERRESTRIAL GRAVITATION.

[3828.]—WITHOUT at all wishing to say anything that may annoy "T. A." I am compelled in answer to his queries (letter 3827) to assure him that he is wandering hopelessly. Why on earth should eight chords in a circle, converging to a point on the circumference, represent the attraction exerted by a globe upon a point at its surface? This is simplifying matters with a vengeance. Of course, if the chords *did* represent all the forces, his method of resolving these forces into a single force would be perfectly correct; but they don't. They do not even in any way come near representing any of the forces.

If "T. A." will insist on attacking questions lying beyond his (present) range, he must not be surprised if he gets explanations "too intricate for his comprehension." I answered as I did because, first, I did not wish to say point blank "it is useless to answer," and secondly, because others might find a use in an answer too intricate for "T. A." But, if "T. A." will only take this assurance from me, that *the attraction of a sphere on a particle outside it or on its surface, cannot possibly be determined without the use of the integral calculus*, he will perhaps understand why I cannot make the matter altogether clear to him. I have a tolerable knowledge of what can be done without the integral calculus (for I took my degree at Cambridge when I was almost wholly ignorant of the calculus), and I have over and over again attempted to master this very problem by considerations—not simple indeed, but still—not directly involving the integral calculus. I have been able to satisfy myself that the thing cannot be done. "T. A." might as well try to catch a whale with a hairline gut and a minnow hook as attempt to master the problem on his present line.

Every particle in the sphere must have its attraction separately taken into account, and then all such attractions must be summed up. Nothing short of this will do, and this sort of summation, viz., of an infinite number of infinitely minute quantities, is the special work of the integral calculus.

RICHARD A. PROCTOR.

HOW WE SEE A DISTANT OBJECT.

[3829.]—"E. J. D.'s" letter (3493, p. 510) invited explanation either from me or from "some of your clever correspondents;" and as I could not explain his difficulty, but greatly wanted to have his query explained, I waited the action of the clever correspondents. As "E. J. D." has now addressed his query to "F.R.A.S.," whom he rightly describes as your very clever correspondent, he is almost certain of an explanatory response, while I look forward, not unhopefully, to some remarks from "F. R. A. S." suggesting what may be the real nature of "E. J. D.'s" difficulty. For between the mirror at one end of the room ("carefully arranged to exclude all light with the addition of the walls, &c."), the shutter somewhere, and the opaque screen projecting from some wall, and the camera at the other end on a similar table "in a right line with the former," I am utterly bewildered.

Whatever may be the nature of "E. J. D.'s" difficulty and its explanation, I feel tolerably safe in denying the justice of the "old theory" "that the eye has the power of directing the electricity (which is everywhere) on a distant object (illuminated) and receiving back the correct image thereof" (that is, I suppose, of the object), "the convex lens having the same power." I cannot quite imagine this to be a correct view of anything in particular. What does "Sigma" say about this power of the eye in directing electricity? I can imagine a pair of eyes directing something very like electricity (in its way) upon a not too distant object, and a correct image of the object coming in the course of events into the possession of the owner of those eyes. But this seems a long way from "E. J. D.'s" difficulty.

I find that by not trying to understand "E. J. D's" explanation, and as it were "averaging everything" in his letter, the idea is suggested that what he really wants to know is how a mirror can be seen when the rays its polished surface reflect do not reach the observer's eye, but are quenched or got rid of. In this case the answer is undoubtedly that scattered reflection renders the frame of mirror discernible. The glass of the mirror is not seen. Indeed, the glass of a mirror can only be seen under exceptional conditions if the mirror be a good one. But we recognise the shape of the mirror whenever any light at all reaches its whole face, because the frame does not specularly reflect the incident light (or much of it) while the quicksilvered glass does.

When the mirror is removed the course of the ray is seen, because the ray illumines the dust always floating in the air. The paper on "Atmospheric Dust," at pp. 5 and 6 should be read. RICHARD A. PROCTOR.

SAVE US FROM DECIMALISM!

[3830.]—ONLY one bit of sense, that of "Scrutator" (p. 661) to at least six recitals (p. 630, let. 3723, p. 661, 3760 2-3-4, and p. 12, 3806) of the stale brags of this paragon of blundering priggery. "But one poor halfpenny 'orth of bread to all this intolerable lot of sack!" The first, indeed, Mr. Petrie sees, like "Scrutator," the delusion of the French standard (for on every detail of the wretched scheme a Nemesis seems to have poured all possible irony); but, nevertheless, he is for pure decimalism, the chief and radical blunder of the whole! And he even fancies our old measures were once centesimal, and in making them so, the perch for example = 200 inches, we should be restoring something lost! I defy him to find proof that our race were ever so absurd as to repeat tens in the successive steps of any table, or to make units in the ratio of 100 or any square number above 36, though Mr. Bottone fancies (p. 662) that ancients "in nearly all cases" made systems what he calls "uniform and consistent throughout." They everywhere knew better than to do any such thing, with any lesser steps than the Chaldean sixties. All over Christendom they had what he calls "*our* mixed quarternary, duodecimal, and ventesimal" money table, and denoted its units by the letters £., *s.*, *d.*, *q.*, which he must be aware never stood for English words. The names and ratios were common to Europe, and so had the actual values—the weights of silver—been at one time; but successive royal swindlers in different kingdoms, of course, debased the standard to different extents; furthest in France, where the *livres*, *sous*, and *deniers* came down to about an *eightieth* of true libræ, solidi, and denarii; but the least in England, where, even since our Tudors, we still have them little under a *third* of the originals.

I must come, however, to the next critic, "Metric System" (let. 3760), who answers his own question, "is it inferior or superior to others in use?" amusingly enough. Ten lines further he tells us he "need not fear the denary division of days." The Chaldean divisions of time he thinks firm enough to last. We need not *fear* denary time will supplant them! So then he tells us which would be to be *feared* if it had a chance; that seems much the same as telling which is the "inferior."

But he meanwhile commits a great error of fact in saying "the week has from time immemorial been universal." It has never yet extended to even half of learned and civilised mankind. A majority of our race, by their own accounts, and as the best informed of our westerns believe, dwell east of the Ganges, and all those nations have not, nor "from time immemorial" ever had a week; but instead thereof a cycle of sixty days; and to which (even more than their cycle of sixty years instead of our century) our astronomy may be extremely grateful, for its immense utility in preserving the exact dates of observations of theirs long before Europe was scientific enough to preserve any.

Next, let me assure "Campanile" (let. 3761) I did not leave his "dodecadic" system unmentioned from oversight, but design. I was quite aware that this preposterous mare's nest (with its two new figures for ten and eleven) is the triumphant invention of about three new geniuses per generation, and will continue to be invented as regularly as circle-squaring or perpetual motion; and that wise "Sigmas" will lay down (like "ours," p. 662) it "would be far preferable" to the immemorially used Ninevite sexagintals. The only news to me is that the dodecadic system was ever taught at St. Cyr, a bit of priggery perfectly worthy of Frenchmen who had produced the hardly more crude and shallow scheme of universal decimalism. Of course they were led to it for the sake of the one advantage of terminating fractions whose denominators are 3 and its powers. But this will never be worth the two added numerals and proportionally bigger multiplication table, and perplexing change of meaning in all figures above 9. It would not even do if we all became, in one generation, sex-digital like those "born to the giant in Gath." Let "Campanile" and "Sigma" just observe that the mere fact of 12 being one of the six very best metric numbers does not make any of its powers even eumetric; nor yet its multiples in general, beyond the first 4—not even 72, the half of the next unit that would be written "100," nor any of those written with a single numeral, except "500" (our 720), nor any written with 00 till the septuple of that, and not only no power of the base 12, but no half or double of any power of it. But in the Ninevite system (which, observe, uses no figures but our ten) the first compound unit (written 1,00) is one of the six that excel metrically all under their double, and not only itself but its multiples, 2,00, 3,00, 4,00, 6,00, 12,00, 14,00, 21,00, 28,00, 42,00, are all eumetric numbers, ten successive ones of that useful series being thus expressed, five with but one numeral, and five with two; and the two upper of the superexcellent ones (our 360 and 2,520) by one and two—namely, as 6,00 and 42,00. These facts make it no wonder that while the dodecadic system, perpetually retried, has never got the least footing; the sexagintal (that "Sigma" dashes off as "far more impossible") has left marks everywhere, from the Chinese day and year cycles to our minutes and seconds, and in its purity (at least for descending notation) held its ground as the standard scientific method, really through "immemorial time," from undated Nineveh and Babylon, through Greeks, Romans, Arabs, and revivers of learning, down to Fahrenheit, and even this miserable century; which made, in its opening years, the experiment by which, "Sigma" tells us, "it is pretty clear that calculations would be greatly facilitated," by "dividing the right angle into 100°," more laboriously and thoroughly than perhaps experiment was ever made, and with utter failure! I have before me and in use Callet's logarithmic tables, whereof about 100 leaves in the middle are taken up by the trigonometric functions of this very division, stereotyped and embodying, probably, some scores of people's some years' labour; and, like most users of the book, I long ago found it worth while just to pass a needle and thread through the outer margin of these 100 leaves, so that they may all turn *en bloc!*

But I am glad of "Sigma's" notable regret that we were not all Goliathites, because the idea has impressed on me how providential for our arithmetic it is that we were *not* so. In that case all human notations would have been either senary or duodenary, and *nothing better*; these would almost have become what "Sigma" falsely lays down the denary notation to be, "an inevitable and natural fact." Even Chaldeans would not have developed the splendid sexagintal improvement for the sake of introducing the third prime number 5, if that number had only presented itself in the petals of flowers and starfish. I never before saw that the five fingers are providential, as well as the ratios of the day, lunation, and year of the planet we are placed on; and thank "Sigma" for the hint. Of course, I totally deny the ground into which he finds it convenient to say the metric system resolves itself. There is no notation "given as a natural and inevitable fact." If there were, all civilised nations would have used the same; whereas it is a historical fact that the Assyrians never had centesimal notation, and the present French have, perhaps, no other. But "Sigma" neither uses historical fact himself, nor allows my way of using it to remain unperverted. There was nothing of the good old Tory, or "whatever is, is right," in my argument from general practice. I never implied that "*these* compound arithmetics," any *particular* ones, must be good because ages had used them, but that compound arithmetic, *as a principle*, distinct from "simple," or the general principle of what Mr. Bottone stigmatises as "mixed" numerations, would not have appeared or held sway (as it has everywhere) if not having real advantages over what he calls "uniform and consistent" systems. I believe we might repeat continually (like the Assyrians) the step 60, but that no lower number has ever been found good enough to be so used. If only the sixteenth century trigonometers had adhered to Ptolemy's notation of the straight measures, radius, sine, &c., which he expressed sexagintally as well as the arcs (instead of absurdly disconnecting the lengths of arc and straight function, and making two incommensurable units), then Briggs would assuredly have made 60 instead of 10 the base of his logarithms (whether expressing *them* sexagintally or not, and I believe they would be best not so); and an intelligent adherence, like that of Fahrenheit, to the tradition of this unrivalled system, by later scientific men, together with a compact way of writing it, as I suggested, by two sizes of figures alternately, without the clumsy and, indeed, outrageously needless °, ′, ″, ‴, &c., would by this time have almost, or quite, reduced the inferior denary notation to its right subordinate place. A little thoughtful example-setting by professors of science (when there was any) had more effect on the world, and would have more even now than they dream. They might easily both have prevented the disgracefully retrograde French "system" arising, and have gradually so leavened all arithmetic with the old sexagintals as to make their unrivalled convenience suggest itself to all without argument. Any compulsion in such matters is ridiculously absurd, or any Government action, beyond setting the best example in its own accounts, and striking the best coins, whose ratios (unless decidedly bad like the French) will in time make their way into all other tables but those of time. And those of time are fortunately still either natural or of the very best artificial system, which money ought to follow, and does with us actually, though not in names and notation.

Herschel's "Yard, Pendulum, and Mètre" is not, as Mr. Bottone thinks, an argument for decimalism. "Philo's" theory (p. 663) of the hundredweight (which I once broached myself) will not hold water. He will find any of these neighbouring numbers to 112 would have had the same advantage:—

96	104	120
124	126	127.

Also, with the right seven weights he could weigh not merely all up to the 112th multiple of the lowest, but all up to the 1,093rd. E. L. G.

SIR J. HERSCHEL ON THE METRIC SYSTEM.

[3831.]—I AM much interested in the discussion now going on in "ours" on the subject of a decimal system of weights and measures, and as but few of your correspondents seem to be aware of the work done by Sir John Herschel on the subject, I think an epitome of his views, with certain additions of my own, may prove of interest.

Sir John Herschel objects to the French standard as being unscientific and inaccurate, and because the meridians have not the same length in different parts of the world. The one chosen by the French philosophers was a line from the pole to the equator passing through Paris. No one can seriously doubt the advantage of having a regular system of weights and measures, instead of suffering from the almost entire absence of system, as we do at present. The chief objection to the French system is not that it is founded on inaccurate observations, for there are so many reliable standard metres in existence that the chance of losing them all is extremely remote. The real objection to its adoption is that the people are so obstinate, and object to make any alteration even for their own convenience. In England the enforcement of a new system would meet with peculiar difficulties, owing to the form of government, and to the notion that the right to inconvenience ourselves and other people is part of the liberty of the subject, and a thing to be strongly contended for. Although an octesimal or a duodecimal system would in many respects be preferable to a decimal notation, it must be admitted by every candid thinker that the latter notation is immutable, and it is in the adoption of ten as its basis that the French system has its great advantage, not in its being founded on any really scientific standard of length. If such fragments of system as we possess could be arranged decimally and "patched" without much change, such a system would be preferred by the great majority of Englishmen, as involving a less radical and confusing change than would necessarily occur on the enforcement of the French system. That our present weights and measures can be so patched, and that there is also the advantage of a thoroughly accurate and scientific standard to work from, I now propose to show. Although the number of quadrants of a spheroidal body like the earth are infinite, there can exist but one polar diameter. The length of a straight line drawn through the earth from pole to pole is 500,500,000in. If our present inch were increased in length by only 1,000th part, an almost inappreciable quantity, the length of the earth's polar diameter would be 500,000,000in. exactly. The increase of the inch by the above-mentioned amount would make a cubic foot of water weigh exactly 1,000oz., instead of being only supposed to do so, as at present. Our measures of length are sadly in want of re-arrangement, which could be effected by the introduction of new measures of 10in., 50in., and 100in., &c.

If a cubic foot of water weighed exactly 1,000oz., we should at once have the connection between measures of length and weights, while the measure of capacity is obtained from the measure of 1 cubic foot = 6¼gals., or 4 cubic feet = 25gals., or 16 cubic feet = 100gals. Now, we have ounces and drachms both as measures and weights, the measure of a fluid ounce of pure water being the space occupied by an ounce in weight. As no inconvenience arises from such an arrangement, which, on the contrary, is found to be advantageous, why should we not do the same with the pound and gallon, making each of them both a weight and a measure? In the fact that 10lb. of water = 1gal. we have the germ of a very easy and convenient decimal system of weights and measures of capacity. At present we have a very deceptive weight we call a "hundredweight," which is equal to 112lb. If we had a new weight and measure = 100lb. = 10gals., it would have the advantage of both convenience and truth, and I think such a palpably beneficial change would be readily adopted. To avoid confusion, the new weight might be abbreviated by the letters "hwt.," while the letters "cwt." would mean 112lb. as at present. Our present ton is equal to 20cwt. = 2,240lb. I would propose a new weight and measure of 20hwt. = 2,000lb., to be called a "new-ton" or "Newton." Such a name would entirely prevent confusion, and would serve to remind the user both of the origin of the weight and of the immortal discoverer of gravitation. For quantities less than a pound, I would suggest the introduction of a new weight and measure of 700 grains = 10th of a pound. This is about an ordinary wine-glass in capacity, and thus might be readily extemporised. It might be called a "verre" (the French for wineglass), or shortened to "ver," and symbolised by "V." A weight and measure of 70 grains = 10th V. = 100th part of a pound would be so near the present apothecaries' drachm of 60 grains that it could replace it in nearly every instance. It might be called a "Newdrachm" (Nd.). A weight and measure of 7 grains has already been proposed by Griffin, and appropriately called a "septem." The smaller weights and measures are rarely employed, except in dispensing, and are therefore used by an intelligent class of men, who would soon become accustomed to them. The proposed table of weights and measures of capacity would therefore be as follows:—

7 Grains = 1 Septem.	S. = 7 grains.
10 Septems = 1 Newdrachm.	Nd. = 70 grains.
10 Newdrachms = 1 Ver.	V. = 700 grains.
10 Vers = 1 Pound.	Lb. = 7,000 grains.
10 Pounds = 1 Gallon.	G. = 70,000 grains.
10 Gallons = 1 Hundredweight.	Hwt. = 100lb.
20 Hundredweight = 1 Newton.	Nt. = 2,000lb.

The majority of tumblers do not hold half a pint as popularly supposed, but just about ½lb. = 8oz., and it could readily be made a definite weight and measure to equal exactly ½lb. = 5 Vers = 1 "Tumbler" or "Rummer."

I cannot but think that such a system as the above would be far more readily accepted than the French or any other perfectly new system. At present we have three "quarts" of different value; the reputed wine quart, the imperial measure, and the "Winchester." The latter is just half a gallon, and a very convenient measure = 5lb. weight. At present the "stone" varies from 5lb. to 32lb., and there is little doubt the introduction of a definite weight and measure of 10lb. would meet with a warm welcome.

In my own practice, as a scientific man, I habitually employ the metric system, but I think it possesses but slight advantages over decimalised inches and grains.

Although the French system is the best in use, it is not the best possible, but I should hail its compulsory use as a vast improvement upon the utter confusion and want of system under which we at present labour.

Sheffield. ALFRED H. ALLEN.

SOME HINTS ON METRICALISM.

[3832.]—THE neglect of this really noble and difficult subject for centuries, and the utter chaos into which *laissez-faire* and "survival of the fittest" (for trade mystifications and rascality) have everywhere brought it, produced at length the crude and wretched French decimals; and now the spread of that pitiful disgrace to European intellect, through the same causes, by mere force of its unity against their anarchic and haphazard multiplicity, daily makes attention to the rights and reason of the matter more urgent: if, alas! we were in an age capable of looking to the real ground of any matter, however trifling or simple! Now, it would be one step toward clearness if every arguer would deign to treat quite separately the question of *standards* and that of *divisions*. There is no shade of excuse for mixing up these. They are so independent that a system might have the very best kind of standards and very worst divisions, or *vice versâ*. The standard question is purely one of physics, not directly mathematical at all. The division question, on the contrary, is nowise physical, but mathematical in the purest sense, perfectly independent of what planet or kind of world we might be in, or how many fingers we might have. There is a third part of the subject, nearly, but perhaps not quite as unmixed with physics as the division question—namely, the *interconnection* of the different tables (as that of weight, value, surface, volume, &c.), *i.e.*, the mode of derivation of one unit in each from the unit of length, which as simplest ought to be their basis.

Now, I maintain, and this is also, I believe, the main position of Sir John Herschel in his "Yard, Pendulum, and Metre," that it is only in this third point, the interconnection of dissimilar units, that the French system is at all commendable, or made any advance, or rather, revival of an ancient principle. In both the main essentials, the standard and the division question, its vaunts are ludicrously false, its failure more than remarkable, unique, ironical, almost supernatural. Its kind of standard (which was to be the earth's circumference) is, in fact, though no worse than many others (as the Winchester bushel), yet of the *worst kind* that any the most savage human race ever has had or can have; but worse remains! I further maintain that the other feature of the unlucky system, its uniformly decimal division, is at the same time the very *worst kind* of division any race have yet perpetrated, and almost as bad as possible. (I grant that the continued powers of 5 or 7 would be slightly worse.)

On the former failure, of course, I have plenty to keep me in countenance. As "Scrutator" says, the length of a platinum bar kept at Paris that was intended to be (but is not) such a fraction of the meridian, is exactly as *scientific* as the length of Punch's nose; and though rather more definite and useable, yet incomparably less so, and inferior in every way, than the kind the ancients fixed on as early as Pericles, with perfect success, a recorded round fraction of the dimension of some noble, world-durable building, some "Hecatompodon," hundred-foot fane, as they called their "intactæ Palladis arcem," whose chief steps, front and flank, of 100 and of 225 standard feet, are just as good for the purpose to-day as when squared and polished this very year 23 centuries, and may, therefore (if no comet falls), be as good for 23 more. And still older and less destructible, and equally uninjured, are the built standards (whether meant for such or not) of the pyramid of Cheops, either its rock sockets or his finished, but never occupied, tomb-chamber; or of the two untouched 400-cubit walls, the west and south, of Zerubbabel's temple-terrace at Jerusalem, by him, of course, religiously copied from Solomon's standard. (They have none of Solomon's work, because many of their stones are *too large*, often double the lengths "of 10 cubits" and "of 8 cubits," that the Bible records as wonders of his time.) Have not such standards, then—widely different from a "bar" kept at Paris, or a "Winchester bushel," but yet artificial—been experimentally found at least as good as any natural invariable length, of which we have really none between the diameter of our planet and the wave lengths of standard rays, as of sodium light or thallium light! Either these latter have to be multiplied some millionfold or the earth's dimension divided some millionfold, to yield a unit we can handle or measure our own works by! Of the two, I believe multiples of the spectral ray-waves would be the more practical and verifiable; but, remember, we have no *direct* natural length standard between them. We can get one of length through gravity-force and the subdivisions of the time-unit, the day. We can take the distance fallen at the equator, or at a given latitude and altitude, in a given day-fraction, as a second; this being, though not measurable directly with any exactness, yet derivable by the multiplier, π^2 from the length of pendulum vibrating that same fraction of the day. Now, the English, Russian, and Swedish foot happens to be wonderfully near the quarter-second fall of bodies at the equatorial sea-level. It might either be modified to exactly that fall, or remaining unaltered, be defined, I believe, as the quarter-second fall at some moderate fixed height (or equal depth) above or below the equatorial sea-level, a height quite accessible on the Andes, even if higher than Quito city. Neither Herschel nor Smyth seems to have noted this near coincidence in our foot.

But I submit that built standards, the idea of Pericles' time, are not yet superseded—they are the most successful to this day. And remember that we, too, and probably many a modern race, have their Hecatompodon in their Parthenon, in some chief Christian virgin's fane, sometimes even nobler on the whole, or as creditable to humanity, as that of Pallas in its prime; some Mary Church, as the massive world-strong one of Chartres, storied with its 8,000 population in stone and gem-like glass; or its contemporary, but extreme opposite, the wondrously delicate Salisbury, our Anglo-Saxon race's Parthenon, and the chief, or rather sole noble work we ever finished on the plan begun. There, according to the best surveys, the ten nave compartments make as accurate a 200ft. standard of our present long measure as could now be made; and what is still stranger, considering the effect of settlement on most buildings' heights, the extreme from floor to cap-stone of spire falls not two inches short of the double thereof. So there we have, well preserved above six centuries, the original of this foot, now base of Anglo-Saxon, Gothic, and Sclavonic measures, all round our hemisphere, and over the two greatest empires. Nor are the round enmetric multiples of the same in such modern monuments as Waterloo Bridge, London, or Grosvenor Bridge, Chester, to be despised even in the face of Cheops' or Pericles' standards. And let me add a disproof of Mr. Petrie's fancy, p. 636, that because our perch is 198in., it was ever centesimal. The perch governed the dimensions of our ancient buildings perhaps earlier than the foot. At least at Salisbury, the choir half of the building (the first built), is planned on a basis of perches, as true to the present standard of them as the nave dimensions are to round numbers of feet. And all the leading lines of Westminster Hall (nearly two centuries later, it is true), he will find by Pugin's measurements to have been of perches, and not of 200in., but of 198in., as at present.

Neither "Sigma" nor Mr. Bottone have any right to pillory me as defending multiplicity or absence of system, or, indeed, in the matter of divisions (which I must defer to another letter) approving any other of our numerous English tables than that of time (common to Europe), and those of our money, troy, and apothecaries' weight. What I say of the rest is simply that, however bad, none of them is worse than, or hardly so bad as, the French decimals. I would alter all, and assimilate all. I supposed it to go (as the French say) *sans dire*, that whatever numerical series is best for one table is best for all; and I would have no two *so* different and incommensurable as the present French table of everything else is with their time. E. L. G.

THE METEOROLOGICAL OFFICE AND ATMOSPHERIC WAVES.

[3833.]—HAVING had occasion lately to look into some of the publications of the Meteorological Committee, more particularly Mr. Scott's report on "Strong Winds and Barometric Differences," and Capt. Toynbee's report on the use of isobars, I found, as it appears to me, a want of information on a subject to which more than five-and-twenty years ago I, in conjunction with the late Sir John Herschel, devoted considerable attention. It would be out of the question within the limits of this letter to point out those particular features of "atmospheric waves," which ought, I apprehend, to have been mentioned, or at least alluded to, in the descriptions of Capt. Toynbee's isobars and Mr. Scott's gradients, and I can only account for the omission by supposing that the director of the office, the marine superintendent, and the members of the Meteorological Committee are unacquainted with the results arrived at by Sir John Herschel and myself. The late director of the office, Admiral Fitzroy, was certainly acquainted with them, for he was the only meteorologist, so far as I am aware, who controverted them, and under these circumstances he would not have employed them in his researches; but in an attempt to trace the progression of barometric differences, and to show the connection of strong winds with these differences, the most important agent, the "atmospheric wave," has been lost sight of. Capt. Toynbee appears not to have suspected that information of the kind was available, for I find in his report that the examination of the isobars of January, 1867, *opened up new views to him* of precisely the same character as I found in my researches on atmospheric waves so many years before; and it is somewhat remarkable that an office absorbing the large sum of £10,000 a year should be content to limit its inquiries to the comparatively small area of 700 miles in diameter, when it has been shown that at least five times this area is necessary for examining the phenomena of barometric differences as "connected with "atmospheric waves." The connection between the prevailing wind and the line of greatest barometric difference is really nothing more than a portion of a line drawn from the crest of an atmospheric wave to either of its troughs at right angles to its direction, the wind must consequently blow at right angles to this line. Much time of the office would be saved and more valuable results secured by determining the general laws of "atmospheric waves" than by confining the operations of the office to the present limited area.

W. R. BIRT.

COLLIERY EXPLOSIONS AND THEIR PREVENTION.

[3834.]—Our friend "King Coal" (8641, p. 587) seems to lay very great stress upon the colliers for being reckless and careless in their daily avocations; in fact, he seems to say that the greatest portion of accidents, if not all, are caused by the carelessness of the workmen themselves. Is our friend aware that prevention is better than cure—hence, if the cause be removed, the accidents would not occur. Now, if a sufficient amount of ventilation be made to travel through all the working places and back "slums," or places that contain gas, both likely and unlikely to keep the gas from accumulating; there would be no fear of any workman igniting the gas in any shape or form. This could be done with care and a proper system of ventilation.

Now, I am aware that the goaf is the likeliest place to contain gas, and there is a way to ventilate the goaf and keep it clear of gas, as well as the working face, if the mine be properly set out at the commencement, and afterwards conducted in a proper systematical form.

Now, I can't see why masters or their managers cannot be made punishable for their negligence as well as the workmen. If a workman is found to have in his possession a tobacco-pipe or matches, or an unsafe Davy lamp, where such are prohibited, they are liable to be brought before a magistrate and imprisoned. Then, why not apply the same law to the masters or their agents if they allow gas to accumulate knowingly in any part of the mine, or neglect to repair anything which is dangerous in its due course?

I am aware that the colliers generally are a class of men that are rather careless over their work, but at the same time I do not like to see too much saddle put on the one horse; let them carry their own burdens according to their merits, then shall we have a chance of havnig these things put right. Arley Mine.

AUSTRALIAN MEAT.

[3835.]—Having been troubled with indigestion for three or four years, and having been unable to eat animal food, I tried Australian mutton and found it agreed with my stomach very well. I had previously tried Liebig's beef tea, but did not appreciate the flavour of it. Before eating Australian mutton, I was quite emaciated, and found great difficulty in walking a very short distance. I can now walk long distances (say 12 miles) amongst lofty hills with ease.

After eating the above mutton, I do not feel any crudities of the stomach or heaviness. I am much heavier, and have a good appetite for other food, which I could not relish before.

It is quite true that a man may eat a large quantity of it, as a child can eat an enormous quantity of tarts and custards. But there is this difference, that after eating an unreasonable quantity of pastry the stomach feels distended and overworked; but after eating an unnecessary quantity of Australian mutton the stomach feels easy and comfortable.

I do not doubt that Australian meat sooner digests, and that the stomach is sooner empty than after eating a meal of ordinary flesh meat, but I believe that the nourishing portion of it is more thoroughly taken up in the system than that of ordinary meat (especially the flesh of an ancestral bull or patriarchal ram), and if a man has a very great appetite he must eat more vegetables to the Australian meat than the other, and I feel convinced he will feel lighter and stronger for eating it. I need say nothing about the difference in price, as every one can calculate for himself, whether he buys good English beef at 1s. or splendid old bull beef at 6d. per lb. Lastly, I cannot perceive any stains on the knives, &c., after using them in connection with this meat. J. Broadhurst.

CALIPER COMPASSES.

[3836.]—In answer to "K. T. L.'s" question as to what "J. K. P." thinks of the caliper compasses (see letter 3825, p. 16), I can only say that in principle they seem perfect, but as I was once told by a mathematical instrument maker that the most difficult job they have to accomplish is dividing a pair of proportional compasses, so I should imagine proportioning the legs of these calipers would be a most difficult job. Besides that, supposing them made, I can conceive only one possible use to put them to, and that is pricking off the width of a sheet of metal which is to be made into a tube of a certain internal diameter, and that width might be got more accurately by twisting a piece of wire round the rod, and nicking it (as people call notching) with a chisel or file. So, on the whole, I should say, don't make them. J. K. P.

A WONDERFUL GUN BARREL.

[3837.]—On p. 539, Vol. XIV., let. 3539, I see the Government officials have been trying the Soper rifles. The last trial was with 200grs. and six bullets; that was quite satisfactory. The writer of the letter, C. H. W. Biggs, says he believes he is correct in stating that no other gun has withstood more than 170grs. of powder and two bullets. I have had a barrel in my hands that has had 18drs. of powder for one charge, and a tap screwed in at the muzzle. When discharged it blew the tap out, but did not injure the barrel, only where it stripped the threads. I think that surpasses the Soper rifle; it is cast on the Bessemer principle, but surpasses the Bessemer; it also can be made cheaply. If it should be a bad ingot, it will stand a heat equal to any iron that is made, and rolled down to No. 32 wire gauge for locomotive tubing.

J. L. Minshes.

COMPETITIVE EXAMINATIONS.

[3838.]—As nobody who knows Prof. Barff's book seems to have noticed Mr. Bottone's recent letter (No. 3686, page 612), permit me to ask him for the "comment" which, he said, was "superfluous." But before he writes let him read the Professor's preface and the paragraph at the end of the article on "Sulphuric acid" (page 174, 2nd edition), when he will, I think, find his quotation from the witty Dean singularly unfortunate. Hedera.

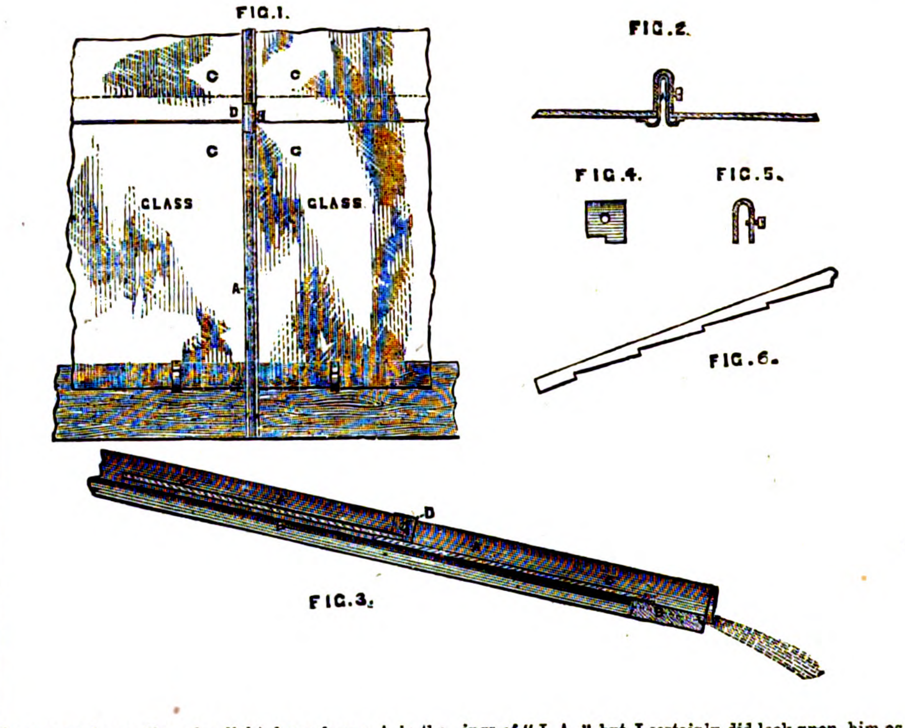
APPARENT LOCAL TIME.

[3839.]—I beg permission to thank N. S. Heineken for the description of his instrument for determining the meridian, at p. 664, Vol. XIV. Perhaps, if made on a rather larger scale, a still greater accuracy may be got, but his gives it near enough for most purposes. I think also the instrument may be simplified by those who wish to ascertain the meridian of one place only, but probably Mr. Heineken wishes to use his at many places.

Philo.

IMPROVED METHOD OF GLAZING.

[3840.]—I beg leave to bring before the notice of your readers an improved construction of sash-bar, especially suitable for greenhouse roofs and lights for frames. The use of putty in fixing the glass is at all times a nuisance, and the necessity of chipping it out in the event of a pane being broken a work of time, besides the liability to damage more panes than you repair when the situation of the fracture is not easily accessible. This sash-bar, and the system of which it forms a part, is patented by Messrs. Rendle & Burrows, and it will be readily understood by the drawings. In Fig. 1, which is



to represent a portion of a light for a frame, A is the sash-bar, C the glass, and D a metal cramp to keep the panes in position. Figs. 2, 3, 4, and 5 show the cramp and its position from different points of view, and Fig. 6 is a cramp intended to run the whole length of a sash-bar where greater strength and security is desired. The sash-bars are made in metal or wood, the latter being necessarily of a different sectional shape to that shown in Fig. 2, although the principle is the same. Thus the wooden bars are about 2in. deep when the cover is on, the bar being cut with a centre tongue, and a gutter on each side. The glass being laid on, the cap, which covers the whole length of the bar, is put in position and secured to the bar by means of screws. It seems to be a convenient and serviceable arrangement, and the makers say perfectly water-tight. Saul Rymea.

PHRENOLOGY.—AMALGAMATED ZINC.—CENTRE MAKING, &c.

[3841.]—(11141.)—Phrenology.—Get McPhunn's "Catechism" and use it as a pocket companion until you have acquired a thorough knowledge of the names and assumed functions of the different organs, referring, when convenient, to one of the phrenological heads made in plaster; they are very cheap now. Then obtain Coombe's "Phrenology," and, if possible, a work by, I think, O. S. Fowler, an American treatise upon the subject; and if you can get a copy of Slade's "Colloquies" study that well. This achieved, try your hand upon your own immediate friends, with whose general characteristics you are more immediately acquainted. Compare the results of your judgment from simple manipulation and the knowledge you have acquired from the books named, with your personal knowledge of the individuals you experiment upon, taking the widest distinctions of character available first, and as you improve by practice coming gradually down to the finer distinctions of development. This will serve you for six months, and then apply again.

(11155.)—Amalgamated Zinc.—By far the simplest method is to make a guttapercha, bath in which the plates or cylinders of zinc can be immersed in mercury after being removed from the sulphuric acid bath. When you have once determined upon the size of plate or cylinder you intend to use, cover it with three or four thicknesses of brown paper, and upon this mould your guttapercha bath, leaving a lip on one side to pour the mercury out when necessary. In the case of cylinders the same arrangement can be made, and the centre space filled up with a wood cylinder, coated with sealing-wax varnish, say 1-16in. less in diameter than the inside of the zinc cylinder. By this means a very small quantity of mercury will suffice to cause complete immersion of the zinc in the fluid metal, and amalgamation will take place rapidly and equally throughout. Wash the zincs thoroughly in a jar, and carefully collect any superfluous mercury that may fall from them, and return it to the bath. Judging from "Yakew's" statement, his cells are too porous for Bunsen's, allowing too rapid exosmose of nitric acid.

(11181.)—Centre Making.—For about the twentieth time let me repeat this rule:—To the square of the versed sine add the square of half the chord, this sum divided by twice the versed sine gives the radius. Templeton was the first I know of who gave this simple rule, and its demonstration has been given in "ours" a long time ago.

(10482.)—Poles of Electro-Magnets.—When previously replying to this query it was farthest from my thoughts to have any intention of wounding the feelings of "J. A.," but I certainly did look upon him as one who had sadly neglected the sage counsel of the Chameleon—

"When next you speak of what you view
Think others see as well as you."

I willingly withdraw any expression of mine that may appear discourteous to him, but he must excuse me for still retaining my firm belief that his experiment was ill-devised in some one or other particular, or he would not have obtained the results recorded. Had his statement merely differed from my own experience I should have doubted the latter, and set to work to verify my conclusions by fresh experiments before I had ventured to write upon the matter, but his single experiment was placed by him in juxtaposition with, and said to disprove, the experience of all other physicists and electricians who have studied and written upon the subject, and in the fervour of my admiration for some of these—notably Prof. Joule—it is quite possible that my pen may have forgotten that "Montaigne" ever had corporeal existence.

(11218.)—Smee's Battery.—If you can get as perfect a deposition of platinum on copper as you can on silver then you have no longer a Smee's cell, but one of your own design, and the relative values of the two will be nearly as the conductivities of the two metals, for which see "Sigma's" papers. With regard to iron, while acting as a negative, it would not, if in any degree pure, be attacked by the dilute acid, but the electromotive force of the cell would be considerably reduced, the very thing which should, if possible, be avoided; and when the plates are not acting as negatives then chemical action takes place on the iron, only giving you a surface of oxide of iron as a negative (a very bad conductor). When you resume operations if you remove this you take away your platinum also, and must replatinise, so that, on the whole, you had better take "Smee" as you find him and stick to him.

(11269.)—SMEE'S CELLS.—In reply to "Intensity's" first query I can only at present quote the authority of Mr. Latimer Clarke, viz., "that Grove being 100 Smee is 25, or quarter the electromotive force when in action, hence his 12 Smee's would be equivalent to three Groves, and I apprehend the electric light they would produce would be a minimum. 2. With the utmost safety, but a serious waste of zinc if your coil is of the ordinary construction; rather join them up in a series of three, that is, four zincs and four silvers in each of the three divisions; then couple these up for resistance or in alternations—*i.e.*, zinc to silver, &c., in the same manner as you now propose to use the twelve. This should give sufficient electromotive force, combined with intensity of current, for any ordinary induction coil. 3. You can use gold in lieu of platinum, but it has two disadvantages—viz., it is dearer and much softer, the latter quality rendering it less useful in withstanding the rapidly repeated blows, slight in themselves individually, but very marked in an instrument under continuous action. Any metal which, in the presence of the atmosphere, can be raised to the temperature produced at the point of contact (when the current is broken at that point) without undergoing oxydisation, will do equally as well as gold or platinum, but unfortunately so far we have not found a substitute that supplies the conditions, ergo we must use gold or platinum, and that is the actual reason.

(11262.)—ELECTRICITY FROM STEAM-BOILER.—If "Boiler Minder" means an ordinary electric bell, in which the result is produced by the use of an electro-magnet, the answer to his query is decidedly No! All the phenomena we have as yet been able to obtain electrically from a steam-boiler belong to, and are consistent with, static electricity, and hence out of the pale of producing dynamic effects. It is possible with proper arrangements to generate electricity of such a tension with a boiler, such as described by "Boiler Minder," as to give a shock to the human system that "no fellah could understand," or that would leave no understanding in the fellow who allowed it to traverse his body, and yet the same discharge would traverse the convolutions of the most delicately made electric bell without giving any visible evidence of its existence—"per contra" a plate of zinc 1½in. square, opposed to a similarly sized plate of carbon with suitable interventions, will ring the same bell for twenty consecutive minutes, while the individual above alluded to may complete the circuit without the slightest inconvenience for hours if he chooses so to do.

(11261.)—I marked this query off for reply, although addressed to another gentleman, but when I reflected that our fourteenth volume was just completed, and the inquirer was "A Subscriber from the First Number," it struck me that, after seven years gleanings from all that has been plenteously shown forth in "ours," the querist must be one of those unfortunate offsprings of Nature's mésalliances, born blind, certainly deaf, and, therefore, should remain in accordance with all natural laws—*dumb*. WM. TONKES.

MUSICAL NOTATION.

[3842.]—ONE word in reply to "Tafa-tefe" (let. 3771, p. 664, Vol. XIV). If he will look at my former letter (3666) he will see that I did not object to the use of figures, as he assumes. What I said was, "I see no advantage in using figures, but calling them do, re, &c., over Mr. Curwen's plan of using the initial letters of these notes," and I stick to it.

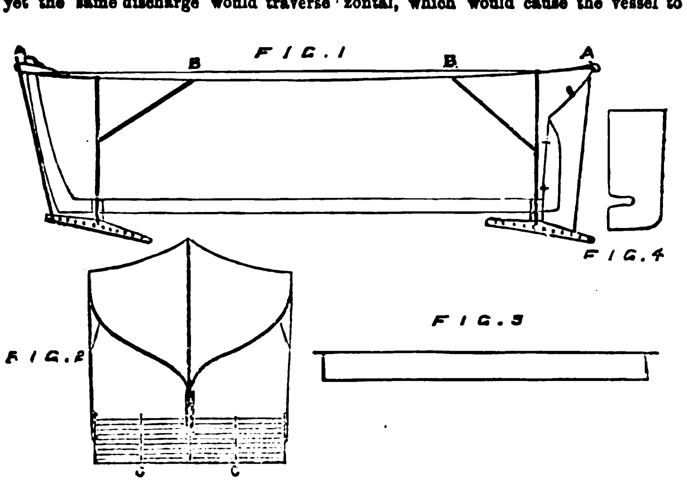
The question of writing figures or letters is trivial: no more precautions are required for the latter than the former, the *f* is the only one with a tail, and in many MSS. it is written f, which exactly corresponds with lopping off the tail of the 7.

It is evident that the cipher and Sol-fa notations are identical in principle; in both the stave and ordinary characters are set aside, a few signs are used to represent tones in key, and a few others to represent time. Their relative merits, therefore, will depend upon the perfection of their detail—a question which can only be decided by those who possess an intimate knowledge of both, and not by the general reading public. H. T. W.

ALLINGHAM'S PROPELLER.

[3843.]—BEFORE entering upon a description of this provisionally-protected propeller, I may premise that having studied the fact which impressed itself upon my mind eight months ago—viz., that if a ship of, say, 1,000 tons be lifted any given height by the action of the waves, there is a force exerted of more than 1,000 tons, and in falling she will exert that force minus the friction of plunging in the water. We will, therefore, assume that there is a force of 1,000 tons exerted every time the vessel's head or stern rises or falls. I don't say this exact weight is mathematically correct, be it understood. The next consideration was if it were possible to communicate this immense power to machinery for propelling, and after repeated trials and failures of the most disheartening nature with a model in a washing-tub in the backyard, I am now in a position to propel any floating body against, sideways, to, or before the wind and waves, doing away at one "fell sweep" with boilers, coals, steam-engines, engineers, stokers, &c., substituting in their place an apparatus which will act effectually as long as the vessel rises, falls, or rolls to one side or the other, which will not probably weigh over 10 tons for a 1,000-ton ship, leaving the whole hull available for passengers and cargo, and, barring accidents, costing a merely nominal sum for repairs.

And now to the proof. Fig. 1 represents a model 3ft. 6in. long, 1ft. 2in. beam, and 1ft. deep. To each end of her is attached a framework, which carries 32 blades or louvres—16 on the port and 16 on the starboard sides. This frame measures outside 1ft. × 8½in., and is proposed to be made altogether of mild steel to obtain the requisite strength combined with lightness. These blades measure 5⅝in. × ⅛in. each, and work freely in the frame on two spindles each (see Fig. 3), slightly overlapping each other. This frame is supported by two flat rods of steel edgewise to the direction of motion, and when lowered into the water slips into the catches attached to the keel (Fig. 4), and is held in position by the stays marked B, thus relieving the rods of the thrust when the ship plunges. Fig. 2 shows an end view of the framework, which is hinged to the vertical rods, and capable of being shifted from horizontal, which would cause the vessel to stop to the



proper angles with the keel in order to produce forward or backward motion as required. As the wave lifts the bow, the blades are lying flat, and present a large surface endeavouring to go forward in the direction of the angle to the ship's bottom. The moment she begins to fall, these blades open to the corresponding angle in the opposite direction, which opening is regulated by guards, as marked C C, Fig. 2. Thus the vessel is converted into a double-acting lever at each end, and if she rolls to one side the blades on that side open, while those resisting the roll are shut; thus is she also double-acting as regards side motion. The reason for keeping these blades as narrow as possible is that they may reverse their angle as soon as possible, so that the least motion of a ship will be sufficient to propel her. In the case of very long vessels, I propose to use a species of float to agitate the framework of blades. In this arrangement it would be requisite to tow the vessel to the open sea as usual with sailing vessels; but if desirable, it can be arranged so as to be worked by a steam-engine until the swell is reached. This system is also applicable to driving machinery by the side of any large reach of water. The only drawback is that if the sea be perfectly without motion (which I think, from experience, rarely happens, except in some parts of the world), my apparatus will not act—the rougher the sea the better it acts, and best when going straight into the wind's eye. JAS. ALLINGHAM.

DR. CARPENTER AND PERSPECTIVE.

[3844.]—DR. CARPENTER, in his article on common sense published in your journal of the 8th inst., states correctly a rule of perspective, but gives a reason for that rule which I think ought not to pass unchallenged. After stating that the perpendicular lines of two towers (for instance, York Minster) must visually converge towards a vanishing point in the sky, whilst common sense tells of the improbability of their being actually inclined towards each other, he says, "And the best proof of the complete possession of our minds with this improbability is to be found in the rule of perspective that all the vertical lines in a building must be pictorially drawn as vertical, so as to represent what is seen by the mental rather than by the bodily eye."

The true reason why all the vertical lines in a building must be pictorially drawn as vertical I had supposed to be because all such lines are parallel to the plane of delineation; thus, if the towers be viewed through a window which will represent the plane of delineation, it is evident that the sides of the window visually converge to the same vanishing point in the sky as the lines of the towers; and, therefore, if the towers are drawn upon the window exactly as they are seen by the bodily eye, it will be found that all the vertical lines are pictorially drawn vertical. For the same reason all horizontal lines which are parallel to the plane of delineation are drawn parallel to the top and bottom of the picture, their vanishing points being the same. This is readily seen whilst travelling in a railway carriage, when the window represents the canvas on which the picture is painted. The rails and telegraph wires all have the same vanishing point as the top and bottom of the window, and if drawn upon the window exactly as seen will be parallel. B. D. T.

LIGHTNING CONDUCTORS.

[3845.]—"PHILO" (letter 3733, p. 638, Vol. XIV.) advises using metal roof ridges, gutters, and rain down-pipes. I am anxious to do so; and will be obliged to "Philo," or any other correspondent, for further details—such as how to establish metallic connection between :—

1. Six-feet joints of cast-iron down-pipes, generally left loose in the sockets.
2. Eave gutter and down-pipe, whether connected by a drop or a head.
3. The lengths of cast-iron rhones of eave's gutter, spigot and faucit, bolted together.
4. Between lead-valley gutters and cast-iron eave gutters.
5. Between the lengths of the lead in valley gutters and ridges which overlap each other, and which, if soldered or otherwise fixed, might be torn by expansion.
6. Between the wire-rope conductor and the lead ridge.

These connections made, how high must the point of the conductor be above the chimney cap? And what addition to the lowest point of the rain-water down-pipe is necessary to carry the lightning safely off from the house into the ground? J. G.

[3846.]—THE destruction of King's Norton Church steeple, described by "J. K. P.," at p. 668, Vol. XIV., shows how useless metal conductors are unless they are well connected with the ground, a point very often neglected. The common expression that the electric fluid made a hole is inaccurate. Electricity causes a hole to be made, sometimes by the sudden production of steam, sometimes by making the particles electrified repel each other: why they repel each other is unknown to me. By the way, the King's Norton I know is in Worcestershire, not Leicestershire. PHILO.

CO-OPERATIVE SOCIETIES.

[3847.]—I AM much obliged to the writers of letters 3775 and 3776, p. 666, for their answers, but I will take the last first, as "E. L. G." seems quite to have mistaken the drift of my inquiry. The suggestion of "Pro Bono" is a good one, if practicable; but a little consideration will show him that so far from there being no difficulty in "so limited a concern" in entering the quantity of every article sold in a book, the fact really is that the difficulty is the greater on account of the smallness of the transactions—*e.g.*, Saturday afternoon—the neighbouring factory has just paid off its hands—there will be five or six customers in the shop at a time for the rest of the day. A. wants 2oz. of tea, 1lb. of sugar, 1oz. of tobacco, 1 pennyworth of biscuits, and a deal besides, amounting perhaps to three or four shillings. B., C., and D. are waiting patiently. Now I ask "Pro Bono" how is it possible for an entry to be made of the weight or quantity of each article sold? and if it were done what are the chances of the sold tallying with the bought weight at the end of the quarter? In large concerns, where a clerk is kept to take the money and book the sales, the system may answer; but anxious as I am to find a "check-system," I fear I must relinquish this one as inapplicable to our case. To "E.L.G." I would say, *Bis dat qui cito dat:* he only promises a solution to my problem, and asks questions. No doubt, though, he is employing the Socratic method, and by answering his questions, I expect to throw a light which shall illuminate both myself and him.

1 and 2. The store I represent is worked by one man (styled manager) and a boy, who are employed to distribute the groceries of the . . . Co-operative Society, so called because its members furnished the capital and "co-operate" through their committee in managing or mismanaging the business.

3. The objects of the society are such as "E. L. G." supposes, and I see no objection to changing its name to the "Distribution League," if any benefit will thereby accrue to the shareholders. I do not see how poor men can be expected to know what exact amount they have expended in provisions in any given year, as they seldom keep such accounts; but as that datum is required only in order to fix the secretary's pay (which in this case is *nil*), that suggestion of "E. L. G." may be passed over. In conclusion, I do not profess to understand clearly "E. L. G.'s" method of co-operation, but I believe the form adopted by our society to be a legitimate and useful one, though without any claim to novelty. About 100 mechanics, &c., club

together, induce their employer to build them a store which they rent at £10 per annum, stock with groceries, &c., and go to work. The distance from a town being nearly five miles, they soon get the trade of the whole neighbourhood, and return £30 to £40 weekly. The said society does not "pay," but the members stick by it. The causes of failure are more patent than the remedy, but they are in hopes of finding a remedy when they meet with an eligible "check system."

F. C. S.

WARMING AND VENTILATING.

[3848.]—I WRITE to describe a warm air ventilating fireplace which I have used extensively in buildings on which I have been engaged professionally as architect: it is called "Lewis's patent warm air-chamber fireplace." The cold air enters the air-chamber at the back or underneath the fire, and can be brought from the external air or from any passage near at hand, and after being made to traverse the air-chamber backwards and forwards by means of gills, comes out warm into the room, or can be conveyed into any other room or passage required by means of pipes. The essential difference between this grate and all others I have seen, and in which, I believe, the patent partly consists, is, that it is complete in itself, requires no air-chamber building, and no more setting than any ordinary register grate.

I have these grates fixed in three sitting-rooms of my own residence, the cold air entering from, and returning warmed into, the hall. During the coldest weather of the severe weather of 70-71 the hall and staircase, three stories high, were nicely aired when only one fire was lit. When two fires were lit they were comfortably warm, and when there were fires in all three sitting-rooms the hall and staircase were as warm as the rooms themselves, and the bedrooms aired also; this result being obtained without using an ounce more fuel than if ordinary grates had been used, and the waste heat allowed to escape up the chimney.

One day when the external air was 25° Farenheit, I tested the velocity and temperature of the air issuing from one of the air-chambers (by means of Negretti and Zambra's standard thermometer and Byron's delicate anemometer) about an hour after the fire was lit. I found the air going in near the hall door at 35° and issuing from the air-chamber at a temperature of 130°, and at the rate of 140 lineal feet per minute, or nine cubic feet raised 91°, or equal to about eighty-two cubic feet raised 10° in temperature a minute; and as the hall and staircase to be warmed contain about seven thousand cubic feet, it follows that when all three sitting-room fires are lit they can raise the temperature of the hall and staircase, &c., 20°, or say from 40° to 60° in an hour after the fires are well burnt up.

There is an entire absence of smoke, offensive smell, or oppressive dryness in the air, the fireplaces being lined with fire-clay tiles.

AN ARCHITECT.

PIANO ALLIANCE.

[3849.]—I SHOULD also be glad to join with other subscribers in some scheme whereby a genuine instrument might be secured at a fair price. I suggest, however, that it might be prudent if we wait a few months, that we may first have the opportunity of seeing what will be shown at this year's Exhibition, as I believe "musical instruments" are to form one of the chief features. I hope, too, that the relative merits of the different pianos and harmoniums then exhibited will be fully discussed in "our" valuable journal, and after such enlightenment, we shall be better able to decide on what special construction of pianoforte to adopt.

BUSY BEE.

DEFECTIVE ORGAN.

[3850.]—IN a recent number was a letter complaining of an organ made by Kemble & Johnston, of Manchester, and asking for advice what to do to it. Mr. Kemble being, I regret to say, dead, I think I may mention a fact which he once related to me, and which may throw light on your correspondent's difficulty.

He said that an organ made by him having got out of order, he went to examine it, and found that through a defect in the hot-water pipes used for heating the building the unfortunate instrument got thoroughly steamed whenever the fire was lighted, which certainly accounted for the state it was in when at length he was asked to see it. As I have mentioned his name I cannot help alluding to his loss as one of "our" correspondents and contributors. He was very fond of experimenting on new devices in his business, and any information which he thereby gained he was always willing to impart to others, and amongst them was the writer of this.

L. C. E.

ORGAN FEEDERS.

[3851.]—THE bellows sketched by "A Young Organist" (letter 3746, p. 642, Vol. XIV.) is not a new invention, having been used both by the English and Continental builders for some years past, but having these alterations:—1. The valves are made to close without springs (in fact, I do not see why those in the sketch which are not inverted should need them); the organ builders do not have any inverted pallets in these feeders—making the top one to draw its wind from the bottom board of the same by leaving a space of about 1½in. between the bottom board of the top feeder and the top board of the bottom feeder; therefore the pallets close by their own weight and the pressure of the wind. 2. The trunk from the bottom feeder is open as far as the reservoir, and a valve is placed on the bottom board of the reservoir just over the trunk, instead of inside the trunk; this also closes by its own weight, &c. 3. The blowing action designed by him would have to be made very strong and heavy if the bellows were large, but a better arrangement is usually employed—viz., having a lever, as in ordinary instruments, working on a fulcrum, placed at any distance from the feeders,

so as to obtain either great leverage, or short traversing distance; this lever is connected to an iron fork (see sketch) the two long arms of which are attached to two gudgeons fixed between the two feeders. Of course, by this plan the reservoir has to be kept at a greater elevation to allow the requisite movement of the lever; and in consequence of this they are sometimes placed in a vertical position at the side of the reservoir, or in a separate chamber (as in the organ at Winchester Cathedral, rebuilt by Hill & Son, blown by water power). I, for my own part, like these feeders, as they give a large amount of wind, and are easily constructed.

E. F. CONRATH.

MACKENZIE'S TOUCH LIGHTENER.

[3852.]—IN the number of the MECHANIC dated Dec. 22, and at p. 346, I notice an article, with illustration, on "Mackenzie's Touch Lightener." This clever contrivance is no doubt of great service in small organs, but I consider it practically useless for large organs. Take, for example, an organ with 13 stops on the great, 14 on the swell, and 8 on the choir. The great organ would require a pallet 15in. by 1¼in.; the swell, 15in. by 1¼in.; the choir, 12in. by 1in. Taking the proportions given in the above-mentioned article, the great organ CC key, with touch lightener and 4in. pressure of wind, would require, say, 10oz. weight to take it down—the swell, with 4in. pressure of wind, would require 10oz. also; the choir, with 3in. pressure of wind, would require 4oz. Now, if the swell be great, and choir to great couplers were drawn, 24oz. would be required to take down the CC key. Octave couplers would, therefore, be quite out of the question. But the pneumatic lever has no limit in this respect, provided it has sufficient pressure of wind. If properly made it is no more complicated than other parts of the intricate mechanism of an organ. I think the pneumatic lever can never be superseded by the touch lightener, as the former is unlimited in its application, whilst the latter can only be successfully introduced into small organs. The promptness of action of the pneumatic lever is another great point in its favour. I have not yet seen the touch lightener working; but I should imagine that when the key is half down there is an unpleasant sensation to the finger, caused by the two surfaces of the touch lightener coming wholly into contact. Can any reader speak on this point?

PNEUMATIC LEVER.

THE MOON'S AXIS.

[3853.]—IN reference to the remark of "F.R.A.S.," that the inclination of the moon's axis to the plane of her orbit *about the earth* determines the amount of libration in latitude, it may be well to notice that the moon really describes *two* orbits—one about the sun, which determines the length of her year, her seasons being dependent upon the inclination of her axis to the plane of this orbit, and one about the earth, which slightly modifies as to shape her orbit about the sun. It is, as mentioned by "F.R.A.S.," the inclination of her axis to this orbit upon which libration in latitude depends. The two orbits are perfectly distinct from each other, the phenomena resulting from one having reference to the moon only, the phenomena resulting from the other being principally witnessed from the earth.

W. R. BIRT.

OCCULTATIONS OF URANUS.

[3854.]—HAD Mr. Clements spent the small sum of *five minutes* in consulting the "Nautical Almanacs" for 1867 and 1868, he would, at all events, have hesitated before he submitted to the readers of the ENGLISH MECHANIC the remarkable query which has drawn forth from "F.R.A.S." the very severe remarks on the probable insane condition of "Captain William Noble, of Uckfield." That the Captain is fully able to demonstrate his own sanity, I have no doubt, for unlike "F. R. A. S.," I have the honour and pleasure of knowing Captain William Noble, of Maresfield, Uckfield, and gladly leave to him, should his eye rest for a moment on the remarkable suggestions to his friends contained in let. 3795, p. 9, the right of a reply. It could rather seem that the concoctor of the query would be the fittest inmate of Hanwell or Colney Hatch, for how he could have ascertained that Uranus was occulted by the moon 187 times in 1867-68, is beyond conception; for in those years Uranus was not once occulted, the only planets hidden by the moon being Mars, Venus, and Mercury. Surely the notion must have originated in his own brain, as there is certainly no foundation for a paper of the title given. Mr. Clements will find a list of Captain Noble's communications to the Royal Astronomical Society in the General Index to the 29 volumes of the monthly notices.

W. R. BIRT.

JUPITER'S SATELLITES AND "F.R.A.S."

[3855.]—MR. PROCTOR is very much mistaken if he supposes, as he seems to do, that I meant anything more than I said respecting this gentleman's astronomical knowledge. All I said was that we—*i.e.*, the majority of your readers—did not know who he is; all I implied was a doubt whether the mere fact of his being a "F.R.A.S." gave such presumption of knowledge as should induce me to place greater reliance upon his authority than on that of Sir John Herschel. If there be anything even apparently disrespectful in that, I beg to disclaim any intention of passing a judgment upon one of whom I know nothing; but I cannot suppose that one who, like "F.R.A.S.," expresses his opinion upon the supposed errors of others with great freedom, would have been offended, even if I had (which I did not) accused him of being seriously in error himself. Neither will Mr. Proctor, I feel sure, be offended by my stating that I think he is not quite correct in saying that Sir John Herschel "only says that the eclipses of Jupiter's satellites are *applicable* to the purposes in question, because they *can* be predicted." He does not say that they "*have been* predicted with the requisite accuracy." The italics are Mr. Proctor's. In my copy of this treatise on "Astronomy," 1833, the words Sir John used are, "This prediction is sufficiently precise and certain to stand in the place of corresponding observation. So that an observer at any station whatever, who shall have observed one or more of these eclipses, and ascertained his local time, instead of waiting for a communication from Greenwich to inform him at what moment the eclipse took place there may use the *predicted Greenwich time* instead, and thence at once, and on the spot, determine his longitude." I presume, as Mr. Proctor seems to say so, that the times cannot be thus determined with such great exactness as Sir John's words imply; but I do not see why "F.R.A.S." should have expressed his surprise that any one relying upon Sir John's authority should suggest resorting to a plan he proposed, when in doubt of a better, which doubt I am sure either Mr. Proctor or "F.R.A.S." could have removed, if they had either of them taken half the trouble to set me right as they have, with very poor success, in trying to prove me wrong. I do not see what other meaning can be put upon Sir John Herschel's words than I put on them, and I still think that if in error, as I suppose I was, I erred in very good company.

PHILO.

LUNAR OBJECTS FOR OBSERVATION, APRIL, 1872.

W. R. BIRT.

MERCURIAL VAPOUR.

[3857.]—AT p. 668 Dr. Stenhouse's charcoal respirator is called Dr. Henhurse's. I fear I wrote the name badly, and hope you will allow me to correct it. The invention is a very valuable one, not nearly so well known as it deserves to be. The inventor, like a true philanthropist, seeks no profit from those who use his respirator, and, therefore, deserves the more honour.

PHILO.

[3858.]—THANKS to "Philo" for his attempt to enlighten my darkness. My object, however, is not to ascertain the effects of mercurial vapour on animal life, but to obtain the means of referring to records of experiments if such be in existence, by which the *habitudes* of mercurial vapour have been determined. Perhaps my questions (letter 3674, No. 362, p. 611), were not sufficiently explicit. I am desirous of knowing the weight in grains of mercurial vapour which fills a cubic foot at the following temperatures—32°, 60°, and 212° Fahr.; also the tension of the vapour at the same temperatures.

W. R. BIRT.

THE A 1 CLOCK.

[3859.]—IT is years since I contrived a clock somewhat on this principle. The string of the descending weight passed once round a fixed pulley, the arbor or axle of which carried an hour-hand, and showed the time on a dial. I would recommend such an arrangement to the consideration of Mr. Stanistreet, as an improvement scarcely interfering with the simplicity of his astronomic clock, and adding to its appearance, if not to its efficacy. I fear, however, the effect of changes of weather on the gut may somewhat mar its qualities as a time-keeper.

C. B. FENNESSY.

CHEAP OBSERVATORY CLOCK.

[3860.]—I HAVE much pleasure in replying to the inquiries of your correspondent "Regulator" (query 11250, p. 677), and giving the particulars desired by him and others on the subject of the timekeeper described at p. 630 of "our" last volume.

1. The drawing of the clock is not strictly according to scale, but the dimensions given below will afford the means of correcting it in this respect.

2. The lantern pinions were made as follows:—A short rod of brass (I used a piece of stair-carpet rod) was firmly held in an American die-chuck, and a hole drilled centrally of sufficient size to receive the arbor of the intended pinion. The brass is then turned away so as to form the frame of the pinion, which is exactly like a miniature cotton bobbin or reel. The holes to receive the pinion leaves are then drilled by a drill made of part of a needle of the same size as the leaves are intended to be (I used No. 8

needles). The drill is placed in a small drilling spindle held in the slide-rest, and worked by a fine cord from the overhead pulley, the pinion being meanwhile held by the index of the dividing plate, and after each hole is drilled it is turned one-twelfth or one-sixteenth of the circle by means of the divisions on the dividing plate of the lathe so as to insure equi-distance of the holes, each of which should be drilled quite through both the discs of the pinion at the same operation. When all the holes are thus drilled the pinion is removed from the lathe, and pieces of needles of the same size are inserted in all the holes, and fixed there by running in a morsel of fusible metal as solder by means of the blow-pipe. This is effected in a moment of time, and if the pinion staves are protected by holding round them a piece of moistened sponge, the heat required for soldering them does not even blue the steel, which retains its admirable polish and hardness unimpaired, and they are so firmly fixed in the pinion that the rough ends may be ground off by a grindstone or corundum disc.

3. The clock might be made to go for eight days by the addition of another wheel and pinion; but it would then require a heavier driving weight, and the weight would descend too slowly to be available for carrying the hour hand as in the A 1 clock, the plan of which I prefer in this respect.

4. The "little wheel" referred to by your correspondent "Regulator" is the ratchet wheel, and its pall or click will be seen just on the right-hand side of the ratchet-wheel in the drawing. The click is formed by a piece of watch-spring bent into shape and riveted to the brass plate which holds the ratchet-wheel and pulley. Nothing could work better than this simple and easily-constructed ratchet and click.

5. The gut is joined by hook and eye of the very smallest size. I adopted this plan for the sake of the facility it afforded of taking out any twist which might occur in the cord when new; but there has been none, as the gut was well stretched by heavy weights before it was used, and if the clock should happen to be stopped for any purpose, I shall probably splice the ends of the gut together as preferable, although it works very well as it is.

6. The drill for serrating the sides of the V groove of the centre pulley, and of the ratchet pulley, must be shaped exactly like the groove, though a little larger. The pulley, of brass, when turned and grooved with a deep and narrow V groove, is held fixed in the lathe by means of the index of the dividing plate, and the drill held in the slide-rest and worked from the overhead pulley is advanced so as to notch the groove pretty deeply, and then withdrawn, the pulley being turned by the dividing plate the desired distance (say one-forty-eighth of a rotation), another cut is taken to the same depth, and so on round the circumference. Although this mode of roughening the pulley is very efficacious for preventing the cord from slipping, I attach still greater importance to the position of the guide pulleys shown in the drawing, which make the cord grip the pulley throughout the greater portion of its periphery, instead of merely resting upon one-half the circumference in the usual way.

7. The dimensions asked for are as follows:—The perpendicular height of the clock frame from the upper surface of the seat-board to the apex of the A-shaped frame is 9in., the depth of the frame about 2½in., the diameter of the 120 wheel is 3·48″, of the 96 wheel 2·8″, and of the scape-wheel 2·0″. Diameter of the 16 leaved pinion 0·45, and of the 12 leaved pinion 0·87. The pulley upon the centre-wheel arbor is three inches in circumference, making the descent of the driving weight and "hour hand" exactly 1·5″ per hour, which affords ample space for divisions, showing five minutes or less of time.

8. The plan of the clock is so very simple that it did not occur to me as necessary to send any section of it with the drawing, nor did I even prepare such during its construction. I hope your correspondent "Regulator" will communicate his "new form of maintaining power," which may interest many besides myself.

JOHN F. STANISTREET.

Abercromby-square, Liverpool.

BUCKMASTER, SNAITH, &c.—To "BEACON LOUGH."

[3861.]—SINCE writing my last letter, I have been informed by letter, from a high authority, "that there is no accepted Government class book for chemistry; certainly not the two mentioned. The ones most generally used are Roscoe's 'Elementary Chemistry,' and Barff's 'Chemistry.'" S. BOTTONE.

"VALENCY v. ATOMICITIES."—To "MERCURIC."

[3862.]—THIS correspondent has evidently not read my "Lessons" and letters carefully, or he certainly would not call my attention to points which I have already discussed, or noticed. As, however, his positive assertions on dubious hypothetical subjects might lead to grave misconception and much fruitless discussion, I feel it incumbent on me to point out a few phrases in his letter, hoping by so doing to lead him to ponder more before venturing on such sweeping assertions. 1. The term "atomicity" to indicate saturating power is incorrect, for "atomicity" points to the number of atoms in a molecule. The atom of nitrogen can only contain one atom: hence to affirm that the atom of nitrogen is "pentatomic," or "triatomic" is as great a perversion of words as to state that 1 is 3 or 5. 2. It was "Beacon Lough" who proposed ammonium as a poser, not I. To this gentleman, also, are we indebted for the formula NH_4 (see letter 3420), which, by the bye, is correct as far as it goes, for it represents a known fact—viz., that in this body there are four parts of hydrogen to every one part of nitrogen. 3. Unless "Mercuric" has weighed ammonium vapour and ascertained its density, I fear that he has very doubtful grounds for asserting that $\left\{\begin{matrix}NH_4\\NH_4\end{matrix}\right.$ is a more correct formula than NH_4. Presuming, however, that my correspondent has not made a statement that has no basis or fact, I invite him to give us in our pages the vapour density of this body at 0° Centigrade. 4. While thanking "Mercuric" for the flattering allusion to "ruses" and blunders with regard to phosphorus pentachloride, I beg to refer him to Odling's "Manual" for information on this point. Perhaps he is not aware that the formula usually given—viz., PCl_5, does not agree with its vapour density. I take no note of the ammonium chloride formula, as the one given by "Mercuric" does not concord with its vapour density. 5. With regard to phosphorus being pentavalent in phosphorus acid, I can only say, as I have said before: Our only certain measure for the valency (always supposing there is such a thing as valency, which I am beginning to doubt) of any element, is hydrogen. Now, no compound of the formula of $P'''''H_5'$ is known to exist; only $P'''H_3'$ is known; and we can (I do not mean to say this *is* so) account for the existence of phosphorus acid, without losing sight of the trivalence of phosphorus, thus:

$$\begin{array}{c} H'--O''--P'''--O''--H' \\ \phantom{H'--O''--{}}|\phantom{{}--O''--H'} \\ \phantom{H'--O''--{}}O''\phantom{{}--O''--H'} \\ \phantom{H'--O''--{}}|\phantom{{}--O''--H'} \\ \phantom{H'--O''--{}}H'\phantom{{}--O''--H'} \end{array}$$

I further call attention to the fact that when we base our calculations of valency on any other element except hydrogen, we introduce an element of error into our reasoning. S. BOTTONE.

SEWER GAS.

[3863.]—"MANUS" (let. 3780, p. 667, Vol. XIV.) does not explain in what respect he thinks I have misinterpreted his remarks on sewer gas, but I now guess he did not mean to say what he appeared to say, that the absence of bad smell is proof of the absence of danger. I, like "Manus," have not by me the number in which his remarks appeared, but I remember a statement implying that the escape of sewer gas into a dwelling would be certainly detected by those whose smelling organs are in good order, which seemed to me to give support to the very common and very dangerous notion that what does not stink won't hurt. It is certain that often, and probably always, that which is the real exciting cause of typhoid or pythogenic (filth-begotten) fever is not offensive, though often accompanied by that which is. I am glad to think that "Manus" does not support the erroneous notion, which he appeared to do. Sulphuretted hydrogen, if uncontaminated with organic matter, never caused fever. It has got a bad character by keeping bad company, as is a common case. P. H. HOLLAND.

THE FAIRLIE LOCOMOTIVE.

[3864.]—IN letter 3787, p. 668, "A. G. Boyd" raises objections to the Fairlie locomotive which I think are more than outweighed by other advantages which he does not mention. Before I say more I may as well remark that I do not approve of the Fairlie system, except under peculiar conditions of gauge, traffic, &c. I will now detail some of the advantages which the promoters of the system claim for it. Firstly:—Fairlie claims to get tractive power with his 4-cylinder engine equal to that of two 2-cylinder engines, and at a less cost. There is less machinery and fewer parts required where four cylinders are fixed on one carriage instead of on two. The space occupied is less, and the whole construction more compact, while the weight, being better distributed, tends to increase the adhesion. There are many other minor advantages growing out of the general plan of design which I will not go into now as I have forgotten them. The one great advantage, however, is that fewer men are required—two, or at the most two and a boy, instead of four. This is, of course, a great saving, especially where the system is largely adopted. It is on the point of economy, I think, that Mr. Fairlie should more particularly base his arguments, and not on superior tractive power, as what little gain (and it is little) may be got by his system in this respect is more than counterbalanced by the practical convenience of two separate engines.

For narrow gauge railways the Fairlie system is more particularly applicable, because it is by its form well suited to a compact disposition of parts, which is so necessary in a narrow gauge locomotive.

I have said that the strongest point of the Fairlie system is the question of economy. Now, although at first this may appear to be a great advantage of the system, I think I shall be able to show that it is not so.

The lowest average life of a locomotive is about seven years, and if it can be patched up so as to work for ten years, there will be a considerable saving effected. It is, therefore, the most economical policy to repair defects as soon as they appear, rather than let the engine work itself out, and so be effective for a shorter period. The consequence of this is that on a large line a considerable percentage of the locomotives is always in the repairing shop. Now, supposing a line is worked with 100 locomotives, and that 50 Fairlie locomotives will do the same amount of work, it is obviously preferable to have 100 locomotives with ten of them in the repairing shop than to have 50 with five laid up.

I may not have expressed myself clearly enough in the foregoing. What I mean is, that to work a heavy goods traffic with efficiency, a greater aggregate stock of locomotive power will be required with the Fairlie system than with the old system, although the actual number of Fairlie locomotives would, of course, be less.

A great deal was made of the power of the Fairlie engine in taking a great load up a long incline in the recent trials, but what is the use of dragging a lot of non-paying loads say 90 miles, so that it may come into action to take the train up the last ten miles of stiff incline? It is truer economy to have a bank engine specially for those ten miles. OSA.

[3865.]—A LETTER (No. 3787), signed by A. G. Boyd, appeared in your number for March 15, which should be replied to, and with your kind permission I do not think this can be done better than by asking you to insert the letter herewith, which I received from the writer, one of the gentlemen who conducted the experiments described in his letter, when Mr. John Fowler and others of the Indian Railway Commission went to Wales to test the Fairlie against the ordinary engines on the Festiniog line. Mr. Allan's letter has never been published, and as it bears particularly on the questions raised in Mr. Boyd's letter, I believe your readers would be glad to see it appear in your very excellent journal. R. F. FAIRLIE.

[*Copy.*]

17 & 18, Leadenhall-street, London, E.C.,
August 18, 1870.

DEAR SIR,—Several weeks' absence in the North has prevented me from replying earlier to your request for particulars of the experiments Mr. Spooner has advised you he carried out, at the request of Mr. Glover, railway contractor, Bombay, and myself on the 8th July last.

Mr. Glover having been called on to tender for a line of railway in India, desired some further confirmatory evidence of the advantages of your system beyond that which he had witnessed a few weeks before in company with Colonel Dickens, Colonel Strachey, Mr. Rendell, and others; and as there were what was considered by many at the time most important experiments omitted —such, for instance, as the testing two ordinary engines coupled together, whose combined power and weight should be equal to or about that of the "Little Wonder" —we deemed it expedient to return to Port Madoc, and finally set at rest this question. The experiment referred to had also been omitted by the Russian Commission, as shown in the printed account of their experiments.

With the exception of Colonel Anderson, of Kattiwar, and Monsieur Barossa, of Brazil, no one was advised of our intentions, as we desired, if convenient and agreeable to Mr. Spooner, to leisurely carry out the experiments ourselves with as little inconvenience as possible to him. You will understand, therefore, why you were not informed of our intentions.

At first Mr. Spooner was of opinion that such a trial was unnecessary, as previous experiments with the single engines had established the fact that two of them were not equal to one of yours. But this, after all, I told him was only an opinion, and we considered it would be more satisfactory, having dealt with simple facts all along, to test the matter, and see what it disclosed—if it proved Mr. Spooner's opinion correct, so much the better for the Fairlie engine. But we wanted the facts, and Mr. Spooner very kindly consented that the trial should be made the following day, if sufficient loaded waggons could be got together. It turned out next day that a sufficient number could not be had, consequently eight empty waggons were added to the train to make up a load approximating to that of the "Little Wonder" on the 16th June.

Unfortunately, M. Barossa, who was very anxious to see and report the trials to his Government, was at the last moment unable to attend; but on the morning of the trials, Colonel Dickens and Colonel Strachey, with Mr. John Fowler and Mr. Rendell, arrived at Port Madoc, and on Mr. Spooner's invitation after their return from examining the line, these gentlemen attended the experiments, which took place as follows:—

EXPERIMENT No. 1.—This was made with the "Little Giant" and "Welsh Pony" coupled together and attached to a train made up as follows—

	Tons	c.	Tons	c.	q.
75 loaded slate trucks weighing			183	13	3
8 empty slate trucks weighing			5	0	3
Passengers			1	0	0
			189	14	2
"Little Giant"	10	0			
Tender	1	2			
"Welsh Pony"	10	0			
Tender	1	6			
			22	8	0
Gross load			212	2	2

Both engines started from near the bridge at Port Madoc at 4·52 p.m., with the steam pressure in each at 150lb. The weather was very favourable, being warm and dry.

Both engines slipped much at starting, but on sanding five or six yards of rails they both went off well. At the middle of the embankment the "Little Giant's" pressure was 160lb., then it dropped to 155lb., and rose at far end of embankment to 160lb., after which it gradually increased until the two engines were pul up by the load, when it stood at 165lb. The "Welsh Pony's" pressure fell to 142lb. at the far end of the embankment, and to 140lb. at the Weighhouse, then a little beyond it rose to 144lb., and increased to 150lb., at which it stood when the two engines were pulled up by the load. The speed of the train increased to the far end of the embankment, then gradually diminished as we got round the curve, and when the whole train was on the incline of 1 in 85·65 both engines began to slip, and slipped frequently over this and the next two gradients of 1 in 100 and 1 in 90·51, on which they were pulled up by the load about 50 yards on the Port Madoc side of the Memfodd Gate crossing.

The distance run from the Port station was 1 mile 5 furlongs and 8 chains (nearly one mile of this distance being over the Traethmaur embankment, which is perfectly straight and nearly level), and the time occupied was 12 minutes, which gives an average speed of over 8½ miles an hour.

Everything was done that could possibly be done to get the utmost power out of these two engines; both were in good order, and their fires were strong and clear at starting, and it will be seen the boiler pressures were well maintained throughout. With their regulators full open, the engines made steam fast, whilst their speed slackened on the inclines, and some time before they were pulled up they were enveloped in clouds of steam. The train was allowed to drop down the inclines and run back to Port Madoc, and the "Little Wonder" was then attached to the train in place of the "Giant" and "Pony."

Experiment No. 2.—The train not having been shunted far enough down the line below the station, the "Little Wonder" stood opposite the water tank, and the rails there being always wet and greasy, she slipped considerably at starting. At the first effort, a link broke about twenty waggons from the front; and at the second, another of the adjoining waggon; after which, on sanding six or seven yards of rail, she made an easy and good start, and rapidly increased in speed until beyond the curve at the far end of the embankment, when she gradually slackened over the inclines of 1 in 85·65 and 1 in 100 to a rate of about 10 miles an hour, at which speed she passed the point where the others were pulled up on the gradient of 1 in 90·51, and went half a mile beyond, continuing to do her work well.

At this stage it was quite apparent that the engine had perfect command over its train, and on Mr. Spooner asking Mr. Fowler if he wished to proceed on further, the latter expressed himself satisfied, and at his instance the engine was stopped.

Her steam pressure on starting was 160lb.; it rose to 162lb. and fell to 158lb. at the signal post on the embankment, after which it gradually increased to 165lb. at far end of embankment, to 167lb. at weighhouse, fell to 160lb. at the gate crossing, to 157lb. at second gate crossing, to 155lb. at signal post, then 153lb. a little beyond, and rose to 155lb., at which it stood when the engine was stopped. The start was made at 5·45 p.m., and the stoppage at 5·55 p.m. The distance run was 2 miles 1 furlong and 3 chains, at an average rate of 18 miles an hour. The fires were not so frequently stoked as those of the other engines.

When the engine was stopped, a conversation took place as to whether it could start the train from its state of rest on the incline, and on Mr. Rendell remarking to me that he did not think the engine could do it, Mr. Spooner was asked to try it. Meantime, the driver, concluding that the experiment was over, and having only to return to the Port, lowered the fires and allowed the pressure to fall to 140lb., when the order to go a-head was given; and this being observed, it was decided to raise the pressure to that at which it stood when the engine was stopped. The rails were sanded for five or six yards, and with the gauge standing at 160lb. a good and easy start was made, and at an increasing speed for a quarter of a mile, when she was stopped, at Mr. Fowler's request, the experiment being satisfactory.

When stopped on the first run, the engine was at the head of the gradient of 1 in 90·51 on a curve of 15 chains, and as the heavier gradient of 1 in 82·71 was within 7 or 8 yards, her second start was practically made on that incline, and on it she attained a speed of 5 to 6 miles an hour, and was increasing when stopped, the gauge then indicating a pressure of 170lb.

For the first second or so after starting she slipped three times, with one-fourth of the train still under the brake, after which she again slipped twice, but went away easily, as stated, at an increasing speed.

Such were the results of the trials between the ordinary engines and your double-bogie engine, and they prove undoubtedly that the double-bogie engine, although only 19¼ tons gross weight as against 20 tons of the "Giant" and "Pony," and with a steam force at the rails of about 6 per cent. less in the "Wonder" than in the "Giant" and "Pony," that there is evidently a very great difference in favour of the double-bogie engine over ordinary engines; and from what Mr. Spooner, Mr. Roberts (of the Brecon line), and Captain Luckraft (of the Bury Port line), affirm, from their experience, there is a very considerable saving in fuel.

Now, how such great differences arise I cannot understand. I am prepared to admit there must be a saving, both in maintenance and fuel, by reason of the absence of flange friction from the bogies, and of oscillation, which increases so much (as proved by the experiments of M. de Weber) the normal load on ordinary locomotive wheels; but whence comes the considerable gain in power neither Mr. Glover nor myself are as yet able to fathom.—I am, dear sir, yours faithfully,

R. F. Fairlie, Esq., Westminster. G. Allan.

ELECTRICAL SPARKS.

[3866.]—"Sigma" is, or affects to be, angry with me for not having correctly understood his remarks: perhaps because I did not read them with the close attention he thinks they deserve, but possibly because he did not express himself so clearly as he would have done had he thought more of explaining what he meant and less of showing that somebody else was mistaken. From the same cause, apparently, he has again, at p. 667, left his meaning obscure, at least to me. I do not clearly understand whether he means to deny the possibility of gas being lighted by a spark from the finger, the electricity being unintentionally excited, or to dispute the adequacy of my suggested explanation of the phenomenon. If the former, he places me in the dilemma of either disputing his infallibility or of doubting the truthfulness of my informant; and as she is a pretty young lady, and he may be, for anything I know, a crusty old bachelor, I cannot hesitate which to do. If he means only to dispute my attempted explanation of the mode in which I imagined that the electricity had been excited—namely, by friction of a very dry shoe against a very dry carpet, he may be right, though no other probable explanation occurs to me, and it does not seem to me impossible that in a very dry air, which would carry away electricity much more slowly than our moist air does, electricity of tension enough to light gas might be thus excited.

He is so kind as to warn me of the danger of trying to rub sparks either out of a cat or out of "Sigma." He is mistaken in thinking sarcasm to be his forte. I do not think he will try, and am sure he will not succeed in riling Philo.

MISTLETOE BERRIES.

[3867.]—Since I replied to qy. 10386, about mistletoe berries, I have received a great number of letters, asking for berries, and how, when, and where to plant them, but I could not spare the time to answer them by post, so I hope the writers will not think me unkind in not answering them; but, sir, with your permission, I will reply to some of the questions through the English Mechanic. First the name, *Viscum album*, from the Latin *viscus*, clammy, on account of the sticky nature of the berries. This may be considered the only true parasitical plant indigenous to Britain, as at no period of its existence does it derive any nourishment from the soil, like *Orobanch*, or from decayed bark or wood, like certain fungi and other Epiphytes. Trees on which it grows here: apple, hawthorn, lime, maple, poplar, mountain ash, and acacia. Situation: the finest specimens are seen on trees growing in clayey soil, or near running streams, but sometimes it is found on the sides of the Cotswolds, at an elevation of 600ft. or more above the level of the Vale of Gloucester. It is seen in almost every conceivable position on trees, under the branches, or on the top, and on branches the size of one's finger, to some as large as a man's body. One may frequently see a number of little plants growing in a crevice, but more often some stuck on the smoothest parts of the bark, where, for the first part of their existence, they look like little warts; but after a time, say twelve months, the first leaves are formed, they are somewhat like the seed-leaves of the cucumber in shape. The seeds may be stuck on the trees in either of the first five months in the year, and should be placed on live, clean, healthy bark, as they will not grow on decayed bark, as has been stated by some writers. Plant high enough to be out of the reach of cattle, as it is said by some farmers to cause abortion in cows. There are male and female plants; sometimes both are found on the same tree, and again one tree is seen bearing only males, and another only females; sometimes as many as twenty bushes are seen growing on one apple tree, of various sizes, from 1ft. to 5ft. in diameter. I see no reason why it should not grow on many other trees besides those mentioned above, seeing it thrives on such dissimilar ones. Why one correspondent has failed to raise a single plant from many hundreds of seeds planted, is a mystery; no doubt birds would pick them out, but one would expect a few out of so great a number to escape them. Where birds are suspected of taking the seeds, a little matting may be tied over for protection. I think it would be better to plant the seeds on the shady side of the tree, in dry soils, and sunny aspects. R. Green.

A PLEA FOR HOUSE PLANTS.

[3868.]—Though "L. S. F." (letter 3792, p. 668) is quite correct in maintaining that plants in houses improve the air, I much doubt the possibility of having so many in any dwelling as to produce any appreciable effect upon the proportion of carbonic acid; neither do I agree with "L. S. F." in attributing the ill effect of close air wholly or chiefly to the excess of carbonic acid, though the proportion of that is not a bad measure of the degree of closeness. I believe the injury is almost entirely caused by that which certainly produces the feeling of closeness, the organic matter contained in pulmonary and cutaneous perspiration. When the watery vapour, with the organic matter combined with it or carried by it in a close room, is condensed with cold, the feeling of its closeness is greatly diminished, without any diminution of the carbonic acid, and if a larger proportion of that acid than is ever found in inhabited rooms be mixed with air, it produces no appreciable effect, if it be untainted with organic matter.

"L. S. F." probably meant to say that carbon is the solidifying principle of most substances possessing life, and wrote "all" inadvertently. "L. S. F." states, inadvertently of course, that carbon is the solidifying principle of all substances possessing life. He meant of most vegetable substances, not remembering at the moment that our bones, the most solid parts of our body, are so because of the phosphate and carbonate of lime they contain, and that some, both animal and vegetable living substances, are rendered rigid by silica, and by other matter than carbon. Though plants give out carbonic acid at night, the quantity is too small to be injurious. Philo.

VOLCANIC MOUNTAINS V.—BOILING FOUNTAINS AND LAKES.—UNDERGROUND SOUNDS.

[3869.]—In the eruptions of mud volcanoes, spoken of in the former letter 3794, p. 668, Vol. XIV., a frequent ingredient is boiling water. There are, however, several instances in which there are thrown up boiling waters, that are not at all intermingled with mud, but in which the water is either pure or impregnated with some mineral which it holds in perfect solution. Of this nature are the Geysers of Iceland and California, as mentioned in letter 3625, No. 361, p. 585. In New Zealand there is another variety of this phenomenon: the boiling water issuing forth not in intermittent jets, as in the Geysers, but in perpetual flowing springs, forming lakes, in which the water remains at the boiling point; these springs and lakes are to be found at Rotomahana. There are several basins raised, one above the other, and strange, all higher than the large lake; the highest is of an oval form, and about 250ft. in circumference; it is filled from an opening at the height of about 100ft. above the level of the lower lakes. At various stages below this upper basin are numerous other springs, from which several similar basins are filled; the whole of these basins empty themselves into the lake below, and the water in all of them is nearly boiling hot, giving forth with a hissing noise volumes of white vapour. These waters are richly impregnated with carbonate of lime, which has formed all round the margins of the basins beautiful incrustations of snowy whiteness. The sand round the lakes is very warm on both banks of the river Waikato; also in this neighbourhood are found numerous basins full of boiling mud or slime, which cannot be approached save with extreme care, owing to the softness and slipperiness of the soil. The largest of these basins is of an oval form, 14ft. long by 8ft. wide, and about as much in depth; it contains hot mud of a bright red colour, being strongly impregnated with oxide of iron; large viscous bubbles are continually rising to the top, and on bursting they emit a fetid sulphurous smell, and in many instances are nearly akin to those of a mud volcano. The underground soundings produced by volcanic forces are very remarkable. For the most part these are the preludes either of shocks of earthquakes or of volcanic eruptions. Those for months preceded the upheaval of the volcano of Jorullo (or Jorullo Monument).

Don Pedro di Jorullo was a Mexican gentleman, who lived about the middle of the last century; his residence was about ninety miles from the coast of the Pacific Ocean, westward of Mexico. In the beginning of the year 1759, underground rumblings were heard, and frequent shakings of the ground, which lasted fully two months, and then rested till September 28, when louder rumblings, like those of thunder, were heard, which caused the Indian servants to flee to the mountains. Next morning they saw that an immense tract of land had been upheaved fully three and a half miles square. The upheaval assumed the shape of an inflated bladder. At the edges this singular elevation rises only about 39ft. above the level of the plain, but so great is the general convexity of the mould that towards the centre it swells up to 524ft. above the original level. At this eruption thick clouds of ashes rose into the air, illuminated by glowing fires beneath, and the surface of the ground seemed to swell into billows like those of a tempestuous sea. Into the vast burning chasms whence these ejections were thrown two rivers plunged into contact, but the water only increased the violence of the eruptions; it was thrown into steam with explosive force; great quantities of mud and balls of basalt were ejected. On the surfaces of the swollen mud were formed thousands of small cones from 6ft. to 10ft. in height, and sending forth steam to heights varying from 20ft. to 30ft. There are other cones, particularly one, which is 1,600ft. high; this constitutes the volcano of Jorullo.

The crater of this mountain (or cone) sent forth vast torrents of molten lava, and it still continues. Many times when passing this scene we paused and reflected over its past history. About a month before the great mud eruption from Tunguaragua, on the 4th of February, 1797, there proceeded from the interior of that mountain noises of the most fearful kind: these would occur suddenly. They were heard by Antonio Pineda, the naturalist, who was there at the time, and they led him to foretell the approach of some great convulsion.

It is stated by Humboldt that on the grassy plains of Calabose, on the banks of the Rio Apure, a tributary of the Orinoco, there were heard over a large extent of country loud underground thunders, unaccompanied by any shaking of the ground, while some streams of lava were being poured forth from the crater of Morne-Garou in the island of St. Vincent, at the distance of no less than 632 miles. There have, nevertheless, been instances of the existence of such underground noises without their having been followed either by an earthquake, by a volcanic eruption, or any other outward appearance whatever. One of the most remarkable cases of this kind is that mentioned by Humboldt as having occurred at Guanaxuato, in Mexico, a mountain city, situated far from any active volcano. He states that noises began on the 9th of January, 1784, and lasted about a month. The sounds were at first neither very loud nor frequent, but from the 15th to the 16th of

January they resembled continuous low rolling thunder, alternating with short loud thunder-claps. The sounds then gradually died away.

A still more singular phenomenon occurs on the borders of the Red Sea, at a place called Nakous, where intermittent underground sounds have been heard for centuries. It is situated about half a mile from the shore, whence a long reach of land ascends rapidly to a height of about 300ft. It is about 26½ yards wide (from personal measurement), and resembles an amphitheatre, being walled in by low rocks. Sounds at this spot of underground rumblings occur regularly at intervals of about half an hour's duration. They first resemble a low murmur, but ere long there is heard a loud knocking, somewhat like the strokes of a bell, and this continues till the land is seen to move. The explanation of this curious phenomenon given by the Arabs is, that there is a convent under the ground there, and that these sounds are those of a bell, which the monks ring for prayers. So they called it Nakous. Philosophers attribute the sounds to suppressed volcanic action, probably to the bubbling of gas or vapours underground. RALPH LOWDON.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustration on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Commercial letters, or queries, or replies, are not inserted. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded; and the names of correspondents are not given to inquirers.

[10578.]—**Alexandra Palace Organ (U.Q.).**—I send, as promised, specification of the organ erected by Mr. Henry Willis in the Alexandra Palace, Muswell-hill :—

GREAT ORGAN.

1. Double Diapason, 16ft.	11. Quinte Octaviante, 2⅔ft.
2. Bourdon, 16ft. tone.	12. Super Octave, 2ft.
3. Open Diapason, 8ft.	13. Piccolo, 2ft.
4. Open Diapason, 8ft.	14. Sesquialtera, 5 ranks.
5. Open Diapason, 8ft.	15. Mixture, 3 ranks.
6. Viol di Gamba, 8ft.	16. Trombone, 16ft.
7. Claribel, 8ft.	17. Bombard, 8ft.
8. Quinte, 5⅓ft.	18. Trumpet, 8ft.
9. Principal, 4ft.	19. Posaune, 8ft.
10. Flûte Traversière, 4ft.	20. Clarion, 4ft.

SWELL ORGAN.

1. Double Diapason, 16ft.	11. Twelfth, 2⅔ft.
2. Bourdon, 16ft. tone.	12. Fifteenth, 2ft.
3. Open Diapason, 8ft.	13. Sesquialtera, 5 ranks.
4. Open Diapason, 8ft.	14. Mixture, 3 ranks.
5. Salcional, 8ft.	15. Contra Posaune, 16ft.
6. Lieblich Gedact, 8ft.	16. Contra Fagotto, 16ft.
7. Flûte Harmonique, 8ft. tone.	17. Cornopean, 8ft.
	18. Trumpet, 8ft.
8. Flûte Octaviante, 4ft.	19. Hautboy, 8ft.
9. Flûte Traverso, 4ft.	20. Voix Humaine, 8ft.
10. Principal, 4ft.	21. Clarion, 4ft.

CHOIR ORGAN.

1. Contra Gamba, 16ft.	9. Gemshorn, 4ft.
2. Viol di Gamba, 8ft.	10. Viola, 4ft.
3. Salcional, 8ft.	11. Lieblich Flöte, 4ft. tone.
4. Claribel, 8ft.	
5. Flûte Harmonique, 8ft. tone.	12. Flageolet, 2ft.
	13. Mixture, 3 ranks.
6. Lieblich Gedact, 8ft. tone.	14. Corno di Bassetto, 8ft.
	15. Trompette Harmonique, 8ft.
7. Vox Angelica, 8ft.	
8. Flûte Octaviante, 4ft.	16. Clarion, 4ft.

SOLO ORGAN.

1. Violoncello, 8ft.	8. Bombardon, 16ft.
2. Viola, 4ft.	9. Trumpet Harmonic, 8ft.
3. Flûte Harmonique, 8ft. tone.	10. Ophicleide, 8ft.
4. Flûte Octaviante, 4ft.	11. Bassoon, 8ft.
5. Concert Flute, 4ft.	12. Oboe (orchestral) 8ft.
6. Piccolo, 2ft.	13. Clarionette, 8ft.
7. Claribel, 8ft.	14. Clarion, 4ft.

PEDAL ORGAN.

1. Double Diapason (open wood), 32ft.	7. Contra Basso (open wood), 16ft.
2. Double Diapason (open metal), 32ft.	8. Octave (wood), 8ft.
	9. Principal (metal), 8ft.
3. Sub-Bourdon (wood), 32ft. tone.	10. Super Octave, 4ft.
	11. Sesquialtera, 3 ranks.
4. Open Diapason (wood), 16ft.	12. Mixture, 2 ranks.
	13. Bombard, 32ft.
5. Violon (metal), 16ft.	14. Trombone, 16ft.
6. Bourdon (wood), 16ft. tone.	15. Ophicleide, 16ft.
	16. Clarion, 8ft.

COUPLERS.

1. Solo to Great Organ.	9. Pedals (in Octaves) on Stops Nos. 14, 15, and 16.
2. Sub-Octave Solo.	
3. Super-Octave Solo.	
4. Solo to Choir.	10. Pedals (in Octaves) on Stops Nos. 10, 11, and 12.
5. Swell to Great, Unison.	
6. Swell to Great Super-Octave.	
	11. Solo to Pedals.
7. Swell to Great Sub-Octave.	12. Swell to Pedals.
	13. Great to Pedals.
8. Choir to Great.	14. Choir to Pedals.

The compass of the manuals is C C to A, 58 notes; and of the pedal, C C C to F, 2½ octaves, 30 notes. There are 6 pneumatic pistons to each clavier, which arrange, in fixed selections, the stops of each organ by the pressure of the finger. There are also several pedals which control the admission of wind to the various organs. The wind is derived from bellows placed in the basement; two of these are blown by a steam-engine of twelve horse-power, and supply ordinary pressures of wind. Another bellows is of prodigious strength, and blown, in connection with a vacuum apparatus, by another engine of eight horse-power. From these bellows the wind passes to 24 reservoirs placed in close proximity to the organs they are to supply. The pneumatic-lever is applied both to the manuals and pedal, as also, upon a new principle, to the draw-stop action. —E. F. CONRATH.

[10616.]—**Oleate of Soda.**—In reply to "E. W. B., Peckham," I beg to inform him I have at last found a chemist who professes to keep it in stock. I think upon analysis it will prove to be olive oil soap. Many thanks to "E. W. B." for his kindness.—SOAP BUBBLE.

[10646.]—**Cream of Tartar (U. Q.).**—Take grape juice and let it ferment, and cream of tartar will be left in the form of an argol. Dissolve the argol in hot water, to which add charcoal to take up the colouring matter, then by boiling and filtering a clear colourless solution is obtained, from which, on cooling, the cream of tartar separates in the form of crystals.—GIG-LAMPS.

[10675.]—**Colouring for Outside Work (U. Q.).** —To mix stone colour for outside work, grind whitelead with raw oil, and add umber as stain. Thin the colour with turps, and put patent dryers to it.—H. B. E.

[10684.]—**Lacquering Brasswork (U. Q.).**—Seeing that this is in the "unanswered" column, I reply: 1st. Why doesn't "C. H. R." follow out the directions already given? 2nd. Carriage work is not lacquered, with the exception of a few occasional armorial bearings, such as hammer-cloth crests, &c.—J. A.

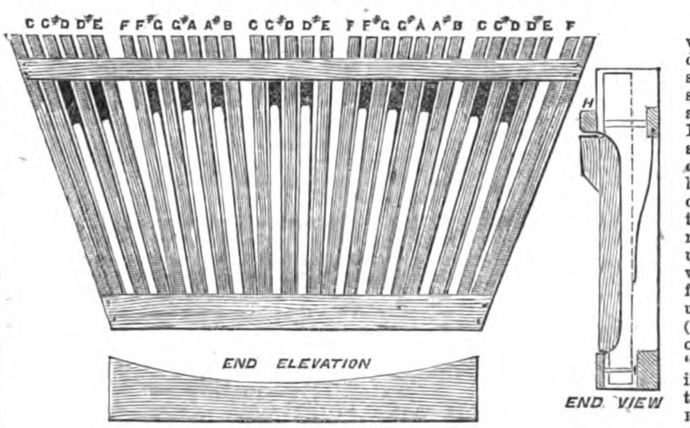
[10692.]—**Terra-Cotta (U. Q.).**—The first process in ordinary preparation is that of grinding the clay used for the purpose, for which the best are the clays of Devonshire, and the brown and blue clays of Dorsetshire; it is then submitted to the mill in the same condition as taken from the pit. From the mill it is removed and placed in vessels, where it is subjected to the action of water, after which it is baked. It may then be mixed with silica in various proportions according to the articles it is intended to form. This silica is made by grinding flint or coprolites, or it may be a mixture of sand used. If the preparation be required for fine work, it is then that washing and evaporation are necessary, but if only for common articles, the proportions of the compound may be mixed in the shape of dry powder, after which a small quantity of water is added, and then the whole may be kneaded or pugged in a mill. As different clays contract in the kiln, the mixture must be complete, or from shrinkage the article will certainly crack. After the clay, be it fine or coarse, has been taken from the slip, kiln, or the mill, it should not be used for four days. It has now two more operations to undergo before it is perfectly ready for use. The first is to beat it with an iron bar. The second is undertaken for the purpose of expelling the air that may have formed a lodgement. This is called wedging, and is performed by cutting the clay in pieces by means of a wire, and then throwing the several portions with force on the mass. Any sculptor might now model a figure in this clay. The greatest risk to terra-cotta compositions is drying. If an ornamental work be distorted in drying, it is destroyed, but this is not so with very common articles, which may be dressed by a carver so as still to be available. The shrinkage in drying is about three-quarters of an inch to a foot, in firing three-eighths of an inch to half an inch in the foot. The consumption of coal is enormous, averaging one ton and a half to each ton of ware to be fired, some of which require three days at a white heat. The revival of terra-cotta manufacture in England is due to the energy, enterprise, and intelligence of two of the "fair sex," the Misses Coade, of Lyme Regis, who, nearly ninety years ago, constructed an establishment in the vicinity of Lambeth, which by their perseverance and good management attained a degree of celebrity. I have seen some remarkable designs in terra-cotta, such as the ornamented columns in the refreshment-rooms at South Kensington. They, I believe, were executed by Messrs. Blanchard, who have carried terra-cotta manufacture to a degree of excellence never dreamed of by early terra-cotta workers. They patented a fire-proof staircase, the great merit of which is that it does not crack and break like stone under the combined ordeal of fire and water.—H. B. E.

[10754.]—**Velocipedes.**—I am now working out one of the thousand and one designs for motive carriages, which I planned when the "veloce mania" was raging, and I thought, on reading "W. R. S.'s" reply to this query, on page 648, that, perhaps, we are both working upon the same principle; mine is a tricycle, devoid of cranks, embodying both power and speed, and just the thing to meet the requirements of Mr. Browett's friend. "A. A. M.," page 619, states that he finds the forward push with the leg to be the best motion for velocipedes; this I rather doubt, it may be superior to that used on the common bicycle; but has he ever tried the old-fashioned vertical tread? I think if he does try it, he will find it superior as regards power, if not so easy a motion for the legs. I remember, when a youngster at school, not half a score years ago, in that locality four-wheelers with vertical tread were in general use, and I have no doubt they are so now, which for speed would put to shame the modern two-wheeler; and, indeed, I have seen its ancestor the "dandy-horse" propelled at a greater speed, which affair, with its rupture-producing and awkward kicking motion, I could never manage nor appreciate. If Mr. Browett's friend wishes to have a crank velocipede, or rather manumotive carriage, allow me to tell him that for ease and power combined a rowing motion is far the best. Both the steering and propulsion of the machine can be done with the hands, and a much longer crank can be used, if necessary, than by any other motion. By a forward push, I suppose "A. A. M." means a horizontal motion, the same as recommended by Mr. H. Reveley in one of the back volumes of "ours." If so, I should like to see his offered sketch.—FREDERIC W. SHEARING.

[10769.]—**Food for Rabbits.**—If "Rusticus" will take the trouble to well dig and manure a few square yards of land, and sow chicory in drills about a foot apart, he will not want for green meat for his rabbits. It may be cut every month or six weeks during the summer.—QUERCUS.

[10807.]—**Gearing Waggon Wheels.**—Many thanks to "Wheelwright" for answering my query; but I have one more question to ask him, and that is—if he had a wooden armed axle to put in, how would he line it out—by one line, as some do it, and get the hollow and length by same line? Does the height of wheels make any difference to hollow and length of bed? Supposing he had to put two new axles to a waggon, would he have the front axle the same length as the hind ones, to make them look straight on the fronts and track the same? A sketch would oblige.—YOUNG WHEELWRIGHT.

[10841.]—**Radius of Surface of Object-Glass.** —I am much obliged to Mr. H. T. Vivian (p. 670, Vol. XIV.), and for his former letter as to finding the two interior surfaces, which was just the formulæ I was short of. He has kindly given me in his last letter all the four surfaces, but I would have been glad if he had just stated the intended focus: is it for 70in., or less? I believe now that the finding of the dispersive ratio would not have been a doubtful matter if I had used a properly corrected eyepiece, not a simple lens. Would Mr. H. T. Vivian advise me to go over this all important matter again, or is he satisfied, with what I have stated, the refractive index is correct? I am in doubt about another matter. Sir J. Herschel says the foci of the lenses in the achromatic eyepiece ought to be as 3 to 2. A book I have seen says 3 to 1. Which may be right? There is a great difference in these proportions.—W. H. CASH.



[10855.]—**Pedal.**—I herewith inclose sketches of radiating and concave pedals, scale ¾in. to the foot; they should be made of 1in. birch, and the sharps should rise 1½in. at the highest point above the naturals. The pins on which the pedals work can be made of ¼in. round wire or old stair rods about that size; two will be required for each note, one at the back and under the stool, and one working in a mortice in the front end of the pedal, just under the thumping rail (marked H); the springs are of ⅛in. iron spring wire. If "Pedal" requires further information, I will endeavour to send it.—E. F. CONRATH.

[10863.] — **Sulphuric Acid.**—ERRATUM. — To make 7 tons of vitriol per week, 2 tons of sulphur (not 20) must be burnt weekly.—GEORGE E. DAVIS.

[10871.]—**Past Transits of Venus.**—In further reply to Mr. Lowdon's inquiry as to the transit of Venus on June 6, 1761, I find from the second vol. of Brewster's "Ferguson's Astronomy," that the sun's place was about 15° 36' of Gemini. The transit was observed at Greenwich by the then Astronomer Royal, Dr. Bliss; in London by Mr. Short; at Hackney by Messrs. Ellicot & Dollond; in Spital-square, London, by Mr. Canton; at Liskeard, in Cornwall, by the Rev. Richard Haydon, and by other persons at various places. It appears that Mr. Short took "an incredible deal of pains in deducing the quantity of the sun's parallax from the best of those observations which were made both in Britain and abroad; and finds it to have been 8·52″ on the day of the transit, when the sun was very nearly at his greatest distance from the earth; and consequently 8·65″ when the sun is at his mean distance from the earth." (P. 115.) "At Stockholm Observatory, latitude 59° 20½′ north, and longitude 1h. 12m. east from Greenwich, the whole of the transit was visible; the total ingress was observed by Mr. Wargentin to be at 8h. 39m. 23s. in the morning, and the beginning of egress at 9h. 30m. 8s.: so that the whole duration between the two internal contacts, as seen at that place, was 5h. 50m. 45s." (Pages 112 and 113.) Elements are given for projecting the transit, but as they would occupy a large space, and probably be interesting to but few of the readers of the ENGLISH MECHANIC, I do not now send them, but should Mr. Lowdon wish for them, and his address be communicated to me, I shall have pleasure in forwarding them to him. This transit appears to have been the second only which has been observed. The first one known to have been observed took place in December, 1639, when Mr. Horrox observed it at Hool, near Liverpool, and his friend Mr. Crabtree at or near Manchester.—C. W. M.

[10873.]—**Tooth Stopping.**—Your correspondent "Dentiste" is at fault in stating that a good amalgam for the above purpose should consist of equal parts of silver and tin. The proportion should be fine silver 4½ parts, tin leaf 2½ parts, but the superior amalgams contain gold. Chemically pure mercury should be used; that which is commonly sold as pure is known to contain lead, antimony, &c., which impurities cannot be separated by distillation, and if used quite alter the compound, and cause it to become discoloured in the mouth.—F. GRAHAM YOUNG, Surgeon-Dentist.

[10897.]—**Boilers.** — It is impossible to answer "Comjee" exactly in the manner he desires. Which is the *best* boiler depends entirely on what it is required to do; but "Comjee" cannot go wrong if he uses the ordinary "saddle-back" for moderate lengths of piping, and the "tubular" where the piping is reckoned by "miles." There are as many boilers as quack pills, and their advantages as described by the vendors require to be taken with a large grain of salt.—SAUL RYMEA.

[10927.]—**Sealskin.**—"Watts" must get some mahogany sawdust from the steam saw-mills, and with plenty of this sifted fine, and perfectly dry, he must soundly rub his sealskin for two or three hours in a tub or pan, working hard with sleeves up; then beat out the dust with a light cane, when he will find it clean probably sweet; but if not, he must take charcoal, reduce it to powder, and put the skin in a box with a layer of this an inch or more thick, under and over it on both sides of skin; put it by for six weeks, then take it out and clean it off with sawdust as before. This latter was till now my own secret for deodorising skins.—PRACTICAL FURRIER.

[10939.]—**Sealskin.**—How to distinguish, quotha? Not so easy! But *nil desperandum*. The skins you may know by their size, 3ft. to 4ft. long, and two fin-holes in the sides. In pieces it may be known by its soft velvety feel under the hand, but best by the shining silky appearance and golden brown colour of the fur under the dyed surface, to be seen by blowing into it; all other furs excepting sea-otter having a dull woolly look underneath. The furs most like seal are dyed plucked otter, and sea-otter pups, both more valuable. Dyed nutria and beaver look rougher, are longer in the fur, and brown and blue underneath. Dyed musquash is too shining on surface, blue under; it also springs back when rubbed the wrong way. Dyed sheared rabbit is much too harsh to be mistaken for seal, and dyed mole, though beautifully soft, may be known by its small size and the blue underneath.—PRACTICAL FURRIER.

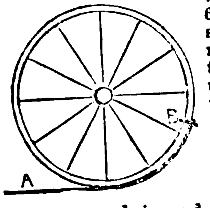
[10956.]—**Musical Box.**—If "Il Trovatore's" musical-box is a large one, he must get some watch hairspring wire, and pin a small length under the tooth, and bend it to form a curve of half-circle like a D laid thus ᗜ, but do not let it quite touch the point of tooth nor stand further out, or it may be drawn up with the pin, but so that the pin in roller will touch damper first. If a small box (and for lesser notes in large ones) he must use a quill split no broader than the tooth point scraped thin, and cemented to the tooth with shellac, dissolved in spirits of wine or wood naphtha, but do not cement it to the extreme point, but let it have a little spring.—H. B. B.

[10966.]—**Doubling Frames.**—I quite agree with "A New Correspondent" in what he says on p. 646, Vol. XIV., about doubling 40 and 60 from the cop, but I am doubling 80 and 100, and they are continually breaking at the nose of the cop. The rollers are 1⅜in. diameter, and they make nineteen revolutions per minute. The spindle makes 4,080 per minute, and there is a great deal of snarling between the rollers and the spindle. I have plenty of drag on the bobbins. When the first layer is going on the bobbins and gets nearly to the bottom, and when the travise is turning, two-thirds of the end snarls and breaks down. Any information respecting the same would oblige—A FAITHFUL WORKMAN.

[10982.]—**Rock Inscriptions.**—A few years ago Mr. F. Good, the well-known publisher in the Minories, went to Syria, and amongst other places visited the district of Sinai, and photographed the Wady Mokattab (the Written Valley). Those photographs are remarkable, not alone for the peculiar interest of the locality and objects they are transcripts of, but even for their artistic beauty, sharpness, and general excellence. It is rarely that we see photographs taken of English scenery, where the manipulator has or can have every help and convenience of chemicals and mechanical appliance, equalling those views from the remote, sterile wilderness of Syria, in definition, purity, and brilliancy. They have been issued as stereograms by Mr. Good; amongst them are slides of the written rocks, and the most remarkable of the "wadys" (valleys or dry watercourses). I suggested to Mr. Good to employ his valuable negatives for the production of lantern transparencies, and although I have not seen them, I have reason to think he has adopted my recommendation.—EDWARD B. FENNESSY.

[10996.]—**How to use a Book without Hands.**—The misfortune that has happened to our friend may result in his becoming very handy with his other limbs happily spared—not that I am going to suggest that he should make an exhibition as I have seen—viz., writing, firing off a gun, and shaving himself with his remaining limbs. But for his sake I fancied myself minus hands and arms, and thought, now what shall I do? The ENGLISH MECHANIC lay before me, and I managed to turn over the leaves quite easily with my lips, using the upper lip for the upper corner, and the lower lip for the lower corner of the sheet. Here no machine is required, or would get out of order, and it is the most natural way as far as I can see, for he can carry his paper or book quite independent of his friends, and he will find many other things that he can do probably much quicker than could be suggested to him; for is not necessity the mother of invention?—FIDDLER.

[11009.]—**Bending Tires.**—Machines for bending tires have appeared in back volumes. (See pp. 560 and 681, Vol. X.) The sketch sent is a plan I saw used by my pater's workmen, when the machine they generally used was out of repair. It is very simple and light—tires can be bent very quick by it. A is the tire, C is an old carriage wheel (if less than the size required it is no disadvantage), B is a horse-shoe put round rim and tire, holding them together. By turning the wheel the tire is bent.—F. W. SHEARING.



[11026.]—**Defective Plating Solution.**—No plating solution is really useful without a separate battery. Dissolve nitrate of silver (1oz.) in clean rain water (half a gallon). Precipitate with solution of cyanide of potassium (do not add more cyanide than is necessary to precipitate; the process must be slowly and carefully performed); wash precipitate four or five times; take up with solution of cyanide, add water to make one gallon, add about 2oz. more cyanide. Set resulting solution aside for two or three days to settle, which is better than filtering. I shall be very glad to give more minute directions for making solution, and also for working it, if desired. I have obtained more help from Gore than from Watts, but find *experientia docet* the best guide.—J. A.

[11028.]—**Pocket Aneroid Barometer.**—Many thanks for the replies given. In reply to "J. A.," the thing wanted is one convenient for the pocket, and able to give, within a yard, the height of cliffs or hills, &c. I should much like some of the results of his tests that he speaks of.—CAMPANILE.

[11031.]—**Model of Church.**—I heartily thank Henry Newman for his kind offer, and shall be glad to avail myself of it. I want to have eight bells to play five minutes. I should like them to play both tunes and chimes, any or as many tunes as you like will do. If not possible for both, I prefer chimes. Height of steeple, 19in.—MODELLER.

[11037.]—**Weight of Metals per Foot.**—As a cubic foot of water weighs 62·34lb. = 997·44oz., or nearly 1,000oz., the weight in pounds of a cubic foot of any substance may be known very nearly by dividing its specific gravity (water being taken at 1,000) by 16, a rule very easy to remember, and sufficiently accurate for most purposes, but so well known that it has probably been already published in your pages.—PHILO.

[11044.]—**Removing Powder and Shot from the Skin.**—If "Abby" has any running wounds from gun-shot, apply milk, or if healed, milk, pricked into the coloured parts the same as ink is used for tatooing, will, I have been informed, perfectly eradicate all colour, it taking the place of the ink, coal, or powder which colours the flesh. A schoolmate of mine has perfectly got rid of marks on his arm in this way.—W. H. M.

[11048.]—**Magic Lantern Sheet.**—It is very presumptuous to speak after a correspondent like Mr. Tonkes, but if the querist is going to perform in a room, he will find a sheet dipped in water will make a "mess;" it drops on the carpet and wets it through. I should advise simply to sprinkle the sheet, leaving no part untouched. If he doesn't warm his lenses, he will, even with a wet sheet, get a cloudy picture at first.—HEDERA.

[11052.]—**Rising and Setting of the Moon.**—Have not your correspondents forgotten that the moon's horizontal parallax enters as an element in the computation of her rising and setting? A table of lunar semi-diurnal arcs, including the effect of refraction, is necessary.—W. R. BIRT.

[11057.]—**Watchmaking.**—Would "Independent Chronometer" please say why is there oil put on the escape wheel of a Geneva lever, seeing that the friction is the same in regard to the ruby pin and fork? The friction in both cases works between steel and ruby stone. He might just as well say "J. O." would do well not to oil the staff holes if the pivots were well polished. It is a well-known fact to every practical man that when oil thickens on many parts of a watch it interferes with its correct time. The best remedy, I find, for that is to have it removed and renewed with fresh oil.—C. CAMPBELL.

[11068.]—**Moth v. Fur.**—As some replies have appeared, allow me to affirm that I often take in furs with moths in, although protected by pepper, camphor, Russian leather, colocynth, or bitter apple, cayenne, cedar, Keating's powder, &c. Now preventives to moth must be either powerful poisons or pungent volatile oils, or spirits, and these, though answering very well in a small way in private houses, would never do in a shop, for if one uses the former, as arsenic or corrosive sublimate, in sufficient quantity to be effective, it will as certainly destroy him as my little friends the moths: and if the latter, as paraffin, creosote, turpentine, or camphor, the smell will drive every one out of the shop, and make the furs unsaleable. Furriers keep their stock by sheer hard work, as follows:—The furs are laid on a table, and rapidly beaten over with a cane in each hand, until neither dust nor hair is seen to fly, the hair is then combed straight, and they are put away. This is repeated every fortnight during the summer, and the hotter the weather, the harder we work. But practice brings dexterity (blisters on hands first), and stock well kept is always half sold. In this way, and in this way only, I can assure "One" I do, and he may keep a stock worth £3,000 always ready for immediate sale.—PRACTICAL FURRIER.

[11093.] — **Champagne Stains.**—Try benzine collas, which may be bought at any druggist's for a trifle.—H. B. E.

[11107.]—**Table of Dates.**—What Mr. W. R. Birt (p. 674, Vol. XIV.) wants could easily be supplied on the same principle as the table I gave before—that is, for the number of days from any time of one year to the same time in any other year, whilst the first table would supplement the other for finding the number of days from any one day to any other.—H. G. M.

[11113.]—**Weights of Wind in the Organ.**—The usual method of obtaining various pressures of wind from one pair of feeders is by making the feeders to supply the heaviest pressure reservoir, and this reservoir feed the several lighter weights, which will, of course, be first inflated in the order of pressure from light to heavy. In each of the lighter reservoirs there is a self-acting valve connected to the top board, so that when the bellows is fully distended, this valve is closed so that no more wind can enter from the heavy pressure until some of lighter are used. Thus, the lightest reservoir is kept full so long as there is any wind in the heavier. It is not absolutely necessary to use expanding wind trunks, but they are preferable, if the bellows lay exactly over one another as the wind can go direct from the top of one reservoir to the bottom of the other. I hope that this explanation will be understood by "W.," if not, I will send him a sketch of the arrangement.—E. F. CONRATH.

[11120.]—**A Question of Sight.**—I am no astronomer, and therefore, perhaps, I do not understand the "A. J. V. G.'s" supposition on p. 674, Vol. XIV., of the sun being equivalent to a luminous point, but to my mind it would seem, on the contrary, that the sun, being considerably larger than the earth, would naturally throw a shadow in the form of a convergent cone surrounded by a penumbra.—H. G. M.

[11120.]—**A Question of Sight.**—We are told that Charles II. put a catch question to the Royal Society in its early days, and "E. L. G." recently came to grief over quoting that event erroneously. I am inclined to give "Fiddler" the credit of imitating the royal scamp, and of putting an absurd question for the purpose of seeing how much wisdom would be exercised about it. At all events he has succeeded in illustrating the fact that there are a number of people always ready to discuss any nonsense seriously, and to take a joke or ironical expression as an argument worthy of serious demolition. Two columns of close print contributed by ten people (including one diagram) over a question which would be reasonable if asked by a child six years of age! The astute "E. L. G." even falls into the trap, and proceeds to demolish poor "A. J. V. G." in pure unconsciousness of the obvious fact that the latter was laughing at the question. And then J. Barwick, who knows all about the space between the stars, and can tell us whether the atom of hydrogen is round, and that of carbon square, now informs us that the moon casts the earth's shadow on the sun! Well, we live and learn. I have seen the electric light cast a shadow from the flame of a candle, and as "action and reaction are equal" it may be that the candle also produced a shadow of the electric light—certainly I did not see it, but that is nothing. However, we may disregard such a mere detail as the relative photometric energies of sun and moon; but as it is now obvious, as Mr. Barwick says so, that "light can hardly be deemed vibration," it will be interesting to learn the process by which the earth's shadow is "cast by the moon on the sun during the eclipse." I really wish the printer's devil would append a note instructing me how to laugh in type.—SIGMA.

[11128.]—**Lantern Pinions.**—"Tubal Kain" is not right (see his answer p. 21, Vol. XV.) in saying that the pitch of the "pins or trundles" is the distance of their centres: though he is right in saying that the pitch should be the same as that of the wheel into which they gear. Take a pinion of 6 pins for simplicity; if their pitch were the distance of their centres, then the circumference of the pitch line would be six times that distance; whereas it should be 3·1416 × 2 or 6·2832, or about 5 per cent. more for such a small pinion. For larger ones the discrepancy would be less; but then lanterns are made commonly with only 6 pins, and not frequently with more than 10, so that the error must not be overlooked, particularly as they tend to act before the line of centres, or to jam, if put too close together.—J. K. P.

[11128.]—**Making Swimming Bath.**—If it is really clay in which you are to cut, you could not be in better case. Throw out the clay the size you want, let the sides have an inclination of 1 to 1; then, with any kind of penn stick, which is heavy enough, well beat the sides and bottom, a piece of rain water pipe with the end filled up will do; it must be thoroughly rammed, never mind the roughness, for the next operation is to cast in some of the excavated clay, which has been cut into small pieces with the spade, having gravel and stones picked out, and, if very compact, watered, and trod down till you get a thickness of 9in., ramming it in 3in. layers. This method will succeed in any soil. 1½in. or 2in. paving stones nicely jointed, and simply laid on the clay will keep the water clear; the joints can be pointed with cement. Flooring tiles which are from 8in. to 12in. square would also do, or the rammed clay can be faced with hard burned bricks set in hydraulic lime, or any good cement; if rough bricks are used they could be plastered with ground Southam lime, which would make a clean white water-tight lining.—S. H.

[11138.] — **Violin.**—It is impossible to answer "J. W. L." in toto; and as for notations he had better begin as he intends to end, or rather must end—viz., in the old notation. By all means get a good violin, and never change it, but make it your friend. To be short, I advise the purchase of "Campagneli's School for the Violin;" it is divided into four parts, 7s. each, and the system contains all that is necessary to know.—FIDDLER.

[11154.]—**Whellaw's New Medical Discovery.**—This is, no doubt, the work called "Whitlaw's New Medical Discovery," and if so, is a description of a new method of treating disease by portable vapour baths, medicated with different herbs, of which it has likewise a copious description, along with some account of the Linnæan system of botany. I read it twenty-five years ago, and it appeared to me to be an adaptation of the Thompsonian or botanic practice of medicine, in which herbs and vapour baths held so important a place. The author professed to have travelled much in America, the birthplace of the Thompsonian practice; the supposition is, therefore, not without probability.—F. P.

[11158.]—**Ermine Fur.**—You cannot entirely remove the colour. To clean, rub it well with dry plaster of Paris and flour or fine white saw-dust; the longer it is cleaned the better it will look. You may further improve it by damping the surface with benzine, and dusting on plenty of plaster of Paris (previously well washed and dried). Allow it to dry, then beat out the dust with a light cane.—PRACTICAL FURRIER.

[11168.]—**Wood Rods.**—If "Joiner" lives near a lead pencil manufactory, the machine used for rounding the pencils before cutting into lengths would suit his purpose, I think. It consists of a small lathe head having a cutter and a hollow mandril. The rod is passed through the mandril, and coming into contact with the rapidly revolving cutter is rounded with rapidity and ease.—RHO SIGMA.

[11175.]—**Cutting Mounts.**—The metal guides are made of steel, about ⅛in. thick, and at least 1in. broad, one side is bevelled off. The knife is passed along the bevel, while the guide is held down firm. Straight guides for straight lines, and an outer segment of an oval for oval mounts, but for different sizes of ovals different guides are wanted; always cut the mount from the body—*i.e.*, lay the guide upon that portion of the mount which you are going to use.—THE WELSH SHEPHERD.

[11179.]—**Covered Wire.**—"Magpie" can get silk and cotton covered wire at any good philosophical instrument dealer's, of many colours, and of various thicknesses, too numerous to mention.—RHO SIGMA.

[11183.]—**Road Material.**—It depends entirely upon the quality of the bottom—if hard, ashes will do; if soft, a layer of handpacked stones 4in. thick, having an area on the bed of 36in. at least; fill in the gaps with gravel, and over that a layer of stone 4in. thick, broken in plan to 3in. cubes, and blind with coarse sand, and on that another course of stone broken to 2in. cubes and filled in with sand. If this is to be "pitched" or paved with granite blocks, it may be of soft stone and 4in. thick; but if the surface of road is not to be block paved, the hardest granite should be used and blinded with gravel, and the thickness from 6in. to 9in. for heavy traffic. Care must be used to prevent ruts and unequal wear.—J. H.

[11186.]—**Length of Sidereal Day.**—"T. H. M." is quite right. See *Nautical Almanac*, 1872, p. 528.—W. R. BIRT.

[11188.]—**Arithmetic.**—£19 19s. 11¾d. being only a farthing off £20—

Say £20 × £20 =	£400	0	0
Less 39 farthings			9¾
	£399	19	2¼

Upon the same principle, £19 × £19—

Say £20 × £20 =	£400	
Less £39		39
	£361	

Am I right?—C. R. F., Shrewsbury.

[11191.]—**Radius and Weight of Fly-wheel.**—Multiply the number of horse-power of engine by 2,000, and divide the product by the square of the velocity of the circumference of the wheel in feet per second, the quotient is the weight of the fly-wheel in hundred-weights. There is no fixed rule for finding the diameter, as with large engines the diameter in feet is more than the number of horse-power, and in small engines, more.—P. W. H. J.

[11191.]—**Radius and Weight of Fly-Wheel.**—Let V = velocity of the periphery of the wheel in feet per second; H = horse-power; D = mean diameter of rim in feet; N = number of revolutions per minute; P = the total average pressure on piston in pounds avoirdupois; and S = stroke in feet. W = weight of rim in cwts. $= \frac{P\,S}{45\,D} = \frac{1344\,H}{D\,N}$. D = stroke, multiplied by 3½ or 4 generally. Sectional area of rim in inches $= \frac{11{\cdot}42\;W}{D}$. In corn-mills, the velocity of the periphery of the fly-wheel must exceed the velocity of the periphery of the stones, in order to prevent back-lash. If your correspondent does not understand algebra, he will require a little more information. For instance, $\frac{P\,S}{45\,D}$ means $\frac{P \times S}{45 \times D}$; $\frac{1344\,H}{D\,N}$ means $\frac{1344 \times H}{D \times N}$; and $\frac{11{\cdot}42\;W}{D}$ means $\frac{11{\cdot}42 \times W}{D}$.—W. AIREY.

[11191.]—**Radius and Weight of Fly-Wheel.**—Rennie's rule for fly-wheel:—

r = radius of wheel.
p = pressure on cylinder.
c = capacity of boiler.
v = velocity of crank-pin.
s = empirical constant, varying from ·002 to ·0015.

$\frac{r}{p} = \frac{c}{v} = s$; this gives the required radius.

Weight = 409 × r^3 × τ; this gives the weight in pounds.—S. TREMAYNE, Cantab.

[11191.]—**Radius and Weight of Fly-Wheel.**—There are many considerations to be examined into in determining these proportions, viz.:—(1) The kind of machinery to be impelled; (2) the regularity of motion required; (3) the rate of expansion of the steam in the cylinder. The radius of fly-wheel is usually from 3 to 5 that of the crank. The weight of the rim is generally 100lb. to 300lb. for each actual horse-power, varying with the rate of expansion used. The larger the diameter the less will be dead weight on the journals. The diameter must not exceed the limit of the tensional strength of the material of which the rim is made (usually cast iron), that it should not be ruptured by the centrifugal force. No engine-maker of any standing would put a fly-wheel with a rim of the same weight to any two engines he would build of one power and size, if they were intended for different purposes. For instance, if for pumping, a light (comparatively) fly-wheel only is necessary, just sufficient to turn the engine over the dead centres; for driving corn-mills and spinning fine threads, a much heavier one, and for rolling mills, a very much heavier one, wherein should be accumulated sufficient force, that the engine or the rolls may not be retarded when the material is being passed through.—TUBAL KAIN.

[11192.]—**Chemical.**—The nitrate of potash will crystallise at a temperature of 490° Fahr.; the carbonate at 499·5°; so, by keeping the temperature of the liquid between 490° and 499·5°. You will be able to crystallise out the whole of the nitrate.—S. TREMAYNE, Cantab.

[11193.]—**Pumps of Portable Engine.**—The reason why the pump won't act is because it has no back pressure valve, which is another valve fixed between the pump and boiler. Even then the valve will sometimes want cleaning out if the water is at all muddy. We have got a small engine drawing water from tanks by siphons, and up these siphons it drew a piece of indiarubber which passed the pump-valves, and lodged in the back-pressure valve, so that we had to run steam down, because the pump valves would not act. You see, in this instance, the pump with three valves would not act. A boiler pump with two valves is not to be trusted at all, if the workmanship is at all defective. The valves should be examined and cleaned every two or three months. A pump with two valves can be generally started with a head of clean water, but not always. The difficulty increases as the pump becomes smaller. I don't see the need of two hose pipes, except he wants to draw from two separate tanks, which is unlikely. One would both cost less and answer better.—P. W. H. J.

[11193.]—**Pumps of Portable Engine.**—Let "A. C. T." get a small wood mallet and give the valve-box a rap or two, and the valves will again work; they have got dry and expanded, which has caused them to stick a little. Do not make mountains of mole hills.—C. A. M.

[11193.] —**Pumps of Portable Engine.** —From the description given the delivery valve leading from the pump to the boiler is leaky, thereby allowing hot water to pass back from the boiler to the pump. The pumps with three valves really are only two. The third valve is a stop back, and serves to retain the water in the boiler when the relief-cock is opened to prevent the feed-pump injecting water into the boiler. It is a much better plan than a pump without the stop back-valve, as the pump is, so to say, constantly at work, and any surplus water that is not required in the boiler is allowed to escape by the relief-cock, and return through the second or small hose back again to the feed-water tank. Any pump can have this auxiliary stop back valve and relief-cock attached to it and the boiler.—TUBAL KAIN.

[11195.]—**McCarter's Improvements in Condensation.**—This improvement consists principally in using oil instead of water for injection; the condensed steam sinks to the bottom of the oil, and is forced from a hole at the bottom of the condenser by the steam from the cylinder at each stroke.—S. TREMAYNE, Cantab.

[11197.]—**Sharpening Steel Scraper.**—Should be held vertically over "oil stone," and rubbed to and fro, the broad way of the blade. This will cause the face to be at right angles with the sides, and slightly convex on the face, so that it will be most prominent in the centre, and work better than if flat. A little tuition and practice in a regular shop will soon instruct "Excelsior."—TUBAL KAIN.

[11197.]—**Sharpening Steel Scraper.**—First file the scraper on the edge straight lengthways with a fine flat file; then lay it flat on the bench, and with a stout bradawl kept flat on the scraper rub hard from one end to the other on both sides, and then the edges.—ELECTRO.

[11197.]—**Sharpening Steel Scraper.**—Rub the edge of the scraper perfectly square on the oil stone, then lay it flat on the bench, and with the scraper sharpener, burnish the flat side near the cutting edge, but holding the sharpener quite flat; then set it up on its end with the cutting edge to the right, and give one stroke up, bearing a little towards the edge you wish to make cut, turn it over and repeat the process on the other angle.—M. O.

[11198.]—**Birch Wood.**—American birch is more likely to warp than, I think, any other wood, and it will be extremely difficult to bore such small pieces without splitting. I have used birch every week (more or less) for above forty years, the only way ⅛in. pieces could be bored with safety is with a sharp drill in the lathe.—M. O.

[11198.]—**Birch.**—Some of it is straight and easily worked; some of it curly and beautiful; it is easily worked. To bore it use a clean cutting carpenter's pin bit in the lengths before cutting them up short.—ELECTRO.

[11200.]—**Horizontal Engine.**—Cylinder 1¼in. diameter by 3in. stroke, diameter of crank-shaft ⅝in., diameter of piston-rod ¼in., diameter of fly-wheel 12in. to 15in. Use either "gun metal" or cast iron. Neither can be melted in a kitchen fire, to be used for that purpose. Better make your pattern, and go to a founder to have it cast for you. The rim of fly-wheel may be of lead.—TUBAL KAIN.

[11201.]—**Lias Insect Beds.**—What better work can "W. F." require than the one named by the Rev. P. B. Brodie, M.A.? It contains eleven plates and one hundred and thirty pages of letter-press, with much information upon the subject. Plate 11 gives a section of the Vale of Bristol; Bedminster Down is one locality named—there are four beds of insect limestone separated by clays, total thickness 1ft. 9in.; these are under the lias and 17ft. 9in. from the surface. This quarry is two miles south-east of Bristol. This may not be the best for the purpose of study, being one of the first which presented itself to my notice; there may be many others far better; but a note addressed to the Rev. Mr. Brodie, Rowington Vicarage, Warwickshire, I doubt not, will receive every attention, having myself experienced his kindness in a liberal supply of specimens of the insects, with his views upon other matters connected with this subject. Perhaps it may be unnecessary to enter more fully into Mr. Brodie's work, since "W. F." appears acquainted with it. Should that not be so, I will gladly assist him as far as possible.
W. PALING, Newark.

[11201.]—**Lias Insect Beds.**—In reply to "W. F.," the insect limestone of the lias crops out at various parts of a tract of country comprising portions of Worcester, Warwickshire, and Gloucestershire. It is also found in parts of Somerset and Monmouth. Insect remains have been found both in the upper and lower lias, but the true "insect limestone" occurs near the base of the lower lias. I believe the finest section to be at Clust Cliff, on the Severn, but the cliff is almost inaccessible. The Garden Cliff, at Westbury-on-Severn, and Wainlode Cliff, a few miles above Gloucester, also present good sections. Throughout this district, wherever the lower lias occurs, it is sure to be accompanied by the insect limestone more or less fully developed. I shall be happy to give "W. F." more detailed and local information if he will favour me with his address.—OSA.

[11213.]—**Carat.** — The carat used in weighing precious stones is four grains, rather lighter than troy grains ($74\frac{1}{16}$ carat grains are equal to 72 troy grains). When quoted in relation to gold alloy it is not an absolute weight, but means the twenty-fourth part of any weight. Thus 12 carats signifies that half the material is pure gold; *i.e.*, 12 parts out of 24, the other 12 being alloy. The seed referred to is a bean, the fruit of an Abyssinian tree called "Kuara."—J. A.

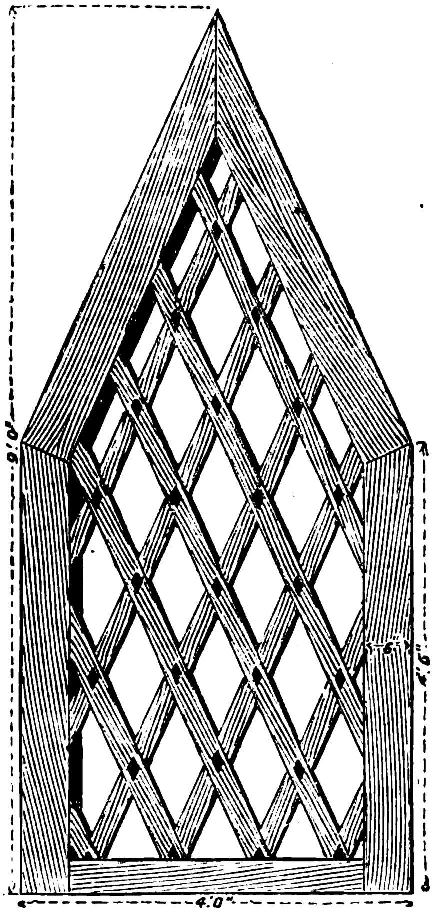
[11213.]—**Carat.**—The exact weight of a j... or goldsmith's carat used for weighing pr...

and pearls is four grains. 2. The weight which expresses the fineness of gold. The whole mass of gold is divided into 24 equal parts, and as many 24th parts as it contains of pure metal is called gold of so many carats. Thus gold of 18 parts of pure metal is called gold of 18 carats. Carat from the Greek, a little horn or pod, and the berry of a pod. From the Greeks it is thought the Arabians borrowed their karat, a weight used in Mecca equal to the twenty-fourth of a denarius or dernier. The carat in Great Britain is divided into 4 grains, among the Germans into 12 parts, and among the French into 32 parts.—Hermes.

[11213.]—**Carat.**—Originally it was the name given to the seeds of the Abyssinian coral flower, and likewise to the carob-tree seeds. Goldsmiths and assayers divide the troy pound, ounce, or any other weight, into 24 parts, and call each a carat, as means of stating the proportions of pure gold contained in any alloy of gold with other metals.—Gig-Lamps.

[11215.]—**Divi-Divi.**—The amount of divi-divi imported into England for 1869 was 22,006¾ tons; in 1870, 29,193¼; and in 1871, first half-year, 15,103.—S. Tremayne, Cantab.

[11216.] — **Garden Gate.**—The accompanying drawing is of a lattice work gate or door of timber. It looks exceedingly well executed in oak and varnished, and especially if kept as massive as possible. If made of



red deal or pitch pine, &c., a good colour to paint is Indian red. I recommend imitation nail heads of wood in preference to iron, on account of rust. By means of a movable sheet of zinc the gate may be made either an open-work or a close one.—Jannifred.

[11218.] — **Smee's Battery.**—Platinised copper will act in a Smee's arrangement, but is not so effective as platinised silver. In electro-plating works where batteries are used (Wilde's Magneto is now being largely adopted) the negative element is generally copper, not platinised; in fact a "Wollaston" with "Smee" arrangement. This battery has many defects, however. I presume T. H. Somerville only wants a small affair, and I should advise him to use either the usual Smee, or Daniell's. Relative to platinising: In outer cell your platinum solution; in porous cell water about 14 parts; sulphuric acid 1 part; into porous cell immerse rod of amalgamated zinc; into outer vessel, and bent round porous cell, your silver or copper to be platinised. Connect the two metals by a wire, and in a short time a good black deposit will be formed, and the job is done. Platinised iron would be attacked. Iron is a nuisance in batteries. I don't except even the Maynooth.—J. A.

[11219].—**Silicate of Soda or Soluble Glass.**—You have taken too much silicate. The white chalk, in fine powder, is laid upon a hard substance. Work chalk and silicate with a table-knife into a very stiff paste, it will set quick; but if anything is cemented with it, the joint should be tied with a string, as it takes a few days to harden. Exposed to air, it will harden in a few hours. Clean your knife with hot water directly afterwards.—The Welsh Shepherd.

[11219.]—**Silicate of Soda or Soluble Glass.**—There is something wrong in your method of preparation. It ought not to dissolve in cold water. See answer to query 11244; prepare a fresh quantity from those directions. Substitute calcined bones, or a mixture of clay and whiting for the chalk, and report progress.—William H. Hey.

[11220.]—**Wheel Tires.**—"Un Jeune Forgeron" gives 14 threads to the inch for the ½in. and ¾in. gas-pipes, which is wrong. It is 13·75 = 55 threads in 4in. I trust "Un Jeune Forgeron" is not one of those gentlemen that think anything is near enough. But remember, if a job is worth doing, do it well. Does E. Fardon wish to cut them in a lathe? If so, he must use compound wheels. Say A into B, and D into C. Here we have A and D drivers. It will not matter whether A is geared into B or C; place them to suit yourself. For a lathe with leading-screw of two threads the wheels are drivers (20 and 80), driven 100 and 110. For a lathe with 4 threads to the leading-screw, drivers 20 and 80, driven 50 and 110. The way to prove if given wheels will cut a given thread is 4 × 4 = 16, the number of threads in the leading-screw. 13·75, the number of threads to cut.

50 and the 110 are driven.—C. A. M.

[11221.]—**Fowling Punt.**—Living many years ago close to the Thames at a part where the water was in some places very shallow, I found it necessary to procure a boat for my fishing excursions drawing little water, and which should be stiff and light. I had seen a description of a fowling punt which I thought would answer the purpose in Col. Hawker's work, so set to work and built one, which I will describe as well as my memory serves me. She was about 15ft. long by 2ft. 6in. wide, pointed at both ends, with a flat floor rising about an inch at each end. The bottom was made of three deal planks ¾in. thick, dowelled together at the edges with iron pins; the sides were each of one plank, also deal, 11in. wide in the middle and 10in. at each end. Across the bottom inside were floor timbers of elm, 1in. square and 1ft. apart. The stem and stern posts were also of stout elm, each about 13in. high. The sides, which were upright, except just at the ends, were then fitted and nailed on, after which they were strengthened by elm knees which also formed ribs. About 18in. were covered in at each end, forming air-tight compartments; there were three thwarts, one forward for the mast, one midships for rowing, and one aft; the two first were firmly fixed by elm knees, the last was movable. She was fitted with a sprit mainsail, small staysail and rudder. In putting the planks together a strip of old blanket, soaked in a mixture of tar, pitch, and indiarubber solution, was placed in every joint, another similar strip being laid over it, which again was covered by a strip of tin, 1½in. wide, fastened by two rows of tin tacks. The same plan was adopted where the sides were nailed to the bottom, the tin being 2½in. wide, half on the bottom, half up the side. This plan was so effectual that there was not the least leakage, the tin did not rot away as might be supposed, but lasted several years. The floor was covered with thin boards, and the whole well painted inside and out. This boat was very stiff and handy, would go anywhere, but was not fast. If I were to build another I should alter the shape aft, as a pointed stern is a mistake in a flat bottomed-craft. When forcing her along under sail in a strong wind I have been nearly swamped by the water curling over the stern. The boat I should now recommend would be one built in the above manner, about 15ft. long, 2ft. to 2ft. 6in. wide, pointed at the stem, but with a stern turned up like a punt, and about 2ft. wide, to be fitted with two fixed and one shifting thwarts; the latter is very convenient, as it leaves the whole after part of the boat unincumbered. There should be swivel tholes, and if any sail be fitted it should be a small working lug. No rudder is necessary, but an extra socket may be fitted on each quarter to ship the tholes in and steer with a paddle. I omitted to state that the sides may be built with two or three strakes, as in ordinary boat building instead of using a single plank. In the former case of course they must be riveted together with the usual copper nails and roves.—A Barrister.

[11224.]—**Books on Ceylon.**—"Damon" should apply to Mudie, Librarian, New Oxford-street, London, for Sir James Emerson Tennant's account of the island, 2 Vols., 8vo., 50s.; also his Natural History, illustrated, 1 Vol. 8vo., 12s. 6d. Sir James was for some years governor, and a more vigilant observer or pleasant writer is seldom met with; his work is the universally accepted authority now. I feel proud to be able to tender a little volunteer but reliable information derived from some personal friends who have been out in Ceylon, coffee planting, for some ten years. Avoid spirits as poison. Clothing should be of the very best light Scotch tweed. Presuming his military friend is a knight of the trigger, his battery should consist of a strong plain No. 12 double-barrel gun, with bullet moulds; a muzzle loader I would suggest for economy. One of W. Greener's, of Birmingham, sporting Snider carbines, with loops to sling; flush sights up to 800 yards, a prettier tool I never handled; at 100 yards you ought to be able to put your shots where you please. Being a military man he will know how to get ammunition economically. The last item, a good belt to carry a revolver that throws a largish ball, and a couteau de chasse, or hunting-knife in case; this latter could be best got at home in the shape of a heavy butcher's knife, such as is used for splitting up a sheep. The country abounds in large game, especially deer, so a large knife is necessary to do the cutting up. A bottle of quinine and a few other medicines would be useful. With these few hints, and Tennant in his hands, he need not fear to embark. Bachelors generally reside in boarding houses, like a colony, but each having his private room; and dine, &c., at table d'hôte. Plenty of good male society at Colombo; female society scarce, and very select, principally married.—Joe.

[11227.]—**Duckweed.**—There are four species of duckweed in England; the flowers are monœcious—that is, male and female flowers on the same plant, and in this case they are inclosed in a spatha or kind of enveloping bract. The flowers are rarely to be met with, but when found it will be in June or July.—Cuprum.

[11227.]—**Duckweed.**—The flowers are very rarely seen, but they spread rapidly by new fronds, budding out from their margins. I watched some duckweed last summer, hoping to see them, but failed. But I am going to watch some this year, and I hope I shall be able to see them, and then will let you know.—Gig-Lamps.

[11229.] — **Ammoniac Chloride.**—NH_4Cl, ammonium chloride, may be made for laboratory purposes by neutralising pure hydrochloric acid with pure ammonia, or by passing a stream of the gas through a solution of the pure acid until saturated, and then evaporating and crystallising the salt. $NH_3 + HCl = NH_4Cl$. This salt, for analytical use, should volatilise completely when ignited on platinum foil. The solution ought to be neutral to test paper, and it should give no precipitate or coloration on the addition of $(NH_4)_2S$.—Hermes.

[11235.]—**Eels in Paste.**—(1.) Flour-and-water paste needs only to be made thin and damp, and allowed to get sour, when it will produce paste eels. Bookbinders' paste is the best. It should be exposed to the air, but not allowed to get dry. A drop or two of vinegar may now and then be poured on it with advantage, or vinegar and water, to prevent its becoming dry. (2.) Bruise black pepper, put some in a galley-pot or tea-cup about ¼in. in depth, pour on it rain or river water to cover it about an inch deep. Stir it well together, and let it stand for two or three days in the open air, when a thin skin will be found upon the top, which reflects the prismatic colours. Put a minute portion of this skin under the microscope, and it will be found to hold animalcula by millions. These living organisms will increase in numbers and in size until the whole of the fluid will seem an animated mass. About half a dozen different and fantastically-shaped creatures may be distinguished, comprising tape-worms, thread-worms, cork-screws, globules, &c. (3.) Cut a wisp of new-made hay into small pieces, and soak it in rain or river water. After a few days a whitish scum will be visible on the surface, which will be found on examination to contain myriads of living creatures of a vast variety of shapes and forms and kinds. Here will be found some of our acquaintance seen in the pepper water; but the majority of these take an oval form, and are in continual motion, darting about with amazing velocity, spinning and performing all sorts of strange gyrations. (4.) Vinegar left uncovered for a few days in warm weather will generate eels, which may sometimes be visible to the naked eye. (5.) The water that drains from dung-hills is so thronged with animalcula as to seem all alive; it must be diluted with water before they can be distinguished. (6.) An infusion of any herb, grain, fruit, or flower in common water will, after a few days, contain animalcula peculiar to the herb, &c., used. (7.) In the spring of the year almost every river, pond, ditch, or puddle will afford subjects for microscopic investigation.—H. G. W.

[11235.]—**Eels in Paste.**—To get them, make white paste, not thick, and let it be until it turns sour; but it does not always succeed. If once got they can be kept for years by occasionally making fresh and adding a drop or two of the old. I have had them about nine years, originally from a single drop on a slide, from which I have bred quarts. I mostly keep about half a pint in a gallipot, with a tin cover with holes to admit air, which keeps the paste clean and white for observation. If "Microscope" will advertise his address, I will send him some. To get animalcula, put any vegetable or animal matter in water exposed to the air for a few days, and you will have plenty; the warmer the weather the better. Hay will produce them as soon as anything: many large enough to be seen by the naked eye as minute specks.—C. Bentley.

[11236.]—**Coins.**—Florins, shillings, sixpences, and threepences are the only silver coins now struck for general currency. The last issue of crowns was in the year 1851, and no halfcrowns have been issued since 1851. No groats (or fourpenny pieces) have been coined since 1856.—Henry W. Henfrey, F.H.S., M.N.S., &c.

[11239.]—**Photography.** — This question is so vague that my answer must be necessarily of the same nature. 1. Before entering the photographic profession, it is absolutely necessary that he should be able to produce really successful results, both in landscape and portrait photography. 2. The apparatus should be of the best modern construction. 3. The lenses should be by one of the best English opticians. 4. The studio for portraiture should be of the form known as ridged-roof. 5. The chemicals should be of absolute purity, and such can be obtained from any respectable photographic chemist. 6. The work sent out should be the best that can possibly be obtained under the then existing circumstances, as a really good photograph is a lasting honour, and an indifferent or bad one a lasting disgrace to the producer. 7. If really good pictures are sent out, always have a good price, and never undersell a neighbour.—R. TUDOR WILLIAMS.

[11239.]—**Photography.**—I would advise "Caswallon-ab-Davies" to get one of F. Coxe's (of Ludgate-hill, London) books called "Compendium of Photography," which will give him every information he requires. At the end of the book is a catalogue, with prices, attached to every article required in the trade. The price of the book is 6d., and is well worth notice. —A. C.

[11243.]—**Deaf and Blind.**—About twelve years ago I saw in the Institution for the Deaf and Dumb, at Manchester, a girl who was also blind, with whom the master conversed with ease by touching her fingers and elbows. I should think this gentleman (or if he has left, his successor) would gladly advise "X. X." as to the best mode of teaching the alphabet to one similarly afflicted.—R. S.

[11243.]—**Deaf and Blind.**—There are many institutions where such afflicted persons are received and taught—the blind by reading raised letters and signs on stout paper. No doubt, by advertisement, the information of the whereabouts of these establishments can be obtained.—TUBAL KAIN.

[11243.]—**Deaf and Blind.**—The use of the Morse telegraph alphabet would be a ready means of communication by means of touch on the hand or arm. After some practice the communication would become rapid by the use of abbreviations and contractions. See single needle dial in No. 361.—WATERMAN.

[11244.]—**Silicate of Soda.**—Preparation: Soluble glass may be obtained by dissolving pure silica in a boiling solution of caustic potassa or soda; but this process is both costly and inconvenient to practise on a large scale. If sand and carbonate of potassa or soda are heated together, the carbonic acid is never entirely driven off, excepting when the sand is in excess; but the whole may be expelled by the addition of powdered charcoal, in such proportion that the carbonic acid which is not decomposed, may mix with a sufficient quantity of carbon to convert it into carbonic oxide. In this way the silica first forms a silicate in the proportions contained in common glass, and drives off the appropriate equivalent of carbonic acid; then, at a high heat, the rest of the carbonate of potassa or soda is decomposed by the carbon, the carbonic oxide escapes, and the alkali, thus freed, either sublimes or combines with the glass already formed. The sand (free from any trace of lime or alumina) and alkali are taken, ten parts of the latter to fifteen of sand and four parts of charcoal; no less quantity of charcoal will suffice. If the alkali is not very pure, another proportion of charcoal may be used with advantage; this accelerates the fusion, and separates all carbonic acid, which would otherwise remain, and have a very injurious effect upon the glass. In other respects the same precautions are to be observed as in the manufacture of common glass. The materials must be first well mixed, then fritted, and finally melted in a glass pot, until the mass becomes liquid and homogeneous. The melted matter is taken out of the pot with an iron ladle, and the pot is then filled with fresh "frit." Thirty pounds of alkali, forty-five pounds of sand, and twelve pounds of charcoal is the average charge. The crude glass, thus obtained, is usually full of air bubbles; it is as hard as common glass, of a blackish-gray colour, and transparent at the edges; sometimes it has a colour approaching to whiteness, and at others it is yellowish or reddish; these are indications that the quantity of charcoal has been insufficient. If it is exposed to the air for several weeks, it undergoes some slight changes, which rather improve it than otherwise. To prepare it for solution it is reduced to a coarse powder. One part of glass requires four or five of water for its solution. The water is first heated to ebullition in an open boiler, the powdered silicate is then added to it by degrees, and must be continually stirred to prevent it falling to the bottom. The ebullition must be continued for three and a half to four hours, until no more glass is dissolved; the liquor will then have acquired the proper degree of concentration. If the ebullition is checked before, carbonic acid will be absorbed from the air, so will too great a quantity of water, for during long evaporation, which is then necessary, the carbonic acid of the water will readily combine with the alkali, and the silica will be precipitated. If the liquor thickens too much before the glass is dissolved, boiling water must be added. When the solution has the consistency of syrup, and a density of 1·24 or 1·25, it is sufficiently concentrated and fit for use. It is then set aside to cool; and also to allow the insoluble portions to settle; while cooling a skin forms upon its surface, which, after a time disappears of itself, or may be re-dissolved by depressing it in the liquor. When the crude glass is of a proper composition, it contains but few saline impurities, and no sulphuret, it may be treated as above, but if any considerable amount of impurities exist, it must be treated as follows:—The powdered glass is exposed to the action of the air for three or four weeks, during which it must be frequently stirred, and if it runs into lumps, as it will in moist weather, they must be broken up. The glass, as stated before, attracts moisture, and the foreign substances either separate or effloresce. It is then easy to remove them. The mass is frequently sprinkled with water and stirred. After three or four hours the liquor is removed; it then contains a part of all the saline impurities, and a trace of silica; the process is to be again repeated. Soluble glass thus treated readily dissolves in boiling water, and leaves nothing to be desired. To preserve it in the liquid no particular care is necessary; even after a long space of time it undergoes no perceptible change, if the solution has been properly prepared. It is well to keep the mixture from contact with the atmosphere. Silicate of soda forms a viscid solution, which when concentrated becomes turbid and opalescent; it has an alkaline taste and reaction. When it has a density of 1·26, it contains nearly 28 per cent. of glass; if the concentration is carried beyond this it becomes so viscid that it may be drawn out in threads like molten glass. When the solution is applied to bodies it dries rapidly at common temperatures, and forms a coat like a varnish. Soluble glass when dried does not undergo any perceptible change when exposed to the air, nor does it attract from it either moisture or carbonic acid; neither has the carbonic acid of the atmosphere any effect upon the concentrated solution; but when a current of carbonic acid is passed through the solution, the glass is decomposed, and hydrate of silica deposited. Soluble glass dissolves readily in boiling water, but in cold water so slowly as to lead to the belief that it does not dissolve it at all. It is, however, never entirely insoluble except when it contains a much larger proportion of silica, or when it is mixed with other bodies, such as the earth's metallic oxides, &c., with which double or triple salts are formed, as in the case with the common glasses. Soluble glass, after being exposed to the air, and afterwards to the action of heat, swells and cracks at first, and melts with difficulty; it then loses about 12 per cent. of its weight. Alcohol precipitates it unaltered from its solution in water. When the solution is concentrated but little alcohol is required to precipitate it. Pure soluble glass may be easily obtained from an impure solution by the use of alcohol. The alcohol being added the gelatinous precipitate is permitted to settle: the supernatant liquor is decanted, the precipitate collected, rapidly stirred after the addition of a little cold water and subjected to pressure. The acids act upon and decompose the solution of glass; they also act upon it when solid, separating the silica in the form of powder.—WILLIAM H. HEY.

[11245.]—**Felspar.**—This mineral is obtained in Cornwall, Devonshire, Scotland, France, Norway, and other localities—in primitive rocks, and of various colours, fusible by itself. "Beudant":—Red common F., Silica, 65·03; alumina, 17·96; potassa, 16·21; lime, 0·35; per oxide of iron, 0·47. Chapman's "Mining":—Silica, 64·2; alumina, 18.4; potash, 16·95; soda a trace. Form, $KOS_1O_3Al_2O_33S_1O_3$, or KO3SiO, 3 (AlO3SiO). Specific gravity, 2·394 to 2.581, H6.—W. P. W.

[11247.]—**Jacketed Cylinder Engine.**—If the present steam pipe is now only sufficient to supply the engine properly, put a new and separate steam pipe and cock of at least 2in. bore, with a condensed water trap (self-acting) to take off the accumulated water from the jacketed surface.—TUBAL KAIN.

[11249.]—**Concrete Walls and Buildings.**—The information your correspondent seeks would necessitate probably more space than could be afforded in the querists' column, but briefly I would state that after three years' impartial trial, not only in erecting buildings with, and in other ways using concrete, Portland cement, but by occupying a house constructed with it, I am satisfied that it is for very many purposes, but not for all, far superior to most other building materials, and that as a rule it is less costly than brickwork construction. But it is evident the cost must depend entirely on the facility for obtaining the necessary materials. The best for the purpose besides Portland cement are broken Portland, Bath, or almost any stone chippings—crushed flints, slag, river ballast, or old bricks and tiles, any of which should be sufficiently small to pass through a 1½in. mesh screen, and also have a due proportion of sand or finely broken material mixed therewith. Although the process of construction is simple, yet great care and discrimination is necessary. The proper proportion of cement should be not less than one part out of eight by measure; the cement should be the best quality, finely ground, and weigh not less than 112lb. per bushel. Walls constructed thus, I estimate to be three or four times the strength of brick walls of the same thickness; and from experience I am able to say that 9in. walls are virtually impregnable against damp and drifting rains. If your correspondent contemplates building with concrete, if only a cottage, he should visit buildings that may be in the course of erection with that material, and by so doing he would gain much more practical information than can be given here, and it would pay him to do so, even had he a hundred miles to travel for that purpose. I am just now completing a building of three floors, almost entirely (roof excepted) constructed with concrete, and which has been tested for strength, the result far exceeding the most sanguine anticipation.—F. P.

[11250.]—**Mr. Stanistreet's Astronomical Clock.**—A reply to this query appears among the letters in this number.—ED.

[11251.]—**Iron Stains in Oak.**—Spirits of salts will remove iron stains in oak.—T. R. B.

[11251.]—**Iron Stains in Oak.**—Oxalic acid will remove iron stains from oak or any other wood.—M. O.

[11252.]—**Illuminated Sign.**—The cloth should be white holland, and the parts that are to appear white left without colour, and if your varnish is good the white will not change.—M. O.

[11252.]—**Illuminated Sign.**—Lead and gas are not cousins, use white zinc.—C. A. M.

[11256.]—**Holly Walking-Sticks.**—I expect W. Hughes cut his sticks in summer, while the sap was high, if so they are sure to split at the knots. They should be cut in winter, and in trimming off the side-shoots be careful to leave half an inch on the stick; tie them together in a bundle and put them away in a dry place for a few months, then pare the knots to "fancy." Scrape off the rind. Sand-paper and varnish them, and they will look well, and be nearly as tough as leather.—R. LANGDON.

[11258.]—**Rollers of Wringing Machines.**—"T. W. R." must use well seasoned sycamore for his rollers, and turn a recess in each end to hold a wrought-iron hoop, which should be shrunk in so as to grip the wood tightly. I have a wringing machine which I treated in this way some time ago, and have not been annoyed by the rollers splitting since, although before putting in the hoops this was a common occurrence.—RHO SIGMA.

[11260.]—**Cutlers' Wheels.**—These have a tire of leather, which is thinly coated with glue and rubbed in emery powder before the glue has set. The emery, of course, adheres, and forms the grinding surface.—EXCELSIOR.

[11263.]—**Gas Tank.**—"A C. S." has not stated the proportions of his tank, or the number of burners or lights supplied from the said tank. The tank requires a cock at the bottom to allow the escape of atmospheric air when charging. Make your connections at the top of your tank for your burners. You will want a cock there so that you can regulate your pressure. A few inches from your cock screw a short piece of ¼in. or ½in pipe into your main or supply pipe; fasten on the other end of the pipe a small piece of flexible tube, and on the other end of your tube place a small pressure gauge (procure a piece of glass tube about a foot long, make it hot in the centre over a flame and bend it in the shape of a U; then half fill with water and you have a gauge). Not knowing the illuminating power of your gas cannot tell you what pressure to give: that you will soon find out by your lights, say about 15 tenths (gas is measured by tenths of an inch). Open your cock and let your water rise 1½in. = 15 tenths if that will do. As your gas is consumed you will have to open your cock to keep the pressure up to 15 tenths. Gas companies have to keep men day and night to look after the valves so as to regulate the pressure. If that pressure will do, and your tank is charged to 30lb. on the square inch, 27in. of water indicate a pound pressure 27 × 30 = 810 × 10 = 8100 ÷ 15 = 547·6, or you have compressed 546·6 cubic feet of gas into the space of one at 15 tenths pressure.—C. A. M.

[11265.]—**Drawing a Boundary Line.**—Field-book:—

30	198	
	260	60
24	248	
	240	30
20	220	
	0	

Total base 1166

260 × 60 ÷ 2	=	7800
240 × 30 ÷ 2	=	3600
		11400
198 × 30 ÷ 2	= 2970	
248 × 24 ÷ 2	= 2976	
220 × 20 ÷ 2	= 2200	
		8146

1166) 3245

Answer $2\frac{461}{583} = \frac{p}{2}$.

—THETAMU, Horsham.

[11265.]—**Lifting Water.**—"Ignoramus" has not stated where he wishes to pump the water from, neither if it is nominal or actual horse-power. An indicated horse-power performs 33,000 units of work in a minute; a unit of work is the force required to move 1lb. through a space of 1ft. in any direction in a minute, 33,000 ÷ 7ft. = 4714·286 units of work per minute ÷ 1,000oz., or 63·5lb. = cubic feet, or by 10lb. equal gallons. Should think a lift pump would answer "I.'s" wants.—C. A. M.

[11266.]—**Lifting Water.**—I take it in the first place that the power of your engine is the nominal horse-power. This is usually allowed to be the power capable of lifting 33,000lb. 1ft. high per minute = 4,714lb. 7ft. high per minute; and as the gallon = 10lb., 471gals. may be lifted 7ft. high per minute by your engine.—EXCELSIOR.

[11266.]—**Lifting Water.**—1 horse-power raises 33,000lb. 1ft. in one minute, and one cubic foot of water weighs 62·5lb. Number of pounds of water = $\frac{33,000}{62·5}$ = 528 cubic feet.—P. W. H. J.

[11271.]—**Naval Architecture.**—There is no connection between the water line and the water way of a ship. The water lines are the parallel lines formed along a ship's hull by the tops and bottoms of the plates, or the sheets of copper; and the water way is the speed of the ship in knots per hour. A ship is said to be water-borne when her double bottom is full of water. 2. The tonnage of a ship cannot be determined from the metacentre evolute, but the centre of effort can; also, the variation of the compass, if the evolute is made of copper instead of iron, as it generally is. 3. I think "dead water" must be a misprint for "head water." If this is so, the head water is never retained in the ship, but is allowed to pass freely overboard. 4. The screw race is only formed when a ship is going out of a narrow harbour or a dock. It is concrete for twin screws, one screw annihilating the screw race of the other. It is abstract for a single screw and for Colman's jet propeller. 5. Marine glue is but sparingly used, principally for fastening the engines and boilers in their places in the ship. 6. The longitudinal bulkhead is always in a line with the double bottom, and is screwed to it. The transverse bulkhead is never abaft the double bottom, and is seldom fastened to the bilge pieces. 7. The run of a ship is connected with the wing passages by water-tight doors. 8. The deck-stringers went out when iron ships were introduced; there are few books on naval architecture that make any mention of them.—S. Tremayne, Cantab.

[11273.]—**Cement for Water.**—"Goethe" should paint (red) the edges and bottom where they go together, and pack with red and white lead (mixed). Let the cistern remain three or four days before letting the water in, and that will make a perfect cure. I have fixed many the same way, and always found them to answer.—Blacking.

[11273.]—**Cement for Water.**—"Goethe" should pour melted brimstone in the joints. Proved.—W. G.

[11276.]—**Extracting Glass Stopper.**—I once got one out by attaching the end of a stick of sealing-wax to the broken stump, and when it was quite cold, warming the neck of bottle by friction with a piece of string taken a "round turn" and see-sawed. Other tight stoppers, not broken, but cemented in by the stuff that was in the bottle, I have got out by putting a drop of rangoon or paraffin oil to the neck, and warming it over a small taper or wax-vesta till you see the oil run in. I have drawn wine-corks by sticking another cork on with wax as above described. A stopper of a varnish bottle, but not a gum bottle, will be released directly by warming the neck. If the broken stopper is very tight in, it must be drilled out. A fiddle-drill with oil of turpentine and elbow-grease will do it. When you have a hole once through, you may chip or file most of the stopper away, or, perhaps, hook it out with a bent wire.—J. K. P.

[11276.] — **Extracting Glass-Stopper.**—Let "A. H." try if immersing the neck of the bottle in moderately hot water will cause sufficient expansion to allow the stopper to fall out.—W. H. W. T.

[11276.]—**Extracting Glass Stopper.**—Stand the bottle upside down in a little sweet oil for a few days, then immerse it for about half a minute in moderately hot water, and give it a few taps.—J. King Harris.

[11276.] — **Extracting Glass Stopper.** — If "A. H." puts the neck of the bottle in hot water the neck will expand and the stopper will fall out.—W. Bright.

[11278.]—**Steam.**—The flow of steam through a long pipe is given by Professor Rankine in his essay on the "Flow of Gases," as follows:—

$$c = \left\{\frac{d^2 \times l \times q}{p - q}\right\} \times \cdot 7854.$$

where d = diameter of pipe.
and l = length of pipe (both in square feet).
q = hydraulic gradient.
p = pressure in pounds per foot.
c = quantity in pints per minute.

"Vulcan" will be able to apply this formula to any numerical example.—C. W. Henwood.

[11279.]—**Fire-Damp.**—I would inform "Vulcan" that I have often observed the drops he mentions in both copper and tin mines, but never in lead mines. Now, as sulphuretted hydrogen never occurs in copper or tin mines, I am under the impression that they are only condensed fire-damp.—C. W. Henwood.

[11284.]—**Holtz's Induction Machine.**—I have not sufficient acquaintance with this apparatus to give the information asked of me, but if the querist resides in London, I may tell him that I saw one of these machines the other day in the window of Mr. Cox, the scientific instrument dealer, Ludgate-hill. Looking at this might furnish the required information; the discs are of window-glass.—Sigma.

[11285.]—**Chemist's Certificate.**—"Phœnix" does not give sufficient information of his position before the coming into force of the Act of 1868, to enable me to give him all particulars which he desires. I should advise him to get the calendar of the Pharmaceutical Society, or write to the secretary of that society (17, Bloomsbury-square, London), and he will then have every information on the subject.—Sidcot.

[11285.]—**Chemist's Certificate.** — "Phœnix" will be required to pass an examination at the Pharmaceutical Society, Bloomsbury-square. Write there to E. Bremridge, Esq., sec., who would, no doubt, return necessary information.—J. King Harris.

[11287.]—**Annuals.**—It is not easy to make a long list of annuals remaining in bloom "at least three or four months;" but it is very easy, by successional sowing, to have any annual in bloom all summer and autumn. I presume "Aster" understands this, but means that he has not time to devote to their successful cultivation in this manner. If so, here is a list of long-blooming annuals, each of which will last a month—some three. Asters and stocks to begin with; Phlox Drummondi, Zinnia, Calliopsis (or Coreopsis), Helichrysum (everlasting), Ageratum, and Linum—all of which may be treated as "half-hardy." Candytuft is an annual which remains in bloom for a considerable time; but the list above given will furnish a garden very fairly, especially if the flowers are cut freely and all the seed pods removed as soon as the bloom decays. "Aster" should buy these in "mixed" packets. A slight hot-bed and plenty of air at all favourable times when the seeds are up will enable him to plant out in May if he starts now.—Saul Rymea.

[11287.]—**Annuals.**—The rocket, the sweet William, the wallflower, columbine, larkspur, double daisy, white and pink, and lupins.—W. Bright.

[11292.]—**Linseed.**—Linseed is only used in medicine for poultices. Boiled in water, it makes a nourishing drink; by many esteemed a specific for consumption.—J. King Harris.

[11294.]—**Dividing Metal Disc.**—To "Disc."—Your disc of 12in. diameter is to be cut into four equal parts, hence the middle piece (which will be a circle) will be one-fourth the area of the whole, and the outside diameters of the intermediate rings will be those circles of half and three-quarters the area of the whole. Now, as circular areas are as the squares of their diameters, we need only consider the diameters which conversely are in proportion to the square roots of the areas; and as the whole area is 12^2, therefore the diameter of the middle piece will be the square root of $\frac{144}{4} = \sqrt{36}$ or 6, and of the two intermediate rings, the square roots of half and three-quarters of 144 respectively, or $\sqrt{72} = 8{\cdot}485$ and $\sqrt{108} = 10{\cdot}392$.—J. K. P.

[11294.]—**Dividing Metal Disc.**—As the disc is homogeneous, the weights of the parts into which it is to be divided will be as their areas:—

Let D = diameter of whole disc = 12in.
,, d = diameter of inner disc.
,, d_1 = outer diameter of smallest ring.
,, d_2 = outer diameter of second ring.
,, d_3 = outer diameter of largest ring.

First, as regards the central disc. Its area is to be ¼ of the area of the whole disc, and as the areas of circles are as the squares of their diameters, the diameter of the small disc must be half the diameter of the larger one—viz., 6in.:—

$$\therefore d = 6\text{in.} \quad (1)$$

The thickness of the smallest ring will be, of course, $= \frac{1}{2}(d_1 - d)$, and its area $= (d_1^2 - d^2)\frac{\pi}{4}$. This area (by the conditions of the problem) is equal to ¼ of the area of the whole disc, and therefore to find d_1 we have the equation—

$$(d_1^2 - d^2)\frac{\pi}{4} = \tfrac{1}{4}.\ D^2\frac{\pi}{4};$$

$$\text{whence } d_1^2 = \frac{D^2 + 4d^2}{4}.$$

Substituting the known values of D and d, we get—

$$d_1^2 = \frac{144 + 144}{4} = 72.$$

$$\therefore d_1 = \sqrt{72} = 8{\cdot}4853. \quad (2)$$

Similarly, we have for the second ring—

$$d_2^2 = \frac{D^2 + 4d_1^2}{4} = \frac{144 + 288}{4} = 180$$

$$\therefore d_2 = \sqrt{108} = 10{\cdot}3923. \quad (3)$$

Treating the outer ring in the same manner, we get—

$$d_3^2 = \frac{D^2 + 4d_2^2}{4} = \frac{144 + 432}{4} = 144.$$

And $d_3 = 12 = D$: which evidently is as it ought to be.—V. B.

[11294.]—**Dividing Metal Disc.**—General solution, applicable to any number of rings and discs:—

Let r = radius of metal plate.
a, b, c, d, &c. = radii of concentric rings.
t = thickness of plate.
ρ = density.

Then, by the binomial theorem, we have—

$$(a + b + c + d + \&c.)t = r\rho.$$

In the example given, take t = 1in., and ρ = 400lb. per cubic foot. Then we find—

a = 3·79 inches.
b = 2·78 ,,
c = 2·50 ,,
r = 12 ,,

—C. W. Henwood.

[11298.]—**Four-inch Centre Lathe.**—The use of a hole up the mandril will be found if you are making (say) a lot of small screws, which may be cut off successively from the end of a rod of metal which is held in some grip chuck, and gradually drawn forward, the tail end passing up the hole in the mandril, and not only being out of the way, but effecting a saving of material. My mandril is drilled right through for another purpose—viz., centreing work that is held in the grip chuck, while the drill is passed through the mandril from the rear end as described in answer to query 10299, p. 441, Vol. XIV.—J. K. P.

[11301.]—**Limits of Resistance in Telegraph Wire.**—The result of the researches of Professor Damerel Stokes in this direction was, that the number of B.A. units in 1 mile of 19 wire gauge copper wire 1,216,750. In one mile of 24 wire gauge, which is the most used size, the number was, 1,723,800.—C. W. Henwood.

[11301.]—**Limits of Resistance of Telegraph Wires.**—Clarke gives the resistance of the iron wires as 7·8 Ohms per statute mile, and 13·5 for number 8. The Ohm is the B. A. unit. I am not quite clear whether these figures refer to plain or galvanised wire.—Sigma.

[11304.]—**Nessler's Ammonia Test.**—This reagent is an aqueous solution of iodide of potassium saturated with perchloride of mercury, and made strongly alkaline by soda or potash. It is a very delicate test, for it is capable of indicating 1 part of ammonia in 20,000,000 parts of water. The indication is an amber-yellow tint in weak solutions, but a heavy-yellow precipitate when the ammonia is in a larger quantity. To prepare it, proceed as follows:—Dissolve 50grm. of iodide of potassium in about 150 cubic centimetres of hot distilled water. Keep the whole in the water bath at a boiling heat, while you add a hot saturated aqueous solution of perchloride of mercury until the red precipitate which forms ceases to be dissolved by active stirring. This point being reached, stop the addition of the precipitant, filter, add 150grm. of caustic soda (or 200grm. of caustic potash), dissolved in water. Add distilled water till the whole equals 1 litre; finally add about 5 cubic centimetres of the perchloride of mercury solution, allow to subside and decant the clear solution for use. The last addition of perchloride of mercury is to promote clearing, and to give sensitiveness.—Sidcot.

[11308.]—**Geocentric Longitude and Latitude.**—I should imagine that the reason why the *Nautical Almanac* is not incumbered with geocentric latitudes and longitudes required, is that they are only wanted by such persons as Zadkiel, Sagittarius, Old Moore, and other persons who profitably combine the occupations of astrologer and quack doctor. The method of conversion is fully described in every elementary treatise, and has been often explained in "our" Mechanic. However, again, tan. $\theta = \frac{\text{tan. dec.}}{\text{sin. R.A.}}$ ω = obliquity, tan. long. $= \frac{\cos(\theta - \omega)\ \text{tan. R.A.}}{\cos.\ \theta.}$ tan. lat. = sin. long. tan. $(\theta - \omega)$.—Chronos.

[11309.]—**Breaking-Strain of Hollow Iron Columns.**—Hodgskinson's formula for cast iron:—

$$P = \frac{R^3 - r^3}{R^3 + r^3} \times \frac{f}{2E} \times \text{cosecant } \theta.$$

Where R and r are the external and internal radii, $\frac{f}{2E}$ = modulus of resilience, and θ = slope or deflection. In the case of the plumb column, $\theta = 90°$.—C. W. Henwood.

[11311.]—**Electric Bell.**—(1.) One cell of the battery named would scarcely be strong enough, but two would be sufficient. (2.) A cylinder of zinc would answer as well as a "wedge" or "bar," but little, if any extra force would be gained. (3.) No. 16 cotton or guttapercha covered wire will be best if to be hung indoors, either copper or galvanised if outdoors. (4.) Gas or water pipes are more suitable for earth connections than the plan suggested by the querist, but as the distance is so short, a return wire would be better.—W. Golding.

[11313.]—**Setting Lathe.**—I don't know, as I never made or even used a shifting head. I fancied they are always made to be quite true when screwed home in one direction, and only to have the power of moving away from the centre in the other direction. For turning taper I use a centre point screwed into a plate, bolted to the collar-plate itself, or else to the collar-plate headstock: which arrangement I consider, on the whole, a better one, and certainly less expensive than making the head to shift. I don't think taper screws are ever wanted to be cut this way; but I may as well say that if they were they would be drunk, owing to the unequal action of the pin of the driver chuck on the tail of the carrier when the work is out of straight with the axis of mandril. I can tell you a very easy way of setting your slide-rest parallel after you have been turning a cone, but that is not the subject of your inquiry.—J. K. P.

[11318.]—**Gravitation.**—In the case of the inverted small thermometer the mercury retains its position by reason of the adhesion between it and the tube. Bodies falling through the air experience resistance in proportion to the surfaces they present. A piece of old leaf would fall through the air considerably slower than the same amount of metal in the form of a small pellet. In a vacuum this resistance is withdrawn. The common experiment of placing a small disc of paper on the upper surface of a coin, when both, on being allowed to fall, reach the ground together, proves this. Bodies attract, and are attracted, proportionally to their masses, as may be understood by conceiving each particle attracted separately, and the sum of attractions will be the total attraction of the mass. Each particle will therefore (excluding resistance of air) fall with an equal velocity.—W. H. W. T.

[11318.]—**Gravitation.**—"C. W. H." is under the not uncommon delusion that the force of gravitation causes heavy bodies to fall to the earth faster than light ones. Galileo, I believe, demonstrated the fallacy of this theory by casting bodies of different weights off the leaning tower of Pisa, where it was seen that they all reached the ground in the same time. The theory of universal gravitation is that every particle of matter attracts every other. Consequently the earth attracts every particle of a heavy body and draws each one to its surface with a known velocity. It matters not whether the body is composed of few or of many particles. Each particle will be made to fall with the same velocity, and the collection of particles which makes up the mass of the body will, therefore, only fall with the same velocity as each particle does. In considering, therefore, the attractive force of one body on another, the elements taken into account are the mass of the attracting body and the distance between the bodies: the mass of the attracted body not affecting the question. What, however, does make the fall of some bodies to the earth slower than that of others is the resistance of the air, as in the case of the sovereign and the feather. By a simple contrivance, however, two such bodies can be made to fall in the same time without the aid of an air-pump. For this purpose a large coin, such as a crown piece, is better than a small one. The feather, moreover, should be considerably smaller than the face of the coin, and should be flat on it. Now, hold the coin with its plane horizontal; place the feather on its upper side, and on letting both bodies drop together it will be found that they will also arrive on the floor together; the coin having shielded the feather during the fall from the resisting upward action of the air. The quicksilver in the tube of the inverted thermometer is upheld by the cohesion of its particles with those of the quicksilver in the bulb.—V. B.

[11327.]—**Monster Magnetic Machine.**—There could not be the smallest difficulty in accomplishing the purpose aimed at. If I were in the business I should be very happy to meet with such a customer as M. Raudnitz; in fact, he almost tempts me to undertake the job. I know Mr. Browning's small machine, and a very good one it is, but do not think it capable of giving off anything approaching ten cubic feet of mixed gases, to say nothing of oxygen alone, per minute; if it would, the simplest plan would be at once to use ten of them, which would give 60,000ft. per ten hours. I cannot undertake to devise the required machine, as it would require certain experiments to settle a few fundamental principles, though I can see that those principles, or rather the exact results of their application, once defined, the instrument itself is a very simple matter, and would run by no means into "thousands of pounds;" and what may perhaps seem incomprehensible, its cost for working would probably not be large.—J. T. SPRAGUE.

[11334.]—**Squinting.**—If "G. W. F." takes him to the Eye Hospital, Moorfields, London, he will get advice, —W. BRIGHT.

[11334.]—**Squinting.**—"G. W. F." asks if anything can be done to cure squinting. Certainly. Surely he knows where to take his little boy for the necessary operation.—SAUL RYMEA.

[11334.]—**Squinting.** — Ascertain which eye is faulty (it is probably but one, which is weak, and requires strengthening by use) and cover the other.—J. KING HARRIS.

[11337.]—**Equation.**— "Smoothing Plane" has asked for the solution of an equation which every one who knows anything of algebra is aware cannot be solved except by Newton's "Approximations," it being the ambiguous case for the solution of an elliptic triangle.—C. W. HENWOOD.

[11337.]—**Equation.**—There appears to be an error in the statement, as S is said to be required, although it is a known quantity. However, I suppose that what are really wanted are the values of l and n. Substituting, therefore, in the second equation, the value of l as given by the first, we get—

$$S = \left\{a + (a + [n - 1]\ d)\right\} \frac{n}{2} = \frac{dn^2 + (2a - d)\,n}{2}.$$

$$\text{Whence } n = \frac{d - 2a \pm \sqrt{(2a - d)^2 + 8dS}}{2d}.$$

Putting this value of n in the first equation, we get the value of l as follows:—

$$= a + \left\{\frac{d - 2a \pm \sqrt{(2a - d)^2 + 8dS} - 2d}{2d}\right\} d.$$

$$= -\frac{d}{2} \pm \frac{\sqrt{(2a - d)^2 + 8dS.}}{4}$$

$$= -\frac{d}{2} \pm \sqrt{a^2 - ad + \frac{d^2}{4} + 2dS.}$$

$$= -\frac{d}{2} \pm \sqrt{\left(a - \frac{d}{2}\right)^2 + 2dS.}$$

—V. B.

[11341.]—**Colouring Photos.**—There are many ways of preparing the cartes for colouring; some recommend prepared ox-gall; others a weak solution of carbonate of soda; others* again a coat or two of isinglass size, with or without a slight addition of carbonate of soda. It is well to use, instead of pure water for mixing the colours, water rendered slightly alkaline by carbonate of soda, as it makes the colour run smoother. Ordinary water colours will do, they should be of the best kinds. Don't be too free with your colour, imitate nature, rather than follow any absolute rule; practice and perseverance are essential.—W. H. W. T.

[11341.]—**Colouring Photos.** — Water-colours will do tolerably well for this purpose, but it is necessary to use a little gum water afterwards by way of varnish. Colours in powder applied with a slightly moistened brush are more generally used.—J. KING HARRIS.

[11391.]—**Galvanometer.**—The question as put is rather puzzling. What galvanometer does it relate to? The common instrument there is no ready means of calculating, because there is no known law expressing the relations of the deflection? In Noad's "Text Book of Electricity," p. 250; or Miller's "Elements of Chemistry," Vol. I., p. 457; also in Tyndall's "Heat as a Mode of Motion," will be found an elaborate process devised by Melloni for the purpose of getting uniform expressions of value for high and low deflections. On this system a special set of experiments would be needed for each instrument. If "Honours" has or will obtain No. 283 (p. 530, Vol. XI.), he will find there a table in which I have shown (Column 3), the value of all the deflections of tangent galvanometers, as compared with 1°. Those of the sine galvanometer can be obtained by a similar process, which is this: dividing the natural sine or tangent of each degree by that of 1°; by logarithms it is still easier. But the only true and satisfactory process is to ascertain the actual definite value of the deflections in some standard of current, as Vebers or chemical equivalents. The practical process for this is to arrange a constant battery—a copper-depositing cell—and the tangent or sine galvanometer, so as to get a very exact deflection for some hours; weigh the copper deposited, and divide by 31·75 (grains). This gives the chemical equivalent of the current, and, divided or multiplied by the time, gives a measure which, by means of the known ratios of the deflections, will give the standard degree of deflection of the unit current, and this enables us to value every other deflection, as is done in Column 4 of the Table for my own instrument, the only one, by the bye, that I know of which is thus enabled to give at a glance all the information needed. With a tangent or sine galvanometer once thus graduated, it only needs this instrument to be used in a circuit with any other to ascertain once for all the value of all deflections of this latter, whatever its form, in fixed units. If "Honours" will look over my papers bearing on this, I think he will find all the information required. I suppose the time will come when instrument makers will sell instruments showing the current passing in Vebers, instead of dividing every instrument into mere degrees, which give no information whatever, thus rendering it impossible to compare observations made with different instruments.—SIGMA.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last E. F. Conrath has answered 10578; "Gig-Lamps," 10646; "H. B. E.," 10575, 10692; "J. A.," 10684.

The electric light has been introduced into the lighthouse at the South Foreland. This is now the third lighthouse station in England at which the electric light is established, and the French have established one at Cape Grisnez.

Workshop Dust.—The injurious effect of exposure to the dust of various manufacturing establishments has not unfrequently been dwelt upon with more or less force; but we are hardly prepared for the result of certain specific investigations on this subject. It has long been a disputed point whether the particles of iron, silica, &c., merely lodge within the air cells of the lungs, or penetrate through their walls into the tissue between them. But Professor Zenker informs us that, on examining the lung of a woman who had been exposed to the dust of iron oxide, used in preparing books of gold-leaf, he found the powder in the tissue between the air-cells and in their walls, as well as in their cavities. From less than two ounces of this lung over twelve grains of iron oxide were obtained by chemical methods, so that, if equally distributed through both lungs, there must have been at least three-quarters of an ounce inhaled. In another case—that of a workman exposed to the dust of a mixture used in preparing ultramarine substances—he found a quantity estimated at fully an ounce.

QUERIES.

[11352.]—**Fox Skin.**—Would any fellow reader be kind enough to inform me what to use to stop the hair from falling off a fox's hide?—L. B.

[11353.]—**Distilled Water.**—What is the chemical difference between this and ordinary water, and in what does its superiority consist?—G. W. B.

[11354.]—**Fire Balloons.**—Referring to a reply to a correspondent, on the subject of fire balloons (see Vol. XIV., No. 342, page 102, Oct. 13, 1871), would you kindly inform me what kind of paper or other material is used in the construction of a balloon 20ft. in circumference, and of the means used of inflating, so that there would be a certainty of its rising?—WM. MCDONALD.

[11355.]—**Model Steamboat.**—Will some kind fellow reader inform me what is the best sort of boiler to drive a pair of marine oscillating engines, 1in. stroke, and 1¼in. bore, not to exceed 8in. in depth, 5in. in width, and 10in. in length; what gauge of copper to stand 80lb. pressure, and the best means of heating same?—N. G. H.

[11356.]—**Candied Peel.**—Will any brother correspondent oblige by informing me of the method of manufacturing candied peel, as sold by the grocers?—RAGUS.

[11357.]—**Berlin Black.**—Would some correspondent give us some information how Berlin black is made, and how it is applied to register grates, to give them that nice black appearance?—REGISTER.

[11358.]—**Pressure of Water.**—Will some kind reader please to give me rule for finding the pressure of water upon a vessel? For instance, say a tank on the ground floor supplied from one on the top of the house, the top tank 25ft. higher than the bottom one, and supplied by a pipe 1in. in diameter. Please give it in plain figures, as unfortunately I do not understand algebra.—R. IRONS.

[11359.]—**Casting Brass Solid.**—Will any kind correspondent give me what reliable information he can on the following subject?—Living in the country, and never having had the advantage of seeing a practical man perform the operation, my castings are generally honeycombed. What is the reason of this? Has running the metal hot or cold, or the way the moulds are made, anything to do with it? Also in what proportion should the metals be mixed for bearings?—DUFFER.

[11360.]—**Sun's Declination.**—I should esteem it a great favour if any of your astronomical contributors could tell me how I can get the correct declination of the sun for an intermediate time, between the apparent noon of each day. The term "diff. for one hour," on page 1 of our *Nautical Almanac* seems to be a very incorrect one. I have always been told the way to find the sun's declination for an intermediate time is to multiply the number of hours elapsed since the preceding noon by the so-called "diff. for one hour" (regardless of second difference), and then add or subtract accordingly. Certainly, in some observations of the sun, a second or two is not of much importance, but would it not be better if our *Nautical Almanac* published a table of second differences, so that you could get a correct declination? There could surely be no objection on account of space, although I see in the later editions of the almanac a gradual decrease in the number of pages, and I suppose a corresponding decrease in the computing staff, but if the almanac is to be confined to a certain number of pages, why not omit the trashy explanation, and insert one or two useful tables?—HENRY WOOD.

[11361.] — **Preserved Meat.** — Would any correspondent explain the modus operandi as conducted in Australia, with regard to the filling, boiling, and soldering up of the tins. The reason why the ends are concave, and what is the use of the bent strips of tin soldered inside the lid?—CURIO.

[11362.]—**Silver Tubes for Meerschaum Pipes.**—Could any of the readers of the MECHANIC inform me how to make bent silver tubes for meerschaum pipes? I can do the straight ones, but often lose a job through not being able to do the bent ones. An answer will oblige—A YEAR'S SUBSCRIBER.

[11363.]—**Hankey's Comet.**—Anxious as "F.R.A.S." always is to assist any one desirous of information, can he give me the method for calculating the next places of Hankey's comet, which, when completed, I would gladly communicate to our MECHANIC. I have De Morgan's well-known sheet of logarithms, a slide rule (by Smith), a sextant and a Gunter's scale, and a very accurately divided triangulator. Should I not have sufficient materials, perhaps "F.R.A.S." will kindly inform me what other articles are required.—YOUNG ASTRONOMER.

[11364.]—**Lettering the Backs of Books.**—Will some reader kindly tell me how the gilt lettering on the backs of books is done, or on slips of leather?—W. STEAD.

[11365.]—**The Wind.**—Will any of your readers inform me from which quarter the wind blows mostly during the year in London?—ANEMOMETER.

[11366.]—**Blankets.**—Will any fellow reader inform me of the best method of washing and whitening blankets that have become yellow? Should any chemical be used?—HOUSEKEEPER.

[11367.]—**Magnesium Lights.**—Can any one tell me how to make magnesium lights? I suppose the addition of magnesium filings to an ordinary blue light would answer; but as the filings are expensive, I wish to avoid experimenting.—T. T.

[11368.]—**Precious Stones.**—Will some of your correspondents kindly inform me what relation in value do the cheaper precious stones, such as garnet, emerald, blood-stone, &c., bear to their settings of nine carat gold? Or if information in this form be not convenient, a reference to a work on the subject will be thankfully received by—CARBON.

[11369.]—**Etching Steel.**—What acid will eat steel quickly? I want it for making a hole into a that I do not wish to soften.—H. D. B.

[11370.]—**Electrical.**—How is it that in the following combination current can be detected? A strip of copper and of zinc, with a piece of cloth between them, are joined together at the ends: then upon exciting this compound strip and bending it round till the ends nearly meet, the current can be plainly felt with the tongue. Now, I should have thought that joining both ends of copper and zinc would have destroyed all current whatever. Which is the negative pole in such a combination? —H. D. B.

[11371.]—**Steel for Lathe Tools.**—As I live a great distance from any town where I can procure steel for slide-rest, eccentric, vertical and horizontal cutter tools and drills, I want to order some useful-sized steel to have by me when required. Would "J. K. P." kindly let me know the most useful sizes and names of best steel? The centre of my 4in. lathe is ½in. above slide-rest. Would he also give me his advice how to mend a piece of the cast-iron frame that the mandril runs in, which is broken out by one of the screws of cross-bar (that keeps the front bearing of mandril in its place) being too tight?—L. S.

[11372.]—**Oval Chuck.**—Would "Jack of All Trades" kindly help me in constructing his oval chuck (Vol. XII., No. 293), as I do not understand B², the micrometer screw and head with divided and sub-divided rings, nor the figures K R R and plan C and section C? If he would give me a few measurements I should be greatly obliged. My face-plate is seven inches and fifteen-sixteenths in diameter.—L. S.

[11373.]—**History of England.**—Can any of "our" correspondents inform me of a good cheap History of England for boys of ten and eleven? I have had Little Arthur's, John's, and McLaurie's, and require one now between the latter and Dickens's. Mrs. Markham's is too lengthy, and Collier's too difficult.—Beta.

[11374.]—**Fixing Belts on Tires.**—I wish to know the proper way to put the belts on Barnard & Bishop's lawn mower tires, and if they can be repaired when broken, and by what process.—Blacking.

[11375.]—**Brickmaking in Canada.**—I should feel obliged if any one of "our" readers who may have knowledge of Canada could inform me of the part wherein soil might be dug suitable for making bricks—sand, clay, and chalks are the necessary materials for composition. If the plant is situated adjacent to some rising neighbourhood the advantages would be more profitable. —Gillem.

[11376.]—**Marble Busts.**—I have several marble busts which are considerably blackened and soiled from exposure to the influence of dust and smoke. Can any one instruct me how to clean (without injuring) them readily?—M. B.

[11377.]—**Pocket Umbilicus.**—I have a small 6in. pocket umbilicus, the internal mechanism of which has become deranged, in consequence of the geodesic having become entangled with the escapement wheel on the indicatrix; in addition to which, I am afraid some teeth of the skew bevils on the permanent axis of rotation have become bent, producing non-isochronous movements in the parabolic governor. Can any of your mechanical readers advise me how to remedy these defects without breaking the air-tight joints in the covers, and so vitiating the vacuum? The cylindrical case of the umbilicus is made of plate-glass, and not of the usual alloy of sheet tin and cast iron.—R. Macmichael.

[11378.]—**Killing Beetles.**—How can I kill the larger kinds of beetles for mounting in a collection without destroying their colour, and in the quickest manner, so as not to cause unnecessary pain?—Sempervivo.

[11379.]—**Wardian Case.**—Will some kind reader furnish some practical hints to a young amateur mechanic who is ambitious of constructing a wardian case, about 3½ft. long, at the minimum cost consistent with completeness and a certain amount of chasteness?— Y. A. M.

[11380.]—**Sand for Casting.**—Could any of your subscribers inform me of the method of preparation of the sand which is applied to the purposes of moulding and casting iron and brasswork?—Leonidas.

[11381.]—**Rhumkorf's Coil.**—Would "Sigma" or some one else kindly tell me how many pint Bunsen cells I could use with safety for working a Rhumkorf's coil, consisting of three layers of No. 18 copper wire for primary; also, how they are to be arranged?—J. S. W.

[11382.]—**Parrot.**—Can any one tell me the cause of and cure for a parrot picking the feathers off one of his wings and his red tail? I have altered his diet, giving no hempseed, and keeping him almost on bread and milk, but it makes no difference. It is a gray bird, and never has meat or bones.—Cygnus.

[11383.]—**Sulphur Soap.** — How is sulphur soap made? What is the quantity of flowers of sulphur used in a pound of the soap, and how is it worked in?— Peronelle.

[11384.]—**Small-Pox: Its Prevention and Cure.** —In No. 333, p. 514, of the Mechanic, phenic acid is mentioned as a cure and preventive of small-pox. Can any one give me any information concerning it? I have tried to obtain it, but have been unsuccessful. Has carbolic acid the same virtues?—F. W. Shearing.

[11385.]—**Salt.**—Will any of your correspondents inform me what are the tests for salt? 1. For purity. 2. For strength. 3. What changes does salt undergo by lying in stock (say) from four to six months? 4. Is there any difference in the quality (chemical or otherwise) of the salts made in different parts of England?—Chloride of Sodium.

[11386.]—**Crystals in Gas Tar.**—About nine months since I had occasion to use some gas tar from the gas works. I procured some in a tin quart can. After I had used what I wanted I put the lid on the can and laid it by in the cellar. Some time after I wanted a little more tar, and to my surprise, when I moved the lid off the can, I saw some beautiful white crystals projecting from the tar on the sides of the can. Now, I should feel obliged if our chemical correspondents would extend their favours and explain the chemical action; also, the equations worked out, so as to explain the formula of these crystals.—Atomic.

[11387.]—**Sundials.**—Will one of your astronomical correspondents kindly inform me whether a sundial might be made to give correct indications by mounting it on a pivot, so as to admit of its rotation in a horizontal plane, and setting it from time to time by a graduated circle divided into days or weeks, according to the degree of accuracy required? Or would it be also necessary to have the gnomon capable of adjustment vertically? Could a similar arrangement be applied to other forms of dial, such as the vertical?—L. C. E.

[11388.]—**To Mr. Fennell.**—Will Mr. Fennell be good enough to state whether the organ shown in section on p. 665 of the last volume is the same as the one of which he formerly sent a drawing? Also, whether he ever made the instrument, or merely designed the case, which was an extremely elaborate one?—L. C. E.

[11389.]—**On Fortifications.**—Will some reader inform me of the plan of the late Earl of Dundonald on fortification? I have a plan of a fortification on hand, and wish to know if they are anything like mine. My plan rises out of the earth, and when down the enemy might stand on the top of it and not be aware of its presence.—J. T.

[11390.]—**Brown Hat.**—Will somebody kindly tell me how to dye my straw hat brown? It used to be an easy matter to get done, but now both general dyers and milliners refuse the work. Having an old fashioned fancy for a brown hat, I tried to do my own, and got a sixpenny bottle of dye for the purpose, but as it was barely enough to cover the crown I thought it dear, so finished it off by adding a bit of one chemical and a bit of another, until the hat was presentable and even wearable; but having no idea of the quantities of the things I used, I am unable to do the same again, so must submit to being another woman guided by "rule of thumb." —Sarah.

[11391.]—**Insulating Coil.**—Will any kind reader inform me whether it is absolutely necessary to insulate each separate coil with ebonite, or is there anything else that would do as well? If properly insulated what is the average length of spark a ½lb. of No. 32 silk covered wire ought to give?—H. Corbett.

[11392.]—**Scent from Violets and Roses.**—Can any one inform me the way to extract the scent from violets or roses?—H. Corbett.

[11393.]—**Metallic Harmonicon.**—Having lately seen a drawing of a metallic harmonicon, would some kind reader give me some particulars about it? What are the breadth and thickness of the ribs upon which the notes rest, the kind of wood best suited for them, and are the pins which keep the notes in their places driven down through the heart of the cord into the ribs? and is it, after all, an instrument that is of much practical value to the musician, or is it only a musical toy?— Valve.

[11394.]—**Opera Glass.**—I wish one of your correspondents would inform me how to make an opera-glass of great power—for one eye would do, and it need not slide.—Inquirer.

[11395.] — **Foreign Wood.** — Can any of your numerous readers inform me what kind of wood it is that is bound outside the cases that cocoa fibre comes in? It is a very dark and heavy wood, and comes in small pieces about 1in. square?—C. C.

[11396.]—**Ivory Handles for Whips.**—I have seen ivory handles for driving whips, apparently turned, but having at irregular intervals knots in imitation of those in holly and other woods? How is this done? I think the result might be produced by turning beads at intervals, and filing same away to form the knots; but a careful examination of one of the handles makes me think it is not done so.—Jannifred.

[11397.]—**Sting-proof Gloves.**—Could any one tell me how I could make a pair of sting-proof gloves, to be proof against the stinging of bees?—Apiarian.

[11398.] — **Stinging of Bees, Hornets, and Wasps.**—What is the best remedy for the stinging of the above to prevent swelling?—Apiarian.

[11399.] — **Water Power Wanted.** — Will some brother reader inform me what size turbine wheel I should require to work a cylinder which is now worked by a man and lad? I have a cistern which I think will supply sufficient water, holding about 400 gallons. I can get 18in. fall from bottom of cistern to top of wheel; will 1½in. pipe be large enough? If not please state what size will be necessary. Of course I can always have that quantity of water in cistern, as I have a good supply. Please state the depth of wheel and size of buckets. A sketch of one will greatly oblige.—E. Tappin.

[11400.]—**Pedals for Pianoforte.**—Would some kind reader give a plan of a set of 29 pedals for practice for the piano, and how to connect them with the keyboard of a 6 octave piano?—J. W. S.

[11401.]—**Electric Formula.**—I have had some years' practical work in the engineering department of a telegraph company—chiefly in construction work. I have purchased Culley's "Handbook of Practical Telegraphy," but cannot understand the scientific instructions for testing, &c. Will some brother reader kindly say if I can acquire this information without a master, and if so what books I must purchase?—Bladud.

[11402.]—**Water Power to Work Saw Bench.**— On page 671 of last vol., your obliging correspondent "Tubal Kain" estimates 7,206lb. of water, having a fall of 6½ft., will give an effective power about equal to 1 horse. I wish to know the size of an opening from a head of water that would allow the escape of that quantity. Would a 3ft. opening, with 6in. of water flowing over the cill, be near that weight? "Tubal Kain" is better at figures than I am, and I hope he will not smile at ignorance. We receive much instruction from the writers in "our" journal. Are the paddles of water-wheel set at right angles from drum, or inclined to receive the flowing water? I hope to turn the above query to some advantage in the western country.— Gillem.

[11403.]—**Gas.**—Will some one tell me where the gas burned in the carriages on the Underground Railway is supplied from?—W. Bright.

[11404.]—**Analysis of Albite.**—Will Mr. Da kindly indicate how I must proceed in making quantitative analysis of albite (Si_6 Oz Nao_2 Al_2 O_6)? an inform me if ZCy_2 is soluble in water, if ferrous sulphate is oxidised into the higher sulphate by passing chlorine through its aqueous solution, if $MnCl_2$ is converted into $MnCl_4$ under the same circumstances, and if potassic nitrite in like condition is converted into the chloride? —W. J.

[11405.]—**Purifying Zinc Wire.**—Will you or any of your readers be kind enough to inform me of any other means of purifying zinc wire for a battery, other than using mercury?—John S. Darton.

[11406.]—**Steam Pump.**—What kind of steam pump is best to try an artesian bearing from a bore hole forty yards deep, which stands thirty-three yards in water?—John Hartley.

[11407.]—**Magic and Conjuring.**—I want to give a lecture on magic, and wish to give as many startling experiments as I can. I should like to make the stage as attractive as a conjuror's. What I mean by magic is those tricks that are done by natural causes; for instance, the double funnel where you pretend to pump water out of a person's arm, the water being kept in the funnel by the pressure of the atmosphere, and is allowed to run out on lifting the finger from a little hole in the handle of the funnel. This is magic. Cooking plum puddings in gentlemen's hats is conjuring. Can any of your numerous readers tell me of any magical tricks?— Mark.

[11408.]—**Sewing Machine.**—Being about to purchase a sewing machine, and reading up the subject, I find those instruments are divided into two classes, such as form the stitch with a revolving hook, and those which do so by means of a reciprocating shuttle Now I wish to know which of those methods is the simplest or the least liable to get out of order, presuming that either make the sewing with similar excellence. I want the instrument for general use in a private family, and for a lady who does not appear to have more than mediocre mechanical ability.—E. B. F.

[11409.]—**Canine.**—Can any brother reader of this very valuable journal put me in possession of a remedy for the falling off of the hair of a retriever pup? I may just state that it is black and three months old, and up to about a month ago had a fair coat of curly hair; since that time it has gradually fallen off until it is almost bare. I have washed it frequently with dog soap to destroy fleas, and have also administered areca nut for worms, both these articles having had the desired effect. I may also state that it is full of mischief and as hearty as it can be, but the hair coming off completely spoils this otherwise promising and valuable pup; therefore, if any of my brother readers can tell me what will cure this failing, he will confer a great favour on—J. A. H.

[11410.]—**Geometrical Question.**—AB is the base of a triangle, of which the sides AC and CB are equal to one another; also D is a point in BC, or in BC produced, where a line drawn from A makes a right angle with DB. It is required to show that the angle DAB is equal to half of the angle ACB at the vertex of the isosceles triangle.—Thetamu, Horsham.

[11411.]—**Line Shaft.**—Will some one give a quick and correct mode of fixing a line shaft, say 160ft. long? —Tyro.

[11412.]—**Painting.**—I have seen an oil painting by M. Zadorecki which very much takes my fancy. Will some one kindly inform me if he is considered a good painter, and if his works are much sought after?— Flactem.

[11413.]—**Lathe Chuck.**—Would "Goat" kindly give a more minute description of the lathe chuck he refers to, in his reply to query 10883, as I do not quite understand him? A detail drawing would greatly oblige—Lilly.

[11414.]—**Unripe Seeds.**—If seeds are gathered before fully ripe will they germinate when sown, and if so is the plant degenerate?—Z.

[11415.]—**Scarlet Runners.**—Will some reader tell me which is the best sort for sowing, and how I can prevent the flowers dropping off, which happened to me last year instead of growing to be beans? Also a few hints for the successful cultivation of this delicious vegetable.—Z.

[11416.]—**Crossbow.**—Would some brother reader inform me how I could make a good crossbow, one that will carry well?—Turner.

[11417.]—**White Polish.**—Will any of your readers direct me how to polish white woods, such as lime and apple? and also give me the recipe of a good white varnish?—Stilton Cheese.

[11418.] — **Absorbing Quality of Printing Paper.**—Can any of your correspondents inform me if the absorbing quality of paper of foreign books can be obviated? I should feel obliged if some one would state a handy method of doing this.—E. W. P. Edwin.

[11419.]—**Half-Horse Power Turbine.**—Would a brother reader of "ours" kindly inform me if it is possible to get, say, ½-horse power (or less would do) from a turbine erected in conjunction with a common house water tap, through which runs a good supply of water through a 1in. diameter pipe, supplied by a main of (say) 6in. diameter?—Aqua.

[11420.]—**Sewing Machine Extras.**—I want to make a few extras for sewing machines. Will "Jack of All Trades" kindly inform me whether the ones in common use are silvered, or are they white metal, polished?—Cleos.

[11421.]—**Photography.**—I am just commencing the practice (or study) of photography, and am, to the best of my knowledge, strictly following the instructions given in all works on the subject. I think I have succeeded in coating the plate with collodion. I immerse it in silver bath for four or five minutes, develop with iron developing solution, fix by plunging in hypo. bath for about ten minutes; the picture looks well till I wash it, and as soon as I flood it with water the picture nearly disappears, leaving little more than the upper part of background, which looks muddled and blotchy. If some experienced hand will kindly come to the rescue I shall be very grateful.—Camera.

[11422.]—**Night and Day Temperature, &c.**—How is it we often hear it said it is never so cold by night as by day, when we know very well, from the readings of the thermometer, that the reverse is the case? Are our bodies less sensible to the influence of cold at night? Again, I have often heard it affirmed by sailors that it never blows so hard by night as by day. Is there any truth in this?—A. E. S.

[11423.]—**Surgery.**—Can any one give me information on this case? Three months ago a person of my family got about a quarter of an inch of the point of a needle in her finger. As it is exactly in the middle joint, no surgeon has been willing to answer for the result of an operation. The finger, at first much swollen and extremely painful, has now, for the last two weeks, resumed its former state, except a little white tumour where the needle went in, and a soft red swelling on the opposite side; it is still painful when bent. Is there any danger?—A COUNTRY SUBSCRIBER. [We hope no one will answer this question who is not qualified to speak with authority.—ED.]

[11424.]—**Botany.**—Wanted, information about a good "Flora," partial or complete, of Wiltshire, or of South of England. Are there any with analytical keys for young beginners?—AME EN PEINE.

[11425.]—**Fitting New Roller and Lever to Watch.**—Will one of our watchmaking subscribers kindly inform me how to put a new roller and lever to a watch, also how measure them?—JOBBER.

[11426.]—**Screw Cutting.**—Will any kind reader of "our" MECHANIC inform me what pitch of screw I want for a 4in. centre lathe, and what size? and what distance from centre of lathe mandril to centre of screw?—DIGBY.

[11427.]—**Degrees in Chemistry.**—Will some subscriber kindly inform me of the best way of preparing myself to take a degree in chemistry? Also what would be the first degree to be taken, and the best place to take it at? Will some one kindly give me a few examples of questions that have been set in the examinations?—AMBITIOUS CHEMIST.

[11428.]—**Violin.**—Can any of your correspondents learned on the subject of violins inform me if a violin having inside the following inscription is likely to be genuine: "Made by Thomas Smith, at the Harp and Hautboy in Piccadilly, London, 1756;" and if genuine would it be valuable?—W. P. D.

[11429.]—**Ferns.**—Will some reader kindly tell me how to get rid of and prevent mildew to ferns kept under a glass shade?—E. T. S.

[11430.]—**Lapidaries' Tools.**—Will some brother reader kindly tell me the way lapidaries cut the pebbles found on the sea-shore, and what tools are required, and how they are polished? Any information on the above will oblige.—J. CHAMBERLAIN.

[11431.]—**Tinned Water Bottles.**—Our corps have been ordered to carry water bottles, and they are tinned inside, but we find that wine, &c., dissolves the tin and causes the iron to rust. I wish to know whether they can be easily plated with silver inside, and how?—if with battery which, and what size will be required? They are black japanned outside.—LONDON RIFLE.

[11432.]—**Tuttle's Comet.**—No one has given the places for every day of Tuttle's comet in "ours," beyond what our friend "F. R. A. S." wrote in the leading article of the ENGLISH MECHANIC for Feb. 23. Would some one oblige me by giving the places for the early part of April?—W. H. SKELTON.

[11433.]—**Porous Charcoal.**—Will any reader inform me how the porous charcoal blocks are made, and what are the ingredients for filters?—J. WALTON.

[11434.]—**Salmon Spawn as Bait.**—Would any reader inform me how to mix salmon spawn as a bait for fishing. I have a book for fishing which says, "Salmon spawn is a good bait for all kinds of fish when mixed in a peculiar manner."—KING FISHER.

[11435.]—**Bootmaking.**—Is it necessary to soak leather in water before using it for the soles of boots? If so, does that not damage the leather, and render it less durable than when worked dry?—CRISPIN.

[11436.]—**Harmonium.**—Is it absolutely necessary that the channels should be all the same width in a harmonium pan?—K. T. L.

A Shower of Stones.—A shower of stones is reported from Rosario, in December. A great tempest was felt, ending in a shower of stones from N.W. to S.W., and doing much damage. The shower lasted ten minutes, and the stones were abundant and large, weighing from a nut in size to a pigeon's egg. The cornfields have severely suffered. It is remarked the like occurrence had not been seen for many years, so it is to be inferred such a phenomenon is not unknown. As the Bernstadt colony was affected some European observations may be received.

The Healthiest Sites for Dwelling-Houses.—The healthiest sites for dwelling-houses (said Dr. Hime, in a paper recently read before the Sheffield Architectural and Archæological Society) are known to be those on trap, granite, and other metamorphic rocks, where water readily escapes, and the soil, and consequently the air, is dry. Cholera is rare in houses on such sites. Permeable sandstone, gravel, and chalk, if unmixed with clay, are also healthy. Sands which contain organic matter, clay, and alluvial soil are always to be suspected. Thorough draining, both subsoil and surface, is a necessary preliminary to building. Dampness of ground necessitates dampness of the air and of the walls. Houses should never be built on ground filled up with ashes and other *debris*. The large amount of organic matter contained in it, which is freely exposed to the action of the air and moisture, becoming decomposed, must cause poisonous emanations destructive to those who, living above, must breathe it.

DOMESTIC RECIPES.

From the *Food Journal*.

PUREE DE LEGUMES.—Boil in some stock with a bundle of sweet herbs, pepper, salt, and spices to taste, any combination you like of such vegetables as carrots, turnips, potatoes, parsnips, leeks, onions, peas, Jerusalem artichokes, etc. When thoroughly done, pass the whole through a fine hair sieve. Mix in a saucepan a piece of butter and a little flour, then add a little of the purée, and when this is well mixed add the rest. Finish by stirring in, off the fire, a couple of yolks of eggs strained and beaten up with a little milk. Serve with or without any sippets fried in butter. N.B.—The above is one way of making use of the trimmings of vegetables produced by cutting them up with fancy cutters.

FILETS DE VEAU A L'ITALIENNE.—Cut from a piece of leg of veal some nice fillets, three-eighths of an inch thick, sprinkle them on both sides with pepper and salt, and lay them flat in a tin, with plenty of salad oil. Put the tin in the oven just long enough to cook the fillets, then drain and arrange them in a circle on the dish, with the following sauce in the middle:—Fry in a little salad oil a couple of shallots, minced fine; when they are a pale straw colour add two or three mushrooms and a little parsley, minced in the same manner; then moisten with enough stock and white wine in equal parts to make the sauce; add pepper and salt to taste, a clove of garlic, some sweet herbs, and a bay leaf tied up in a bundle. Let the sauce boil half an hour, and remove the bundle. Melt a piece of butter, add a very little flour to it, then the sauce, stir it well on the fire, and it is ready.

CRAPPIT HEADS.—A Scottish dish, of which the name signifies stuffed heads. It consists of the heads of haddocks, stuffed with a mixture of oatmeal and suet, flavoured with onions chopped small, and pepper, to which the roes of the haddocks are sometimes added. The heads are then placed in a pudding dish with a little suet, sprinkled with oatmeal, and baked in an oven. This was formerly a favourite supper dish in Scotland, and is mentioned in "Guy Mannering" as one of the good things prepared by the landlady of a village inn for a guest to whom she wished to show particular attention. Although a very pleasant dish, it has, however, fallen much into disuse.

OMELETTE AU PARMESAN.—Beat up three eggs with pepper and salt to taste, and a tablespoonful of grated Parmesan cheese; fry a light colour, and serve with plenty of grated Parmesan stewed over the omelet.

USEFUL AND SCIENTIFIC NOTES.

A Cosmopolitan Move.—It is asserted, and, we believe, on good authority, that Prince Bismarck is about to summon to Berlin an International Congress, to discuss the present postal arrangements of the world; and that he is prepared to lay before the members the following proposals, as a basis for negotiation:—1. That all the States of Europe, Russia in Asia, Turkey in Asia, Canada, the United States, Algeria, &c., shall form one postal union. 2. That throughout this union there shall be adopted a uniform rate of postage of twopence per half ounce. 3. That throughout the union, newspapers, printed matter, patterns, &c., shall be conveyed at the rate of one penny for every two ounces. 4. That to all countries not included in the Postal Union double the above rates shall be charged. 5. The uniform registration fee for all parts of the world shall be twopence.

A Wave of Cold.—The meteorological observations now made and telegraphed daily in America disclosed, in February, the path of a great atmospheric wave of cold across that continent. The *Chicago Tribune* states that on the night of the 11th the telegram to that city announced that at Fort Benton the thermometer had suddenly fallen to 15° below zero, but none of the other signal stations exhibited any marked change of temperature. On the 12th, the thermometer fell 35° at Omaha. At Chicago it stood at about 43° until midnight, with a very light movement of the atmosphere; the icy wind then arrived, and the mercury dropped 33° in ten hours, and fell still lower in the evening, the wave passing on towards the south-east. It traversed the distance from Fort Benton to Chicago at the rate of 25 to 30 miles per hour, and it is stated extended at least 100 miles north of the line from Fort Benton to Omaha, but not so far to the south. The barometer rose as rapidly as the thermometer fell.

Copper Gas-Pipes.—The *Journal de l'Eclairage* notices an accident which once more proves the danger of using copper gas-pipes. A workman having, with a three square file, cut almost through half the diameter of a gas-pipe of red copper of ⅜in. internal diameter, which supplied the Liége station, was removing the tool when an explosion similar to the report of a rifle ensued, and the workman was much burnt. Some gas-pipes having been taken down, they were found covered with a blackish coating, and showed evident signs of corrosion from ammoniacal condensation. The black matter was analysed, and was found to consist of an acetate of copper, which exploded between 203°-248°, producing water, copper, carbon, carbonic acid, and traces of carbonic oxide.

Pearls.—Mr. R. Garner lately read a paper before the Linnean Society, in which he referred to the theory, now generally adopted, that the production of pearls in oysters and other molluscs is caused by the irritation produced by the attacks of the minute parasite known as *Distoma*, and believed that, by artificial means, this parasite might be greatly increased. British pearls are obtained mostly from species of *Unio*, *Anodon*, and *Mytilis*, but it is probable that all molluscs, whether bivalve or univalve, with a nacreous lining to the shell, might be made to produce pearls.

Coating Oxidisable Metals.—A process devised by M. Nagel, of Hamburg, for coating iron, steel, and other oxidisable metals with an electro deposit of nickel or cobalt, consists in taking 400 parts, by weight, of pure sulphate of the protoxide of nickel by crystallisation, and 200 parts, by weight, of pure ammonia, so as to form a double salt, which is dissolved in 6,000 parts of distilled water, and 1,200 parts of ammoniacal solution, of the specific gravity of 0·909, added. The electro deposit is affected by an ordinary galvanic current, using a platinum positive pole, the solution being heated to about 100° Fahr. The strength of the galvanic current is regulated according to the number of objects to be coated. For coating with cobalt 138 parts, by weight, of pure sulphate of cobalt are combined with 69 parts of pure ammonia, to form a double salt, which is then dissolved in 1,000 parts of distilled water, and 120 parts of ammoniacal solution, of the same specific gravity as before, are added. The process of deposition with cobalt is the same as with nickel.—*Iron Age*.

Liquid Glue.—An excellent liquid glue is made by dissolving glue in nitric ether. The ether will only dissolve a certain amount of glue, consequently the solution cannot be made too thick. The glue thus made is about the consistency of molasses, and is doubly as tenacious as that made with hot water. If a few bits of indiarubber, cut into scraps the size of a buck shot, be added, and the solution allowed to stand a few days, being stirred frequently, it will be all the better, and will resist the dampness twice as well as glue made with water.

Insanity in France.—History teaches us, says the *Lancet*, that when a nation passes through great political storms, that period is always followed by an increased development of insanity, which generally takes a suicidal form. The throes through which France has lately passed have already materially increased the number of lunatics in that country. The inmates of the various asylums and maisons de santé have more than doubled in the course of the last eighteen months, and the Morgue in Paris is barely large enough to contain the bodies which are daily found in the Seine. Among the Communist prisoners who are now in durance at Brest, Cherbourg, Lorient, and elsewhere, the tendency to insanity is very marked, two per cent. having become deranged since their imprisonment. The appointment of a medical commission to inquire into and report upon this question would be both wise and humane.

The Productions of Florida.—White oak, live and water oak, gum, bay, hickory, magnolia, palm, dwarf palmetto, pine of several varieties, Indian corn, cotton, sugar cane—which, unlike the Louisiana cane, reaches a full maturity—sweet and Irish potatoes, celery, radishes, rice, tobacco, indigo—the principal production under the British occupation of Florida; Sisal hemp, the magney plant or Agave Americana, castor bean, the mulberry, peas, pea-nuts, wild arrowroot, rye and oats, tomatoes, cucumbers, melons, beans, cabbages, turnips, beets, oranges, lemons, limes, citrons, peaches, grapes, figs, pomegranates, plums, blackberries, olives, bananas, pine-apples, guava, tamarind, plantain, cocoanuts, &c. Wheat does not succeed; but flour may, of course, be readily procured by the immigrant who is not willing to live on Indian corn, sweet and Irish potatoes, rice, or the almost countless fruits, added to his meats and fish. As for cattle, they may live on outdoor supplies, and range for ten months of the year in Northern Florida, and for the whole year in Southern.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

The following are the initials, &c., of letters to hand up to Tuesday morning, March 26, and unacknowledged elsewhere :—

W. H. Cuell.—G. R. Hallane.—Philip P. Hanson.—L. Michals.—Geo. E. Jee.—Young Moulder.—George Lampbard.—Wm. Moore, jun.—John Ridgway.—R. G. Kent.—P. W. Mayor.—C. Scopas.—Greybeard.—S. Bottone.—R. A. Proctor.—Cameo.—Old Dog Tray.—The Harmonious Blacksmith.—W. Pengelly.—Sigma.—W. R. Birt.—Fred. Harrison.—A Shipbuilder.—Eureka.—J. C. M.—Moneta.—O. W.—G. H. S.—John Clegg.—Zoo Andra.—F. T. S. S. D.—Interrogator.—Fond of Singing.—E. Naylor.—A New Subscriber.—Samuel Davis.—S. G.—Wm. Hutchins.—N. Du Fai.—J. Walton.—M. Paris.—J. B.—Jack of All Trades.—R. S. T.—Screw.—Photo.—M. R. C. S.—Hy. Newman.—A. Z.—E. H. W.—H. D.—R. Langdon.—A. W. C. Price.—W. H. Harris.—W. C. Hughes.—G. H. Hurst.—A. J. White.—G. F. H.—W. G. Clarke.—An Anxious Mechanic.—Rosse.—G. A. D.—Rata.—Semaj.—Full Stop.—W. J. H.—H. F.—A. J. V. G.—R. Tervet.—Samuel Smither.—J. R. Proctor.—E. B. Fennessy.—Experior.—C. B. B.—Iriosal.—Archer.—Touchstone.—Country Tinker.—W. Bright.—Matthew Berth.—A., Liverpool.—Ultima Thule.—Lyons.—Anxious.—W. W.—Bed of Stone.—Champagne Charlie.—Geo. Knott.—B. H. Harris.—Henry White.—King Fisher.—Ralph Lowdon.—F. R. A. S.—E. R. E. A.—T. Leith.—Ambitious Chemist.—R. D. D. Masey.—Excelsior.—W. R.—H. Sheppard.—A. J.—S. Pearce.—Vega.—L. W. D.—B. H. Rochdale.—Æneas.—Digby.—G. D.—Zeta.—Youngster.—A Chemical Student.—F. B. T.—R. G. A.—A Subscriber.—S. W. Dudley.—J. Westwood.—Wm. Richardson.—R. O.—W. H. Skelton.—Old Coin.—Barbaros.—F. T. C.—Geo. N. Dobson.—A Young Student.—C. N. Abbett.—L. C. E.—W. H. Hey.—W. P. D.—Philadelphus.—E. T. S.—A Young Reader.—J. Chamberlain.—Khoda Bux.—Jobber.—Thetamu.—Telescopic.—W. E. Henning.—F. A. Edwards.—Welshman.—J. W.—J. W. Card.—Northern.—J. D. Hardy.—Galashiels.—Fletcher and Sinclair.—Coastguard.—E. A. Hansom.—J. H. H.—Detritus.—Sharp and Good.—Boatswain.—Social Reformer.

JOHN SHAW.—Yes.

B. BUDD.—Your letter is not forwarded, because it is our rule not to forward such letters.

Education, Labour, L. Langdon, Youngster, and C. P. E. Your queries are advertisements.

L.—Monthly, price one shilling, and a poor shilling's worth it is. Judge for yourself.

S. SMITHER.—Ornamental Turning, No. 7, next number.

FRAZER HALLE, LL.D.—Scientific Education next week.

J. K. P.—Your other answers next week.

E. L. G.—The P.S. to "Save Us from Decimalism" came too late for this number. It will appear as a separate letter next week. The answers will also appear then.

V. C. B.—Don't ask silly questions.

J. D.—The Organ Built, No. 6, next week.

CERVUS.—Though you doubtlessly disclaim with truth that you have no interest in the books you recommend, still the insertion of your letter would look like an advertisement, and would certainly have the effect of one.

FIDDLER.—You have wandered rather too distantly into the regions of speculation in your letter on "A Question of Sight," to render it suitable for our columns. Please see our answer to "Phœbus" in last number, p. 26.

PNEUMATIC LEVER.—Please send the draught of "the novel arrangement from Germany."

R. IRONS.—We should be glad of the particulars of galvanising iron works in general.

ONE WHO CONSIDERS DARWIN A FOOL.—You are more emphatic than you are polite or truthful. Darwin, in all probability, if he considered you worth consideration at all, would prefer that *you* should entertain such an opinion of him.

SENEX.—Your answer about combing hair smoothly over the head being the cause of baldness cannot be correct, as women would then become bald sooner than men.

JAMES SMITH.—Your query, if inserted and answered, would have no general value, as it would only be useful or interesting to *one* person—yourself. We desire our space to be occupied with information useful or interesting to the largest number.

Correspondents whose communications are not inserted for reasons given in "Hints to Correspondents."—Vermilion, E. Barber (1st reply), Alpha (University Club), Peronello (first query), J. H., F. B., Clock Fancier, Semperviva (first query), Thomas Marshall, Manxman, Thomas Stone, Reed Maker, C. Williams, Samuel Hill.

W. T.—It is unreasonable that you should ask "F.R.A.S." to give you the desired information. Your letter is not forwarded because it is contrary to our rules, and if it were not "F.R.A.S." would not comply with your request.

A COUNTRY SUBSCRIBER.—Ask a surgeon. It is astonishing how complacently some of our subscribers submit serious medical questions to a host of people whom they have never seen, and who will never see them; and of whose qualifications they are entirely ignorant. We expect one of these days to receive a query asking for information on the best and easiest way of amputating one's own leg.

JOSEPH DAVIES.—We should be glad to receive a short series of letters on the subject of nail making.

MILLER.—See indices to back vols.

G. W.—For information on tinning see pp. 91, 141, 164, Vol. XII.; 649, Vol. XIII.

TRUEFITT.—Too frivolous. Write to some of the "Penny Dreadfuls."

EDMUND W. COCKE.—For paint for engine, see pp. 318, 366, 368, and 417, Vol. XIII.

J. L. REILLY (Boston, U.S.A.)—We cannot send volumes by post at all, nor back numbers, except at greatly increased postage rates. For the same reason we had better not send you monthly parts. Any instructions should be given through the agency by means of which you subscribe. Back numbers are 5d. each including postage.

H. B. E.—In No. 367.

LIVERPOOL SUBSCRIBER.—See reply to "Country Subscriber."

BATTLE.—See indices to back vols., and the next six queries you send try and let *one* of them be about something that has not been answered in back numbers.

CYFEACH.—For information on galvanising iron, &c., see pp. 432, 478, 623, 576, and 622, Vol. XII., 343 and 546, Vol. XIII.

G. WHITTLE.—For directions to make collodion balloons, see p. 332, Vol. XII.

A NOVICE IN THE ART.—An illustration and description of Cantelo's apparatus for egg-hatching, was given in reply 6503, No. 310, Vol. XII.

C. J. RECORDON.—We have no space for any more replies to the query.

J. RAE (Sydney, N.S.W.)—The photos. with your second letter are quite clear, and will appear in our next number. We cannot send the vols. to you for M. Tornaghi, as recent regulations of the English Post Office prevent their transmission by post. We therefore have commenced his subscription with the last number, which begins Vol. XV., and await your further instructions. We have never sent duplicates of your vols., and trust the original parcel has by this time reached you. We shall send weekly numbers, and not monthly parts, as the postage for the latter is so heavy.

A WATCHMAKER.—Your question is too vague. You had better send the battery to the makers to be repaired.

BOOTS.—Badness of leather, or a habit of buying boots too narrow for your feet.

ADAM.—"Traditions of Pre-Adamite Races," are matters of too vague a nature for our pages. Never mind about your "decent," but pay more attention to your spelling.

ADVERTISEMENT.—We will not help you to disfigure the streets.

W. D. T.—Yes; apply at the Patent Office.

EXCELSIOR.—We shall be glad if one of the correspondents using this nom de plume will change it.

R.—Try poison. If your dogs are good for anything they will not interfere with a kitten if brought into the house young, and care taken to familiarise them with it.

UN ECOSSE.—The "editor is *not* agreeable." It is unreasonable of you to ask Mr. Tonkes to repeat information after he has referred you to page and volume, and when you can obtain the number for twopence!

A. J. F.—For information on skeletonising leaves, see p. 566, Vol. XI.

W. F.—We do not intend reporting them this year.

JAMES CUNLIFFE.—See back numbers.

CYPHER.—There is a difficulty in reproducing music in our pages, especially of other than the established notation. We were enabled to illustrate "H. T. W.'s" letter by the kindness of the Rev. Jno. Curwen, who voluntarily offered to supply the necessary stereos. If the supporters of your system will do the same, we will print yours. We do not see, however, that it is at all necessary, as the principle of the cypher system is apparent to any one who has seen the tonic sol-fa notation; neither do we see how the printing of your first letter would have prevented what you call the "extraordinary assertions" of "A Schoolmaster." "H. T. W.," in a letter to us, expressed a wish to know more of the cypher system. We have therefore made an exception to our rule, and forwarded your letter to him, and advised him to communicate with you by advertisement in these pages.

J. A. WILSON.—Similar answers preceded yours.

INQUIRER.—Between freezing and boiling temperature, rods of glass expand 85in. in 100,000; of copper, 171in.; of cast iron, 109in.; of brass, 188in.; and of steel, 114in.

R. H.—Yes; you will easily understand how—though the principle is somewhat differently applied—by reference to an article on the magic box, on p. 350, Vol. X.

ROBERT HARRISON.—For information on vulcanising indiarubber, see p. 415, Vol. XIV.

A. LUFFKIN (Iowa, U.S.A.)—See reply to J. L. Reilly for reason why back numbers are not forwarded.

W. D.—What *do* you mean?

E. TOYE.—See "Sable's" articles on painting magic-lantern slides, and his occasional answers.

C. T. C.—Beckwith's sewing-machine is an American invention many correspondents have been inquiring about.

T. STINGER.—Your reply is an advertisement. See notice to advertisers on first page.

THE INVENTOR.

APPLICATIONS FOR LETTERS PATENT DURING THE WEEK ENDING MARCH 19, 1872.

750 J. H. Johnson, Lincoln's Inn, for improvements in machinery or apparatus for separating or sorting various substances. A communication.

751 W. Rose, Halesowen, Worcestershire, for improvements in treating waste boiler plates and other similar plates for the manufacture of gun barrels and nail rods.

752 E. Watteeu, Middlesbro'-on-Tees, for improvements in explosive compounds. A communication.

753 S. Gibson and J. Gibson, Hebdenbridge, Halifax, for improvements in sewing machines.

754 J. Simpson, Wortley, Yorkshire, for a new or improved device for protecting growing celery and cardoons.

755 S. Barton, jun., Cannon-street, City, for an improved rose and nozzle or jet to be used in connection with syringes and other apparatus for distributing water.

756 W. L. Anderson, Limehouse, for an improved mode of fastening gaiters, leggings, and other articles, and in the fastenings employed therefor.

757 A. M. Clark, Chancery-lane, for improved mechanism for changing the shuttles in looms. A communication.

758 R. A. Browne, Richmond-hill, Surrey, for an improved utensil for poaching eggs and other culinary purposes.

759 W. A. Smith, Princes-street, Hanover-square, for an improved purse-glove.

760 W. R. Lake, Southampton-buildings, for improvements in the manufacture of boots and shoes, and in apparatus therefor. A communication.

761 S. Deards, Harlow, Essex, for an improved apparatus for heating water for warming conservatories and other buildings.

762 A. M. Clark, Chancery-lane, for an improved battery gun. A communication.

763 T. Bradford, Fleet-street, for improvements in the means of heating cylindrical or other surfaces used for mangling, calendering, or ironing textile or other fabrics.

764 W. R. Lake, Southampton-buildings, for improvements in machinery employed in the manufacture of leather. A communication.

765 C. W. Heaton and E. E. H. Francis, Charing-cross Hospital, for improvements in apparatus for filtering oil and other liquids.

766 S. J. Beaman and J. Onions, Wednesbury, for an improved puddling furnace.

767 A. Schanschieff, Taunton-terrace, Middlesex, for improvements in apparatus for facilitating telegraphic signalling upon railways. A communication.

768 T. J. Smith, Fleet-street, for improvements in apparatus for the production of gases for heating and other purposes. A communication.

769 A. Schanschieff, Taunton-terrace, Middlesex, for improvements in apparatus for receiving telegraphic signals and despatches. A communication.

770 W. R. Lake, Southampton-buildings, for an improved apparatus for preventing injury to railway carriages by the displacement or removal of the rails, the slipping of the wheels therefrom, or other like accidents. A communication.

771 S. R. Gregg, Lombard street, City, and D. Evans, Cassland-road, South Hackney, for improvements in the method of forming the surfaces of roads, railways, footpaths, platforms, and other roadways, which improvements are applicable to the construction of bridges, pillars, and other buildings.

772 J. Bavin, Lambeth-walk, Lambeth, for improvements in steam engines and in generating steam.

773 W. R. Lake, Southampton-buildings, for an improved roll for spinning machines. A communication.

774 W. J. Lockyer, Bristol, for improvements in the preparation of artificial manures.

775 W. Palliser, Cromwell-place, South Kensington, for improvements in boots and shoes.

776 J. Somerville, Dublin, for improvements in gas retort lids and mouthpieces, and machinery for luting the same.

777 E. Edwards, Southampton-buildings, for improvements in dial plates for calendar clock and watches. A communication.

778 W. G. James, Storey's Gate, Westminster, for improvements in the construction of traps for drains.

779 J. C. Mewburn, Fleet-street, for a new or improved safety thermometer or alarm apparatus for steam boilers and other purposes. A communication.

780 A. M. Clark, Chancery-lane, for an improved safety boat-lowering and detaching apparatus. A communication.

781 H. B. Barlow, jun., for improvements in the manufacture of healds for weaving and in heald shafts. A communication.

782 Sir J. Whitworth, Manchester, for improvements in wheels to run on railroads and common roads.

783 W. R. Lake, Southampton-buildings, for an improved electric torch for lighting gas. A communication.

784 E. Kaulbach, Warwick-street, Regent-street, for the improvement of the means of obtaining parallel motion, and of converting curvilinear into direct rectilinear motion.

785 J. Collinge, Manchester, for improvements in reaping and mowing machines.

786 W. R. Lake, Southampton-buildings, for improvements in boot and shoe heels. A communication.

787 A. Longsdon, Denmark-hill, Surrey, for improvements in ships or vessels of war, and in forts, batteries, and other armed or military structures or apparatus for use on sea and land.

788 M. Payne and C. H. Payne, Thrapston, Northampton, for improvements in brick-making machines and in apparatus connected therewith.

789 J. Kincaid, St. James's-street, Middlesex, for improvements in the permanent way of tramways.

790 R. A. Robertson, Victoria Docks, for improvements in evaporating liquids and in the apparatus to be employed therein.

791 P. Jensen, Chancery-lane, for improvements in boring through earth or other soil by means of water pressure, and in apparatus therefor. A communication.

792 R. Clachar, Glasgow, for improvements in presses for pressing cotton and other fibrous substances into bales. A communication.

793 F. S. Thomas, Baker-street, Pentonville, for improvements in the materials for making roads, ways, and floors.

794 J. Russell, Bonnyfield, Stirling, and W. R. Hutton, Stirling, N.B., for improvements in obtaining zinc.

795 W. E. Thomas and E. Taylor, Salford, for improvements in the method of and apparatus for fixing rollers on to the axles of wringing, mangling, and other machines.

796 J. Warburton, Bingley, Yorkshire, for an improved cork fastener and apparatus or machinery for making the same.

797 J. Barnett, Aberfeldy-street, Bromley-by-Bow, and W. Vokins, Mark-lane, City, for the economisation of fuels and prevention of incrustation in boilers.

798 J. Barnett, Aberfeldy-street, Bromley-by-Bow, and W. Vokins, Mark-lane, City, for improvements in furnaces.

799 M. Benson, Southampton-buildings, for improvements in washing, cleansing, and purifying petroleum and other kinds of oil, and in the apparatus for performing the same. A communication.

800 E. Laporte and C. D. Fontaine, Brussels, for improvements in the preparation of tobacco.

801 F. W. Gerhard, Wolverhampton, and J. Light, jun., Bradley Staffordshire, for improvements in the production of iron and steel.

ARTICLES.

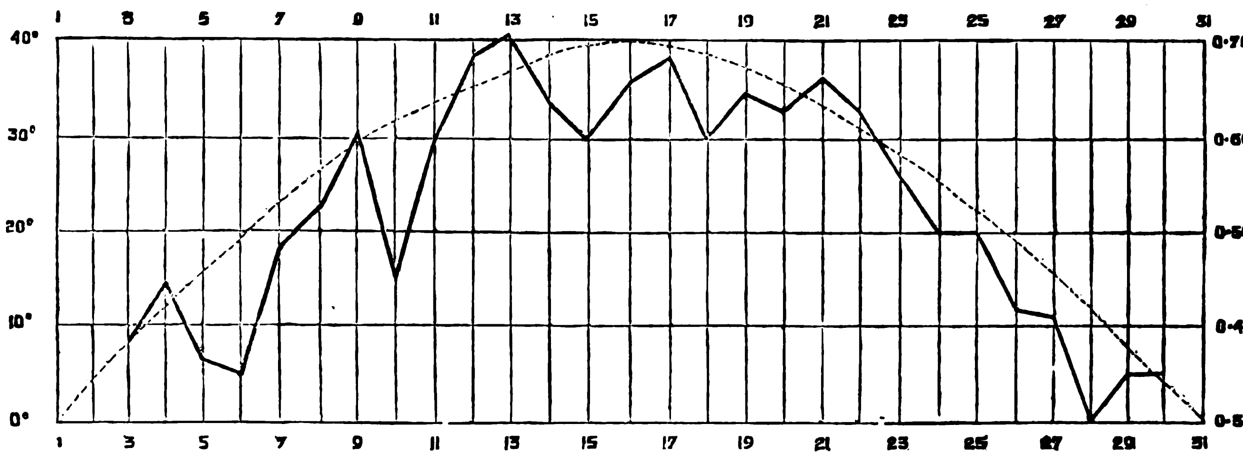
LUNAR METEOROLOGY.

By W. R. Birt, F.R.A.S., F.M.S.

ALL meteorological processes depend more or less on the sun for their existence. It is his heat that warms the surface of our planet, the earth; its atmosphere, partaking of the warmth communicated by his beams, is rendered capable of sustaining the maximum density of aqueous vapour at its then existing temperature, and all the meteorological phenomena we are acquainted with follow. As the sun affects the terrestrial surface so does he those of the other planets of his system, and it may, perhaps, contribute to a clearness of conception if the operation and effects of heat upon those planets be considered under the term planetary meteorology; and in like manner, if we are able to trace the effects of heat upon the moon's surface, and detect appearances which cannot be referred to known agencies, but which are not unlike many meteorological phenomena on the earth and planets, the classification of such effects and appearances under the designation of Lunar Meteorology—although we are unable to detect by optical methods the existence of a lunar atmosphere—may be both suitable and legitimate.

We have already hinted that heat is the agency which contributes in the greatest degree to meteorological phenomena. The development of heat on the surface of a planet or satellite is proportional to the altitude of the sun above any given spot on the surface, and we know that the diurnal and annual progressions of temperature on the earth's surface are functions of the sun's altitude and declination. Although we cannot measure the effect of heat on the moon's surface thermometrically, yet, as we know that on the earth the sun's rays are capable of effecting changes of colour in terrestrial bodies, so changes of colour of portions of the moon's surface are not unlikely to be exponents of the effect of the heating power of the sun upon them.

There are three methods by which alterations in the tints of lunar objects may be ascertained: *First* by estimation, *second* by comparison with a graduated series of tints to which a more precise numerical value can be applied than to mere estimation, and *third* by the use of an instrument so constructed that the observer may readily record the numerical value of the tint presented to his notice. In carrying out a series of observations on either of these methods the obstacles are considerable, but not insurmountable. There is nothing particularly inviting in registering night after night the colour of a small spot on the moon. What is to come of it? is a not unlikely question, and unless the observer has faith in obtaining results that will repay him for his labour, either from the discussion of his own observations, or from a combination of them with the observations of others, he is apt to grow weary, especially if he has to wait two or three years before any of his observations can be turned to account. Again, it is not improbable that his enthusiasm may be insufficient to carry him through so irksome a labour, if a thought crosses his mind that he is only one of several workers, and that somebody else may reap the benefit of his exertions, forgetting that if a few earnest observers are banded together to raise the bucket from the well, the dissemination of the truth when once obtained is of far greater importance than the *aggrandisement* of one or even of all who have sought for and found it. The present popularity, or the enduring reputation of a great discoverer, is as nothing compared with the truth found and promulgated. We revere such names as Copernicus, Kepler, Newton, Herschel, and others; but what would those names be without the great truths which the men who bore them were the instruments of *unveiling?*



The study of Lunar Meteorology must necessarily be a difficult one. The ordinary training of the astronomical mind is inadequate to grapple with it; it does not depend upon accuracy of measurement, nor can it be elucidated by instrumental methods except in one important particular. A keen eye to detect with facility minute differences of colour, a correct appreciation of definition, contrasted with a want of that necessary quality for seizing the smallest detail as manifested on neighbouring portions of the moon's surface, and a disburdening of the mind of any preconceived opinions as to the existence or non-existence of hypothetical conditions, are among the elements of successful study. These, however, are not all the requisites; it is not only exceedingly difficult, but almost impossible, for one observer to carry on the inquiry single-handed. Co-operation is necessary, and co-operation of a peculiar kind. The mere detection of differences of colour or definition in the present state of selenography is not of itself sufficient to establish the existence of Lunar Meteorology. Astronomers have been trained in a different school: they ask for *proof*, and they have a right to demand it, and proof can only be obtained by a long series of observations. Several observers must unite in a course of laborious and almost uninviting observation, and register night after night the general appearance, kind of definition, colour, and brightness of a small portion of the moon's surface. It is only after two or more years that these records can yield any fruit, and the fruit will greatly depend upon the character of the mind that undertakes the final investigation.

Discoveries of whatever nature, whether commanding the admiration of mankind or confined to the knowledge of a few, are mostly the results of laborious investigations conducted by means of weight and measure into which number necessarily enters. We have said that the progress of lunar meteorology does not depend upon accurate measurement, except in one particular: that particular we will now examine. Of the three methods alluded to for determining changes of colour on the moon's surface one only has yielded any result: it is that of *estimation*, but this would have been useless without *number*. A well-known spot on the moon, Plato, has been selected for the observations, and some half-dozen observers entered energetically into the work: mostly three gradations of tint were observed—light, medium, and dark. In the course of two years 133 estimates were made, varying from very light to very dark, and to each estimate a numerical value was attached—light 0·33, medium 0·50, and dark 0·66. The observations treated in this way have yielded a curve which unmistakably tells us that the material of the floor of Plato undergoes changes of colour immediately dependent upon the altitude of the sun above its horizon, and also that these changes of colour bear (with regard to the moon) the same relation to solar influence as the expansion of mercury in our thermometers does on the earth.

Although it has long been suspected that the *forms* of objects on the moon's surface are affected by the angle of illumination, as it is termed—*i.e.*, the angle in which light falls as dependent upon the altitude and azimuth of the sun—the apparent variations arising from changes in the illuminating angle have, so far as we are aware, never been subjected to a close comparison; and, while changes of colour, so far as regards the aspects of bodies, have been supposed to depend upon different illuminations, we believe this to be the *first* instance in which the connection has been really shown; indeed, in the curve before us we have something more than mere change of aspect, for the deepening of the tint as the sun approaches the meridian, in our opinion, arises from a temporary change effected by heat in the material of (or over?) the floor of Plato, whatever it may be. We must not, however, regard the present result as one warranting us to lay down our arms. If we desire to become really acquainted with lunar physics we must be up and doing, for it is only one, perhaps, of a long series of results conducing to this end; certain bright spots have been suspected of fading, and certain light areas, if earlier records be correct, have become permanently darker. The ocean of lunar research is before us: we have picked up one pebble, we hope many more will follow.

Passing from the consideration of the effect of solar heat upon the colours of lunar objects, as partaking of the nature of a meteorological process, we may bestow a thought or two on a few phenomena in which heat may be intimately concerned. It has been our lot on several occasions to witness simultaneously on the moon's surface two very different aspects, and we have found instances on record precisely the reverse of those which we have noticed. It would swell this article to too great a length to quote such instances, or give our own experiences, suffice it to say, that we have remarked the definition of a region—the Mare Serenitatis, for example—to be anything but clear and distinct: scarcely a crater could be detected upon it; at the same time the region to the east, including the Palus Putredinis, and the Palus Nebularum, has been so clear and well defined, that very minute objects could be readily discerned. As the manifestation of these different states, although synchronous as regards the earth view, are referred to different portions of the luni-solar day, and appear to be connected with the position of the sun in the heavens, they may be appropriately classed as meteorological phenomena.

In the foregoing remarks we are not aware that any theoretical considerations have been introduced; a connection between changes of the sun's altitude and colour has been shown, and a connection between clearness and obscurity of the moon's surface on the one hand, and the sun's altitude on the other, hinted at. So far as th… remarks may be supposed to have a theore… bearing, it would be on the vexed questi… lunar atmosphere; but whether the cont…

on this question be terminated in the negative or affirmative, the facts mentioned above, as well as their connection with and dependence upon solar influence, will remain as ascertained portions of selenographical science.

REFERENCES TO ILLUSTRATION.

Curves of solar altitudes and variations of colour at the Lunar Crater Plato.

The dotted curve is that of the sun's altitude, the continuous curve that of the variations of colour.

The horizontal lines represent intervals of 10 degrees of altitude, and 0·10 of chromatic variation.

The vertical lines represent intervals of twelve hours in the luni-solar day, from sunrise to sunset.

IRON AS AN ELECTROTYPE.

WITHIN the last ten years or so the attention of electro-metallurgists in England and on the Continent has been devoted to the attempt to discover a successful method of forming an electrotype in iron, and it was only so recently as last year that the announcement of the success of the researches of M. Klein, an official of the state paper-mills at S. Petersburg, was publicly made, and specimens of bank-note and other plates, medals, a page of printing type, and sundry other articles produced by the process were placed in the International Exhibition two or three months before its close. Although the publication of the *modus operandi* of M. Klein's process, and the exhibition of some of its most satisfactory results, are so comparatively recent, we believe that iron electrotypes have been in use in Government departments in Russia for nearly four years, especially for printing bank-notes. Most of our readers are aware of the great strides that have been made in the art of electrotyping since the time of its discovery by Mr. Spencer in England and Professor Jacobi in Russia some thirty years ago, a discovery which has developed into an important manufacture, not the least useful branch of which is the employment of electrotypes, both in letter-press and what is commonly known as copper-plate printing. Up to the present time copper is the metal which has given the most satisfactory results from all points of view, as the production of electrotypes in that metal is remarkably easy, and consequently cheap, while they are sufficiently durable to answer all ordinary purposes. As substitutes for the original wood engravings they are almost invariably employed in standard works which are likely to run through numerous editions, the wood blocks being thus preserved in as good condition as when they left the engraver's hands. The copper electrotype has also proved itself a formidable rival to the ordinary stereotype for works which are repeatedly reprinted, such as Bibles, prayer-books, &c. But copper has its disadvantages for the purpose as well as its advantages. Although far more durable than wood and the ordinary type-metal, it is yet all too soft to withstand the wear and tear of many thousands of impressions; it is liable to corrosion if put away damp; and it is utterly unsuitable for use with certain coloured inks—*e.g.*, red, which, containing vermilion, a compound of mercury and sulphur, eats away the fine lines of an engraving in a very short time, rendering the copper electro totally useless for printing purposes.

Up to the present time the only process which has been much employed in obtaining a harder and more durable surface is that of M. Jacquin, known as acierage, which consists in coating a copper plate with a thin film of iron. It has been asserted, however, that the iron electrotype plates of the new process are almost indestructible; that they are better able to withstand the inevitable accidents constantly occurring in printing-offices; and that, above all, they can be produced at a cheap rate. As a matter of fact there can be little doubt that the process of iron electrotyping, once understood and reduced to working order, would be as cheap as, if not cheaper than, the employment of copper, while, as far as the chapter of accidents is concerned, iron would not be so liable to damage as the softer metal. But with regard to indestructibility it is not so easy to draw the line, for though iron would doubtless be the most suitable material where the printing surface is always protected from damp, as in bank-note printing, the tendency to rust must be eliminated before iron can hope to supplant copper in the far more general and widely-extended developments of letter-press printing, where, from the nature of the surrounding conditions in those situations where durability would be most serviceable, the electrotypes would be subjected to frequent dampings, occasioning action of a most destructive character. Whether any means can be found to obviate this defect remains to be seen; the utility of the discovery is in other directions of so much importance that we proceed to lay before our readers what is known of its principal features and the uses to which it has hitherto been put in the arts.

The first specimens of iron electrotype were, we believe, exhibited at the Paris Exposition of 1867, and were produced by M. Feuquières, but according to Professor Jacobi, although they presented a tolerably good surface, the reverse was full of small holes, and altogether they were much inferior to those of M. Klein, produced by an entirely different method in the following year. M. Klein had previously made many experiments upon the subject, and after witnessing the results of M. Feuquières he returned home and subsequently brought the art to its present degree of perfection.

Professor Jacobi, who has written more on this special branch of electro-metallurgy than any other savant, states that the quality of the iron deposit depends almost entirely on the greater solubility of the anode, and with this fact in view, M. Klein combined the iron anode with one of copper—Professor Jacobi afterwards modifying this arrangement by substituting charcoal made from horn in place of the copper, by this means obtaining more powerful results. From the account of his experiments recorded by M. Klein in a letter to the Academy of Sciences of S. Petersburg, we learn that his first attempts were made in coating engraved copper-plates with iron, for which purpose he employed a bath of the chlorates of ammonia and iron, to which was added a small quantity of glycerine; but, in endeavouring to obtain a thicker deposit, this process was found to be unsuitable, as the iron not only cracked on the surface but fell off in brittle flakes. To remedy this M. Klein prepared three baths, the first consisting of a concentrated solution of the crystals of double salt—$FeO,\ SO_3 + NH_4O,\ SO_3 + 6\,HO$; the second was composed of the same salts, but mixed in the proportion of their equivalents; while the third was prepared from a solution of sulphate of iron by precipitating the iron with carbonate of ammonia, dissolving the precipitate with sulphuric acid, and removing excess of acid. These solutions were concentrated as much as possible; and iron plates, with a surface nearly eight times that of the copper, were used as the anode. Using a Daniell battery a deposit was obtained in about 24 hours, but this was a complete failure, being full of holes and breaking up easily. With the weaker action of a different battery slightly improved deposits were obtained, but still so far from the results desired that M. Klein cast about for the discovery of the cause and the means of remedying it. This he ultimately found to be the acid character of the bath, which he attributed to the fact that more iron was deposited than was dissolved, and in order to give the anode a greater solubility M. Klein united a plate of copper with the iron, as before mentioned—the result being that the bath composed by the first method remained in good condition after many hours' working, and the deposits became perfectly satisfactory. The process is one, however, requiring great care and attention to prevent too free a disengagement of gas, the best results being obtained by keeping the current so that neither oxygen nor hydrogen is disengaged. Prof. Jacobi found that this stage could be ascertained by means of a galvanometer, which indicates when the current is too feeble or too strong.

Such are some of the facts of probably the most important invention in electro-metallurgy since the primary discovery of that art. For the mere coating of a plate with an iron face, the process of M. Jacquin before referred to has been used with excellent results for some years. In this a solution of hydrochlorate of ammonia (1 to 10 of water) is placed in a trough lined with guttapercha, a plate of iron nearly as long and as deep as the bath is connected with the positive pole of a Bunsen battery, and another plate about half the size of the other attached to the negative pole. These are immersed in the solution, and the bath left for several days, till it arrives at the proper condition for working. The article to be coated is then substituted for the smaller iron plate attached to the negative pole, and immersed in the bath; if the article is not immediately covered with a bright coat of iron the bath is not ready, while it should not be allowed to remain in after the bright coating begins to show a black deposit around the edge. But this process is, we believe, only applicable to the coating of copper-plates or electros, or articles made of alloys of that metal.

METALLURGY OF IRON AND STEEL.

(*Continued from p. 29.*)

THE Hindoo process of extracting iron, as previously described, is in use not only in that country, but has been employed from time immemorial in India, Burmah, Borneo, Madagascar, and Africa. These people, however, do not get perfectly pure ore to operate upon, and one common impurity in it is silica (a compound of silicon and oxygen). It has the property of uniting with the oxide of iron to form a slag, and when we extract iron from ore of this sort we get, in addition to a lump of metal, a quantity of fusible glass-like stuff called "slag"—a silicate of iron. After these people get their iron out of the furnace, they cut it into two pieces (or more, according to the size of the lump) and work each part separately (*i. e.*, heat it and forge it) under the hammer, and in this way they will produce good iron, in *small pieces*, at about £8 per ton. Now, we are apt to look down on these people with boastful superiority, but let us see what they have done. They have produced a solid iron column at Delhi, between 40ft. and 50ft. high—accounts vary as to depth in the ground, according to one it is 16ft.—in circumference 5ft., and highly ornamental at top. A cast of this column is now in the South Kensington Museum, and a piece of the iron which the lecturer had had presented to him he had submitted to be tested, and it turned out to be wrought iron. It was probably forged piece by piece, end on by hammering. According to one account it was made 900 B.C., but another and more probable statement put it at 400 B.C.

Carbonic oxide (CO) is a most important agent in metallurgical operations; and its applications form one of the most valuable steps in modern times. It is a colourless, inodorous, highly poisonous gas, burning with a very hot blue flame, and forming, with the oxygen of the air, carbonic acid. Passed over red hot iron oxide it takes up an atom of oxygen and forms CO_2. It may frequently be seen burning at the top of a common fire with a blue flame, and is due to the carbonic acid produced at the bottom of the fire taking up an additional atom of carbon, and becoming two atoms of carbonic oxide. The greater part of the iron extracted in this and other countries is obtained from the oxide of iron, by the application of this carbonic oxide.

CATALAN PROCESS.—This mode of extracting iron is so called from the Province of Catalonia, in Spain, where it is extensively carried out, as also in the south of France. There is a small furnace in a corresponding forge, with a blowing machine outside, and very rude premature hammer moved by water power. Their forges are no better than mere hovels or respectable cow-houses. Their size may be imagined from the fact that the lecturer, when in the Pyrenees, being anxious to see one of these places, actually passed by it without being aware of its existence. The ore employed is the peroxide, combined with water, or, as we call it, brown iron ore, and it is very good for the purpose. In an angle of the forge is fashioned the furnace of the best material they can find to resist heat, if not fire-brick, of good igneous rock, as gneiss, &c. The furnace is nearly square, 3ft. or 4ft. deep, and 3ft. or 4ft. in section at the top; one wall is vertical, another not quite so, but leaning upwards and outwards. The left-hand side is of blocks of iron and stone; the other side is entirely of iron; the back is wholly of fire-brick or stone, while the front consists of two large plates of iron, nearly vertical, and not quite meeting down the centre. Near the bottom of this slit is a horizontal bar of iron, which serves as fulcrum for the rod used in stirring up the iron, the upper part of the opening being stopped with clay. The bottom is formed by a large stone of porphyry or anything of that kind, and on the right side there is a bank or platform.

Now for the blowing machine. Theirs is only to be resorted to in cases where water-power is available, and the mountain streams of the Pyrenees furnish this in abundance. It is called a

Trompe, and requires a fall of water about 20ft. or 30ft. At the top outside the forge is a tank, usually of wood, provided with a continuous flow of water, and containing not less than 10 tons. At the bottom nearly on level with the furnace is an airc-hest of wood; it may be made round, but it is best made trapezoidal in plan, with narrow end towards fire; this wind chest is completely closed, with the exception of four openings, two for the entrance of the water, one for its exit, and one for exit of air. This chest is put in connection with the tank above by two pump "trees," or pipes, generally trunks of pine (from the mountains) hollowed out, the upper ends being fixed in, but projecting a little above the base of tank, and lower ends in broad part of top of chest. Over the top of the pipe is a wedge-shaped body, or plug, at the end of a lever, and a chain from the other end of the lever goes down into the building close to where the workmen stand, and by means of this plug they can regulate the blast by letting a greater or less quantity of water flow down the trees. Just below the tank, oblique (downward) holes are bored in the side of the trees, or a kind of funnel arrangement is made at top, the object being to bring air into contact with the flowing water, by which a large quantity is carried down into the chest. An opening is made near the bottom of the broad end for the outflow of the water, and at top of opposite end for the air into the blast-pipe, the arrangement being made so as always to have a certain quantity of water left in the chest. A mercury or other gauge is inserted in the pipe to measure the strength of the blast. At the broad end of the chest, and underneath the opening of the trees, is placed a ledge of wood, and exactly underneath the openings are laid two stones, which effect a double purpose—namely, prevent the otherwise enormous wear of the wood, and also throw the water more forward and scatter it, and thus effect a more complete separation of the water and air. It is said, on good authority, that there is no apparatus known which gives a more uniform blast than the "trompe" if properly constructed and regulated. There is one great objection, however; the air is always very moist, saturated with water, and the smallest diminution of temperature causes it to be deposited; moreover, it carries along with it into the furnace a quantity of finely divided particles of water. With a height of about twenty or thirty feet they get a pressure of one or two pounds to a square inch.

The trompe has been used for the ventilation of mines. Its principle is seen whenever a liquid is poured from one vessel to another, like the froth on beer, &c., when poured out. An experiment was made to show how the principle might be usefully employed in the house when a continuous blast for blow-pipe, &c., is required, if water power be available. A large funnel was fixed to the top of a pipe, the lower end of which communicated with a bell jar set in a large vessel of water, as in collecting gases, &c., in water troughs. When water ran down the funnel and pipe, a strong continuous current of air was forced through a lateral pipe communicating with an opening in the neck of the jar.

The tube from the chest carrying the air passed first into blast-pipe—a rather loose leather bag—and again by a pipe into "twyer." This twyer is a sheet of copper folded over into form of tube, the upper part having its edges somewhat open, the lower part against the furnace, having the edges overlapping. By means of the trompe an air current, having a velocity of about 6ft. per second, is maintained.

While the furnace is still warm from the preceding charge, a layer of charcoal is put in, then the iron ore (previously crushed to coarse gravel), and then charcoal is piled round this ore and beaten down with spades, &c., the object being to prevent, as far as possible, the gases produced during combustion from traversing the charcoal, but to turn them amongst the ore. The hot CO formed from the charcoal as above described acts on the ore in two ways, first driving off the water, and then reducing it. Charcoal and ore are added from time to time as required. About 1,000lb. of ore are used for a charge, and 30 per cent. of metal is obtained, or a lump weighing about 3cwt. After being exposed in the furnace for about five or six hours, the melted metal falls through to the bottom, and a slag is formed precisely similar to that in the operation of puddling.

Three men are required to get out the lump, and having got it out, they at once proceed to work it. They make it hot, and then hammer it with a large hammer (worked by water-power) on a large stone for anvil, then cut it into two pieces, and work each piece separately. These pieces are again divided in halves, and the four lumps worked into bars, being heated from time to time to the right degree of temperature. The hammer is at one end of a lever, the other end being depressed by four pegs fixed on the axle of a water-wheel.

It is altogether a very simple process, the useful effect, however, is estimated at only one-tenth of the total amount of power employed. It requires a large quantity of charcoal, and a large amount of labour, and, in fact, it can only be usefully employed where the latter is cheap and abundant. Under this system the total profits of an ironmaster for a year would amount to about £150. On this account it has been generally given up, but it is still in use in some parts of the United States, as well as North Spain and South France. The iron obtained is very good for certain purposes; on examination it is found that the mass is not perfectly uniform, some parts being considerably harder than others, and more steel-like. By modifying the proportions of iron ore and charcoal used we get different degrees of hardness—*e.g.*, by increasing the quantity of charcoal the iron becomes harder and more like steel.

ERRATUM.—On p. 29 read "the Hindoos, who have no *double* bellows, properly so called," &c., instead of "who have no doubt," &c.

ON THE TREATMENT OF ASTHMA.*

IN the summer of 1870, I was summoned to a lady suffering from an acute attack of asthma. For several nights she had been restricted to the sitting posture, bent over a table, with the forehead resting on her hands. The distress was very great indeed. She was subject to frequent attacks of the kind, complicated to a very moderate extent with catarrh and bronchitic exudation. Her physician, a gentleman who holds high professional rank, was out of town. Nothing had been omitted in the treatment, which of late was simply palliative. She was recognised as constitutionally asthmatic, and little hope was entertained of permanent amendment. The asthma first occurred on the subsidence of nervous symptoms a few years previous. It had not, as far as I am aware, any marked organic basis. There was observable on the legs an eczematous eruption. Under these circumstances, I directed that the chloroform liniment of the *British Pharmacopœia* should be rubbed briskly into the chest for an hour's space, if possible; and this was done daily by a very efficient attendant, who had sufficient intelligence to comprehend and carry out the treatment. Very early much relief was experienced. On the return of her physician to town at the end of three days she was already so very much changed for the better that he directed the treatment to be continued. From that time it consisted in the daily repetition of the rubbing process for a month, or nearly so, without aid from medicine, and with little restriction as to diet. Beyond the information I received that she was daily improving, I had really little or nothing to do with her professionally after one or two visits. Under the hands of her attendant, she speedily got rid of the asthma. The patient went out of town in the autumn, and enjoyed perfect health and spirits. She took much walking exercise, with exposure, in the cold of the ensuing winter; and, what is very singular, two years have since elapsed with no return of the asthma.

I shall now make a few observations on this method of treatment. For some years, in Paris, asthmatics have been in the habit of resorting to a rubber in the Boulevard Saint Michel, a certain Widow Pau, who pursues there very much the method which I have laid down, only that her nostrum is a secret. She is resorted to by a few wealthy people from this country, and has honourable mention in some of our West End clubs. At the end of the treatment, her patients are presented with a little book or brochure containing her successes, which may be said to be fairly written for a book of its class. The cure is subject to disappoint for a few days; but generally great benefit will be found in a fortnight, or even in less time. There is a hint that it is best suited to cases with catarrhal and bronchitic complication. The instance which I have here brought forward seems exactly to correspond with those which are boasted of and detailed historically by Madame Pau.

Before giving directions as to how this treatment should be carried out, I will speak as to the rationale. Counter-irritation, especially by blister, issue, and moxa, are of such well established repute in the treatment of asthma, that I need not dwell on them; but, besides this, a jolting vehicle, anything that leads to displacement of the air stagnant in the vesicles, is proved to give relief in many instances. I should advise, then, that the frictions should be made with such roughness as the case admits. Slight blows with the palm of the hand or the end of a towel on the ribs are quite allowable; and the friction should be extended to the front of the neck at the lower part, where the vagi enter the chest. I do not think that the composition of the liniment need trouble us, provided it be warm and works easily. Anything like Roche's embrocation would answer very well.

I am not without some experience of asthma, and I am persuaded that the present method will be found a valuable addition to our therapeutic means. If proved not to be novel, it must be conceded that it has fallen into utter neglect.

* By GEORGE GASKOIN, Esq., Surgeon to the British Hospital for Diseases of the Skin.

SEA SICKNESS.

JAMES GARDNER, M.R.C.P. Ed., in a letter on this subject in the *British Medical Journal*, says:—"Old sailors have frequently told me that, although they have never suffered from sickness in sailing ships during a long voyage, yet they invariably suffered when crossing in the Channel steamers. So far as regards myself, I have never suffered from sickness, although swinging and a rotatory motion on shore always affected me so much that I never could waltz. It appears to me that the sickness arises from three causes: first, impression on the brain; secondly, on the stomach, through the sympathetic system; and thirdly, on the imagination; chiefly, however, on the stomach, as those persons who have a healthy digestion and are careful in diet are better able to withstand the attack. Much depends on the position of the person, and on that of the berth. At either end of the vessel there is, of course, in a head sea, most motion, and, therefore, the nearer the centre is the best place. I have found also that, after trying all other plans, a fixed berth placed athwart ships, or across, is preferable. Iced champagne with dry biscuit, or an effervescent draught with a few drops of sal volatile or chloric ether, I have found give the greatest relief. As a preventive, in the short passage across the Channel, I would recommend that precaution should be taken not to go on board with an empty stomach, and that something solid should be taken, either a chop or a steak, with a glass of bitter ale or cold brandy and water, no pastry, and not to overload the stomach; if the weather be fine, to keep on deck as much as possible, and to keep the attention employed. I consider it would be a great advantage and comfort to passengers if the Channel steamers were larger, giving more space above, and below better ventilated. There should be more attendants and appliances to meet emergencies. The present steamers are too sharp in the bow, not high enough in the water, and too long in proportion to breadth, so that they have a short, pitching, jerking motion, to which old sailors succumb. It would be far better and answer the purpose to have a separate class of steamers—in the summer season especially—for carrying passengers.

BELL'S PATENT FEED-WATER HEATER.

THE products of combustion seldom or never leave the flues of a Cornish boiler at a less temperature than 400°. The feed-water from the hot well has a temperature of not more than 100°, while that of the water in the boiler is probably 290°. A considerable saving in fuel may be effected by utilising the heat of the waste gases in raising the temperature of the feed-water in the case of the best set boilers, while the saving will be very considerable indeed when the boilers are so badly set that a good heater will raise the temperature of the feed to that of the water in the boiler. A large number of patents has been taken out for feed-heaters applicable to stationary boilers. One great difficulty attending their use is due to the rapid deposit of soot on the heating surface, because it is colder than the escaping products of combustion. To get rid of this difficulty various forms scraper have been adopted from time to time with varying success.

In the annexed engravings we illustrate a very ingenious feed heater, the invention of Mr. A. Bell, of Clara-street, Huddersfield, which has been for some time in successful operation at the works of Messrs. Thomas Ackroyd and Son, worsted manufacturers, Birkenshaw, near Leeds, where it has given such satisfaction that a second has been ordered.

It will be seen that the heater consists simply of three coils of cast-iron pipe. Mr. Bell has succeeded in doing that which has hitherto been regarded as almost an impossibility, namely, casting a complete coil of pipe in one piece; and we commend these coils to the attention of our readers, as likely to prove useful for many other purposes beside those for which they have been designed.

The arrangement of the heater, or "fuel economiser," as Mr. Bell calls it, will be understood at a glance. The mode of working the scrapers which keep the heaters free of soot will be gathered from the sketch, Fig. 3. There are two scrapers to each coil; these are propelled by two vertical arms, A A, which are attached to a crosshead, B B, at the top and bottom of each coil, these cross-heads being fixed to the centre shaft C by means of set screws; therefore, when the centre shaft revolves by means of the worm and wheel, Figs. 1 and 2, the crossheads are propelled round, carrying the upright arms, and thereby forcing the scrapers in their course before them round the screw until they reach the bottom of each coil, when the reversing motion, fitted to the boiler gear by its own action, reverses and propels the scrapers to the top, and so on alternately. The lower halves of the scrapers are kept up to the pipe by means of small balance weights. It will at once be perceived that the pipes cannot escape being thoroughly cleansed, which is a very important object; the simplicity of the arrangement is also so complete that there is scarcely any possibility of its getting out of order. The machine can be constructed of any number of coils, either in single or double rows, according to the number of boilers in use. Each machine is fitted with a safety-valve, stop-valve, and mud-tap. The cost is, we understand, extremely moderate, and the space occupied very small.

REVIEWS.

Spon's Dictionary of Engineering, Civil, Mechanical, Military, and Naval. Edited by OLIVER BYRNE. London: E. & F. N. Spon.

THE fifth division or volume of this valuable work has just been issued by the publishers, and ample opportunity is now afforded for judging of its character and scope. The editor is carefully and faithfully following out the plan laid down in the specimen part, and the work will undoubtedly be the best of its kind in the English language. Mr. Byrne was the editor of Appleton's "Dictionary of Machines, Mechanics, Engine-work, and Engineering," but since that work was published so great have been the strides made in science and in the various fields of ingenuity and industry that scarcely an article which appeared in his previous dictionary could be admitted in the present without either modification or amplification. The title of the book is in itself a very illusory guide as to its real character and scope; no subject which can possibly be said to be connected with engineering, in however indirect a manner, being omitted. The nature and properties of labour-saving machines are fully explained; useful instruments, important tools, and ingenious mechanical contrivances receiving especial attention, while such subjects as engines, hydraulic machines, bridges, embankments, mines, and the various cognate matters of which these are but generic headings, are treated in the fullest manner possible in a work not specially devoted to them. The rudiments of the arts and sciences described are not deemed unworthy of explanation, and such articles as "Algebraical Signs," and "Atomic Weights" are written in the clearest style, so as to place them within the intellectual grasp of the average mechanic. Woodcuts are supplied in abundance, from a cow-milking apparatus to a bradawl, while the machinery employed in the principal arts and manufactures is illustrated by the best and most modern examples. Altogether the work is most elaborate, and should find a place in the library of every mechanics' institute, and in the office of every engineer, civil and mechanical.

A Dictionary of Chemistry. By HENRY WATTS, B.A., F.R.S., F.C.S. London: Longmans.

WATTS' "Dictionary of Chemistry" is so well known that we need say no more than that this is the supplemental volume, bringing the record of chemical discovery and knowledge down to the commencement of 1870, with addenda of important matters up to the end of 1871. It contains nearly 1,140 pages of matter, including interesting and valuable articles on electricity, heat, chemical action of light, spectral analysis, beer, proteids, aniline and the aniline colours, analysis by flame reactions, and many others too numerous to mention.

Science Primers. Chemistry. By Prof. ROSCOE. *Physics.* By Prof. BALFOUR STEWART. London: Macmillan.

WE have received two of the series of "Science Primers" jointly edited by Profs. Huxley, Roscoe, and Balfour Stewart. They are published at a cheap rate, and are written in the simplest language, the object of the authors being to state the fundamental principles of the sciences in a manner suited to pupils of an early age. A series of simple experiments has been devised for the purpose of bringing the mind of the pupil into immediate contact with Nature, and to impress upon it indelibly the chief truths of each science. The editors consider that "the power of observation in the pupils will thus be awakened and strengthened," but they are careful to point out that "the amount and accuracy of the knowledge gained must be tested and increased by a thorough system of questioning." These little volumes are pure gold throughout; there is a total absence of the flashy experiment, but the truths enunciated are enforced and explained in a simple yet entertaining manner. We have read every word, we believe, of Balfour Stewart's "Physics," and we see no reason why it should not be adopted as an ordinary class reading-book, as well as a text-book for the acquirement of a knowledge of its special subject. Now that there is a prospect of science being taught in schools to a small extent, we hope the trustees or managers will not begrudge the money for the purchase of the necessary apparatus and materials for performing the experiments described in these "Primers." What we have said of the "Physics" primer, applies equally to the one devoted to "Chemistry;" and if the subsequent volumes of the series are as good, a want long felt will be well supplied. Science will be better—more widely—understood, and the seeds thus sown at school will, we may hope, give an abundant yield of fruit in the years to come.

Scales for the Ready Comparison of British and Metric Weights and Measures. By A. L. NEWDIGATE, M.A. London: E. & F. N. Spon.

THESE are a series of twelve slips of very stout card on which are printed, in such a manner as to be readily compared, the scale of an English weight or measure and the corresponding metric weight or measure. Thus, on the scale comparing English feet with mètres, we find that 100ft. are marked, and that they nearly correspond with 30·5 mètres; the two measures being printed close together, the feet divided to the half-foot, and the mètres to décimètres. Each mètre up to nine has its equivalent in English feet shown to six places of decimals and each 10ft. has the equivalent measure in mètres up to the same number of decimals; while on the back of the scale inches and sixteenths are given reduced to decimals of a foot. As a specimen of the utility and approximate accuracy of these useful scales we suppose a question put: The length of the tunnel at Mont Cénis is 12·291 kilomètres, how many English miles is that? By referring to the scale, we find that opposite 12·291 kilomètres is 7·64 miles, and according to the table at the back ·64 of a mile is equal to 5 furlongs 20 yards = 7 miles 5 furlongs 20 yards. If greater accuracy is desired, by making use of the equivalents for the kilomètres which are given to 6 places of decimals we readily bring the sum to 7·6374 miles, and as by the table ·6364 mile = 5 furlongs 20 yards, and ·001 = 2 yards, the correct answer is 7 miles 5 furlongs 22 yards, which is found in practice in much less time than it has taken to write the explanation. These scales must be remarkably useful to all who have to convert metric measures into English ones.

A Treatise on the Theory of Friction. By JOHN H. JELLETT, B.D., President of the Royal Irish Academy. Dublin: Hodges, Foster, & Co. London: Macmillan.

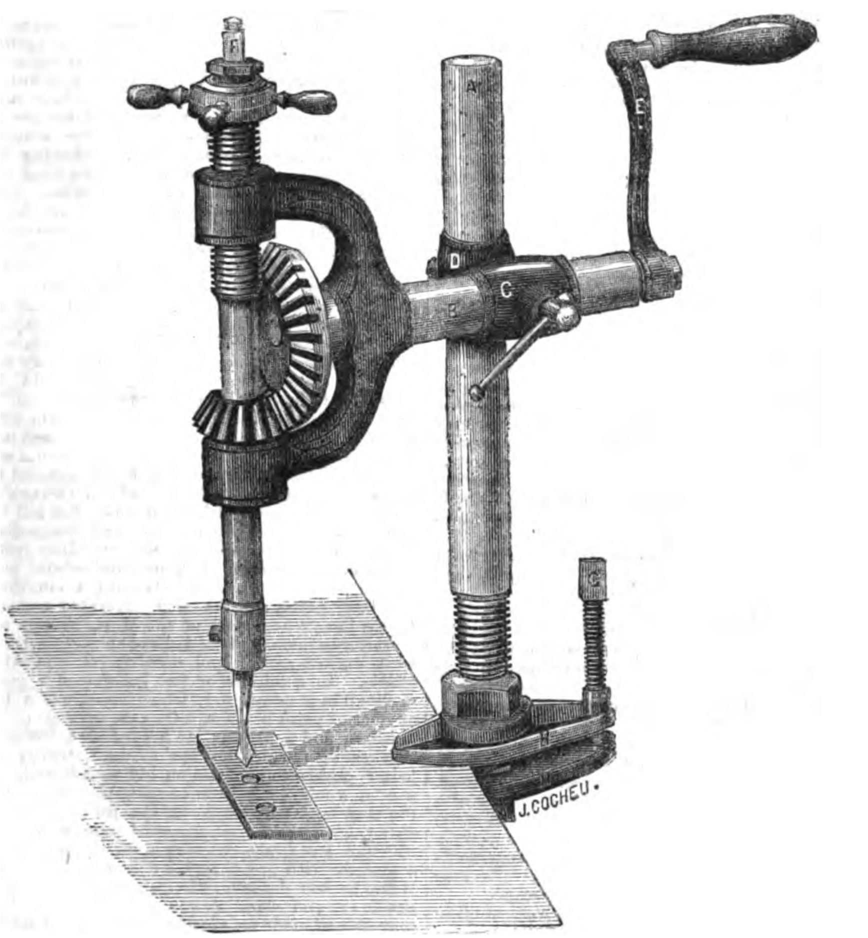
THE author of this book considers that the theory of friction, as a part of rational mechanics, has scarcely received the amount of attention it deserves, and as a consequence he has attempted to meet what he felt to be a want. It seems probable he says, that many students have been led to regard friction less as a part of rational mechanics than as a correction to be applied before the investigations of that science can be made practically useful. Such an idea is a mistake. The theory of friction is as truly a part of rational mechanics as the theory of gravitation. The force, friction, is subject to laws as definite, and as capable of mathematical expression as the force of gravity. All we can say of the book at present is that it is worthy of the attention of mathematicians, and the author, who thinks the theory is deserving of more ample discussion than has yet been bestowed upon it, will think himself repaid, for certainly a laborious work, if he succeeds in obtaining it.

An Elementary Treatise on Curve Tracing, by Percival Frost, M.A. (Macmillan), a subject which, in the words of the preface, presents so many faces pointing in directions towards which the mind of the intended mathematician has to radiate, that it would be difficult to find another which combines so many valuable hints of methods of calculations to be employed hereafter, with so much pleasure in its present use.—*A Handbook of Sewage Utilisation*, by U. R. Burke (E. & N. F. Spon), is a brief account of the various processes of deodorisation and utilisation hitherto experimented upon.—*How to Cook*, by T. L. Nichols, M.D. (Longmans), is merely another cookery book, strongly spiced with the author's crotchets. On p. 33 we are told that "swine are always unclean and often diseased, and infested with the germs of tapeworms and scrofula." Livers and kidneys should be avoided, but sweetbreads and tripe "ought to be as pure as any portion of the body."—*Popular Science, Domestic Hints, Eminent Men, Animal and Vegetable Life, Oddities of History*, and *Thoughts for Times and Seasons* (Griffin & Co.) are six manuals edited by John Timbs. They are made up of useful and scientific notes and "elegant extracts," and are generally taken from acknowledged authorities or standard works.

A Holtz electric machine, one of the largest and, probably, most effective in the world, was forwarded lately to the University of Pennsylvania. The revolving-plate is 36in. in diameter, and the machine is capable of giving an 18in. spark

A UNIVERSAL ANGULAR DRILLING MACHINE.

We illustrate in the annexed diagram one of the useful American inventions introduced by Mr. Churchill, of Wilson-street, Finsbury. This is a drilling-machine capable of being fixed in almost any position, and of drilling a hole at any angle. It is, we believe, made in two sizes, the upright shaft A being either 1¼in. or 1½in. in diameter, the whole machine weighing respectively 28lb. or 36lb., and drilling up to ⅝in. or 1in. holes. Attached to the shaft A, which is 2ft. long, by the collar or movable joint C D, is an arm, B, which is permitted by the joint to swing to any point right or left of the shaft A. The collar or ring D turning on the shaft A, and being secured by a set-screw, enables the operator to drill in a circular line, while the arm B, turning in the socket C, allows the drill to be worked at any angle from the perpendicular. The whole of these parts are also adjustable as to height on the shaft, and can be raised or lowered to suit the length of the drill or the thickness of the work. The crank E is shown in the position for drilling small holes—*i.e.*, on the spindle passing through



arm B, the gearing being 2 to 1; but for large holes the crank should be shifted to the spindle F, which is provided with a ratchet attachment for the purpose. It will be seen on examining the engraving that the screw thread on the shaft, together with the screw G, and the clamps H H, enable the workman to secure the machine on benches of any ordinary thickness, or to any support which affords a holding place within the limits of the clamps. It will also be apparent that by means of the joint and ring, C D, the drill can be worked at any conceivable angle. This is one of the handiest and most useful American inventions that have been introduced to the notice of mechanics.

DEFAULTING SOVEREIGNS.

An ingenious machine has been recently devised which threatens, in the course of a few months, to stop the career of certain sovereigns who have been travelling about under false pretences. As our readers are aware the British sovereign is a very "noble" coin. When issued from the mint the intrinsic value of the metal alone is exactly equivalent to that of the finished medal of Queen Victoria which many of us regard with so large a share of our affection. But by contact with the world this noble sovereign loses several of its glittering particles, and is looked upon with a suspicious eye by certain gentlemen who have a penchant for trying everything in the balance, and rejecting all that are found wanting—or, rather, of rating sovereigns at their proper value, for as long as they are of true metal and good they have no objection to take them in and send them to be re-formed. With a view to assist them in this labour Mr. James M. Napier, of the firm of D. Napier & Son, Engineers, Lambeth, has invented and perfected a machine to provide bankers with ready and accurate means for rejecting light gold at the counter in presence of the proprietor, "and so place them in a position to charge the user with the loss of weight and terminate the career of the large quantity of worn and fraudulently reduced coins now in circulation, as well as to maintain the integrity of our gold currency at the expense of the wearers of it." The machine referred to differs considerably from those in use at the Bank of England, constructed by Messrs. Napier. It covers a space of 8½in. by 5½in., or little more than a half-sheet of notepaper, and is worked by turning a handle. The most interesting feature in it is the employment of electricity to take note instantaneously of the action of the weighing beam, and to dispose a directing apparatus to determine the destination of the light coins. The machine is self-supplying from a reservoir; its ordinary speed is 60 per minute, and a touch sets it for sovereigns or half-sovereigns. The details are worked out with a view to simplicity, handiness, and durability, while the results combine rapid treatment and exactness.

VALUE OF AGRICULTURAL CHEMISTRY.

The following is a portion of a lecture delivered by the Rev. J. Smith, B.D., at Newhills, Aberdeenshire. Mr. Smith, responding to the wish of several farmers of the parish, that he would give a course of instruction on agricultural chemistry, has, for the last few months, been delivering lectures weekly before well-attended meetings of agriculturists. On the conclusion of the course Mr. Smith said:—Considering the season of the year, we have found it advisable to make our reading and conversation converge as much as possible to the subject of manures. When our course commenced, ammonia was selling at £80 per ton, being a rise of £8 to £10 since the previous season. At the present moment, this indispensable substance is valued at something like £100 per ton, or about 1s. per lb. This fact must surely be more powerful than any words in enforcing the adoption of the best methods of retaining the nitrogen of our manure heaps, preventing its escape by evaporation or drainage, and in showing the importance of not allowing a drop of waste liquid from dwellings and offices to be lost. The rapid increase in the cost of ammonia may be expected to stimulate the spouting of premises, the formation of tanks, the making of the bottom and sides of dung-courts impervious, and similar mechanical improvements. And these would be not merely agricultural but also sanitary improvements, which, if generally adopted, might help to ward off typhoid fever, diphtheria, and other diseases from farmsteads, where, strange to say, they are but too common. The enormous price of a main ingredient of manures may contribute more than anything else could possibly do to promote such studies as we have been engaged in, and so to intellectualise the agricultural mind—an appeal to the pocket being generally more efficacious than verbal advice. The farmer must have ammonia, and generally a great deal more ammonia than can be produced on the farm; and when this substance costs 1s. per lb., it is surely of immense pecuniary interest to him to ascertain what quantity of ammonia will be most remunerative in his circumstances, and in what form he can purchase it most cheaply. Now, how is he to satisfy himself on these points? Take, for example, the turnip crop, on which, I believe, most of you, gentlemen, are in the habit of bestowing £2 to £3 worth of fertilisers per acre over and above a dressing of farm-yard. Well, the manufacturers prepare a turnip manure, and doubtless these special mixtures are often compounded with great anxiety and skill to meet the requirements of the plant. But the experiments conducted under the superintendence of Dr. Voelcker, and reported in a late number of the *Journal* of the Royal Agricultural Society, concur with many former experiments in showing conclusively that the same turnip manure produces very different effects on different soils. And this is just what might have been expected when we consider how soils differ, both as regards the proportion of organic and inorganic matter, and also with respect to the constituents of the inorganic matter. Thus the very nature of things renders it impossible to compound a turnip manure that shall be at once effective and economical in different soils. Without going beyond our own parish, it would be very surprising indeed if the mixture that proved most remunerative on Clinterty should also prove most remunerative on Oldmill. And it is gratifying to learn on reliable evidence that a moderate dose of a fertiliser may in some circumstances be more profitable than a heavy dose; for in the experiments of the Cirencester Chamber of Agriculture, as just reported upon by Professor Wrightson, 3cwt. superphosphate per acre for swedes was found more profitable than 6cwt., a result which is the more remarkable that soluble phosphate is the specific for the turnip crop.

"ARGENTO" PICTURES.

THE following description of the manipulations for obtaining "Argento" pictures are given by Mr. Wenderoth, of Philadelphia:—

A carbon print is made by exposing a piece of carbon tissue, sensitised by bichromate of potash, under an ordinary negative, in the usual way of printing carbon prints. A metal plate with a silvered surface is taken and ribbed by rubbing it with a sanded brush, to deaden the polish and to give effect to the picture. The plate is then cleansed with spittle (nothing else answers the pupose so well), and then laid upon a sheet of paper on a table flowed with diluted alcohol. The carbon print is now laid face down upon the print, paper laid upon it, and a squeegee (made of a piece of wood and several thicknesses of ordinary bed ticking wrapped over one end) used to force out the superfluous alcohol between the picture and the plate, and to make the one adhere to the other. The alcohol also serves to prevent the occurrence of air-bubbles.

The whole is now immersed in a pan of water of about 100° temperature, and developed in the usual way, leaving on the plate a picture, the shades of which consist of the coloured gelatine and the lights, or rather, the highest lights of the surface of the plate exposed under colourless gelatine. This part of the operation, as all carbon printers know, is most fascinating and beautiful—more like the developing of a collodion plate than anything else. As soon as the superfluous colour is all washed away, the pictures (now on the metal plates) are removed from the water, and hung upon a line by clips to dry.

To render them more lasting still (though a carbon print on a metal plate seems to be as permanent as anything can be) they are, when dry, hermetically sealed to glass in the following manner:—A little stand should be provided, made of a plate of cast iron, say one quarter of an inch thick and twelve by twenty inches in size, smooth on the upper surface, riveted to a leg at each corner. This plate is heated with gas, or a coal oil stove, the heat being applied at one end, so that the end of the plate furthest from the heat will be considerably cooler than the other. Now lay the picture upon the iron plate at the warmest end. When it becomes warm, drop upon it a small piece of white wax, which will soon melt, and naturally spread over the whole surface of the picture. Now, having first heated the glass, place it upon the surface of the picture, place them under a weight on the cooler end of your iron plate, where they will gradually cool and become effectually sealed together. They are then cleaned and mounted in a case or frame, as desired.

The results are very beautiful, and are made more brilliant by the metal plate on which they are mounted. The prints are made by "cut outs," so that, when finished, the white metal plate forms the margin, which adds greatly to the effect.

HOW A MAN FEELS WHEN FREEZING.

DURING the recent cold weather, Dr. McMillan, a young dentist, while travelling from North Middletown, Ohio, to the adjoining town of Paris, was overcome by the intense cold, and came near being frozen to death. He narrates his experience, in the *Cincinnati Enquirer*, as follows:—

"After having proceeded about three miles on my journey, my feet became very cold. By stamping my feet upon the floor of the buggy I imagined I was perfectly warm, as my feet troubled me no longer, and the cold sensations through my body ceased. I, however, felt dull and sleepy, like a man who is drunk. I didn't care for anything. At this point, I believe, I began to freeze, and ought to have known it, but felt so comfortable that I did not examine my situation. After I had driven about three miles further my hat was blown off, but, being in a hurry to reach Paris, I did not stop to hunt for it. When I had proceeded perhaps a mile further, letting the reins lie in the bottom of the buggy and paying no attention to my driving, my horse shied off the side of the road and ran upon a rock pile. I then attempted to get the lines and pull him off, when I discovered I had lost the entire use of my right, and could barely use the left hand; with this one I attempted to pull him off the rocks, but the buggy wheels being locked, I could not do it. I then got out of my buggy, and in doing so struck the bridge of my nose across the wheel and cut it severely. I then went to the head of the horse, took hold of the bit and attempted to pull him around, but he would not move. I then commenced to unharness him, with the expectation of pulling the buggy off the rocks myself, feeling all the time very sleepy. When I had almost completed the task of unhitching the horse from the buggy, the desire for sleep became so great that I could bear it no longer, and I laid down upon the rocks by the side of the horse and went to sleep. I must have lain there some fifteen or thirty minutes, when I was aroused by a coloured boy who found me. Upon his asking me where he should take me, I told him to Paris, still not being aware of my critical condition. Upon arriving in Paris, my feet were put into cold water, which entirely, I think, cured them, as they do not hurt me. My left hand does not give me much pain, and I think will be all right in a few days; but my right hand was badly frozen; nothing seemed to do it any good, and I am afraid I shall lose three, if not four, of my fingers. Last night, when I arrived in Paris, I could give no account of myself, but this morning I remember every incident."

SUGGESTIONS FOR MAKING HALF-WORN-OUT IRON SHIPS PERFECTLY SEA-WORTHY AT A SMALL COST.*

THERE can be no doubt that the half-worn-out plates of iron ships may be much strengthened by the application of the cements in ordinary use, composed of silicate of lime and alumina. The plates are found covered with scales of oxide of iron, and when the cement is applied in a wet state, an imperfect chemical union is formed, consisting of silicate of iron, lime, and alumina, which hardens into an artificial stone of some strength; the plates are firmly backed up, and the ship is much strengthened throughout her structure; as long as there is little cargo in the ship, she makes but little water, and seemingly is in perfect order for the longest sea-voyages.

This, however, is delusive, for when the ship is loaded, say 20ft. deep, and her plates are a little strained by the motion of the ship, she begins to leak; for although the scales of iron, strengthened by the artificial stone, may easily resist the pressure of water where it is only 2ft. or 3ft. deep, with a pressure of 1lb. or 1½lb. on the square inch, yet they generally yield to a pressure of 10lb. on the square inch, or 1,400lb. on the square foot, in 20ft. of water. At that depth a little water oozes through some small orifice on the outside of the plate, and collects behind a strengthened scale; it gradually accumulates, and, as surely as in a Bramah press, acts with a 10lb. per inch pressure on the scale, and forces it from its place; an inward current of water is then established, which is sure to enlarge the leak. Sometimes the scales are of sufficient strength to resist this pressure, but the risk is great. It is instructive to remember that the scale of cement was found to be gone off from the lowest part of the bottom of the *Megæra* near the keel, and several bottom shales of iron andplaster were detached in the of that unfortunate ship.

By affixing cement upon the inside plates of an iron ship, a most deceptive trap is laid. In dock, under survey, the ship appears abundantly strong, and resists the strenuous and honest strokes of a wood mallet; borings may be taken which seem compact—the ship may not even leak till a small hole occurs deep in the outward surface from working in rough water; when the ship labours, the trap falls, and lucky are the sailors if they escape.

In cementing vessels it would be well to fill in solid between the frames, and flush with the lining or ceiling about the bottoms of coal bunkers, leaving a course for water in the centre of each bay by inserting a piece of iron piping; the bottom parts of the vessel, fore and aft, should be filled in to nearly the top of the floor plates, and such other parts as it is difficult to gain access to.

Should it be desirable to preserve an iron ship for future use, whose framework is of adequate strength, but where the state of the plates is precarious—this may be accomplished by lifting all platforms, and everything that covers over the inside of the plates in the hold; a sheathing then can be fixed all over the plates outside from keel to deck, of say 4in. thick, of pitch pine above and American elm under the deep water secured by means of metal screws 3in. long, turned from the inside of the plates into the wood. Where the plates happen still to be of sufficient strength, the application of an iron washer with a hole through its middle for the screw would be found enough; but where the plate is weak, a butt plate secured between the frames may be advantageously employed. I should recommend a screw, cast in Prince's metal, ¼in. in utmost diameter, with six turns in three inches. This screw will support 1,200lb. without drawing, and cost 2d. The stem, keel, and such like parts, can be sheathed, and fastened by means of metal screws and nuts, countersunk in the wood, and covered with stoppers of guttapercha and sand; the outside of the wood sheathing thus cut off from all electric communication from the iron plates and frames can be coppered, and thus the transport will sail better by far than before, but the copper should be kept at least 3in. distant from all ironwork, such as the screw propeller. If this wood sheathing be caulked with oakum, made from new tar rope (not oakum picked in gaols from old rope taken from the marine-store dealer), the ship may be safely sent out for a five years' cruise, without fear of her leaking, and if the attachment of the screws be inspected and made good, the sheathing will remain good for fifteen years, with merely re-caulking, the ship thus sailing at small cost.

* Read by William Poole King, Esq., before the Institute of Naval Architects.

MORE "PSYCHIC" MANIFESTATIONS.

THE following account of some curious psychical or spiritualistic phenomena are published by the *Edinburgh Courant*, which must be responsible for the truth of the statements contained therein. It appears that in the shop of a Mr. Nicol, Edinburgh, there are at present on view several paintings which have a peculiar interest attached to them, not so much on account of their intrinsic value as works of art as from the fact that they have been produced in the dark by a person while in an entranced or somnolent condition. The circumstances which have lead to the production of these pictures may be briefly stated. During the last visit to Edinburgh by Mr. Home, the spiritualist, his séances were attended by several gentlemen who were sceptical as to the power attributed to spiritualism, and they formed themselves into a club, which held meetings twice a week for the purpose of investigating the subject. After a number of experiments they succeeded in producing some of the so-called phenomena, but nothing that could not have been explained by natural laws. In the course of their inquiries the members of the club sought information in spiritualistic literature and from other sources; and they soon learned that a wonderful "painting medium" was to be found in the person of a Mr. D——, a journeyman cabinet maker in Glasgow. It was stated that this man, in his normal state, had no knowledge of painting, but that when he fell into a trance he painted excellent pictures in oil. In order to satisfy themselves on the point a meeting was held in a house in Edinburgh, at which the "medium" was present, a temporary easel was erected, and a piece of millboard, prepared for oil painting, was nailed on it. The "medium" then sat down on a chair, and said that the company need not refrain from conversation, as it would not hinder the manifestations. In the course of ten minutes he fell to all appearance into a deep sleep, and immediately started to his feet, his countenance being entirely changed, and bearing a more intellectual aspect than before. He shook hands with a number of imaginary persons in the room. His eyes were shut during the greater part of the time, except when he spoke to them, and the balls of the eyes appeared to be turned round, and nothing but the whites visible. In a minute or two he opened a parcel, made up in a newspaper, which contained a large number of paint brushes, a tin case with oil colours in tubes, and a pallet. He first of all selected the brushes with which he was to work, trying their points on his tongue and on his thumb nail, as a painter would do. He then selected colours from the tins, and put them on the pallet. Having changed the position of the easel from what it was when he was awake, he took a pencil and outlined a picture with great rapidity and no little skill. While he was drawing, the gas was once or twice put down, and when it was put up it was found that he had made as much progress in the dark as in the light. Some of the gentlemen present stood close to the easel, and they afterwards stated that the eyes of the medium were shut all the time. After the picture had been outlined, Mr. D—— took up the pallet, and commenced to paint, not in a slow careful manner, but in slapdash style, and the result was that in 32 minutes a picture of Loch Achray was completed. The spiritualists say that more wonderful manifestations can be obtained in Mr. D——'s presence, namely, the production of "spirit paintings," in which the medium's hand is not called into exercise at all. The production of these spirit paintings takes place (of course) in total darkness, and at the meeting which Mr. D—— attended a specimen was given. The medium took his seat at one end of a table, and the colour box was placed at the opposite end. Several gentlemen sat between him and the colours, so that he could not reach them without the company being aware of the circumstance. He took from his pocket a number of cards and rubbed them with his hands, as if feeling for a card suitable for the operation. He appeared from his manner to be asleep, but was able to answer questions and carry on a conversation. He at last chose a card the size of a carte de visite, prepared for oil painting. It was marked on the back, so that it could be checked, and laid on the top of the colour box opposite the brushes. The company were told that they would probably require to wait some time before any manifestations would be shown. The light was then put out, and in a few minutes there was a sharp sound, as if a wire was being drawn over a piece of paper, and a noise was made as if a brush was thrown on the table. That was the signal for the lighting of the gas, and the company then saw the card close to the place where it had been laid. On turning it up it was found that a picture had been painted on the under side, and was still wet. As some of the company had doubts as to the experiment, a request was made that it should be repeated. The light was again put out; and in a short time a pencil was dashed on the table. On the cards being examined, it was found that there were two subjects very cleverly drawn—a faithful portrait of Hugh Miller and a sketch of a girl! Mr. D—— was in the trance about three hours; and when he awoke he appeared to take great interest in the pictures—an interest which could not be simulated. He said that he had seen in a shop window somewhere the original of one of the pictures he had drawn. We state the above facts simply as we have ascertained them.

Our contemporary says that the greatest pains were taken to test the truth of the statements made, and that the reporters whose evidence is given are by no means to be regarded as spiritualists. Still, it is a remarkable thing that the "spirits" must have "darkness" before they can exhibit their talents, and few sensible people will believe in these supernatural paintings unless they are permitted to furnish the cards and see them painted in broad daylight, the handmaid of Truth.

THE STEAM JACKET.

THERE is a practical objection to the use of the jacket to which we have not yet referred. High-pressure steam, especially if quite dry, appears to exert a peculiar solvent effect on cast iron. Already we hear rumours in numerous directions of the rapid wear of the high-pressure cylinders of compound engines, an evil which grows in proportion with each augmentation of the weight of the casting. It appears to be fortunate that the remedy for this evil affords the best possible method of applying the true theory of the jacket in practice. In certain cases the jacket is made by putting a thin steel tube into a cast-iron cylinder bored out to receive it. The Reading Works Company have brought this system of construction to great perfection, for example, with excellent results. How far the scheme is applicable to marine engines we are unable to say. We suggest that, especially in marine engines, instead of steel—notably an uncertain material—hard brass, or more strictly speaking gun-metal, liners should be used for the high pressure cylinders. Properly made, the material is much harder than cast iron, and will take a beautiful surface; while the material, being an excellent conductor, would comply with one of the fundamental conditions of eminent success in using the jacket. The idea is a mere extension of the system of lining air pumps. We do not claim it as original, but we believe this is the first time the scheme has been mentioned in any journal; and it appears to us to be well worth the consideration of engineers engaged in the construction of large steam engines working with considerable pressure.—*Engineer*.

PRESERVING PLASTER CASTS.

A CORRESPONDENT of the *Athenæum* writes:—"In view of the approaching Royal Academy and International Exhibitions, it may be worth while to draw the attention of sculptors to the use of paraffin for saturating the surface of plaster of Paris casts, instead of employing stearine, or clogging them with coats of paint. Paraffin, from its comparatively unchangeable nature, its few chemical affinities (*parum affinis*), the variety obtained from peat or mineral tar, indeed, having been tried for ages by exposure to all sorts of cosmical vicissitudes, seems, *à priori*, more likely to be durable in colour and other qualities than stearine. It softens at 110°, melts at 130°, and is then easily applied, in one or more dressings, to casts made previously warm in an oven or on a covered stove. It imparts to the plaster an agreeable appearance of subdued transparency, combined with solidity, far preferable to the effects produced by stearine. The casts soon acquire an ivory-like tone, and their surface is destitute of any greasy feel or any unpleasant glare; unlike those dipped in stearine, they do not appear, after a trial of many months, to turn yellow—moreover, paraffin is very cheap. Of course the casts to be treated with it must be clean to begin with, and any seams should be neatly finished off. When properly saturated for half an inch or less in depth from the surface, the paraffined casts are smooth and dry to the touch, so that dust, if it gathers upon them, does not adhere to them, but may be removed by a fine brush, or may be washed off with a soft sponge and *cold* water, either with, or better, without soap. Warm or hot water makes them adhesive, melts the paraffin, exposes the pores of the plaster, and causes dirt to sink into the surface in patches or streaks. Any exposure to undue fire heat or solar heat also affects them injuriously, and, of necessity, oily dusters or greasy fingers will soil them. With care, however, they may be kept, even in London houses, without the hideous covering of a glass shade. This process of paraffining casts appears to be admirably suited for works intended for public exhibition, which are necessarily subjected to the influence of many atmospheric impurities. It not only enables them to be preserved in a comparatively clean state, but it substitutes for the dull, cold, and ghastly whiteness of the raw plaster an agreeable hue, substance, and surface. The suggestion of this use of paraffin was made by Professor Marshall, and it has been practically tested by Mr. Thornycroft and his son."

ON ECONOMY OF FUEL AND PREVENTION OF SMOKE.*

THE heating surface being in proportion to the result required, there is still in all furnaces, and particularly in those of marine engines, a loss amounting to at least 25 per cent., arising from imperfect combustion. Indeed, it has recently been stated, on the authority of a Royal Commission, that our best Cornish engines only utilise one-eighth of the coals burnt, and the majority of engines not more than one-thirteenth.

In order that I may explain the object that I have in view, and the principle of my system, by which I seek to prevent this loss, it is necessary to consider the nature of those effects which we find in operation in the furnaces of our engines.

When coal is burnt in the open or in the ordinary house grate, the principal products of combustion are carbonic acid and water; a certain portion of finely-divided carbon escapes combustion and constitutes the soot or visible smoke of a coal-fire. When the decomposition of coal is effected in retorts or vessels from which the air is excluded, the products are much more numerous and complicated, a large amount of volatile matter is expelled, partly in the form of hydrocarbon gases, and partly in the form of hydrocarbons in the state of vapour, solid coke remaining in the retort.

Now, different parts of the furnace frequently represent the conditions of the open fire and retort, also constantly varying in place and temperature. In the laboratory, if we want a smokeless gas flame, we adopt some contrivance similar to the Bunsen burner, in which a mixture of air and gas takes place (as in some varieties) through wire gauze, the particles of air and gas being thoroughly distributed through the entire volume; the molecules of each gas coming into individual contact, a condition that is essential, and the result is a smokeless flame, in which glass tubes and white porcelain capsules may be heated without becoming blackened.

This would not be the case with the ordinary gas-jet burning in the open; the supply of air in this is abundant, but it is not commingled with the flame, only coming into contact with the outer shell, producing a flame that deposits a thick soot on any other object placed in it, pointing out the absolute necessity of maintaining the conditions of combustion that we possess in the Bunsen's burner.

It would be simply ridiculous to attempt to make gunpowder by the haphazard throwing together of saltpetre, sulphur, and charcoal. The proportions of the gun and projectile might be the best, but what result should we have from an explosive so prepared? It is doubtful whether it would ever burn. Is there not a close analogy between this and the well-constructed boiler and furnace, and the condition of the combustible material represented in the latter by the imperfect mixture of air and flame?

Not only may vast quantities of unconsumed carbon pass off in a dense smoke, but also volumes of invisible and inflammable gases escape ignition, as they would from the retort of a gas factory, and at a low temperature the furnace may actually be distilling hydrocarbon oils, as in one specially built for that purpose.

It is this visible loss in smoke, and visible loss in unconsumed gases and vapours, which it is our object to save by the proper admixture of the atmospheric oxygen.

Various contrivances have been proposed for this purpose, and adopted with more or less success. Improvements at the bottom of the furnace, as in the ventilating fire bars, which make a better distribution of the air, at the lower part of the fuel. In others the air has been admitted at the fire-door, and at the back of the bridge; but the volume of air has generally been greater than necessary, chilling the gases below the point of ignition, the stream of cold air only coming into surface contact with the heated gases, as some ocean currents of hot and cold water are said to flow side by side without mingling with each other.

It is, therefore, the thorough admixture of the heated gases with air, as in the Bunsen's burner, which is the essential feature of the system which is the subject of this paper.

The object in view I seek to attain as follows:—

In each tube of an ordinary tubular boiler is inserted another of much smaller diameter, perforated at its end nearest the fire in such manner as to cause an induced draught when required, by a current of air flowing through the said tube, or being forced through by a blower or steam jet, this being under perfect control by opening or closing a valve. Each of the boiler tubes is in this manner filled by a smokeless flame of great intensity—the deposit of soot and dust is reduced to a minimum, there not being any smoke except on first lighting the fires. No obstruction is offered to cleansing the tubes, and the inner ones can be separately unscrewed, or removed in sets, when it is required to prick out the perforations or to renew the ends.

The expense is small, the air pipes costing not more than a few pence per foot, and no alteration for their introduction being required except of a most trifling nature.

The same system is applicable to locomotives and other engines.

* By Captain J. GORDON MCDAKIN, late 42nd Highlanders. Read before the Institution of Naval Architects.

WANT OF OBSERVATION IN THE FARMER.*

PERHAPS the best way of testing whether the farmer acts justly by his workman is to seek an answer to the question whether the latter does or does not generally receive a full equivalent for the value of the labour he is able to supply. Of course this point is not so easy and simple to solve as in the case of many manufacturing matters, but reasonable conclusions might be drawn by any one thoughtfully estimating the value of crops and the proportion of cost which labour represented in their production. Probably little difficulty would be found in showing that the labourer's pay, taking all the year, came fully up to, or exceeded, a fair valuation of the work he did. This being so, no rise of wages could take place under existing circumstances without a dead loss to the employer. How, then, could effort be made to improve the status and raise the income of the labouring man? The answer seems plain and inevitable—increase the value of his work. But how, again, can this be done? By making him a better workman in the matter of individual tasks. Seize systematically every method for making men dexterous at sowing a field, ploughing a furrow, mending a harness, sharpening a hoppole, foddering a bullock, and managing a yard of dung. This was not a matter of vague generality, but of hard fact. He (Dr. Monckton) had seen with his own eyes, within twelve months, important tasks so badly done that double the wages might have been paid for good work with profit to the farmer. He had seen wurtzel seed so unevenly drilled in point of depth, that five times the man's daily pay was thrown away, because he had never been taught that mere holding straight was not drilling, but that regular and shallow deposit of the seed was even more essential. He knew a hop-garden of favourable clays, and not of running sand, that had been drained three times in nine years, because of the imperfect fall secured on the earlier occasions. He had seen last season gangs engaged in hop syringing; the work accomplished by one gang would be more cheaply paid for at £1 a day than that by the others at a crown. Again, why should not every farm of reasonable extent see that some of its hands could thatch, or stack, or build a pig-sty, or paint a waggon, or shear a sheep, or mend a fence? It had been too much the custom for a whole parish to depend on one thatcher and sheep shearer, who often earned 30s. in three days, and was drunk for the rest of the week. Surely our own workpeople might be enabled to benefit by these rather better paying jobs. A great industry had sprung up in the country in the use of creosote. How many of those now listening had ever so studied the matter as to know the very best time, temperature, and method for the process? He had himself seen professors of the art, men who let out tanks, and took contracts for their neighbours, and who did not even know what a thermometer was, and yet pole-dipping could never be done to the best advantage without its aid. Many workpeople in charge of those tanks now receiving 2s. 6d. a day, would be better worth 4s. if rendered more observant, more painstaking, and better instructed.

THE DIRECTION OF LABOUR.

But this leads us to the second method of augmenting the value of the workman's toil—viz., a more skilled and studied direction of his tasks. Of course it was clear in connection with what had already been said that the master must instruct himself, and exercise increasingly his own wits as well as those of his workman, and this feature must never be blinked. Not only morally, but in business aptitude, the man will be what the master makes him. Take a clutch of pointer puppies and give four away to four different people; the value of their labour in two years will depend almost entirely upon the pains and skill with which their respective masters have set and kept them to their work. An army of soldiers may be of exemplary skill and courage, and yet see their efforts nulli[...] by unwise or insufficient planning and direc[...]

* From a paper read by Dr. MONCKTON, be[...] Maidstone Farmers' Club.

In the matter of labour a farmer must be exercising a perpetual foresight to make his operations dovetail and harmonise. The job of to-day must be habitually so done as to render more cheap and effective the work of to-morrow. Labour so directed will yield value and show a result. Without such management, men, though industrious and well enough master of each particular task, will inevitably muddle away time, and waste money —*laboriose nihil agendo*.

ORNAMENTATION OF SILVER PLATE.

ORNAMENTATION of silver plate is at the present day quite a work of art compared with the specimens handed down to us from the last century; but, by the aid of steam, a more intelligent class of workmen, and a better class of tools, added to a purer taste for the elegant, have worked wonders in this respect, and now even the commonest articles of silver plate bear the impress of beauty. One of the most striking inventions of a recent date for such ornamentation is that by Mr. J. A. Rhodes, of Sheffield, a description of which cannot fail to be interesting, and we quote the following from a recent article in *Nature*:—"A thin plate of metal perforated by punching, shows a depression of the edges of the perforations, while the surface of a plate cut by saw piercing preserves its even uniformity. It may be supposed that the figures so cut out would at times be remarkable for beauty of form, and, indeed, they are so more or less, but still it seems to have been left for Mr. Rhodes to utilise these, so as apply them to relief ornaments. It must be remarked that Mr. Rhodes is not only his own designer, but for nearly twenty years has been the designer and piercer to the principal firms in Sheffield, and his ability and taste are, therefore, well known in the trade. The idea is very simple, but, like all other ideas of value, might have remained a long while dormant, had not Mr. Rhodes, Columbus-like, put it to practical application. To give our readers a clear idea of the new method of ornamentation, we will take the tea and coffee service for example, and suppose the panels complete and ready to become the design. A plate of gold having been provided of a suitable substance, the intending design is drawn on it, and so prepared and applied that the design or ornament becomes solidified with the metal of the vessel, with an appearance of having been adapted by some curious and singularly precise method of casting, and quite excluding all supposition of parcel-gilding." After referring in detail to some engravings of spoons and a salt-cellar, which appear along with the articles, the writer adds:—"With respect to the cost of these table requisites, they are brought generally within the means of householders, unless the ornament be unusually rich. The low relief ornaments, on the less expensive products, are worked in aluminium; and for objects yet less costly it is not necessary that they be of silver. We all know the infirmity of gilding, or parcel-gilding; its existence is only a question of a few years, while, on the other hand, the substance of the superimposed gold or aluminium will, with fair treatment, last half a century, without any very conspicuous show of wear and tear. This invention, being only in its infancy, is open to amelioration in perhaps many directions. One advantage which strikes us most forcibly and directly, would be the picking out, or clearing with a sharp point those bas-relief forms which may not be sufficiently definite; and thus the invention would be raised more nearly to the level of fine art. The process, as we understand, does not limit designs to the flat bas-relief, but is susceptible of the adaptation of compositions even approaching high relief, and the latter manner of treatment would raise well-considered products into competition with the most beautiful and valuable metal works of the most celebrated producers of any time. There is nothing *repoussé* that could equal what may be conceived of the prominence of detail and delicacy of finish of such works. Their effect would resemble that of inserted ivory-carving, with, if necessary, sharper cutting. This is only an idea of the perfection to which the invention may be carried, for nothing of this kind has yet been produced. Mr. Rhodes has patented as well a method of ornamenting metals with enamel or of embellishing with enamel a superimposed metal design."

An Important Discovery.—An important discovery bearing on the antiquity of man has just taken place, Mr. Edward Charlesworth, F.G.S., one of the correspondents of the English Mechanic, having discovered in the Suffolk crag, or older Pliocene beds, teeth of the extinct shark (Carcharodon), apparently perforated by human agency, as well as many concretionary nodules with longitudinal perforations unlike those produced by the action of boring mollusca. The specimens will be exhibited and described at the meeting of the Anthropological Institute on the 8th of April. If this discovery is verified, it will carry back the existence of man in England to a period coeval with the mastodon arvernensis, and far more ancient than the mammoth age."

SCIENTIFIC SOCIETIES.

HACKNEY SCIENTIFIC ASSOCIATION.

AT the usual fortnightly meeting, held on March 12, Mr. W. R. Birt, F.R.A.S., Vice-President, read an able paper on

The Rewards of Science.

Mr. Birt said: The similes of running a race, climbing a ladder, or striving to attain the summit of a steep and rugged ascent, have very frequently been employed to indicate the earnestness of men in seeking to obtain a recognition of their labours in whatever departments their energies have been exerted. In the ancient Olympic games the successful competitor received a laurel crown, perishable in itself; yet the fact of the successful termination to him of the conflict in which he had been engaged, opened up rewards of a much higher and enduring character. The chariot of the warlike conqueror was prepared for him, and in it he was seated, to be conveyed by four horses to his own city. On his passage homewards he was received in every city with the greatest acclamations, but he was not permitted to pass through the gates of his own. He had been a conqueror in athletic games, or in the horse and chariot race, or he had excelled in poetry, in eloquence, or the Fine Arts, and his own citizens would not receive him as an ordinary citizen. He had won the crown, the symbol of the friend to humanity; he appeared before them as a conqueror, and he must enter the city as such through a breach in the walls. The painters and sculptors of his country perpetuated the game he had won. A statue commemorative of his victory was erected in the sacred wood of Jupiter, at Olympia, and his name was celebrated by poets and thus handed down to posterity.

The cultivation of science may be likened to a race, or still more to the climbing of a hill, from the summit of which, to speak hyperbolically, we obtain an unbounded prospect. Methinks I see a number of hard-working students running this race—climbing this hill. Every portion of the natural world is ransacked by them to obtain materials with which to construct their theories, or by which they hope to enlarge the boundaries of knowledge. Here and there they separate into little groups, with the object of thoroughly exploring portions of the hill in the course of their toilsome journey to the top, others give their attention to the natural productions of the hillside—the trees, the flowers, the grasses which adorn it; others, again, not content with earthly things, turn their attention to the heavenly, as night after night the earth is enveloped in darkness and the spangled sky showeth unto them knowledge. By the aid of their instruments they sound the depths of the illimitable space above them, and they put such questions as these to themselves:—How are these mighty orbs distributed in the illimitable space? What is the physical constitution of the sun shining above us? What was that wonderful shower of stars which fell a few years ago from the sky?—with others of a like nature. A partial solution of these questions urges them onwards in their researches.

Now and then I behold some little commotion among the groups; I am desirous of ascertaining to what it is due, and upon attentive consideration I find that an advance in knowledge has been made by a successful investigator, and his fellows are about to reward him by a mark of their approbation, which he receives at their hands. The award is made by a few who have themselves been rewarded by their fellows by being elevated from the mass of workers to the positions which they occupy, some having already received a similar mark of approbation, while others are still striving for it. This mark is considered as the impress of the sovereign upon the genuine coin: it gives currency to philosophical thought, the ideas worked out by the recipients are generally received as exponents of truth: they are, in fact, rendered current among philosophers.

Dropping the figure, it may not be uninteresting if we offer a few impartial remarks on the "rewards of science" given in this country. The groups of ardent workers, our scientific societies, give rewards of a minor character—the publication of papers, appointment as office bearers and members of councils, the highest reward in the gift of a society being the "medal," or in some cases "medals." In the distribution of these rewards the greatest care should be, and generally is, exercised in the appointment of officers and members of councils, for on them depends the award of the medal which is to stamp in the eyes of the general public the philosophical value of the work of the medallist. In most societies the appointment of office bearers and members of council is by ballot, a list having been presented by the retiring council of fellows recommended by it as suitable for the various offices to be filled. To the vote by ballot or the recommendation of the retiring council there cannot be the least objection, for it is presumed that a body of gentlemen forming the élite of the society are above prejudice, and, besides, it is a guarantee that none but gentlemen duly qualified by a practical acquaintance with the branch of science cultivated by the society will be recommended to fill the offices.

There can be no question that in our larger scientific societies the appointment of a fellow as member of council carries with it a prestige equivalent to a reward for services rendered to science, and to give an opportunity for rewarding a labourer in the field which it is the province of any particular society to cultivate, provisions exist in some by which no fellow can serve in any office for a longer period than two years, at the expiration of which a member of council may be advanced to a higher post, as secretary or vice-president, and a successor recommended from among the fellows, and as the society should be presided over by a gentleman well versed in the branch of science cultivated by it, the greatest care is generally exercised by the retiring council in recommending a gentleman qualified in every respect for filling the chair at the expiration of the then president's period of office. The rewards, therefore, in the gift of a society are—publication of papers, appointments to the various offices, the highest being the presidency; beyond this is the medal.

A consideration of the rewards given by the Universities and the State will not occupy us long: a mention of them will be sufficient for our present purpose. Honorary degrees, appointments in the gift of the Government, honours conferred upon the most distinguished cultivators of science, and pensions granted to those who have made remarkable discoveries, are the principal. As may be readily imagined, the attainment of these rewards depends more or less upon the recommendations to the Government of the recipients by influential men who are personally acquainted with them.

The "Rewards of Science," as we have thus sketched them, are emphatically external. They are marks of the estimates which men make of the labours of their fellows. They are by no means to be despised, yet it is exceedingly important that they should not be overvalued. From the very nature of things, especially when every field of inquiry is literally crowded with labourers, a small minority can only hope to succeed in obtaining the 'crowns" of the various societies, and a still smaller the more substantial rewards of the State. And are no other rewards within the reach of the student? Must he depend entirely upon his fellow-man for the recognition of his labours? Most assuredly, if he undertake the cultivation of science only with the hope of one day becoming great and eminent, the probability is that he will fail in the attainment of his object. There are rewards superior to any that man can bestow. We know that ability for scientific research is not confined to the rich and great, and many a student who has occupied his leisure in the acquirement of knowledge has also contributed to its extension without even attaining a position beyond a worker; also many a student has undervalued the results which he has obtained, and for want of sufficient energy in making them known, they have slumbered, until some one, having obtained similar results and remarked their bearing on our present knowledge, has given them to the public, who has reaped the advantage. The real source of satisfaction to the student is a love of science for its own sake, or rather, for the sake of the Bestower of every good and perfect gift. We have heard of "Nature's Aristocracy," a better expression would be, "God's Aristocracy" consisting of men on whom such gifts are bestowed. In the employment of his gift, each step the student takes is accompanied with its own reward. "For there is nothing better than that a man should rejoice in his own works, for that is his portion." The pleasure experienced in every advance which to a student is really a discovery, is the highest, the greatest the purest reward, because he regards it as the result of a gift bestowed upon him.

There is another source of pleasure to the scientific worker, which consists in the publication of the results of his labours. While deriving satisfaction from these labours, he would not add to the stock of knowledge unless he were to communicate the results to his fellows. From the very birth of science a communication of the results of the labours of its votaries, either orally or in writing, has been the means of increasing and perpetuating knowledge. In the present day the channels are numerous through which information may be communicated to mankind. Publication in the transactions of societies implies a supervision on the part of councils or editors, and must be regarded in the light of a reward. There are, however, channels of a different kind through which students may communicate their views to their fellow workers, and in which such views are freely and impartially discussed. Other channels are also open which need not be specified here. It is the press that gives stability to works of science. A thought embodying a fact brought for the first time to light is committed by its author to this general repository of all knowledge; it may, from a variety of circumstances—its non-acceptance by those who are looked up to as the leaders of the scientific thought—its being in advance of the age, and the general body of scientific men being unable to appreciate it—lay dormant and buried, but there it is, not only to spring forth at some future time and bear fruit in due season, but to testify that the author had not laboured in vain. Many are the cases that might be cited of fresh discoveries which the press had already chronicled, but little notice had been taken of them at the time, the discoverers were little known until some striking phenomenon was observed and great publicity given to it, when the earlier publication was thought of and the original account disinterred to the honour of the pioneer who thus received his due reward, if living, and if removed from this state of existence, the press bore testimony to a successful result of his labours.

The members of this association are cultivators of true science in a true scientific spirit, and seeking their reward only in their work. Such need not be disheartened if their labours are not readily appreciated. In the great majority of instances in which real knowledge has been communicated to mankind it has always been so, the first announcement of a fact is received with caution, often with distrust, the general recognition of it may be long deferred, but truth can never alter, and the highest reward a man can have is the satisfaction of knowing that in communicating to his fellow man a new truth he is a benefactor to his race.

Mr. Birt concluded by presenting to the library a valuable series of works on the subject of lunar changes, and a cordial vote of thanks was accorded to the eminent lecturer by the assembled members.

USEFUL AND SCIENTIFIC NOTES.

Cochineal Insects.—It takes, says the *Virginia State Journal*, sixty-five thousand cochineal insects to make one pound in weight, and the amount imported into America during last year was 1,849,842lb. The annual slaughter of these harmless insects, therefore, to supply carmine for American ladies' toilets, and the various dyes and tints for their ribbons, feathers, and dresses, actually reaches 120,239,780,000 in number! These figures are perfectly awful, but some of the uses of carmine are worse.

Syrup of Coffee.—This preparation is of great use to those who have long journeys to make. Take half a pound of the best ground coffee; put it into a saucepan, containing three pints of water, and boil it down to one pint. Cool the liquor, put it into another saucepan, well scoured, and boil it again. As it boils, add white sugar enough to give it the consistency of syrup. Take it from the fire, and when it is cold put it into a bottle and seal. When travelling, if you wish for a cup of good coffee, you have only to put two teaspoonfuls of the syrup into an ordinary coffee-pot, and fill with boiling water. Add milk to taste, if you can get it.

The Artesian Well in Boston, U.S.—The work of boring this well was begun in the latter part of the month of March, 1871, and has been going steadily forward up to the present time, the progress made being from 1ft. to 15ft. each day, at a cost of 15 dollars per foot. The well had reached a depth of 1,000ft. when we last heard of it. When the work was first commenced, a drill would last thirty-six hours without sharpening; now the same kind of drill will only last one hour. The diameter of the bore is 5in.; the drill is 4in. across. The drill and iron shafting which connects it weigh now 1,200lb., and the rope by which it is lowered weighs 900lb. The power is furnished by a 16in. horse-power engine, with a walking-beam of 36in. stroke, at the rate of about thirty strokes per minute. It is said to be the intention of the company to keep the drill at work until they obtain a sufficient volume of water for their use, unless their money gives out, or the drill goes through on the other side.

Level and Angle Indicator.—We have received from Messrs. Fletcher and Sinclair, of Liverpool, a handy instrument bearing the above title, which combines in a portable form the properties of a level, an angle indicator, a mariner's compass, a simple form of theodolite, and a sundial, together with a handy table for ascertaining the height of distant objects. All these are contained in a flat compact mahogany case, which is only 10in. long by about 4in. broad, and which itself contributes to the formation of the level and angle indicator.

Copying Drawings by Electricity.—A method of rapidly copying drawings or engravings is suggested by M. Chanderay, who uses the induction coil for this purpose. The method adopted by draughtsmen consists in puncturing holes through the design, and thus obtaining an outline, which is subsequently transferred by sifting plumbago or other powder through the holes—a very laborious task where the drawing is large or has much detail. In the plan proposed, a table covered with tin foil is connected with the negative pole of the inductorium, and on it are placed as many sheets of paper as the spark will penetrate. A metal bar, insulated with guttapercha, serves as the positive pole, and as a pencil for copying the tracings. This point is moved about on the outline of the engraving, and sparks pass through the paper to the tin sheet underlying it every time connection is made, puncturing four holes through the tissue at each passage. It is said that but little skill is required to guide the pencil, as the ink tracings, being ...ed conductors, carry the pencil easily along.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor of the ENGLISH MECHANIC, *31, Tavistock-street, Covent Garden, W.C.*

All Cheques and Post Office Orders to be made payable to J. PASSMORE EDWARDS.

"I would have every one write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

*** *In order to facilitate reference, Correspondents when speaking of any Letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

CONGRATULATORY — CRITICAL — OPTICAL — ASTRONOMICAL — COSMICAL — ARITHMETICAL—SOLARIOLOGICAL—AND COMETIC.

[3870.]—BEFORE entering upon the more immediate object of this letter, that of replying to various queries which, directly or indirectly, have been put to me, I would refer to two or three communications which appear in No. 365.

Let me, then, commence by saying that it was with sincere pleasure that I read (in letter 3804, p. 11) the gratifying account by the Messrs. Lambert and Taylor, of their pursuit of the most sublime of all the sciences, under circumstances of considerable difficulty and discouragement, so many thousand miles from where I write; and ask them to accept my assurance that (under whatever lack of appreciation they may carry on the study of astronomy in Auckland) they will certainly not want sympathisers among the numerous astronomers who are numbered among their brother readers of the ENGLISH MECHANIC.

And next, I would ask "E. L. G." whether he seriously regards his reply (10091, p. 19) to a question as to the formation of turret-shaped hills, as a *scientific* one? Because, if so, I would commend to his attention Mr. Scrope's "Volcanoes of Central France" (notably p. 206), Hugh Miller's "Testimony of the Rocks," and Lyell's "Antiquity of Man," as three among a score of books which will show the utter fallacy of his answer. If he will further supplement the theoretical knowledge thus acquired by some field practice under the guidance of a competent practical geologist, I think I may venture to hope that he will never again drag in the quasi-mythical Noachian Deluge to account for phenomena of which it neither does nor can afford any explanation whatever.

Admirable as is the suggestion of Mr. M. Paris (letter 3807, p. 12), it occurs to me that his scheme would break down in a point of detail. I fear that there are scarcely enough departed men of science to stand as godfathers to every "bright particular star" in the heavens; while it would be obviously invidious to seek our "lights" among the livers.

In compliance with the request preferred by "E. J. D." (letter 3823, p. 16), I have turned back to his original question (contained in letter 3493, p. 516, Vol. XIV.), and, after having carefully perused it three times, confess my entire inability to make head or tail of it. I utterly fail to picture to myself the relative positions of his "hole in the shutter," "screen" (the screen is peculiarly unintelligible) "tables," and "camera;" and am therefore reduced to the necessity of questioning my querist. Firstly, then, has he ever himself tried the experiment whose explanation he is desirous of obtaining? And, next, should he have done so, would he mind rendering it apprehensible to my very limited capacity by the aid of a diagram?

Pending the result of the observations of the transit of Venus in 1874, "A Young Astronomer" (query 11281, p. 24) may take the "lineal value of one second of arc as the mean distance of the sun," at 450 miles, without much chance of error.

Will Mr. H. Ellis (query 11308, p. 24) permit me to point out that the *Nautical Almanac* is not a treatise on practical astronomy, and that, therefore, nothing more can reasonably be demanded than that it should contain a full and complete explanation of the tables of which it is composed. This, to give it its due, it does. I may add that, inasmuch as there is internal evidence in Mr. Ellis's question that he is not unfamiliar with computation, it will, perhaps, suffice for his purpose if I give him the formula for calculating the longitude and latitude of a heavenly body, from its right ascension and declination. Let us call L the longitude of the star, l its latitude, and ϖ the obliquity of the ecliptic. Then say sin. R.A. cot. dec. = tan α. This being so,

$$\text{Tan. L} = \text{sin.}\ (\alpha + \varpi)\ \text{tan. R.A.}\ \textit{cosec}\ \alpha.$$
$$\text{Tan.}\ l = \text{cot.}\ (\alpha + \varpi)\ \text{sin. L.}$$
$$\text{Sin.}\ l = \text{cos.}\ (\alpha + \varpi)\ \text{sin. Dec. sec.}\ \alpha.$$
$$\text{Sin. L} = \text{tan.}\ (\alpha + \varpi)\ \text{tan.}\ l.$$

If Mr. John Taylor (query 11323, p. 24) had looked at the Moon herself, instead of "in several astronomical works," I think that he might have answered his own question. I assume, *in limine*, that he is aware that a fixed star rises, souths, and sets every day 3m. 56s. sooner (by ordinary clock time) than it did on the preceding one. Very well, then, if the Moon were coincident with such a star, and apparently immovable like it on the face of the celestial vault, she would do the same. But if Mr. Taylor will notice the Moon's position in the heavens with reference to any bright star on a given night, and repeat his observation at the same hour on the next one, he will see that she has travelled many times her own diameter towards the *East*; in fact, she goes right round the Earth, from West to East, in the course of a lunar month. Without, then, puzzling Mr. Taylor with any consideration of the Earth's diurnal rotation, it may suffice to point out that as all the heavenly bodies rise in the East, the farther the Moon travels towards that region the later she will rise. I suppose that this is what your correspondent means by "retardation."

Let me try to clear up the wonderful difficulty of W. W. J. Porter (query 11339, p. 25), by the intimation that there is nothing in existence answering to a sidereal *day of the month!* Owing to a cause which I despair of here explaining to him, the face of the night sky *does* alter in the course of ages; but this has nothing to do with the condition of things, in consequence of which Mr. Porter predicts the occurrence of so eccentric a result 188 years hence. Perhaps, in this connection, he would not mind turning back to some articles on Time, by the present writer, in your tenth and eleventh volumes? As for the second part of his query, it will probably be enough to observe that the Earth's axis remains parallel to itself (so to speak) during its entire orbit round the sun; and that—owing to the (practically) infinite distance of the Pole star—that orbit, 184,000,000 miles in diameter! shrivels up into a mathematical point as viewed from it.

I think that a perusal of Whiston's vagaries would satisfy Mr. J. Songest (query 11348, p. 25) that Mr. M. Paris was in error in supposing that the ex-Lucasian Professor and Editor of "Josephus," held the "origin of the solar system" to have been cometic. What Whiston really did say was, that the great comet of 1680 was in our part of the universe at the time of the creation of the world; and that, happening to "collide" with us (as our American cousins say) it sent the earth spinning on its axis. Subsequently (and this I commend to "E. L. G.") we got into its tail, and the "deluge" was the result. I ought, perhaps, further to state that Whiston goes on to predict that this identical comet is to cause the general and final conflagration of all things mundane. It strikes me though, that in such event the watery tail might possibly play upon us. In which case we should, doubtless, merely be very much put out.

It only shows to what little purpose many people read their MECHANIC, when we find the subject of multiplication by concrete quantities (qy. 11188) again cropping up in there columns. Once for all, multiplication by a concrete quantity is IMPOSSIBLE. How can we conceivably say 20 *pounds* times anything? What would be the numerical result of 17 vibrations × 11 cheeses? Inasmuch, however, as this has all been previously set forth in former volumes with no apparent result, perhaps the most conclusive way of dealing with those, who, like "C. R. F." (p. 45), gravely give directions for performing an impossibility, will be to select one of their own examples and see what their wild notion leads to. I assume that it will be admitted that £20 = 19,200 farthings. Let "C. R. F.," then, square each of these quantities, according to his method, and compare the results. If it be true, as he asserts, that £20 × £20 = £400; then assuredly 19,200 farthings × 19,200 farthings ought to be = £400 too. Is this so?

It was from no forgetfulness—as far as I am concerned—that I omitted any reference to the moon's parallax in the reply touching her rising and setting at Melbourne, in my letter (3795, p. 9). I imagined—merely as a matter of course—that my querist knew that her R. A. and Dec., as given in the *Nautical Almanac*, were geocentric.

I am, of course, ignorant for what purpose Mr. Henry Wood (query 11360, p. 49) requires the sun's declination with such extraordinary accuracy; but I think he must be almost, if not quite, unique in his wish that (what he calls) "the trashy explanation" of the contents of the *Nautical Almanac* should be omitted, merely to make room for a table of second differences in connection with the sun's declination! Why can he not make such a one for himself? If he will honour me by turning to a letter of mine (2087) on p. 305 of your thirteenth volume, he will find directions how to proceed. To refine, however (for any practical purpose), upon the method exemplified on p. 539 of the *Nautical Almanac* for this year, seems to me a little like standing upon half a sheet of note-paper in order to see better over the heads of a crowd.

It would be futile even to attempt to answer the query (11363) of "A Young Astronomer," on page 49; inasmuch as it contains internal evidence that the mathematical acquirements of my brother correspondent are of infinitely too rudimentary a character to permit him to deal with the computation of the ephemeris of a comet. The calculation of its path by the aid of "a slide rule (by Smith), a sextant, a Gunter's scale, and a very accurately divided triangulator" would be "Hankey" (panky) work indeed; amounting, in fact, to legitimate conjuring. I must entreat our "Young Astronomer" not to imagine that I wish to discourage or be unkind to him; but the determination of a cometary orbit is really a matter of considerable difficulty. Certain geometrical relations are represented by equations, and these equations have to be solved by successive approximations. I only know that it is a task that I would not face, except under compulsion. I assume, by the way, that it is *Encke's* comet which my querist refers to.

It is on record that a patient, going to the famous surgeon Abernethy, and commencing the detail of his symptoms with "Oh, Doctor! if I lift up my arm like this, such a frightful pain runs through my shoulder," was summarily extinguished by the coarse rejoinder, "Then what the devil do you lift it up for?" Proceeding upon something of the same principle as the brusque old doctor, I would venture to ask "L. C. E." (query 11887, p. 50) if a sundial will give correct indications when immovably fixed, what in the world can he want to mount it on a pivot, and rotate it in a horizontal plane for?

I am unable to give Mr. Skelton (query 11482, p. 51) any further information with reference to the comet of which he speaks. It has not, that I am aware of, been yet observed in these latitudes.

A Fellow of the Royal Astronomical Society.

JUPITER'S SATELLITES AND "F. R. A. S."

[3871.]—I am glad that "Philo" did not mean what he seemed to imply anent "F. R. A. S.;" for the latter has so long and so ably contributed to the columns of the English Mechanic that few of your readers can bear patiently to read unpleasant remarks respecting him. "Philo" speaks of the freedom of "F.R.A.S.'s" comments; but I have never seen a line in any letter from "F.R A.S." which could be regarded as unpleasant, save when he has had occasion to castigate a rude correspondent. I must admit that once or twice when this has happened he has "lashed out" in a manner commanding my hearty sympathies.

I quite readily concede that the passages quoted by "Philo," taken apart from the context, seem to indicate that Sir John Herschel entertained an erroneous opinion about the accuracy of prediction respecting Jupiter's satellites. But when the omitted sentences are supplied (as in my letter), Sir John Herschel's opinion assumes a different aspect. It may be that in the edition of 1833 those sentences are wanting. In that case, we learn that Herschel entertained erroneous views in 1833, and corrected them subsequently. In any case, Airy's statement on this subject is decisive of the matter. If "Philo" wants further evidence, let him hear what Hind (from whom the "predictions" are received) has to say respecting them. "Independently," he remarks, "of defects in the tables, there are difficulties attending the observation of these phenomena which unfit them for *accurate* determinations of longitude."—*Explanation of Nautical Almanac.*

I should be sorry to deprive "Philo" of the satisfaction he seems to derive from having "erred in good company;" though I have yet to learn that Sir J. Herschel actually made the mistake imputed to him.

A word as to the Astronomical Society. In that society, as in all scientific bodies, there are individual members who are not authorities in the branch of science to whose cultivation the society is devoted. Yet I imagine that there are few societies in which the percentage of such members is smaller than in the Astronomical Society. Speaking for myself, I must say that in addressing communications to the Fellows of the Astronomical Society, I always feel that it behoves me to exercise exceptional care, because of the large proportion of first-class critics in an average audience at any of our monthly meetings. It must always be a source of gratification to our Fellows, that a man like the late Professor De Morgan, whose special views would not permit him to put himself in nomination for the Royal Society, accepted and retained a Fellowship in the Astronomical Society; and that Sir John Herschel, who declined the presidentship of the former society, held four times (that is, during eight years) the chair of the latter. Richard A. Proctor.

HOW TO USE A BOOK WITHOUT HANDS.

[3872.]—Our desideratum, kindly inserted in No. 361, query 10996, has brought many admirable replies, and we shall be proud indeed if a perfect solution be arrived at through the active intelligence of your right-hearted contributors, whom so many readers of "our" English Mechanic have learnt to respect and esteem. There are, no doubt, many cases besides that of our disabled engine driver where it would be hailed as a real Godsend; many military men and officers, mechanics, miners, and others have to endure this terrible affliction. The helplessness is bad enough where the man cares little for mental pursuits, but is tenfold distressing when the intellect is healthy and vigorous. For every response we tender our best thanks—that of "M. O." has been read with genuine emotion, and if he will refer to "Addresses Advertised" we shall gladly put him in direct communication with this case. We have seen "Dominy's" plan, but fear it is too expensive, complicated, and limited; it never came into much practical use, and we do not know the present makers; the patent must have run out. The suggestion of "W. R. S." seems good, but the beads being so much below the eyes, the tongue has to pick out the right one, and will often miss. We have not the means handy of testing that of "Philanthropist," but a neighbour (Mr. Tenz, the ingenious Swiss carver and modeller to the Palestine Exploration Commission) saw something like it in Paris and considers it quite practicable. "Philo," and all your readers, shall certainly hear of our success, with the editor's permission. "Cireb's" suggestion, with the little cut, is excellent: the plate is improved by a cross form, which gives firmness to the cane or stick; it requires more practice than one would think, as the action of "a wet finger" (no dummy) is both peculiar and heavier than one is conscious of. The plan of "Carolus" has the qualities of great merit—accessible, light, simple, general, and at once practicable. Guttapercha for the tube is the pleasantest, and the little instrument stands in a glass ready for use, leaving the head and eyes free.

Our first idea was to mount the pages upon something like a long towel, reviving the ancient "tench," the rollers to be moved by a pedal, but we wished to see what could be found applicable to an ordinary book. Any opening of the English Mechanic to an armless intelligent man must be a real treat; but to be able, without troubling others, to read the whole number weekly would be an inexpressible boon, and if "M. O." can invent such a revolving desk as to accomplish this, he ought to be crowned!

The writer could not see our armless engine driver yesterday as he was thirty miles off again with the limb-maker, who, after ten weeks' painful anxiety, is still pursuing the needful experiments. The stumps are extremely short, not more than three inches. Still, we hope on. T. M. W.

A METHOD OF MULTIPLICATION.

[3873.]—"E. L. G.," in replying to query 11054, reproduces a very neat method of multiplying by ·78539, &c. The following, which (to save space) I have illustrated by the same example, is much shorter, easier remembered, and more correct:—

	13·78125	
	9·646875	given number, but 1 place out.
	9646875	repeat, but another place out.
	19293750	ditto, × 2 another place out.
	1929375	repeat, another place out.
Sum	10·82379375	
Less	275625	{given number, × 2, six places out.
	10·8237661875	

Screw.

TO MR. DAVIS AND "CHEMICAL STUDENT."

[3874.]—Mr. Davis in his reply (p. 18) asserts that a portion of my method for the practical separation of the metals in the hydric-ammonic sulphide group is incorrect, or, as he styles it, a *lapsus calami*, with which he seems perfectly familiar. As the matter stands his assertion is more or less correct, but his deductions do not appear to be exactly the same. The method given by myself is quite correct, with this simple addition, that the acetic acid solution must be treated with $(NH_4)_2S$, and the zinc from this precipitate dissolved out with acetic acid. This clause was left out by misadventure. Even had it not, however, no trouble would have been found, as both the zinc and the manganese would have given their respective reactions. As the matter stands Mr. Davis is not quite correct, as the precipitate would not, as stated, contain CaC_2O_4, $BaSO_4$, MnO, Mn_2O_3, and ZnO, but simply $BaSO_4$ and CaC_2O_4, and, as on adding acetic acid, nothing but a mere trace would have been precipitated, the filtrate would, of course, then have been treated for zinc and manganese, and at once found. As in the case in point zinc, magnesium, and manganese not being precipitated under the circumstances, and unless with very bad manipulation, would not be thrown down by sodium phosphate in testing for Mg, but would remain in the filtrate from the precipitate. In conclusion, I hope that Mr. Davis will be so kind as to point out in this way any more such mistakes that he may detect in my correspondence. J. B.

ALLINGHAM'S PROPELLER.

[3875.]—Since forwarding the description (let. 3843, p. 39) of my propeller to you, I have been trying the model in the Mersey, and find that the speed is increased considerably by making the blades 1⅞in. broad each, instead of ¼in., and so reducing the number on each side to 10 instead of 32, which, of course, simplifies the construction still more.

John James Allingham.

ELECTRIC SPARKS.

[3876.]—I should not think it worth while to say anything about "Philo's" remarks (3866, p. 42) had he not put a distinct question; and as he seems to have so very limited a power of comprehension I will endeavour to bring my reply within his range. I do *not* "deny the possibility of gas being lighted by a spark from the finger, the electricity being unintentionally excited." I do not claim to be infallible, or to know anything except from experiment and deductions therefrom. On the other hand I do not believe that such an occurrence ever took place, because no experiment or deduction therefrom within my cognisance justifies the belief. I trust "Philo" is able to distinguish between the two mental conditions of not denying, yet not believing, though he has some extraordinary notions as to what constitutes evidence; he really is the first person I have heard of who would admit that he would decide a scientific question according to whether an opinion came from "a pretty young lady" or "a crusty old bachelor." I know juries are influenced in that way, but the jurors do not usually give that for a reason. At the same time it may be satisfactory to "Philo" to learn that I am neither crusty, nor old, nor bachelor, and certainly not a pretty young lady. Further, I assure him I am not "mistaken in thinking sarcasm to be my forte," for I do not think so, and should be sorry if it were. Sarcasm is like pepper—a useful seasoning, but not a main element of diet. As an intellectual cook I consider it useful when making up a hash ent of scraps of pretentious ignorance, and things of similar nature. If "Philo" has received a sprinkling he has to thank himself only; he took upon himself to write very strongly on matters that he knew nothing about; he was further pleased to speak very offensively and personally, and to falsify what I did say very plainly, whether he is able to understand it or no. Any one who takes that line with me stands a very fair chance of a sharp return, just as any one who courteously disputes any proposition or argument is secure of an immediate and kindly discussion, as "Philo" ought to know, if he is not a very recent reader. I think he is a recent contributor, as I do not remember his signature, and in the few recent letters I have observed there are so many errors of fact and deduction that it is scarcely probable they would have long escaped attention, to say nothing of the spirit some of them display; even this last letter, where, instead of apologising for his misconception, he again attributes motives to me that he has no sort of right to assume, he implies that I am angry with him because he did not give my remarks the attention I think they deserve. It is a matter of the smallest moment to me what attention he gives them, but before he or any one else presumes to remark upon anything said either by me or any one else, it is their duty to give the matter honest attention, not to falsify; and if from either some real obscurity or from their own incapacity there is a misapprehension, when that is pointed out it is the duty of an honourable man to apologise, not to exercise his powers of casuistry and repeat the offence.

Sigma.

AUSTRALIAN MEAT.

[3877.]—You have, Mr. Editor, lately inserted several letters—pro and con—on Australian meat, and I was somewhat surprised to see the manner in which some correspondents gave their opinions, on what I thought insufficient foundation, as to the comparative non-nutritious properties of this meat. I am afraid prejudice in such matters with some people goes a long way. Besides, many people who have been eaters of English beef and mutton all their lives, make a meal or two off Australian meat, and because they don't feel as well, or fancy they don't, after the first meal or two, they jump to the conclusion that English beef and mutton are cheapest. My opinion, founded on my own experience is, they are mistaken; and I also beg to give the following corroborative testimony:—

Some careful calculations have been made at St. Cuthbert's Parochial Board, Edinburgh, as to the cost of feeding the 424 inmates of the establishment, and it was found that the quantity of meat used in the ordinary soup was 51lb., which cost, at 6d. per lb., £1 5s. 9d. Less Australian meat, viz., 38½lb. was used to obtain the same amount of soup, and the cost was only 19s. 11½d., showing a saving in the day's food of 5s. 9½d. By varying the cooking of the colonial meat, and making it into a potato hash, 8½d. a day more was spent; but even with this extravagance the saving over fresh meat was 5s. 1½d. It is in such comparative results as these that the real value of the meat is to be found.

It should be noted that both home and colonial meat was estimated at 6d. per lb. When it is borne in mind that colonial meat can be had at two-thirds of the cost of home meat, the difference will be still more striking. Economical.

CURIOUS PHENOMENON.

[3878.]—Has any photographic reader of the English Mechanic noticed the curious result of dropping a semi-congealed particle of collodion from the corner of a plate into a pan of water, or, better still, a tub? Owing probably to the repulsion of the ether and the water, it immediately gyrates, sometimes with great regularity and surprising speed, and at other times slowly and eccentrically. The appearance often is exactly that of a comet flying through "space," as depicted in our astronomical primers.

Cornubiensis.

THE PROPOSED BRIDGE CONNECTING ENGLAND AND FRANCE.

[3879.]—The object of this publication is to show the practicability of constructing a safe and durable bridge between England and France that would meet the requirements of both nations, for we may rest assured that the capitalists of Europe would not risk their money to complete such a gigantic undertaking, except something more practicable in detail can be brought to bear upon the subject than the plans and schemes which have hitherto been proposed and brought before the public.

If we are by any means to connect the two nations a bridge should be constructed of sufficient dimensions to allow of three separate lines for railway traffic. The horse and carriage way should at least be 30ft. in breath, and the side paths for foot passengers not less than 10ft. or 12ft. each.

Like Mr. Hawkshaw and others I had long thought of a tunnel, but when I considered the many difficulties required to be overcome, and the faults that would in all probability be met with in the chalk formation, even at hundreds of feet below the bottom, I consider the work of a tunnel an absolute impracticability, as no shields could be employed with any degree of safety to render a rush of water impossible.

On the other hand, the difficulties connected with a bridge to span some twenty miles of a sea whose maximum depth is about 168ft., or say 170ft., and this part the water is never still (it is that of a rapid tideway running at the rate of three miles per hour for about six hours of every spring tide, and with strong and long continued up or down channel gales), a still greater surface velocity is imparted, reaching, probably, to the bottom, across the entire channel; and to construct a bridge this bottom must be reached, and strong massive stone piers or abutments brought up from a vertical depth of 170ft. to the surface, sufficiently strong to resist the greatest storms which are known to occur in this part of the channel. We have no experience of diving at this depth either with bell or helmet; and to construct shields or cofferdams of sufficient dimensions and strength, the expense becomes discouraging, as the pressure of sea water at a depth of 170ft. is nearly 76lb. per square inch, so that if circular shields or cofferdams were employed only 32ft. in diameter, or 1,206in. in the circumference, the average pressure on the first 2ft. in height from the bottom would be nearly 76lb. per square inch, or 2,199,744lb. on that portion of the circumference alone, which is only the 85th part of the total height to the surface of the water. It will be observed that this pressure is equal to a crushing force of 982 tons, which every part at that depth would have to resist; the next succeeding 2ft., would have in like manner to resist 969 tons; the pressure, of course, diminishing in proportion, as the surface is approached; therefore, the total force that such a shield or cofferdam would have to resist would amount to nearly 41,736 tons.

It is easy to imagine it to be within the limits of a mechanical possibility to construct them sufficiently strong to resist this pressure, and some plan might be found to connect them together in parts and sink them to the bottom at the place required for the foundations, but when it is considered the risk of water bursting up from the bottom, and the enormous expense and labour required in raising and resinking them for each pier or abutment in that vast structure, I have no confidence in the use of shields or cofferdams at such a depth in sea-water.

The plan by which I propose to overcome these difficulties will be best explained in the general description of the bridge, which, according to my plan, would consist of a huge wrought iron tube, similar to those used in the Britannia Bridge over the Menai Straits, resting upon stone piers or abutments brought up from the bottom at a clear distance from each other of about 459ft., and carried up to a height sufficiently above high water so as not to interfere in any respect with the shipping.

The tube would be divided into three separate compartments running through the entire length; and to allow sufficient space for the treble set of rails within the outer shell would require to measure about 45ft. in breadth; and to obtain the greatest strength the sides should be about 30ft. deep, or, between the top and bottom cells, nearly 26ft.

Under every circumstance, I would propose that the tube should be made sufficiently strong to sustain not only its own weight, but in addition to that load 3,000 tons, equally distributed over each length between the supports, a load many times greater than it will ever be required to carry.

Fig. 1 will give an idea of the general construction of the great combined tube, showing the three separate sets of rails within. It will be observed that the top cell projects 2ft. 6in. over each side, making a breadth of 50ft. on the top available for a roadway. The side railings should not be less than 6ft. in height from the footways or paths to the iron cope plates. The railings can be either plain or ornamental, and should be put up after the lengths of the great tube are set in their places.

Fig. 2 is a plan of a portion of the piers or bottom towers, extending in two parallel rows in a direct line from shore to shore, except at the union towers, each 32ft. in diameter, set in pairs 56ft. apart from their centres, and 469ft. from centre to centre of each pair. It will be observed that this length is reduced to about 250ft. at the union towers and shore abutments. The object of this is to balance the tension on every part of the combined tube extending across the channel. The expansion and contraction that would take place in a continuous stretch of this length will be further explained in fixing the lengths.

Fig. 3 is partly plan and partly section of one of the piers or abutments 8ft. above the water line, where the circular towers, coming up in pairs from the bottom, are united into one oblong tower or pier 84ft. over the extremes by 32ft., where it curves in at this height to 26ft., then running up with a straight batter on all sides, except in the recesses, where the tubes are raised. The seats or beds for receiving the cylinders of the 8 hydraulic presses that are required in raising the tubes should be provided with cast-iron plates to prevent the pressure of the cylinders from injuring the stone work.

I will now endeavour to explain the plan of erecting the circular towers, or abutments, and in preparing them for their deep foundations. It is to be understood that a careful survey of the various depths has been taken where the bridge is intended to cross, and the nature of the deposit resting at the bottom on the chalk formation ascertained. This will serve as a guide in constructing the circular shrouds wherein the foundations are laid upon the surface of the water, and gradually sunk down inch by inch, as course after course of the finished mason-work progresses.

A plan so novel and so convenient cannot fail to recommend itself as the best means of erecting buildings of this class in deep water, as the workmen can at all times continue their work either at the surface or at as many feet above it as may be found convenient.

The first thing required in this process is a hollow cylinder or shroud 32ft. in diameter, constructed of wrought-iron plates, with butt joints well riveted together. All the lap plates are put on the outside.

The rivet-holes in the shroud plates are countersunk on the inside, so that the interior presents a plain and smooth surface.

Fig. 4 is a sectional elevation of the shroud, showing the angle irons for fixing the timbers B and C of the foundation. The upper course of timbers B are well jointed together, and made to fit accurately into the shroud, so as to be perfectly water-tight; but the timbers C are kept a little apart from each other, so that a free passage is left at the ends of each, communicating with the groove E cut round the circumference of the timbers. This groove communicates with a pump fixed on the outside of the shroud not shown in the Fig. There is also a valve opening outwards or upwards on a line at P that can be opened and shut at pleasure.

The top timbers T are all well jointed together and fixed to a circular guide of plate iron H, made to slide freely through the whole length of the shroud to the bottom timbers B and C.

The leathers A are for securing a water-tight joint, and are, in addition to the water, pressed out against the interior of the shroud by indiarubber bands.

All the shrouds should be constructed on shore, and the bottom timbers B and C securely fixed in their places. The timbers T require only to be temporarily fixed to prevent the water from forcing them inwards during the time that they are being floated out to their places.

This is accomplished by means of a steam tug taking two of them in tow and proceeding out with them to where two pontoons are securely moored, having on board, and in readiness, all the appliances for letting them down where the towers are required to be brought up; and as they approach, the water is allowed to flow into them until their bottom ends sink considerably, bringing them nearly to a vertical position in the water; and whenever they are cast off from the tug the valves should be regulated, so as just to keep them from touching the bottom, while the ends of the guide ropes are passed round the windlasses, so that they can be correctly guided to their places; and when they are correctly set, the pumps should be put in motion; but sooner as the inclosed water under the timbers B and C escapes through the pump valves, keeping them open so long as any sinking takes place—that is to say, it freely escapes through the valves when the pumps are at rest, as it is evident that if no provision was made for an escape to take place, the water would be forced down under the bottom edges of the shrouds, and would burst up on the outside, tearing and cutting away the beds surrounding them. The proper time that should be chosen for this operation should be when the tide is near the turn, so that before it again begins to flow the pumps are put in motion, and a vacuum, so to speak, speedily formed amongst the particles of matter under the timbers B and C, thus bringing not only the weight of the shrouds to bear on the bottom, but, in addition to that of their own weight, the weight also of the whole quantity of water inclosed within them. Thence, including their own weight, it will be found that they are thus each securely bound or fixed to the bottom with a load, not including the pressure of the atmosphere, equal to about 4,000 tons—a weight which neither gales nor tides will be able to disturb.

The time required to secure them thus from the time that they are cast off from the tug need not occupy more than fifteen or twenty minutes. The bottom valves are then shut by means of the side rods, and the temporary fixings of the timbers T of the great pistons removed; and if it is found that the water does not raise them to the required height, they can be raised by forcing in an additional supply of water through the feed valves from the pumps. The stability of the shrouds are further secured by strong timber frames uniting each pair together at their upper extremities.

These frames are for carrying the travelling cranes required in lifting the stones, &c., from the boats and placing them on their beds. When this is completed, the erecting of the permanent towers can be immediately proceeded with.

The stones should all be prepared on shore, and accurately fitted, so as to shorten, as much as possible, the labour of setting them in their places.

The foundation courses are carried up perpendicular and in a solid form for about 6ft. or 7ft. from bottom, to where the inverted dome X starts and intersects the surrounding walls at a height of about 17ft. from the base, thus forming a hollow space within each tower 22ft. in diameter, and extending up to W, as shown by the dotted lines R, Fig. 5.

The object of the bottom dome X is to distribute the weight equally over every part of the foundation, and as each course of the stonework is completed, the person in charge of the bottom valves regulates the sinking, so that the underbeds of the finished course are lowered only the depth of themselves, thus bringing the upper-beds for the next course to the same height from the scaffold on which the workmen stand when engaged in laying the courses in their proper places.

The scaffolds are suspended by iron rods from the frame-work above that carries the cranes, &c., and should be placed or arranged convenient, as it is desirable at this stage that the mason work should make rapid progress, and whenever it is found that they have reached the bottom, the scaffolds should be removed, and the interior of the towers filled in with concrete, or if not, it is desirable that they should be filled up with water to the surface level, which can be done by means of a siphon, thus bringing a weight to bear on each, in addition to that of the stonework, equal to nearly 1,600 tons. The upper domes W (Fig. 5) should be completed, and the space surrounding them left as a clearance of the shroud, filled in with a durable composition of cement, thus completing them, so far as the deep sea buildings are concerned. They should be left to stand over the winter months before commencing the surface towers that are to support the tube.

Before leaving this part of the subject, I may state that the weight of stonework in each tower just immediately before they reach the bottom amounts to 4,600 tons. The iron shrouds have to resist the internal pressure, as the stone-work is about 800 tons heavier than the water displaced—that is to say, the specific gravity of the stonework at the depth of 170ft. is that much heavier than the water, so that the pressure under the timbers or piston T before reaching the bottom amounts to nearly 90lb. per square inch, whereas, at full tide the shrouds are pressed only by the surrounding water to 76lb., and at low water may not exceed 60lb. per square inch; therefore, the shrouds should be made sufficiently strong to resist the difference of this pressure, otherwise they would burst.

The bilge water at E, before having been filled in with cement as mentioned above, is kept constantly at the same level as the water on the outside by means of a siphon, so that the pressure is balancing equally in all directions except under the timbers. This, being understood, it will be observed that the shrouds should increase in strength towards the bottom.

The thickness of the plates and the pressure at the various depths may be expressed as follows:—

Depth in feet.	Pressure in pounds per sq. in.	Thickness of plates in inches.
10	4·4	half.
20	8·9	,,
30	13·3	nine-sixteenths.
40	17·8	,,
50	22·2	five-eighths.
60	26·7	,,
70	31·1	eleven-sixteenths.
80	35·6	,,
90	40	three-quarters.
100	44·4	,,
110	48·9	thirteen-sixteenths.
120	53·4	,,
130	57·9	seven-eighths.
140	62·3	,,
150	66·8	fifteen-sixteenths.
160	71·2	,,
170	75·7	one
180	80·1	,,

Before commencing the surface towers the framework and the upper portion of the shrouds at the flange joint should be removed, so that the arch connecting each pair of the under towers can be bridged over with the stonework at the desired height, as shown in the drawings Fig. 5.

During the time the buildings are in progress the erecting of the tubes on shore should not be neglected, and as they are completed they should be floated out to their destinations in precisely the same way as that adopted with the tubes of the Britannia Bridge; but I would strongly advise a different plan to be taken in the raising of them, as they are nearly double the weight of the Britannia tubes; it would be very unsafe to trust to any combination of chains, as the snapping of a single link would cause considerable delay. The friction also to be overcome in such a combination of chains as would be required to raise a weight nearly 3,000 tons would be very great.

The plan by which I propose to raise them is from below, as it is safe and more expeditious, as when they are brought in between the towers they are immediately rested upon the temporary timbers shown by the dotted lines Fig. 5. The pontoons are then withdrawn, and the pumps for raising the presses are put in motion by means of a steam-engine placed with the pumps on the timbers at the opposite side of each tower.

The pressure pipes leading from the pumps to the hydraulic presses pass through ports left in the stonework at K; the four presses in combination for raising each end of the tubes should have a clear lift or range of 8ft. 3in., so that the 8ft. lengths of packings have a sufficient clearance to be put in as each lift is completed, and in addition to the cast-iron packings the tubes are further secured by following them up with wood packings. During each lift the tubes are raised about 3in. per minute, so that in one day, from the time that they are rested upon the temporary supports or beams, they can be raised to their permanent places.

The number of hydraulic presses employed should not be less than 24, as the first set—viz., 8, are required to remain in their places before the tubes are riveted; the second set can be in operation raising the next length while the third set are fitting up to be in readiness for the next succeeding length, and so on.

The short lengths passing through the towers should be fitted up in their places, and should rest upon cast-iron frames which project down a few inches on the edges of the stonework. Each of the 459ft. lengths are raised 2ft. 6in. at one end above the level, while the lower end is riveted to the tower length. The raised end is then lowered to the same level as the length passing through the next tower, and then riveted to it; so that by this process, instead of any deflection taking place in the tube with its own weight, it can be made to raise itself upwards in the centre between the supports, but this should not be carried too far; if the proper limit be observed it will greatly add to the strength and rigidity of the tube, as the tension of wrought [illegible] is greater than the force required to crush it; [illegible] reason the tower lengths should be well secu[illegible] cast-iron frames, as the greatest compression [illegible] lengthways at this point.

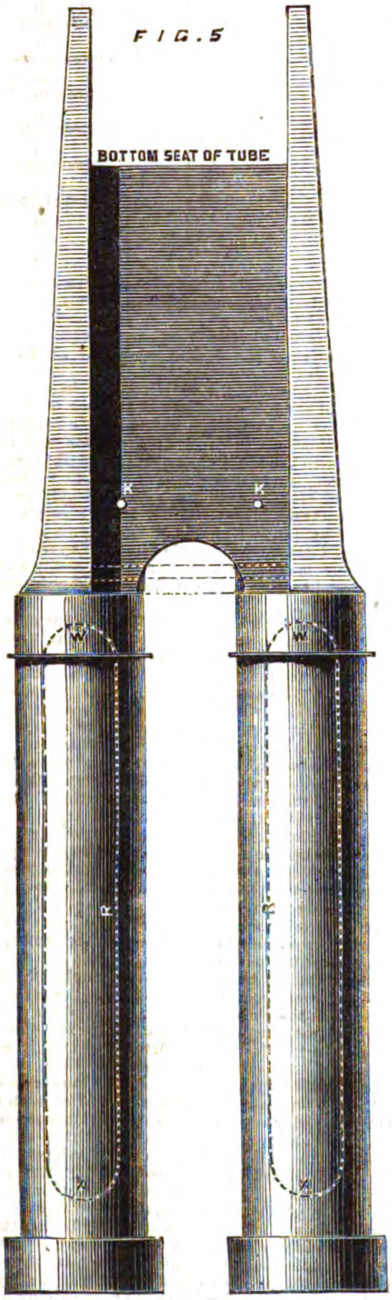
It will be observed that no provision [illegible] supporting the tubes on rollers, as they [illegible] the towers and abutments, whereas the

Britannia Bridge are supported on 32 sets of nicely adjusted rollers, set in pairs consisting of 22 rollers each, and with this adjust the greatest expansion that takes place in the entire length of 1,513ft. does not exceed 3in. or 10½in. per mile.

In a length of 20 miles at this rate the expansion would not exceed 17ft. 4in. From this statement it may be inferred that nearly one half of the expansion must be resisted by the friction of the rollers caused by the weight of the tubes they are supporting; for it is found that the expansion of wrought iron between 32° and 212° is ·0012, or for every increase of 15° from 32° up to 212° it expands ·0001 part of its own length. Therefore a tube 1513ft. long, exposed to the rays of the sun during the heat of summer, would undoubtedly at times reach 82°; the expansion at this temperature (if not partly resisted) ought to be 6·052in., and as the combined or treble-way tube when finished would consist of an entire length stretching from shore to shore, I would propose that the expansion and contraction that would take place in its length, from 32° up to 92°, or say 100°, should be overcome simply by its own weight and the strength or weight of the land or shore abutments.

FIG. 2

FIG. 5



This at first sight may be thought impossible, but from what is known of the properties of iron it will be found to be the only safe and practical plan that can be adopted in any iron structure of such vast dimensions, as the expansion from 32° to 90° on a length of twenty miles would amount to 42·24ft. All the lengths composing the tube should be set and riveted together in their places at a temperature of about 52°, maintained by artificial means during the whole time of uniting the lengths together, and securing the ends of the tube to the land or shore abutments. It will be observed that the expansion between 52° and 92° would be 28·16ft., this would have to be resisted by a force or weight equal to what would compress or shorten the tube to the same extent.

The contraction between 52° and 32° would be 14·08ft.; the force or tension to resist or overcome the contraction must act in a contrary direction. To find the force required to resist the expansion of any length of wrought-iron tube, multiply the number of square inches contained in the cross section by 2,492, the sum found will express the number of pounds required to compress any length of the same tube ·0001 part of its own length.

Example.—Although the plates, angle irons, &c., of the great tube vary in thickness between the supports they should be arranged so that the section is the same in all parts of the length—viz., 3,600 square inches. This, multiplied by 2,492 is equal to 8,971,200lb., or 4,005 tons. The force required to compress it ·0001 of its own length, or 10·56ft., therefore, to resist or compress it 28·16ft., it would require 10,680 tons.

To prevent dispute I may mention that the number 2,492 is the 10,000th part of the force in pounds corresponding with the modulus elasticity of wrought iron; 1in. being the unit, 17,800lb. per square inch would compress or extend it the 1,400 part of its own length, or 75,428ft., which is equal to the expansion or contraction that would take place between 32° and 139°, a temperature or atmospheric heat unknown, even at the equator.

I am not sufficiently acquainted with the formation of the shores to state the dimensions and the precise form the land abutments should have. This and the approaches leading to the bridge can be modified according to circumstances. The double set of union towers are further intended to facilitate the progress required to be made in raising the lengths of the main tube, and to give time for connecting their ends to the short lengths passing through the towers; as many as six lengths of the great tube can be in progress at the same time, raising fixing, &c., as they divide the bridge into three sections of 6⅔ miles each, so that by beginning the work of setting the tubes at

FIG. 1

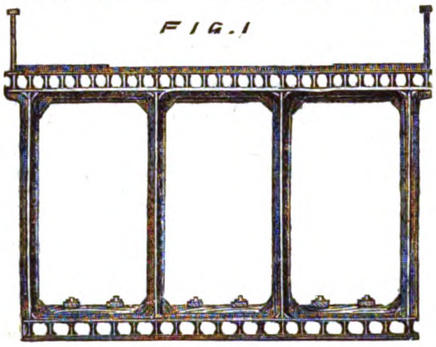


FIG. 3

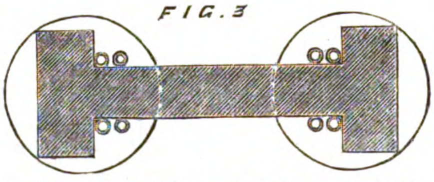


the centre of each section and working from right and left of each starting point, they can be completed much sooner than otherwise.

The side tubes, as will be observed at the above named towers, should be constructed similar to the corresponding lengths of the main tube, and are for supporting the station-houses, &c., that should be erected for the comfort and convenience of passengers besides those who are required in connection with the great structure, and during the winter the tubes should be lighted up with gas, and the method of ventilating them so adjusted that the atmosphere at all times could be kept free from the obnoxious gases that are generally found to accumulate in railway tunnels. The following items will furnish sufficient data for calculating the costs, &c., of the entire structure.

Column 1 gives the number of tubes, &c., required to complete the bridge.

Remarks.	Number of tubes, &c.	Length in feet.	Weight in tons.
Wrought iron...	222	459	743700
	6	240	10500
"	227*	10	16344
"	8*	240	9300
"	462†	85	45000
Total			824844

* Side lengths at union towers.
† Shrouds average length.

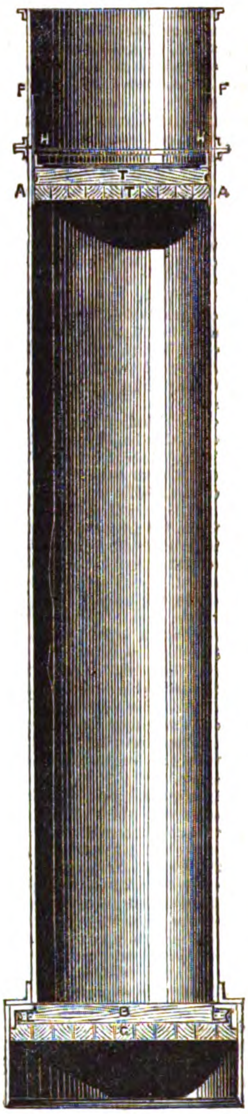
		Height in feet.	
Cast iron			37000
Stone work	227 *	104	1623050
"	2 †	85	4200
"	462 ‡		119160
Total			2857010

* Surface towers. † Shore abutments.
‡ Bottom towers' average height.

Concrete or composition for footpaths, carriage-ways, &c.	87500
Timbers for foundation, &c., 1,593,700 cubic feet, or	39842
Total	3846196
Or, including station-houses, side railings, water, gas-pipes, &c., say about	4000000

And by employing suitable machinery for constructing the various parts of the ironwork, &c., the whole might be completed and opened for traffic within four years from the time of commencing the work, at a cost not exceeding £18,000,000, as it would be found, by adopting the plans I have given of building the bottom towers and resisting the expansion and contraction of the tube, that a considerable saving of time and money would be effected; and in conclusion, I would further

FIG. 4



propose that my plan of constructing a roadway on the top of the great tube should receive due consideration, as such a mode of communication would undoubtedly be preferable to any class of underground tunnels, and if carried out would serve as a useful monument to illustrate the enterprise and wisdom of the age in spanning the waters of the channel with a stupendous bridge worthy of the nations it would unite together in friendly intercourse with each other.

The experiments, so far as have been made with the circular shrouds, have been perfectly successful in every respect. Sholto Douglas.

PIANO CONSTRUCTION.—TO MR. SCHUCHT AND HIS FELLOWS.

[3880.]—Is Mr. Schucht again poking his fun at the remarkably serious individual the unpractical "Harmonious Blacksmith"? After enumerating some of the difficulties of increasing the power of the sounds of piano trebles, he very coolly suggests that I, the unpractical blacksmith, of all men, should give such eminently practical man as himself a hint or two how to get over those difficulties. Verily, as Mr. William Shakespeare hath it, some men (the blacksmith to wit) have honours thrust upon them.

With regard to giving hints, I might say, "Would that I could." It does seem rather presumptuous for an unpractical blacksmith even to hint at (much more to attempt to specify, to practical pianoforte-makers) the probable means of improvement; besides which Mr. Schucht *estopps* me to some extent by refusing me the privilege of proposing certain "little dodges," some of which I may remark, *en passant*, are generally supposed by pianoforte-makers to greatly influence results.

In my subjoined observations on this subject, I have purposely avoided merely theoretical—which are but too commonly synonymous with controversal—matters; but I do feel compelled, in reply to Mr. Schucht's assertion, that "when we hear the deepest bass note we also hear all the notes in the piano," to exercise the free Briton's privilege of becoming like most of my neighbours, a dissenter. Very possibly all the notes of the piano may be then and there present among the "obertones" of the said lowest bass strings, especially if we hypothetically include all the theoretically possible "obertones of those obertones," but to say we hear them all is simply saying the thing which is not. Possibly, were our ears as cultivated as those of the angels, who are popularly supposed to listen continuously to the heavenly music of the spheres, whatever that music may be, we might hear all those sounds; but the writer's ears, however musical they may be, are not, he is happy to aver, quite long enough to enable him to imagine he does hear all of them. Seldom, indeed, does he hear, in a well-made piano, more than one or two of the said obertones, *alias* harmonics, of the said open string, especially if it be as tight as it ought to be, which, by the way, it seldom is.

Mr. Schucht says we cannot make a piano treble, the mass of whose materials shall equal that of those of the bass; quite true. We can't make a fiddle as big as a double bass; perhaps, if we could, it might be inconvenient to "chin" it, excepting by the Anakim. We can't make a piccolo as big as a pedal-pipe; a trumpet as big as a bombardon; a free reed which sounds C, three octaves about pitch C, quite so large as the one which sounds the so-called 32ft. C C C C of the bass; neither can we make a pipe in unison with the first of these reeds quite so big as the huge pedal-pipe whose sound is unisonous with the latter. There are, however, a few things we can do to compensate to some extent for the differences in their masses, or of the masses of air contained in such pipes. One of these things is blowing the small pipe or reed with air at greater pressure, something like which it is possible to do with piano strings—but of this more anon. Another thing is employing more little pipes than big ones, and this is the very course indicated by Nature, who endows a dozen little children with voices quite capable of out-squalling any one man—or woman either. N.B. The latter is saying something; in fact a good deal.

Mr. Schucht also says, "If a pianoforte-maker discovered a method of making a treble equal in power to the bass, he would at once apply the same means to the tenor and bass, which would leave the treble as relatively weak to them as at first;" this seems to me very doubtful. Not to mention that organ-builders do not commit such an absurdity, for they no more use as many pedal-pipes as they do treble ones than a wise harmonium-maker uses as many reeds of 16ft. tone as he does of 4ft.; the "unwise" harmonium-makers do, hence the relative weakness of the trebles of their vile, coarse-toned instruments. I think Mr. Schucht pays but an ill compliment to the taste and judgment of his fellows in assuming they would act so absurdly, besides which, it is just possible the means employed to augment the power of the treble might be inapplicable (or, at least, not desirable to apply) to the tenor and bass. One such means, hereinafter described, certainly is not, for its application to the bass would induce a very bad and "harmonicky" quality of tone. Keeping down the power of the bass that it may not overpower the treble is no novelty; in fact, we practically do it daily by covering the bass hammers more thickly than those which strike the treble strings. Possibly Mr. Schucht has read Messrs. Broadwood's little book, printed for private circulation in 1862, and will remember they distinctly state that in addition to using softer hammers to improve the quality of and keep down the power of the sounds of the bass strings, they also purposely avoided treating that portion of the soundboard which was under the bass strings in the same manner as they treated that portion beneath the treble strings, lest the sounds of the former should overpower those of the latter. Probably Messrs. Broadwoods are not the only makers of horizontal grand pianos who have done the same or similar things, for the practice is very common in some other musical instruments, and is universal in those collections of them, designed to be performed on together, which we call orchestras.

When we design an orchestra we usually employ more fiddles than contra basses, more cornets and flutes, than trombones, ophicleides, and bombardons. When we build an organ or harmonium we don't put quite so many C C C C pipes or reeds into it as we do of those which produce treble sounds; and we ordinarily do something very like this in the piano, for we use more unisonous strings for its treble than for its lowest notes. May I guess even Mr. Schucht himself employs but single strings for the latter, and two or three strings for his trebles, notwithstanding he has estopped me from suggesting the use of three strings instead of two, forgetting that it is a practical fact that many mickle strings, if not equal to are at least more suitable than only one to be used along with his single but muckle bass string.

Probably no other unpractical individual ever experimented further in the multiplication of unisonous strings in piano trebles than I have done. On C, two octaves above pitch C, I have tried no less than seven No. 14 strings 3in. long, but the honest truth is that I found little or no increase of loudness when the number exceeded five. Probably the failure resulted from the weakness of the action, I being then unable to strike seven strings more forcibly than five. In the orchestra seven fiddles have not one bow common to all, but seven bows, one to each. Let me add, each of these seven bows has a separate fiddler, one to each, to "saw" with them in every instance I ever "sawed," in other words, seven times the motive force when needed which one fiddler could apply to one bow. Now my seven strings were all struck by one hammer, certainly somewhat heavier, about a fourth, than usual. Seven strings mean more than twice the resistance to the hammer's blow that three strings can have, and as I had not then learned how to increase the force of the blow in proportion to the increased resistance of so many strings (at least not without increasing the weight of the touch, until it became too great for pleasant performance). For I then only had the means of experimenting with the common horizontal grand action, Der "English Mechanic" of Mr. Schucht and his countrymen, which, in common with all other actions, however excellent, cannot, without too much increasing the weight of touch, be made to strike so powerful a blow when its hammer is horizontal as when it is inserted in the top of the butt, as it must be for upright strings; hence, we need hardly be surprised to find if I produced powerful sounds from three, considerably more powerful sounds from four, and yet more powerful strings from five strings, that after that number were used, but little if any increase of loudness resulted, probably because the same force of impact (being distributed over so many) each string was not moved so far, and consequently they did not lift the soundboard so high, and the aërial wave generated by its motion, was less ample than it would have been had the seven strings been raised by the hammer as far as five strings were. It is, however, hardly worth while theorising about the matter, because I have since learned that three No. 17 wires 4in. long, properly struck, yield a louder sound than five No. 14 wires, whose length is only 3in.

However unpractical I may be deemed I have far too keen a sense of commercial considerations, and, let me add, of business responsibility, to recommend Mr. Schucht and his fellow manufacturers to make pianos with five strings in the treble for each note. Some of the very best trebles I have yet heard had but two unisons, and not to mention the increased cost of construction resulting were five strings used, which after all would not be so very heavy, I greatly fear the tuning of such instruments would be found rather costly. Besides this merely pecuniary consideration, which I for one would be quite willing to pay the additional cost of if proportionate excellence resulted, I (although I have but little faith that my future life could be largely influenced by human maledictions) would rather not (for his sake) desire the tuner should wish me located in a region whose temperature is popularly supposed to be unpleasantly high every time he doth his office, for, after all, I have written in disparagement of their class. I do acknowledge that tuners are "men and brothers." Now I much desire to be at peace and brotherly love with all men, yea, even with tuners.

Had not Mr. Schucht estopped me, I would also have suggested that those hammers which are what he terms pointed at their striking faces, are generally believed to cause treble strings, not only to produce louder sounds, but also sounds of more "penetrating" quality, especially if the said hammers be rather thinly covered. Now this "penetrating" really is worth something in musical instruments—in fact, but for it the trebles of pianos would be almost inaudible. I have not the slightest desire to inflict on Mr. Schucht and my other fellow readers a long tedious disquisition on timbre, and the probable (query hypothetical) causes of the great differences thereof, which may, or may not be, caused by the predominance of the different "obertones" we hear, but I will simply appeal to notorious facts within our daily experience. A familiar example of this penetrating quality of tone is heard in the sounds of the common military fife, which may be heard above all the other instruments in an orchestra, but no flute, or stopped diapason pipe, in unison with the fife, would be audible under the same circumstances. Without pretending to verbal scientific accuracy—a thing not to be expected from ignorant blacksmiths—we commonly say the sound of the fife penetrates through those of all the other instruments. I am sorry to add it doth also "penetrate" my poor ears very unpleasantly indeed, but, nevertheless some people do really like it, just as the "Sans-Culottes" of North Briton are said to like the bagpipes. Well, *De gustibus*, &c.

Besides the ordinary practice of increasing the penetrating quality, and, therefore, the apparent power, of piano trebles by employing thinner coverings for the treble hammers than are used for the bass hammers, which practice is now probably carried as far, especially by the English makers of horizontal grand pianos, as is compatible with the production of sounds of pleasing quality—perhaps in some instances even yet further—although I think if their bass hammers were made heavier and covered yet more thickly, which latter is the practice of most continental makers, the quality, at least, of their bass tones would be greatly improved. There is another simple and old fashioned way of increasing the power of the trebles—viz., to go back to that exemplification of the wisdom of our ancestors which is shown by giving hard knocks. This obvious and time-honoured method seems to have totally escaped the penetration of modern pianoforte makers, at least, I have seen no modern examples of its carrying out. Like all "ancient" men whose education belongs to the period when Windham wrote "Pugilism is the Salvation of England," I have great faith in hard knocks, if not for the civilisation of mankind, at least for the production of loud sounds in the treble of pianos, for when this process is applied to their strings it induces much the same consequences which result from its aplication to juvenile humans—to wit, it causes them to "cry aloud."

Hard hitting in pianos may be carried out by two methods, we may either make our hammers double the weight they were without increasing their velocity, which, however much it would improve the bass would greatly deteriorate the treble, in fact, although doubling the total force of the blow, it would also render it what Mr. Eavestaff termed "thuddy," which is just what we don't want it to become; to confess the truth, it often is far too much so already. Thuddy blows answer very well for driving piles or forging red hot iron, in both of which cases the long continued contact of the ram or hammer does no harm, but for inducing the musical vibrations of short strings the sooner the hammer rebounds from them after it strikes them the better, because their vibrations must be at least sensibly impeded, not to say damped, by the continuance of contact between the hammer and strings; in a word their tones, never anything too long, become yet shorter and more "blocky" the more time elapses before the hammer rebounds. I think it follows that heavy hammers, which strike thuddy blows, "arent" exactly what we want for piano trebles, so, as we don't desire to damp our strings before the hammers have time to rebound from them, we shall have to copy the wisdom of our ancestors, who made grands before the first quarter of this century expired, in so far as making light hammers strike hard by moving them at a high velocity when they do strike is an example thereof.

Strange to say, ye modern practical men (who probably elevate their nasal organs at the name of the blacksmith, and piously thank heaven they are not as that unpractical sinner is—well, happily, like Thomas Ingoldsby's celebrated jackdaw, he don't feel one penny the worse) seem never to have perceived the advantages of this system. Indeed, so far from increasing the velocity of their treble hammers, they have, in most of the actions they employ, actually reduced their velocity about one-third, driving them no faster—sometimes a trifle slower—than they do those in the bass. In the old grands, whose touch was what we should now term very shallow—only about ¼in. deep—the hammer was moved eight or nine times as fast as the key, in modern actions they seldom move more than six times faster, and its weight is about double that of the old hammer. Such being the facts, need we wonder that modern hammers, especially when heavy loaded strikers are hung to them, strike "thuddy" blows? Probably their blows are rather more powerful than those of old grand trebles. Additional weight, however, is but a bad means of obtaining additional force, although its evil consequences may be to some extent compensated for in modern pianos by employing No. 14 to 16 wire in lieu of No. 10 and 12 wire for their treble strings.

I will say something more on "Piano Construction" in another letter.

THE HARMONIOUS BLACKSMITH.

KING-NUMBERS.

[3881.]—MAY I ask "E. L. G." (let. 3654, p. 607) to publish in the columns of the ENGLISH MECHANIC his demonstration that there are no other king-numbers than those he gives in the letter I refer to, and also the method of ascertaining each step in the series of "noble" numbers there given, which method he there says he "may explain in another paper"? I have noticed a fact in connection with the table he gives, which I should be glad to publish in these columns, but should like to see his demonstration of what he asserts before I do so. May I be allowed to point out what appears to me to be an error in his letter? He says, "the two lowest king-numbers, two and six, are the only ones that, multiplied, produce a third king-number." Surely, 6 times 60 is 360.

ALFRED M. BOX.

COLLIERY EXPLOSIONS AND THEIR PREVENTION.

[3882.]—ALLOW me to express my gratification that "King Coal's" opinion (letter 3816, p. 14) does not materially differ from my own as to the best. I think the only effective method of diminishing the frequency of explosions—*i.e.*, by ample supplies of air well distributed, and insuring attention to that by rendering it more costly to neglect than to observe the conditions essential to safety. I quite agree that as a rule accidents are most frequent in the smaller collieries, but, on the other hand, when explosions do occur most lives are endangered in large ones. To limit this exposure of very many lives to one risk, the select committee of the House of Commons recommend that large fiery mines should be divided into sections or pa[...] so that not more than 100 miners should work [...]

same section. Such division would cause both cost and inconvenience possibly greater even than the additional security to life would compensate for; that, however, should not be assumed without careful consideration. My impression is that if the lives of colliers were insured, as they ought to be, it would be found cheaper to adopt the precaution than to pay for the risks, and unless the precaution would cost very much more it ought to be adopted, for the lives of our countrymen, especially if they be husbands and fathers, are of extreme value.

I do not see any probability of the cost of compensating for lives lost by explosion being greater than I assumed, for, wreckless as the pitmen often are, they will not be more but less so, when greater carefulness by others becomes common, and my calculation is based upon the assumption that fatal accidents will not increase, while they will most certainly diminish, if danger be made more costly than safety to those who can most effectually enforce precautions. PHILO.

EXTINCT VOLCANOES.—VI.

[3883.]—There are a good many traces of extinct volcanoes in Italy, besides those of the Phlegrean fields. In general character they resemble those previously described. The chief localities are certain lakes near Volterra in Tuscany, which give forth very hot and sulphurous and boracic acid vapours; a small sulphurous lake near Viterbo, continually giving forth bubbles of gas; and the lake of Vico, between Viterbo and Rome; Mount Vultum, in the Apennines in the province of the Basilicata; and Lake Agnano near Naples. Of these the Lakes of Vico and Agnano are the most interesting—the former, as the ancient Lacus Cimini. Old authors state that its site was once occupied by a town, whose ruins used to be visible at the bottom of the lake when the water was clear. The ground where the town is said to have stood is supposed to have been engulfed during a volcanic eruption, when the said lake was formed. The Lake Agnano is the site of an ancient volcanic crater, and on its margin is situated the Grotto del Cane, so famous for the deadly vapours it exhales—these consist of carbonic acid gas, in combination with watery vapour. This celebrated grotto is thus described in his work on volcanoes by Dr. Daubeny:—"The mouth of the cavern being somewhat more elevated than its interior, a stratum of carbonic acid goes on constantly accumulating at the bottom, but upon rising above the level of the mouth, flows, like so much water, over the brim, hence the upper part of the cavern is free from any noxious vapour, but the air of that below is so fully impregnated that it proves speedily fatal to any animal that is immersed in it. Also it is impossible to fire a pistol at the bottom of the cavern, for although gunpowder may be exploded even in carbonic acid by the application of a heat sufficient to decompose the nitre, and consequently to envelop the mass in an atmosphere of oxygen gas, yet the mere influence of a spark from steel produces too slight an augmentation of temperature for this purpose." Similar phenomena, but on a grander scale, are presented by the extinct crater on the Island of Java, called Guevo Upas, "the poison valley." It is level, about half a mile in circumference, surrounded by precipitous rocks. From various parts of its soil carbonic acid gas is discharged in such quantities as to prove fatal to any animal venturing nigh. This valley gave rise to the celebrated figment about the upas tree which once obtained such general belief in Europe that it was credited even by Dr. Darwin.

There is another extinct crater in Java where are exhaled vapours equally deadly, but which exert a most peculiar effect on the dead carcases subjected to their influences. Instead of their being, as in the Guevo Upas, reduced to skeletons, the carcases have all their bones dissolved by the vapours, while the flesh, skin, hair, and nails are preserved from decay.

To the westward of the town of Le Puy there are a number of small volcanic craters, of which the two largest are the Lake De Bouchet and the crater of Bar, which also appears to have been at one time a lake, but is now dry; the former has its greatest diameter about 2,300ft., with a depth of about 90ft.; and the latter is on the top of a mountain which is composed entirely of such substances as are ejected from volcanoes. Its diameter is about 1,660ft., and its depth about 130ft., while it is almost perfect in its form. The mountains near Vienna exhibit streams of lava which accommodate themselves to the existing valleys near Agde, also on the shores of Gulf of Lyons, on the top of a hill—viz., St. Loup, there is an extinct volcano whence have descended two streams of lava, apparently of recent origin. On one of them the town of Agle has been built—the other projects into the ocean.

The district of Eyfel, on the borders of the Rhine, is another in which extinct volcanoes abound; they occur mostly in the form of circular craters, which are now filled with water, their borders consisting of volcanic ejections; they also exhibit various superficial streams of lava. One of the most remarkable of these round craters lies near Andernuch, a little west of the Rhine. It is named the Lake of Laach, and is nearly two miles in circumference; on its margin are found numerous volcanic ejections exactly resembling those of Mount Vesuvius. Notwithstanding these evidences that the extinct volcanoes of Eyfel have been in activity since the country acquired its present formation, there are no historical records of their operations. There is, indeed, a passage in Tacitus referring to fires that issued from the earth near Cologne, but his description does not warrant the conclusion that the event to which he alludes was of the nature of volcanic eruption. The Drachenfels, on the eastern bank of the Rhine, and the other mountains in its neighbourhood, belong to the more ancient volcanic formation. The same may be affirmed of the other mountains scattered throughout Germany and Central Europe generally, in which rocks of volcanic origin occur.

But of all the extinct volcanoes in the world none is so remarkable as the Dead Sea. This singular collection of salt and bitter water has the level of its surface depressed 1,312 feet below that of the Mediterranean, thus indicating an enormous subsidence. The Dead Sea occupies the site of what was formerly the plain of Jordan, described as having been well watered everywhere, like the land of Egypt. One part of it, called Sheddem, was full of slime pits, the only indications of volcanic action. When the cities of Sodom and Gomorrah, which stood in the plain were destroyed, it is said it rained upon them fire and brimstone from Heaven, but it appears that they must have been primarily discharged from the earth, for the smoke of the country went up as the smoke of a furnace. The phenomena, therefore, most likely resembled in the first instance those of Jorullo, but the catastrophe seems to have ended like the great eruption of Timor—the whole of the plain having been ingulfed and replaced by the salt lake, whose depressed level so clearly indicates the nature of its origin. RALPH LOWDON.

NOMENCLATURE, &c.

[3884.]—I was a few days ago working my way slowly and laboriously through an old manuscript book on alchemy written in 1608, and as I read page after page about "aurum potabile," "the elixir," the "white blood of the green dragon," and so forth, I could not help thinking that there was a strong resemblance between the jargon of the seventeenth century and the nomenclature used in the science of the nineteenth, and wondering whether it was necessary to involve matters in extra obscurity by the use of terms that are almost unintelligible except to the initiated, especially when each writer seems to invent whole sets of new ones, or, worse still, employs old ones in a new sense. Far be it from me to say anything against our talented and obliging friend "Sigma," but he is an instance in point, and has employed several names—Farads, Vebers, &c.—that are, I think, quite new, in his recent papers in the English Mechanic.

It is, however, in chemistry that the most outrageous names occur: even the "white blood of the green dragon" is a joke compared to the polysyllabic combination of Greek and Latin that occur in organic chemistry, and in inorganic too, for that matter. Then, too, what a grammatical barbarism is such a compound as Platinic Chloride. True, it may be a syllable shorter than, but is it so easy to pronounce as, its old name chloride of platinum. As for zincic chloride, I can make nothing of it; if the "c" is hard, the word borders on the ludicrous, if it is soft the name of the metal is lost.

Just now we are having a battle about valencies; and atoms and molecules are flying about pentads and hexads in a most alarming manner. In connection with this, I remember in some book on chemistry a remark that it was scarcely an explanation of a fact to say that "substances combine because they have an affinity, and they have an affinity because they combine," yet all this discussion about "valencies" seems to my feeble comprehension to be very much in the same style.

Another thing that often strikes me in my discursive reading (I am a Jack of all Trades in reading, and I fear I must add a master of none in understanding); is the tendency to dwell on minutiæ rather than on broad facts.

Take astronomy as exemplified in our pages; look at those straggling sketches intended to represent some mountain or crater of the moon, and then read the long discussion as to whether a little crooked mark is a cleft or a rill. What on earth does it matter which it is? moreover, no two observers ever seem to agree in their sketches.

Again, read Secchi's papers on sun flames, divided by him into a hundred different kinds, yet who would dream of classifying the shapes of the flames that flicker up and down in our grates? Is the one of more real use than the other?

Then take microscopy: what pages have been written, what a paper war rages as to (say) Eozoön canadense! What hours have been spent over infinitesimal differences in the markings on the Diatomaceæ or the specks in a tadpole's tail!

I might dwell also on microscopical anatomy: has medicine or surgery been sensibly benefited by all the thousands of observations on blood corpuscles, striated muscle, and so forth? Has cancer been checked by means of knowledge gained from the examination of its cells? Has tubercle been arrested? Has any practical result followed from all this prying into the laboratory of life? Some trifling knowledge may have been gained, but I much fear that the true answer to the question must be—Very, very little. L. C. E.

BEES AND BEE-KEEPING.

[3885.]—The weather anticipated in my last letter has come upon us with a vengeance, and wind and rain, sleet and snow, with the temperature below freezing-point, have stopped all bee operations, and confined the bees to their homes. The immediate effect of it will be that the queen will cease to deposit eggs in the cells, and the bees will huddle together for mutual warmth. In a strong stock little harm will arise beyond loss of time, as there would at no time be more brood in the hive than could be covered and cared for by the nursing bees, and, although the temperature outside the hive is so much lower than it was, it has happily caused the foragers to keep within the hive and so to keep up the temperature within; but with weak stocks the effect will be very severe. When stocks are reduced by sudden stress of weather to the verge of starvation, the bees cease feeding the queen on prepared food and allow her honey only; they consume all the eggs, and as the pressure increases the larvæ also, and all the prepared food stored in the cells, with the larvæ for its sustenance. As time goes on, and the pressure becomes greater, they unseal the cells of the full-grown nymphs and eat all the soft parts of their bodies, throwing out at the mouth of the hive only the bony formation of the head and thorax, and after that sheer starvation induces them to swarm out, which they often do, and pitching on the ground close by, perish in a heap. Amateur bee-keepers hardly ought to need reminding that a little help would prevent so dire a catastrophe. C. N. ABBOTT.

DUST IN THE SPECTROSCOPE.

[3886.]—I have great pleasure in replying to the courteous request of your correspondent, "A Fellow of the Royal Astronomical Society," as to the best method of cleaning the slit of a spectroscope. I fear, however, that I shall not be able to render him much assistance. When a spectroscope is of considerable dispersive power the slit may be opened for such a distance that particles of dust will not fill up the space between the jaws, and still the instrument will give a tolerably pure spectrum. But when the instrument has a very low dispersive power, the slit can scarcely be wider open than the three-thousandth part of an inch, and it is, of course, exceedingly difficult to prevent particles of dust of this diameter from lodging between the jaws of the slit: this causes the spectra to be striped with the longitudinal lines which so much annoy observers.

All this is, no doubt, well known to your correspondent; my object in writing it is not for his information but for many other readers in whose interest he evidently writes. As your correspondent says, a camel's-hair pencil is of no use—generally I have found it make matters much worse—but a freshly cut splinter of dog-wood should have been useful. I have found any small piece of soft wood, cut carefully round, and rubbed on a cloth, so as to free it from all small particles, effectual, if used in the following manner:—First blow on the slit, allow time for any slight amount of moisture which may have condensed to evaporate, close the slit by means of the screw motion, open it a tolerable width, and wipe the edges of the jaws with a splinter of wood; blow on the slit again, close the jaws of the slit completely by means of the screw motion, and on re-opening the jaws will generally be found free from dust. Though this method is not always successful on the first trial, it is the best method I have yet been able to find, and after some practice your correspondent, who I have good reasons for thinking is a most expert manipulator, will be certain to succeed at any time. JOHN BROWNING.

ATMOSPHERIC DUST.

[3887.]—It may interest your readers to learn that Dr. Tyndall's cotton respirator has been anticipated by the inhabitants of some parts of South America. "The fact, which seems well authenticated (Boussingault), that the inhabitants of South America are enabled in some localities to withstand the attacks of endemic diseases by mechanical application, such as veils placed before the organs of respiration, so as to sift the air from morbid solid particles, supports the organic nature of malarious poison. Absorbent porous bodies used instead of veils, such as charcoal, have been long disused in manufactories from their power of condensing gases, which are replaced by the inspired air in its passage through them, and are thereby carried into the circulation."—Dr. R. D. Thomson, in "Cholera Report," 1854.

Dr. Thomson holds the opinion, which I some time ago stated to be mine, that putrefying bodies are not to be dreaded, but living matter. I believe fresh sewage to be far more dangerous than old. Putrefaction gases may kill, but do not give contagious or infectious diseases. And, I may add that what we require in a disinfectant is something to kill the living germ, not an agent to prevent comparatively harmless putrefaction. It must also be remembered that the cilia in the lungs enable them to free themselves from germs and dust for the most part. We have always some ridiculous bugbear which pays to keep alive. M. PARIS.

POTATO CULTURE.

[3888.]—Having seen various articles on the above subject in your paper, I venture to send a few remarks. For some years I have paid considerable attention to the subject, and I will state what I believe to be the best means for insuring a good crop. 1. Wide setting, about 25in. between rows, and 15in. between the potatoes, liberal manuring, and large sets (whole). 2. As soon as the tops are 3in. or 4in. above ground, I pull out all the sprouts, except three of the strongest. This is a certain means of insuring large potatoes, and though fewer in number, a better sample and greater weight of crop. I earth up very high. If disease appears I mow off the haulm close to the ground, as soon as any spots are seen on the leaves; by this means I saved, last season, a splendid crop of "lapstones" when my neighbours lost most of theirs. I cannot agree with your correspondent who blames manuring for the disease—it is quite the contrary in my experience, and without manure planting potatoes is waste of time and ground. INQUIRING [illegible]

SCIENTIFIC EDUCATION.

[3889.]—IN my communication to you of November 10, 1871, I reported the last contributions towards an exact science of mind in support and extension of the soul-theory of Plato. Permit me to report progress in relation to the exact science of reasoning or exact logic. A. Jiram Row, in his lecture at St. George's Hall, reported in the ENGLISH MECHANIC of the 9th ult., takes us back to and endeavours to resuscitate lower forms of barbaric thought which some of our own naturalists have also attempted unsuccessfully to render again fashionable. They are attempting vainly to turn the dial of the world backward at least six centuries. There are few things more difficult than the exact observation of facts. The exact interpretation of their natural language is a rare achievement. To the man of average capacity, who has toiled long and painfully, and has at last been able to exhibit a few hitherto unobserved and unexciting particulars, the result is most disappointing. His is no master-mind, and he is unable to so grapple with the groups of particulars as to generalise subtly and reach discovery. So he abandons the straight and narrow path of fame to gather Olympic dust in the broadway of sensation. The last public rebuke of Huxley appeared in the *Morning Post*, then reporting his lectures at Kensington. The writer then quoted against him the "Brancassine criteria," "Man cannot reason by means of uncertainties," "The recognitions of man cannot extend beyond the limits of certainty," "Certainties must spring from an exact experience," "Superstition, scientific, is the acknowledgment of uncertainty as certainty," "Exact logic must have as its basis an initial certainty." These criteria, part of the "Doctrine of Logical Limits," first published, the writer states, in 1842, are obviously a further development of the English school of philosophy founded by Roger and Francis Bacon, as opposed to the metaphysical schools both of the Continent and India. Let us contrast the really scientific education of the English school, according to its last development, with the Indian substitute. "Man," says the former ("Exact Philosophy," Book 1) "is certainly a part of nature. He is physically carbon, oxygen, hydrogen, nitrogen, chlorine, iron, lime," &c. "The chief elements of the external world are constantly becoming physical humanity." Now, mind is also a part of man—his chief part. What any one may imagine mind to be is a quantity outside critical logic, which acknowledges the existence of certainties only. Certain it is that mind is a part of man; therefore of nature. It is impossible for an exact thinker to take any known quality of mind and attach it to inanimate entities. It is impossible to dislocate one quality of mind without dislocating at the same time all its other qualities or congeners. To infer that a brickbat has a soul is an impossible inference. Logical inference, strictly so-called, is an entity altogether beyond mere human volition. So soon as an inference is exposed as having the fatal quality of uncertainty it becomes extinct. It is destroyed by the first criterion, or first law, just quoted. Exact logic is limited to facts or certainties; it sweeps away into nothingness all mere sayings, as the "Modern Oracular" ("Exact Philosophy," Book 2.) It annihilates the use of all inexact terms, especially those which are often applied to inanimate objects, and which, according to exact experience, are never known save as mental entities. To say that a "stone endeavours," or that any object known to be senseless acts, operates, contrives, arranges, &c., is to use spurious terms. These belong to the follies of fable, and are mythic verbiage, belonging not to mythology, but to the "hyper-supernatural." Mythology usually assumes the presence of some form of mind. The mythos of monstrosity assigns all its marvels to the absence of it. It, in fact, ignores its very existence. Now, when A. Jiram Row talks to the higher class of educated Englishmen about "concrete existence in all its varieties" as only the expression of a principle of an unconscious self-existence, they think it wholly unnecessary to exhibit any law of exact logic, any "Brancassine criteria" for the extinction of this rare bit of the modern and ancient oracular. It is a self-annihilator. It is plainly metaphysic jargon. Its author shut out mind from his mental collection, and his saying merely signifies exactly that exclusion.

There are those amongst us who would drag us back to the mythic teaching of the middle ages. We have not the stone of transmutation, the alkahest, the elixir vitæ, upheld as searchworthy; but we hear occasionally of something infinitely more marvellous—unconscious—protoplasm; natural selection, that, unmentally, selects; and psychic force; all ultra-miraculous agencies. All these new discoveries teach us that, since more can be achieved without mind than with it, a lunatic asylum is the place wherein to find a master-statesman, the most skilful administrator, a sovereign, or even a god!

Professor Huxley did not reply directly to his critic, but he replied indirectly; as may be seen in the ENGLISH MECHANIC, No. 343, p. 112. There, at Owen's College, he complained that scientific men were reproached for departing from the Baconian or scientific method, and for not being allowed to guess, or imagine, or speculate, or invent hypotheses. "Nine-tenths of what scientific men dealt with were," he adds, "only probable conclusions, and that we must wait more than a century for real evidence of the truth of Darwin's hypothesis!" Now we have a good answer to this complaint. Newton obtained his grand results by rigorously observing and interpreting natural facts, and not by speculating. Of the speculative method he speaks with colossal disdain:—"Philosophia naturalis id revera præcipuum sit et officium et finis," he affirmed (Opt. 28, Qu.) "ut ex phænomenis sine fictis hypothesibus arguamus et ab effectis ratiocinatione, progrediamur ad causas." "We make clear or prove by reasoning from results and without fictive hypotheses," was the Newtonian method. What would he have said to the century-to-come Darwinian possible?

FRASER HALLE.

SAVE US FROM DECIMALISM!

[3890.]—WHAT we sorely need of "Philo" (p. 12) is fewer words, indeed; though I will not say, as he does of me, "in proportion to his ideas"—ideas of a sort being, with him and most of us, enough to spare, but far better ones even than his being by no means the things wanted, especially in this metric matter; but judgment and real thought, of a kind he never betrays a trace of—thinking out some one thing, however small, to its end.

To adopt one of his last ideas, he must have a very low estimate of expected readers to set up gravely a parallel between the new French measures and an *invention*; moreover, such an invention as logarithms! as if this crude expedient (dashed off in the hurry of the most furious revolution, to supersede a chaotic host of local and trade standards) involved any invention at all! But above all, a brother to logarithms! Why, it is not half so comparable as the man of Wagga-Wagga is "just like Roger!" They were both men, at least, and had both been in England and Chili; but all the parallel we can find here is that both things were once new, or, rather, new to Europe! It is suited to the same order of mind as Mr. Bottone's comparison on p. 588, of two sums which, because they are stated, in different notations, each by a 7, an 8, and a 5, are to be taken for one question! and when offered the choice which of the two he will state in both notations, so as to work one identical question in both (p. 608), declares off, with the falsehood* that I proposed he "should first reduce English notation to decimal," and flatly refuses to compare the two methods on any one sum at all.

And, by the way, what clap-trap and hocus-pocus are all these comparative calculations hitherto? We are shown long multiplications, reductions, and the rule of three, involving long division; as if any of these were practically used. They must necessarily be taught to school-boys, to ground them in the theory of the matter; but who in England uses them in real accounts? They are avoided, and in commercial reckoning can be totally so, and even short multiplication used as little as possible, and all else is done on the principle of the rule the school-books call "Practice." This form or application of short division, not merely the most valuable and used rule, but the very cream and practically *sole* used portion of the school arithmetic, arguers like "Sigma" and Mr. Bottone simply ignore, the fact being that its whole value and prevalence that so well earn its name, are one great protest against and evidence against decimalism! It all hangs simply on that superiority I have been pointing out, of the truly *metric* numbers, those *artfully-chosen* ones that connect the units of our ancestral weight and measure systems (that "Sigma" ascribes to *accident!*) over the mere denary powers that arise from the accident of counting by fingers. The rule of "Practice" in the school-books is prefaced by lists or tables of all the "aliquot parts," as they are called, of £, a ton, &c. Systems formed by "accident," or any such as Mr. Bottone imagines were what he calls "consistent," repeating the same multiplier step after step, would never have had large units, like the £ or ton, with these numerous submultiples, or sufficiently divisible, *i.e.*, sufficiently *metric*, to lead to this most useful and rapid method, so well-named "Practice." The miserable Gallo-Chinese pseudo-system in question miscalling itself "metric," in which alone, of all systems, *accident* really has a chief part, scarcely admits of any such method, only of its barest rudiments, as dividing by 2 and 4 instead of multiplying by 5 and 25, and I suppose French school arithmetics have no such chapter; but few people can have any idea—I had none myself till yesterday—of the height to which you must carry the powers of ten before they will compare, in number of divisors, with the upper numbers of my "eumetric" list, on p. 607. Reckoning the number of divisors exclusive of unity, it will be found that

In 1,000 are	14, or no more than in	120
In 10,000 are	23, but 1 more than in	360
In 100,000 are	34, or no more than in	1,260
In 1,000,000 are	47, but 1 more than in	2,520
In 10,000,000 are	62, or no more than in	7,560
In 1 milliard are	98, or no more than in	45,360
In 100 ditto are	142, or no more than in	110,880
In 1,000 billion are	254, or no more than in	1,081,080
In 10 trillions are	391, or no more than in	6,486,480

Thus we find it would take 20 decimal places to make a denary unit divisible by merely *as many* divisors (and not near as common or convenient ones) as a unit of only 7 figures derived from the "noble number" system yields. And observe that the highest prime factor in this 6,486,480 is but 13, so that supposing a metric table having this for the ratio of its highest and lowest units, there need be no step larger than 13, and children could as well learn to carry thirteens as they now do twelves from pence to shillings. But such a table, instead of the three steps 7, 11, and 13, might embody them in the single step 1001; it being actually easier to carry 1001's, or to divide (in our denary arithmetic) by 1001 in one line, than by 13. Now, considering that 13 has a place in our time system, being the number of weeks in a quarter of a year, I (having more faith than "Sigma" in the "survival of the fittest") can by no means venture to predict that we shall always be Chinese enough to perpetuate even a system following the noble numbers no farther than those whose largest prime factors are 5, 7, or 11. We already have all these (the 7 in avordupois weight, and the 11 in long and land measure), and we might by combining them with the next prime (13) make the largest unit in any table the noble number 720,720, the most divisible under a million. Thus if we had, for the poor's sake, like most of our neighbour nations, a unit, mite, or lept (λεπτον) as small as the tenth of our penny, we could keep accounts by:—

60 lepts	= 1 tanner.		
360 ,,	= 6 tanners	= 1 deniar (*denarius*).	
2,520 ,,	= 7 deniars	= 1 guinea.	
55,440 ,,	= 22 guineas	= 1 min (*mina*).	
720,720 ,,	= 13 mins	= 1 talent.	

And each unit would have the most numerous *aliquot parti* or "practice-table" possible in its range, and the talent be the lowest sum having 237, two talents the lowest having 287, three talents the lowest having more, four the lowest having more, five the lowest having more, six the lowest having more, nine the lowest having more, ten the lowest having more, twelve the lowest having more, fifteen the lowest having more, twenty the lowest having more, and then 24, 30, 45, and 60, each a noble number of lepts. Only above this last do the numbers begin to involve the factor 17. Such a system (which need involve the calling in of no coin but the farthing) would lead to exactly parallel tables of weight and all kinds of measure, and be carrying out the ancient and truly scientific metric principle that gave us the arithmetic of "*Practice*," as far as I think it likely to be carried, whether under our rude denary notation, or the superior Chaldean sexagintal, that is certain (if there be "survival of the fittest") some day to displace ours. But supposing the fact of 2,520, being the highest of what I term "king numbers" (the highest that must be doubled to become more divisible), be taken as a sort of natural reason for stopping thereat as the highest unit, and so having no carryings of more than tens and sixes (as at present) and sevens, then it is somewhat notable that the largest English coin yet struck was for exactly this number of our commonest and practically lowest coin, the halfpenny (which has so long been so notoriously our copper unit that our name for coppers is neither farthings nor the short word pence, but "*halfpence*"). The *five-guinea piece* was exactly 2,520 "ha'pence," and (supposing we revived this fine coin (our present sovereign being, for a rich nation, one of the lowest maximum ones), and replaced the present two gold ones by its third and seventh (they might be called terce or bezant and sept or mark), and restored for the awkward "ha'penny" the name obol, we should have—

60 obols	= 1 deniar (half-crown)	
360 obols	= 6 deniars	= 1 mark (or sept)
2,520 obols	= 7 septs	= 1 min (*mina*)

And pounds would be reduced to these mins by simply adding a cipher, and the half of them, and halving the sum. Nor would any present coin become superfluous but the gold ones and the florin. The "practice-table," or list of divisors of this min, would be 47, that of the pound being but 19.

In the matter of names there is vastly more consideration required than projectors like "Philo" dream of, and I will explain, if you grant me a future column, the grounds for wishing the above names, especially "deniar," min (and talent perhaps) thus revived.

The most amusing thing is that "Philo" himself says he is "not convinced that a decimal division of days and hours will be better than that now in use"!!! Then, how on earth can he have discovered a decimal division to be better than sexagintal of anything else? Is not division division? He might as well say the decimals are best for weighing meat, but he is "not convinced they are best" for cheese! And does he not begin his next paragraph by telling us "of course the full advantages will not be obtained unless all weights and measures of things *to be bought* or *sold*, as well as money, are divided decimally"? Are weeks, days, hours, then, things not either bought or sold? That "money, value," and time ought to be divided "in like manner," he says I assert, "which is easier than proving." If, "in like manner" means commensurably, and proof is wanted that they ought to be so related, I shall certainly not deign to give more than "Philo" himself has. Moreover, so unlucky is he, that even the reason he offers me for use against decades of days is fallacious, and cuts exactly the other way! That 7 divides natural years better than 10, is the reverse of the fact. One year exceeds 52 weeks more than twice as much as 2 years differs from 73 decades, and more than the four (with their bissextile) differ from 146, and these make the nearest group of true years to a whole number of days under a century. The week (like the Bhuddist 60-day cycle) is purely *artificial* (which word does not necessarily imply *human*) and as for "a feeling" of anything "right as well as expedient," in the weekly rest, I challenge him to produce, apart from the Bible, one shadow of ground for either more right or more expediency in leaving a seventh of days for rest than a third or a three-thousandth.

On one point I will readily take "Philo's" word that, speaking out of book, my general denial of civilised decimalists before Marat was against a fact, and that "every one knows" the Chinese have remained so from "before history." He is entirely welcome to th[e] sapient example, which adds to the analogies I kn[ow] exist between the two wisest in their own conc[eit]

* Is this "parliamentary" or ordinarily civil? We think not. A correspondent may be in error without knowing it, but "a falsehood" involves intentional dishonesty. "E. L. G." is well able to defend his positions without the free use of offensive epithets, and we trust, for his sake and our own, that he will cultivate the temper which becomes the true philosopher.—ED.

nations. But having returned to that opening of his letter, I wish to know where is the "bad taste," of which he "will say nothing," in my quoting the glorious system's own originators? If anything be ushered into our world in an extraordinary way, with unique pomp—a birth, say, proclaimed by angels, or as this was, by most remarkable men, with unparalleled trumpet flourish, as pre-eminently this or that, or in the name of one or the other—in short, if a goddess brings us a glorious system, is she not to have the credit? Does good taste require the authors of a good thing to be ignored, and all their most vaunted reasons and views of its why and its connections? If you are advocating, say weekly rest, or trial by jury, do you keep Moses or Alfred out of view? Or if I am explaining gravitation, must I avoid the bad taste of either quoting or naming Newton more than once or at all? If the "metric system" be good, I repeat, glory to Marat and the Goddess of Reason. E. L. G.

DECIMAL COINAGE.

[3891.]—I have read with much interest the correspondence on the proposed change in our currency to a decimal system. I am strongly in favour of such a change. But if the change be made, so that 1,000 farthings equal one pound, and we reckon either by pounds and farthings or by pounds, florins, and farthings, why is there any necessity for giving any other name to the new 10-farthing piece than 10 farthings? A new name would be a useless element of confusion. In America, where they reckon by dollars and cents, the 10-cent piece, though called a dime, is yet in practice never named in calculations, or but rarely in retail transactions. I would suggest the following as the series of coins for the new decimal system:—Farthing; halfpenny equal 2 farthings; penny equal 4 farthings; 10-farthing piece equal 10 farthings; 20-farthing piece equal 20 farthings; shilling equal 50 farthings; florin equal 100 farthings; crown equal 250 farthings; half-sovereign equal 500 farthings; sovereign equal 1,000 farthings. The following method to be adopted for making the change:—First, withdraw all the half-crowns, and issue more florins; after that is done, and not until after, issue the new 10 and 20-farthing pieces; call in all the sixpences, fourpenny, and threepenny pieces, and enact the new scale of values. The new silver 10 and 20-farthing pieces to be respectively by weight a tenth and a fifth of the florin. When the people have got used to a decimal currency, they will very soon wish for a decimal system of weights and measures. To attempt to decimalise our weights and measures before decimalising the coinage is putting the cart before the horse. Moneta.

[3892.] — The remarks of your correspondent, "Philo," at the close of his letter (3806), being in purport very similar to mine inserted in your paper of the 22nd February, perhaps you will allow me to say a few words on one or two exceptions.

"Philo" proposes to call in the threepenny and fourpenny pieces, and to issue no more halfcrowns or sixpences. I should say it would be very inconvenient to have no silver coin between the shilling or half-florin and the cent. or chequer (which "Philo" proposes calling it, but which I fancy it would be better to designate a piastre, being about the value of the Egyptian and not very far from that of a Turkish piastre); and I would suggest that a quarter florin should still be issued. Half-crowns might be allowed to die out or wear out, but while in circulation would, of course, be 12½ cents. (piastres), or 125 mils (farthings); and the same might apply to the fourpenny pieces (of which there are few now in circulation, and those well worn), which might be used as one-half piastre pieces, or they might be withdrawn. The threepenny pieces must, of course, be withdrawn. A Subscriber.

COSTLESS VENTILATION.

[3893.]—A constant supply of fresh air is so important to our well-being, and in the prevention and cure of disease, that the subject needs no comment; an attendance, however, at any public meeting, is only necessary to convince how much this axiom is ignored —or if admitted, how unsuccessfully met; "crowded to suffocation" indeed, being the conventional term used to express a full assemblage.

For some time I recommended to my patients the plan of opening the window-sash at the top, and stretching out on a frame a corresponding depth of tarlatan, to intercept blacks and prevent draught; but the principle is wrong and the result unsatisfactory, as the draught is directed downwards on the sitter, and not upwards towards the ceiling; the screen, too, is anything but ornamental, and becomes clogged with blacks, so as to require removal and repair.

The method I now use is simple, economical, quite free from draught, and does not get out of order. Raise the lower sash of the window, and place in front of the opening at the bottom rail a piece of wood of any approved depth—from two to three inches is sufficient: this leaves a corresponding space between the meeting rails in the middle of the window, through which the current of air is directed towards the ceiling; heavy blacks cannot ascend with the air, which is driven so high as to be warmed before it descends; light blacks are not admitted in ordinary conditions of the atmosphere, though doubtless they are in cases of violent commotion caused by very high wind—the more the lower sash is raised, the more the difficulty of blacks entering between the meeting rails is increased. The principle may be modified in various ways, making the bottom frame of wire blinds supersede the strip of wood, or if this be placed above, and the top sash drawn down to a corresponding depth, the same result will obtain; in a word, open the lower sash of the window two or three inches, and block it up anyhow, and the air enters the space in the middle and is carried to the ceiling.

The opening between the meeting rails will doubtless be found to admit more air than the various patented plans so erroneously applied to the top of the sash, whether of wire gauze, perforated zinc, or glass louvres; and while I am satisfied of a constant current of fresh air inwards, I am disposed to believe that occasionally there is a passage of heated air outwards, in which case the latter is always at the sides of the window, the fresh air rushing in at the centre;—however, provision should always be made for the escape of heated foul air from the ceiling, through a large valvular opening in the flue or elsewhere.

It will be seen that this simple plan is adapted for the cottages of the poor and the mansions of the rich; in the latter, however, the draperies must be arranged so as not to interfere with the current of air towards the ceiling: it may be used in any weather, day and night, summer and winter; indeed, in the house of a medical friend, to whom I had demonstrated the plan, to insure constant action, the window of his reception-room has been nailed open, and the same is the case in several rooms in my own house during the milder months of the year; a modification of this plan may be adapted to French casements, by allowing the upper portion, generally fixed, to fall inwards on hinges.

But, although the above plan answers for ordinary daily ventilation for windows without overhanging drapery—at night, with gas in crowded rooms, it is not at all equal to the occasion; in these cases I adopt the following, also costless, very efficacious, and which may be used with overhanging draperies:—

At 9in. above the height of an ordinary person, say 6ft. 6in., place a small hook in moulding of shutter case farthest from the window on each side, and another 9in. below the moulding on each side, in front of window-sill; tightly stretch across the window a length of linen or calico, with small loops or rings to attach to the four hooks, leaving the calico 9in. larger than required to hang down loosely on each side; this forms, what is, I believe, technically called by architects a "hopper." Throw up the lower sash as required, and draw the blind down to the lower rail of the window-sash, wherever it may be. The air enters in full volume, strikes against the broad surface of the calico, and is directed upwards towards the ceiling. Here is the advantage of a window more or less open, with privacy, and without draught. When not in use this calico can be rolled up into a very small compass.

Costless Filter.—Take a flower-pot and plug the hole, not too tightly with a piece of sponge; add a layer of powdered charcoal about 1in. thick, then the same quantity of clean sand, and on that some coarse gravel. P. Hinckes Bird, M.D., F.R.C.S., F.L.S.

1, Norfolk-square, Sussex-gardens, W., London.

METAL MINES REGULATION BILL.

[3894.]—It is proposed to enact by this bill that an adequate amount of ventilation shall be constantly produced in every mine, so that the air shall be in a fit state for working therein. No attempt is made to define how bad air may be to be deemed fit to work in, nor how its state is to be tested; and perhaps in a first attempt it is expedient to leave this indefinite, and to be content with enacting that there shall be some ventilation, leaving it to the justices in case of complaint to decide if it be adequate. It would, however, be far more satisfactory if it were possible to enact that the proportion of carbonic acid shall not exceed a certain ratio, and perhaps some of your numerous readers can suggest an easy method of showing in a mine when such proportion is reached or approached.

Two methods have been proposed, assuming that the maximum proportion of carbonic acid should never be allowed to exceed ten times its usual proportion in the open air of about 4 parts in 10,000, which would be ·4 per cent.

Dr. Angus Smith suggested that half an ounce of limewater be shaken in a 7½oz. bottle, filled with air containing 4 per cent. of carbonic acid; as much carbonate of lime will be formed as if the same quantity of limewater were shaken in ten times as much air containing ·04 as much carbonic acid—*i.e.*, the same quantity of CO_2 in ten times as much air, and this quantity would render the limewater perceptibly turbid. The plan is as simple as possible, and the only objection to it is, that a mine, being a nasty dirty place, it is difficult to keep the bottles used clear, so as to render the turbidness of the limewater equally visible, a difficulty easy to overcome by those who wish to overcome it, but formidable if those who have to use the method do not wish it to be successful. Another plan: I have tried also to estimate the impurity of air by the length of time a candle will burn in a limited quantity of it, but without obtaining consistent results, chiefly, I think, because the flame differed in size, and, therefore, burnt up the air confined at different rates. Moreover, when the oxygen was nearly all burnt, the flame, instead of going out, became gradually smaller but still continued to burn, and the exact moment at which it began to fade could not be distinctly marked, but I do not despair of the difficulty being overcome or avoided.

I shall be very grateful, and the poor miners will be greatly benefited, if any one can devise a method by which the quality of mine air can be tested with approximate correctness, by some instrument, not too costly, which can be easily carried into and used in the level of a mine.

I have tried, but with only partial success, that of a lamp with only a limited supply of air, enough to burn brightly if the air be pure, but dimly if it be impure. The difficulty with this is to estimate by the eye the diminution of light of a lamp where there is no undiminished light to compare with it; moreover, other causes than diminution of oxygen affect the brightness of the light, and it is difficult to exclude all such sources of error—such as the exact length and quality of the wick, the condition of the tallow or oil, the temperature, and other circumstances unknown to me. Philo.

ATOMICITIES.

[3895.]—With Mr. Bottone's kind permission, I will take upon myself to answer "Mercuric's" letter (3801, page 11). To do so effectually I must ask "Mercuric" a few questions. 1. Has he obtained the vapour density of ammonium to enable him to affirm, *ex cathedra*, that its formula is $\begin{cases} NH_4 \\ NH_4 \end{cases}$ instead of NH_4? 2. Does not Mr. Bottone, in his table, refer the valencies of the elements to that of hydrogen, and has "Mercuric" ever prepared NH_5 PH_5, &c., that he lays down as law that nitrogen and phosphorus are pentavalent. 3. If, as "Mercuric" has been "led to believe," the five atoms of chlorine are directly combined with one atom of phosphorus, in phosphorus pentachloride, how does it happen that its vapour density is 104·25, instead of being 208·5? 4. Can "Mercuric" make the vapour densities of ammonium chloride NH_4Cl, cyanide NH_4CN, sulphydrate NH_5S, agree with their calculated molecular weights? Until he can do this, I fear he is much more astray than Mr. Bottone, who at least honestly tells us not to place too much trust in any of the existing hypotheses. N. Du Fai.

CONTACT OF COMETS WITH THE EARTH.

[3896.]—Some numbers back remarks were exchanged on the question whether the earth had increased in bulk by extraneous deposits since the creation, the result of which was an assertion from "E. L. G." that there was clear proof of comets having come into contact with the earth in former times; and what still more surprised me was the apparent certainty with which he looked upon a flood as at least one of the results of such contact. That comets should at times come in contact with the earth might have been expected; but what of the supposed result? I write this because the correspondence has ceased without any explanation, or any remarks on the subject by other correspondents. I venture, therefore, to call "E. L. G.'s" attention to it, and request him to favour us with all the information on this interesting subject which he is able to furnish. J. C.

REMARKABLE ELECTRICAL PHENOMENON—LIFE IN DARKNESS.

[3897.]—I think Mr. Highton (letter 3808, p. 13) will find in Faraday's researches that Faraday paid a good deal of attention to this matter, and came to the conclusion that a wire so circumstanced acts as a Leyden jar. In fact, all partially insulated wires behave more or less in this way.

I would call the attention of those of your readers interested in this curious subject, life in darkness (letter 3821, p. 15) to the fauna and flora of our cellars. There are many cellars to which not a ray of daylight ever penetrates, and rarely illuminated by lamp or candle, yet inhabited by numerous spiders, which cannot live by eating one another. In one cellar I visited I never could find anything caught by their webs. The water mains in London are said to contain enormous quantities of some species of polype, and in them there must be absolute darkness. The spiders I mention appear to be of the kind forming cobwebs elsewhere inlight but what flies into their nets is a mystery to me. M. Paris.

BOILER CONSTRUCTION AND MANAGEMENT.

[3898.]—I have much pleasure in offering "T. L. F." (letter 3813, p. 13) my advice, assuring him that it is practical, and for the most part based upon experience. In the first place, I think his variable eccentric may be very ingenious, and might answer his purpose, but I think the matter may be very much simplified by putting a valve close to the boiler and having a return pipe (between that and the pump valve), with a tap in it, so that by partly opening the tap the surplus water may be returned to the feed water cistern; after a few trials you will be able to set the tap so as to just supply the waste, and it will require very little attention.

With regard to the boiler I certainly should not advise a copper one, as the cost would be very considerable, and unless he is very young, and means to live to be very old, I think a good iron boiler would last as long as he is likely to need one.

If "T. L. F." means to have a self-contained boiler I should think a vertical one would suit him, as they take very little room, and make steam rapidly; he might have a valve in the chimney (like a throttle valve), which could be worked at the lathe by the aid of a little cord and a few pulleys.

I am daily using an engine (for driving an 8in. centre screw-cutting lathe) that I believe would just suit him; it is a horizontal engine, the cylinder is 11in. long and 3¾in. diameter, and with the steam at 50lb. is capable of driving two or three lathes. If you only want to drive one lathe, of course something smaller would do. Screw-cutter.

DUST IN SPECTROSCOPE.

[3899.]—The longitudinal lines referred to by "A Fellow of the Royal Astronomical Society" (letter 3796), as seen in the spectroscope when the slit is nearly closed, are due, I think, not to particles of dust adhering to the edges of the slit, but to imperfect polishing of one or more of the prisms. The surface of the glass evidently retains traces of the emery cuts, which, although exceedingly fine, are quite perceptible when viewed with the least possible quantity of light admitted through the slit. Having seen these lines repeatedly in one of Mr. Browning's star-spectroscopes, I came to the above conclusion, which is, I think, the true solution. Mr. Browning will perhaps tell us.

F. Bird.

THE METRIC SYSTEM.

[3900.]—Having waded through the three or four columns contributed to this subject by "E.L.G.," pages 36 and 37, it seems to me they can be resolved into the expression of some few mathematic crotchets, and the very compact assertion as to the metric system, that "its vaunts are ludicrously false, its failure more than remarkable, unique, ironical, almost supernatural." "E.L.G." is really a very clever fellow, and one of wide if rather superficial information; but I must submit that his style of scientific argument is only fitted for a circle of ancient maidens enjoying their tea flavoured with brandy instead of milk.

It is pure childishness to rave and foam in this fashion, and to suppose that mere contemptuous reviling will prove a system to be absurd which has gained the approval of the great majority of scientific men, and is steadily forcing its way into practical adoption in commerce, notwithstanding the serious objections to a change which must cause great temporary inconvenience.

There are only two modes of treating the subject—viz., the scientific and the practical, and these two must be connected together. If we were commencing the world anew, and arranging a perfect system to be employed by new created man, such arguments as are employed by "E.L.G." might be worthy discussion, and we might weigh the relative merits of decimal, duodecimal, sexagesimal, &c., notations; but the world counts by tens, and we may pretty safely assume that the world will count by tens for a good many ages yet to come, if not as long as man himself endures. It is, therefore, utter waste of time to discuss the advantages any other system of notation might have. Therefore we need not discuss any more whether the duodecimal notation which "E.L.G." calls a "preposterous mare's nest" is any better or worse than his favourite Assyrian double notation by 6 and 10, which appears to me to be a preposterous complication. One thing is perfectly certain, whichever may be better or whichever worse, the world will have nothing to say to either of them.

All we have to do, then, is to settle how we can make the best use of our ten figures and the arithmetic based upon them. Men of science have answered that by reducing all measures they use to some decimal system. They either adopt the French system, or they use a grain or a pound as their unit and decimalise from it, ignoring all other weights; or if they try to adopt the English system, they use Griffin's septem (7 grains), referred to by Mr. Allen (p. 37), as the unit, being a decimal division of the pound and gallon, and therefore convertible into common measures; but they entirely ignore those measures themselves, that is to say, they are unanimous as to the necessity for a decimal system. Practical men would be equally unanimous if they once tried such a system—that is to say, no human being would ever think (except some occasional fantastic dreamer) of changing from a decimalised system to any other. The one only reason against adopting a decimal system now is that the change would involve great inconvenience, and this applies to any change whatever, equally to any of "E. L. G.'s" fads, to any decimalising of existing weights and measures, and to the French system.

If this be so (and few will dispute it), the base of a new system, the unit, is perfectly indifferent; we may with equal advantage adopt the metre, the foot, the cubit. All we have to care for is to establish a standard unit; so also whether that unit is a rod of platinum carefully preserved from injury, or the width of the doorway of St. Paul's Cathedral, or the length of a pendulum at a given spot, is equally a matter of mere detail, argument about which is only scattering dust about the true object of any importance. Let us suppose we have to decide whether the English foot shall be used or the French metre. We know the foot very well; but when we divide it into tenths instead of inches, or when we multiply it by 10 or 100, will not the new denominations be equally strange, the change of calculations equally great as though the metre and its consequences had been substituted for the foot? If we take the cubic foot for our base of capacity, will our market women be less puzzled over the loss of their familiar bushels and pecks than if they were asked to use the litre.

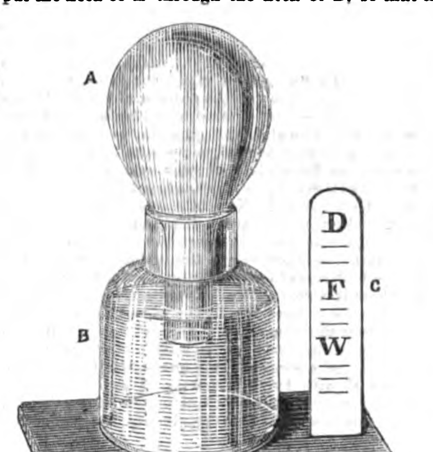
The foot, we are told, is common to England, Russia, and some other nations, and we are invited to use this for their convenience. What results? We go through all the nuisance of a change, retaining only one familiar link to the past, and after enduring all the nuisance we have a system in only limited use, unless we can persuade all the rest of the world to go through a similar trouble by changing their whole system. The rest of the world would say: No, gentlemen, we have shown you the way, we have already the decimal system you intend to use, we are satisfied with our unit, take it and the system together, and follow our example; don't suppose we will again go through the heavy annoyance of a change, in order to enable you to gratify your pride by forcing the English foot upon the world; you had much better follow the good example set you, and adopt the French metre, already adopted by many nations and by scientific men all over the word.

There might be plenty of units devised far superior to the French metre, and for scientific purposes a new modification of some parts of the system will probably be employed in order to correlate the measures of force as well as matter to the atomic system of nature, but the practical considerations I have set forth entirely dispose of all such questions. We must take the metre or stay where we are.

Sigma.

SIMPLE WEATHER-GLASS.

[3901.]—I have had a weather-glass like sketch in use for twelve months. It acts very correctly; A, Florence flask; B, pickle bottle. Well wash the grease out of both glasses. Now pour clean cold water into B, put the neck of A through the neck of B, so that the



end of A is 1in. below the surface of the water. That done, the weather-glass is complete. Directions for reading:—Let it stand for a day. When the water is half-way up the tube it denotes fair weather, when at the top dry, when at the bottom wet. For the other points you must notice its movements. C is the scale. The best place for it is in an out-house.

W. Bright.

ORNAMENTAL TURNING.—VII.

[3902.]—Next to the spiral twist for ornamental purposes, fluting has a very neat appearance. The work to be fluted must be finished off in the lathe as for plain turning. The article should also be turned lighter than work that has to be twisted, for the reason that only a small quantity of the wood is removed by fluting. The best tool for the purpose is a ⅜ or ¼ turning, or some may prefer carving, gouge; but it must be borne in mind that the gouge should be ground somewhat different to that for turning purposes (I am now stating what I deem to be the most workmanlike manner). To the general turner, who is oftentimes pushed for a moment, certain makeshifts are made which should not be tolerated by an amateur. I have myself frequently turned a column and fluted the same at one operation with the same small gouge; but no doubt I could have done the job in a more workmanlike manner with proper tools.

A

The best mode of proceeding is this:—Having prepared the work by turning, papering, &c., mark out one, two, or three strands, same as for twist (the tool described a few numbers back will be the best for those unused to marking out; to the general turner in common work marking is not required); when marked, the only skill required is to remove the lines so marked with a sharp gouge, ground so that it presents more of a square face than for turning. It is chiefly at the top and corners where it cuts. Care should be taken that the cut is of equal depth from top to bottom. The pulley should be held in the left hand, the gouge in the right hand, resting on the T rest a trifle above the centre of the work. The handle of the gouge should pass under the right arm; by so doing it helps to steady the gouge and facilitates the cut of the flute. The gouge should be held at the same angle as the mark on the work, the gouge held firm, the pulley gently moved round at the same time cutting the work with the gouge. Afterwards finish off with glass-paper and a piece of deal cut in the shape of a wedge, called in the trade a burnisher; it will cause the work to shine; with a little practice, fluting can be easily acquired. In a future number of the Mechanic I will send sketches of a few chucks for different purposes, with the use of the same. I have spent a deal of time since I had first to do with the trade of turning upon different chucks. My idea, always prominent, was to do as much as possible in the lathe, thereby saving an amount of hand labour. To tell of my failures would amuse some of "our" mechanical readers no doubt, but as that would not instruct, I shall only state what I know to answer. It behoves all of us to moot any new plan, but at the same time it should be stated that it has not been tried, thereby saving inexperienced persons both time and money.

I send for the editor's approval a sketch of an aquarium stand. I turned hundreds of them for the trade some eighteen months ago; they are very simple, and any person at all used to the lathe can manufacture one. Materials required: Square piece of wood (mahogany has the best appearance) about 6in. square on the face, by 4in. deep, a piece of board 10in. square, 1in. thick; turn as pattern, the top A should be hollow, same as a saucer, with a 2in. hole in the centre 2in. deep; the bottom of the piece should be turned with a rabbet to be fixed in a hollow turned in the bottom. When finished, taken out of the lathe, and fastened together by means of two screws underneath. A common bell-glass, to be purchased at most glass warehouses, makes a very neat aquarium, with a little shingle and a few weeds—a pretty window ornament for the summer months. I may here state for our readers' information that a 12in. bell-glass can be purchased for about 2s. or 2s. 6d., and will hold a pail or more of water.

My attention has been called to your remarks in "Answers to Correspondents" in favour of a Practical Amateur Turners' Society in London; being a cockney myself, and having acquired a knowledge of wood-turning, and its intermediate branches, I would have no objection to forward such movement in London. If "March" has a few friends of the same mind, who will advertise their address, I will communicate with them with a view to form such society as required. At present I am connected with the sawing trade, being proprietor of a Band and Circular Sawing Mill. I have had also considerable experience with societies in general, being secretary to four societies at the present time.

Samuel Smither.

LIGHTNING CONDUCTORS.

[3903.]—Referring to "Philo's" letter (3846, p. 39), King's Norton, called commonly Norton-by-Galby, or simply Norton, is 6¾ miles E.S.E. from the centre of Leicester town. The spire was totally thrown down, and, I believe, every stone split from dowel to dowel: these were copper. The tower was split in front as far as the clock, which was about on the level of the roof. In my letter (No. 3793, p. 668), I used the word steeple for tower incorrectly. The repairs, without re-building the spire, cost, I think, over £400.

"Philo" should recollect, when he says that I used a common but inaccurate expression, that the actual words I used, see letter 3793, and used intentionally were "the fluid or whatever you call it" made a hole. Now, though ignorant I am meek. I did not presume to say that the lightning was a fluid and made the hole, nor that the expansion of steam produced from the water of crystallisation in the hydrate of the mortar by the action of electricity did it; not yet that a repulsion of particles, produced no one knows how (for "Philo" admits he does not, see p. 39), did it. I merely stated that there was lightning (so-called) and a hole, evidently due to its action. I remember the hole was much bigger inside than outside the tower. If "Sigma," who knows well at least what is the opinion held at the present day about electricity and its action, were to tell me that it is a fluid and does the work of a solid, I should bow to his authority without arguing; and, *mutatis mutandis*, do not intend to argue it with "Philo," nor bow to his authority either. As he has omitted to give any answer to my question in letter 3793, first line, I will observe that I have an impression that Ferguson in his "Electricity" makes the statement that surfaces conduct, or else that the power of conducting is proportional to the surface: I think the former, but it is thirty years at least since I read the passage. I doubted it then, and disbelieve it now. If he were speaking of something very thin, like tinfoil; then the surface and section would vary together, which might account for the statement being made, even if it is not true generally. I should like to know whether it is or not. I will give "Philo" another chance of answering a question—viz., this: Is he quite sure that under any ordinary circumstances an electrical discharge (including lightning) through water, produces steam enough to do any damage? Or, putting it another way, does he mean to stand by the statement made in lines 6, 7, 8 of his letter 3846, which includes substances only partly charged with moisture, or saturated therewith?

J. K. P.

WHAT HAS BECOME OF THE PSYCHIC

[3904.]—Some
comments on M
challenge to
"psychic forc
claims. Mr.
certain exper
him. These
the exhibitio
to have bee

As these gentlemen expended a large number of words, and no small amount of temper without agreeing, you suggested that similar experiments should be made in the presence of competent and reliable witnesses, when no mistake could be made as to what did or did not take place. You also offered this meeting of scientific gentlemen a room free of expense, and every opportunity of eliciting the truth. The only condition you insisted on was that the experiments, whatever they might be, should be performed in the light. I have been anxiously watching our World of Science from that time to the present to know the result of the offer. I fully expected that Messrs. Crookes and Varley would have met you on your own terms, but I have looked, and looked in vain. I suppose that negotiations must have commenced and been broken through because you could not agree upon terms. If so, I for one would like to know wherein you differed, or what is the cause of the experiments not having been made, or if made, what is the result. I cannot believe that the spiritualistic or "psychic force" party so lacked courage or confidence in their newly-discovered principle as not to come up to the scratch. But whatever the cause of the silence, I think an explanation of some sort is due to your readers all over the world, and I hope, Mr. Editor, you will vouchsafe to enlighten us at your very earliest convenience.

A Member of the Society of Arts.

[The truth of the matter is we have no information to impart, and no explanation to give beyond the fact that Mr. Varley and his friends never accepted the challenge, and we have heard nothing of them in any sense. We suppose they considered "discretion the better part of valour."—Ed.]

SUN'S DECLINATION.

[3905.]—Henry Wood (qy. 11360) can scarcely have read the "trashy explanation" to the *Nautical Almanac* with sufficient care. However, the following will, perhaps, be sufficient guide for him. Should he require the sun's declination for transit over any meridian other than Greenwich, he must first find the variation in one hour of longitude for a time midway between the meridian required and that of Greenwich, and multiply this variation by the difference of longitude, and apply it with the proper sign to the sun's declination at Greenwich transit, which will give him the correct declination for the meridian required.

Example. Required the sun's declination at transit at Quebec (long. 4h. 44m. 49·02s. W.) on April 8, 1872. The long. being W., take the difference betwen the variations in one hour for April 8, and succeeding day—viz., 0·32", the proportional part of which for 2h. 22m. 24·51s. (*i.e.*, midway between Greenwich and Quebec) is 0·03", which, subtracted (because the variations are decreasing) from 55·89", the variation for April 8 gives 55·86" for the variation required. This quantity, multiplied by the difference of longitudes, gives 265·2", which, added (because the declinations are increasing and the long. is W.) to the sun's declinations on April 8) gives N 7° 30′ 9·9" for transit at Quebec. Should the declination be required for any other time than at transit, find the corresponding Greenwich mean time, and proceed as before, taking care to apply the correction found to the sun's declination given on p. 2 of the almanac, which is for Greenwich mean noon, the variations being assumed the same for mean as apparent noon. Henry Wood will perceive that the variations given in the almanac are for the instant of apparent noon, and represent the sun's motion in declination through the period, a half-hour before to a half-hour after transit, and by finding the variation midway between Greenwich noon and the time required he is virtually correcting for second differences, and his results are obtained to the utmost nicety.

If our querist will take the trouble to look at the later *Nautical Almanacs*, he will find instead of less information being given a much larger amount is now contained in them, notwithstanding the actual number of pages is less, which has apparently been achieved by a closer arrangement of some of its details. For instance, I am now looking at the almanac for 1875 (the last published), and observe that the list of the Elements of Occultations has been given for all stars down to magnitude 6½ instead of magnitude 6, and the consequent number of stars increased from about 500 to above 1,500 per annum, also that the variation in 10 minutes is given for the moon's R.A. in addition to the variation in declination previously given, which will enable the astronomer to calculate the moon's position at any intermediate time with the greatest precision, and including the effect of second differences by the same method as that explained above for the sun's declination. Also, that the independent star constants (as they are termed) for correcting the places of stars, are given for each midnight throughout the year, instead of each fifth as formerly, a very great boon to professional astronomers who wish to get the mean place of an uncatalogued star. The positions are given daily for five circumpolar stars instead of two, and are, moreover, fully corrected for nutation, and in the moon culminating division the moon's semi-diameter and horizontal parallax is given at transit, thus avoiding the trouble of interpolation from the noon and midnight values given at p. 3 of each month. I think that Henry Wood will see that he has been rather rash with his statements respecting the quantity of information given in the almanac, and will likewise inform him that I have understood that the explanation he terms "trashy" was compiled by the highest professional and nautical astronomers for the use of seamen, and has been universally praised for its clearness, and pronounced adapted to the meanest capacity.

Altair.

THE ORGAN BUILT.—NO. VII.

[3906.]—After carefully getting the whole of the top fold finished, as directed in my last letter, proceed with the lower fold; begin by fastening the ribs to the middle frame with the tape, then put the leather on over the tape, and allow it to dry; now lay the middle board of the bellows on the bench with the trunk band upwards, and fasten the ribs to the tape in the same way, and put the leather on over; when dry, turn the bellows up again, and begin with the feeder; get two battens 2ft. 8in. long, 3in. wide, and the same thickness as the ribs, fix one firmly on the feeder board at the end where it is to be hinged to the middle board; the other is to be fixed to the middle board, but under it in shallow grooves fix four pieces of webbing; nail the webbing to the middle board, then glue and screw the batten over it; the webbing must be left long enough to turn down to the feeder board, to which it must be firmly attached, as shown in Fig. 1; then along the joint glue a piece of leather both inside and outside; now proceed to fix the ribs in the same way as directed for the lower fold of the reservoir; when dry open the reservoir to its full height, and cut out a pattern in paper of the four corner pieces for the lower fold; then, when you have got the pattern nicely to fit, cut your corner pieces out of unstrained leather, pare the edges all round neatly, and glue on, well working it down at the corners and edges; a small cut will have to be made in the middle of each side of the leather where the two ribs are joined, so as to get the corner piece to lay flat on the rib. Now take one of the strips of leather, such as the ribs are fastened together with, and cut sixteen pieces 2in. long; pare the edges neatly, and glue a piece over each cut in the middle of the corner pieces on both folds to prevent any leakage there; when neatly done it gives a nice finished appearance to the work; when dry, open the feeder wide and put on the corner pieces the same way. Now get a piece of inch board 10in. × 8in., and in the middle of it cut a hole 5in. × 4in.; get a piece of three-quarter stuff 6in. × 5in. and cover it with two thicknesses of leather, leaving the leather projecting an inch at one end for a hinge; now fix this over the hole by glueing the projecting

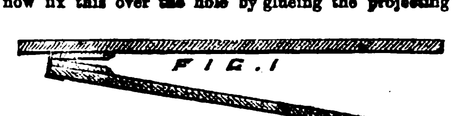


FIG. 2

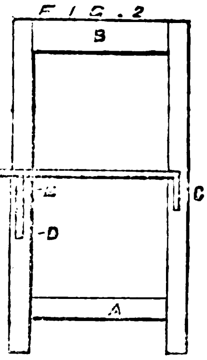


leather firmly down, and over it nail a thin piece of wood; bore a hole in the middle of the valve large enough to let a piece of tape go through; fasten one end of the tape to the middle board of the bellows, put the other end through the hole in the valve, then firmly screw the valve board with the valve to the inside of the bellows down on to the top board of the bellows over the hole left for it, a thickness of leather being placed between the boards to make it air tight. Now try the bellows; having closed the holes for the wind trunk, place a weight of thirty or forty pounds on the top, and if your work is good the bellows will be nearly a quarter of an hour going down; ascertain what height you want the bellows to rise, and tie a knot in the tape at that height, so that the valve may be pulled open if the bellows rises beyond that point. While the bellows is inflated, carefully examine it to see if there are any leaks, and stop them, as afterwards it will be difficult to do so. Now proceed to get out the stuff for the frame. For this purpose you will require four pieces of stuff 3in. × 3in. and 4ft. 4in. high, two rails of inch stuff 4ft. 9in. long and 4in. deep, also two rails of inch stuff 4ft. long and 4in. deep, and two more the same length, but 6in. deep. Plane all up true, and tenon two short rails into the posts, the top of the bottom rail being eleven inches from the ground, and the other being level with the top of the posts. Be careful to place the deep rail at the top for the windchests to lay upon; these two pair of rails and posts make the ends of the frame. Next tenon the long rails into the posts, the rail at the back to be 2ft. 5in. from the ground, the front one to be 2ft. only. Get out two pieces of ¾in. stuff, 4ft. 8in. long and 7in. wide, lay one end on the back rail, and to keep it level, fix a block (the same width as the board and 5in. deep) on to the front rail. Screw these two pieces down to the rails exactly 2ft. 6¼in. apart, which is the width of the keyboard, so that the frame of the keyboard will rest on these boards, and the keys will be between. Fig. 2 shows how the frame is put together. A, bottom rail for bellows to lay on; B, top rail for the windchests; C, back rail to support keyboard, &c.; D, front rail; E, block to keep key rail level.

With regard to the feeders described by "A Young Organist" (3746), they are well known, only in his drawing he shows springs to close the valves, which will not answer; but as in my letter I am describing one specific instrument, I do not think it wise or necessary to show in how many ways it may be made. In all probability, if six organ-builders should build such an organ as I am describing, we should find six different patterns. The French feeders are powerful and good, but cannot be blown by the foot.

J. D.

SPONTANEOUS COMBUSTION, ELECTRICAL, MAGNETIC, &c.

[3907.]—(10941.)—Spontaneous Combustion.—I will readily grant "Manus" the excuse he asks for, on condition that he will equally excuse me for informing him that he has introduced two elements tending to assist spontaneous combustion (if such a thing really exists), which did not enter into the original query, and were not, therefore, taken into account in my reply—viz., the immediate presence if not absolute contact between the oily waste and a metallic substance, and secondly both exposed to an Indian sun. Neither of these conditions were presupposed by the querist, nor would they be suspected by the general reader; but had they been so, and as I have never been at Poonah, and therefore knew nothing of the habits and eccentricities of the men who are employed in the gun factory there, I am not in a position to deny either of the statements made by "Manus" of the two cases coming under his cognisance.

But I must record the implied facts that "Manus" is not in a position to contradict me, as in the first place it was the man who used the oily waste, and not "Manus," who witnessed the phenomenon, if it really occurred, and "Manus" could not have been present in the second instance, or he would not have given £5 to a man for giving the alarm of fire! I presume, in my ignorance of the customs of Poohnees and other Indian tribes (with whom "Manus" is familiar), that they never indulge in the vile habit of smoking, indigenous to the barbarian practices of European or American workmen; and, therefore, a stray spark from a contraband pipe could neither have assisted the sun in the case of the oily waste nor the linseed oil in that of the saturated sawdust? For my own part, I have never seen nor heard of a true case from a competent eyewitness that would lead me to believe in what "Rube Rawlings" calls "Spuntainyas Kumbuxshun," either in the arid wastes of the "Praiaree" or the handful of cotton waste exposed as the original querist indicates.

(11188.)—Arithmetic.—Sir,—The circle squarers, lunarian rotatists, and Parallaxians have been driven ignominiously from your pages into Lethe. Spare us then, oh! spare us from a re-inundation of nonsense-mongers — worse if possible than any or all of these—viz., the "multipliers" of £19 19s. 11¾d. by £19 19s. 11¾d. Never did Phœnix rise from its ashes with greater certitude and perseverance than does this nonsensical evidence of untrained mathematical reasoning. "Ours" has already in earlier numbers teemed with it—and what scientific journal has not been bored with it *ad nauseum*? For the love of those who would "live and learn," in mercy place a *veto* upon it.

(11295.)—Electrical.—I do not think I misunderstood "Forked Lightning," since by desiring to exhibit 12in. sparks he is evidently more desirous of showing the more glaring effects of electricity than communicating the principles upon which the science is based. All the phenomena necessary to be exhibited to an audience, say of 300 persons, in order to convince their eyes as well as their ears in a lecture, can be as well produced by a disc of ebonite 12in. diameter giving a ½in. spark under favourable circumstances, as by the largest machine yet manufactured, and with the additional advantage of the lecturer running no personal risk, even by misadventure. When the London Panopticon was in its glory in Leicester-square (shame to the metropolis that allowed such an institution to be degraded to its present level), it possessed, I believe, the largest plate machine ever made and the phenomena produced by it were truly striking and magnificent, and great and earnest was the applause drawn from adult and juvenile spectators at every new effect produced. Yet I dare venture to aver that vastly more real knowledge of the science of electricity was not only communicated to but instilled into the minds of his large audiences by the six so-called "Lectures to Juveniles," given by Professor Tyndall a few years ago at the Royal Institution's Lecture Hall, and if I remember rightly, the most costly and elaborate instrument he used was a large glass tube and a thick stick of sealing-wax—more real knowledge, I say, was communicated than the monster machine ever afforded from the day of its construction to the present date. The Winter machine was fully illustrated and described in an early volume of the English Mechanic, but I have not time just now to refer to it.

(11311.)—Electric Bell.—One "Lelanche" should work a bell if properly constructed—that is, the arms of magnet wound with a large number of fine wire helices. 2. A cylinder would be preferable to a wedge of zinc, as offering greater surface, if the other conditions of construction admit its use. 3. No. 16 wire would be ample, or ordinary iron telegraph wire, if more readily obtainable, insulated would do equally well, but would be less pliable for indoor fixing. 4. For indoor work, and only such a short circuit, a return wire would be far preferable and more reliable than an earth plate; I have recently seen some triple coated cotton wires admirably suited for indoor work, as the two wires can be twisted together where they pass through a wall, requiring but a very small orifice through the wall, and yet giving very fair insulation.

(11327.)—MONSTER MAGNETIC MACHINE.—Although addressed directly to Mr. Sprague, I feel that gentleman will forgive me for saying a few words in reply to this query. In the first place, I think, Siegm. Raudnitz, of Bohemia, ought, when such large sums of money were at his disposal, to have ascertained as a fact beyond doubt that a small machine of Browning's was "capable of producing ten cubic feet of oxygen per minute," and in a case where such a sum as the monster would require, the purchase of one of these small machines would not involve an unnecessary outlay in order to determine the fact. The principle thus once proven, over a fair space of time and not by got up séances, would be worth all the opinions of all the electricians the earth has given birth to, and nothing more than a mere question in simple proportion or two would be required to guide "S. R." safely as to whether he should speculate his thousands in a single monster or a given number of small machines of definite capacity tending towards the effects he desired to attain. These data settled definitively in his own mind, I scarcely think it credible that a nation who have supplied a Britannia tube over Menai, a bridge across Niagara, a Great Eastern steamship, or even that trifling little matter called the Atlantic Telegraph, would fail in utilising the proferred capital (under good security), so that all "S. R.'s" wishes might be fully realised. There is surely a link wanting somewhere that "S. R.," of Bohemia, must supply before "any fellah can understand" his axioms.

(11835.)—TO MR. TONKES.—It is not only my opinion, but my absolute belief, that $\frac{1}{0}$ is a true mathematical representation of infinity in so far as a finite mind can form a conception of infinity. I am not inclined, and much less is it my intention, to be drawn into the metaphysical inquiry of "infinite divisibility," to which the query of "S. J." evidently tends. If he wishes for a full development of the expression used, I must refer him to Liebnitz or De Morgan's "Differential Calculus," or, better still, to E. A. Poe's "Eureka"—in either of which he will find ample room for study for his genius instead of wasting it in playing bagatelle with symbols, which have neither definite nor defineable meaning. I can believe in one infinity! of two I know nothing, and believe less if possible. "Infinity within, infinity without, below creation," vide P. B. Shelley for details of demonstration. He wrote metaphysically, I tried to do so mathematically.

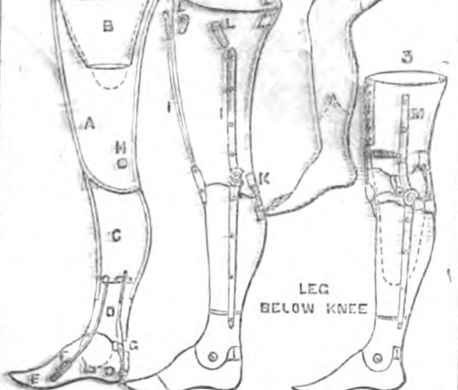
(11846.)—I am sorry that my time is so limited just now that I cannot comply with the request of "T. H.," especially as I have in one of the early volumes given full details and drawing of Siemen's coil, which was, I believe, the first practical development of Poggendorff's theoretical view of how a coil should be made; he certainly hit the right nail on the head, and Messrs. Siemen drove it home. The use of the discs is simply to divide the secondary into as many separate compartments as you desire, which will depend upon the length of wire used and the effects supposed to be obtainable at the terminals. Their position is transverse to the axis of the fasciculum and primary coil, so that they form, in fact, a series of secondary coils, each insulated by the discs from its neighbour, thereby avoiding the danger too often experienced in coils (as ordinarily wound in successive layers) of the static inductive charge, set up in the secondary, flashing back to the primary or the fasciculum, instead of becoming developed through the extremities or poles of the secondary, electricity always choosing, by "natural selection," the shortest path to equilibrium or a state of quiescence; the natural result being either destruction to your insulation, or quite probably disruption and melting of the secondary wire itself; whereas, if your secondary is divided into a series of coils by ebonite discs, the disruptive discharge would only affect seriously one or two, at most, of the coils, leaving the rest uninjured; and as I before stated the injured ones can be readily replaced, as compared with rewinding and insulating a whole coil. I mention the disruptive discharge incidentally, but I do not think it possible for any such phenomenon to take place in a coil with the secondary so divided; and the facility of cure is equally easy, let the fault arise how it may—therein lies the advantage.

(11818.)—GRAVITATION.—A vacuum, per se, does not affect the force of gravitation, it simply removes the opposing resistance of the atmosphere, which in some cases, such as the light down of feathers, soap bubbles, balloons, &c., is so great as not only to counterbalance gravitation, but to give the appearance of the existence of an opposing force (repulsion) even greater than attraction itself, causing such matter to rise from the earth instead of falling toward it. Take away the resistance of the atmosphere (that is, form a vacuum), and down plumps any or all these buoyant substances with the same velocity as the heaviest metal—viz., that due to the unresisted force of gravitation. "C. W. H." must remember that the same sovereign can be drawn out into such a state of tenuity that it would fall even in the open air no more rapidly than the feather. Well now, that is just what nature has done with the material of which the feather is composed, for a very wise and apparent purpose. The whole rationale of this subject was fully discussed, and all the difficulties attending it explained away, in one of the early volumes of "ours;" the discussion was, however, somewhat ludicrously brought to a termination by the original querist (being unable to comprehend the arguments adduced) naively inquiring "how is it, then, that a plank loaded with bullets does not rise up through them as the same plank would through water, it being specifically lighter than either the water or the bullets?" It was supposed the querist had been "raised" in Mobile.

WM. TONKES.

ARTIFICIAL LEGS.

[3908.]—THE subject of artificial limbs has more than once been referred to in the ENGLISH MECHANIC. I was invited a short time since by a poor man, whose son had the misfortune to lose his leg, to contribute through the medium of its columns some information on the subject. "S. H.," in his query of March 8, says:—"I suppose it is too much to expect manufacturers to give instructions," &c. There are some, no doubt, who would be reluctant to do so. As a subscriber, and one who has benefited by the information imparted by others, who have been always ready to answer any query I have sent, I feel pleased to give you my experience on this subject without feeling that I shall sacrifice anything by so doing. In writing this article, if I may call it one, for the better understanding the subject, I will divide it into the following sections:—1. The human leg and its principle of construction. 2. How and by what rules an artificial leg should be made. 3. Amputations, and the points at which to amputate when the surgeon has the option. 4. The construction of legs. And lastly, the fitting and adapting them to individual cases. First—the human leg. The legs of the body correspond to two pillars, the heads of which are secured in their sockets at the pelvis or large basin which takes the abdomen. Upon the pelvis is reared the spinal column and head. This upper structure is supported by the legs or pillars beneath. Now, these two pillars do not run down vertically from their head or socket; if they did the feet would be as wide apart as the hips, but the thighs from the hip joints diverge in towards the knees, so that the knees almost touch. This divergence or incline inwards is more in women than in men, as the pelvis is wider on account of the extra weight they have sometimes to carry. From the knees the legs run down vertically, almost to the feet, so that when a man stands properly erect his feet stand pretty close together, but to make the base firm the feet turn outwards to widen the base of standing. If you stand erect and bend the knee forward and look over it at your toes, you will find that the great toe is almost in a line with the outside of the knee, leaving the foot its width outside of the knee. These, then, are just the curves given to the natural leg



that the gravity of the body may be well sustained. I would next say a few words about the joints in the leg. The knee joint is a simple hinge joint, the centre of which is eccentric—that is to say, the centre of the knee joint is not in the centre, but extends back towards the back of the leg. Thus, when a man is standing erect the swell of the thighs stands almost in a line with the toes (see dotted line No. 1). Thus the gravity of the body falls in front of the knee centre, and the knee, so to speak, becomes locked; thus he stands at ease in perfect comfort and safety. The ankle joint is a simple hinge joint with a little lateral motion; the toes also are a simple joint. The foot in construction resembles an arch, on the centre of which the leg bone rests. Thus the leg bone does not come down in a line with the heel; if it did the foot would fall every time with a thump, and jar the whole upper structure; but the heel, which is one of the abutments of the arch, projects back; thus in walking the point of the heel touches the ground first and pitches at an angle; thus the foot falls gently down, and the jar is broken as soon as the foot is flat, the tendon Achilles draws the heel up and throws the body on the great toe, which becomes the pivot on which the body moves and turns. I have given just in this simple way the construction of the human leg—what I may call its mechanical part, in which points an artificial leg is materially affected, and the closer we keep to the natural limb the more perfect we become in constructing an artificial limb.

2. How and by what rules an artificial limb should be made. An artificial leg for amputation above the knee should not be made almost straight, as many are, but from hip to knee it should diverge inwards, and take the same lines as the natural limb. The foot, instead of being straight with the leg, should turn out, so that when the knee is bent, the foot should be nearly its whole width outside the knee; if made straight with the leg the toes will turn in in walking when they should turn out; the knee centre should not be in the centre, but extend back to the back, so that when standing erect the gravity of the body may fall in front of the centre to lock the joint and enable the wearer to stand in safety (see dotted line H, sketch No. 1). If the centre of the knee be put in the centre of the knee the wearer cannot stand in safety, because the moment the gravity of the body falls behind the knee centre the knee gives out, and down he comes, because there is no natural rectus muscle to help the knee. A patent leg was represented in the columns of the MECHANIC a few years ago for amputation above and below knee. The mechanism and workmanship was all that was desired, but the knee-centre of the leg for above the knee was in the centre, thus it was a matter impossible to wear the leg in safety. The inventor had lost his leg below the knee, and made a leg that answered his purpose well; and he set to work to make one above the knee, but it was wanting in principle. If the knee-centre had extended back another inch or inch and a half, the leg would have been perfect, but it was not my place to correct the defect as a manufacturer. The ankle-joint of the leg should give just simple flexion and extension, and all lateral motion avoided; any lateral motion, of which there has been so much ado about, gives an unsteady motion to the foot (as the will has no power to control), and is more liable to get out of repair. As a limb maker gets every makers' limbs to repair in the course of a few years he can see their construction, and see which answers best; and the greater number from experience would say simple flexion and extension is best: it is all that is necessary, and when makers of limbs sometimes pretend they have some wonderful internal mechanical contrivance, I say, without hesitation, it is all moonshine; you can have nothing simpler in construction than the sketches represent.

3. Amputations, and the points at which a leg should be amputated. The success of an artificial limb in a great measure depends upon the nature of the operation. Bad operations and badly-fitted legs are bad indeed—a man may as well be out of existence as without his legs he is in constant misery and pain. The best place to amputate when the surgeon has the option is at the lower part of the middle third downwards from the joint (see cut No. 4). This leaves a good lever and stump for the patient to use the limb, and it makes a good stump for the mechanic to adapt his limb to. A stump too long or too short presents difficulties to the mechanic, and is always an annoyance to the loser of a limb. Long stumps come in the way of the mechanism; in short ones you cannot get sufficient grip; other stumps have not much muscle, and the edges of the bone seem to be protruding through the skin. The bones in operating should be cut up so as to have a good cushion of muscle under end of the bone. The edges of the bone should also be filed or nipped off to prevent the round edges cutting through the muscle and skin. The nerves should be drawn down with forceps, and cut off so as not to be brought up with the flap. The best flap is the posterior and anterior flap, as it brings a good cushion of muscle up under the bone; but should not be cut up too high laterally. Some legs are amputated from disease, often scrofula; the disease sometimes lingers in the stump, which makes the wearing of a leg tedious.

4. I now come to the manufacturing of the legs. Different makers employ different material and different plans of construction; but the principal, with knee, ankle, and toe joints, are much the same. Legs in general are made of wood, willow, nominally called cork, because of its lightness, the sockets of which are hollowed to fit the stump. But to the construction of my own manufactory I shall confine myself. No. 1 represents a section of my leather leg. A and C are leather buckets made of the best light ox-hide. The foot and shank D D are made of wood—willow. As my original business was working in leather, I have a process whereby I can mould the hardest butt leather to the anatomy of the leg. The shank D is secured in the leather calf bucket C. The tendon at the back G is made of metal hinge, and is regulated by screw nuts. F is a spring of vulcanite rubber, or a spiral spring, secured by gut to flex the foot. Thus, when the foot pitches at the heel, the foot falls flat; the pressure on the heel extends the foot; when the pressure is off, the foot flexes, and the tendon Achilles supports the ankle and helps the heel up when standing on the toes. E the toes, a leather sheath to shape, stuffed with horse hair. This gives the crease in the boot and takes away the woody appearance of the foot. J is the outside of the leg. The thigh and calf bucket are secured together by the lateral steels J. Jointed at the knee with catch joints, K is a laced tendon to save the strain on the knee joint, and prevent the click of the same. I is a spring which is regulated to bring the leg forward in walking, and acts as the rectus muscle. L L L L are where the straps are secured for fixing the leg.

8 represents a leg for amputation below knee, the bearing being taken in the taper or cone of the thigh, leaving the knee free to act without bearing under it, and the stump free from pressure. The lower part is the same in construction as leg above knee.

For a working-man an artificial leg is expensive in the wear and tear of the ankle joint. He cannot afford two legs, so by securing the peg in the shank he can knock about to work; but when dressed for church, can take out his peg and put in his foot. This can be applied to a leg above or below knee.

Lastly comes the fitting. A leg for [illegible] mechanism may be well executed, but if [illegible] is useless. For amputation above knee [illegible] the stump without pressing the muscle [illegible] make a socket on the cast of leather [illegible] into the top of the leg, No. 1 B. Great [illegible] fixing this, or it will throw the leg [illegible] thus transferring the fac-simile [illegible] leg, leaving the end from pressure.

tain amount of bearing. On setting the bone the leg is bound to fit. Till within this last month I have fitted a leg a week for four months in succession to all kinds of operations. I have not had a single case where the patient has not been enabled in one hour after the leg is on to walk with and without a stick, and walk up and down stairs, which is the drill they have all to go through. The boy represented in the MECHANIC some time back with both legs off, one close under the knee and the other in the middle of the thigh, thinks nothing of walking five miles; in fact, as he walks the streets he is taken no more notice of than an ordinary individual. I fear I have taken too much of your space, and the chances are that you will not be able to find room for this article.

JAMES GILLINGHAM.

WARMING AND VENTILATING.

[3909.]—NOTHING can be more mischievous in every sanitary point of view, than the admission of a room's supply of fresh air warmed to the extreme degrees named by "An Architect" (letter 3848), or indeed, to any degree above the external temperature when that is higher than 56° Fahrenheit. For either the room is self-ventilating (like a lantern or the House of Commons), or it is (like English architects' rooms) non-ventilative, preventing by its malformed ceiling all possible escape of the immediately breathed air, and fouling the whole contents as speedily and permanently as possibly. Now, in the former rare case, the heated fresh air will simply rise straight to the outlets and pass away, instead of the foul, which is less light, wasting all the heat it has received, and leaving the room fouler than if it had not passed through. But in the other case, the common one, it will rise as quickly to the mischievous ceiling, displace thence the breathed air that is always there, collecting and cooling, and send it down to be rebreathed even quicker and more perpetually than the successive supplies of more and warmer breath would have done. If our dwellings admit of being made more wantonly pestilent, "An Architect's" treatment (p. 40) makes them so.

E. L. G.

PROTOPLASMIC LIFE.

[3910.]—IF the pages of the ENGLISH MECHANIC are familiar to the eyes of Dr. Crace-Calvert, perhaps he will kindly favour us with an explanation how happens it that he—having succeeded in preparing water so that it will keep for months without life appearing—asks 'why did not life appear in the liquid contained in the flask as well as in the tubes which had been exposed to the air?" (Vide p. 33 ante.) Now granting that, by the means described in the *Chemical News* of July 14th, 1871, Dr. Calvert is enabled to prepare water so nearly optically and chemically pure as to be absolutely free from all "germs" (an attainment which Professor Huxley once ridiculed, as one utterly hopeless to strive for), then the question naturally arises, why should Dr. Calvert put the above interrogatory? For from what possible source, contained in the flask in question, were living things to derive their origin? Whence were they to get their nitrogen? Surely Dr. Calvert does not impliedly accuse Abiogenists of entertaining an idea—obviously too absurd—that living things arise spontaneously in a flask containing chemically pure water. What Abiogenists really contend for is, that living things may and do arise *de novo*, in solutions in which all pre-existing life had been destroyed; that as regards the paucity of life observed in one result and the abundance of life in another result, much depends upon the nature of the solution employed; and, that when living things are said to come into being *de novo* they are only supposed to originate from the re-arrangement of non-living matter which previously existed in a state of solution. If, out of the many writers on the subject of "Spontaneous Generation," there be one individual who has expressed his belief to be that it is possible for organisms to arise in fluids similar in condition to the contents of Dr. Calvert's flask, then, perhaps, Dr. Calvert will be so kind as to acquaint us with name of writer and title of work. I do not suppose that Dr. Calvert has examined the contents of his flask in order to ascertain whether crystals of any particular salt have appeared therein, but why not? As well might he expect crystals to appear as living organisms.

A. J. V. G.

ARE ANTS PIRATES.

[3911.]—"SAUL RYMEA" (letter 3778, p. 667, Vol. XIV.) quotes a "popular authority," in which it is stated that ants eat the centres of flowers. He does not state the name of the authority; and I would remind him that popular authorities are not by any means authorities in regard to reliability. All I can say is, that the ants whose acquaintance I have made have to all appearance been almost exclusively animal feeders—sweet articles, whether animal or vegetable, coming in for a share of their attention. The argument that the ants are blameable for part of the mischief wrought by the aphides on account of their consumption of the honeydew seems to me new and curious; but supposing it to be a fact that the ants in consuming the honeydew actually do cause the aphides to produce more of it than they otherwise would, it would only be an additional cause for the destruction of the aphides; thus sending the ants elsewhere to procure food, resulting in more profit to the gardener and horticulturist. I may say more on this subject at some future time.

J. C.

THE LATHE AND ITS ACCESSORIES.

[3912.]—I SEND you photographs of an epicycloidal chuck which I have just constructed. From the photographs it will be seen that I have not departed from the principle of Bergeron, the father of the chuck, for all the others are but modifications of the one figured in the "Manuel de Tourneur." I mean giving eccentricity by the flange movement of the radial arm carrying the change wheels. I have done this after a careful consideration of the admirable though complicated chuck of Mr. Plant, because I think the flange movement is the simpler. It avoids the necessity of the eccentric chuck movement, the radial arms, and link motions, all rather difficult for an amateur to construct, and it is equally efficient, as whatever amount of eccentricity is given, the wheels are always in gear.

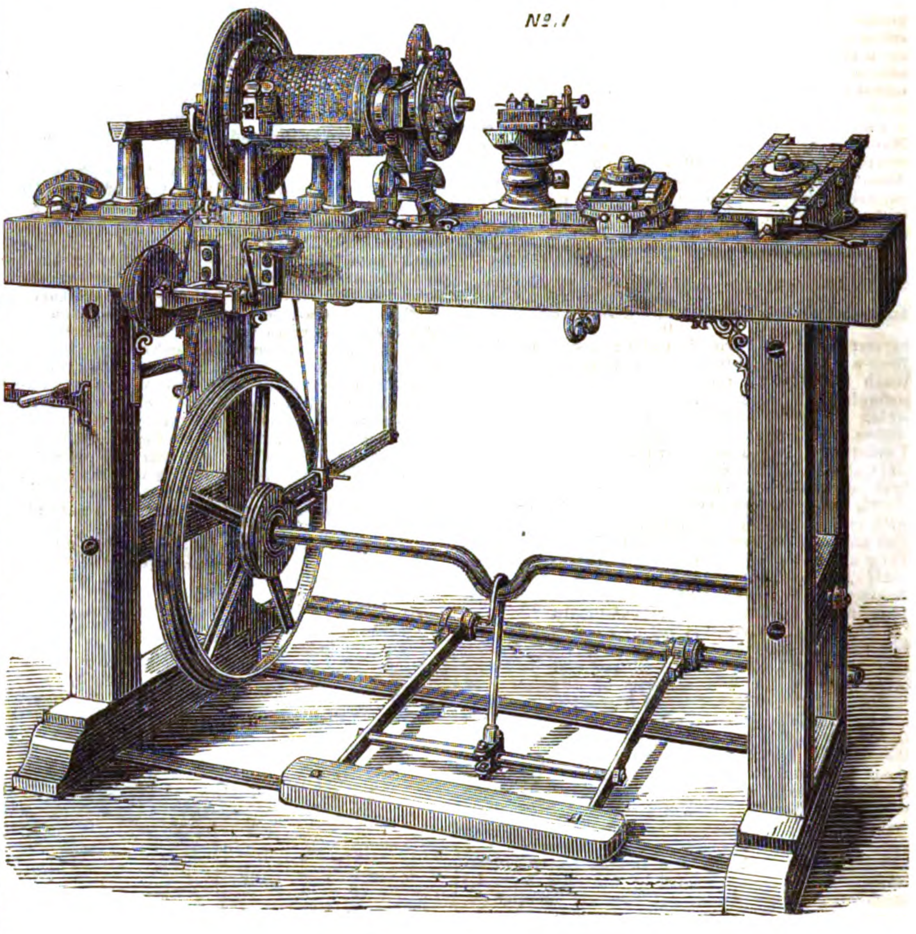
In my old chuck the reversing motion was obtained by an intermediate wheel slipped on when required. In the new one I employ what I call the sun and planet motion. The steel bracket (see 6, No. 4) carrying the planet wheel is pierced at one end (*a*) to receive the spindle of the wheel (8, No. 4), the centre of motion of the radial arm, and at the other end has a slot concentric with the centre of No. 8, so that the sun and planet wheels are always in gear, and the motion is direct or inverse, according as the pinion on the axle of the driving wheel (13) gears with the one or the other.

So much for the principle of the chuck, now for its construction. To return to the photographs. No. 1, of which I now inclose a better proof, shows the chuck screwed on the nose of the rose engine. It will be seen that the lathe can be worked either by the hand or the foot. To the right of the slide-rest is a double eccentric and oval chuck, and farther to the right a straight line chuck, both belonging to the rose engine. By using a magnifying glass, the whole details may be seen at a glance.

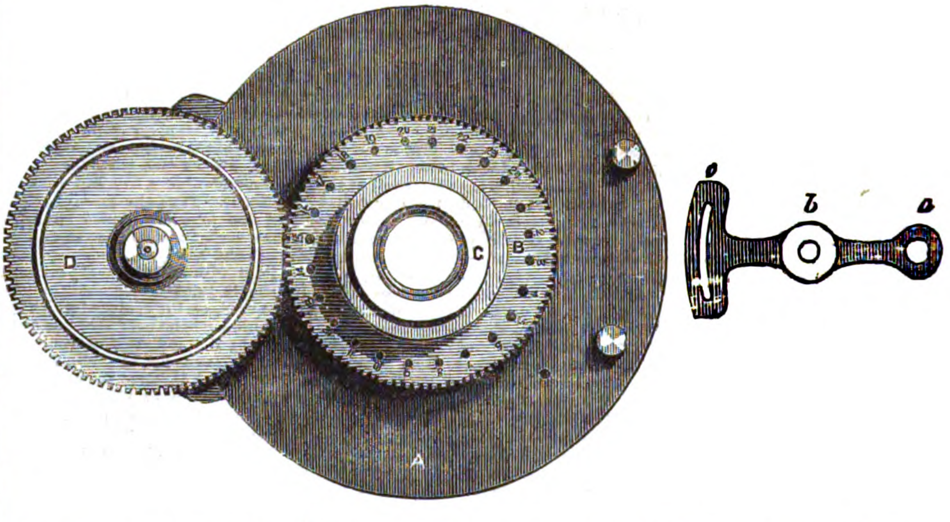
No. 2 shows the back of the chuck, the foundation plate A, which is merely a face plate, very true on both faces, with boss C to screw on the nose of the lathe. On this boss the wheel B revolves, except when held fast by the pointer placed in one of the holes shown. It then remains stationary, and gives motion to the driving wheel D, which, in its turn communicates motion to the wheels in the front of the chuck. This arrangement is the same as that adopted by Mr. Plant.

No. 3 is a front view of the chuck, showing all the wheels in gear, a combination which gives 180 loops in one continuous line.

No. 4 will give a better idea of the construction of the different parts, as the driving wheel (13), the main wheel (14), and the division wheel (15), are removed to show the position of the radial arm (2), and the central stud (5), on which 14 and 15 turn. Both are countersunk to turn on the bosses, which gives steadiness to their motion. These wheels are fixed on the stud by



No. 2



the washer 19, having a key way to fit a pin on the stud and the screw 18, which allows them to turn without a shake.

Instead of the slot in the foundation-plate, concentric with the centre of the lathe mandril adopted by Bergeron, I employ a bracket, seen at 12, whose inner surface beds truly on the periphery of the foundation-plate, with slots to allow of lateral motion for different sizes of pinions, and two capstan-headed screws to fix it in place. This is a better arrangement, as the screws do not interfere with the pinions, whatever their size.

When the mill-headed pin 4 is in place, as here, the chuck is all at centre, and would make dots or circles, according as the slide-rest is central or not.

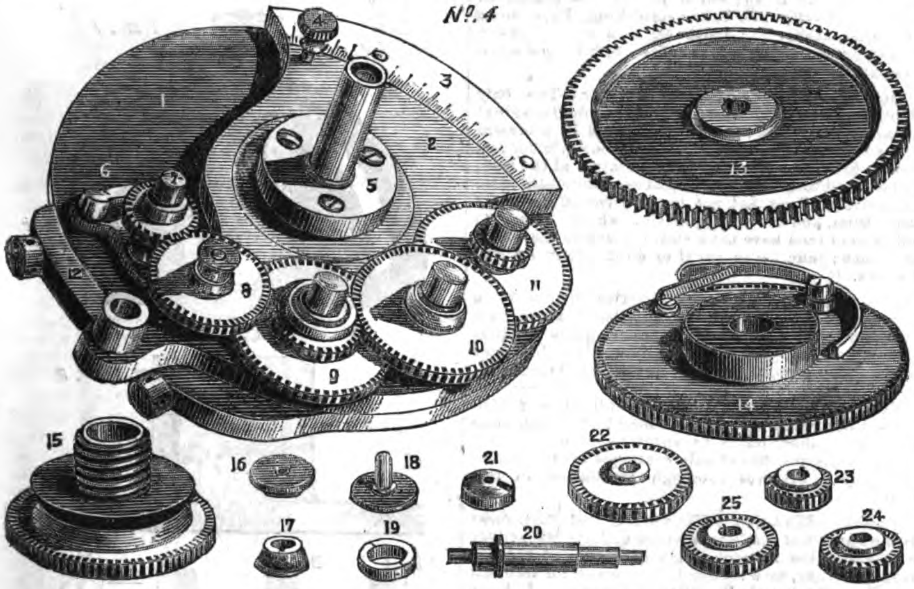
The boss of the main wheel, which I originally intended to make the depth of one of the change wheels, I subsequently made the depth of two, and ultimately I extended it to the depth of three, for a reason which I will immediately explain. The bracket 6 for carrying the planet wheel 7, and the bracket 12 for the axle of No. 13, are made of the same height as the upper surface of the radial arm carrying the change wheels.

addition of a division plate. It is not quite completed; but I do not consider it a part of the chuck, any more than the rose engine, though both may be combined to give variety to the figures. It is merely a combination of the eccentric with the epicycloidal chuck.

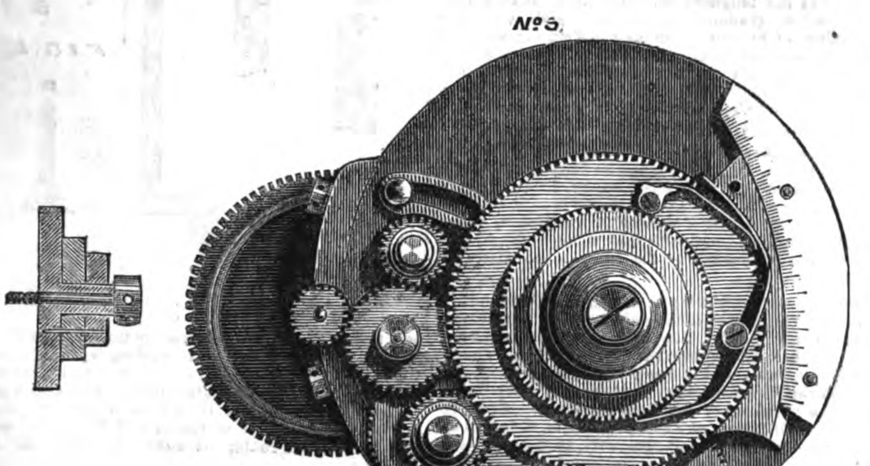
I should have noticed the rest of the disjecta membra of the chuck in No. 4. The part 3 is rebated and kept in position by two capstan-headed screws, which are loosened to allow the radial arm 2 to be moved to the right for eccentricity. 3 is graduated for the purpose. 20 is the axle of 13, passing through 12. The wheel 13 is keyed on the flanged end, and the nut 21 retains it in place. 22, 23, 24, 25, are the change pinions keyed on the other end of the axle. 17 is a washer of the thickness of the wheel, which is placed above or below the pinion to correspond with the level of 8 when in gear or out of gear with the main wheel, and 16 is a mill-headed nut for retaining the pinions in place.

I have not had sufficient time to try the powers of the chuck. The few trials I have made have been satisfactory; but I shall, no doubt, find several alterations necessary as I proceed. I am not foolish enough to

No. 4.



No. 5.



The sizes of the wheels may easily be calculated, as the main wheel of 120 teeth is 4in. diameter. In the number of teeth I was restricted by the number on the division plate of my lathe. The numbers adopted are as follows: The fixed and driving wheels on the back of the chuck 96 each; on the front the planet wheel 7 has 24, gearing with No. 8 of 40, attached to one of 20 below, which moves No. 9 of 60 teeth, carrying one above of 30, which gears into No. 10 of 60 teeth, having one of 24 below, which turns No. 11 of 60 teeth, which has one of 20 on a level with the main wheel, and gearing with it.

The advantage of the depth of the boss of the main wheel will now be perceived. The whole of the pins on which the change wheels revolve are of the same height as that of No. 11. In plate No. 3 it will be seen that the whole of the wheels are on a lower level than the main wheel, except the last, which gears with it; but the position of the pins is so arranged that any one of the series may be made to gear with the main wheel by inserting a washer of the thickness of the wheel, and raising it to the level required.

The arrangement for placing the figures on any part of the plate is the same as in my old chuck, with the

compare the workmanship of an unpractised amateur like myself, working by gaslight for amusement, with that of an experienced mechanic, such as Mr. Plant; but I have studied the action of the epicycloidal chuck for years, and believe the principle I have adopted is simpler and fully as efficient as that of the single geometric chuck, which, however, I have never seen but on paper. Of one thing, at least, I feel assured, that the amateur who may wish to construct one for himself will have no difficulty in deciding to which to give the preference.

I could send you some specimens on wood and metal, but they are rather heavy for the post, or rather for the pocket; but I may find an opportunity of forwarding some soon by a private hand. I need hardly add that nothing will afford me greater pleasure than explaining any portion of the work that may have been overlooked to any one who has the curiosity to ask for information.

I may state that the depth of the boss of the main wheel is ten-sixteenths of an inch. The wheels and washers are each three-sixteenths, which leaves one-sixteenth for clearance. To insure centrality in the wheels and washers on the same axle the larger wheel is cast with a boss on one or on both sides. On this boss the smaller wheels and washers are fitted, and soldered in some cases, and in others fixed with a pin screwed into the larger wheel.

The axles of the wheels, the bracket carrying the planet wheel, the screws, spring and catch, are all of steel, burnished and tempered blue. The rest of the chuck is of gun metal polished and lacquered. It is a handsome instrument when mounted on the lathe, and if it works as well as it looks I shall be quite satisfied.

Sydney, N.S.W. JOHN RAE.

COMPETITIVE EXAMINATIONS.

[3913.]—I FEAR that some little misconception has arisen in "Hedera's" mind with regard to my design in pointing out the paragraphs in Professor Barff's admirable little work. My intention was not to criticise Professor Barff, for he is, evidently, a thorough master of his subject; and what is more important, a truth-seeking and unbiased writer. Nor did I propose entering into the merits of the terms "anhydride" or "acid," as "Hedera's" reference to the preface and p. 174 would lead one to infer. My only purpose was to show that although Williamson and others have demonstrated that when sulphur is burned at high temperatures a compound (call it what you will) containing one equivalent of sulphur united to three equivalents of oxygen, is formed, yet this *fact* is to be ignored by candidates under examination, and something else substituted. Professor Barff, like a conscientious man, teaches the *truth*, for in the text he quotes Professor Williamson to prove that the above compound *is* formed. Like a conscientious adviser, in the fly-note he tells the reader that to meet the wishes of the examiners the intending candidate had better not say *that*, but something else. Is comment necessary? I believe not; but should "Hedera" feel disposed to make any I will read it with great pleasure. The stricture which I threw out does not apply to chemical examinations only; for while under examination, some time back, by the Civil Service Examiners, I ventured to correct an error in a dictation, in which a verb in the past and present tenses, both referring to the same time and action, was made use of in the same sentence; but the examiner politely told me to mind my business, telling me that I was expected to write exactly as he dictated, whether correctly or otherwise.

S. BOTTONE.

TELESCOPE WORK FOR MOONLIGHT NIGHTS.

[3914.]—PERMIT me, if you please, as one who is greatly attached to the pursuit of observational astronomy, very sincerely to thank your valued correspondent, Mr. Birt, for his communication (letter 3856), entitled "Lunar Objects for Observation, April, 1872;" and also to express a hope, in which I feel quite sure that I shall be joined by many other subscribers to the ENGLISH MECHANIC AND WORLD OF SCIENCE, that Mr. Birt will kindly continue to give a similar list for each successive month, so that henceforth we may anticipate that gentleman's working catalogue of lunar objects for examination and research, with much the same feelings of interest and pleasure as we have long been accustomed to regard the "Astronomical Notes" of "our" obliging guide "F. R. A. S." ROGANS.

AIR-BLADDER IN FISHES.

[3915.]—"LATRATOR" (let. 3810, p. 31), if an old dog, must have had his sensitive feelings very often hurt by persons either not quite up to the last new thing in science, or else tenaciously clinging to an old creed. I may in this case comfort him with the assurance that there are no signs of anybody's "advocating" the Borellian theory. I put forward the view generally held by writers on natural history and comparative physiology, and if I am not mistaken one still to be found in Müller. I wear my scientific creeds very loosely, and am quite willing to adopt the one chosen by "Latrator," to whom I owe particular thanks for the correction. M. PARIS.

The Speed of Bicycles.—Some idea of the speed at which bicycles may be made to travel can be gathered from the exploits of the proficient riders at the recent amateur champion meeting of athletes in London. The four-miles bicycle championship drew five entries, but F. V. Honeywell (Surbiton) had no difficulty in proving himself the swiftest, his times for the miles being—first, 4m. 35s.; second, 8m. 49s.; third, 13m. 9s.; fourth, 17m. 21s. The pace was slow at first, but it warmed up in the last mile, and he came in very fast. Keen, the bicycle builder, and said to be the most accomplished bicyclist out, started on a 52in.-wheel to do two miles under seven minutes, which he accomplished with $2\frac{1}{2}$ seconds to spare—the first mile being travelled in 3m. 29s., quite good enough to show the great pace which can be obtained on a large-wheeled bicycle.

A BRUTE of a man, says the *Farmer*, has been rightly served by an Edinburgh magistrate for cruelly ill-using a horse injudiciously intrusted to his charge. He belaboured the poor dumb animal until it fell on its knees, and then beat it again more savagely for falling. It was only after half an hour's "exercise" of this nature that the wretch cried "enough." For this fiendish gratification the magistrate, Bailie Cousin (all honour to him), gave him—heaven save the word!—thirty days, without the option of a fine. We should like to see all of the same kidney served in a similar manner.

REPLIES TO QUERIES.

₊ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustration on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Commercial letters, or queries, or replies, are not inserted. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded; and the names of correspondents are not given to inquirers.

[7182.]—**Time in England and New Zealand.**—The difference of time between two places is according to the relative difference in longitude, measured in degrees. Greenwich longitude is 0° 0′ 0″, and consequently a vessel sailing from the Thames, say to Wellington, New Zealand, goes east (via Cape of Good Hope) 174°32″. The earth revolving from west to east, we New Zealanders see the sun sooner than you do in England by 11h. 30m., so that when you are at church on a Sunday morning, we are going to bed the same evening. For public convenience a mean time is calculated, this is deduced from the mean meridian of longitude of the islands, which is 172°30″ east; this gives New Zealand time 11h. 30m. in advance of English time.—RATA, Wellington, New Zealand.

[9846.]—**New Zealand.** — For £ read lb. The following is from statistics published annually by the General Government of New Zealand:—Export value of wool during the year 1861, 7,855,920lb., value £523,728; 1865, 19,180,500lb., value £1,141,761; 1869, 27,765,636lb., value £1,871,280. 1861 and 1865 are valued at 1s. 4d. per lb. 1869 is the value declared by shippers, statistics for 1870 not yet published. The wool of 1869 exported to the United Kingdom was 26,360,152lb.; New South Wales, 882,404lb.; Victoria, 1,023,080. I will send 1870 when published, which will answer another correspondent, as to quantity shipped to America.—RATA, Wellington, New Zealand.

[10702.]—**Terrestrial Gravitation.**—From the reply to my query on p. 18, I fancy "Philo" cannot have read my letter on p. 406, nor Mr. Proctor's remark thereon in letter 3386, or, even at the risk of being somewhat tedious, he would have given the easy proof mentioned on p. 18, "that the joint attractive force of all the particles of a homogeneous sphere is the same as it would be if the attraction of all of them were exerted at the centre," because it is exactly what is required to show that the attraction at the equator of an oblate spheroid is less than at the poles. At present I am of opinion it is greater, and that if $\frac{R^3}{R^2} = R$, then $\frac{R + E^3}{R + E^2} = R + E$, and $\frac{R - E^3}{R - E^2} = R - E$, these equations shewing it to be so. Perhaps, before working out his easy proof, it would be as well if "Philo" ascertained the results of a few experiments upon the behaviour of liquid matter.—T. A.

[10739.]—**Centre Drill Chuck.**—This is no more than a piece of good round iron, ¾in., fitted to the ordinary round drill socket. A hole is bored up the back for clearance, considerably larger than the wire used for the drills within ⅜in. from the point, which is drilled the size of wire, a nut is tapped half way in with a thread, the other half a cone. The end of chuck is chased or screwed, and cone turned to fit the nut. The cone of chuck is then split from the point up, about ⅜in., in three places, into the central holes, which allow it to act like a spring forceps, and when the wire is put into its place and the nut tightened up, it holds it very firm. It will need case hardening, which can be done with prussiate of potash, or wet some finely-powdered charcoal with a solution of the same, and encase it therein in an envelope of old tin, and give it an hour or two's roasting at a dull red heat. Then slack it in water, when it is fit for use. Serve the nut the same.—JACK OF ALL TRADES.

[10776.]—**Gilding on Glass** (U.Q.).—If "Old Limelight" will use isinglass instead of size he will be able to gild his glass bright. It is what japanners always use. A pinch between the thumb and finger to half a pint of clear soft water, boil for a minute or two, and strain through a piece of muslin.—R. O.

[10816.] — **Scouring Paisley Shawls.**—The following is a most excellent recipe for scouring Tartan shawls, and I should think might with perfect safety be used for Paisley plaids. Scrape 1lb. of soap, and boil it down in sufficient water to make it a thin jelly. When cold, beat it with the hand, and add three tablespoonfuls of spirits of turpentine and one of spirits of hartshorn. Wash the shawl thoroughly in this mixture, then rinse in cold water until all the soap is taken off. Next, rinse it in salt and water, in order to prevent the colours striking. Wring the water out (with a patent wringer, if your correspondent has one), fold between two sheets, taking care not to allow two folds of the article washed to lie together; mangle and iron with a cool iron.—CHAMPAGNE CHARLIE.

[10822.]—**Permanent Polish** (U.Q.)—French polish: Wood naphtha, 4oz.; gum shellac, 1oz.; benzine, ½oz.; dragon's blood, ¼oz. Finish with wood naphtha.—SHAWFORTH.

[10829.]—**Electrical** (U.Q.)—This batch of questions really involves a complete treatise. 1. The copper deposited at the bottom of porous cells is due to local actions set up by particles of zinc and maintained by a process of conduction. 2. They waste the sulphate and break the pots. 3. "Square inches exposed to action" has different meanings in different cases. 4. The resistance of each pot depends on its porosity. 5. Strength of current should mean quantity, and intensity of current is the same. 6. The back of the plate takes part in the action, though much less than the front.—SIGMA.

[10882.]—**Damp Walls.**—Red brick is very porous, and rain comes easily through it, as I know from experience. The only cure is a coating of Portland cement, I have been told. Our village school-rooms were so treated. Waterglass might be first tried, but the best thing is the cement.—M. PARIS.

[10922.]—**Engine Query.**—Your valve has too much lead.—JACK OF ALL TRADES.

[10928.]—**Varnish for Oxford Frames.**—If required dark, use brown hard varnish; if light, use white hard varnish. If the grain is not very porous the varnish will fill it up; but if porous, use plaster of Paris mixed with water before varnishing. Paper down well after each coat; finish off with glaze. Many frames are only polished or rubbed with linseed oil.—SAMUEL SMITHSON.

[10930.]—**Want of Steam Power.**—The only thing I can recommend, if not done, is the following: An ash-pan damper; your boilers should be protected with some non-conducting material, your cylinder and steam-pipe also. Contract your chimney at the base, and exhaust these, if possible, and use your steam more expansively. Last, but not least, drive off a regular strap drum, and not off the driving wheel. If you do not succeed then have more steam space in the shape of a dome; your boiler ought to do it.—JACK OF ALL TRADES.

[10941.]—**Spontaneous Combustion.**—As a supplement to what "our" correspondent "Manus" adduces on p. 16 I could, if necessary, quote similiar cases where combustion, almost immediate, has been produced by rags, containing linseed oil, being carelessly thrown aside. Many years ago Sir W. O'Shaughnessy represented to the authorities at Calcutta, that linseed oil (raw more than boiled) was, more than any other, liable to spontaneous combustion, owing to the quantity of pulp contained in it. I think the subject deserves thorough ventilation in this country.—J. G.

[10950.]—**Madeira.**—The remark that Portuguese is the hardest of the Romanesque dialects was simply copied from the *Athenæum's* leading article of the previous Saturday, on a society lately formed for translating Portuguese and Brazilian literature. I know nothing of the language, but have heard that it contains more grammatical niceties and as many anomalies of pronunciation as the French; which, I suppose, is as far from Latin and anomalous as any of those languages, and would be the hardest to one knowing Latin only, though it is the easiest to us from its poverty, and also its nearness to English in idiom, and in number of identical words.—E. L. G.

[10954.]—**Circulation of the Blood.**—Is not "C. W. H." (p. 18), wrong when he supposes excess of carbonic acid gas in the air to be identical with "oxygen starvation"? Carbonic acid is held by good authorities to be not a diluter like nitrogen, but a sedative poison. I may add that when respiration is affected the circulation of the blood is so also.—M. PARIS.

[10954.] — **Circulation of the Blood.**—If a "Fellow of the Royal College of Surgeons" will reconsider the case, he will, I doubt not, give up the old and still prevalent opinion that the course of the circulation in the veins towards the heart is dependent upon what is often called motion—i.e., greater pressure of the air upon the blood out of the chest than in it. First, because the difference of such pressure is, unless in exceptional cases, very small; secondly, because the veins are not provided with rings as the suction-pipe of a fire-engine, and as the windpipe is, so as to remain open if exposed to excess of external pressure; but like soft hose-pipe would become flat when not distended with blood as they do; while thirdly, it is evident from the fact of the veins becoming more distended if the free passage of blood be impeded, as by a bandage round a limb, that the blood is driven onwards by force from behind, not drawn towards the heart, as is often supposed. It does not necessarily follow that the blood is sent throughout the whole circulation by the force of the heart alone, nor is it.—M. R. C. S.

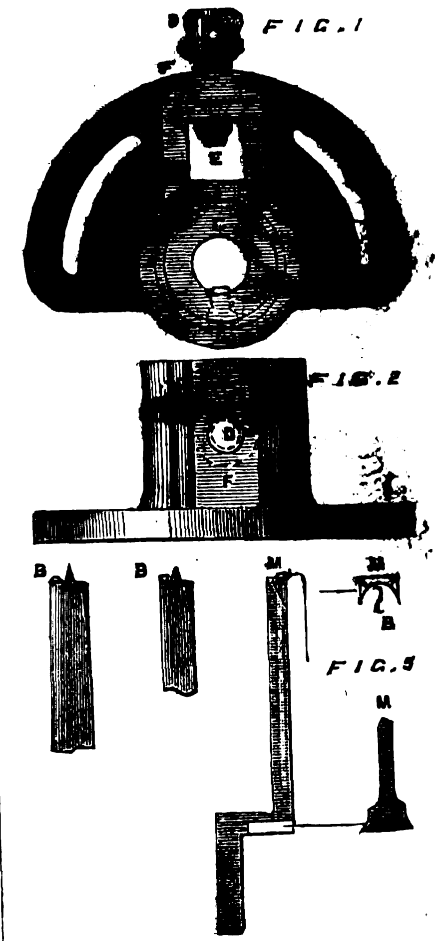
[10966.]—**How to Use a Book Without Hands.**—Let our friend pick up a bit of indiarubber with his teeth, and apply it to the leaf he wishes to turn over. He will find it has sufficient adhesion to the paper to turn it over easily.—ASSOCIATE.

[10974.]—**Polishing Granite.**—"Buz-Fuz" need not be so sceptical. The information supplied by me was quite correct. "Parepa-Rosa" afterwards, in a more detailed manner, accurately described the process. If "Buz-Fuz" will advertise his address I can send him pieces of granite, varying in colour and quality, which were polished in the manner described. If the piece he wishes to polish is of large size he need not attempt the task. It is not to be expected that a person at his first trials can easily accomplish that which is hard work for those in the trade. If the piece is small he may have some hopes of success. "Learn to labour and to wait!"—IRIOBAL.

[10987.]—**The Organ.**—The thicknesses of the bars are the nominal thickness of boards as bought; half-inch boards never measure half an inch. If "J. Butterworth" will lay out his soundboard as described, then lay his bars on, he will soon find the spaces required. The tenor C channel should be ⅝in. wide, and the upper G ⅛in.—J. D.

[10996.]—**How to Use a Book Without Hands.**—My father, who was confined to his bed, and gradually lost the use of all his limbs from rheumatic gout, so that at last he was unable to feed himself, had a very simple way of gratifying his taste for reading without trouble to others. His book was placed on a reading stand made to fit his bed, and he turned over the leaves with comparative ease by a long porcupine quill, which he held in his mouth.—A. J.

[11001.]—**Mortices in Hard Woods.**—The annexed sketch, if carried out, will serve you. It will require some fitting, but I believe it will be found to pay. It consists of a chuck of cast iron, see Fig. 1, that being a front or top view, and Fig. 2 showing the side; F B B are the boring tools, and M M M various views of the mortising tool, which is fixed in the holder or chuck in a mortice E, to any distance from



the boring tool to suit all sizes, by the set screw D, the said tools being packed with packing upon the front side next the bit, so that it will clear, the bit revolves while the chisel remains stationary. This chuck to be bolted upon the face of lathe head or general joiner, and as the mouth of mortising tool forces the chips into the hole the router bit clears it.—JACK OF ALL TRADES.

[11017.]—**Stuffing for Sofa.**—Everything is used for this job—such as cocoanut fibre, hay, straw, rushes or sedge, horsehair, shavings of wood, &c. You can use any of them, or all, as they are more generally mixed. Having a fillet run around the inside for nailing the canvass and webbing to, and outside for the cover, first proceed to nail on the webbing across, then the lengths interlaced; having finished that, strain your canvas and nail it. This should be done with broad-headed clouts, about ⅜in. or ½in., and they should be put into some boiled oil and turned out for a day or two to dry before using, as that prevents them from destroying the material. Now, having made your canvas-bed and your stuffing material, well beat and packed uniformly, spread it evenly over the same, and with a long upholsterer's needle tack it down lightly in its place. For this purpose I make needles out of steel umbrella ribs, which are eyed, tempered, and only need a point. Pass the cover over it and cut to fit, tack down in its place with Flemish tacks, and finish off with brass beading, which can be bought at most ironmongers, or with gimp and gimp pins. After that knot it down, either with leather buttons or tufts of worsted, as the case may be, to match cover, fastening your twine upon the underside.—JACK OF ALL TRADES.

[11052.]—**Rising and Setting of the Moon.**—A friend has pointed out an error I made on p. 673, Vol. XIV.), in subtracting 24·4m. from 19h. 22·6m. which should leave 18h. 58·2m., not 19h. 0·22m. In this case even the large mistake of 2m. is of trivial moment to the amateur observer. The disc of the moon occupies more than 2m. in passing the meridian, and the error of declination thus induced would only change the fifth figure of the logarithm. Strictly, when the semi-diurnal arc has been tentatively found, the declination corresponding to the approximate times of rising and setting should then be employed to give a more correct semi-diurnal arc. But in ordinary cases on shore this refinement is unnecessary, because from intervening hills the moments of rising and setting are not perceivable. In my case the moon is sometimes a quarter of an hour behind the predicted time, her presence, however, throwing a glow over the eastern sky. With a perfectly clear horizon the full orb of the moon would be distinctly seen, when in reality the upper edge was barely becoming visible. This is caused by refraction. Consulting Rios' table, which specifies the ascensional difference for all latitudes from 1° to 64°, and declinations from 1° to 30° inclusive, I find the arc to be added to 6 hours for lat. 37°, dec. 24°, to be 1h. 18m. for lat. 30°, dec. 25°, 1h. 25m. The easiest way of interpolating quantities in tables of double or treble argument is that given by Loomis. Thus the difference for 37° and 38° is 3m., $\frac{5}{6}$ of 3 [because lat. is 37 $\frac{5}{6}$] = $2\frac{1}{2}$m. Again, the difference between 24° and 25° is 4m. $\frac{37 \cdot 8}{60}$ of 4m. = $2\frac{1}{2}$m. As all these quantities are additive, we get

$$\begin{array}{r} \text{1h. 18m.} \\ + \ 2\frac{1}{2}\text{m.} \\ + \ 2\frac{1}{2}\text{m.} \\ \hline \text{1h. 23m.} \end{array}$$

which agrees with the calculated arc within less than half a minute. Rios' table fills two quarto pages, and would occupy a full page of the Mechanic. If desirable I would send a copy. Perhaps such a universal table might be useful to your numerous amateur astronomical subscribers.—Thomas Buchanan.

[11054.]—**Calculating Contents of Cylindrical Vessels.**—Your correspondent "E. L. G." has made a still greater mistake than A. J. Shaw, or there is a misprint. 1ft. 8in. is 1·666ft, not 1·75, nor yet 1·72.—W. H.

[11054.]—**Calculating Contents of Cylindrical Vessels.**—I think if "E. L. G." will kindly refer to qy. 11054 (No. 363, p. 648), he will see that A. J. Shaw's formula is right, and far simpler than that which he gives. There is in that letter, I believe, a typographical error, and, as the human race are all prone to error (typos not excepted), it is there given area of base = $1{\cdot}72^2$, &c., &c.; whereas it should have been $1{\cdot}75^2$, &c., that being the decimal equivalent in feet for 1ft. 9in. Hence, as I take it, not an error on the part of A. J. Shaw. The cubical contents is also correct, as near as it is possible to get it. Now, in "E. L. G.'s" letter (p. 19, No. 365) there is also an error, whether clerical on his part, or misprint by "typo," I don't know. It is 1ft. 8in., instead of 1ft. 9in., although the result coincides with A. J. Shaw) = 10·823 cubic feet. There is no simpler formula, that I am aware of, than $D^2 \times {\cdot}7854 \times H$ = cubic contents, where—

D = diameter in feet or inches, as the case may be.
H = height in feet or inches, as the case may be.

${\cdot}7854 = k$, or the co-efficient ratio $= \frac{\pi}{4}$,

unless you use the slide-rule; then ·7854 on C, put over 1·0 on D, gives the diameters of circles on D, and the corresponding areas on C. In this case it would read 1·75 on D = 2·4 on C. This, multiplied by 4·5, the height, would give 10·8 the cubic contents, and sufficiently near for the majority of purposes.—Tubal Kain.

[11054.]—**Calculating Contents of Cylindrical Vessels.**—Thanks to "A Barrister" for calling attention to my "terrible blunder." I should have said "the solid content of a cylinder is equal to the square of the semi-diameter × the height × 3·14159," or, to put the formula in another way, "the content is equal to one-fourth the square of the diameter × the height × 3·14159." I distinctly remember my attention being several times distracted when writing my replies to queries for that week, which may account for my mistake. I hope this explanation will be accepted: apologising to the querist for having so nearly led him into a fatal error.—Excelsior.

[11061.]—**Polishing Mahogany.**—This is bright, and is composed of equal parts of shellac and pale resin; it is used for carved work in general, as it is not possible to polish such, and is used pretty generally now for cheap goods.—Jack of All Trades.

[11075.]—**French Polishing.**—See reply 11061. You need a soft brush. I find the human hair far better than camel's-hair brushes. It needs no preparation.—Jack of All Trades.

[11075.]—**French Polishing.**—If the article is in the lathe use French polish with a rubber, and finish off with spirit; but, if not so particular, use brown hard varnish, paper down, then use glaze with a brush; this is a so-called trade secret.—Samuel Smither.

[11080.]—**Turkey Stone Cutting.**—Use a piece of zinc or copper, or iron hooping will do, and silver sand.—Jack of All Trades.

[11081.]—**Organ Pallets.**—If "E. F. C." will try the experiment himself and let us know the result, it would be satisfactory to a good many of us. Where would "E. F. C." put his pallets—into the channels, or where? The last sentence in the query is unnecessary.—J. D.

[11089.]—**The Organ.**—The inside line on the scale is three-eighths from the other line, and, therefore, two seven-eighths from the left or straight edge; of course seven pipes are less than the three-inch C. The sizes given are the inside diameters.—J. D.

[11096.]—**Varnishing Wall Paper.**—If your paper has not been sized, and you varnish with turpentine varnish, into which you have put a little linseed oil, it will have the desired effect in places. But as the article has been more or less pasted and saturated in places with boiled paste it will be glazed in patches, which would be difficult to eradicate, but if your paper was put on with raw flour and rosin for paste, it would stand a better chance of success.—Jack of All Trades.

[11109.]—**Soldering Iron.**—If "G. E. E." gets some of the best German silver and melts it down with one-fourth zinc he will have a solder that will suit him.—Jack of All Trades.

[11112.]—**Artificial Leg.**—There is no spring required at the toe joint, as that is only for the convenience of getting on the boot, as the patient can no more bear the thrust upon the flesh than upon the stump; it is made to take its strain equally, the bucket being packed with some coarse worsted material, and the bottom with a horsehair cushion, and sometimes a spring, cork, or indiarubber. It is held up by three straps to a strap that passes around the waist, and a shoulder strap is used. I have used, or rather fitted up, the old timber toes in various ways; the legs of some telescopic with a spiral spring; the shoes for some made of leather, and an indiarubber ball inside; and I have used cork for the same. In all cases the heel should either be of cork or rubber, and the thrust of dead head should be upon the knuckle, and not upon the pin-hole or tenon. Indiarubber is very good when warm, but in cold weather becomes very hard. Where it is in contact with parts having any circulation of the blood it can always be depended upon for its elasticity.—Jack of All Trades.

[11117.] — **Water-Wheels.** — I am obliged to "Tubal-Kain". Being accustomed to 5ft. and 7ft. wheels, but not knowing the rule, I am obliged to copy from others. Finding the fourth bucket to come square with the centre staff, I am now in a fix to know how to find the number of buckets. Should feel obliged to "Tubal-Kain" for an answer.—Youngster.

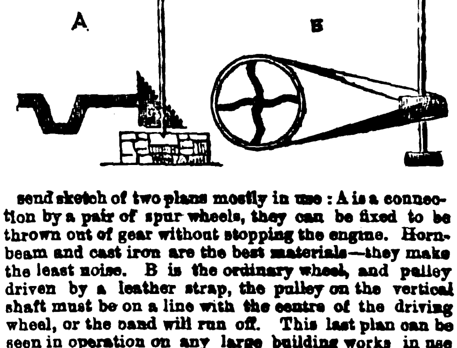
[11119.] — **Heat of Brick Kiln.** — This is a thing that has been wanted some time. Leave two clearances right across from the entrance, about 1ft. apart, and when the entrance is bricked up, make it so that you can take out a brick, and inspect it about half-way down; you will have a better idea from there than the top part.—Jack of All Trades.

[11120.]—**A Question of Sight.** — Something must surely have prevented your acute correspondent, "E. L. G." perceiving the ironical tenor of my remarks at p. 674. My meaning would, however, have been more obvious had the compositor italicised the words underlined in the "copy." "V. B." asks "Why should 'A. J. V. G.' consider the sun as a luminous point?" Why, indeed! The fact is I never had so considered. I distinctly said "*if* the sun be regarded as a luminous point," &c. But who, other than an idiot, *would* so regard the sun? The virtue of the whole question is in the "if;" and so with "Fiddler's" question. If the ether which fills space, not only transmitted light from a luminous source by wave motion, but also scattered light like our dust laden atmosphere; and if at a distance from the earth, of (say) 30 or 40 diameters, a reflecting screen could be placed, so as to represent the walls in "Fiddler's" room, then, and then only, would inhabitants of our earth be in a position in anywise relative to that of the supposed dwellers on "Fiddler's" orange. Because "Fiddler" would not trouble himself to ascertain whether the causes which obtained to produce the effect observed in his experiment also obtain in nature, he rushes his absurdities into print, coolly informing us that probably there is more therein than is apparent at first sight.—A. J. V. G.

[11120.]—**A Question of Sight.**—Steady! J. Barwick, steady! Sound has not a velocity of 11090ft. (!) per second through atmospheric air. You surely made a slip there (p. 20), and meant 1109ft. Yet why say sound has one-eighteenth the velocity of light: the one hundred and eightieth is nearer the mark.—Touchstone.

[11120.]—**A Question of Sight.**—Mr. Barwick darkens this very simple matter as much as the querist and "A. J. V. G." themselves. We know nothing about the comparative nearness of atoms, of ether, or of air, or any other matter. The velocity of sound in air is only a tenth of what he states, and is just the same (at the same temperature) if the atoms be twice as near or twice as distant. "Fiddler" need not cut off "from himself" either direct or reflected candlelight—their reaching him nowise affects the experiment, but their reaching the orange. His own face, even if a negro, will send it more than the moon does the earth. Direct rays from the largest suns do not injure "our sight power" if we are distant enough, as in looking at the Pleiades or the Milky Way; but reflected ones will very speedily, if he puts his eye at the solar focus of, say, a tablespoon. Light cannot be said to be "deemed" vibration: it is as well known to be so as it is known that Ireland is smaller than England. Light does not cease "instantly that combustion stops." If we are as far off as from many stars, we may not begin to see the light till the combustion has already ceased 1,000 years. An earth's shadow "cast by the moon on the sun" is sheer nonsense. The distance of what he calls the "focus of the shadow" of the earth, namely, the extreme extent of her shadow, is readily reckoned, being that at which the earth and sun subtend the same angle; this angle being least when we are farthest from the sun, on July 1, our shadow is then longest, and shortest on January 1, when we are nearest him. It extends but four times the moon's distance, and therefore can approach no other body. If we had a satellite 1,000,000 miles distant, or as far as Jupiter's fourth is from him, it would be too distant ever to be eclipsed.—E. L. G.

[11126.]—**Turning Perpendicular Shaft.**—"One in a Fix" wants to turn a shaft vertically without bands or wheels. It is very unusual to do so; of course it could be driven by a crank and connecting rod, by so doing it would be of no advantage, on the contrary, a vertical shaft is required to revolve to do certain work. The best plan is by a pair of spur wheels, or the next best plan by a strap; by these means the speed can be regulated as required, but if driven by a crank a new crank is required if the speed be altered.



send sketch of two plans mostly in use: A is a connection by a pair of spur wheels, they can be fixed to be thrown out of gear without stopping the engine. Hornbeam and cast iron are the best materials—they make the least noise. B is the ordinary wheel, and pulley driven by a leather strap, the pulley on the vertical shaft must be on a line with the centre of the driving wheel, or the band will run off. This last plan can be seen in operation on any large building works in use for driving the mortar-mills, or for pumps at any pumping-station.—Samuel Smither.

[11129.]—**Greek "Upsilon."**—It ought to have been said that this is a misspelling of the letter's name, tolerable only in French—due, I believe, to French astronomers, and which ours (begging Mr. Proctor's pardon) ought not to copy, knowing as they must that its established rendering in our letters for 2,000 years, and the only one intelligible on any principles of transliteration is *Hypsilon*. As all words beginning with it were aspirated, so the tendency to mix an *h* with the sound when emphatic may be noted now, as in French priests saying mass. The "Harrow Fellow" had better have let this query alone. "The English *u* gives the *only* sound of the Greek upsilon,"—(the *Harrow* upsilon, that is). Now first, what is "the English *u*"? Rule, mule, pull, cull, curl! Here are at least four sounds, if you pass over mere difference of quantity, rule and pull as nothing. Next, how can there be an *only* sound of a letter that is notoriously in ancient Greek always a vowel, and in modern mostly a consonant? But the best of the joke is among all the five or six "English *u*" sounds, it happens to be certain we have neither the ancient vowel Υ nor the modern consonant! (See "Argent Sable's" reply.) Then, our "Harrow Fellow's" way of writing in English the Greek for "I strike," oak, and circle, could not be reconciled with any possible way of distinguishing other words. His "tupto," "drus" and "kuklos" could only represent τουπτω (were there such a word), δρους and κουκλος; the termination os representing none but ως, while us is the sole rendering of ους, and υς of υς.) The historical and sole right way of putting these words in our letters, even at Harrow, is *typto*, *drys*, and *cyclus*; and innovations like "A Harrow Fellow's" can only lead to the most barbarous confusion, and puzzles like the MSS. of the dark ages.—E. L. G.

[11133.]—**Curing Bacon.**—Have a cistern built of bricks and Roman cement, about 2ft. deep, and line with Roman cement. Have a grating made of wood edgeways, and about 6in. deep, put in the bottom for the flitches to rest upon. After they have laid for a day or so, take for every peck or 7lb. of salt ½oz. of saltpetre, a ½lb. brown sugar, and ½lb. basalt; (powder and well mix, and having run a large knife under the blade-bones and knuckles of cushions and gammons, and well crammed with the compost, put about a couple of inches of water in the bottom of tank. Well rub the flitches with this compost, and lay them one upon the top of the other, with a good sprinkle between. After they have been there for four days, turn them about; let them be for four days, turn again, and sprinkle some more; turn over three or four times, then put them into the brine, and in three weeks they will be ready for smoking. For which, take out, drain and dress dry with pollard, and hang up in smoke; left for a week.—Jack of All Trades.

[11141.]—**Phrenology.**—Procure Dr. Gall's works or Fowler and Wells' works. I have read phrenological works for years past. Although I do not indorse all that is written, I have obtained a deal of useful information from such sources.—Samuel Smithers.

[11148.]—**How to Disinfect a House.**—"A Barrister" may think it "absurd" to talk of filling a house (as I have done a small outhouse) with chlorine, and it would be absurd to use the quantities necessary for such filling if any one had ascertained, by "practical knowledge of the subject," what proportion of chlorine and air may be depended on as infallibly disinfecting. I should not myself, however bad the case, employ in a house (as I did in the outhouse) the full quantities I named, or perhaps a quarter; but this would be pure matter of guess and risk. A practical knowledge that some known fraction is as safe as displacing the whole air by chlorine may, and I hope does, exist; but plainly, if "A Barrister" had this knowledge any more than I have, he would have stated that fraction. The question being absolutely "how to disinfect" a place, however bad, I confined myself to saying how this may be done infallibly, leaving to the querist's judgment how far he would go. There is neither difficulty nor danger in arranging to capsize a whole carboy of acid into a pan by pulling a cord outside the house. If the old sulphurous acid plan, used before the discovery of chlorine, be really comparable to it (Davy, and all since him, say not), there must be a minimum proportion of sulphur to air required, for the "pound in each room" (large or small) is, to quote "A Barrister," a "nice joke." I have not the slightest faith in it, and the sulphur dioxide being a vapour, not a gas, and uniting with steam to deposit itself, corrodes paper and vegetable cloth, and hangs about woollen things with its vile odour, as every one knows; whereas chlorine flies off without leaving a trace, and when dry (as I directed) neither bleaches nor corrodes dry things. But beware of thinking you can get it thus good and harmless from muriatic acid instead of salt and sulphuric, and do not confuse it with the vile vapours given off by chloride of lime; they are very different. Mr. Davis's reply (p. 21) is very suggestive, and from what we hear of the virtues of carbolic acid I should certainly try that plan on a house of any size, rather than trust to a very partial filling with chlorine. But as for clothes or bedding, I would simply put them in a closet or case in the open air, with all but its top made airtight, and an arrangement for capsizing sulphuric acid on mixed salt and manganese within it, in the quantities adequate to displace all the air by dry chlorine, as described in my former reply (p. 675). This is both cheaper and more fully verified as effectual, I believe, than any baking or imbuing with vapours; and however offensive the clothes, the chlorine will leave them more scentless than if new from the loom.—E. L. G.

[11148.]—**How to Disinfect a House.**—Chlorine and sulphurous acid are both cheap and effectual disinfectants, and as much as will fill the place with a decided smell of the disinfectant, if continued an hour or so, should be sufficient to destroy all organic impurity; there is no occasion for any such quantity as "E. L. G." speaks of. He proposes for a house enough for a good-sized town. Iodine, though dearer than the others, is one not so dear as to make its cost prohibitory; it is less disagreeable than chlorine, and less injurious to clothes and some furniture than sulphurous acid. It has not been very much used, but some of your readers have no doubt tried it with good effect for preventing annoying smell, and probably for destroying infection—I say probably, for that is often difficult either to prove or disprove, as many exposed to infection are not affected, and many who are affected have been injured otherwise than by the way assumed. —M. R. C. S.

[11149.]—**Examination Question.**—I fail to see why an examiner should not set such a question, as it is only by such physico-chemical questions that he can assure himself that the student has acquired a knowledge of the laws of gaseous combination, and the laws which control the rational formulæ of volatile compounds.

First Experiment.

Original gas	= 100 vol.
After the addition of oxygen	= 400 „
After explosion ($16\frac{1}{4} \times 4 = 65$)	= 465 „
After absorption of CO_2	= 295 „
After absorption of OH_2	= 25 „

This residual gas can consist only of unburnt oxygen. The total amount of oxygen burnt is equal to 305 volumes (found by adding half the aqueous vapour to the carbonic anhydride), which is 5 volumes more than what was added to the original gas. This 5, plus the residual 25, equals 30 volumes, which must have been combined in the original gas. The volume of hydrogen equals the volume of aqueous vapour (270). The volume of carbon vapour equals half the volume of carbonic anhydride (85).

O = 30 vol.
H = 270 „
C = 85 „

385

Percentage composition :—

385 : 100 : : 30 : 7·78
„ : „ : : 270 : 70·02
„ : „ : : 85 : 22·2

100·00

Second Experiment.

Original gas	= 100 vol.
After the addition of oxygen	= 400 „
After explosion ($17{\cdot}5 \times 4 = 70$)	= 470 „
After absorption of CO_2	= 290 „
After absorption of OH_2	= 10 „

This residue consists of oxygen. The total oxygen consumed equals 320 volumes, found according to the above method, being 20 volumes more than what was added to the original gas. This 20 volumes, and the residual 10 volumes, equals 30 volumes, which must have constituted the original gas. Hydrogen equals [illegible] volumes; carbon equals 90 volumes.

O = 30
H = 280
C = 90

400

Percentage composition :—

—R. Tervet.

[11166.]—**Area of Segment of Circular Ring.** —"Bernardin," on p. 22, has fallen into a greater mistake than "Thankful" by his rather indefinite data for the question. What meaning can be attached to apothegm, or, accuracy to ·866? He certainly must mean $\frac{1}{2}\sqrt{3}$, ·8660254, the cosine of 30°. As the breadth must undoubtedly be understood as the difference of radii of the two sectors (not the difference of the two cosines) with radii 70 and 50 respectively, as "Bernardin" intimates. The solution must be thus:

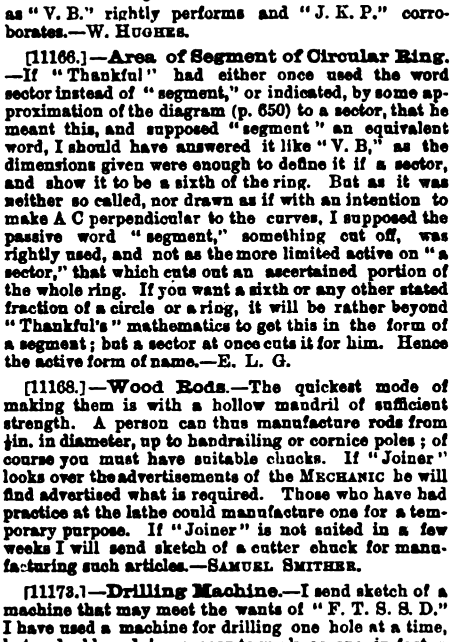
$$\frac{70^2 - 50^2}{6} \times 3{\cdot}1416 = 1256{\cdot}64,$$

as "V. B." rightly performs and "J. K. P." corroborates.—W. Hughes.

[11166.]—**Area of Segment of Circular Ring.** —If "Thankful" had either once used the word sector instead of "segment," or indicated, by some approximation of the diagram (p. 650) to a sector, that he meant this, and supposed "segment" an equivalent word, I should have answered it like "V. B," as the dimensions given were enough to define it if a sector, and show it to be a sixth of the ring. But as it was neither so called, nor drawn as if with an intention to make A C perpendicular to the curves, I supposed the passive word "segment," something cut off, was rightly used, and not as the more limited active on "a sector," that which cuts out an ascertained portion of the whole ring. If you want a sixth or any other stated fraction of a circle or a ring, it will be rather beyond "Thankful's" mathematics to get this in the form of a segment; but a sector at once cuts it for him. Hence the active form of name.—E. L. G.

[11168.]—**Wood Rods.**—The quickest mode of making them is with a hollow mandril of sufficient strength. A person can thus manufacture rods from ½in. in diameter, up to handrailing or cornice poles; of course you must have suitable chucks. If "Joiner" looks over the advertisements of the Mechanic he will find advertised what is required. Those who have had practice at the lathe could manufacture one for a temporary purpose. If "Joiner" is not suited in a few weeks I will send sketch of a cutter chuck for manufacturing such articles.—Samuel Smither.

[11173.]—**Drilling Machine.**—I send sketch of a machine that may meet the wants of "F. T. S. S. D." I have used a machine for drilling one hole at a time, but a double rod is as easy to work as one, in fact, a dozen could be worked at once at the same speed and



bore the same depth. Of course the inquirer understands the ordinary machine for drilling, therefore I need not enter into full details. A is a drilling-machine with two rods driven from the lathe; it can easily be adapted for steam power; one rod drives the other rod by means of a pair of 1in. cog-wheels, same size, and of course the same speed.—Samuel Smither.

[11186.]—**Length of Sidereal Day.**—The apparent discrepancy between my statement of the length of the sidereal and mean solar day, quoted from Herschel, and that quoted by "J. M." from the *Nautical Almanac* is apparent only. As the year contains 366¼ sidereal days, but only 365¼ solar days, one being apparently lost by the earth's revolution round the sun, the mean solar day must be nearly 1·365th longer than the sidereal day, and the hours, minutes, and seconds longer in the same proportion; the sidereal day, which is 3m. 55·91s. shorter, reckoned in solar time is 3m. 56·55s. shorter; reckoned in sidereal time, the real difference being the same—the pendulum of a sidereal clock having a rather shorter pendulum, about a fifth of an inch shorter, if I recollect right, and if wrong, no doubt "Sigma" will set me right in his usual polite manner.—Philo.

[11186.]—**Length of Sidereal Day.**—There must be a difference between the interval of two returns of a star (supposed to have no proper motion) to the meridian, and the return of the equinoctial point; which latter, I believe, is what astronomers always understand by a sidereal day. Moreover, as the precession is not uniform from day to day, the latter cannot be so constant a period as the former.—E. L. G.

[11188.]—**Arithmetic**—Will J. Lewis try and reduce £19 19s. 11¾d. to decimals, and then multiply. First to the decimal of pounds, the results of which will be a little short of £400. Secondly, to shillings and decimals of a shilling, and then multiply; the result will be nearly £8,000. Thirdly, to pence with decimals, the result will be nearly £96,000. And, last of all, reduce the sum to farthings and then multiply; he will find the result to be nearly £384,000. If the above four results do not open his eyes let him try to multiply 19lb. of sugar and 7oz. of pepper by 19lb. of soap and 7oz. of snuff. By means of which operation perhaps the requisite number of grains of common sense will be found. But, joking apart, a little experiment of the above kind is very good for practically showing that concrete numbers cannot be multiplied together.—Moneta.

[11188.]—**Arithmetic.**—Messrs. Harris, Lewis, & Denoarigbe can evidently enjoy a joke, else how is it possible to account for the gross absurdities perpetrated by the trio in their worse than useless replies (?) to the above query? From the several replies to this query the inference is inevitable that pounds multiplied by pounds give a product in square pounds in the same manner that length multiplied by breadth would produce a denomination to be referred to the table of land measure. Perhaps it may be the characteristic of our Transatlantic brethren to answer a question by asking another question. Will Mr. Lewis kindly condescend to define a square pound? When this is done in a satisfactory manner the point will be conceded in his favour. Until then the replies (?) are worse than useless, and are equally unworthy of the nineteenth century and of the English Mechanic.—Jas. Hastie.

[11188.]—**Arithmetic.**—The object of a "Yankee answer" was to induce J. Lewis to consider whether his question had any meaning, and if so, what he meant, and whether he could not say it. Multiplying a concrete quantity by another concrete quantity (or the same) has no meaning. He might as well talk of subtracting 10 yards from 15 pounds—what is the remainder? But £19 19s. 11¾d. is £19 $\frac{959}{960}$, and though you cannot speak of multiplying this sum by itself (which is nonsense), if you take away one of the two £ symbols, then you can multiply that sum by the abstract number 19 $\frac{959}{960}$, or this abstract number by itself, and in two lines, by my method of squaring, lately discussed, and used in reply 11054 (p. 19). It is $20 - \frac{1}{960}$, and therefore its square is $= 400 - 2\left(\frac{1}{960}\right)20 + \left(\frac{1}{960}\right)^2$ If it be the money £19 19s. 11¾d. that is to be multiplied (not, observe, by £19 $\frac{959}{960}$ but by 19 $\frac{959}{960}$, without the £), you have but to subtract from £400 twice $\frac{20}{960}$£, that is 40 farthings (not J. King Harris's 20) and add $\frac{1}{960}$ of a farthing. So that the answer is £399 19s. 2 $\frac{1}{3840}$d. O'Gorman's "rules" are nonsense.—E. L. G.

[11192.]—**Chemical.**—"Oxygen" can try this plan for separating his nitrate and carbonate of potassium, which I think he will find to answer:—Evaporate down cautiously, and allow to crystallise, when crystals of nitrate containing a little carbonate will be obtained. To separate these repeat the above two or three times, when crystals of nitrate practically pure will be obtained. The carbonate can be best purified by evaporating the remaining liquors (from each crystallisation) down to dryness and igniting with charcoal, then redissolve in water, evaporate down, and crystallise, when carbonate of potassium will be obtained.—J. B.

[11193.]—**Pumps of Portable Engine.**—I cannot understand the explanation of "Mendex," p. 23, No. 365, nor can I conceive how the placing of a third valve in a pump would convert it into a self-acting machine, able to empty a pond, although a siphon would do so. The cause of the engine feed pump not drawing is because the water in the barrel of pump gets so hot as to form vapour, which vitiates the vacuum. The remedy may be applied either by placing a valve as close as convenient to the boiler, so that the water in feed pipe may keep cool, or by raising part of the suction pipe higher than the pump, so that, on starting, some of the cold water will flow of its own accord into the barrel of pump, which would cool it.—A., Liverpool.

[11217.]—**Platinic Chloride.**—I think Mr. Somerville will find this plan answer. Add to the solution chloride of ammonia and a little alcohol, let it stand a sufficient length of time for a precipitate to form, then filter, and wash the precipitate—which will, of course, be the ammoniac chloride of platinum—with chloride of ammonium and alcohol; then ignite it, and if the chloride of platinum be desired treat the spongy platinum obtained in the usual way.—J. B.

[11225.]—**Jupiter's Satellites.**—I have to thank "F. R. A. S." for his prompt reply to my query, and at same time to say my lat. is 50° 40′ 38″ and long. W. = 3° 14′ 10″, for which I reckon 12min. 57sec. for the culmination of a star after Greenwich (allowing also for acceleration). Am I correct in supposing that such a small interval would have no effect as to the instant, whether viewed at my station or Greenwich, or at any rate only the fraction of a second?—Vega.

[11229.]—**Ammoniac Chloride.**—Before telling "J. N." how to make the substance mentioned above I may as well tell him that he cannot make it cheaper than he can buy it. He can make it readily in the following manner: Take pure hydrochloric acid, if slightly diluted it will be better, and neutralise with ammonium hydrate (common ammonia); he can tell when it is neutral by its neither turning red litmus paper blue, or blue red. Having neutralised it, evaporate down cautiously, and allow it to crystallise, when crystals of ammonic chloride will be obtained.—J. B.

[11244.]—**Silicate of Soda.**—Silicate of soda, or soluble glass, is usually made on the small scale by fusing together in a crucible 15 parts of sand with 8 parts of carbonate of soda and 1 part of charcoal. The mass thus formed is scarcely soluble at all in cold water, but dissolves when boiled with water, yielding a strongly alkaline liquid. With regard to the manufacture on a large scale, I must refer "S." to some of the back volumes, where several excellent descriptions have been given, with engravings of the furnaces used in the process. I am sorry that I do not know which number it was in, but perhaps some of "our" correspondents may remember.—J. B.

[11265.]—**Drawing a Boundary Line.**—Or rather correcting a boundary line incorrectly laid down. The piece marked I projects beyond A B, the following pieces, viz.:—2·20 × ·20 + 2·48 × ·24 + 1·98 × ·30; or, altogether, 1·6292 chains. The other piece marked G projects beyond A B, the following pieces, viz:—2·40 × ·30 + 2·60 × ·60; or, altogether, 2·28 chains, and the difference between these two is ·6508 chains. Therefore G projects ·6508 chains more than I, and the boundary will have to be drawn towards I to make G project less, and I project more, which it will do both at the same time; or, in other words, half of ·6508 square chain has to be taken off G and added to I. Now, A B is, altogether, 11·66 chains long, and hence $\frac{\cdot 3254 \text{ square chains}}{11\cdot 66 \text{ chains long}}$ will give the distance A B has to be shifted. This, worked out, gives $2\frac{461}{583}$ K. P.

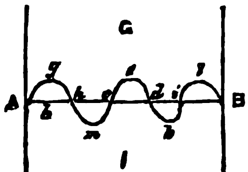
[11265.] —**Drawing a Boundary Line.**— (1) Find the area of the triangles A *g h*, *c e d*, *i l* B, which are cut off from the field I by the trial-line A B.

$$\frac{(220 \times 20) + (248 \times 24) + (198 \times 30)}{2} = 8146 \text{ square links.}$$

(2) Find the area of *h m c*, *d k i*, cut from G.

$$\frac{(240 \times 30) + (260 \times 60)}{2} = 11400 \text{ square links.}$$

(3) Divide the difference of these two results by the



total length of the trial line A B, and the quotient will be the answer required.

$$\frac{11400 - 8146}{220 + 240 + 248 + 260 + 198} = \frac{3254}{1166} = 2\,\frac{922}{1166}.$$

Dividing the fraction by 2, we get $2\frac{461}{583}$ links as the distance which the trial-line A B must be moved towards I, in order that the area of the three triangles cut off from I may equal the area of the two triangles cut off from G. Assuming the surveyor to be in the field I, the "heights" *g e l* are termed "offsets," and *m k* "insets."—EXPERIOR.

[11266.]—**Lifting Water.**—I think if "Ignoramus" were to get a small centrifugal pump it would answer his purpose best, as it discharges a continuous and steady stream, and is little affected by sand, mud, or grit. There was a small centrifugal pump exhibited at the Bath and West of England Show at Southampton, 1869, worked by a one-horse engine, that delivered a stream of water at the rate of 20 gallons a minute.—A COUNTRY TINKER.

[11271.]—**Naval Architecture — Misapplied Wit.**—On p. 47, there is a tissue of rubbish signed, "S. Tremayne, Cantab," which led me to refer to the question on p. 677, which I find is a similar tissue of rubbish, addressed by W. M. Hirpen, to "S. Tremayne" or "Jack of all Trades." Perhaps these people, who have not sense enough to understand the use and purpose of the question department of the ENGLISH MECHANIC (and whose mental calibre is about equal to that of the young ruffians who break windows and wrench off door knockers in search of amusement befitting gentlemen), will have the goodness to address their future witticisms to *Fun*, or, as that periodical might indorse the communication "Declined without thanks," some of the more destitute of the dismal prints which call themselves comic might be induced to welcome Mr. W. M. Hirpen, and gratify his laudable desire to see himself in print.—SIGMA.—[See "Answer" to "A Barrister."—ED.]

[11274.]—**Cement for Stourbridge Clay Fire Backs.**—Fire clay, 42·5; loam sand, 42·5; glass, 10·0; chloride of sodium, 5·0. Another: Fire clay, unburnt, 66·6; burnt, 33·4. Mix well with ammoniacal liquor.—G. D.

[11276.]—**Extracting Glass Stopper.**—Warm the bottle and put a drop or two of turpentine round the stopper, then give it a smart blow on the bottom with the hand, turning the bottle upside down, of course.—EUREKA.

[11276.]—**Extracting Glass Stopper.**—With a feather rub a drop or two of salad oil round the stopper close to the mouth of the bottle, which must then be placed before the fire at a distance of eighteen inches; the heat will cause the oil to insinuate itself between the stopper and the neck. When the bottle has grown warm, gently strike it on one side and then on the other with any light wooden instrument. If it will not yet move, place it again before the fire, adding another drop of oil. After a while, strike again as before, and by persevering in this process, however tightly it may be fastened in, you will at length succeed in getting it out.—F. T. S. S. D.

[11276.]—**Extracting Glass Stopper.**—Put the bottle into boiling water, the expansion of the air will drive out the stopper.—W. L. GILES.

[11276.]—**Extracting Glass Stopper.**—If there is no stump left by which to take hold of with pinchers, a hole must be drilled in the stopper, into which to cement or to screw a strong wire; then warm the bottle gradually in very warm water to expel air; when warm, hold it upright, and keep some water round the stopper until it is cold. Whilst the bottle is cooling, the water is drawn in and loosens the stopper. Twice or three times repeated has always been successful in laboratories.—BARBAROS.

[11277.]—**Soap Boiling.**—The following is a rough outline of the manufacture of soap:—A vat is charged with barilla, kelp, or potash, or a mixture of all three; a small quantity of quick lime is added, and afterwards water sufficient to slack the lime. Near the plughole of the vat some straw is generally placed to prevent any solid particles from passing through when the ley is drawn off. Water is then added to fill up the vat; after standing several hours, the solution is drawn off into a lower reservoir. Water is again added to the material in the vat; the first ley is removed from the reservoir into one nearer the boiler; and then the second ley is drawn off. This is done on purpose to have two leys of different strengths always at hand when boiling. The number of waters added to the materials in the vat depends chiefly upon their quality and the experience of the operator; a good workman can generally tell by the taste whether the water has dissolved the whole of the alkali. The ley being ready to ladle out of the reservoir, which is near the boiler, the tallow or oil, having been weighed, is put in. When it is sufficiently melted, the workman begins adding the ley and stirring the mixture. The alkali and the oil soon begin to unite and form a milky fluid. As more ley is added the mixture thickens. This is continued for thirty hours, and sometimes more, till small portions of the soap, taken out from time to time, assume a proper consistency. The workman then adds a quantity of common salt, which has the effect of separating the watery part from the soap; which contains a proportion of neutral salts, that existed in the crude alkali, especially when more than enough has been added. The fire is now withdrawn, and the mass left to cool. The watery part is found at the bottom, and is removed by means of a pump fixed to the side of the boiler. When this is removed, the fire is rekindled, and if the mass does not melt freely, a little water is added. As soon as the whole becomes liquid, and is made uniform by stirring with wooden poles, the fire is again withdrawn, and the mass allowed to assume a proper consistency for lading. It is laded into square moulds; these are composed of a number of strata lying one upon another, so that when the soap has become solid each layer of framework can be removed, beginning at the top, and the soap is cut into bars or cakes, with a fine brass wire at every interval. Yellow hard soap is formed of soda and tallow, but it also contains resin, and sometimes palm oil. In boiling the yellow soap, the resin and oil, or tallow are put in the boiler first. The ley is prepared in a similar manner to that for the white soap. Soft soap differs in its composition from hard in containing no alkali but potash. Soft soap made with colourless fat is a white unctuous substance, about the consistency of lard. If the fat is coloured the soap partakes of the same colour. On the Continent it is generally coloured with metallic oxides. Those made with yellow oil are sometimes coloured with indigo, which gives them a green colour. The oils generally used are the cheaper oils—such as rape, linseed, hemp, &c. In Holland it is made with whale oil. This oil is forbidden to be used in some parts of the Continent, owing to its offensive smell. In this country all soft soap is made with whale-oil, which gives a transparent mass of a yellow colour. In commerce, it is seldom quite transparent, for the yellow part is generally interspersed with white spots, giving the whole a strong resemblance to the inside of a dried fig.—WILLIAM H. HEY.

[11277.]—**Soap Boiling.**—Soap is composed of fatty substances, soda, and potash. The proportions vary entirely with the kind of soap required, and even for similar kinds of soap the proportions of ingredients are varied by different manufacturers. Ordinary white soap requires 10 to 14 cwt. of tallow or olive oil per ton, and from 10 to 14 parts of soda, and 15 to 20 of potash to every 100 parts of fat. In manipulation, again, different manufacturers vary most considerably, so much so indeed that it would be almost useless to state any particulars. The moulds are of wood or cast-iron, those of the latter material being used for yellow soap.—EXCELSIOR.

[11278.]—**Steam.**—My own formula is $V = 8 \times \sqrt{P - p} \times 2{\cdot}3$. It does not agree with that given by other authorities. It is, however, deduced by experience. Where—

V = the velocity in feet per second.
P = the pressure of supply in pounds per square inch, atmosphere included.
p = the back pressure in pounds per square inch, atmosphere included.

Care being taken to allow for the friction of passage through long pipes, their diameter being increased to maintain the pressure. Arguing from theory, it is impossible to have a steam pipe too large; but with size is also increased the disadvantage of condensation, both by convection and radiation; therefore, there is a practical limit, and a near approximation to a definite size for general use.—TUBAL KAIN.

[11280.]—**Light for the Middle of a Room.**—The treatment must depend on at least three dimensions that the querist has omitted to give. 1. How high are the tops (highest glass) of the side windows above the objects you want to illuminate in the middle of room? 2. How distant, and (3) how high (above the same level) are the nearest buildings outside the windows? State these for both sides if there is any difference between them. Almost the last words of Sir David Brewster were some valuable hints on this subject in the *Builder*; but everything turns on the position and height of neighbouring walls, if any. The treatment of such a room in a street or in open country will have to be totally different.—E. L. G.

[11280.]—**Light for the Middle of a Room.**—I have found a few sheets of tin fastened to a board very effective in throwing light upon dark passages, staircases, cellars, &c., and I should think "One in the Dark" might make an arrangement to effect his purpose. A hint might be taken from the stations (under ground) of the Metropolitan Railway.—F. F. C.

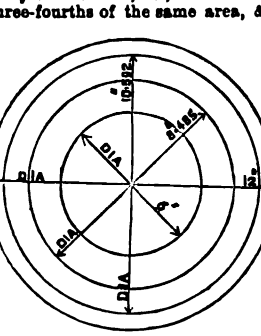
[11281.]—**Value of One Second on the Sun's Disc.**—This question will vary in its result according to the values assigned to sun's parallax and to the earth's semi-diameter. Taking the parallax, as given by the *Nautical Almanac*, 8·5776, which is the value assigned by Encke, and the earth's diameter 7912·5, which is Bessel's determinative, we get $\frac{7912\cdot 5}{2 \times 8\cdot 5776} =$ 462 miles, for the sun's parallax is nothing more than the angle subtended by the earth's semi-diameter at the sun's mean distance.—WILLIAM HUGHES.

[11281.]—**Value of One Second on the Sun's Disc.**—The value of one second on the sun's disc is equal to the sin. one second multiplied by the sun's distance. Taking the mean value of the latter as 91,400,000 miles, we have ·00,0004,848 × 91,400,000 = 443 miles. For the value, when the sun is respectively nearest and farthest from the earth, we have 436 and 450 miles.—G. F. H.

[11285.]—**Chemist's Certificate.** — "Phœnix" should write to the Registrar of the Pharmaceutical Society, Mr. Elias Bremridge, 17, Bloomsbury-square, London, W. C., who will give the required information in full.—PHILADELPHOS.

[11292.]—**Linseed.**—This seed is a nutritious and fattening food, the value of which is well known to farmers. As a remedial agent, the crushed seed, containing all the oil, is much used for poultices, which remain soft and comfortable longer than those made with ordinary linseed meal or bread. Linseed oil, mixed with an equal quantity of lime water, is useful as a first application to burns and scalds. The decoction of linseed (linseed tea) is drunk to allay irritation of the mucous membranes in catarrh, bronchitis, dysentry, gonorrhœa, &c.; and its frequent use is not likely to be injurious, for linseed contains nothing but what the digestive organs may assimilate as food.—PHILADELPHOS.

[11294.] — **Dividing Metal Disc.** — The most simple way that I know of is to find the area of the 12in. disc. Divide the same by four, which will be the area of each of the three rings and disc required. Now find the diameters by dividing quarter the major disc area by ·7854 and extracting the square root of the product for diameter of minor disc. Then take two-fourths of major disc area, &c., for diameter of No. 1 ring, and three-fourths of the same area, &c., for No.



2 ring, and the product will be No. 3 ring as required. As shown in sketch, weights, as a matter of course, are equal.

Areas.

$12^2 \times \cdot 7854 = 113\cdot 0976.$

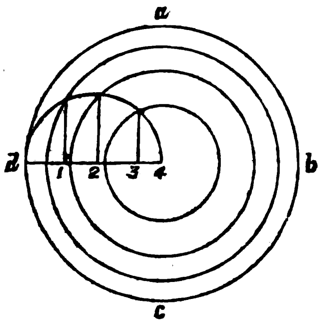
$\frac{113\cdot 0976}{4} = \frac{28\cdot 2744}{\cdot 7854} = \sqrt{36} = 6$ diam. of minor disc.

$28\cdot 2744 \times 2 = \frac{56\cdot 5488}{\cdot 7854} = \sqrt{72} = 8\cdot 485$ „ of No. 1 ring

$28\cdot 2744 \times 3 = \frac{84\cdot 8232}{\cdot 7854} = \sqrt{108} = 10\cdot 392$ „ of No. 2

SEMAJ.

[11294.]—**Dividing Metal Disc.**—Let *a b c d* be the disc; draw any radius, as *d* 4, divide it into the same number of equal parts as it is required to divide the disc into; draw a semicircle on *d* 4, and erect per-



pendiculars from the points of the division to cut the semicircle from the points of intersection of the perpendiculars and the semicircle; describe the circles as per Fig., which will give the required divisions.—G. F. H.

[11294.]—**Dividing Metal Disc.**—First find the centre of the disc. Per question, the radius is 6in. Then, as circles are to each other as the squares of their diameters, the radii taken from the centre of the disc will be—

$$6\sqrt{\tfrac{1}{4}},\ 6\left(\sqrt{\tfrac{2}{4}}-\sqrt{\tfrac{1}{4}}\right),\ 6\left(\sqrt{\tfrac{3}{4}}-\sqrt{\tfrac{2}{4}}\right)\text{ and }6\left(1-\sqrt{\tfrac{3}{4}}\right)$$
$$= 3,\ 1{\cdot}242642,\ {\cdot}953514,\text{ and }{\cdot}803844\text{ inches.}$$

"Disc" has not specified what other divisions he wishes, so it is impossible to comply with his request in that particular; but perhaps the following may be useful, viz.:—Having given the radius (r) to be divided in (n) equal parts, other conditions as per query:—

$$r\sqrt{\frac{1}{n}},\ r\left(\sqrt{\frac{2}{n}}-\sqrt{\frac{1}{n}}\right),\ r\left(\sqrt{\frac{3}{n}}-\sqrt{\frac{2}{n}}\right)\cdots$$
$$r\left(1-\sqrt{\frac{n-1}{n}}\right).$$

—Jas. Hastie.

[11296.]—**Chemical.**—Try black oxide of manganese.—Excelsior.

[11296.]—**Chemical.**—I think "Forked Lightning" will find that a mixture of sulphide of antimony and sulphur will answer his purpose, as it is both cheap and readily explosive.—J. B.

[11297.]—**Spruce Beer.**—Pour eight gallons of cold water into a barrel, and then boiling eight gallons more, put that in also; to this add 12lb. of molasses, with about half a pound of the essence of spruce, and on its getting a little cooler, add half a pint of good ale yeast. The whole being well stirred, or rolled in the barrel, must be left with the bung out for two or three days, after which the liquor may be immediately bottled, well corked up, and packed in sawdust or sand, when it will be ripe and fit to drink in a fortnight. Remember that it should be drawn off into quart stone bottles and wired. If "Constant Reader" wishes, I have a good recipe for white spruce beer, also white spruce wine.—J. H. Gilbert.

[11298.]—**Four-Inch Lathe.**—The hole is intended to carry the end of a boring bar.—Eureka.

[11300.]—**Air-pumps.**—The stuffing boxes of air pump may be packed with cotton that is well greased with tallow, or by a number of leather washers that fit the rod and interior of the stuffing-box tightly; they should be previously dipped in melted tallow that is not hot enough to curl them up. Both these packings are good, and I generally like to pack with leather about half way up, and finish with the cotton afterwards; this method effectually prevents any loose filaments of cotton being drawn through into the barrel. The large piston has no packing at all, it is merely a solid block fitting the bore pretty accurately, and having 10 or 12 fine grooves turned on its surface to baffle the air should it try to get past it. The small piston may either be made in the same way or consist of leather washers bolted tightly together, and turned afterwards to fit the bore. This makes a good piston, which lasts a long time. There is no valve in the pipe that connects the two barrels, and this is the finest feature in the whole arrangement, tending not only to simplification, but materially assisting the attainment of the best result, as there is no impediment to the free passage of the air. Siemen's pump has two barrels of different sizes, but the pistons are both on the same rod, and there are five valves altogether. It has never been popular on account of this complexity, and cannot by any theory be considered equal to the one I have described. I hope "Last" will find these additional particulars of service. Any proportion may be adopted for the barrels, 1½in. for the small one, and 4½in. for the larger being a good construction.—Henry Turton.

[11302.]—**Circular Brass Box Levels.**—Oil is oftentimes used in place of spirit for these.—Excelsior.

[11304.]—**Nessler's Ammonia Test.**—Nessler test for ammonia is prepared thus: Add to a solution of mercuric chloride, a solution of potassic iodide, till the red precipitate first formed is nearly all dissolved. Then add large excess of caustic potash; let the mixture stand in a stoppered bottle for three or for days, decant when clear. It gives a brown precipitate when added to a solution containing a salt of ammonia. This consists of $HgHg_3NI$. (From "Miller's Inorganic Chemistry," page 217.)—G. H. A.

[11304.]—**Nessler's Ammonia Test.**—This reagent is an aqueous solution of potassic iodine saturated with mercuric iodide, and rendered strongly alkaline with soda or potash. Take of iodide of potassium 3·5 grammes, mercuric chloride 1·6 grammes, water 40 c. c. Solution of potash, a sufficiency. Dissolve the iodide of potassium in 10 c. c. of water; the mercuric chloride in 30 c. c. of water. Add the latter to the former gradually till a permanent precipitate is formed. Then add solution of potash till the fluid measures 100 c. c., and filter. As exposure to the air renders this reagent somewhat turbid, therefore keep the stock in large bottle, which only should be opened to supply small bottle, which is kept to hold that which is in immediate use. This reagent added in excess to a liquid containing a trace of ammonia or its salts, assumes a brownish tinge or brown precipitate, according as the proportion of ammoniac compound is less or more, tetramercuric diammoniac diniodine being formed.—Hermes.

[11304.]—**Nessler's Ammonia Test.**—The best way of making the Nessler test is this, which is based upon one of Miller's:—Dissolve fifty grains of iodide of potassium in a small quantity of hot distilled water. Place the vessel containing this solution in a water bath, and add cautiously to it a strong aqueous solution of bichloride of mercury, shaking up as it is added, so that as fast as the precipitate is formed it will be redissolved. After continuing the addition of the bichloride of mercury for some time, a point will ultimately be reached at which the precipitate will cease to dissolve. When this begins, stop the addition of the bichloride of mercury, filter, and add to the solution 150 grammes of solid caustic soda in strong aqueous solution, then dilute the liquid so as to make its volume equal one litre, add to it about 5 c.c of a saturated aqueous solution of bichloride of mercury, allow to subside, and decant the clear liquid, which is the Nessler test. It is advisable to keep a stock of the test in a large bottle, which should only be opened to supply a small bottle kept for immediate use, as exposure to the air renders the Nessler test somewhat turbid.—J. B.

[11309.]—**Breaking Strain of Hollow Iron Columns.**—In long (*i.e.*, in proportion to diameter) hollow cast-iron columns the breaking weight in tons is equal to

$$42\,\frac{D^{3\cdot5}-d^{3\cdot5}}{l^{1\cdot63}}$$

where D = outer diameter in inches, d = inner diameter in inches, and l = length in feet. The formula for the strength "when standing at an angle" would be of no practical use. Who ever heard of an iron column being so disposed with reference to its load?—Excelsior.

[11310.]—**Logarithms.**—These are for facilitating calculations. By the addition or subtraction of logarithms of numbers the same purpose is served, as if the numbers themselves had been respectively multiplied and divided. Use Chambers' "Mathematical Tables."—Excelsior.

[11310.]—**Logarithms.** — Undoubtedly the best hand-book of logarithms for general purposes is that published by W. & R. Chambers, in their educational series. It is a 7-place table, and contains, in addition to the usual logarithmic tables, tables of the trigonometrical functions and their logs., together with a variety of useful matter (price 3s. 6d.). A smaller table, of 5-place logs., containing the logs. of natural numbers, and the trigonometric functions only, is that published by Walton (James). It is very convenient and suited to the pocket, and the logs. are readily turned up in it (price 1s. 6d.). It is said to have been compiled under A. De Morgan's supervision. A larger volume of 7-place logarithms, by Bruhns, has just been published (Williams & Norgate), price about 5s. Schion's tables, edited by De Morgan, are also very generally used, but the work is large and expensive. A full description of the method of using logs., &c., is appended to each of the above, except that of James Walton.—A. B.

[11310.]—**Logarithms.**—I wonder Mr. Proctor has the patience to answer many questions of this class. Remember that he is an advanced mathematician, and that logarithms are understood, at least as far as their application, by any sharp schoolboy of sixteen. The use of the tables is always carefully explained in the preface to each volume, but then the preface to any work is exactly what is not looked into, instead of being made the subject of careful reading. As to hyperbolic logs., I am not ashamed to say that I have not the remotest idea of their practical application, which is in connection with the calculus, but I believe that the hyperbolic log. has to be multiplied by a certain amount —viz., ·43429—to convert it into a Briggs's or common log. It would be a very one-sided arrangement to give the logs. of numbers from 9,999 up to 20,000, and to go no further with numbers of five digits. They have, however, been calculated to 100,000. I think the mathematical tables at 1s., by Law, in Weale's "Rudimentary Series," a very handy book, and it contains full instructions.—J. K. P.

[11314.]—**Polishing Oak Floors.**—The floor is first planed smooth, then smeared with beeswax dissolved in turpentine, and finally polished with short bristle brushes, loaded with lead; sometimes the floors are stained before the wax is put on, to give them a darker appearance. It is considered rather laborious work to get up a good surface.—E. F. Conrath.

[11314.]—**Polishing Oak Floors.**—Use the following:—4oz. beeswax, 1oz. castille soap, 6oz. soft water, 6oz. turpentine, 1 drachm borax; put into a jar and allowed to remain till dissolved.—Excelsior.

[11314.]—**Polishing Oak Floors.**—Polish your oak floor with the edge of a glass bottle and elbow-grease.—W. G. A.

[11317.]—**Sugar Boiling.**—The reason of the sugar crumbling after being boiled is either too little cream of tartar was used, or your cover does not fit your pan. The cover should be without a rim and kept on the sugar for ten minutes after it boils; if you read and practice with care the recipes I have sent I do not think you will have much trouble. The white stripes in mint cushions are a portion of the sugar pulled on a hook until white, then double up until even and regular.—L. W. D.

[11318.]—**Gravitation.**—"C. W. H." is mistaken in supposing that bodies should fall with velocities proportioned to their masses. Their masses have very little to do with it in the case of terrestrial gravitation, the proportion being that of the joint mass of the earth and attracted body. The denser the body the more rapid it will fall, simply because the air resists it only to the same degree that it would a substance of the same volume but less mass, whilst the momentum, but not the velocity, of it is greater than that of a less dense body of equal size. The different velocities being attributable to the resistance of the air, of course when the resistance is removed the velocities are equal.—G. F. H.

[11318.]—**Gravitation.**—1. The mercury in an inverted thermometer would have to alter its form so much, and take so much more lengthy and narrow a figure before it could descend, that, even supposing the vacuum perfect (which it rarely is), its cohesion keeps it in the compacter form, and so suspends its small weight in the bulb. 2. Apart from resistances (as friction and air), because the weights of bodies are proportional to their masses, gravity (at one place) gives them all the same velocity. A pull of a pound can only give to a pound of matter the exact velocity that a pull of a grain gives to a grain of matter. Hence both fall together when they have only themselves to move, as in vacuo. It is very different when the lighter thing has to displace (and raise) perhaps half its weight of air, and the heavier thing not a thousandth of its weight.—E. L. G.

[11318.]—**Gravitation.**—The fact mentioned by "C. W. H.," in the opening sentence of this query, operates in nowise to the prejudice of the theory of gravitation. The phenomena was observed in 1792 by Huygens, and is evidently a result of the adhesion of the mercury to the internal surface of the capillary tube. The "guinea and feather experiment" is certainly capable to demonstrate the "contrary effect" which obtains on removing the resistance offered by the air to the motion of bodies (differing in density) when falling by the attraction of gravity. The resistance of the air is proportional to the surface which the body presents in the direction of its motion. Now the guinea not only may present a smaller surface than the feather, but also the force which it exerts to overcome the resistance is many times greater, because of its greater density, than is exerted by the feather; *ergo*, the guinea will reach the earth's surface before the feather; remove the resistance of the air by allowing the bodies to fall in vacuo, and guinea and feather will fall towards the earth's surface with equal rapidity. Attraction is proportional to the mass of the body which attracts (if the distances of different attracting bodies be the same); *ergo*, the attraction exercised by the earth on a guinea bears to the attraction exercised by the earth on a feather the same proportion as the mass of the guinea bears to that of the feather, and, neglecting the air's resistance, they fall with equal rapidity.—A. J. V. G.

[11321.]—**Galvanometer.**—Although this query is addressed to "Sigma," I have taken the liberty of attempting to reply to it. The examiner doubtless refers to a method, due to 'Melloni,' described in his own work (where the querist will find it at the end of the tenth chapter, I believe) "On Heat," last edition.—A. B.

[11324.]—**Salt Damp in Walls.**—Unless "W.M." has particular reasons to think that there is salt in the sand, he may be sure that it is not salt, but saltpetre; he may convince himself by throwing a little on the fire, when he will see little stars sparkling. The cause of this is dampness from liquid manure, although at some distance, outside or under the wall.—Barbaros.

[11328.]—**Organ Stops.**—To "A Subscriber who appreciates the Mechanic." The scale of the Lieblich Gedact varies in different instances, but the usual dimensions are CC = 3in. × 2 3-19in. Tenor C 1⅞in. × 1⅜in. Middle C 1¼in. × ⅞in. Treble C = ⅞in. × 7-16in. It will have to be set out in the manner described by "J. D." for the stopped diapason, to get the other notes in the octave. The lowest notes should be of ¾ pine, the next 2 or 2½ octaves of ½in., and the remainder of ⅜in. stuff. The heights of mouths vary with the pressure of wind, but for 3in. are generally about one-half the width of the pipes, diminishing to about one-third in the treble. The salicional scale depends upon that of the open diapason, the tenor C 4ft. of the former being of the same diameter as the middle C 2ft. of the latter. The Cremona is a reed stop, having very short cylindrical tubes; in consequence of the small scale the length is little more than half of a full scale trumpet; for it is a noticeable fact that whereas, in flue work, the increase of scale reduces the length of the speaking part of the pipe, and *vice versâ*, in reed pipes it is just the reverse. The Cremona is now frequently placed in a box to subdue the reediness or harshness common to this stop.—E. F. COWRATH.

[11334.]—**Squinting.**—I would advise "G. W. F." to procure a letter and take his little boy to one of the ophthalmic hospitals in London, where by undergoing an operation he would be cured. A friend of mine was quite cured by so doing.—J. CHAMBERLAIN.

[11334.]—**Squinting.**—Spectacles having blackened glasses (perhaps metal discs would answer), with a small perforation in each, are said to be a safe remedy for this defect in vision.—J. G.

[11334.]—**Squinting.**—Squinting frequently arises from the unequal strength of the eyes, the weaker eye being turned away from the object by the fatigue of exertion. Cases of squinting of long standing have often been cured by covering the stronger eye, and thereby compelling the weaker one to exertion. "G. W. F." could try the above with the little boy.—F. T. S. S. D.

[11336.]—**To Mr. Tonkes.**—May I ask what is "S. J.'s" definition or idea of what is expressed by the sign 0 in mathematics? It does not signify what we call "nothing." It is merely an infinitely small number. Since then, 1 is, at any rate, an appreciable number, it must be an infinite number of times greater than 0, or

$$1 = 0 \times \infty$$

$$\therefore \infty = \frac{1}{0}.$$

Or, again, since 0 is an infinitely small quantity, its reciprocal must be an infinitely large quantity—*i.e.*, must be $= \infty$. Again, how can "S. J." make $\infty + \infty = 2\infty$? How can there be a number which is $>$ infinity? "S. J." is justified in writing—

$$1 : 0 :: \infty : 1$$
$$\text{and } 1 : \infty :: 0 : 1$$

But he cannot write—

$$\frac{1}{0} = \frac{\infty}{0}$$

$$\text{deducing it from } \frac{1}{0} = \infty$$

Since, if we allow 0 a value on the left-hand side of the equation, it is only fair to do the same on the right. He cannot, therefore, write—

$$1 : 0 :: \infty : 0$$
$$1 : \infty :: 0 : 0$$
$$1 : 0 :: \infty : \infty$$
$$\text{or } 1 : \infty :: 0 : \infty.$$

Which are, as he says, "most truly absurd."—W. L. GILES.

[11336.]—**To Mr. Tonkes.**—Perhaps by the time "S. J." has mastered the following he may be able to comprehend Mr. Tonkes:—

$$x(x - x) = x^2 - x^2$$
$$(x + x)(x - x) = x^2 - x^2$$
$$\therefore x = x + x,$$
$$\text{or } x = 2x.$$

—EXCELSIOR.

[11337.]—**Equation.**—It is simple enough to those who understand it, but to solve it requires more data than is given on p. 25, No. 365. To render it more simple to an ordinary arithmetician, I supply the missing signs:—

$$= a + (n - 1) \times d \qquad (1)$$
$$S = \frac{(a + l) \times n.}{2} \qquad (2)$$

By formula (1) $l = a$ plus n, minus 1, multiplied by d. By formula (2) $S = a$, plus l, multiplied by n, and divided by 2.—TUBAL KAIN.

[11337.]—**Equation**:—

$$S = \frac{(a + l)n}{2} \therefore \frac{2S}{n} - a = l.$$

$$l = a + (n - 1)d = \frac{2S}{n} - a.$$

$$2l = \frac{2S}{n} + (n - 1)d.$$

$$l = \frac{S}{n} + \frac{(n - 1)d}{2}.\text{—Answer.}$$

—THETAMU, Horsham.

[11338.]—**Marseilles Soap.**—This is an oleo-margarate of soda, produced by boiling an aqueous solution of caustic soda with olive oil. An analysis by Braconnot gave:—

Oily acids	68·40
Soda	10·24
Water	21·36
	100·

—W. W.

[11339.]—**Astronomical.**—It is not true that 365 solar days are 366 sidereal days. It takes 365·254, &c., solar days to equal 366·254, &c. (the same exact fraction) sidereal days.—E. L. G.

[11341.]—**Colouring Photos.**—Lick them. Yes. —EUREKA.

[11348.]—**Meteors, Comets, &c.**—Perhaps I should have said "of the earth," but if Whiston could have shown our globe to have been originally a comet, undoubtedly the other bodies in our system must have been comets also. Whiston's rather absurd theory was, as everybody knows, intended to explain the Noachian deluge.—M. PARIS.

[11353.]—**Distilled Water.**—Distilled water is water which by distillation has been separated from all the impurities which ordinary water contains. It is, therefore, peculiarly adapted to all delicate chemical processes, such as electrotype, photography, analysis, &c., where the introduction of impurity would deteriorate or falsify the results; but it is not adapted for drinking, as it contains little or no air, and hence is vapid and disagreeable to the palate. For some further details, see the article on water in the "Lessons on Chemistry," page 578, Vol. XIV.—S. BOTTONE.

[11357.]—**Berlin Black.**—This is identical with Brunswick black, for which I gave a recipe at p. 442, Vol. XIV. That recipe is excellent. Should "Register" require more information, let him read "Larkin's Iron and Brass Founder," where he will find many thousand useful hints.—S. BOTTONE.

[11358.]—**Pressure of Water.**—"Templeton" says the side of any vessel containing a fluid sustains a pressure equal to the area of the side, multiplied by half the depth. Thus, suppose each side of a vessel to be 12ft. long and 5ft. deep, when filled with water, what pressure is upon each side?

12×5 = 60ft. the area of side
2·5ft. = half the depth, and
62·5lb. = the weight of a cubic foot of water.
Then $60 \times 2·5 \times 62·5 = 9375$lb.

I would suggest to "R. Irons" that if a pipe of any bore, no matter how small, be attached to a tank, the fluid in it will exert the same pressure upon the tank in proportion to its height as if the sides of the tank were carried up to that same height.—A., Liverpool.

[11360.]—**Sun's Declination.**—See "Altair's" letter.

[11361.]—**Preserved Meat.**—The reason why the ends of the tins are concave is because of the vacuum produced during boiling and subsequent cooling. Hence, the atmosphere presses with a force of about 15lb. to the square inch on the surface of the tin, and thus produces the concavity.—S. BOTTONE.

[11367.]—**Magnesium Lights.**—The most effectual and satisfactory mode of producing these lights is by burning the wire or ribbon in a lamp expressly made, in which the wire or ribbon is fed through the nozzle of a small pipe as fast as it is consumed. Nearly all our leading philosophical instrument makers supply these lamps.—S. BOTTONE.

[11370.]—**Electrical.**—In this case the tongue acts the part of the liquid in the cell of a battery, and the copper is the negative plate, as it is in the cell, though the wire from it is the positive pole externally.—SIGMA.

[11378.]—**Killing Beetles.**—1. Place them under a wineglass, in which a few pieces of blotting paper, moistened with a saturated solution of cyanide of potassium are laying. This is a painless mode. 2. Throw them in *boiling* water, and dry on blotting paper. 3. Immerse them in a solution of corrosive sublimate in alcohol. I always use the first method both for *Lepidoptera* and *Coleoptera*.—S. BOTTONE.

[11378.]—**Killing Beetles.**—Pin them by one pin with their backs downwards tightly to a large cork, when in this situation open their mouths with a bent needle, and let a drop of the strongest rectified spirits of wine fall into it from the end of a quill or small feather. For the smaller beetles boil some spirits of wine and dip them in for an instant, and afterwards dry them carefully in an oven.—FANTAIL.

[11381.]—**Rhumkorff's Coil.**—The number of cells depends on the size of the coil, and the insulation of secondary. About two to six Bunsens coupled in series are commonly used.—SIGMA.

[11382.]—**Parrot.**—Let "Cygnus" give "Polly" pills occasionally of bread-paste and cayenne pepper, let her have plenty of fresh air and sunlight; a little fruit now and then will do her no harm; certainly keep all fats and animal food away from her. She should also have plenty of fresh water, not only for drink, but for the bath, of which she will gladly avail herself. I had a fine bird which used to moult all the year round; before she came into my possession she never had any tail to show worth speaking of. She was then fed from the dinner table with any food she would take. When I got her she never had anything but bread and milk, a little fruit, not too much hempseed, and abundance of water. She never moulted again in the eight years I had her, but had always a splendid plumage and tail. Poor "Polly" was shot once in both wings, one of which was broken, she having been out all one night "on the spree" miles away, but she survived this accident by careful nursing for several years, only to be poisoned by burglars.—GEORGE BELL.

[11387.]—**Sundials.**—No sundial could possibly give correct indications for any other hour than noon, either by rotating it on a pivot or adjusting the gnomon vertically, as the fundamental principle of all sundials is that the twelve o'clock line must be truly in the plane of the meridian, and the elevation of the gnomon equal to the latitude of the place. The correction for the equation of time by the tables is far simpler in appliance than any "setting" of the dial could be, were it even possible.—GEORGE BELL.

[11393.]—**Metallic Harmonicon.**—This is only a toy, and is of no service to the musician. An instrument—in which are vibrating metal strips in connection with key and hammer action—has been lately revived by Messrs. Cramer & Co., under the name of the "Bell Pianetto." This is really a useful little instrument for practice, and as its tones resemble strongly those of a harp it is agreeable as well as useful. A patent for this instrument was taken out towards the latter end of last century, so "Valve" need be under no apprehension if he make one for himself. If he can call on Messrs. Cramer he can see the construction; if not, let him write again and I will give details.—S. BOTTONE.

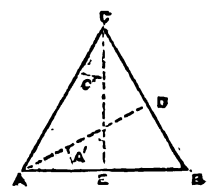
[11398.]—**Stinging of Bees, Hornets, and Wasps.**—Strong brandy or spirits of wine; also vinegar applied with the finger or small sponge.—FANTAIL.

[11400.]—**Pedals for Pianoforte.**—If "J. W. S." will call on Messrs. Broadwood and Sons he will see their "Pedalier," and will immediately understand what he is to do to get the desired result.—S. BOTTONE.

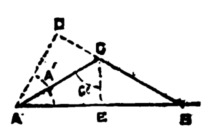
[11403.]—**Gas.**—It is obtained from the company's mains, and is led by a hose into long metal cisterns on the top of the cars, where it accumulates under considerable pressure. From these cisterns it passes into the burners. A gauge, showing whether the cistern is empty or full, is placed on one side of the car.—S. BOTTONE.

[11405.]—**Purifying Zinc Wire.**—Zinc wire should never be used for a battery. Mercury does not purify zinc at all; it amalgamates it. Pure zinc may be obtained by precipitating its sulphate by an alkali, mixing the oxide thus produced with charcoal-powder, and exposing the mixture to a bright red heat in a covered crucible, in which the pure metal will be found as a button at the bottom when cold.—S. BOTTONE.

[11410.]—**Geometrical Question.**—The sides A C and A B being equal, the angles A and B are therefore equal. The angle A C B at the vertex of the isosceles triangle is consequently 180—A—B, or, B being equal to A, 180—2A, the half of which is 90—A. The triangle D A B being right-angled at D, D A B is equal to 180—90—B. But the angle B being common to both triangles is equal to the angle C A B as before, therefore D A B is equal to 180—90—A = 90—A, which is shown above to be the half of angle A C B. If the side B C has to be produced, the same reasoning will apply, substituting D for C.—GEORGE BELL.



[11410.]—**Geometrical Question.**—Let A C B be an isosceles triangle, and let A D be a line drawn perpendicular to B C. As all the angles of a triangle are equal to two right angles, and also that things which are equal to the same thing are equal to one another, therefore the angles A D B, D B A, B A D are together equal to the angles A C E, C E A, C A E. Of these, the angle A D B is (by construction) equal to the angle C E A, and the angle C A E is equal to the angle D B A (angles at the base of isosceles triangle), then the remaining angle D A B is equal to the remaining angle A C E, which latter is half of the angle A C B. Therefore the line A D described at right angles to B D forms with the line A B an angle equal to half the vertical angle of the isosceles triangle. N.B.—The above letters are applicable to both the accompanying illustrations.—C. P. H.



[11410.] — **Geometrical Question.** — "Undergraduate," T. Odger Phelps, "S. M. B.," H. D. Mead, W. Hughes, R. Lupward, Wm. Cook, "V. B.," R. Arrowsmith, "Just Promoted," and "E. L. G." have also answered this query.

[11421.]—**Photography.**—Coat your plate with collodion; let it "set" until the bottom edge takes the impress of the finger pressed against it, without sticking to it. Immerse into the bath, and leave it there (moving it up and down) until all oily streaks have disappeared. Now expose and develope. Does the picture come out well without any fogging? If it does, wash it in a very gentle stream of water. Fix it, by immersion in a saturated solution of hyposulphite, but do not leave it ten minutes. As soon as the creamy iodide is removed, withdraw the plate, and wash again carefully in a gentle stream of water. If your picture still comes away, you may be sure of one of three things. 1. Your chemicals are impure, or your glasses dirty. 2. Your collodion is made with bad gun-cotton, and is what is technically called "rotten." 3. You wash too heavily, so as to carry off the film bodily. I should be inclined to think, from the "mottled" appearance, that dirty glasses lie at the bottom of all the evil.—S. BOTTONE.

[11422.]—**Night and Day Temperature.**—If "A. E. S." will hang out a minimum and maximum registering thermometer, he will soon see how much truth there is in the assertion. With regard to winds, I am not in a position to say anything positive; but from personal observation, I think that winds are rather more prevalent at night than in the day.—S. BOTTONE.

[11427.]—**Degrees in Chemistry.**—Read, mark, learn, and inwardly digest, the contents of Roscoe's and Barff's "Chemistry." In the latter work you will find most of the questions propounded by [illegible] ers from 1865 to 1871 [illegible] —S. Bo[illegible]

[11429.]—**Ferns** [illegible]
give a little air, [illegible]
inserting a wed[illegible]
drainage to th[illegible]

[11434.]—S[illegible]
water, strain [illegible]

—PANTILE.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "R. O." has answered 10776; "Shawforth," 10832; "Sigma," 10839.

10938 Electric Lamp, p. 597
10942 Plan for Setting Retorts, 597
10944 Portland Stone, 597
10946 Joiners' Tool-chest, 597
10951 Applying Goldleaf to Silk Fabrics, 597
10958 Model Boiler, 597
10960 Straightening Tinned Wire, 597
10963 Brazing Fishing-rod Ferrules, 597
10965 Racks and Pinions for Telescopes, 597
10968 Polishing Watch Steelwork, 597
10970 Corking and Sealing Bottles, 597
10975 Australian Meat in the Royal Navy, p. 598
10976 Tartan of Clan of Sir R. Murchison, 598
10984 Lapidary's Developing Solution, 598

11007 Roman Sepulchral Inscription, 598
11008 Tilt Hammer, 598

QUERIES.

[11437.]—**Sash Tool Handles.**—By what process are the handles of painters' sash tools made?—Simpleton.

[11438.]—**Lemon Marmalade.**—I should feel very much indebted to any of the readers of the Mechanic, who would tell me how lemon marmalade is made, and also vegetable marrow preserve.—A Young Housekeeper.

[11439.]—**Cost of Chamber Sulphuric Acid.**—Will Mr. G. E. Davis have the goodness to inform me the cost of manufacturing hydrated sulphuric acid at 118° Twaddle?—S. O.

[11440.]—**Double Bass and Violin Stain.**—Would any correspondent be kind enough to give me the sizes and thicknesses of a full-sized double bass, and the kind of wood best suited to make one? Would good selected yellow pine make the breast or does it require the legitimate Swiss pine? Also what would make a good stain for a violin—reddish brown or any other good colour? and oblige—Benson.

[11441.]—**Dyeing Cotton Thread Jet Black for Polishing.**—Can any of our readers inform me the best method of effecting the above?—M. B.

[11442.]—**Old Wives' Science.**—Can any reader of "ours" tell me what is the reason that if the sun shines upon the fire it puts it out?—A., Liverpool.

[11443.]—**Warming Greenhouses.**—Will "E. T. S." please inform me how he uses his petroleum lamp to keep the frost out of his greenhouse? (Reply to query 10083, page 442, Vol. XIV.) Is there any piping to carry off the fumes of the lamp—if not, do they affect the plants at all?—Anxious.

[11444.]—**Bursting of Compressed Air Receivers.**—I beg to solicit the opinions of your numerous correspondents on the following:—What would be the effect of the bursting of an air receiver (say, for example, 30ft. long, 6ft. diameter, and made of ⅜in. boiler plate)? Would the receiver be merely laid open, allowing the compressed air to expend itself, without doing any further damage, or would it be accompanied by the disastrous results usually attending the explosion of steam boilers?—Lyons.

[11445.]—**Electrical.**—Would Mr. Tonkes kindly give me a little information? I wish to make a medical coil, powerful enough to affect three persons when their hands are joined. I propose to make it as follows:—The paper tube to be 1in. diameter, 7in. long, with four layers of No. 16 cotton covered wire for primary; secondary, 6 layers of 32, with a further length of No. 32, soldered on. Will Mr. Tonkes kindly give me his opinion on the above coil, and say how I am to insulate it properly?—J. H.

[11446.]—**Small Coil.**—I wish to construct a shocking coil small enough to carry in the waistcoat pocket, battery included. I have tried hitherto, but without success, as I make it too bulky, owing to bad arrangement of the different parts. Will some of our electrical contributors oblige by giving me full instructions for constructing one? perhaps Mr. Tonkes will oblige.—An Anxious Mechanic.

[11447.]—**Blundered Coin.**—I have a copper halfpenny of Charles II., with a blunder in the title, which, instead of reading "Carolvs a Carolo," is "Craolvs a Carolo." Has any brother collector met with a similar coin?—Moneta.

[11448.]—**Chronometer Balance Spring.**—Would any of your horological correspondents kindly give some information on the steel chronometer balance spring in watches? I have been informed that they are not to be had unless one gives a good price for them. I have a lever watch which I gave £6 5s. for some eight or nine months ago, with a chronometer balance spring (at least I was told so), and it has never yet kept good time. Is there any deception in them? if so, how can it be detected? Also what effect will dampness have upon the balance?—O. M.

[11449.]—**Angelet.**—I have in my possession a gold coin, which seems to be an angelet of James II., but I cannot find any description of it in any work on coins. On the obverse a ship with the title, &c., JACO. II. D. G. M. B. F. . . . ET. HI. REX. On the reverse an angel with a spear standing on a dragon, and the motto, SOLI. DEO. GLORIA. I am sorry to say it is much worn, and pierced in two places, and weighs in its present condition but 30 grains.—Moneta.

[11450.]—**Adjusting Equatorial.**—In adjusting the equatorial "that the polar axis may be placed at the altitude of the pole," according to the rule given by Chambers, p. 640, last edition, it is recommended that the declination of some favourably situate star be obtained, and compared with its declination given in the *Nautical Almanac*. An example is given, a Ursæ Minoris being the star selected. Referring to the *Nautical Almanac* for the present year I find the apparent position of this star (given at p. 371 for the upper transit of Greenwich) for this day is 88° 14' 17·6". My position is some degrees (2° 21' 23") north of Greenwich. Under the circumstances should I not apply a correction to the declination given in the *Almanac* for the difference of latitude? and if so what correction should be applied? I make the inquiry since no mention of any correction is made by Chambers or in Loomis, where the same rule is given.—Lamrock.

[11451.]—**Weight for Safety Valve.**—I have made a safety valve for a boiler, and have tried to work out what weight I shall require for that valve, and the distance to place it on bar, but I cannot get it right. My lever from A to B is 16in.; weight of lever, 12½oz.; weight required to balance ditto at A, 1lb. 14oz.; weight of valve, 7oz.; diameter of valve at E, 1¼in.; distance from A to C, 3in.; required to know what weight I want and what distance I am to place it from the fulcrum A, to blow off at 25lb., 30lb., 35lb. and 40lb.?—E. Nayler.

[11452.]—**Rain-water Tanks.**—I am about to construct a large rain water-tank to avoid wasting the rainfall off the roof of a house, and shall be greatly indebted to any one of experience in such constructions for advice as to the best method of building them, the section of bottom and sides, and as to the cover. My cistern should contain 1,500 cubic feet. I have clay, stone, and gravel for concrete, but no bricks. How is the connection best made between the roof and the tank, and how is it to be cleaned out?—Rosso.

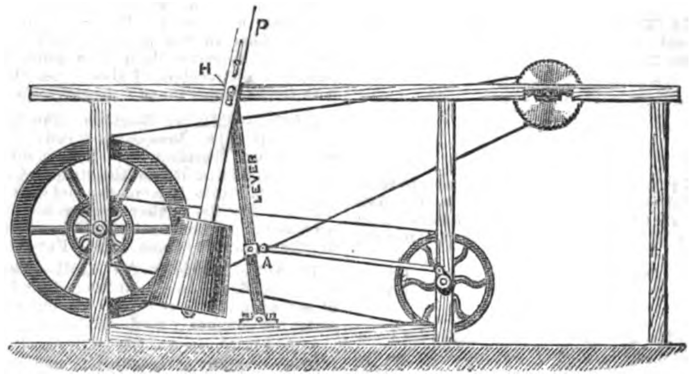
[11453.]—**Saturn.**—In looking through some foreign observations of Saturn, I find it stated that the ball of Saturn has been observed. Would any readers inform me whether the semi-diameter given in the *Nautical Almanac* is for the ball or the ring of Saturn?—William Hutchins.

[11454.]—**Commercial.**—I occasionally find E & OE, written at the foot of a bill or account to the left hand corner; would any one inform me what is the meaning of it?—R.

[11455.]—**Daisy Extractor.**—Can any brother reader of the Mechanic inform me how to make an implement to extract daisies, roots, &c., from lawns, with a drawing?—F. T. S. S. D.

[11456.]—**Saw Sharpening and Gulleting Machine.**—Can any brother reader inform me how to make the above machine, to be driven by steam? I want it to sharpen circular saws and pit saws, with a drawing of same.—F. T. S. S. D.

[11457.]—**Motive Power for Amateurs.**—I send drawing of a saw bench I am fitting up, and which almost explains itself. It will be seen that the long bar, P, which is suspended from the roof, acts as a pendulum, swinging backwards and forwards from the roof, the requisite movement being given with the handle H. This pendulum works a lever hinged at the bottom; on this lever is the sliding part A which can be fixed in any position (on the lever) by the thumb screw. In this manner the swing of the pendulum is regulated. Could any reader tell me if it is possible to arrange a system of weights so as to work a ratchet wheel in connection with the above pendulum (same as in clocks), and if it would swing the pendulum fast enough? If this is possible "there is the motive power for amateurs." I should like to know of any improvement to the above.—Zoo Andra.



[11458.]—**Carmine Staining.**—Should this be done to sections of animal tissue immediately after cutting or after the maceration in glycerine, and when in case of the use of re-agents? Does the same answer apply to sections of vegetable tissue?—Interrogator.

[11459.]—**Printers' Ink.**—Instructions for making the finest dark blue and red inks, for ball programmes and fancy work, would be very acceptable. The common colours run too light.—W. J. H.

[11460.]—**The Bee Hive.**—Mr. Abbott, at p. 19, recommends Mr. Godden to keep his glass hives under cover except when under observation, as they are dangerous things in a house. I wish he would be so kind as to explain the particular danger, and how to avoid it. I have a hive in a conservatory with entrance from the outside, but many of the bees came into the conservatory, apparently trying to enter the hive, and some of them died before I could pick them up and carry them to the hive entrance. Is it probable that the bees were really trying to get into the hive when they saw it? When we covered it over with a cloth fewer bees came into the conservatory, but I am not sure that that was because the hive was hidden. They made very little honey last year, flowers being scarce hereabouts. I live at South Kensington, about half a mile from Kensington Gardens, and a mile from Battersea Park: are such distances too far for bees to fly for food?—Philo.

[11461.]—**Reviving Black Cloth Coats, &c.**—Would some of your correspondents give a recipe for reviving black cloth coats, waistcoats, &c.? I have tried solution of carbonate of ammonia and dilute spirits of hartshorn. These remove grease, &c., but leave the cloth of a whitish hue, and when a trifle threadbare, make it look worse than before.—A. Desroirs, Dublin.

[11462.]—**Steel Hardening Paste.**—At an extensive machine works in Lancashire a few weeks ago, saw the turning tools and drills dipped red hot into a patent red paste. The blacksmith said this cooling or dipping improved all tools before tempering, and that it was a patent. As this was all the information I could get, I shall be pleased to learn more about this red steel paste.—A. B. C.

[11463.]—**Working Engines.**—I have two twelve-horse horizontal non-condensing engines worked by a twenty-four horse double tubed Cornish boiler—one of the engines (only) working three or four days in the week, the other six days. Is there not a great loss in fuel by working with the one boiler? What should I save by getting a separate boiler to each engine? A reply from any of your numerous readers will much oblige.—Dolomite.

[11464.]—**Spring Beds.**—When I lived in Paris I used to sleep on a bed made with metal springs, which required no mattress or feather bed. Is such a bed to be got in London, and where?—Associate.

[11465.]—**Problem.**—Two trains 92ft. and 84ft. long respectively, move with uniform velocities on parallel rails in opposite directions; they pass each other in 1½ seconds; when moving in the same direction, their velocities being the same as before, the faster train passes the other in six seconds; find the rate at which each train moves.—Puzzled.

[11466.]—**Vermin and Pigeons.**—Can "Jack of All Trades" or any other kind reader tell me of a wash to destroy vermin in pigeons and pigeon houses, also, which kind of food is best for them, and what amount ought to be given daily to each bird, and would camphor prevent the nits and fleas breeding in the nests?—Fantail.

[11467.]—**Tests for a Telescope.**—Would our obliging "F.R.A.S." kindly furnish me with a few tests for a 4½in. With-Browning reflector of 5ft. focus, also the theoretical dividing, and light-grasping power of the same. For picking up the tests I have Mr. Proctor's new atlas.—A. L. B.

[11468.]—**Observation Book.**—Will some kind astronomical friend tell me a good plan for an observation book, as to the arrangement of its parts, &c., so that I could refer without trouble to any observation before made.—A. L. B.

[11469.]—**Air and Warmth.**—How many cubic feet of air space should a dormitory contain? And what heat is the most wholesome for an Englishman to keep his room to?—Associate.

[11470.]—**Pocket Barrel Organ.**—What is a pocket barrel organ, and how is it constructed?—E. B. F.

[11471.]—**Bow.**—Would any reader kindly tell me the best kind of wood to make a large bow, about 6ft. long?—Archer.

[11472.]—**Plaster of Paris.**—I read and hear that when plaster of Paris is mixed with water and left to dry, it solidifies and becomes a hard and solid mass; but when I try to use it, it crumbles down almost by a touch. Will some practical correspondent tell me why this is, and how I may correct it? Also, ought it not to allow of being placed in water without softening again? for it is, as I read, used instead of porous earthenware vessels in Daniell's and other batteries.—C. B. B.

[11473.]—**Weak Voice.**—Will some kind reader inform me of the best means of strengthening the lungs, and whether milk is a good thing?—Fond of Singing.

[11474.]—**Botanical Specimens.**—Can any one inform me what is the most convenient and effectual method of preserving botanical specimens?—G. A. D.

[11475.]—**Artificial Butter.**—Can any of your readers inform me how this is made? I believe a patent was taken out for it in France, in 1870, and also that it was made regularly in Paris during the siege.—A Subscriber.

[11476.]—**Pattern Making.**—Will "Jack of All Trades" or any other kind subscriber tell me of some good book or books on pattern making?—Delta.

[11477.]—**Lamplough's Pyretic Saline.**—Will some of our chemical friends kindly give me the result of an analysis of the above? I have analysed it to the best of my ability, but being a beginner, I should like to know how near the truth I am.—H. C. J.

[11478.]—**Silver Bath.**—Will some one please tell me how many plates (carte de visite size) 8oz. of nitrate of silver solution ought to be sufficient for?—F. C. G.

[11479.]—**Tempering Cutting Tools.**—I have a quantity of small cutting tools to harden and temper. I should esteem it a favour if any one could give me some little instruction how to heat them in a lead bath to prevent oxidation of the lead, or how to construct a lead bath on the best principle; also what plan I am to adopt to temper them in an oil bath heated to about 580°, and what oil I had better use.—An Old Subscriber.

[11480.]—**Model Steamboat.**—I have a small double-acting oscillating cylinder. Can any one tell me if it would be able to turn a small pair of paddles, about 3½in. diameter? Could any one also give me instructions how to cut out a model steamboat, as small a size as can be made, with a cabin three inches deep, showing the shape at different parts by diagrams? how much lead should be put on the keel, and about how much would it cost?—DESIROUS.

[11481.]—**Organ Building.**—To "J. D."—I have got all my pipes made, and am now busy with the windchest, but I fancy I have not enough standing room for the pipes. Does it matter if the wood pipes are placed quite close to each other, both sideways and back to back? I am going entirely by your directions, so please continue your valuable papers, otherwise I, with a number more very likely, shall be thrown on my beam-ends. I should like to ask a number of questions concerning my work, but I refrain from troubling you, as I have no doubt you will explain all before long.—ALEPH.

[11482.]—**Algebra.**—I should be glad if any of your readers would work out the following equation, as I cannot arrive at the answers:—

$$x : y = z : t$$
$$x + t = 14$$
$$y + z = 11$$
$$x^4 + y^4 + z^4 + t^4 = 24929$$

—PUZZLED.

[11483.]—**Dyeing Parchment.**—Will any correspondent be kind enough to give me the following information? How can I make some good colours as dyes for white parchment? A permanent red and a permanent blue are what I am n need of most, which must not be affected or changed by coming in contact with water, oil, or grease. Also, give the method of applying the dye.—PARCHMENT.

[11484.]—**Manures and Their Values.**—Can any one inform me if there is any clever little book on agricultural chemistry where all the different kinds of manure are treated of, as well as their relative value and different effects on the soil? Also, will some one say what would be the best way this time of the year to crop a piece of ground of four acres? The whole thing is almost new to me. I have not any manure. I intend to work on the small farm system more than the garden system—that is, I mean to grow potatoes, and either turnips or mangolds, and a small portion of wheat and cabbages. I intended to keep a cow or two for the manure. Perhaps a better plan could be suggested. Are there any manures that would do instead of farmyard manure? The land is only of moderate quality.—WILLIAM RICHARDSON.

[11485.]—**Florentine or Brown Bronze.**—Will "Jack of All Trades" or any other contributor of "ours" kindly tell me if any of the bronzes mentioned on p. 642, Vol. XIV., query 10661, will do for tinwork, or one that will, and how they are applied?—R. O.

[11486.]—**Arithmetical Question.**—A settler in the Far West beginning his building had the misfortune to lose his rule in a rift. Having, however by good chance prepared two rods of 5ft. and 7ft. respectively, with these aids only he measured the length, breadth, and various proportions (in feet) of his log-house. Pray, how did he accomplish this, being unacquainted with geometry? The log-house was 48ft. by 28ft., and 11ft. high.—THETAMU, Horsham.

[11487.]—**Preventing Rust.**—Will any of your readers inform me how to prevent iron from rusting that is exposed to a damp atmosphere? I have tried tallow and oil with no good result. No paint allowed.—COASTGUARD.

[11488.]—**Coating Wooden Concrete Moulds.**—Thanks to "Jack of All Trades" for his recipe for waterproof mastic. I have put up a boiler, and shall try it. I now want a recipe for coating wooden moulds in which I form concrete cornices, &c., so as to enable me to withdraw the moulds sooner than I can when the concrete is in direct contact with the wood. I have tried linseed oil, but it discolours the cement. Will any of the gums, such as shellac, copal, &c., dissolved in spirit, form a coating to which the concrete will not adhere?—KHODA BUX.

[11489.]—**Weight of Cattle.**—Will any correspondent be kind enough to give me a rule by which I can ascertain the approximate weight of cattle by measurement? Problem: A farmer bought a heifer calf, which at three years of age began to breed a heifer calf every year, and the whole issue at three years of age commenced to breed heifer calves in like manner. Required, the number of the farmer's stock at the end of twenty years.—SHEPHERD.

[11490.]—**Dumpy Level.**—Will any brother reader tell me what is wrong with my dumpy level, and how to rectify it? I cannot get the air bubble to remain in the centre of its run during a complete revolution of the level.—SHEPHERD.

[11491.]—**Kid Dressing.**—Will some one be good enough to inform me how I can restore kid skins that have been once dressed, but are now gone rough and brown?—J. R., Leicester.

[11492.]—**Carbonic Ink Paper.**—Can any of your correspondents inform me how carbonic ink paper is made?—TELEGRAPH.

[11493.]—**Indiarubber Overcoat.**—Will any of your subscribers kindly inform me how I can prepare the adhesive solution for repairing the seams in the above? I have had one in wear for some time, and now the seams are giving way, but otherwise the coat is very good.—W. P.

[11494.]—**Utilising Slack.**—Will you oblige by requesting some of your talented correspondents to describe the mode of utilising slack by making it into "patent fuel" (a mixture of slack and fine coal), with a description of the ovens or furnaces in which it is prepared, &c.? Or is there any work published where the information can be obtained?—AN INTENDED UTILISER.

[11495.]—**Double Oscillating Steam Cylinder.**—I have a double oscillating steam cylinder, 1½in. stroke, ¾in. diameter. It is supplied with steam from a strong tin boiler, supplied with heat from three burners burning spirits of wine. I cannot make the steam raise the piston. Is the cause from the steam not being strong enough, or is it from the different parts of the engine not being put together properly? Would two brass tubes put through the boiler increase the power of the steam?—VELOCIDADE.

[11496.]—**Lotion of Hydro-Sulphate of Soda.**—Will any one state how the lotion of hydro-sulphate of soda is prepared? Does it destroy organic tissue?—F. N. B. [A portion of this query being commercial was omitted.]—ED.

[11497.]—**Removing Oil Stains from Billiard Cloth.**—Is there any way of removing colza oil stains from a billiard cloth?—W. BELFIELD.

[11498.]—**Re-'Scaping Old Verge Wheel.**—Will "West Cornwall," "Tometer," or any other practical hand say which is the best way to re-'scape old verge wheel by hand?—B. JAMES.

[11499.]—**Zymotic Diseases.**—We are told that every particle composing our bodies is removed and replaced by a new one within a short period. We are also led to suppose that immunity from a second attack of a disease like small-pox is owing to the first attack having exhausted the soil. Will any reader explain this?—M. PARIS.

[11500.]—**Welding Cast Iron.**—Would any of my fellow subscribers inform me how I may weld two pieces of cast steel together? Should feel obliged for a good recipe or two.—DYRUS.

[11501.]—**Exhalations and Consumption.**—Doubtless, many of your readers have frequently noticed the newspaper extracts from medical reports of the decrease of consumptive cases in localities where the surface moisture is rapidly carried off by good drainage. It would be interesting to me to hear why this is so, and what effect exhaling water has upon the human lungs. It has also occurred to me that it might be found by a parity of reason that the evaporation of water from stoves in close rooms was injurious to persons of delicate chests.—CORNUBIENSIS.

[11502.]—**Stair Noses.**—What is the best protection for the edges of stair canvas where it is much trodden on, and soon gets worn out? I have seen angle pieces of brass, and also slips of lead fastened to the nose of the stair, but probably this would cost as much as a new stair covering.—R. H. P.

[11503.]—**Wollaston's Differential Barometer.**—Would some correspondent describe Wollaston's differential barometer, and how it is applied to determine the draught of chimneys? A sketch of the thing would make it easier understood.—VENTILATION.

[11504.]—**Photographic.**—Can any of your correspondents give the name of a good substitute for canvas or carpet in a large photographic studio? The sitter's part has a square of carpet; it is the rest of the room I don't know very well what to do with. Besides the first cost of canvas it wears off in places, and it has occurred to me that it would be possible to stain the floor in imitation of tiles, and then varnish; the tiles to be the width of the boards.—CORNUBIENSIS.

[11505.]—**A Wooden Pump.**—A friend of mine has a wooden pump on his farm which has become worn by the action of the bucket so that no water can be drawn, and a new bucket cannot be substituted, as it won't go down to the loose place. Is there any alternative but taking up the pump and reboring.—CORNUBIENSIS.

[11506.]—**Refractive Index of Glass.**—How is the refractive index of glass found? Has it anything to do with its specific gravity?—ZETA.

[11507.]—**Mathematical Astronomy.**—Allow me to appeal to "F.R.A.S." or Mr. R. A. Proctor to solve a question for me. It is, of course, possible to find the orbit, mean distance, and other ephemerides of any planet or comet from four or five observations of its R. A. and. dec. What mathematical knowledge is required for this? and would an acquaintance with the elements of spherical trigonometry co-ordinate geometry (algebraical) and conic sections be sufficient, or must I study the differential and integral calculus. Also, would it be possible for "F.R.A.S." to indicate in a letter the outlines of this method?—ARISTARCHUS.

[11508.]—**Star Magnitudes.**—Will "F.R.A.S." or some other of your correspondents kindly give the magnitudes of Argelander, Struve, and Herschel, equal to those of Smyth for stars above the tenth magnitude? I should not ask, if it was not that they are essential to all who wish to use the various star catalogues, and as many of our correspondents, as Mr. Knott, Mr. Burnham, &c., use different scales, without such a table these letters can but be of limited use. If "F.R.A.S." is unable to spare the time, perhaps one of these gentlemen might.—ARISTARCHUS.

[11509.]—**Adapting Barrel to Pianoforte.**—Will any subscriber tell me how to adapt a barrel to a pianoforte (one of Bord's)? How are the barrels made? How are the pins made to act on the hammers? and would it interfere with ordinary playing? with any other information that would be a guide to the same. A drawing would greatly assist me.—G. W. WOOLVEN, Sydney, N. S. W.

[11510.]—**Defective Sewing Machine.**—Will "Jack of All Trades" tell me the reason of the cotton not slipping off the hook freely (one of Wheeler & Wilson's machines) it hangs on the bevelled part after the brush has let go, when the point of the hook has passed the brush, the loop still clings to hook. Any information about machines in general would be acceptable to many readers out here.—G. W. WOOLVEN, Sydney, N. S. W.

[11511.]—**Rubber Tires.**—Could some of our scientific readers tell me if there is not a disadvantage in the rubber tires of bicycle wheels in consequence of the suction which there must be, I think, caused by the flattening of the surface of the rubber on the ground with the weight of the rider upon it. We know that it is much easier for a horse to draw a cart, &c., over a hard smooth road than over a soft one, because it don't draw so heavy, as it is termed. I suppose it is the suction that causes the heavy drawing. Applying the same principles to the rubber and iron tires, which would be the lightest drawing? Rubber tires must make the bicycles go quiet, and give nicely to the unevenness of the roads; but is there not more suction, and therefore do they not draw heavier? Perhaps some one who has had some experience in riding wheels with iron and rubber tires can give an explanation to the above, and oblige—A CONSTANT READER.

[11512.]—**Lathe Chuck.**—I observe in No. 362 a description by "Geist" of a chuck for turning oval handles. I wish him to tell me how he holds the other end of the handle. Perhaps "G at" or "Semper Paratus" will instruct me.—T. LEITH.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

The following are the initials, &c., of letters to hand up to Tuesday morning, April 2, and unacknowledged elsewhere:—

R. Gay and Co.—John Browning.—J. S. Darton.—H. Dolan.—Wm. Houlker.—Francis Hawkins.—E. T. Sutcliffe.—Geo. Read.—R. G. Moberly.—W. H. Bailey.—Thos. W. Cowan.—R. Nelson.—R. W. Burchard.—J. Clark.—E. H. Greg.—W. L. Pendered.—J. and H. Crace.—H. W. Hollis.—Col. Anderson.—A. Ledger.—H. E. Havergal.—Jas. Johnson.—Wm. Atwood.—J. E. Muspear.—T. C. Mulvany.—W. G. Roberts.—V. B.—E. S. H. Hallett.—Porter and Lane.—Robert Neilson.—Webb and Co.—Charles Baker.—Lieut. Col. Fendall.—E. James.—Q. E. D.—E. J. D.—Billiardist.—B. J.—Agricola.—E. L. G.—Sheet Iron.—Wallace.—Zeta.—Argyrius.—Bachelor Jubilant.—Colombo.—Simple Equations.—Ramsgate.—E. Barber.—R. A. G.—A Constant Reader.—Aspirant.—W.—A Barrister.—Illusionist.—R. M.—Lambrook.—Reed Maker.—W. R. A.—Redivivus.—C. J. R.—Geo. Blackledge.—W. J. Trinder.—Beacon Lough.—J. H. Lancaster.—J. K. P.—Sceptic.—M. A. B.—J. Still.—W. H. Robinson.—Querist.—E. W. J.—A New Subscriber.—Saul Rymea.—R. A. Proctor.—Fidelio.—Chisel.—R. R. Forbes.—Drinkwater.—O. J. L.—Holiday Time.—W. and B.—Old Shoreham.—Organist.—J. G.—W. T. M. D.—H. J. Skelton.—The Harmonious Blacksmith.—Bobo.—Daleth.—C. S. W.—Monte Cristo.—J. M.—Mancuniensis (what a name!)—Ralph Lowdon.—Bernardin.—J. Pemlington.—J. R. D.—J. C.—Excelsior.—Schoolboy.—W. Millard.—A. J. W.—Mercurio.—J. C. P.—Fe Sut.—W. Horrocks.—V.—Zoo Andra.—Un Irlandais.—Peter Wallace.—Thetamu.—C. J.—Gouge.—Jas. S. Cooke.—Cordwainer.—C. W. H.—No. 170.—Rat-Tat.—T. L.—Joiner.—C. E. S.—Yoiza.—J. W. Leamington.—Joe.—West Cornwall.—T. A.—Harry Bailey.—F. T. S. S. D.—Q. E. D.—H. Price.—A. P. S.—J. Asher.—T. H. Sanders.—H. E.—James Ridout.—J. W. Fennell.—G. Lamb.—Domestic.—W. R. Birt.—J. Birmingham.—G. R.—Zulo.—Melodious.—J. O. Phipps.—S. K. S. T.—Wm. Cooke.—R. Lupwards.—Practicus.—J. R. Nichols and Co.—Anglo-American.—A Pattern Maker.—H. C. Symons.—W. E. Cannabe.—Walter Winning.—Robert Walker.—W. Quy.—Tantalus.—F. L.—Novice.—J. C. S. Kenny.—Wm. Oldfield.—William Tonkes.—A Constant Reader.—W. Hughes.—Reader.—S. Bottone.—F. R. A. S.—Capital and Labour.

A VETERINARIAN.—See "Hints to Correspondents," No. 4.

SEMPER VIVO.—Look in future, before you write complaining. Your query was replied to in No. 363, p. 644.

J. FRANKLIN.—We do not remember the query.

R. D. O.—See indices to back vols.

C. MACE (Reading).—Stamps only sufficient for one advertisement.

TUBAL KAIN.—Should be glad of the paper with diagram at your convenience.

COTTON OIL, J. L. S.—Your queries are advertisements.

JAS. HASTIE (Goatfoot Collieries, near Kilmarnock).—The ENGLISH MECHANIC is regularly published on Thursday morning, and if you do not get it till Monday, the fault must be the agents, not ours.

A. KING and E. W. L.—You can't be constant subscribers, or you would not ask to be answered by post.

W. OLDFIELD.—Yes.

E. L. E.—You must try and work out the sums for yourself. The ENGLISH MECHANIC is not a schoolboy's organ.

R. G. B.—See last few numbers for information on incubators.

A CHUMP.—Lay the case before some well-known and trustworthy neighbour, such as mayor, clergyman, or magistrate, or any man of honourable character. From what you say the lawyer is acting dishonestly.

W. C. BUCKNELL.—See "Hints to Correspondents," No. 4.

E. RAE.—Shall have attention.

DOLOMITE.—First query inserted, the second is an advertisement, as it can in no way interest any one but yourself.

A BARRISTER.—Thanks for your letter on query 12271 and answer. "Sigma" has also replied. There are always rascals to be found, and the correspondent who asked and answered this question is one. We sometimes receive hundreds of letters a day, and in the hurry of preparing for the press for this and other publications it is almost impossible to prevent a query like this occasionally slipping into our columns. During the last two years we have received scores of queries and answers, written by men who have more time and money than wit, and who, we suppose, think they are playing practical jokes. But they hardly ever find us napping; we don't even acknowledge their letters, but we keep them as testimonies against them, and it is very likely that one of these days there will be a nice little exposure in our columns or in a law court, as we have no doubt that we shall be able to trace the handwriting to the authors. "A Barrister," or "Sigma," or any other corresp[illegible] may see [illegible] handwriting, and so help us [illegible]

P. N. HASLUCK.—See answer t[illegible] letters are preserved, and [illegible] are the greatest offender[illegible]

J. W.—See pp. 259 and 2[illegible] wire covering machine.

WELSHMAN.—Write to th[illegible]

B.—No room for such profitless communications. You first ask an involved arithmetical question, then solve it in your way, and conclude by asking "E. L. G." his opinion of the solution. Did the thought ever occur to you that the available space of the English Mechanic is in a sense public property, and that it should not be wasted in airing individual idiosyncracies? If not please bear the hint in mind. We esteem those correspondents the most who say the best things in the fewest words, so that the largest possible number may receive the greatest benefit.

H. F.—See indices to back vols.

A New Subscriber.—Ask any maker. You can hardly expect us to engrave representations of ordinary concertinas and accordions, that you may be told "the difference between them."

Communications which can only appear as advertisements to hands from M. A. Adams, Ultima Thule, A Young Student, J. W. Card, Jupiter's Moons, W. J. Porter, Peterborean, A Brewer, J. Gilfillan.

R. S. T.—To destroy moths in furniture, &c., see p. 21, Vol XIII., also recent back numbers.

Ralph Lowdon.—If we understand your query aright its insertion would be irreverent, especially at this season. The event is not one for discussion in these pages.

Subscriber (St. Austell).—We do not know the makers. Address was given, write them.

Pododaktylos For.—For cement for aquariums, see pp. 308 and 582, Vol. XIV.

L. W. D.—A pint contains 34·66 cubic inches.

Q. Yorke.—The society you speak of does not answer the want that "March" wishes to see supplied. We have again and again received complaints of the kid-gloved character of said society, and heard wishes expressed that a more robust one should be instituted, and in more than one instance from members of the said society themselves.

THE INVENTOR.

APPLICATIONS FOR LETTERS PATENT DURING THE WEEK ENDING MARCH 26, 1872.

817 G. H. C. Hedley, Wolverhampton, for an improved fire-lighter.

818 R. Gorga, Belfast, Ireland, for a synoptic system and characters employed therein for the more easy learning of the pronunciation of English and foreign languages.

819 G. Pashley, Sheffield, for a new or improved valve for hydraulic and other purposes.

820 E. Feldtmann, Mark-lane, City, for an apparatus for heating and ventilating railway passenger carriages. A communication.

821 M. A. Soul, Southampton-buildings, for a new or improved balloon locomotive or navigable balloon. A communication.

822 C. Dumbleton, Fareham, Hants, for improvements in apparatus for cutting or forming screw threads upon wood, metal, and other material.

823 S. E. Holten, Gracechurch-street, City, for improvements in mechanical writing instruments, applicable for reporting and other purposes. A communication.

824 W. Marshall, Bootle, Lancashire, for improvements in clog bottoms.

825 J. Copeland, Manchester, for an improved valve to be used for regulating and stopping the supply of steam, water, air, gas, or other fluids.

826 W. Garey, Aberdeen, for improvements in preparing paper for photographic purposes.

827 J. H. Johnson, Lincoln's Inn-fields, for improvements in compositions to be used in fireworks and for signalling purposes. A communication.

828 W. R. Lake, Southampton-buildings, for improvements in printing telegraphs. A communication.

829 W. R. Lake, Southampton-buildings, for improvements in printing telegraphs. A communication.

830 W. R. Lake, Southampton-buildings, for improvements in apparatus for raising, retaining, and lowering boats. A communication.

PATENTS SEALED.

2511 J. Verity, for improvements in the construction of chimneys for gas burners and oil and other lamps, and in reflectors and protectors for the same.

2518 T. C. Eastwood, for improved machinery for preparing and combing wool, flax, silk, cotton, and other fibrous substances, and noils and waste from such substances.

2527 C. A. Hardy and A. E. Stayner, for improved method and appliances for shafting picks and other tools, such as are generally formed with an eye.

2528 J. Bailey, for a new or improved joint for screw piles.

2531 E. Baudot and E. Roettger, for improvements in obtaining motive power by the heat diffused in the air or any other fluid or liquid body.

2533 J. Shepherd, for improvements in apparatus for separating water from steam.

2537 A. Wallis and C. J. Steevens, for improvements in apparatus for heating the feed water and partially condensing the exhaust steam in portable engines, locomotive engines, and other engines wherein the cylinders and boiler are fixed together.

2546 A. Pécaud, for a new brake to be adapted to railway carriages.

2568 R. Long, for an improved freezing machine and refrigerator.

2604 T. Jackson, for the improvement of pianoforte actions.

2643 H. Sprengel, for improvements in the preparation of explosive compound.

2665 A. H. Still and D. Lane, for improvements in the manufacture of illuminating gas.

2705 R. P. Williams and J. Price, for improvements in the permanent way of railways.

2778 W. H. Tayler, for improvements in stoves for burning gas or gas and air, for general heating and cooking purposes.

2783 J. H. Johnson, for improvements in disintegrators.

2827 G. Kallmeyer, for improvements in sewing machines.

2840 W. R. Whitelaw, Glasgow, for improvements in furnaces.

2852 A. M. Clark, for improvements in traction engines.

2868 E. de Zuccato, for improvements in apparatus for making and copying drawings and writings.

3225 E. Korting, for improvements in steam engines.

3215 R. B. Evered, for improvements in taps or valves.

3260 J. H. Johnson, for improvements in extinguishing fires, and in apparatus or means to be employed therefor.

117 W. H. Franes, for improvements in machinery for combing wool and other fibres.

131 J. H. Greenhill, for improvements in disintegrating machinery.

149 A. M. Clark, for improvements in applying colours or tints to photographs, albumenised and other surfaces.

199 D. Joy, for improvements in the means and apparatus for the removal of slag from blast furnaces.

329 W. R. Lake, for an improved method of preparing and preserving hops for the manufacture of beer, and for medicinal purposes.

387 W. R. Lake, for improvements in engines to be operated by gunpowder or other explosive material.

2551 S. Schuman, for improvements in fulling or walking and felting wollen and hair fabrics, and in the means and mechanism employed therefor.

2559 H. P. Armstrong, for improved instruments or apparatus to aid in teaching persons to play upon keyed or stringed musical instruments.

2561 N. C. Underwood and W. Adshead, for improvements in the mode of felting hat bodies and other felted fabrics, and in apparatus therefor.

2567 C. de Chastelain, for improvements in the mode of and apparatus for intercepting, collecting, and filtering fæcal and sewage or drainage matters.

2572 H. Turner, for improvements in the formation of plastered ceilings and cornices, being also applicable to wall surfaces generally.

2580 W. E. Gedge, for an improved screening apparatus.

2581 E. T. Hughes, for improvements in reeling machinery used for forming threads or yarns into skeins or hanks.

2587 J. M. Plessner, for improvements in obtaining motive power, and in apparatus to be employed for this purpose.

2589 C. Catlow, for improvements in looms for weaving.

2591 H. Stapfer, for improvements in the filtration or separation of mineral or other oil from oleaginous matter or from matter or compounds containing oil, and in apparatus therefor, applicable also to the filtration of some other matters.

2593 T. Waller, for improved arrangements for the supply of fresh hot or cold air or mixed hot and cold air in infirmaries, hospitals, and other buildings.

2596 T. Varley and F. H. Varley, for improvements in electric telegraphs, part of the invention being applicable to other purposes.

2597 N. D. Spartali, for improvement in apparatus for propelling vessels.

2605 J. H. Kearns, for an improved blotting-pad book diary.

2611 J. E. Liardet, for improved mechanical arrangements for working and protecting ordnance and other fire-arms, and for the defence of the men in charge of the same.

2614 H. Kinsey, for improvements in steam winches, partly applicable to steam engines generally, and to other purposes.

2626 W. I. Ellis, for improvements in machinery for forcing and exhausting air or other gases.

2628 L. Pocock, jun., for improved means or apparatus to be employed in the drying of guano, manure, or other similar substances.

2635 O. Demailly, for improvements in disaggregating textile plants and wood, and in the apparatus in connection therewith.

2640 A. Browne, for an improved revolving pistol toy.

2643 J. Gowans, for a new or improved traction car for drawing or propelling vehicles on tramways.

2644 J. Gowans, for improvements in machinery used in the construction of tramways and railways and applicable to other similar purposes.

2648 H. Walker, for an improved apparatus for making button-holes.

2659 J. Burrow, for improvements in treating sewage and other matters.

2676 T. J. Smith, for an improved process for treating filaments, threads, and fabrics to render them suitable for dyeing.

2678 W. E. A. Hartmann, for an improved mode of and apparatus for burning pulverised fuel.

2703 P. Brannon, for improvements in the construction of fire-proof houses and other buildings.

2717 J. Lodge, for improvements in the manufacture of artificial fuel.

2731 J. Homan, for improvements in rolled iron joists and girders.

2740 C. D. Abel, for improvements in the manufacture of iron and steel, and of alloys of various metals, and in the apparatus employed in connection therewith.

2748 H. S. Dunn, for improvements in boring and winding machinery connected with boring for minerals, wells, blasting and such like purposes.

2756 E. J. Harland, for improvements in apparatus for propelling vessels.

2828 W. R. Lake, for an improved inkstand and appliances to be used in connection therewith.

2963 W. Weldon, for an improved method of drying chlorine gas.

3217 W. R. Lake, for improvements in lamps or lanterns chiefly designed for out-of-door situations.

3241 J. Hodges, for improvements in purifying paraffin.

3284 M. Tildesley, for an improved application of certain known materials to be used in the annealing of cast iron to produce malleable iron.

3342 W. Verity and B. Verity, for an improved perforated fire-clay gas burner adapted for heating or cooking purposes.

4 H. Highton, for improvements in electric telegraphs.

37 W. E. Newton, for improvements in preserving edible animal and vegetable substances.

194 T. K. Scruton, for improvements in the manufacture of neckties or cravats.

202 A. Higginson, for improvements applicable to motive-power engines, engine governors, and pumps.

249 G. Abraham, for improvements in the fittings of window sashes.

261 J. Boyd and W. Henderson, for improvements in machinery for weaving hair cloth.

839 J. H. Johnson, for improvements in nail machines.

840 J. H. Johnson, for improvements in burning hydrocarbons, and in apparatus to be employed therefor.

ADDRESSES.

WATER-WHEELS (Query 11117).—Wheels 5ft. and 7ft. in diameter. Particulars would oblige "Youngster."—CHARLES BREWER, Illogan.

TO BRASS FINISHERS.—WANTED, the Name of a Firm that can supply finished Brass Castings, pattern patented, weight about 10oz.—D. C., Post-office, Stockton-on-Tees.

FOR "ARMLESS ENGINEER," Address, Care of Mr. WALKER, 10, Turncroft, Stockport.

WILL "F. P." (No. 11249) on Concrete Buildings kindly inform W. BUTLER, Witham, Essex, if he may see the building "F. P." is erecting?

"ASSOCIATE" is asked to Advertise his Address in order that some CRYOLITE may be offered him. It is Mr. H. B., Clyde-villa, Surbiton, S.W.

Terms of Subscription,

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post Free.

Volumes V., VI., VII., VIII., IX., X., XI., XII., and XIII., bound in cloth, 7s. each.

Vol. XIV. will Shortly be Ready.

Indexes for each half-yearly volume, up to Vol. X. (except Vols. II., V., and X.) inclusive, 2d.; Post Free, 2½d. Cases for Binding, 1s. 6d. each.

⁂ Subscribers are requested to order Cases and Vols. through their booksellers, and not to send direct. The new regulations of the Post-office prevent their transmission through the Post.

To American Subscribers.

Subscribers in the United States can be supplied with the ENGLISH MECHANIC post free from this Office, for the sum of 18s. (8 dols. 25 c. gold) per annum payable in advance.

☞ The remittance should be made by International Post-office Order. Back numbers cannot be sent by the ordinary newspaper post.

Notice to Subscribers.

Subscribers receiving their copies direct from the office, are requested to observe that the last number of the term for which their Subscription is paid, will be forwarded to them in a *coloured wrapper*, as an intimation that a fresh remittance is necessary, if it be desired to continue the Subscription.

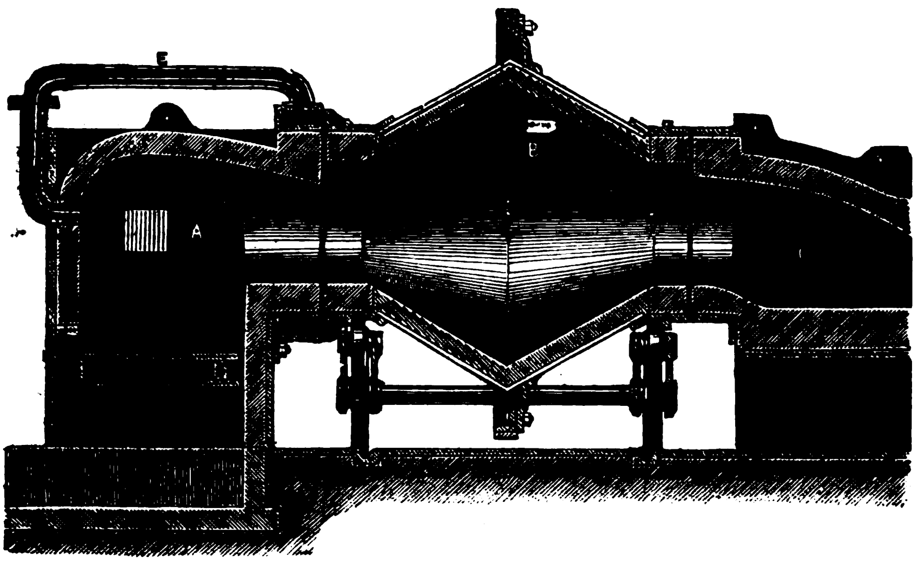
ARTICLES.

PUDDLING MACHINES.

IN the account of Danks's rotary puddling furnace, which we gave on p. 579 of our last volume, we alluded to the probability of supplementary reports being presented at the meeting of the Iron and Steel Institute, in order that a clearer idea of the whole bearing of the new invention on the iron industry might be rendered more easily obtainable than was possible from the necessarily incomplete description of the process furnished by the Commissioners on their return to this country. Mr. G. J. Snelus, one of the Commissioners, has now presented to the Institute at its recent meeting, as full a report on the scientific, practical, and commercial aspects of the process as the time at his disposal enabled him to accomplish; and from the manner in which the invention was spoken of at the meeting, a great and important change in the manufacture of iron is about to be inaugurated. In fact, it has been stated that Mr. Danks has entered into an agreement with a number of iron-masters, representing various districts, to permit them to put up 200 furnaces on his plan in consideration of a payment of £50,000 in six months. As few of the manufacturers intend to remove their old hand-puddling furnaces, this will represent an enormous increase in the puddling power of the industry, equal to an additional make of 300,000 tons a year.



The theory of the puddling process is described by Mr. Snelus at the opening of his report, and if we give an abstract of this, the advantages obtained by the employment of Danks's furnace will be apparent to our readers. Pig iron is the metal in what may be termed its raw state; it is combined with sufficient carbon to render it fusible at what is comparatively a low temperature, and is possessed of little malleability. A few other elements are generally found in the raw pig, such as sulphur, phosphorus, silicon, and manganese, and the object of the puddling process is to render the iron malleable by removing these "impurities" and the excess of carbon. This is accomplished by submitting the iron to a process of oxidation, the oxygen for which is obtained, in the old process, partly from the "fettling" or lining of the metal bath, and partly from the air which finds its way in through the door at which the puddler introduces his rabble or stirring-rod. By this means the carbon is converted into carbonic oxide or carbonic acid, the silicon into silica, the phosphorus into phosphoric acid, and the manganese into manganous oxide, and these are either carried away or pass into the slag. What becomes of the sulphur is not positively known, but it is believed to unite with the slag as sulphide of iron, or, becoming oxidised, to pass away with the gases from the furnace. In the Danks furnace, however, the whole of the necessary oxygen is obtained from the fettling, and it was the failure to secure this necessary property in the lining of the metal bath that proved so great a stumbling-block to the introduction of a machine for mechanical puddling; for some years ago Mr. Menelaus, who is a most untiring experimenter in this direction, all but succeeded in producing a rotary puddling furnace, being stopped solely by the difficulty of procuring a suitable compound for fettling purposes. It was at this stage of the invention that Mr. Danks, of Cincinnati, took up the subject, and after numerous experiments hit upon a method of fettling with a material which gave the desired results. The revolving chamber or puddling bath of his machine, which we illustrated on p. 579 of the previous volume, is constructed with longitudinal wedge-shaped recesses on its interior face, which assist in firmly holding the mixture forming the first or initial lining of the puddling chamber. This lining consists of an ore free from silica, ground up and mixed with lime cream, so as to form a kind of mortar, which adheres to the plates forming the revolving chamber, and when dried becomes refractory, and sufficiently cohesive to allow of the fettling proper being melted upon it without itself melting, or separating from the plates of the furnace. On this initial lining a quantity of ore, free from silica, is melted and distributed over the whole surface by slowly revolving the chamber, and while this coating is in the molten state large lumps of similar ore are thrown in, and being cold cause the melted metal to set round them and fix them firmly, thus producing a rough lining with a largely increased surface to act upon the charge of pig iron. It is absolutely necessary that these lumps should be of such a texture that they will not crumble with heat, and they must be nearly free from silica. "Tap cinder"—*i.e.*, cinder obtained from a heating furnace where a bath of oxidised iron is used to protect the plates instead of sand—is a suitable material both for the lining and the lumps, but where this cannot be had, and ores free from silica are difficult to obtain and expensive, Mr. Snelus thinks it would pay to oxidise scrap iron for the special purpose. A great advantage of the mechanical puddling process is found in the larger yield of metallic iron, a portion of which is obtained from the lining of the furnace; for it is obvious that if the necessary oxygen for oxidising the carbon in the pig is obtained solely from the oxide of iron forming the lining the latter must be reduced to the metallic state, and so help to swell the yield of puddled iron. It is also worth mention that under these conditions the carbon is oxidised to its highest point, and more pure metal is obtained than when carbonic oxide alone is produced.

The fettling having been successfully accomplished, the pig iron to be puddled is introduced in large lumps, the charge being generally about 600lb. The chamber is then slowly rotated at intervals, so as to expose the charge equally to the action of the flame, and when the whole is in the molten state the chamber is made to revolve about once every half-minute for the first eight minutes or so in order to insure the perfect action of the cinder upon the molten metal. At this stage of the process a jet of water is directed against the lining on the descending side, so as to solidify a portion of the cinder, which is thus carried under the melted iron, and rising up through it combines with and removes the impurities in a more effectual manner than has hitherto been the case, even with hand puddling. Mr. Snelus thinks that the jet of water also has the effect of carrying off sulphur from the cinder. In about ten minutes after the pig iron is all melted the cinder is run off, carrying with it a large portion of the products of the sulphur, phosphorus, and silicon, and the iron begins to boil. The chamber is now made to revolve six or eight times in a minute, and a high temperature being kept up the iron is thrown about violently till the process is complete, and the speed being reduced the ball begins to form. The stopper hole is now opened, and the ball partially solidified by means of a tool, when the head-piece is removed and the ball taken out by means of a lifting-fork, as described in the previous article.

The defect of the process as here described, however, consists in the fact that the time taken to melt the charge is actually longer than that occupied in puddling—viz., from 30 to 50 minutes for a charge of 600lb., and this time consequently represents a large consumption of fuel. It is so far satisfactory to find, nevertheless, that this defect is one the removal of which offers no insuperable difficulty; for finding that while the new puddling furnace is economical in the working of its own peculiar duty, it is a bad melter of the iron, Mr. Snelus points out that the charge must be melted elsewhere and brought to the mechanical puddler in the molten state. By the adoption of this method, he thinks that not only would a moiety of the fuel be saved, but twice the number of heats might be obtained in the same time. The arrangements for firing and regulating the blast of the furnace form an important part of the invention, and contribute largely to the success of the system as a whole. The puddler has, in fact, complete control of his fire; by means of a valve he can so regulate the blast as to urge the furnace to an intense heat or to almost stop combustion altogether. This blast also serves to prevent the entrance of air at the joint between the revolving chamber and the furnace, the full pressure inside stopping its ingress, and thus avoiding all waste of iron which might be caused by the admission of free oxygen.

With regard to the cost of puddled iron by the Danks process, Mr. Jones, the member of the Commission who has drawn up the supplemental report upon this part of the question, estimates a saving of 10s. 8d. a ton, but considers that this is considerably underestimated. Mr. Danks, however, claims a saving of £1 a ton, and it is probable that when the machine is brought into extensive operation, that figure will be reached if it is not exceeded. The effect of so large a reduction in the cost of producing malleable iron, together with the ascertained fact that 12 of Danks's rotary puddlers will turn out as much as 50 of the old hand-worked furnaces, for which of late years it has been difficult to obtain a supply of competent men, owing to the laborious and exhausting nature of the work, will speedily make itself felt in commerce. So that taking into account that this new rotary puddler dispenses with the killing labour of its human namesake, besides doing his work better and cheaper, it is not to be wondered at that the report of the Committee has been received and adopted by the Iron and Steel Institute, and that arrangements are being made for the erection of a large number of Mr. Danks's furnaces. The opinions expressed at the meeting were unanimous in its favour, and, together with the high commendation pronounced by Mr. Menelaus, must be very gratifying to Mr. Danks.

It must not, however, be supposed that while success has thus fallen to the lot of an American, it has not been striven for, and in a measure obtained by, our own inventors. Mr. Spencer has succeeded in constructing a rotary puddling machine, in which the revolving chamber is made up of troughs. The results obtained from this machine are described as being highly successful, but as the iron is divided into comparatively small balls, although this is convenient for after operations, the general opinion was that from the greater expenditure of the fuel and the increased size of the machine itself, it was not so valuable an innovation as the Danks machine. We may, however, give an illustration and description of it in a future number. In the mean time we illustrate what we may term an adaptation of Mr. Danks's principle to the existing furnaces, the joint design of Messrs. Howson and Thomas. The object of these gentlemen is to construct a machine which, while operating on the principle of the rotary puddler, shall utilise as much of the present working plant as possible, so as to avoid the large expenditure of capital rendered necessary by the impending revolution in the iron trade. Experiments have as yet only been made under imperfect arrangements, but the inventors consider that with more complete details their machine will provide a satisfactory makeshift for the Danks's furnace, and thus avoid the total loss of the now "old-fashioned" plant which is still sound and good. The section represents an ordinary puddling furnace, from which the hearth is entirely removed, and the revolving chamber B mounted in its place. A is the ordinary firegrate, which, however, it may be advisable to slightly modify, and C is the flue leading to the uptake, which would remain in much the same state as at present. The revolving chamber, B, is of wrought iron with cast-iron trunnions, and is preferably constructed of two cones, fitted base to base, for convenience in lining. The trunnions are mounted on rollers on a carriage which runs on wheels in a direction across the axis of the furnace. By means of this carriage the chamber is run out between the flue and the firegrate for the purposes of being lined and charged, and for removing the puddled ball. The lining is made of bricks of ground oxide of iron burnt very hard, and the shape of the chamber being favourable a lining thus formed will wear down to ½in. without giving way. The great difficulty to overcome in adapting this chamber to the present furnace consists, of course, in rendering harmless the cold air which finds its way in at the gap between the chamber and the firegrate—a gap which is obliged to be left in consequence of the expansion of the casing by heat. This is accomplished by making the opening against which the trunnion works of two cast-iron rings inclosing an annular space which communicates either with the chimney, by means of a separate flue, or with the fire, as shown in the figure, by means of a pipe, E. A draught is thus formed in the annular space, which draws away the air leaking in at the joint, utilising it at the most serviceable point, and reducing leakage into the working chamber to a minimum. Screens are provided to prevent loss of heat when the chamber is run out, and the puddled ball is readily removed by tipping the chamber when it is drawn beyond the screens, which are perforated with holes for observation and manipulation. The chamber is worked by a steam-engine with 7in. cylinder and 7in. stroke, the gearing giving revolutions of three and six to the minute. It is probable that within the next few months great improvements will be made in the puddling process, now that so many minds will be directed to the subject, and are acquainted with what has been already accomplished; for economy in fuel alone is well worth anxious study and enterprising experiment.

LESSONS ON CHEMISTRY.*

By Selimo R. Bottone.

(*Late of the Istituto Bellino, Novara, Italy.*)

(*Continued from p.* 30.)

119.—OTHER compounds containing chlorine and oxygen exist, but their constitution is doubtful, their composition uncertain, and their very existence as definite compounds is, by many, disallowed. We will notice briefly a few of these bodies, referring the reader who may be desirous of entering into details to the works of Gmelin, Watts, and Millon.

120.—Euchlorine.—If a mixture of a chlorate along with hydrochloric acid be gently heated, a bright yellow explosive gas is evolved, which is the body in question. The composition of this body is constant; but as, by exposure to cold, it resolves itself into chlorine gas and another oxide of chlorine, it is regarded by chemists as a mere mixture. Its composition would appear to be

$$Cl_7', 2Cl_2'O_5'', Cl_2'O_4''; \text{ or } Cl_{11}'O_{13}''.$$

Some chemists look upon this as the missing link in the chain of oxides of chlorine, and represent its formula by a submultiple of the above proportions—viz., $Cl_2'O_2''$. (See Odling, Becquerel, Gmelin, &c.)

121.—Chloro-Chloric Acid.—*Synonym: Chlorate of Chlorine Trioxide.*—When a current of euchlorine is passed through a series of U-shaped tubes, cooled by a freezing mixture, this body condenses as a red fluid, while chlorine gas escapes. It resembles strongly chlorine tetroxide, but differs from it, inasmuch as it does not boil till it reaches 89·6° Fahr.[1], nor explode below 70° Fahr.[2] The composition of this body has been given by Millon as $2Cl_2'O_5''$, $Cl_2'O_3''$, or, what amounts to the same thing, $Cl_6'O_{13}''$. Its formation from euchlorine may be expressed thus:—

$$Cl_{18}'O_{13}'' = 2Cl_2'O_5, Cl_2'O_3'' + 7Cl'.$$

122.—Chloro-Perchloric Acid.—*Synonym: Perchlorate of Chloride Trioxide.*—On exposing chlorine trioxide to the action of light, at a temperature of about 68° Fahr., this compound separates as a reddish brown liquid, smelling somewhat like bromine, and fuming strongly in the air. When acted on by caustic potash, a mixture of two molecules of potassium percholate, $K'Cl'O_4''$, and one molecule of potassium chlorate, $K'Cl'O_3''$ is formed, hence its composition is supposed to be

$$2Cl_2'O_7'', Cl_2'O_3'' = Cl_6'O_{17}''.$$

123.—We have seen that the most stable compound of chlorine with oxygen is chlorine heptoxide; indeed, all the others are resolved into this by heat; hence Millon, who gave the subject much attention, inclined to the belief that the only definite compounds of chlorine with oxygen are chlorine monoxide, chlorine trioxide, and chlorine heptoxide.

Section 6c.—Compounds of Oxygen with Bromine.

124.—Several oxides of bromine corresponding with those of chlorine are known. They present great analogy with the relative chlorine oxides; but as they have been little studied, and are up to the present of no practical use, we shall confine our attention to the three following, which are the most important.

A. Bromine Monoxide.—*Synonym: Hypobromous anhydride*[3]. *Symbol:* $Br_2'O''$ (?) *Molecular weight:* 176 (?).

125.—Up to the present time this body has not been isolated. In union with the elements of water it forms the following compound:—

A (2). Hypobromous Acid.—*Synonym: Hydrogen Hypobromite*[4]. *Symbol:* $H'Br'O''$. *Molecular and combining weight:* 97·0.

126.—Properties.—Almost exactly those of hypochlorous acid; but as bromine holds oxygen with greater tenacity than chlorine does, its bleaching powers are not so active. The hypobromites are almost indistinguishable from the corresponding hypochlorites.

127.—Preparation.—When an aqueous solution of bromine acts on mercury oxide it gives rise to mercury bromide and hypobromous acid. (See 101.)

B. Bromine Pentoxide.—*Synonym: Bromic anhydride.*[5] *Symbol:* $Br_2'O_5''$? *Molecular weight:* 240 (?).

128.—Like the relative chlorine oxide this body is unknown in the separate state.

B (2). Bromic Acid.—*Synonym: Hydrogen bromate.*[6] *Symbol:* $H'Br'O_3''$. *Molecular and combining weight:* 129.

129.—Properties.—A colourless, almost inodorous, oily fluid, strongly acid to the taste. It first reddens and afterwards bleaches vegetable blues. In all its properties it strongly resembles chloric acid, but owing to the greater affinity of bromine for oxygen it does not part with its oxygen so readily.

130.—Preparation.—By acting on potassium hydroxide, $K'H'O''$, with bromine, a mixture of a bromide and a bromate is produced. From this the acid may be prepared in the same manner as recommended for chloric acid, or advantage may be taken of the power which bromine has of abstracting oxygen from the oxides of chloride by the following proceeding:—Chlorine is passed into a warm concentrated solution of potassium carbonate. Potassium chlorate is thereby formed. On adding an equivalent of bromine this latter seizes on the oxygen of the chloric acid, expels the chlorine, and takes its place, thus:—

$$K'Cl'O_3'' + Br' = K'Br'O_3'' + Cl'.$$

From the bromate bromic acid may be prepared as mentioned at paragraph 115, substituting the bromate for the chlorate.

C. Bromine Heptoxide.—*Synonym: Perbromic anhydride.*[7] *Symbol:* $Br_2'O_7''$ (?) *Molecular weight:* 272 (?).

131. Unknown in the free state. Combined with the elements of water, it forms:—

C (2). Perbromic Acid.—*Synonym: Hydrogen Perbromate.*[8] *Symbol:* $H'Br'O_4''$. *Molecular weight:* 145.

132.—Properties.—Very similar to those of perchloric acid; but its oxidising power is not so great, and its affinities are not so powerful.

133.—Preparation.—By adding bromine to perchloric acid as long as chlorine is evolved. The interchange is expressed by the annexed equation:—

$$H'Cl'O_4'' + Br' = H'Br'O_4'' + Cl'.$$

By this we learn, that although the affinity of chlorine for *hydrogen* is greater than that of bromine, yet this latter element has a stronger attraction for *oxygen* than chlorine has, and hence is able to expel chlorine from its oxygen compounds.

Section 6d.—Compounds of Oxygen with Iodine.

Several of these have been described. We shall notice the three most important.

A. Iodine Monoxide.—*Synonym: Hypo-iodous anhydride. Symbol:* $I_2'O''$ (?). *Molecular weight:* 270 (?).

134. This body is unknown in the free state.

A (2).—Hypoiodous Acid.—*Synonym: Hydrogen hypoiodite. Symbol:* $H'I'O''$. *Molecular weight:* 144.

135.—Properties.—A pale, straw-coloured, transparent liquid, smelling somewhat like ozone. It first reddens and then bleaches vegetable blues, but the bleaching action is very tardy and imperfect.

136.—Preparation.—If a few crystals of iodine be placed in a watch-glass, under a glass bell, with a stratum of well-slaked lime surrounding the watch-glass, the iodine gradually volatilises and is absorbed by the lime, which becomes of a more brilliant white, and is found to possess properties similar to those of "chloride of lime," but not nearly so active. Care must be taken that the temperature does not exceed 60° Fahr., as in this case little or no hypoiodite is formed.

When the body thus formed (consisting of calcium iodide and hypoiodite) is distilled along with dilute nitric acid, or, better, with dilute acetic acid (1 part acid to 4 of water), hypoiodous acid passes over. (S. Bottone.) It is worthy of note that the "iodide of lime," prepared as directed above, possesses more active bleaching powers than does the free acid itself. If, in the preparation of the acid (from the hypoiodite), sulphuric acid be used instead of nitric, or if the nitric acid be too strong, iodine, together with hydriodic acid, and not hypoiodous acid, is liberated.

B.—Iodine Pentoxide.—*Synonym: Iodic anhydride.*[9] *Symbol:* $I_2'O_5''$. *Molecular weight:* 334.

137.—A white crystalline solid with a strong acid taste. Prepared by heating iodic acid (see below) to a temperature not exceeding 338° Fahr. It dissolves freely in water, and if the solution be concentrated, crystallises from it, without taking up water.

B (2). Iodic Acid.—*Synonym: Hydrogen iodate.*[10] *Symbol:* $H'I'O_3''$. *Combining weight:* 176.

138.—Properties.—Iodic acid forms colourless, six-sided tables, very sour to the taste, and reddening litmus strongly. It is very similar to chloric and bromic acids. Like them it combines with metals to form a class of bodies called *iodates*, which, like the corresponding chlorates, are decomposed by heat. The iodates differ from the chlorates, inasmuch as the iodates of the heavy metals, instead of yielding oxygen and an iodide, give, on heating, metallic oxides, iodine, and oxygen. The iodates of the light metals, however, behave like the correspon[illegible]

1 Gmelin.
2 Idem.
3 Hypobromous acid.
4 Hydric hypobromite.
5 Bromic acid.
6 Hydric bromate.
7 Perbromic acid.
8 Hydric perbromate.
9 Iodic acid.
10 Hydric iodate.

chlorates, that is to say, they give off oxygen, and are converted into iodides, thus:—

$$M'I'O_3'' = M'I' + 3O''.$$

139.—PREPARATION.—Iodic acid may be prepared by several methods. 1. 1 part of iodine and 40 parts of nitric acid of the specific gravity of 1·5, are to be boiled together in a porcelain capsule, until all the iodine dissolves. The solution is then to be cautiously evaporated to dryness, redissolved in water, filtered through asbestos (while hot), and allowed to crystallise. In this process the nitric acid loses its oxygen, which it gives up to the iodine, thereby converting it into iodic acid. The results of the operation may be seen by the following equation:—

$$I' + H'N'''O_3'' = N'' + H'I'O_3''.$$

In practice, however, pure nitrogen is very seldom evolved, the nitric acid being generally reduced to a lower oxide, and not to nitrogen itself. 2. If a current of chlorine be passed through water containing iodine in suspension, hydrochloric acid and iodic acid are formed. By virtue of its superior affinity for hydrogen, the chlorine combines with this element, while the iodine seizes on the oxygen thus set free.

$$I' + 3H_2'O'' + 5Cl' = 5H'Cl' + H'I'O_3''.$$

The resulting iodic acid may be purified from the hydrochloric acid by boiling, and allowing the liquid to crystallise.

The iodates of the lighter metals may be conveniently prepared by dissolving iodine in a solution of the metallic oxide, and then passing a current of chlorine through the liquid. A chloride, along with an iodate of the metal employed, is the result. The following equation illustrates the interchange:—

$$3M_2'O'' + I' + 5Cl' = 5M'Cl' + M'I'O_3''.$$

From these iodates the acid may be obtained in the mode described for chloric acid.

c. IODINE HEPTOXIDE.—*Synonym: Per-iodic anhydride.*[11] *Symbol:* $I_2'O_7''$. *Combining weight:* 366.

140.—PROPERTIES.—A white spongy mass, freely soluble in water. It is obtained by cautiously heating the next compound to about 320° Fahr. At a higher temperature oxygen and iodine are given off.

c (2). PER-IODIC ACID.—*Synonym: Hydrogen per-iodate.*[12] *Symbol:* $H'I'O_4''$. *Combining weight:* 192.

141.—PROPERTIES.—Per-iodic acid is a white solid, which crystallises in colourless plates, somewhat resembling potassium chlorate. The crystals are permanent in the air. At 266° Fahr. they fuse without undergoing any change. At a higher temperature they lose the elements of water, and are converted into per-iodic anhydride. The acid, as well as its compounds with metals, bears a strong resemblance to per-chloric acid and its compounds; and, although the oxygen is much more tenaciously held, yet the periodates (and iodates) deflagrate when heated with charcoal.

142.—PREPARATION.—By adding iodine to perchloric acid, when the following substitution takes place:—

$$I' + H'Cl'O_4'' = Cl' + H'I'O_4''.$$

143.—Besides the compounds above mentioned, others, supposed to contain oxygen and iodine in different proportions, have been described by several chemists; but their existence is very doubtful. What little is known of them may be found in Gmelin's "Dictionary." The names of these doubtful bodies are:—

Iodic oxide (?)	Hypoiodic acid, I_2O_4 (?)
Iodous acid (?)	Subhypoiodic acid $I_{10}O_{19}$(?)

144. No compounds of oxygen with fluorine have as yet been obtained.

[11] Per-iodic acid. [12] Hydric per-iodate.

METALLURGY OF IRON AND STEEL.

(*Continued from p.* 55.)

A METAL which requires for fusing a very high temperature has the remarkable property of "welding." Iron may be exposed to a considerable range of temperature before melting, and all the time it retains a pasty dough-like state. It is not so with all metals, some pass almost immediately from a solid to a liquid condition. If at that temperature we bring two pieces of iron together, and press them firmly into contact, union takes place, or, in other words, welding occurs. In the Catalan process the iron falls to the bottom of the furnace particle by particle, forming one spongy lump, but the particles brought into contact during the process of hammering become firmly united into a solid compact mass, while any slag which might be diffused through it (and there always is some slag) is expelled by that operation. The lump is familiarly known as "blooms."

As was mentioned before, by varying the proportion of ore and charcoal (or other carbon used as fuel) we get a variety in the quality of the iron produced. The greater the quantity of charcoal used the more steely is the iron obtained, for metallic iron, when exposed to carbonaceous matters at a high temperature, has the property of imbibing or taking up a portion of that carbon, which, although the iron may remain quite solid, becomes diffused through the mass, and it is in this way that steel is produced on a large scale.

Let us endeavour to trace the progress of the growth of the iron manufacture from its rudest stages, as seen in the Hindoo and in the more advanced Catalan process. Man would try to economise fuel and labour, and probably his first idea would be to construct a furnace having a greater altitude. This is done in the "Osmund furnace," so named from the kind of iron produced, used in Sweden. It is a step in advance of the Catalan forge. In the winter time, the Swedes, not being occupied by their agricultural operations, produce very good malleable weldable iron from the ore; but instead of the Catalan forge they employ a much deeper furnace. It is made of material capable of resisting fire, cased outside with wood, and the ore and fuel used is oxide of iron and charcoal. In many cases it is the "lake ore," or brown oxide—*i.e.*, the peroxide combined with water. This ore is formed at the bottom of certain lakes in Sweden, near the places where the rivers supplying these lakes enter, and principally on reedy ground; it is composed of particles of various sizes, some are small—"pearl ore," others larger, "money ore;" sometimes "cake ore," while a kind composed of very small particles is known as "gunpowder ore." In the winter time, when the lakes are frozen over, holes are made in the ice, and the ore dredged up and washed. It is found that in places where the ore has been removed, in the course of about twenty or thirty years a fresh supply has been deposited. The furnace is charged with ore and charcoal, and after some hours (during which the blast is kept up by bellows) a lump of iron is formed at the bottom. This is not extracted from the top as in the Catalan process, owing to the greater height of the furnace, but a contrivance is made for extracting the metal from the bottom. At the bottom of one side a hole is made, or a part of the furnace is made removable, a hole being left for the outflow of the slag. A larger lump of iron can be made in the same time by this method than in a Catalan forge.

Now we come to a furnace 16ft. or 20ft. high, in section quadrangular or circular, with the blast injected at the back by a double-acting bellows worked by men or by water-power. In the front part a space is left which can be closed or unstopped at will. In such a furnace it was found that either malleable or cast iron could be produced. When charged suitably for the production of wrought iron, a lump of metal from six to seven hundredweight might be extracted at the front part of the furnace, with great hooks and chainwork attached to a drum connected with a water-wheel. When extracted the lump is divided and subdivided till the parts are sufficiently small to be forged into bars, heating and hammering during the working as required. There is usually some cast iron accompanying the production of a malleable lump—even in the Hindoo process a small quantity occurs, and therefore the discovery would soon naturally be made that by altering the proportion of the charge malleable or cast iron could be produced at pleasure.

Now we have come from the Hindoo direct process to the modern blast furnace, though at present only on a small scale. And first the furnaces were made higher and more capacious; some years ago a furnace 30ft. or 40ft. high was considered very large, now in Middlesbrough district furnaces have been erected, with the best possible results, not unfrequently 80ft. high: in some cases 100ft. All are not constructed of a similar form, some are everywhere circular in section, others like two truncated cones set base to base. The furnace is constructed of a material which stands a good high temperature, and what better than good honest fire-clay? The interior may be made of good fire-brick, the exterior of some refractory material. By the term refractory applied to clay is meant a substance which has the power of resisting a high temperature without melting or softening. There must be a good solid foundation, where water cannot have access. The part of the bottom immediately underneath the shaft of the furnace may be made of good fire-brick, or of good sandstone, or of some portions of the slag. This latter forms one of the most refractory bodies accessible to us. Next, there must be provided the means of injecting air, through three apertures usually—one at back and one on each side. For that purpose is provided three arched recesses large enough to allow a workman to get easily through. The front part of the furnace is prolonged forwards, because from that part the molten iron is tapped out. In front of this opening, to prevent the iron running away, is placed a strong dam of good thick cast-iron plate, and lined internally with some fire resisting substance. The lower part of the furnace is left open, the top is closed more or less during the working. The furnace shaft is bound firmly by rings of iron round it at intervals from top to bottom, and to prevent accidents from the breaking and falling of the rings chains are hung longitudinally round. A more common method now is to make the rings more expansive, and to encase them in stout boiler plate. Now as to the means of injecting the air: in each of the three openings is placed a large iron twyer. The twyer, if introduced into the furnace would burn away, so precautions are taken to protect it as much as possible by using a water twyer. It is constructed of wrought iron, and consists of two hollow truncated cones, the smaller inside the larger, coinciding at both ends and welded together. There is a clear space left round the inner cone (owing to the inequality of their sizes), and at the thicker end, away from the fire, two wrought-iron pipes communicate with this space, and it is so contrived that when the furnace is in operation a plentiful supply of cold water thus passes around the inner cone. This water twyer does not prevent altogether the burning of the iron, but it keeps it from burning so rapidly away as it would otherwise do. Round the furnace above the twyers is constructed a circular iron pipe suspended above them, and bent or elbow tubes run from this, the nozzle of one being placed in each of the twyers, and the elbow (containing a hole in the joint) serving to allow of inspection, or, in case of hot blast, of ascertaining the temperature. The blast is injected under considerable pressure—not less than three pounds to a square inch—and is produced by double-acting cylinders (about 14in. diameter). In order to support the lower part of the furnace, that part in which the metal accumulates, in some cases water "boshes" are employed, being thick plates of cast iron, through the interior of which water is circulated. The term "bosh" is applied to the lower contracted part of the furnace, and is doubtless a corruption of the German *bosche*, a slope, probably introduced by the German workmen brought over by Elizabeth.

Now let us see what occurs in the blast furnace, and for this purpose we will suppose it is in working order, having had time to dry. To simplify matters we will also assume that the materials employed are quite pure. The fire must be made slowly, and brought up gradually; the material employed may be coal, coke, or charcoal: we will suppose it to be an easily combustible fuel of pure carbon. We must keep adding this from time to time till we have filled the structure with it, all the time injecting air at a pressure of three or four pounds. The bottom aperture is closed so as to make the air find its way upward, and thus we get an upward stream of carbonic oxide and nitrogen. Hitherto we have been considering the fuel only; now we will put into the top of the furnace oxide of iron, no matter which kind. In the first place, the temperature of the furnace will be the highest towards the lower part, and the oxide of iron and fuel being added alternately, as the former descends, it at length reaches a place where the CO streaming upward is sufficiently hot to to act upon and reduce the oxide, and so we get the iron in a metallic state. CO is the grand agent in the reduction of iron ore; almost the whole of the iron produced in the world is produced from the oxide by means of this agent. The CO, by combining with the O in the ore, becomes converted into carbonic acid, and this latter product must not be allowed to remain for one second in contact with the iron, or the reverse action would occur and the iron again be oxidised.

removal is effected by keeping up a good blast. The rapidity of reduction varies with the nature of the ore and with respect to its compactness. The iron after being thus reduced still goes on descending with the glowing carbon to a hotter part of the furnace, and when these two substances are heated very strongly in contact with each other they combine, and we get an easily fusible, comparatively speaking, "pig iron." The term "carburisation" is applied to this part of the action. Descending to still hotter parts the iron becomes perfectly melted, and owing to its high specific gravity falls down on to the hearth.

Practically, we cannot get either pure carbon or pure ore. The ores which we are obliged to use contain certain materials which are very difficult to melt, *e.g.*, silica, which cannot be melted under ordinary conditions. We often have ores with silica or clay, and our fuel employed contains earthy matters. In this case the iron will be reduced as it descends into the furnace, being influenced somewhat by the impurities mixed with the ore; if this stuff associate with the reduced iron, that metallic iron will be intermixed with this infusible stuff, and so contact between the reduced iron and the highly heated charcoal prevented. But in order to get pig iron we must have that contact. The material existing in most of our ores and in fuel is easily converted into a glass-like, easily melted substance—slag—by lime. We, therefore, put in chalk or limestone with the ore, and the same phenomena exactly take place as before. The slag resulting from the addition of lime will contain all the silica and clayey impure matter of the ore, and the ashy matter of the fuel run together. This compound is much lighter than pig iron, and they will not mix with each other; the consequence is the slag swims at the top of the melted iron. Thus from the ore, limestone, and fuel put in alternately at the top of the furnace, we get two things at bottom—slag and pig iron. A hole is made in the side of the furnace for the slag to flow away through, and out of the dam. When the bottom part of the furnace has become nearly full of melted iron it is drawn off. A hole is there, but stopped with clay during the reduction; now with a long bar of iron the clay is broken out, and the metal allowed to run into moulds, sometimes of iron, sometimes of sand, running parallel to the furnace, and thus we get the bars commonly termed pig iron. The limestone is called the "flux."

MICROSCOPICAL NOTES.*

ARTIFICIAL CALCAREOUS FORMATIONS.—Professor Harting has been for some time engaged in researches into the origin and structure of certain organic calcareous structures, and has succeeded in imitating Nature in the manufacture of some of the more interesting forms of these structures. These results may be obtained by placing in the liquid containing the organic matter—albumen, solution of gelatine, a mixture of these, blood, bile, mucus from *Arion rufus*, tissue of the umbrella of *Aurelia aurita*, and the liquor obtained by triturating chopped-up oysters in a mortar; salts which, by their double decomposition, produce insoluble salts of calcium. These salts are, on the one hand, calcium chloride, calcium nitrate, calcium acetate, magnesium chloride, and, magnesium sulphate; and, on the other hand, sodium bicarbonate, potassium carbonate, sodium phosphate, and ammonium phosphate. The experiments occupy many weeks, owing to the extreme slowness of the reactions involved. The most frequently occurring form effected by calcium carbonate in connection with albumen, gelatine, or the other organic substances mentioned, the Professor christens *calcospherites* (Fig. 1, copied from the author's figure in the *Quarterly Journal of Microscopical Science*); when these are formed in the midst of the liquid and it is perfectly tranquil, they are perfectly spherical ("a") and vary from the ·002 of a millimetre to ·2 of a millimetre, and become larger in proportion as their formation takes place with greater tranquillity and slowness. They often contain a nucleus, and all of a certain size are seen to be formed of concentric layers and radiating lines. If the state of equilibrium of the fluid be not perfect the *calcospherites* undergo in the course of their development transformations in consequence of which their form is very much modified, and they become ellipsoidal, oval, or lenticular bodies. One very remarkable form, the *conostat* is shown in Fig. 2, and is characterised by the presence of a cup or goblet-shaped enlargement which becomes filled with air, and by this the conostat remains floating.

When developed in the neighbourhood of one another, the *calcospherites* mutually adhere and form dumb-bells, plates, and polyhedric bodies, recalling the structure of the shells of various *Lamelli branchiata*, &c. (Figs. 3 and 4.)

In certain definite circumstances the calcium carbonate, combined with albumen, forms very thin curved laminæ, precisely resembling the calcareous plates of the "bone" of the Sepia. These concretions consist of a *combination* of calcium carbonate with organic matter, which is the sole residue when the salt is removed with an acid. If the development has taken place in albumen, or a liquid containing it, this fundamental organic substance remains with the form and structure of the calcareous body; but *this fundamental substance is no longer* albumen, but is albumen transformed

FIG. 1

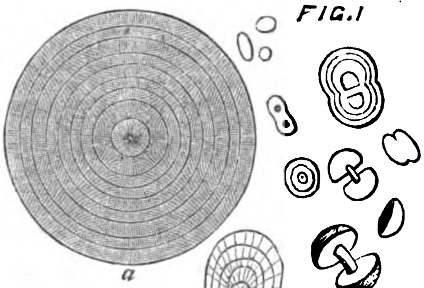


FIG. 2

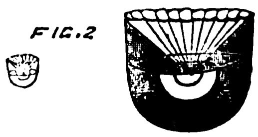

FIG. 3

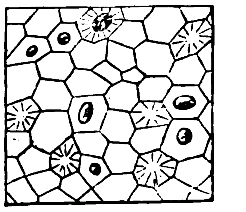

FIG. 4

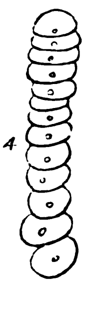

FIG. 5

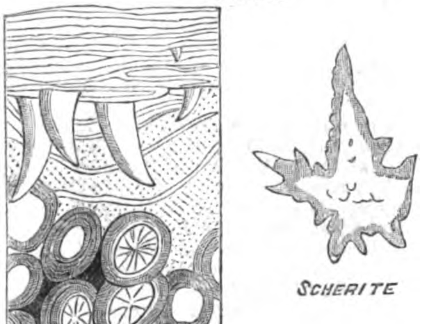

into a substance, the chemical reactions of which are those of conchyoline, and resemble those of chitine. The author calls it *calcoglobine*. If a fragment of calcic chloride be placed in albumen it is dissolved, and after some days the albumen is transformed in *calcoglobine*, which also presents a fibrillar structure, and after having been washed gives all its chemical reactions.

When calcium phosphate and calcium carbonate are liberated by the double decomposition of calcic chloride and neutral sodium phosphate, or ammonium phosphate, in a solution of albumen or gelatine, the precipitate consists of a combination of the organic material with the two calcareous salts. If the calcareous phosphate constitutes only a small fraction of the constituent, *calcospherites* are formed, but among them are some which form the starting point of various ulterior formations that may be reduced to two fundamental forms, which under certain definite circumstances appear more or less perfectly developed. The first form consists of plates, often of a considerable size, and more or less curved. They are either perfectly homogeneous or show fine fibres, sometimes disposed in a parallel manner, sometimes divergent, and concentric bands, and have precisely the conformation of the calcareous substance which constitutes the internal layer of the shell of the *Lamelli branchiata* and forms almost exclusively the shell of Gasteropoda. On other plates are thickened patches similar to those which exist on the external layer of the scales of osseous fishes. Under the influence of a low and constant temperature there are developed both on the *calcospherites* and on the plates curved spinous projections (Fig. 5). If the liquid contains in addition gelatine, these projections have a warty appearance, and they themselves have either secondary projections or they branch until they come to precisely resemble the *sclerites* of Alcyonaria. Similar *sclerites*, but different in form, are developed in cartilage, which is first impregnated with calcium chloride, and then placed in a solution of potassium carbonate mixed with a little sodium phosphate. All these calcareous formations become charged with any colouring matter contained in the liquid, and thus the coloured calcareous formations of nature may be closely imitated. Biologists will wait with impatience the publication of the author's complete memoir on this most interesting subject.

Structure of Tendon.—Dr. Mitchell Bruce, in an exhaustive but purely technical article on the structure of tendon, gives the following method for preparing cross sections of this tissue, which may be of value to some of our readers. The distal half of the tail is removed from the living animal (rat), the skin stripped off, and the organ placed in a ·5 per cent. solution of chloride of gold for fifteen or twenty minutes, after which time it is removed and exposed to the light in distilled water until coloured. It is then placed in a one-tenth or one-eighth per cent. solution of chromic acid for two or three days until the bones become softened, then transferred to alcohol for a quarter or half an hour and then cut into sections. The sections when cut should be washed in water and mounted in glycerine.

Illumination of Opaque Objects.—The following ingenious plan, which our "binocular" friends may find useful, is taken from the *Lens*, a new American Journal of Microscopy. A beam of light is sent down the oblique body of the binocular microscope, the prism being in position for use binocularly by a plane mirror rectangular prism or ordinary drawing camera, and is directed by the Wenham prism through the objective upon the slide. A small portion of the centre of the field will, if all the adjustments be correct, be brilliantly illuminated. This ought to be of service to diatomists.

New Staining Reagent.—Molybdate of ammonium, a concentrated solution, is diluted with two to three parts of water; to this are added as much iron filings as will lie upon the point of a knife (!) and commercial hydrochloric acid slowly added drop by drop with continual agitation till a deep blue, almost black, colour is produced. When it has acquired the desired colour it is allowed to stand for ten seconds and then filtered. Merkel recommends this for use in staining preparations of the nervous system.

Batceria and Putrefaction.—Professor Cohn has conducted researches into the relation between bacteria and putrefaction, and concludes that all putrefaction is accompanied by the development of bacteria; it is wanting if the access of these be prevented; it commences as soon as they are present even in the smallest number; it proceeds in the same ratio as these multiply, and with its completion ceases also their multiplication. They are then precipitated either as a powder or in gelatinous lumps (zooglea), just as yeast precipitates in completely fermented sugar solution. There can thus be no doubt that there is the same relation between bacteria and putrefaction as between the yeast fungus and fermentation. They are, therefore, exciters of putrefaction (*saprogenous*), whilst the other accompaniments of putrefaction—mould, fungi, and infusoria—are only to be regarded as accompaniments (*saprophilous*). There is no genetic relation between bacteria and mould fungi. Professor Cohn's paper—a print of a lecture delivered before the Silesian Society for Natural Culture, reprinted in abstract in the *Quarterly Journal of Microscopical Science*—is worth careful study by those interested in sanitary science, and especially by our medical friends. We have not space for a further reference to it. H. P. H.

THE HEATING OF RAILWAY CARRIAGES.

THE means hitherto in use for this purpose have found only a limited application, owing chiefly to the trouble of working them, and the expense they involve. In a pamphlet recently written by Mr. C. Rieches, of Hanover, treating of this subject, he enumerates the following modes:—1. Heating by stoves. 2. Heating by cases or vessels; (a) filled with hot water; (b) filled with sand; (c) filled with glowing charcoal; (d) acted on by a spirit flame. 3. Heating by steam. 4, Heating by heated air.

The first plan, heating by stoves, though it makes the train independent of stoppage at stations for heating purposes, is open to the objection that much space is taken up, and the heat is unequally distributed. For spacious compartments arranged for a comparatively small number of passengers, stoves are suitable, and on some of the East Prussian railways they have been used with success. The fuel is supplied from above, and without incommoding the passengers, and the heating effect is regulated by the admission of air, by an apparatus under control of the officials. The stoves require frequent attention, however, and in a long train this becomes burdensome. In the special kind of stove just referred to it is necessary to use charcoal, as any other fuel would be apt to cause extinction of the fire.

Heating by vessels or cases filled with water or sand is of frequent use. The sand absorbs a much larger quantity of heat than the water, and gives it out more slowly. The cases are sometimes placed under the seats, sometimes between them; in the latter case they are either placed loose under the feet or thrust into hollow spaces made to receive them. Sand is preferable for cases placed under the seat, and water for the others. This method, is, however, also expensive and troublesome. Heating apparatus is required at the stations, and if all the carriages are to be supplied, there must either be long delays in exchanging the cold for hot vessels, or a large staff of men must be employed to do the thing quickly. Where sand is used, it is renewed every four hours; water must be renewed much more frequently.

Another mode is that of filling cases with an artificial fuel, which, in Kienast's method, consists of pulverised charcoal, nitric acid, and starch. At first this was put in iron cases 628mm. long, 105mm. broad, and 65mm. high, which were perforated in the sides. This was found, however, to be productive of headaches, and the fuel was, therefore, put into closed cases, which were pushed from the outside under the seats. The fuel, as used, was made up in half-pound pieces, 105mm. long, 80mm. broad, and 60mm. thick. In an experiment on the line between Aix and Berlin, eight pieces were used, in four cases, for the heating of one compartment. After a 16 hours' journey, the pieces of charcoal were still glowing, and a thorough heating of the compartment had taken place. The cost of a hundredweight of the fuel is 10 thalers (30s.), and the heating now referred to cost 10½sgr., or about 1s.

A further method is that in which the heating is produced by a spirit flame. The apparatus consists of a long flat case, with perforated sides, and a top of wire gauze. A spirit lamp of peculiar shape is suspended in the interior, in such a way that no harm can come of the case being turned on either of its axes. The flame is surrounded with wire gauze, and between the top of it and the cover is a steatite plate. Cross-bars are placed above the case, and there are bags placed over these for receiving the feet. The oil supply lasts 50 hours, and the cost is very small.

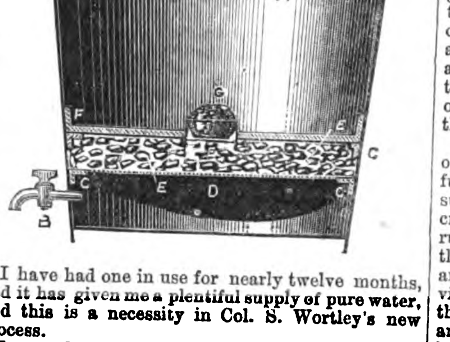
We come next to the heating by steam, a method developed in various forms by Haag, in Augsburg, and which has many advantages. The heating effect can be controlled during the journey from one point in the train; and it can be readily applied to an entire train, while, with suitable arrangement of the pipes, the heat is equably distributed, and no additional apparatus is required at the stations. The pipes may be variously arranged; a main-pipe may be placed along the entire length of the train, with other pipes branching off into the compartments, or the pipe conducting the steam may be used directly for heating the carriages. In the former case, there is the objection of presenting a larger amount of condensation surface, while it has the advantage that it is possible to shut off the supply of steam from single compartments. It is always of importance so to lay the pipes that they may be filled only with steam. It is inconvenient to use steam at a high tension, on account of the necessity in such a case of having strong and accurately fitting joints between the carriages. Two atmospheres may be regarded as the limit. The steam may be brought either from the locomotive boiler or from a boiler specially constructed for the purpose. In the latter case there is the taking up of space to be considered, and the increase of about 20cwt. dead weight. In a long journey a fresh supply of fuel and water must be taken in, and the apparatus requires a special attendant. These objections fall away when the steam is taken from the locomotive boiler, and allowed a certain expansion before admission into the pipes. Where a separate vessel is employed the supply of steam is soon used, and it becomes difficult to preserve the normal tension, and on the other hand steam taken from the locomotive boiler diminishes the working power. In recent experiments made with reference to this on a railway in Lower Schleswig, the steam was taken from the locomotive, and it was found that a very small quantity of additional fuel was adequate to produce the required supply. The question of cost was decided in favour of the plan adopted.

Finally, in the use of heated air, the casing of the stove is formed of some badly conducting material. The cold air enters the stove by openings in the lower part, gets warmed, and rises to the roof of the carriage. By this means a slow circulation is produced, and the temperature is equalised more than in the method first specified. This plan is adopted on many of the Hanover railways. In some cases the heated air is conveyed by pipes from the stove to the ends of the carriage.

A. B. M.

A CHEAP WATER FILTER.*

LAST summer, not believing my drinking water to be pure enough, I had a filter made to order. First, I bought a galvanised iron pail, and then had a tap inserted about an inch from the bottom. Just above that, on the inside, were fixed three or four small zinc ledges, on which was placed (loose) a false bottom of perforated zinc. About 2in. above that were fixed similar ledges, on which was placed a zinc tray, having a lead rim, and in the centre a small circular box with a perforated bottom. This box is let into the tray and soldered; it is filled with fine sponge, which I tie down, and through which passes all the water to filter. The rim (about an inch high) should be wrapped round with cotton wool, so that all the water must go through the sponge. Between the tray and false bottom is filled with charcoal broken to about the size of nuts.



I have had one in use for nearly twelve months, and it has given me a plentiful supply of pure water, and this is a necessity in Col. S. Wortley's new process.

I append a section of the filter:—A, galvanised pail; B, tap for drawing off purified water; C, small zinc ledges; D, removable false bottom of perforated zinc; E, charcoal; F, zinc tray, lead rim; G, sponge box (3in. diameter) and sponge; H, handle.

If any water escape between the rim of the tray and the pail—which you can tell by the bubbles—you must rap the rim until it ceases to do so. The sponge should be kept clean, and the charcoal changed occasionally.

* By ALBERT DUMSDAY, in *Photographic News*.

POLYZOA.

THE following interesting account of these beautiful creatures, and of the method of preparing them for examination, is from the pen of Mr. Lattey, M.R.C.P., and was read before the Quekett Microscopical Society a few months ago:—

Amongst the vast number of animated beings of whose very existence we should have remained in profound ignorance were it not for the invention of the microscope—so justly termed a sixth sense—few afford more beautiful or interesting objects for our contemplation than the group to which the name of Polyzoa has been given; so called from two Greek words—polus (many) and zoon (animal)—being always found aggregated together in masses, and many of them resembling minute plants, so much so as to have been classed, by early observers, amongst the members of the vegetable kingdom. Their complex organisation has obtained for them a high position in the animal kingdom, and the exquisite form which some of them possess cannot fail to excite our admiration. When, for instance, we see the elegant Sertularians, projecting like fairy ferns from the side of a rock-pool, attractive by their graceful forms, even before the microscope has revealed the beautiful little creatures studding their branches like living flowers, or the Polyzoary of the Halodactylus, with its exquisite bell-shaped creatures emerging, one by one, from the jelly-like mass coating the seaweed, like the ribs of a folded umbrella, stripped of its covering, and then gradually expanding into a beautiful bell, the ciliæ fringing its ribs, or tentacles, in perpetual motion, keeping up a constant eddy in the surrounding water so as to bring the floating particles of nutritious matter within the grasp of their open mouths.

Amongst all these creatures, none are more curious than the species of Bugula, called Bugula avicularia, from its possessing those strange appendages called birds' head processes, and most appropriately so, from their very exact resemblance to the head and beak of a bird. They are attached to the margins of the cells by means of a footstalk, and each has two "mandibles;" the upper one fixed and the lower one movable, just as in birds, and they are opened and shut by powerful muscles within the "head." A most singular and curious sight it is to watch the movements of these "objects" when a portion of the Polyzoary is viewed under an inch or two-inch objective, so as to allow a number of these bodies to be in sight at once. It will then be seen that each head keeps up a continual nodding movement, throwing itself slowly back, which its joint-like union to the cell allows, at the same time gradually opening its jaws, or rather depressing the lower jaw until the mouth is open to its full extent, and when the head has gone back as far as it can reach, it suddenly resumes its former position, the mouth closing at the same instant with a sudden snap, and entrapping any luckless animal that may be passing at the time; and then the same proceeding takes place over and over again, without any intermission. It certainly is a most singular—I might almost say ludicrous—sight to see all the avicularia within the field of the microscope practising this perpetual "snapping." The great size and apparent strength of the animals which they are capable of seizing and retaining in their grasp must impress us with a sense of the enormous strength of the muscles which move the jaw, for they seize and retain not only small vermicules, but such large creatures as caprellæ, entomostracæ, &c.; and very curious it is to watch the writhings and struggles of one of these comparatively gigantic victims in its vain efforts to escape from the jaws of its tiny captor. Not unfrequently the captive is seized by another, or even two more avicularia, in other parts of its body, thus making assurance doubly sure, and so deadly is the grip, that I have never seen one of them relax its hold on the application of the medium which is fatal to themselves.

Various have been the conjectures as to the office of these "heads without bodies," and their exact function in the economy of the animal—some supposing that their office is to protect the delicate creatures over whom they mount guard from the rude contact of foreign bodies which might injure their frail structure; but many equally delicate animals, the Halodactylus, for instance, are unprovided with any such protection. Others suppose that they are destined to entrap the passing animals, and hold them in their firm grip until decomposition has diffused them in the surrounding water, thus furnishing the creatures with a supply of nourishment; this, to my mind, appears the most feasible explanation. I have found these animals in great abundance at Ilfracombe, especially upon the rocks near the harbour, mostly depending from the under surface; the Campanularia dichotoma in the same locality on the leaves of brown sea-weeds, and the Sertulariæ growing from the sides of rock-pools at St. Leonards and Exmouth. The Halodactylus may be found in any locality where there are rocks, encrusting the stems and fronds of the common bladder wrack (Fucus vesiculosus) at low water, especially during spring tides. It looks like a firm gelatinous coating of a brown colour, and has a semi-transparent appearance. When put into fresh sea-water, it is seen to become gradually, as the animals emerge from their cells, overspread with what appears, to the naked eye, to be a minute white downy covering.

If it is desired to make preparations of any of these creatures, the following will be found a successful plan. Their extreme sensitiveness, and the rapidity with which they withdraw themselves into their cells upon the slightest touch or jar, makes it necessary to adopt a peculiar plan of proceeding. I would premise that before commencing operations with the Halodactylus it is desirable to cut it into the length required to fit the cell in which it is to be placed whilst the animal is contracted, as it may then be cut in any direction without injury, but when expanded it requires to be very carefully handled, as, if the bells are in any way pressed or put out of shape, they cannot be restored. For this reason it should be so cut as to fit the cell tightly, so as to prevent its being shifted. The object is to coax the animals out of their tiny homes, and to keep them out until you can kill them. To accomplish the first object, it is best to keep them out of the water for several hours, and then to put them into fresh sea-water in any appropriate vessel. I have found a circular glass dish, such as is used for cakes of transparent soap, answer very well, as it can be put upon the stage of the microscope, and the effects of different stages of the operations watched, which is of importance. Some alcoholic spirit must now be added very gradually—spirit of wine, brandy, whiskey, or gin, it matters not which—when they will be observed to come out in greater numbers, evidently attracted by the taste of the spirit, and as it continues to be added they become evidently excited, withdrawing into their cells, and coming out again, bending about, and the ciliæ meanwhile moving in a most rapid manner. This continues for some time, until at length they begin to flag in their movements, which become more and more sluggish, the animals being apparently drunk. This is the moment to pour off the alcoholised sea-water, and pour upon them the preservative fluid, which has the desired effect of bringing out all that are still left in their cells, and gradually killing them, and it has the immense advantage of being at the same time a most excellent fluid for preserving them, so that they can remain in it. I find it of great service to let the Halodactylus lie for a considerable time in this fluid before finally putting them up, as a certain amount of deposit takes place from the sea-weed, which it is better to exclude from the cell. The preserving fluid I use is one recommended by Dr. Beale, as a modification of Thwaites', and is prepared as follows:—

Mix three drachms of creosote with six ounces of wood-naphtha, and add, in a mortar, as much prepared chalk as may be necessary to form a smooth thick paste; water must be gradually added to the extent of 64oz., a few lumps of camphor thrown in, and the mixture allowed to stand for two or three weeks in a lightly covered vessel, with occasional stirring; after which it should be filtered and preserved in well-stopped bottles.

HINTS ON PAINTING.*—IV.

(*Continued from p. 689, Vol. XIV.*)

Varnishing.

THE varnish-room should be well cleaned, walls dusted, floor well wet, and if the weather is cold, a temperature of seventy-five or eighty degrees maintained by a clean tight stove, or what is better, steam pipes. The carriage part and body having now been nicely rubbed down and well cleaned, we begin with the carriage part. Raising all the wheels from the floor by two boxes or barrels placed under the axles, we prepare the varnish and brushes. American finishing varnish is good enough for this part, and with our oval varnish brush and flat "tool" we take our position in front of the wheel with our left hand on the rim to turn it, with the "tool" we spread the varnish heavily between the spokes, and up the front as far as the V shape of spokes extend; then with the large brush we lay on an abundance of varnish on the side of the spoke nearest our left hand, then opposite, and then reach over and cover the back.

Now, wiping out all the varnish in the brush on the edge of the cup, we repeat the operation with the dried brush, laying off the varnish smoothly and removing the bubbles. Next we varnish the hub, and wipe with the "tool" around the "butt" of the spokes; then varnish the inside of the rim between the spokes, finishing the back and front sides last. We keep the wheel turning for a moment or two until the varnish flows evenly, and proceed with the other wheels in the same manner, finishing the springs, axles, &c., lastly.

The body is next looked after. Taking our body finishing brushes (the fitch hair brushes are best for the buggy), we begin with the inside—for which we should have a pair of brushes and a cup expressly. In laying on a heavy coat, we level it off nicely, leaving the brush marks faintly perceptible up and down the panels, always leaving the work before it begins to set.

The outside we next look after, and flow the varnish on very heavily, but as evenly as possible. We lay off from end to end, then across from bottom to top, and repeat; wiping out the brush on the cup, and leave the panel with the last movement up and down. We clean out under the mouldings with a small brush, and bear in mind that a heavy flow must be wiped upward, never down. Having been all over the body with a piece of whalebone—which should be at hand, one end being sharpened to a point—we go over the work, picking out any hairs, dust, &c., and then close up or darken the room and leave the job to dry.

In cleaning a body preparatory to varnishing, I find it an excellent plan to use, after dusting with the dusting brush, a piece of silk dampened with sweet oil. With this I gently wipe the job over, but not enough to grease the surface, and it removes every little particle of dust or lint left by the shammy and duster.

Varnishes.

There is no class of people more pestered with pedlars, if I may so term them, than carriage-makers are with varnish agents. Every few days an agent of this sort makes his appearance, and sometimes proves an intolerable bore. I do not frown upon the enterprise and go-a-head-a-tive-ness of the agent or his employers, for such a spirit is well enough; but I have frequently had occasion to object to the perseverance of such men in seeking the foreman, after a denial from the "boss," and trying, sometimes by bribery, to get him to assist with his influence in introducing the vaunted varnish. Some bosses, to get rid of the agent, order varnish "for trial," and the workman then has to run the risk of spoiling his job; for being unacquainted with the varnish—and all varnishes manufactured by different makers have their respective peculiarities—he goes at the work with more or less nervousness or hesitancy, and is almost certain to turn out a poor job.

Always "let well enough alone," if you have good varnish and know how to use it; let the new man, with his new varnish, negotiate with some new shop, where new work is done, by new hands.

I do not wish to be understood as taking a stand against improvement, but as a general thing, there are too many changes with regard to varnish made in many shops. Neither would I speak disparagingly of varnish manufacturers, but would give all a fair show. Let those, however, who prefer one maker's goods patronize him. "Each one to his taste." I echo the sentiments of a score of painters, and should not be judged harshly therefor.

There are different opinions existing as regards the necessary qualities of varnishes—some preferring a quick-setting varnish, and others, a slow-setting one to enable them to "lay off" well; consequently each must try for himself. In re-varnishing old work it is not well to put English on the old surface, it being apt to "crawl" or "pit." A newly finished job should always be washed with clear cold water, and dried with a clean shammy, before allowing it to leave the paint shop; this hardens the surface and prevents the dust from sticking to it.

If varnish is found to "crawl," wipe the surface with a damp shammy. Never dilute varnish with turpentine, as it kills the gloss. If too thick, warm it by the stove or place the cup on a warm iron.

Polishing.

Polishing on carriages is now among the things of the past; but to describe the method will not be amiss, perhaps.

Finish your job as smoothly and cleanly as possible with American finishing varnish, and let it stand atleast ten days; then rub down with pumice-stone the same as if a rubbing coat; clean off, and rub again with rotten-stone ground fine, until the marks of the pumice-stone are all obliterated; next rub with rotten-stone and oil until a gloss appears. Then substitute Spanish whiting for the rotten-stone; this should be washed, *i.e.*:—Mix the whiting in a pail of water, until like milk: let it settle a moment to get the stones, dirt, or lumps out; pour off the milky liquid into a clean pan, and let it settle thoroughly: pour off the clear water and dry the sediment; it will be an impalpable powder, and mixed with the sweet oil will produce a good polish on the panel. Clean all off with soft silk, and you have a glossy surface, superior to varnish in point of wear—but not in looks.

Fancy boxes may be polished in this way, and are better than varnished surfaces. Furniture, pianos and fancy articles are generally polished, and there are preparations to be had at furniture stores for re-polishing, which answer a very good purpose.

Painting Coaches, &c.

The *modus operandi* of painting heavy jobs differs but little in the foundation coats from light work: therefore I will not enter into details with regard to it. The workman must be more particular with this work, but one who can paint a buggy well should be able to get up a good job on heavy work. Confidence in your abilities is one half the battle.

The panels of such work are generally painted in colours, while the pillars, top stripe, quarters, deck, &c., are always black. Umber colours, lakes, greens, and blues are some of the best colours used on this work. To prepare the body for any of these colours, we should use a ground colour in the place of lampblack on black work

The following are a few of the grounds most approved.

Lake.—Indian red and vermilion mixed to a dark brown, though some prefer a black ground for lake. Lake should never be mixed to dry "dead," but with a subdued appearance, by putting in varnish enough. The best way is to try it on a board before laying on. If "dead," it loses one-half its brilliancy, and will be apt to be cloudy.

Ultramarine.—Mix a medium blue with keg lead and Prussian blue.

Vermilion.—A light pink colour is generally used as a ground for vermilion, but if a pure white ground is gotten up from the beginning, you will find the colour to cover well, and lose none of its pristine beauty. Don't forget to put flowers of sulphur into your vermilion, (as spoken of on page 606, Vol. XIV.) to preserve the colour.

Green.—Green and all heavy bodied colours will cover well on the lead colour without any ground colour.

To Paint Panels Carmine.

To make a good job with carmine, we should get up an English vermilion ground, into colouring varnish, well rubbed down with pumice stone; for we cannot rub a great deal after the job is glazed. Some painters mix their carmine glazing with rubbing varnish and oil, but you will find such jobs frequently "spotted;" the best way is to mix in English varnish, adding a little gold size for a dryer; this flows evenly, and does not cloud or spot if properly put on. When a job is glazed, rub it carefully and apply a coat of American finishing and rubbing, mixed in equal parts. This can be rubbed for finishing coats, whereas if rubbing varnish be put on over the glazing it might crack—but the mixture will stand the wear of years.

Ultramarine blue panels can be made the same way, the ground being gotten up with Prussian blue. A beautiful wine colour or lake may be made by glazing Indian red or brown with carmine. A brilliant green may be produced by a light pea green glazed with verdigris or with Paris green. Striping may be glazed in the same manner, but of course on dead striping colour. Some painters put on glazing the same as, and in the place of, colouring varnish. I think this a very poor plan, as you have no chance to rub the surface until there is so much varnish over it that the colour is injured.

The workman by experiment can discover many splendid variations of shades and tints by the glazing process, and his labours will be better rewarded by knowledge acquired in that manner than if I were to extend this article to greater length with more precepts.

Striping.

When tube colours are used for striping, there will be no trouble experienced in mixing, as they only require thinning with turpentine, and the addition of a little sugar of lead. We must use our own taste in striping; though governed a little by prevailing styles. It would be folly for me to dictate any particular style. The manner in which striping is done can be learned in three minutes by looking at a workman while at work, but long experience is required to perform the operation well: suffice it, then, for me to say, get good tools and colours and practice on a wheel or board painted for the purpose, until you can master the art, for only practice, patience, and perseverance can accomplish it.

When striping on solid colour, the ends of the stripes or any imperfections can be "cut off" or improved with a little of the "dead" colour, but on a glazed or light colour the "cutting off" would show, therefore, when thus employed on these colours we have a little oil ready, and before the stripes are dry, we draw a pencil filled with the oil across the ends. Then the stripes will dry everywhere but in those places where the oil is, and then they can be washed off with soap and water after all the rest is dry, and thus leave the stripes with a square end. Bronze striping is fashionable, while glazed stripes are always considered beautiful. Striping with a mathematical or drawing pen will be found excellent on panels or sleighs. Scotch plaid work is now out of fashion, as well as cane work, or raised cane. The latter "raised Cain" with many who did not know its secret, and although an extended article could be written on that kind of work alone, and would be considered interesting by some, its antiquity will not warrant more than this brief notice.

* From the "Carriage-Painter's Manual." By F. B Gardner. New York: S. R. Wells.

THE INDUSTRIAL CLASSES IN BRAZIL.

THE daily papers lately contained a notice from the Consul-General of the Empire of Brazil, setting forth the facilities which will be afforded on certain conditions to intending European emigrants to that country. How far the prospects of such persons are favourable or otherwise we will endeavour to show. Brazil occupies such a vast territory that great differences are to be found in its various divisions in respect of natural advantages, such as wood, water, climate, and roads, and the reports of the consuls of the seven selected towns contrast accordingly. Para, for instance, in the most northern province, is situated as nearly as possible on the equinoctial line, whereas Rio Grande is about 33 deg. south latitude. But the land is so much elevated above the sea, and is so well watered by magnificent rivers, that though it lies mostly within the tropics, the climate is, on the whole, healthy and delightful. Some of the ports are an exception to this rule. Though splendid to the eye, they lie low, and as the drainage is deficient, epidemic of fever sometimes occur. Brazil is at present in a transition state, as the emancipation of the slaves is being now rapidly carried out. When this measure has been fully accomplished it is reasonable to suppose that it will be followed by a considerable demand for labour. The Government is also constructing railways and new roads in the interior, and the greatly increased steam communication already conveys large importations of ready-made goods of every description. These are chiefly, as far as we are concerned, manufactured cotton goods, wrought and unwrought iron, linens, and woollens, and we receive from Brazil in return, raw cotton, coffee, and unrefined sugar. In fact, our Brazilian trade is nearly three times as large as that of France, and five times as large as that of any other country. The country is peopled by a very mixed race. The original Portuguese settlers intermarried extensively with the Indian women, and there was a further intermixture of race with the African slaves. The Indian element preponderates in the north, while at the seaports the population is chiefly European, the Portuguese predominating. Besides these there are not a few groups of settlers —English, Swiss, and German—who have formed, as it were, separate colonies, having obtained grants of land from the Government. Most of these are in a very flourishing condition, and the men have built for themselves good dwelling-houses. In some cases they have established manufactories, in others they pursue agriculture, but they receive every encouragement from the Brazilian authorities. There are a considerable number of English miners, many of them Cornishmen. In one mine alone there were upwards of 140 European miners and mechanics employed; according to Captain Burton's report, they were well paid and cared for, and as their cottages were built for them by the company, and let to them at a merely nominal rent, they ought to put by money.

European artisans and mechanics are not here, as in most foreign countries, exposed to the disadvantage of having to compete with cheap native labour. The Brazilian is not by nature a handicraftsman. He prefers keeping a shop or breeding and selling cattle; but above all he desires a place under Government. As a workman he is independent, careless, and deficient in steady industry. When he has earned a little money he gives up a job and remains idle until he has spent it. The rate of wages is very high. Tailors, shoemakers, saddlers, ship carpenters, get from 8s. to 10s. per day. Blacksmiths, joiners, carriage builders, bakers, hatters, tinkers, and painters, from 4s. to 6s. 6d.; masons and bricklayers, 4s. to 6s. At Sao Paulo, smiths, turners, and moulders get from 8s. to 10s., railway labourers from 4s. to 6s. There is, according to Consul M. Heinssen, a great demand for female domestic servants. Chambermaids and general servants receive from £2 10s. to £3, and cooks £4 per month. As a rule, all engineering and constructing work, machine making and repairing, saddle and carriage making, brewing, &c., are done by Europeans. The Portuguese are the most numerous, but, though they are hard workers, they are disorderly in their conduct; the Germans are very steady and save much money. A very profitable branch of labour for six months in the year is the extraction of the juice of the rubber-tree. A single man will put up a temporary hut in the forest, and, with a provision of dried fish and mandioca root, in addition to the fruit and game which abound everywhere, can live very comfortably. About 8lb. of rubber is an average day's work, value 13s. 4d.; but some men have been known to earn as much as £2 13s. in one day. The operation is performed in a very primitive manner; but already an American and an Englishman have produced two inventions for performing it more expeditiously and methodically. The Tapuyo, or civilised Indian, is very fond of this kind of work, but it is at present carried on in a most wasteful and short-sighted way, for though the accessible rubber districts are becoming exhausted, no care is taken to plant young trees to re-supply them. It is stated, however, that vast supplies exist in the interior, and when more roads are constructed, it is evident that with care a source of considerable riches might be established by industrious and enterprising colonists. Under the same conditions plantations of cotton, rice, sugar, and cacao would prove a valuable branch of agriculture.

The daily wages to be earned in Brazil by a good workman are, as we have shown, exceptionally high; with regard to the purchase power of money, the statements given by the consuls vary according to the district. In Para it is estimated as about half what it is in England. In Rio de Janeiro an English mechanic would be about as well off with £20 a month as he would at home with £15. In Pernambuco the purchase power is from half to two-thirds, whereas in Rio Grande, Consul Callander, after balancing the high house-rent against the cheapness of food, considers money goes about as far there as here, and Consul Heinssen agrees with him. Consul Dundas thinks that supposing 10s. there is worth only 5s. here in purchase power, still, to a man who chose to save money, the advantage would be considerably in his favour, and explains it thus:—The milreis (coin of the country) may only buy there as much as a shilling would here, but it is valued at 2s. exchange. His savings, therefore, he could convert into sterling at the current rate of exchange; and if he earns 9s. a day, he can live on 5s., or less, very comfortably, and he has the full value of what he is able to lay by. It is affirmed that a steady skilled mechanic, even if married and with a family, ought to save at least one-fourth of his wages, but at the very least he would find himself with about 35s. in hand at the end of each month. From the evidence given we should place this much higher. If emigrant workmen in a distant country insist on having imported luxuries, such as tea, wine, butter, bottled English ale and porter (the only way it can be procured), and wheaten flour, of course they can spend any amount of money; but a reasonable and intelligent emigrant adapts himself to the customs and requirements of the country, and accepts its luxuries in exchange for those he has left in England. For example, in Brazil he would use coffee instead of tea, the small-beer and wine made in the country instead of bottled ale or spirits, and flour made from the mandioca root or maize instead of wheat; while delicious tropical fruits and various kinds of game unknown here, but cheap and abundant there, would very much abate the severity of his self-denial.—*Pall Mall Gazette.*

RESTORING CHARRED MANUSCRIPT.

THE wholesale destruction by the fire in Chicago of the receptacles used for the safe-keeping of valuable written and printed documents has called for some means of restoring burnt manuscript and the like, at least so far as to permit the same to be deciphered. A resident, Mr. J. V. L. Blaney, of the burned city, has attempted to meet the necessity by a patented process, which he describes as follows:—

The charred paper is to be first separated into single leaves, and then immersed in a solution of a soluble compound of silver or copper for such a time as may be required to render the printing or writing sufficiently legible. A solution of the nitrate of silver containing forty grains of that salt to one fluid ounce of distilled water is preferred. If the restoration is only required to be made on one side of the sheet, the solution may be applied with a brush, or by floating the paper upon the surface of the liquid.

The process succeeds best in a dark or a feebly-lighted room. After sufficient legibility has been attained, the paper should be soaked for some time in pure water to remove the excess of the salt used—in the case of silver salts, a dilute solution of hyposulphite of soda or of cyanide of potassium may be used—after which the paper may be exposed to the light, and, when dry, covered with a transparent mucilage or varnish, for preservation.

THE PREVENTION OF PUTREFACTION AND THE DEVELOPMENT OT PROTOPLASMIC AND FUNGUS LIFE.

THE following is an abstract of two papers by Dr. F. Crace-Calvert, F.R.S., read before the Royal Society, on the relative power of various substances to prevent putrefaction and development of protoplasmic and fungus life:—

To carry out this series of experiments, small test-tubes were thoroughly cleansed and heated to dull redness. Into each was placed 26grms. of a solution of albumen containing 1 part of white of egg to 4 parts of pure distilled water, prepared as described in my paper on protoplasmic life. To this was added 1000th, or 0·026grms., of each of the substances the action of which I desired to study.

The reasons why I employed 1 part in 1000 are twofold. First, the employment of larger proportions would, in some instances, have coagulated the albumen; secondly, it would have increased the difficulty of observing the relative powers of the most efficacious antiseptics in preventing the development of the germs of putrefaction or decay.

A drop was taken from each of the tubes, and examined under a microscope having a magnifying power of 800 diameters. This operation was repeated daily with the contents of each tube for thirty-nine days, and from time to time for eighty days. During this time, the tubes were kept in a room the temperature of which did not vary more than 3°—viz., from 12·5° C. to 15·5° C.

In order the better to show the influence of the antiseptics used, I examined two specimens of the same solution at the same time, one of which was kept in the laboratory, the other in the open air.

A marked difference was observed in the result; the one kept outside becoming impregnated with animal life in less than half the time required by the other, while as many vibrios were developed in six days in the tube kept outside as were developed in thirty days in the tube in the laboratory.

A summary of the results of the experiments given in the following table, in which the substances are grouped according to their chemical nature:—

	Days required for Development of	
	Fungi.	Vibrios.
1.—STANDARD SOLUTIONS.		
Albumen kept in laboratory for comparison	18	12
Albumen exposed outside laboratory	None	5
2.—ACIDS.		
Sulphurous acid	21	11
Sulphuric acid	9	9
Nitric acid	10	10
Arsenious acid	18	22
Acetic acid	9	30
Prussic acid	None	9
3.—ALKALIES.		
Caustic soda	18	24
Caustic potash	16	26
Caustic ammonia	20	24
Caustic lime	None	13
4.—CHLORINE COMPOUNDS.		
Solution of chlorine	22	7
Chloride of sodium	19	14
Chloride of calcium	18	7
Chloride of Aluminium	21	10
Chloride of zinc	53	None
Bichloride of mercury	81	None
Chloride of lime	16	9
Chlorate of potash	19	17
5.—SULPHUR COMPOUNDS.		
Sulphate of lime	19	9
Protosulphate of iron	15	7
Bisulphite of lime	18	11
Hyposulphite of soda	18	11
6.—PHOSPHATES.		
Phosphate of soda	17	13
Phosphate of lime	22	7
7.		
Permanganate of potash	22	9
8.—TAR SERIES.		
Carbolic acid	None	None
Cresylic acid	None	None
9.—SULPHOCARBOLATES.		
Sulphocarbolate of potash	17	18
Sulphocarbolate of soda	19	18
Sulphocarbolate of zinc	17	None
10.		
Sulphate of quinine	None	25
Picric acid	19	17
Pepper	None	8
Turpentine	42	14
11.		
Charcoal	21	9

In comparing the results described in the above table, the substances can be classed under four distinct heads—viz., those which prevent the development of protoplasmic and fungus life; those which prevent the production of vibrio life, but do not prevent the appearance of fungus life; those which permit the production of vibrio life, but prevent the appearance of fungus life; and those which do not prevent the appearance of either protaplasmic or fungus life.

The first class contains only two substances, carbolic and cresylic acids. In the second class, also, there are only two compounds, chloride of zinc and bichloride of mercury. In the third class there are five substances, lime, sulphate of quinine, pepper, turpentine, and prussic acid. In the fourth class is included the remaining twenty-five substances. The acids, while not preventing the production of vibrio life, have a marked tendency to promote the growth of fungus life. This is especially noticeable in the case of sulphuric and acetic acids. Alkalies, on the contrary, are not favourable to the production of fungus life, but promote the development of vibrios. The chlorides of zinc and mercury, while completely preventing the development of animalcules, do not entirely prevent fungus life, but I would call special attention to the interesting and unexpected results obtained in the cases of chlorine and bleaching powder. When used in the proportion above stated they do not prevent the production of vibrio life. In order to do so they must be employed in excess; and I have ascertained, by a distinct series of experiments, that large quantities of bleaching-powder are necessary. I found that part of the carbon was converted into carbonic acid, and part of the nitrogen was liberated. If, however, the bleaching-powder be not in excess, the animal matter will still readily enter into putrefaction. The assumption on which its employment as a disinfectant has been based, namely, that the affinity of the chlorine for hydrogen is so great as to destroy the germs, is erroneous.

The next class to which I would call attention is the tar series, where neither the carbolic nor the cresylic acid fluids gave any signs of vibrionic or fungus life during the whole eighty days during which the experiments were conducted. The results obtained with sulphate of quinine, pe[illegible] and turpentine, deserve notice. None of t[illegible] vent the development of vibrio life; bu[illegible] of quinine and pepper entirely prevent [illegible]ance of fungi. This fact, together wit[illegible] able efficacy of sulphate of quinine in cases of intermittent fever, would lead to the supposition that this class of disease is due to the introduction into the system of fungus-germs; and this is rendered the more probable if we bear in mind that these fevers are prevalent only in low marshy situations, where vegetable decay abounds, and never appear to any extent in dry climates, even in the midst of dense populations, where ventilation is bad, and putrefaction is rife. The results obtained in the case of charcoal show that it possesses no antiseptic properties, but that it prevents the emanation of putrid gases, owing to its extraordinary porosity, which condenses the gases, thus bringing them into contact with the oxygen of the atmosphere, which is simultaneously condensed.

The above results have been confirmed by a second series.

A series of experiments was also undertaken, substituting gelatine for albumen, and was continued for forty-seven days. Vibrios appeared in two days in the standard gelatine solution, and bacteria after four or five; and during the whole time of the experiment, life was far more abundant than in the albumen solution. A distinct putrid smell was emitted after twenty-six days. With bleaching-powder it took twenty days for life to appear, instead of seven, as in the case of albumen; while at no time during the twenty-nine days which remained was life abundant. No putrid odour was emitted; but a mouldy one could be detected on the thirtieth day. With chlorine solution vibrio life was only observed after forty days; no putrid nor mouldy smell was given off at any time. The protosulphate of iron gave, with this solution, results quite different from those with albumen, in which, it will be remembered, vibrios appeared in seven days, and fungi after fifteen: whilst, with gelatine, neither protoplasmic nor fungus life appeared during the time the experiments were continued. Another substance, arsenious acid, also presented a marked difference in its action in the two solutions, for although with albumen twenty-two days elapsed before vibrios were present, and eighteen before fungi, with gelatine animal life appeared after two days, and at no time did any fungi exist. The effects of the other substances with gelatine were so similar to those with albumen that it is unnecessary to state them here.

Another series of experiments was undertaken as complementary to those described above, and consisted in adding to a solution of albumen, swarming with microscopic life, one-thousandth part of the substances already enumerated, and examining the results produced immediately after the addition of the substances, and after one, six, and sixteen days; but in this abstract, only the results obtained in the first and last cases will be noticed.

The solutions were placed in test-tubes similar to those described in my last paper. The experiments were begun on September 20th, 1871, the solutions being kept at a temperature of 15° to 18° C. In the standard solution, the amount of life and putrescence increased during the whole of the time. The first class includes those substances which completely destroyed the locomotive power of the vibrios immediately, and completely prevented their regaining it during the time the experiments were conducted:—Cresylic acid.

The second class contains those compounds which nearly destroyed the locomotive power of all the vibrios present when added, and afterwards only one or two could be seen swimming about in each field:—Carbolic acid, sulphate of quinine, chloride of zinc, and sulphuric acid.

The third class are those which acted injuriously on the vibrios on their addition, leaving only a small number retaining the power of swimming, but which allowed the vibrios gradually to increase in number, the fluid, nevertheless, containing less life after sixteen days than the standard putrid albumen solution:—Picric acid and sulpho-carbolate of zinc.

The fourth class includes those substances which acted injuriously at first, but permitted the vibrios to regain their former locomotive power, and which, after sixteen days, contained as much vibrio-life as the standard putrid albumen:—Chloride of aluminium, sulphurous acid, and prussic acid.

The fifth class contains those compounds which acted injuriously at first, destroying the locomotive power of most of the vibrios, but which afterwards permitted the vibrios to increase more rapidly than in the standard albumen solution:—Bleaching-powder, bichloride of mercury, chlorine solution, caustic soda, acetic and nitric acids, sulphate of iron, and the sulpho-carbolates of potash and soda.

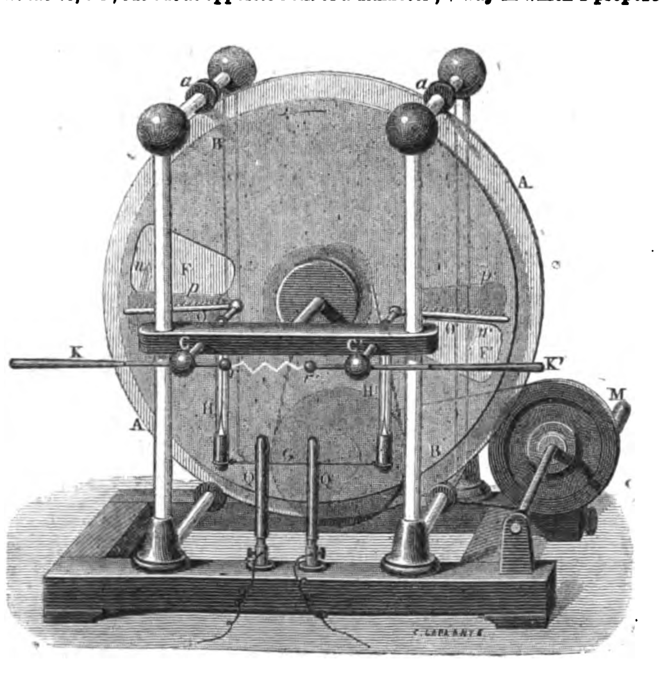
The sixth class contains these compounds which exercised no action on the animalcules either at first or after sixteen days:—Arsenious acid, common salt, chloride of calcium, chlorate of potash, sulphate of lime, bisulphite of lime, hyposulphite of soda, phosphate of lime, turpentine, and pepper.

The seventh class includes those substances which favour the production of animalcules, and promote putrefaction:—Lime, charcoal, permanganate of potash, phosphate of soda, and ammonia.

HOLTZ'S ELECTRICAL MACHINE.

SEVERAL inquiries as to the construction of Holtz's electrical machine having appeared in our columns without eliciting a reply so satisfactory as queries generally obtain, we have thought it advisable to make an abstract of the best description with which we are acquainted, and have accordingly borrowed the illustration and description contained in the supplemental volume of Watts' "Dictionary of Chemistry" just published by Messrs. Longmans.

This is a contrivance by which a very small initial charge is made to give rise to an indefinitely great quantity of electricity of high tension; its action may be described in general terms as equivalent to that of an electrophorus and a condenser combined together in such a way as to act upon each other alternately, the condenser being first charged by the electrophorus, then reacting upon it so as to increase the charge of the cake; next being charged by the electrophorus to a higher degree and reacting upon it more strongly than before; and so on, the charge of each becoming gradually greater and greater until the insulation is overcome. The form usually given to the machine is shown in the figure. Its construction is as follows: A circular plate of thin and very flat glass, B B, is mounted upon an insulating ebonite axle, so that it can rotate in a vertical plane, and a second glass plate, A A, also as thin and flat as possible, is fixed parallel to it, with its centre in the same horizontal line, and at a very short distance (⅛in. to ¼in.) from it. At the middle of the fixed plate there is a round hole, through which the axle of the movable plate can pass without touching, and there are two deep notches or *windows*, F F', cut out at opposite ends of a diameter;



at the back of the glass (that is, on the side turned *away* from the rotating plate) a piece of paper, *p*, about 2in. broad is pasted along the lower edge of one of these openings, and a similar piece, *p*, is pasted along the upper edge of the other opening, each of these pieces of paper having projecting from it a couple of tongues of stiff paper, *n n'*, long enough to project through the opening and just touch the movable plate; both the papers and their projecting tongues are well varnished. On the side of the movable plate which is farthest away from the fixed plate, and opposite to the two pieces of paper just mentioned, are two collectors, O O, each consisting of a row of metal points projecting from an insulated metal arm to within a very small distance of the rotating plate. These collectors are connected with the main conductors of the machine, C C, each of which is provided with a movable discharging rod, K K', by means of which they can at will be placed in electrical connection with each other, or separated by any required interval. In order to put the machine in action, the two conductors are connected together, the movable plate is set rotating at a moderate speed, and while it is moving, an electrified body, such as a piece of ebonite excited by friction, or the cover of an electrophorus, is brought near to, or into contact with, one of the paper armatures. Both the papers then rapidly become strongly charged with opposite kinds of electricity, and if the knobs, *r r'*, of the discharging rods are separated to a short distance, a stream of sparks is seen to pass between them. These sparks become less frequent, but larger and brighter, if each of the conductors is connected with the inside coating of an uninsulated Leyden jar. The sparks also increase in size, but diminish in frequency, when the discharging knobs are moved farther apart, but if the distance between them is made greater than a certain limit, depending chiefly upon the insulation of the different parts of the machine, the sparks cease to pass altogether, and, unless the knobs are quickly brought nearer to each other, the machine soon ceases to act.

For further information as to the action of the machine, and for an explanation of the principles which govern its construction, we must refer our readers to the book itself, which assuredly deserves a place in every public library and chemist's laboratory in the kingdom.

OUR FOOD SUPPLY.

THE Rev. Henry Moule, writing from Fordington Vicarage on the inadequacy of the food supply of this country, comes to the following conclusions:—Let farmers, whatever be the extent of their holdings, make a more provident use of straw, and of stalks of almost every kind, for food for cattle and sheep. Let them make a more provident use of their pastures. Full two-thirds of the pasture of most inclosed fields in the ordinary mode of grazing are wasted. Let far the larger proportion of cattle be fed in stalls, and in that proportion would this waste be prevented, and economy of straw, &c., be promoted. With the abundance of food thus provided there would soon be an end put to the wasteful slaughter of calves and lambs; and by this means alone the stock of a farm would soon be increased. But beyond this, if the manure of the stalls be carefully preserved, and treated in the way in which I propose to treat the refuse of towns, and of which I gave a general idea in the *Times* of December 3, 1871, then the corn produce and the live stock of our 47,000,000 acres might soon be doubled. For, with a due supply of dry earth to the stall and the proper admixture of other substances with this earth, a single cow will produce 12 tons of manure per annum, one, or at the most, two of which shall very largely increase the produce of an acre of pasture. On an ordinary farm two or even three acres are deemed requisite for one cow. If this stall feeding be practised, and the cows be properly tended, and the pasture duly manured, one acre will keep two cows; and, if the land be good, even three cows. The remaining 10 tons of manure from one cow might be applied with great advantage to 10 acres of land, drilled in with corn or the seed of roots. If so, then, together with a saving of nineteen-twentieths on the ordinary carriage of manure (which would of itself admit of a larger amount of human labour throughout the year), 10 cows, besides keeping up their own supply of food from three or four acres, would afford an annual supply of manure for 100 acres of corn or roots, the almost inevitable result of which would soon be the doubling of the live stock and a very large increase of the corn produce of the country. Much more than this, however, might be effected by calling in the aid of the working classes themselves.

PHOTOGRAPHY FOR THE UNINITIATED.*

(*Continued from p. 270, Vol. XIV.*)

A FRIEND said to me a day or two since, that my letters to you were all well enough in their way, but did not enter as fully into detail as the subject required. He stated that they were too general in their character, and had the appearance of passing too hastily over the subject. If such is the fact, then I have succeeded in doing just as I intended, so far as writing in a general rather than in an exhaustive style. To write exhaustingly would be to write a volume. That I never intended, as quantity to the uninitiated is rather more confusing than instructive. For detail and formulæ I refer to the most excellent works of Vogel and Lea. It may be well, however, to look over the letters which I have written, and upon a few points be a little more explicit, and also make some changes and additions.

In letter No. 4 (p. 34, Vol. XIV.) wherein I wrote as to the use of albumen as a substratum upon the plate, and recommended its flowing thereo

* From the *Photographic News*.

while still wet, I have to add as follows:—At a recent meeting of our photographic society, it was stated by Mr. Gardner, as the result of his experience, that if the plate was well rubbed with a piece of canton-flannel or Joseph paper dampened with a solution of alcohol slightly acidulated with acetic acid, that over this dried surface the albumen would flow as freely and as well as collodion. He strongly recommended the use of dilute albumen without the addition of ammonia. This plan presents advantages over the one directed in my letter above referred to, and is fully worth a careful trial. As yet, not having had an opportunity to test it, I cannot speak from personal knowledge as to its merits.

While considering the use of albumen, I may as well state that in my experience it materially "slows" (*i.e.*, lengthens) the time required for the exposure of both wet and dry plates; it decreases intensity in the dry and increases the same in the wet. At the same meeting above referred to, this subject was discussed, and Mr. Newton stated that if a small portion of alcohol was added to the dilute albumen in place of the ammonia the "slowing" effect would be overcome.

The troubles most often met with in out-door photography, in my experience, are those which I shall name in a general way, and suggest the most likely cause of such, so far as my practice and experience go.

Fogging.

This may arise from many causes. 1. From diffused light, either in the operating-room during the sensitising and developing processes, from some defect in the camera or plate-shield. 2. By use of a freshly-made sample of collodion. 3. By the bath lacking in acidity. 4. By the use of too little acid in the developer. These are but a few of the many possible causes, but the most probable.

As to the finish, I need only say, examine the room and articles referred to with great care. To make certain as to the room, go through all the operations of sensitising and developing a plate within the room; if it remains clear, next test your camera and shield, by proceeding the same as you would in full use thereof, except removing the caps from the lenses. If both of these stand the test, you may rest satisfied as to them. As to No. 2, add a trifle of an older and redder collodion to the new lot, until you have it a reddish-yellow tinge, or a drop or two of an alcoholic solution of iodine. If fog still continues, add acid to the bath, as directed to do when making it up, exercising even greater caution. Finally, try more acid in the developer, and be more cautious to wash the plate well before you leave your dark room for the purpose of "fixing." A fog from light is deep-seated and throughout the film; that from the collodion, bath, developer, and insufficient washing, is of a surface character, and can, when dry, be to some extent removed, and leaves below a polished silver surface not easily forgotten when once seen.

Stains and markings result most often in warm weather, from a too great delay in the various operations, especially in keeping a plate too long between the time of its removal from the nitrate bath and development, also from dipping before the film has properly set, from improperly dipping, from improperly draining the plate, from a wet and sloppy plate-shield, from shaking or reversing the plate or shield, scum upon the surface of the bath, &c.

Spots and Pinholes.

Oftener dust than anything else causes them; keep clean. Fixing solution allowed to fall upon the table or floor, becoming dry soon, raises a fine powder or dust, and spoils your work as fast as made; improperly filtered collodion, bath, and developer; sudden shutting of the slide of the plate-shield, dirty camera, and an old bath solution which requires to be overhauled—about which I shall write you some of these days.

Dirty fingers, wet with developing and fixing solutions, used when collodionising or sensitising, do not help matters.

Pressure in Steam Boilers.—The question as to whether the pressure in a steam boiler was equal or different at top and bottom, concerning which there seems to be some difference of opinion amongst engineers—though it is difficult, from the simplicity of the facts involved in considering the question, to see how a difference of opinion should exist—has nevertheless been experimentally determined by the Messrs. Hunter, at their establishment in Philadelphia. An elbow was attached to the end of the blow-off pipe which entered the mud-drum; into this a plug was screwed, and tapped to receive a ½in. pipe; to this a steam gauge was attached and the cock opened. On comparing the indications of the gauges attached at top of boiler and to the top of drum, as above described, it was found that the pressure was greatest at the bottom, by 1½lb., proving, as might readily have been predicted, that the pressure upon the bottom of a boiler is equal to the steam pressure indicated above, plus the weight of a water column equal in height to the difference in level between drum and surface of water in boiler, and in diameter to that acting on the gauge.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor of the ENGLISH MECHANIC, *31, Tavistock-street, Covent Garden, W.C.*

All Cheques and Post Office Orders to be made payable to J. PASSMORE EDWARDS.

"I would have every one write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

**** In order to facilitate reference, Correspondents when speaking of any Letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

CONTACT OF COMETS WITH THE EARTH.

[3916.]—THE certainty of "astronomical catastrophes" (as the *Spectator* euphemises falls of comets on our earth), both past and future—the former being a fundamental fact necessary to all true geology (as I showed "F. R. A. S." in your columns above three years ago)—depends on a vast mass of evidence of various kinds that may be divided into—1. The proofs of the average rate at which this planet is (so far as accessible statistics can show) encountering comets, *i.e.*, observe their ponderable matter or heads, not merely their showy and mysterious tails, which, being non-ponderant, there is no reason to suppose we should even be aware of passing through; and much evidence that we actually have passed through, as in the last day of June, 1861, without knowing it, and, probably, our ancestors in almost every age as unconsciously. Entering a ball of *ponderant matter* (which every comet's head demonstrably is, however many hundred or thousand times rarer than hydrogen, or than the best "vacuum" of our Geisler tubes) is a very different thing indeed, and yet a thing just as demonstrably happening to our earth from time to time, and therefore one that any *geology* must needs take note of—whatever the deluge of books of the kind "F. R. A. S." commends to my attention on p. 61 (which, with thanks to him, I have seen enough of, and which I cannot call anything but *Lyellology*) may do or leave undone. 2. The past duration of our planet as an *inhabited* one, whether by vegetables, animals, or men, is, of course, a point co-ordinate to this proof; because its age might be found such that there might be a probability of *no* comet having *yet*, since man's existence (or even since far earlier geological periods) met, overtaken, or fallen upon her. A comparison, however, of cometary statistics with the demonstrable past duration of animal life (which though not so great as most Lyellists fancy, is certainly more than a million years) leaves no chance of this time having elapsed without sundry and probably many cometfalls. In fact I shall show that (supposing there were no traces or no geological facts indicating their effects, or no effects but what might be explicable without them) it would not be open to a scientific theorist to assume there have been none. On the contrary, he would have to explain how it happened that such events had left no traces. It would be no more allowable for Scrope or Lyell to say, "perhaps in these 1,000,000 years no comet may have happened to fall," than to account for some peculiarity in the surface of an English building ten years old, by saying "perhaps it has never been wetted; this being a dry locality, there may not have happened any shower here during these ten years." Scrope, in the page to which "F.R.A.S." refers me (letter 3870—he names no page of the other books), harps upon what he thinks an "unlimited" allowance of time might do to certain strata; he insists on "incalculable duration," on "almost unlimited drafts upon antiquity," and a page later, breaks into this beautifully scientific style—

"Time! Time! Time!"

Yes, Mr. Scrope, don't you wish you may get it? Suppose time would give the effects you vainly attempt to explain (which it would not, and has *no tendency* towards), in order to get your "almost unlimited drafts," you have first to get millions of comets out of the skies! For in this actual universe and order of *known* nature, the *average* drafts afforded you between cometfall and cometfall are quite limited and quite calculable. All the Lyellology, to "a score of books", of which "F.R.A.S." would commend my attention, is the *mythical* geology of a *mythical* and unknown universe, one without comets! 3. But a third part of the evidence, that might or might not exist, is the presence of facts on earth not explicable but by cometfalls, or the last cometfall. Were there no such facts at all, this would nowise tend to alter the astronomical necessity that (in the time known to have elapsed) we must have picked up comets, or exonerate a science of geology from taking account of such necessity, and explaining how falls might take place and leave no effect but those seen. In fact, however, the globe is covered with millions of effects utterly inexplicable without a cometfall, and one almost datable to a century, certainly between forty-five and fifty-one centuries ago; and the attempt to geologise without this, and to account for extant phenomena by "causes now in action" alone, has been so resolutely and perseveringly made in this generation—we may say the life of Lyell from early manhood till now mainly given to this one attempt—that all time will really be indebted to him and his compeers for making it impossible to say this trial has not been fully made, fully exhausted, and the result utter and ridiculous failure. (*Vide*, "score of books" in question, and any valley on earth).

The multiplicity of evidence bearing on all these points is so great that in the *embarras de richesse* I should really scarce know where to begin best such information as "J. C." (p. 68) asks for; especially in fragments, the only way the ENGLISH MECHANIC could admit it, as any such fragment seen alone is sure to call up some grandiloquent "venture to hope," like that of "F. R. A. S." (p. 61, par. 3), from Lyellists, who little dream the ridiculous figures they and their "science" are infallibly doomed to cut in a few years more. As "J. C." is chiefly surprised at my looking on a general deluge as "one of the results" most certain to have accompanied each past cometfall, perhaps that is the point I had better first examine; leaving any calculation about the average frequency of falls, as he admits they "might be expected." But I shall have to be guided by the directions that his or other "surprises" and objections may take. Wherever they may lead I promise to follow, and to show that, in short, every kind of evidence that could be fancied on this point exists, and in abundance; and also much, I believe I shall show, that could not be fancied *à priori*. And there is no conflict of evidence. All is harmonious, and tells one tale. "F. R. A. S." is not going to have his wish to hear no more of a "quasi-mythical" deluge, I can assure him. The geologers have had "a chiel amang ye takin' notes," and from him or others, a good deal about the "*quasi-mythical*" they are not going to hear the end of. They are now in a trap much easier to get into than out of, and with some nuts to crack that I have often warned them to beware they did not break their teeth on.

E. L. G.

THE METROPOLITAN CRATER OF THE MOON —LUNAR MAPS—CATALOGUES, &c.

[3917.]—MR. BIRT says (let. 3606) that he failed to find, either in a certain unpublished map that lay before him, or in Schmidt's "Rillen auf dem Monde," any appearance of a cleft figured in M. Gaudibert's sketch of Tycho (let. 3485). Regarding its absence from the Rillen it may be inferred that Schmidt did not look on it as a rill properly so called; and, certainly, it appears to me as no other than one of those clefts that separate the terraces of crater ramparts. In some instances the clefts, after running a certain distance in a more or less rough, and often interrupted, parallelism with the contour of the exterior ridge, are seen to strike across the latter, forming a gap, as M. Gaudibert shows in the wall of Tycho, and as may also be well observed in the not distant crater of Bullialdus. The cleft, or ravine, found by M. Gaudibert outside Tycho, certainly runs from the south-west in the direction of the gap, but I could not say from my own observations that it forms a part of the same formation. I have often noticed a cleft longitudinally splitting the exterior south-western slope of Plato, and reaching with its northern end the summit of the wall. It is very well defined, and is, I should say, quite as striking a feature as the cleft in Tycho, but still I never looked on it as anything more than a chasm between terraces] formed, perhaps, by a landslip.

We must all heartily concur in the tribute paid by Mr. Birt to M. Gaudibert's interesting communications that appear in the ENGLISH MECHANIC, and we must also see the force of Mr. Birt's remarks relative to a catalogue of lunar objects. The chief point now sought to be discovered in lunar science relates to evidences of topographical change which would prove the continued action of the forces from which the aspect of the moon has been derived, and for this purpose catalogues and maps of the most comprehensive possible character are required. All observations up to the present seem to show that no recent indication of those forces operating on a large scale is to be expected, and that there is little use in seeking for new formations except in a locality of which every visible feature, even to the smallest, is correctly mapped and catalogued. Any one who has examined those catalogues and sections of his great map which Mr. Birt has, up to this time, been enabled to publish, must see that it is by such aid as they afford, that we can hope to detect with any certainty a new feature appearing on the moon's surface.

Another great map—the result of thirty-two years' labour—has been completed by Dr. Schmidt, of Athens, but it is, unfortunately, not as yet given to the public. With a diameter of six French feet—double that of Beer and Mädler's—it is executed in a style that makes it what may be called a panoramic view as well as a map, while it exhibits a wealth of detail that looks perfectly astounding in the work of a single observer.

Birt's far larger map, on a scale that will give it a diameter of no less than 16ft. 8in., is constructed on quite a different plan, showing the features only in outline, so that additions can be conveniently drawn on it if necessary. Besides references to previou[s] authorities, and the names and synonyms of [the] principal objects, it gives several measurements [in feet] and metres, with statements and symbols d[...] of character and hypsometrical relations; everything is marked with a number of [...] full description is found in the catalogue.

It cannot be too deeply regretted that of these two great works, one (Birt's) has only a small portion finished, and the other, though complete, is not likely to be published for a considerable period. The difference of design in their construction prevents all rivalry between them, and the time may be expected when both will be considered indispensable to the student of lunar physics. J. Birmingham.

ATMOSPHERIC DUST.

[3918.]—I am glad to find that M. Paris wears his scientific creeds loosely, for there is hope, under these circumstances, that he will recant those most heretical opinions expressed in let. 3887, p. 66. Surely the doctrines that "putrefying bodies are not to be dreaded, but living matter," and that "fresh sewage is far more dangerous than old," were enunciated without receiving much consideration from our friend. The first statement appears to me to be a contradiction in terms, for it is when bodies are putrefying that living matter predominates. Life out of death is true of everything in a state of nature; for though a dead body may not be the cause of the life—may not generate it—it is undoubtedly the source of its development. Kill a bullock and leave its carcase in a field: it will putrefy, and become the habitation of innumerable living things, apparently generated by it, but certainly developed and nourished by it. Some of these living things we see with the naked eye, and it is only reasonable to suppose there may be others we do not see. Whether this life is spontaneously generated by the dead carcase is immaterial to the point; if the dead matter had not been there the life would not have made itself apparent, even if it had existed as a germ, and certainly not if spontaneously generated. So, if the carcase had been utilised before putrefaction set in, no dangerous living matter would have been developed. The same argument applies to fresh sewage. What is there—what can there be—in *fresh* sewage to give rise to the microzymes (?) of contagion? it is only where we allow the sewage to putrefy that it becomes so rich a field for the development (or it may be generation) of living germs. True, we want a disinfectant to kill the living germs, but failing that, it would, I think, be advisable to do what we can to prevent putrefaction, or at all events to remove the putrefying body to a safe distance.

But where does M. Paris imagine that living germs have their origin? If they are originated by the ordinary process of reproduction, the parent germ must have conditions suitable for its multiplication; if it cannot obtain these it will, in the ordinary course of things, die and leave its place unfilled. A thistle seed in a farmer's writing-desk is powerless for good or evil so long as it remains there; but let the farmer drop it in one of his fields and allow it to grow unheeded, and it will remind him in after years of his carelessness. Just so with "living germs": while few in number, and separated from their food-matter, they are harmless or nearly so; but give them the opportunity of multiplying in "putrefying" matter and they then spread contagion all around.

Medical men are divided in opinion on what is known as the germ theory of disease—some agreeing with Professor Tyndall, others considering that disease is produced by the action of dead or dying matter upon living tissue; but I never yet read or heard of any scientific man who could venture to assert that putrefying bodies and festering sewage were not dangerous.

Dr. R. D. Thomson (letter 3887) appears to think that "gases" are the cause of disease; but what gas known to the chemist has ever afforded the slightest suspicion of being the actual "fermenting poison" of zymotic epidemics? Still, M. Paris must acknowledge that the activity of the living germs may be largely increased when surrounded by "putrefaction gases." The lungs, no doubt, are able to throw off a large proportion of the germs and dust which reach them, but that some of the latter is retained we know, and there is every reason to believe that the poison of typhus, variola, and other diseases, whose course the skill of the physician is utterly powerless to stop, is conveyed into the system in this manner, as well as in the food we eat and drink.

Let us, then, prevent putrefaction of dangerous matter, and remove also those conditions which appear congenial to the development of unhealthy fungus life. Decaying matter is doubtless only elements "out of place;" but while they are trying to lift themselves into more respectable positions, they are helping to create fresh supplies of the very matter in which they are so unpleasantly mixed.

It just occurs to me that the blow-fly, with a natural instinct, always deposits its eggs on those parts of a carcase where putrefaction commences earliest; and an accidental cut made in the surgeon's finger while dissecting a "subject" is often attended with fatal results, which never accrue when more extensive wounds are made in operating on the living body.

Saul Rymea.

ALLINGHAM'S PROPELLER.

[3919.]—Unfortunately for Mr. Allingham, his very feasible invention (as shown on p. 39) is, slightly altered, very old. The old form was a framework fixed to each side of the ship, and propulsion was effected by rolling instead of pitching, with similar venetians. It is, perhaps, not necessary to inform the inventor that an unmasted ship rolls (from side to side) more than she pitches in a seaway.

He will find the ship scarcely moves with the most carefully arranged machinery, this being, perhaps, one of the most ineffectual arrangements of utilising the motion of the waves for propulsion.

Cleethorpes. Amos Applevard.

CONCRETE BUILDINGS.

[3920.]—I had intended, with your permission, to have inflicted on your readers, in answer to query 11249, a history of my experiments in concrete during the last two years, but want of time has prevented me. I will, however, when I have finished what I am now doing in concrete—which will involve not less than one hundred thousand cubic feet of work—give you in detail my failures and my successes. The former are numerous. I will back up "F. P." in his advice in telling an intending builder in concrete to visit works that have been executed before he goes to the expense of a single bushel of cement. If your correspondent has the determination to stand over the work, to see all done, and not leave it either to his foreman, carpenter, or labourers, nor yet to a contractor, he will not regret substituting concrete for either brick or stone, either on the score of economy, strength, durability, or freedom from damp. Close attention is required from the beginning to the end. Without close attention your correspondent had better use bricks and mortar. On the score of economy he must not be led away by the flaming accounts of the cement doctors. I have before me an account in which an equal number of yards of cement, sand, gravel, and broken stone are made to produce an equal number of yards in work. My experience has shown me that under no circumstances could I get more than 60ft. to 66ft. in the solid out of the 100ft. of material measured in—even in the case of walls. For roofing, which requires very hard beating, 7·28ft. of cement and gravel produced only 3·34ft. in the solid. A cubic foot of gravel and sand containing stones not larger than would pass through a 1½ inch screen would weigh about 84 or 85lb.; a block of pure flint would weigh about double that per cubic foot; the interstices must be filled partially or entirely with cement and sand, or air, or both. To make the calculation as to the comparative economy of concrete and brickwork—a rod of brickwork will take about 4,500 bricks, 26ft. of stone, or 86ft. of chalk, lime, and 70ft. to 75ft. of sand. Three hundred and six feet of concrete, in proportions of one in ten—*i.e.*, 9 parts gravel 1 part cement,—will require about 410ft. of gravel and sand and 46ft. of cement. As to labour, I believe the usual calculation for ordinary brickwork in walls not less than 9in. thick per rod is 3½ days of a bricklayer and labourer. In cement I have found that it takes six labourers, two stout lads, and a carpenter, to keep frames going to mix and fill about 240 cubic feet per day in walling. The labour bill for concrete is higher than that of brickwork. The economy will depend on cost of cement and aggregates. Mr. Tall puts his labour at 2s. per yard, and 6d. per yard for the carpenter; in other words, $1\frac{3}{27}$d. per foot. From the above your correspondent can make his calculations as to cost.

Quality of Cement.—Your Portland cement should weigh 112lb. per bushel; the heavier the cement—provided it is passed through not less than forty-gauge sieve, or 1600 holes to the inch—the better. The heavier the cement the slower it sets, and the harder it is when set.

Gravel.—The real economy of concrete depends upon the quality and cost at which sand, gravel, and other aggregates can be produced. I have lately taken to washing my gravel—I only regret I did not do it from the first; the slightest quantity of loam destroys the effect of a large quantity of cement. If neither gravel nor sand is procurable in the neighbourhood burnt clay ballast makes excellent concrete—in fact, better than sand and gravel.

Mixing.—The cement, gravel, and sand should be turned over no less than five times—three times dry and twice wet. By turning over I do not mean simply chucking a shovelful from one side of the mixing board to the other, but turning clean over a half shovelful at a time, so that cement, sand, and stones are all intimately mixed.

Water.—The quantity of this depends much on the state of your gravel and sand. In no case should it be more moist than moist brown sugar; on this you will have a battle long and fierce with your workmen. Do not give in. The drier the concrete is put in the firmer it sets.

Filling in Frames.—I again say put in as dry as you can, and ram as hard as you can, and do not fill oftener than twice a week or five times a fortnight. The fever speed of filling upon filling is utterly destructive of good work. One cement doctor recommends his framing as superior to that of a rival by reason of his being able to fill twenty-four inches at a time as against that of his rival, who can only fill eighteen inches. Eschew as you would poison the filling your cement out of buckets. The use of buckets induces the workmen to mix the concrete with far too much water. Fill from the barrow in small shovelfuls, and let the shoveller take his time. This will secure more ramming from the man inside the frame. To the height of twenty feet run your cement on planks and stage; above that height set up a horse run.

As to the frames to be used, you can hire or buy either Tall's or Drake's. If you have any ingenuity you can construct your own. The expense of framing is the great drawback. If you are going to build only one house, *hire*; if you are going to build several, and are not in a hurry, *buy*, or make for yourself. I am afraid I have gone into this at greater length than fair play to other contributors will justify. If your correspondent requires more information, a letter addressed to "P. T. A.," Post-office, Southampton, containing real name and address, will be answered by

Khoda Bux.

SCIENTIFIC NOMENCLATURE.

[3921.]—"L. C. E." (let. 3884, p. 66) must have a marvellous faculty for discovering likenesses, if he discovers so strong a resemblance between the old alchemists jargon of names and those bestowed by modern chemistry. The old names were absolutely arbitrary and meaningless, with the exception of some very few classes, such as the "vitriols," which did recognise a connection between the substances thus named; many of the names were even intended to conceal the substance they indicated from all but advanced adepts. Modern chemistry, on the other hand, gives names intended to exactly describe the constitution of the substance; this certainly results in some considerable confusion at present, but only because the rapid growth of knowledge shows that many names thus given (and given correctly in the then state of knowledge) are not sufficiently correct.

The polysyllabic names of organic compounds are thus attained—for instance, "L. C. E." may consider that such a name as phenyldibenzamide is a grammatical barbarism fit to be compared as mere jargon with the "white blood of the green dragon;" but this latter name has no meaning whatever, it may possibly indicate that in a given experiment a white precipitate forms in a green solution, or some such reaction, but phenyldibenzamide describes the exact substance; it tells us that it is an ammonia, the three hydrogen atoms of which have been substituted by 1 atom of phenyl and 2 of benzoyl:—

$$\left.\begin{matrix} C_6H_5 \\ C_7H_5O \\ C_7H_5O \end{matrix}\right\} N$$

It is true this is "intelligible only to the initiated," but this is so with all knowledge; it is absolutely impossible to make astronomy or chemistry intelligible to an ignorant country bumpkin, and just as those who wish to read the classics must learn their languages, so any one who wishes to comprehend a science must do so by long sustained effort and labour. Science is organised for its students—the initiated—not for mere lookers on. "L. C. E." illustrates this by his examples, he prefers chloride of platinum to platinic chloride, and seems to suppose the latter, which he calls a grammatical barbarism, is adopted only because it is a syllable shorter. Not so: chloride of platinum is incorrect because vague, for there are two chlorides, and the terminals ic and ous distinguish them; better names might be, and, doubtless will be, devised, when chemical theory is better defined, but they serve during the present transition state of the science. Zincic chloride, on the other hand, is erroneous and very few chemists would use it, because there is only one known chloride, and its proper name is, therefore, zinc chloride, $ZnCl_2$.

Electrical terms are very much misunderstood by "L. C. E." It is only since some ten years or so that the idea of exactly measuring electricity and its effects has been thoroughly developed; units for the purpose being devised they required names, and the committee of the British Association adopted Clarke's suggestion, and gave to these units the names of distinguished electricians, and hence we have the Volt, the Ohm, the Veber, the Farad. These names, therefore, are given by the highest possible authority—that, namely, which devised the measures they now indicate, and, so far from being introduced by me in my papers as novelties, as "L. C. E." supposes, they are the established terms used by all electricians. Of course, they are known only to the initiated, because to them only has the idea of definitely measuring electricity become a thing of reality. One name alone have I on my own authority employed, as it was not only my right, but my necessity to do. I used the term equivolt because I for the first time introduced the idea of a definite electric measure, connecting the other measures with what Faraday called the equivalent of electricity, and thus combined the hitherto distinct ideas of "tension" and "quantity" in one unit; this, of course, needed a name, and following scientific precedent, I gave it one which describes its value—viz., a volt of electric tension acting through a chemical equivalent in grains—hence the term equivolt.

The four last paragraphs of "L. C. E.'s" letter must really be read in the light of the preceding one. Many scientific disputes may be valueless, very many may seem so to those who have no comprehension of their meaning. It is easy to sneer at the "hours spent over infinitesimal markings on the Diatomaceæ or the specks in a tadpole's tail." Some day the latter may suddenly throw light upon some obscure problems in the mystery of life; but suppose they never give us one particle of knowledge, are we to count for nothing the training in habits of exact observation, of rigidly minute recording of facts? Is it nothing that for these studies, worthless it may be in themselves, men are earnestly giving themselves to the improvement of instruments of priceless value for other and most momentous purposes?

May not the true lesson be, not that Secchi's observations on the sun flames are worthless, because "no one dreams of classifying the flames that flicker in our grates," but that some one may yet study these latter flames and read therein some of the secrets of the universe?

What use is it? Oh! despicable formula, beloved by the "practical" man. Where would the world be if there was no nobler spirit than this? if men of science were not ever ready to give their time, their lives, for things of—no use? Cancer is not checked, tubercle had not been arrested; therefore, ye delvers in the mines of science, break up your tools—seek no farther. What use is it? Does the tin or coal miner act thus? Is he content to give up his [illegible] after digging for a few feet?

In 1819 Oersted discovered that a magnetic needle moved when an electric current passed in its neighbourhood. Poor fellow, what waste of time. Why did he not dig potatoes? that would have been useful. Ampère, Faraday, and a lot of other foolish people played for years with a lot of wires and steel needles, and philosophical instrument-makers made complicated toys (they, however, were useful, of course, because they were for sale). In 1845 Wheatstone patented his telegraphic instrument—26 years, O "L. C. E."! during which you would have said, "Has any practical result followed?" "Some trifling knowledge may have been gained." But now, ask the shareholders in submarine cable companies. Ah! the most "practical" men now can see what use it is, but between 1819 and 1845 how grand their contempt for the poor triflers of philosophers!

There is no knowledge of which we can say it is of no use: the most insignificant things in appearance may prove to be guides to priceless truths. The man who asks of his studies the question "what use is it?" will never pass beyond mediocrity, will never feel his heart thrill with that glowing energy, that delight in truth for truth's own sake, which is the reward of the true scientific man, who finds in his studies themselves their own exceeding great reward. SIGMA.

LIGHTNING CONDUCTORS, LIMITS OF RESISTANCE IN TELEGRAPH WIRES, &c.

[8922.]—(8846.)—IN reference to the destructive force of a flash of lightning when impeded in its progress by non-conductors, if we may place any reliance upon the researches of competent authorities, we shall not have to fall back upon any recondite hypotheses, such as the instantaneous formation of steam, nor the unknown or at least ill-understood repulsive action, in order to account for any phenomena fairly attributable to this cause. Mr. R. Hunt, in his paper read before the Institute of Civil Engineers so far back as 1857, stated (and I have never seen nor heard of his statement being challenged) that "the mechanical effect of a flash of lightning was analysed, and it was shown that the power developed through 50ft. was = 12,220 horse-power and that the initial explosive force was equal to a pressure of 300,000,000 tons! Surely there is force sufficient here to account for any of the pranks played by intercepted discharges; may I add that the presence of water would be more likely to increase the conductivity of the structure, and hence lessen the danger, than to form steam and thereby increase it?

(11301.)—LIMITS OF RESISTANCE IN TELEGRAPH WIRES.—Our friend "Sigma," in replying to this query (p. 48), has omitted to state that the 7·8 Ohms refer to No. 4 iron wire, and I think it may be taken for granted that Clarke's experiments were confined exclusively to galvanised wire. Wherever Mr. C. W. Henwood got the figures from which he has given in the reply preceding "Sigma's" I cannot conceive, especially as having reference to the question as originally put. Who, in the name of all that is wonderful, ever uses No. 19 much less No. 24 wire gauge copper wire for "ordinary overhead telegraph wire"? But granting that any one should be so insane as to try to use such line wires, where, when, or how did Professor Stokes get the million and a half Ohm resistance per mile from with a copper conductor?

(11359.)—CASTING BRASS SOLID.—The chief fault lies in not giving sufficient ventilation in the top box for the escape of gases and steam generated in the process of solidification, and, above all, the allowance of sufficient git or head of metal to supply the contraction due to the casting, while cooling a good git is little if any loss of metal, and almost invariably insures sound castings. Mr. Allan's mixture for bearings, well tested under severe trials, is—copper 16, tin 3, zinc ½. The temperature must be determined by experience alone. All alloys are difficult to manage in casting in consequence of the difference of affinity between their components and the oxygen of the atmosphere at the high temperature to which they must of necessity be raised in order to run them into moulds; this inevitable evil must be conquered as much as possible by excluding the air during the mixing of the ingredients, and by expertness in pouring, two necessities only to be obtained by constant care and practice.

(11370.)—ELECTRICAL.—I know of no hypothesis by which such a phenomenon can be accounted for, other than that the delicate nerves of the moistened tongue offer less internal resistance in the couple than the cloth, which in the case assumed, forms the remaining part of the internal resistance of the cell. In this case part of the current will flow through the tongue, and give evidence of its existence, and part—but probably (according to circumstances)—will pass through the cloth. In order to test this thoroughly allow me to suggest an exhaustive experiment. Let "H. D. B." drink (say) three glasses of what is sold in London under the name of Scotch whiskey, and while doing so smoke as many "sensation cigars" at one penny each, and having previously arranged the cell he describes, retire to rest (if he can rest at all after such an ordeal); the next morning immediately upon waking apply the terminals to his tongue, and favour us with his experience of the sensation he feels of electricity passing through what a recent writer calls "the rubicund engine of expression." My impression is that would be nil, but the experiment is worth a trial by earnest student. In either case there would, of se, be no poles, as the whole would form a closed it, but the current would flow in the same direction every other dynamic combination.

(11391.)—INSULATING COIL.—It is not absolutely necessary to insulate the secondary from the primary by ebonite, but when setting out to make an expensive machine, it is wise to use every precaution to avoid failure, and this is one of those precautions. I have a bad memory of names, especially of those I do not think it worth while remembering, but I do remember that some short time ago an attempt was made to "haul me over the coals," because I insisted upon this very point. The success of the projected keel-hauling I, sir, must leave in the hands of your "Constant Readers," contenting myself with the expression of opinion I then gave, that any induction coil intended for the exhibition of effects, wherein electricity of high tension was to be obtained between the terminals of the poles of the secondary coil, should be so constructed as to have a full and perfect insulation between the secondary coil and primary coils. The ground assumed by my opponent was that in the three coils forming the primary the tension never rose so high as to require the interposition of special insulation, but he forgot, as I find many of your readers do, the object of the generation of this current of large volume at low tension—viz., the setting up in the secondary of a static charge of extremely high tension, but small quantity (intensity of current), which charge would please itself whether it would overcome the resistance of atmospheric air placed between the terminals of the secondary, and so exhibit the 2in. 3in., &c., arc of flame or, finding a better conductor internally, flash back through the protective insulating medium with a large metallic mass, invitingly opened before it, and restore equilibrium through the shortest and most tempting track, leaving the intervening insulation, and, consequently, the coil itself, a perfect wreck. With such a coil, however, as that indicated by H. Corbett, no such extreme precautions are necessary. A sound coating of sealing wax, varnished, or at most two turns of brown paper saturated with paraffin, would be ample, but as for the length of spark obtainable, that is a matter that, I believe, cannot as yet be predicated, it must be discovered by the stern hand of experience alone. One thing is very certain, if he immerses the terminals of his secondary in the Thames there will be no necessity for calling in the aid of the floating fire-engines.

(11401.)—ELECTRICAL FORMULA.—When I first glanced over this query I gave vent to a mental exclamation "Go to Bath," for "Bladud" was vividly impressed upon my memory, but upon more mature consideration a Pickwickian softness fell upon my spirits, and I resolved to ask the Prince, What are the particular formulæ that give you pain? I have read Culley (1863 edition) earnestly and thoughtfully, and except a few minor trifles (light as air) which have been all or nearly all corrected in a later edition which I have read, but unfortunately do not possess, if ever there was a science reduced to practice in one volume that science is electricity, and Culley is the author. In speaking thus emphatically, sir, let me be thoroughly understood. I know as much personally of Mr. Culley as I do of the individuals whose duty it is to trap bears and utilise their grease for lubricating the northern or southern poles, and I think my name will clear me from any suspicion of trying to thrust a contraband advertisement upon you when I say that the work referred to is the most ample yet succinct, most elaborate yet simple treatise ever yet offered, not merely to the British public, but to the telegraphic world. If, therefore, Prince "Bladud" finds any difficulty in comprehending any of the formulæ it contains, let him at once engage a master to teach him the first four rules of arithmetic, and assist him to a slight knowledge of their application, and all will go well; but if in the mean time he has any particular difficulty to contend against (*bonâ fide*, mind, or I shall bowl him out) I shall most willingly render him all the assistance in my power when he tells us where his ailing lies.

(11405.)—PURIFYING ZINC WIRE.—John S. Darton has surely made a mistake. Zinc wire in any condition is surely not used for the construction of a battery; true, it is made, as Pulvermacher's old form of chains attest, but I have never been able to obtain it in London; but even if procurable for battery purposes, I for one am at a loss to know what "J. S. D." means by purifying. Zinc can easily be amalgamated by combination with mercury, but it is thereby adulterated, not purified. Will "J. S. D." kindly say what he really does mean?

(11406.)—STEAM PUMP.—Try one of Wilson and Co.'s "persuaders"—vulgo, donkey pumps: manufactory, Wandsworth-road, London, S.W. They will fetch "spirits from the vasty deep," and water is sure to follow. WM. TONKES.

LIGHTNING CONDUCTORS.

[8928.]—THERE is considerable interest in the several details given by "J. K. P." (let. 8908, p. 69), of the destruction of the church steeple at King's Norton. The partial conduction by the pendulum of the clock, and the splitting of the stones, evidently in the partial lines of conduction formed by the copper dowels, are good illustration of the law of least resistance, like the fact that the lightning will find its way into a building in order to follow the path provided by gas and water-pipes. All this shows th great importance of connecting by good cond every metallic portion of buildings. In churche large factories perfect safety might be obtai carefully guarding the elevated parts, steeple neys, &c., above the roof level, connecting t gutters, &c., and then leading good conductors the gas-fittings. I do not mean that the reg ductor should not be led to the earth; but that the chief discharge would be quietly led through these very paths which usually constitute a source of danger by inducing the electricity to force through obstacles, such as walls, to reach them.

As to some of "J. K. P.'s" questions, he appears to have overlooked a letter of mine as to surface action. Surface relates only to static electricity: it collects upon them in readiness for discharge; this is the condition of the clouds and the earth in a thunder-storm, these surfaces being in opposite electrical conditions. When the discharge occurs, the electricity (so-called) becomes dynamic, and conduction takes place on the laws of resistance; a wire would be as good (nay better) as the same metal beaten out into foil.

I certainly shall not tell "J. K. P." that "electricity is a fluid, and does the work of a solid," because it is pretty well known by this time that I do not believe in the existence of any such thing as electricity at all, regarding the effects we class under that name as due simply to "a mode of motion," a development of energy among the molecules of matter, which, when the rate of motion exceeds the measure of the cohesive forces of matter, breaks the matter up. It is the enormous tension put upon the lines of conduction which renders lightning so destructive, because it concentrates an enormous amount of energy upon the resistance to be overcome. The conductor, by reducing the resistance, allows the energy to be exerted in developing a rapid but harmless current, and in heat spread through a large mass of earth. SIGMA.

[8924.]—IN answer to "J. G." (p. 39), absolute contact of the metal of lightning conductors, though desirable, is not essential to their success; for electricity of high tension will pass from one conductor to another near it, though not in contact; the only danger is lest it should pass through some part of the building it may damage, but this is unlikely if the break of metallic connection be small, and the contact with the ground good. Nothing can be better than contact with a water or gas main; if that be not within reach, "J. G." should carry his down-pipes so as to reach soil which is always damp.

I think it would be prudent to see that the eave gutters are in contact with the down-pipes, and in connection with the ridges, and it would be well to connect the chimney conductor directly with the down-pipes by copper wire rope (which will not easily rust away), as well as with the roof ridge and gutters.

The more completely all the metal is connected the better. PHILO.

CIRCULAR SAW-SPINDLE.

[8925.]—I DON'T know how many years old the patent of the saw spindle shown on p. 13 may be; but I know I designed years ago—and have made and used—an exactly similar device. And probably, as in other cases, many others have long used it also. HEWETT.

THE SOPER RIFLE.

[8926.]—FOR some time past I have been compelled to forego all writing; however, this morning the restriction was taken away, and I hasten to say a word to two gentlemen who have had the kindness to misread my last letter upon the Soper Rifle. In our experiments in January our sole aim was to find the weakest place in the weapon. The question was, will the breech stand a greater strain than the barrel, or *vice versâ*? The result of our experiments was to blow the breech to pieces, the barrel remaining intact, without the slightest injury. I then stated that I believed no gun had withstood a similar strain, but that in all other cases the breech mechanism had been rendered useless by a slighter strain. I had no idea, and can scarcely conceive of my letter conveying the idea, that my remarks would be taken as referring to the strength of the barrel. The gun depends upon its weakest part —will that part bear all ordinary and a great marginal strain? if so, the gun is strong enough for military purposes.

I would humbly suggest that any gentleman who desires to make remarks upon any subject should at least read the letters treating the subject before taking up your space. C. H. W. B.

WARMING AND VENTILATING.

[8927.]—THE novelty of "Lewis's patent warm air-chamber fireplace" described by "An Architect," at p. 40, is by no means evident to me. I presume it has some peculiarity in its design, for its principle is too old to be a legally protected monopoly. Neither is the advantage evident, of confining air in a chamber, if that to be warmed is taken "from and returned into the hall," as stated. The only apparent advantage of confining air to be warmed being that fresh air warmed, if confined in a channel, is forced into the dwelling, so as to diminish, and if in sufficient quantity prevent, all cold air draught

"An Architec warm-air chamber raised 9 cubic from 85° to 180° or ed 10° in tem- important better if, all en- ately. and pen

INFLUENCE OF COLD ON VEGETABLE GRAINS.

[3928.]—M. Duclaux, who formerly experimented on the effects of the cold on the eggs of the silkworm, and found that the winter cold was a necessary condition of their hatching, has communicated to the Académie des Sciences a note on vegetable grains as influenced by cold. Some grains, falling, when ripe, into the ground, pass the last months of heat in the year without germinating, and it is not till spring that they show signs of life. Such are the grains of Belle-de-Nuit (*Mirabilis jalapa*) and of Volubilis (*Ipomœa purpurea*). M. Duclaux experimented with grains of these plants, on account of the similarity in their evolution to that of the eggs of the silkworm. Having taken them immediately on ripening, and before they were exposed in cold nights, he divided them into three lots. One was kept in a chamber heated constantly to about 15°. The two others were exposed (one for a month, the other for two months) in a glacier, with a surrounding atmosphere of 3°. On the 10th of November he sowed grains from each of these lots in pots, which were then placed side by side in a heated chamber. Germination commenced on the 25th of January, and after the 15th of February it appeared to cease. The following was the result:—

Belle-de-Nuit (6 grains in each pot): Grains exposed to cold 2 months, 5 grains had germinated; grains exposed to cold 1 month, 3 grains had germinated; grains not exposed to cold, 0 grains had germinated.

Volubilis (12 grains in each pot): Grains exposed to cold 2 months, 0 grains had germinated; grains exposed to cold 1 month, 2 grains had germinated; grains not exposed to cold, 0 grains had germinated.

The cold of winter has, therefore, a real influence on the germination of these grains, and this influence is operative in certain cases, just as on the eggs of the silkworm. But, M. Duclaux asks, is it equally necessary? He thinks not: for grains that have been kept all winter in a heated chamber germinate none the less in their season when they have been sown at a proper time, and everything takes place as if what they specially needed was a variation of temperature, which might be either that of zero from the ordinary temperature, or this latter from the usual heat of the days of spring. He proposes to investigate further the fact that in such conditions they germinate with different degrees of activity. If, in fine, there be grains, which, like the silkworm's eggs, need to pass the winter before opening, there are others which germinate immediately after having become ripe, and when placed under favourable conditions. Most grains, indeed, are capable of this; but the discovered influence of the winter's cold on some is a presumption that the others do not entirely escape it. A. B. M.

"PHILO'S" HUNDREDWEIGHT THEORY.

[3929.]—In refutation of this theory of the origin of the 112lb. (p. 663) I gave "Philo" (p. 36) six other numbers each equally the sum of only seven that would make up every multiple of the lowest, not exceeding their total. But he will find this equally possible with any total below 128, the seventh power of 2. And similarly his pedlar could make six weights serve for all the units under 2^6, and n weight for all those under 2^n. If, however, he notes that the seven making the 112 are each an aliquot part thereof, this property, I grant, is less common. Still, it is shared by 96 and 120, the latter a more convenient unit than 112. To have this advantage a number only needs to be the difference of two powers of 2 (say, $2^a - 2^b$) such that b is less than $a-1$, but not less than $\frac{1}{2}(a-1)$. Thus, any of the following series (continually doubled) can be weighed, like the 112, with aliquot parts only:—

6, 12, 24, 48, 96, 192, 384, &c.
28, 56, 112, 224, 448, 896, &c.
120, 240, 480, 960, 1920, &c.
496, 992, 1984, 3968, &c.
2016, 4032, 8064, &c.

Because the $6 = 2^3 - 2$, the $28 = 2^5 - 2^2$, the $120 = 2^7 - 2^3$, the $496 = 2^9 - 2^4$, &c. And their doubles are $2^4 - 2^2$, and $2^6 - 2^3$, &c. E. L. G.

A SUGGESTION FOR THE POSTAL AUTHORITIES.

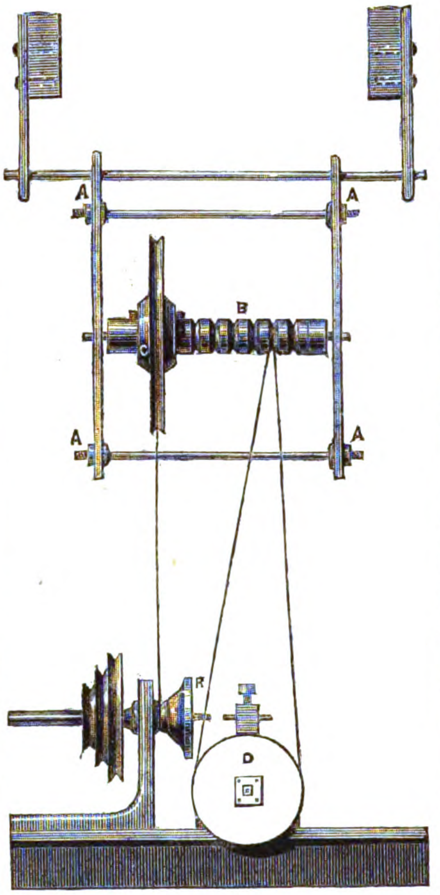
[3930.]—Having frequently observed in the country lines of telegraph poles along roads which, with their tributaries, are quite unprovided with direction posts, it occurs to one that (pending the time when the Post Office or some other government body undertakes the supply in a complete way of these useful guides) Mr. Scudamore might well give a general direction, that in future lines, and in cases of renewal, the poles should always be so arranged as to bring one at each junction and at cross roads. Could there be any objection to such an arrangement, and to allowing the parishes to encircle such posts (to avoid morticing and so weakening the posts) with stout iron bands, or tubes, constructed with three or more sockets to receive the direction boards?

These boards, fastened into the sockets with brass screws, could readily be removed for that re-lettering which Devonshire direction posts, at least, proverbially lack. Jannifred.

[We have had little opportunity of judging the dispositions of those who manage the telegraphic department of the postal service, but if they at all resemble their brethren who control the newspaper post, we fear any *useful* suggestion is likely to meet with but a cold reception.—Ed.]

SPIRAL GRAILING.

[3931.]—I was much interested in the article (p. 34, No. 366) on the subject of "Spiral Grailing." It is now over twenty-five years since I commenced in a small and simple way as an amateur turner, dabbling a little in ornamental work as well, and I very soon found, as "G. C. C." states, how difficult, not to say almost impossible, it was to "grail," or "line"—as I have been accustomed to hear it called—the surface of my work evenly, in concentric circles by hand, and I came to the conclusion that to effect the object satisfactorily, the operation must be self-acting, and if so it must be by making one continuous spiral cut from circumference to centre; and the cut being so very fine and close (almost invisible to the naked eye) I did not see that it could make any difference in the effect, whether it was concentric or spiral. I therefore set to work (more than twenty years ago) to construct a very simple and inexpensive apparatus, which I found to answer the purpose admirably, and, from its working independently of the overhead motion, it obviates some of the difficulty which "G. C. C." describes, as sometimes arising when that motion is made use of for the purpose, from its not having sufficient range backwards or forwards. A A A A is a light frame, the sides of wood about 2in. by ⅞in., connected top and bottom by stretcher rods, of (say) ⅜in. iron (wood would do); the size of frame is about 15in. square. B is a spindle of wood about 2¼in. diameter, working with an iron pin driven in the ends, in the sides of the frame. C is



a wooden wheel or pulley, 11in. in diameter, and ⅞in. or ⅝in. thick, strengthened at the boss by a piece glued on each side to make a broader and firmer bearing on the spindle. A key bed is cut in the spindle, and one to correspond in the boss of the pulley, and a wooden key, slightly taper, fixes it sufficiently firm; the rest of the spindle has a series of V grooves turned on it. This frame is suspended from the ceiling by an iron rod passing through the tops of the two sides, on which it can swing backwards or forwards, in order the better to adapt itself to any altered position of the slide-rest, and is hung in a line with the lathe bed, and as directly over the pulley on the slide-rest as it conveniently can be. It can be worked from the lathe mandril pulley, or, if that gives too quick a speed, it can be worked from the chuck as shown in plan, which is the mode I adopted. As I generally used the screw chuck, I turned a V on the back part where it screws on to the nose of the mandril, and which is 1⅜in. in diameter; from this a ⅛in. or three-sixteenths of an inch gut goes over the 11in. pulley in the frame, another gut from the spindle itself down to a 7in. pulley (of wood) D on the slide-rest screw. This arrangement makes a spiral that it requires good eyesight to see, but if too fine, the speed can be easily modified, as required, by having one or two different-sized pulleys for the slide-rest, and by driving it from lathe mandrils. If the frame is found to be in the way of the working of the overhead motion, by attaching a cord to the bottom rod and passing it over a pulley overhead, it can be pulled up and out of the way when not in use. It would be an improvement if the frame were suspended by indiarubber bands. Many years ago I constructed a very simple effective over-head motion, which I have not seen represented in the various plans of that apparatus which have appeared from time to time in your paper. If you think it worth while, I shall be glad to send you a sketch. N. N.

[Please send.—Ed.]

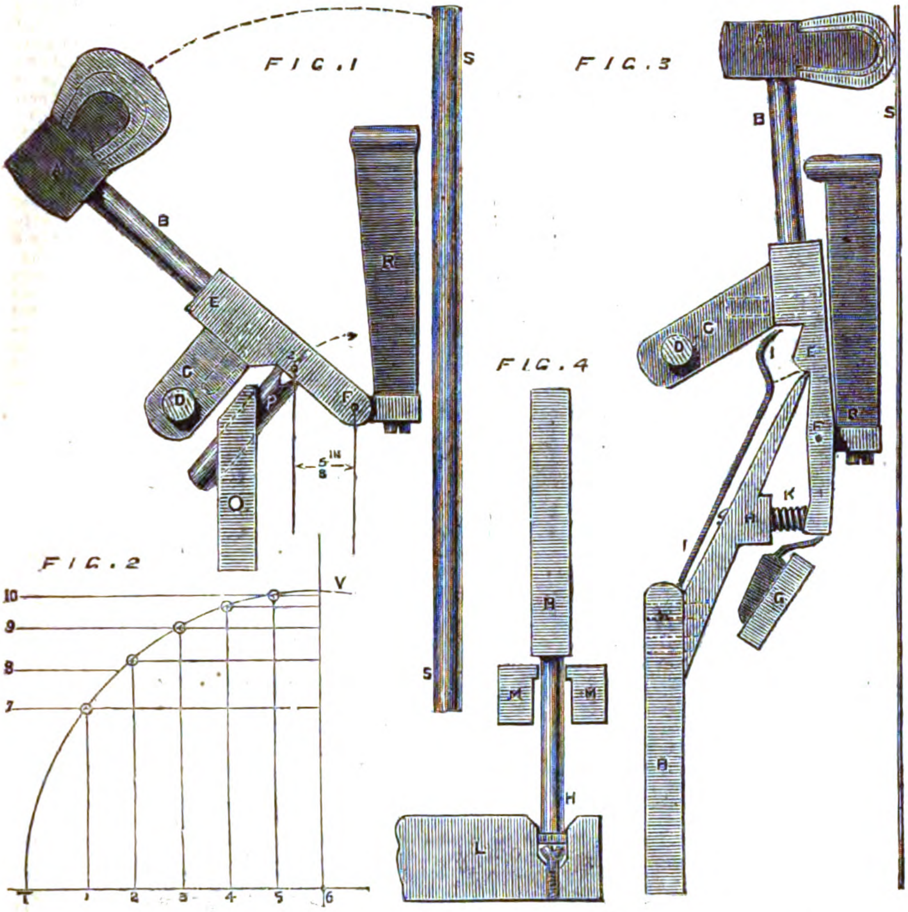
HOW WE SEE A DISTANT OBJECT.

[3932.]—I have paid some attention to the discussion on the above subject, but I am sorry to say I have not been able to understand what the difficulty is or what is its explanation. I think the matter might be simplified if we were to take into consideration that objects are discerned not so much by the presence of reflected light as by its absence. This may seem a somewhat Hibernian way of expressing myself, but I will explain. Objects, then, are discerned by their shadows or shaded parts. If I were to look out upon a landscape and the light were to be reflected to my eyes from every object and from every part of each object with the same degree of brilliancy I should discern nothing but a broad field of uniform light, and if the uniformity of reflection were perfect I should not discern even the faintest outline of any object. In every landscape there is a point of greatest illumination or highest light, be it a white cloud, a chalk cliff, or a shining river. This point the eye unconsciously takes for its standard of illumination and discerns all other objects by their relative dimness. If I wish to make a drawing of this landscape I take a white sheet of paper; this paper reflects the light equally from every part, it therefore represents what the landscape would appear if every object reflected the light in an equal degree, a broad field of uniform reflected light. Having made an outline I proceed to shade—that is, I begin to obscure the light reflected from my paper in different degrees on different parts of my paper according to the objects I wish to represent, so that the objects begin to be discernible on my paper, not so much by the reflected light from my paper—for that was there before I began my drawing—but rather by my obscuring that reflection in certain parts by covering my paper with a less reflecting substance, be it pencil or sepia, so that it appears to me that objects are discerned not so much by the reflected light thence proceeding as by the varying degree of absence of reflected light—in other words, shade. Of course I do not contend that reflected light is not a necessary condition of visibility. Of course we could see nothing in total darkness, neither could we discern any object in uniform light. I merely contend that we discern objects by their comparative darkness—in fact, by their shaded parts. Bobo.

[3933.]—I beg to thank Mr. Proctor for his very kind letter (let. 3829, p. 36) and am very sorry that he should have been kept eight weeks trying to find out the meaning of my letter (3493, p. 510), particularly as he says, "And as I could not explain his difficulty, but greatly wanted to have his query explained, I waited the action of the clever correspondents." He further says, "I am utterly bewildered." Mr. Proctor says, "In this case the answer is undoubtedly, that scattered reflection renders the frame of the mirror descernible. The glass of the mirror is not seen." And he further adds, "but we recognise the shape of the mirror whenever any light at all reaches its whole face, because the frame does not specularly reflect the incident light (or much of it), while the quicksilvered glass does." The ray of sunlight is supposed, in the present case, to strike the centre of the mirror only; where, then, does the incidental light come from, by which Mr. Proctor says the frame is made visible? He says that the frame does not reflect specularly. Well, the frame is moulded in certain curves, and every curve has its proper angle of reflection, and at all events the light is reflected in right lines. The theory of light says "every ray of light carries with it the image of the point from which it was emitted. If, therefore, the pencils of rays from every point of an object are united in the same order in which they proceeded when first emitted, they will form a perfect image or representation of that object, at the place where they are thus united. The rays of light proceeding in straight lines, it is obvious, that to make an object visible at any place to which a straight line can be drawn from it to the eye, they must be detached from every physical point of it in all directions; but only those rays which enter our eyes can render them visible to us." Now, according to this theory if one or more pencils of rays happen to be reflected by any cause from the direct line, the points in any object from which such rays came must be invisible to the observer. Now, the atmosphere is full of organic dust, and as it is sufficiently dense to make the sunbeam luminous; it is evident that this dust opposes the passage of the rays of light which, if the distance be extended, the ray is utterly lost. I did not ask Mr. Proctor what rendered the sunbeam luminous; but I want to know how we see it, when standing some distance off? There is nothing to reflect the light but the organic dust, and the rays, as stated above, cannot penetrate far in a lateral direction. The same observations will apply to distant rocks, &c. We see the entire of the illuminated parts; and less distinctly parts in shadow. But I cannot conceive how rays of light can reach us from every point at the angles of reflection being innumerable. I only use argument to satisfy myself that I comprehend the explanation, and not for the purpose of putting forward a new theory. I have no doubt the necessary explanation will be given me. E. J.

PIANO CONSTRUCTION.—PART II.—To Mr. Schucht and his Fellows.

[3934.]—Several methods naturally suggest themselves to any one familiar with ordinary piano actions by which increased velocity may be imparted to the treble hammers. Perhaps the very simplest and most obvious of all is that used by the old grand makers, who were, in this matter, somewhat in advance of ye modern practical men. They made the butt shoulder or notch considerably higher than the horizontal plane in which the hammer centre was posited. Now, it is obvious the higher the shoulder (against which the hopper acts when lifting the hammer) be made, the farther that shoulder—and the hopper confined to it by the spring and guided by it—must go over towards the perpendicular plane in which the hammer centre is situated; in other words, the nearer a perpendicular drawn from the top of the hopper (when it has lifted the hammer to the string) will approach that in which the hammer centre is fixed. Of course, as it thus approaches the latter the acting length of the leverage, measured horizontally from one perpendicular to the other, becomes diminished; consequently, if the hopper be supposed to be raised by the key with an uniform velocity throughout its path, it will communicate a constantly increasing velocity to the hammer it lifts. The hammer's velocity may be thus accelerated to any extent admissible in practice, indeed, far beyond any such extent.



I may remark this old-fashioned, but most effective, method of communicating accelerated velocity to the hammer may be easily carried out in Carey's or Molyneux actions, which are but modern modifications of the old grand action arranged suitably for upright strings, and in which the escapement takes place at the butt—in my opinion, by far the best place for it. It is hardly applicable to sticker actions, in which the stickers are hung from the butts by leather hinges, because very high quirks would subject the leather hinges to excessive wear. It would also be unsuitable, unless some other means of causing the hammer to fall from the strings than the common loaded sticker were employed, because, as the sticker hinge would be but little in front of the vertical plane of the hammer centre when the hammer touches the strings, its weight would have but little power to pull the hammer back. This plan, however, answered very well in a model I had constructed, in which the sticker—which may then be made as light as is consistent with needful rigidity, a very important consideration when it is hung to a treble hammer—is attached to the hammer by a bushed wire centre; the hammer may be returned either by a spring, which is, perhaps, preferable for strings less than 5in. long, or by a comparatively light counterweight projecting nearly horizontally, which I much prefer for the tenor and bass.

In some actions the hopper is "set off" towards, instead of from, the centre; in all these communicating accelerated velocity to the hammer as it approaches the strings is very easy, all that is required being to make the butt shoulder in the same horizontal plane as the hammer centre, or at least not more than from one-sixth to one-fourth the radius above it. In the latter case, the leverage will become shortened as the hopper rises to some extent, and it will be yet more rapidly shortened by the set-off motion. As in these actions there can be but little objection to the set-off motion commencing with and continuing throughout the motion of the hammer, I think an oblique, double-centred lever, the position of whose fork is capable of adjustment for the purpose of determining the instant the hopper shall escape, would not only be the simplest method of causing the escapement, but also be found to be a very efficient guide for the hopper, which would require no other guidance, if its clothed lower end be made to rest on the head of a screw which forms the bottom of a socket in the key. This is the cheapest effectual method of supporting and guiding the lower end of a hopper I have yet thought of. It has no friction in the hole in the rail, which prevents it from straying about when the action is lifted out (off the keys), because it cannot touch the sides of that hole when in use, and it never becomes noisy, but in common with all actions in which the hoppers are connected directly with the keys, when used for a transposing instrument, it renders necessary the shifting of the keys with the hammers.

In horizontal actions the imparting of increasing velocity to the hammer as it rises soon reaches its practical limit, in consequence of the increase of resistance to the finger which necessarily ensues. When we consider that to double the hammer's velocity the leverage must be diminished one-half, and that doing this must (if the weight of the hammer remains the same) double that resistance to the finger which is caused by the hammer's weight, it is obvious that greatly increasing the hammer's velocity must be limited to the treble (where, fortunately, it is alone desirable), whose hammers are all the better for being what Dr. Ussher would deprecate in febrile patients—viz., "light-headed." Probably, if we can, consistently with their being strong-headed enough—they must not be thick-headed—make them sufficiently light-headed, we may succeed in carrying out this principle, so far as to increase their velocity three or even four-fold at the instant they strike the strings. I need hardly point out to our grand makers, and those who play on their instruments, what influence this would have on the power and quality of their trebles, usually so inferior to that of their bases; it would, as one Will Shakspeare sayeth, "Reform them altogether." Nay, it would convert many a well-made grand with a weak treble into a superior instrument to the very best we now have.

If we may hope, by reducing the weight of the treble hammers of grands to augment their velocity three or four fold, what may we not hope to effect when we come to carry out this principle in upright instruments? In these the hammer's weight resists the finger so greatly when it is on the rest that, in ordinary actions, the weights of the bass hammers are limited thereby, although they might be made at least double the weight they usually are made, to the great improvement of the bass tone. It is obvious that the radius at which the hopper or hammer-lifter acts on its butt being a given quantity, a hammer must resist the finger in proportion to its weight, and that there are only two possible means—so long as the key-balance remains unaltered—by which that resistance can be diminished, one being the reduction of the hammer's weight, and the other the elongation of the radius at which the hopper acts. Now, as the hammer's velocity is not of the slightest practical importance during any other portion of its path, than that at which it strikes the string; it cannot matter how much we increase the radius at which the hopper acts at the commencement of the hammer's motion, so long as that radius becomes short enough to cause the hammer to be impelled with sufficient velocity at the instant it strikes the strings. From this it will be perceived that this principle not only enables us to drive the treble hammers much faster than we now do, but also to employ much heavier hammers for our bass strings, and thereby augment the power.

A moment's reflection will enable the reader to perceive that as the hammer of an upright piano rises towards its strings more and more of that hammer's weight becomes supported on its centre. Consequently, as a mere matter of course, less and less of its weight presses on the hopper, and resists the finger. In a model, constructed for me by my late friend and fellow correspondent "W. T.," in which the escapement occurs from the hammer's centre, which, by the way, is the only one centre in this action, because its damper is attached to the hammer. The latter is provided with an inside check, *à la* Stumpff, which insures good and low repetition. I may remark *en passant* that this action, from its great simplicity and the fewness of its parts, notwithstanding its immense power, costs actually less to make than the common cottage action without a check. The hammer centre is about ⅜in. from the string, and the leverage at which the hopper acts on the butt diminishes while the hammer is rising, until, when it reaches the string, it becomes barely one-fourth what it originally was at the commencement of the key's and hammer's motions. The same weight—2oz.—exactly balances the hammer in every intermediate position between ⅛in. above its rest to within ⅜in. of the strings. I guess, Mr. Schucht, you will allow this is a tolerably equal touch, and that this is a test few upright actions in ordinary use would bear. It is, indeed, more nearly equal than any pianist would require, because an instrument whose touch is 2¼oz. at the commencement of the key's motion, and increases to 3oz. at the instant the hammer strikes, has, by an eminent professor, been deemed very far from unpleasant to play on—much less so than he deemed the common cottage and Zeiter's grand actions, in both of which the resistance to the finger is greatest at the commencement of the key's motion and diminishes as the hammer rises; and it would diminish to a much more sensible extent in the former action were it not for the nearly uniform resistance caused by the loaded striker and the damper, which act throughout the whole of the key's path. When the resistance to the finger—tested by a weight laid on the key—is perfectly equal throughout the whole depth of touch, the mere inertia of the key, &c., will always cause a sensation of slightly greater resistance at first, so that the touch becomes apparently lighter and more pleasant when the resistance is rendered a trifle less at the commencement. Messrs. Broadwood and others effect this in grands by delaying the contact of the key with the damper lever until the former has descended from half to two-thirds its path. Of course, if the damper be attached to the hammer, in which case it causes no additional resistance to the finger, this plan is inapplicable, and it is seldom applied to upright instruments which have Collard dampers, although to them it easily may be by leaving a space of about one-tenth of an inch between the damper lever and the button which lifts it. If the damper lever be properly—*i.e.*, thickly—clothed no noise ensues.

A moderately increasing resistance to the finger being, as I have shown, not only admissible but actually used in modern practice, we may fairly be entitled to employ it for the more important purpose of increasing the power of cottage trebles. When the acting leverage is shortened to one-fifth or sixth the increase of resistance to the finger is in about the proportion 12 to 9 or 3oz. to 2¼oz.; need I tell so practical a pianoforte maker as Mr. Schucht that this will enable him to obtain trebles whose power his customers would be "very much surprised to hear." Probably so great an increase in the force of the blow as this might necessitate some increase of material in the form of strings. Say, instead of those he now uses, three No. 16 or 17 4in. long on his top C.

Besides improvements in scales and actions it seems probable some increase of power may be obtained by improved bellying; many designs for which have been published. In 1860 Mr. Nosworthy designed a method of increasing the power of the trebles (see his patent, May 29, No. 1323, price 10d.), by extending the soundboard in upright pianos (and in down striking horizontal grands) above or beyond the hammer line, the strings being supported on a metal bar, which acted as a bridge, and which was itself supported (on the bracing) by pillars. Others, notably Godwin and Alfred Wornum, have done, or proposed to do, the same thing by other means. That such an extension of the soundboard would almost certainly affect the timbre may be admitted; a great length of soundboard below the bridge is found to do this. That it would increase loudness is non proven. I fear the vibrations of strings from 2in. to 3in. long cannot—unless they be bowed or its equivalent—be made to endure long enough to cause vibrations which produce sounds audible to human ears at those portions of the surface of the soundboard which are more than 3in. or 4in. from the bridge. In No. 208 of English Mech...

Mr. Jenkinson—with whom I much desire to communicate—proposed to apply to pianos Stein's system of constructing clavichords—that is making the unisonous strings continuous end on, instead of side by side, as they usually are. I suggested how this might be carried out in No. 218, but must confess the mechanical difficulties are very great indeed, not to say impossible, which word, of course, English mechanics don't believe in. Probably nothing—excepting improvements in actions—yet suggested for increasing the power of piano trebles is so promising as this. Mr. Jenkinson proposed to place both his belly bridges on the same soundboard, the strings, of course, resting on a metal bridge similar to Mr. Nosworthy's arrangement, but after all the principle of Mr. Jenkinson's design really is making two trebles to one piano. Now, for doing this there can be no necessity that only one soundboard shall be employed. If, from any practical considerations, it be thought desirable to employ two soundboards it may be done—that is to say, a second soundboard might be provided for those strings which are above the intermediate bridge near which the double-headed hammers strike, which bridge might then be made of wood and double pinned, the pins being as close together as they conveniently could be inserted, so that the two hammer heads may not be far apart. The Harmonious Blacksmith.

P.S.—Having in this paper referred to two upright actions which have not yet been published, it has occurred to me that those references would be more intelligible if diagrams of the two actions were printed. It therefore, intend sending those diagrams shortly.

DESCRIPTION OF THE FIGURES.

N.B.—The same parts are lettered alike in all the figs.

Fig. 1.—A, hammer-head; B, hammer-shank; C, arm carrying counterweight D; D, counterweight which returns the hammer; E, hammer-butt; F, hammer-centre; O, sticker; P, arm projecting from sticker which supports the centre wire of the sticker-hinge Q; Q, sticker-hinge; R, hammer-rail; S S, the string for lowest A ¼in. diameter.

Fig. 2.—This is a diagram, double the real size, representing the relative positions of the hammer-centre F and the sticker-hinge Q at the commencement and the termination of its motion, also, at three intermediate places. For the purpose of rendering more easily understood the gradual diminution of the leverage at which the force which moves the sticker acts on the butt, I have drawn five equidistant upright lines parallel to line 6, which represents the vertical plane in which the hammer-centre F is situated. From line 1 to that plane is exactly 1¼in., but from line 5 to it is but ¼in.—viz., only one-fifth the distance of line 1. As the sticker-hinge Q rises from line 1, it successively passes through the points at which lines 2, 3, 4, and 5 intersect the arc T V, which represents its path—each of those points being ¼in. nearer the line 6 than the line immediately to its left. A moment's thought will enable the reader to perceive that as the sticker-hinge Q travels from lines 1 to 2 the leverage at which it acts on the hammer becomes reduced ¼in. When it has arrived at line 3 that leverage is reduced another ¼in., and so on until it becomes diminished to only ¼in. when it arrives at line 5. Consequently it must—assuming the rate of the sticker's ascent to be uniform—then be driving the hammer four times faster than it did when it commenced to move it at line 1. The fact that the hammer is propelled with a constantly-increasing velocity until it is stopped by its striking against the strings is, perhaps, even yet more conclusively demonstrated by the lines 7, 8, 9, and 10. Line 7 intersects the arc T V, which represents the hammer's path when the sticker-hinge Q is in its lowest position, and the spaces between these lines represent three equal divisions of the total rise of the key under the lower end of the sticker by which it is lifted. As the key rises the first third of its path it moves the sticker from where line 7 intersects the arc to where it is intersected by line 8, between which points of intersection there are but few degrees of the circle. The space between the intersection of lines 8 and 9 include about half as many more degrees as the space between 7 and 8 does, but the space between the intersections of lines 9 and 10 actually includes more degrees than both the other two spaces. Consequently, the hammer must be moved through rather less than half its total path by the motion of the key through the first two-thirds of the depth of the touch, and through rather more than half its path by the descent of the key during the last one-third of the total depth of the touch.

Fig. 3.—A, hammer-head; B, hammer-shank; C, arm carrying counterweight; D, counterweight which returns the hammer; E, hammer-butt; F, hammer-centre; G, damper; H, hopper, which carries the check J and the set-off screw K; J J, the flat-headed wire check; K, set-off screw passing through hopper H, and regulated in front.

Fig. 4.—M M represents the section of a rail extending across the action, whose use is to prevent the lower portions of the hoppers H from straying about when the action is lifted out of the instrument. The holes in this rail should be bored about three-sixteenths of an inch larger than the cylindrical portion of the hopper H, excepting for about ⅛in. of its thickness at top, which should be bored about one-fiftieth of an inch larger than the socket which receives the lower end of the hopper and its clothing, so that the latter may be lifted through this hole without injury when a single hopper is taken out of the action. N.B.—The cylindrical portion of the hoppers ... never touch against the inner surfaces of this ... these holes are bored in any of the positions ... be compelled to assume by the back... -d motions communicated during performance to the upper ends of the hoppers in consequence of their being guided by the hammer-butts. L represents the back part of a key, near the end of which a socket, about three-tenths of an inch in diameter, is bored for the reception and confinement of a circular piece of thick box-cloth or felt, which is glued on the bottom end of the hopper H. This piece of cloth or felt should fit in its socket without shaking, but not tightly, so as just to be pushed in easily and confine hopper laterally. This socket is countersunk at top for the more easy introduction of the hoppers when the action, after being lifted out, is replaced in the instrument, and its depth adjusted by a screw in the key, on the head of which the hopper rests. This affords the means of readily and cheaply regulating the height of the top of the hopper to suit the position of the butt-shoulder, against which it acts when lifting the hammer, and enables the regulator to take out any of that abomination yclept "waste touch." The head of this regulating screw ought to be slightly rounded to prevent its edge from cutting into the cloth or felt. I much doubt if many of my practical friends in the pianoforte-making line will readily contrive a much cheaper effectual method of guiding the lower end of the hopper than this, but truth compels me to add it has not much originality. I have been told Messrs. Collard and Mr. Kohlman both inserted strikers into sockets bored in keys, although they did not employ the head of a screw to form the bottom of the socket. I believe the rail M M also to be original in so far that it does not touch or guide the hoppers during performance. The Harmonious Blacksmith.

HERSCHEL NO DECIMALIST.

[3935.]—Mr. Allen well says (letter 3831, p. 86) he will give us Herschel "with certain additions" of his own, but these he should have distinguished. The fact is, we have about ten lines of Herschel at end of first paragraph, and all the rest is Allen. I beg, therefore, you will reproduce the sentences wherein the late philosopher did mark his position toward the question of decimal divisions, because their cautious guarding against the exact ideas it is now sought to father upon him is not a little remarkable. In p. 4 of the essay entitled the "Yard," &c., he insists on the independence of the two questions of standard and division:—"What is intrinsically the best and most available unit of linear measure to adopt as a basis? and secondly, what system of numerical multiplication and aliquot subdivision of such unit for measures of length, and of its derivative units of area, of capacity, and of weight (for these all refer themselves naturally and easily to the unit of linear measure, or at least ought to do so), is most advantageous—either in a great mercantile community like our own, or for the great mass of mankind in the ordinary transactions of life? It cannot be too strongly impressed, and too perseveringly borne in mind, that these two questions stand in no natural and necessary relation to each other, but are perfectly independent. We may resolve, with perfect logical consistency, either to toss aside our present system *in toto*, and adopt the metrical" [French] "one in preference; or to retain our fundamental unit (the Imperial foot or yard) and decimalise our system of denominations. . . . We may, too, retaining all the convenience of our existing denominations (*so far as they are convenient*), superadd to them, by permissive legislation, the additional convenience of a decimal system for facility of calculation, relying on its holding its ground *if really affording* such facility, or working its way into general use, and ultimately driving out the old system, *if found* by the mass of the population to be practically preferable. This last is the course I would myself prefer, and I think it best to say so in the outset, lest those who may take a contrary view should imagine a foregone conclusion to be urged upon them under the semblance of free inquiry." Accordingly, the essay continues purely on the question of standards; that is, according to "Sigma" (p. 69), is exclusively devoted to "only scattering dust about the true object of any importance"—and he does not touch that of decimal or other divisions, save to expressly *disclaim* it (p. 20),—nor allude to it again till the last paragraph, p. 23, where he says:—

"On the subject of decimalisation, it will be gathered from what I have said that I would make any decimalised denominations, which anybody might agree to buy, sell or contract by, *permissive*. There seems a doubt whether such is now the case [1863] and if so, the law should, I think, be altered. But I would leave untouched all our present *denominations* and their relations to the standard, and the only new measure I would legalise would be a "module" (or some other name *at present unoccupied*) of 50 modular inches, being the exact ten millionth of the polar axis, leaving its use quite voluntary."

In p. 20 however, he had well remarked—on the mètre and its decimal subdivisions—that we must "carry out the change in all its train of consequences, to the rejection of our entire system of weights, measures, and coins. If we adopt the mètre, we cannot stop short of this. It would be a standing reproach and anomaly—a change for changing's sake. The change, if we make it, must be complete and thorough. And this in the face of the fact that England is, beyond all question, the nation whose commercial relations, both external and internal, are the greatest in the world, and that the British system of measures is received and used, not only throughout the whole British Empire (for the Indian "Hath" or revenue standard is defined by law to be eighteen British imperial inches) but throughout the whole North American Continent, and (so far as the measure of length is concerned) also throughout the Russian Empire; the standard unit of which, the Sagene, is declared by an imperial ukase to contain *exactly* seven British imperial feet, and the Archine and Verschock precise fractions of the Sagene. Taking commerce, population, and area of soil, then, into account, there would seem to be far better reason for our Continental neighbours to conform to *our* linear unit could it advance the same, or a better *a priori* claim, than for the move to come from our side," [and by parity of reasoning, for *their* return to divisions by 3, 12, and even 7, rather than for our decimalising].

As "Sigma" accuses me (p. 69) of raving against a system "that has gained the approval of the great majority of scientific men," I wish he would name one of this majority. The *only* scientific man, French or not, that is known to me as having *ever* used the decimal angular measures is Laplace; a first-rate one, I grant, but I am not sure that even he rejected hours and minutes, or persevered in the angular decimals; and if he did, "Sigma" has a few more to find to make up a "majority." E. L. G.

THE FAIRLIE LOCOMOTIVE.

[3936.]—For the last few years few things have come before the public so frequently as the merits of the Fairlie arrangement of locomotive, and without desiring to detract from the alleged advantages of this system, I should wish to know the reason this invention is so frequently praised. Trials are frequently made of these machines (and the results always published if favourable), which are really of no practicable value to engineers. Take, for instance, those chronicled just recently, made on a branch of the Manchester, Sheffield, and Lincoln Railway—a steep gradient and curved, and a fair sample of the lines on which most of Mr. Fairlie's experiments have been carried out. It was proved that these enormous engines took an enormous load up bank with a fair expenditure of fuel, but the inventor cannot claim novelty or advantage in this, as the same company, did they require it, could easily build far heavier engines than they at present use, and that without increasing the fixed wheel base. Indeed, of what utility were the trials at all? Surely it was but an easy matter to calculate beforehand the tractive force of the engine as well as an approximation to the total (adhesive) weight. For narrow gauge railways, such as the 3ft. and under, undoubtedly some sort of bogie or "double bogie" is necessary, and it yet remains to be shown by other than newspaper commendation whether Mr. Fairlie's or one of the several other systems devised is best. Until some durable flexible tube is invented, a universal joint—such as is necessary with the engines under discussion—must be a tiresome nuisance when under great pressures and always changing its position. Amos Appleyard.

[3937.]—Although concurring in most of his views, I cannot understand the argument of "Osa" (let. 3864, p. 41), that 100 locomotives of the usual type, with 10 laid up, will be better that 50 Fairlie's, with five under repair, seeing that, as the latter may be made with counterpart boilers and bogies, only one-third of each engine need remain idle—the parts being interchangeable, as in a military rifle. The advantages of the regularity of water level over the fire-box on inclines, and the contingency of one of the motions breaking down, when three cylinders will still remain effective, are also overlooked. G. R.

CO-OPERATIVE SOCIETIES.

[3938.]—Though this is not about co-operative societies, it can only appear under that false title, that it may be known to continue the subject of letters 3655, 3775, 3776, 3847, which "F. C. S." persists in calling by something else's name, until it can be shown that by saying the thing that is, instead of the three that is not, some "benefit will accrue to the shareholders." First, I entirely agree with him that the proposal of "Pro Bono" to "enter the quantity of every article sold" must be preposterously impracticable. It would at least double the storekeeper's work, and, therefore, in any just system, double the entire expense of the "society." For no system is just till it arrive at this: that his remuneration consist wholly and simply of a settled and uniform fee for every parcel sold. The customer A who comes for "2oz. of tea, 1lb. of sugar, 1oz. of tobacco, and 1 pennyworth of biscuits," must pay, besides their marked price, four of these uniform fees—one for the storeman's trouble on each parcel, and must take them away with tin checks recording simply his payment for the goods (not these fees), and giving him claim at the future settling day to proportionate dividend of the surplus (miscalled "profits"). But if B buys and takes away a cwt. of cheese and nothing else (but the checks for its price) he is only to pay one such fee. On these fees the storekeeper is to live, and the whole of the surplus in prices to be returned to customers—that is to say, apportioned among them all (whether shareholders or not) according to their amounts of returned checks; but the dividends so *apportioned* can only be *paid* to those who are full shareholders. The dividend of him who is not yet a full shareholder is not payable, but only to be credited to him in the books, as going towards making up his share. It belongs to him, indeed, so as to be payable to heirs in the event of his death, or to himself after leaving the neighbourhood, and leaving it long enough in the store's use to entitle him to the benefits he has enjoyed, as I explained in the case of "co-operative societies" proper (*i. e.*, factories) in last vol., let. 3044, art. 5, 6; and in fact everything there said, except art. 3, will apply to a joint-store as well as to a factory. Even a mere grocery store (whether in village or city), once adopting the principles of right dealing —but no society without them—will afford a basis for every social reform, the overthrow, at least, of all the enemies there enumerated, the adventure trader, the sickness doctor (*i. e.*, every doctor, whether farming men for health-fees or not, who takes any sickness fee at all, from anybody), the undertaker, the burial club, the assurance company, the baby-farmer, every special benefit-club, every eleemosynary degrader, and, indeed, eventually all these foul cankers that call themselves "society" while they are burning society down; and that poor old England, day by day, has less time left wherein to kill or be killed by.

If "F. C. S." had referred to the pages I mentioned, he would have seen that if I only promised solutions now: I had given or begun discussing them before, and if *bis dat qui cito dat*, I had given them twice already to the best of my power, as long as I am the only correspondent who will touch them at all. It may be that, as "Mr. 1872" complained to the editor (p. 26) I keep "outside the questions in erratic wanderings," and say "but little on the questions themselves." Then whose fault is it that they are left to one so erratic? Why does not "1872" or some one take up "the questions themselves"? Are they too trifling?

Of the store "F. C. S." represents, after what he now tells, I have no hesitation in saying, stick to it as the members may, it will not pay, never pay, until these changes at the least; and how many more, he does not afford me the means of discovering. 1. They must get rid of their unpaid secretary and obtain a paid one, to be paid in the manner I indicated (p. 666). 2. Consequently, they must each be able to state pretty nearly his last year's cost of bread, and also that of groceries. "F. C. S." does not see "how a poor man can be expected to know this." If the converse proposition had been stated, that he did not see how a man incapable of telling this can be other than poor, very and increasingly poor, that would be a remark worthy of a secretary, paid or unpaid; and I should say, keep him. But his actual remark seems to enounce the harsh dogma that a man can only be poor by having been a reckless sluggard, which I take leave to dispute. As a poor man, I maintain that in these days one may be very poor without any such heedlessness and sloth as he says must be expected in "a poor man." 3. They must have a secretary who will use language (whether secret or common) consistently. It is quite open to them, if they think it profitable, to talk by contraries, agree that "hold fast" means "let go," or that a worker shall be called manager, and on the other hand, "manage" be their lingo for "work," or any other secrets of dialect. But they must not have a secretary who will say in one sentence (3847, par. 2), that they have one "manager" to many "co-operators," and in the next that many "manage or mismanage," and only one works; their lingo, however strange, must consist with itself. 4. They must not have a secretary who does "not profess to understand" the methods I have been partially describing (let. 3044, &c.), but on the contrary, he must profess to understand and take interest in even more than those, and to correct me therein, and pursue those questions considerably further. E. L. G.

[3939.]—IT is so very important to avoid the temptation to, or even the suspicion of, fraud, that it is worth while to take much trouble and incur some expense to guard against it. To do so without trouble is impossible, but I think the following plan is the least troublesome one proposed. Let books be prepared of alternate leaves of thick and thin paper, each with corresponding numbers. When a sheet of carbon paper is interposed, whatever is written on the thin paper will be marked also on the thick. It will not require very much trouble or time to write down what every customer buys and what he pays for it, and to tear out of the book the page of thick paper on which it is marked in duplicate corresponding with the leaf of thin paper, with the same number of page. The thick leaf the customer keeps as his voucher to entitle him to his share of so-called profit (really saving of shopkeeper's profit), while the total of the amounts of sums shown on the thin leaves of the books as paid by all the customers is the sum that ought to have been received and be in the till.

This is the plan customary in many drapers' shops, where, as an additional precaution, the customers' accounts are written by one person and checked by another, being initialed by both. After a little practice there is not much loss of time, while mistakes and frauds are scarcely possible, which are very common where no such system is adopted. Mistakes they are always called, but they are generally made in favour of the seller, so far as I have observed. PHILO.

COLOUR.

[3940.]—YOUR correspondent "E. H." (letter 3413, No. 856) is inclined to doubt the sufficiency of the theory of three colour sensations to explain all the phenomena of colour, and thinks that the sensation of white, though produced by a mixture of red, green, and blue lights, may be really a simple indivisible sensation. There seems, however, no need for this more complicated and difficult hypothesis; and there are phenomena which strongly oppose it. The only thing which "E. H." mentions as leading to his view is that "if a red object is placed in juxtaposition with a white object, the tone or strength of the red does not seem at all lowered, as it should be if the red sensation is present in the white sensation, for the red in the white must be very much richer than that of the red object." But let us examine this matter more closely, and there will appear nothing inconsistent with the accepted doctrine.

To do this well, two similar spots of the same red should be placed, one upon a white ground and the other upon black, side by side. In shifting the eye from one to the other we are immediately struck with the comparative darkness of the spot on the white, so that we must shade the spot on the black to make it match the other. Still the white, as "E. H." observes, does not lower the tone of the red, but leaves it as nearly a pure red as before—perhaps it even a little improves it. This is just what we might expect; because no red that we can procure is free from a very considerable mixture of green and blue, which dilutes the red with white, and the brighter white of the ground takes off from this diluting white at least as much proportionately as it takes off from the red, and the result entirely accords with the theory.

The following fact, however, tends still more to establish the doctrine that white is a compound sensation. When the eye has been fixed for a while upon a brilliant red, green, or blue spot, upon a perfectly black background, and is then suddenly directed to a white or gray surface, there appears a sea-green, pink, or yellow spot, slightly darker than the white or gray. This appearance is easily explained as the effect of a diminished sensibility for the red, green, or blue constituent of the white or gray, as the case may be; but if white is a simple colour, what can be the cause of so remarkable a phenomenon?

The great cause of the hesitation which many feel in admitting the compound nature of white is the extraordinary brightness of white objects as compared with those whose colours approach to a pure red, green, or blue, a circumstance that arises mainly from the fact that substances which reflect all kinds of light commonly reflect them all powerfully. If we take a pure gray, more or less approaching to black, we find it by no means so difficult to imagine in it a combination of the different colours. Indeed, when a gradation is carefully made from the colour of scarlet vermilion to that of fresh verdigris, passing through pure gray of medium brightness, the eye is at once satisfied that there is a uniform increase of red from the verdigris end to the vermilion end, and a uniform increase of seagreen from the vermilion end to the verdigris end. The like may be equally well effected with respect to green and blue, and their complimentary secondaries pink and yellow, by making gradations from the colour of emerald green to that of light rose madder, and from the colour of French blue to that of lemon yellow, through the same pure gray. When such gradations are well made, the eye in viewing them seems to see the different complementary colours by turns in the gray, and thus to be able to analyse white by itself. The difficulty of conceiving yellow to be a compound of red and green arises from a similar cause—the intense brilliancy of the yellow, which is produced by a combination of all the brighter rays of the spectrum; and if its brightness is reduced till it becomes an olive green, the middle colour of a gradation between red and green, it is by no means difficult to see both red and green in it. WILLIAM BENSON.

"SCREW'S" ✕ MULTIPLICATION.

[3941.]—I WAS somewhat puzzled by "Screw's" figures in letter 3873, as other readers may probably be, to know how (13 78125 being given) 9·646875 comes to be "given number, but one place out." Of course he means "7 times given number." I only multiply by 2 twice and 3 (the latter a part of the figures only), and he by 7 and 2 twice (and the former the whole of the given figures). To compare the results, it is easiest to operate on 4, so as to get the relative approaches to the well-known 3·1415926536, and the 0's will show the number of figures required if the given number were complex:—

"SCREW'S" METHOD.

	4·00000000
Given number × 7, one place out	2·80000000
Same, another place out	·28000000
Same, × 2, another place out	5600000
Same, another place out	560000
	3·14160000
Deduct given No. × 2, five places out	800
	3·14159200

MY METHOD.

	4·00000000
Add 20th	4·20000000
Deduct quarter	1·05000000
And Do. 2 places out (A)	1050000
And 3 more places out	1050
	3·13948950
Add ·2 of A	210000
And ·3 of same, 3 places out	315
	3·14159265

being a hundred times nearer than 3·141592.

E. L. G.

ERRATUM.—In let. 3873, p. 62, the first line of the sum should be, "Given number × 7, but 1 place out."—SCREW.

CALIPER COMPASSES.

[3942.]—IN reply to "K. T. L." and "J. K. P." (letters 3825 and 3836) the above articles are sold in Manchester under the name of "Roller-coverers' Compasses," and are used for covering with leather small iron rollers used in cotton machinery. G. W.

AMATEUR TURNERS' SOCIETY.

[3943.]—SEEING from time to time the many queries and answers concerning mechanical manipulation in your journal, I am surprised that in this metropolis and its suburbs some central institution has not been established in order to afford means of intercommunication between amateurs who are interested in the mechanical arts. I venture to suggest that it would be quite possible to hire a room in some readily-accessible situation near some station of the Metropolitan Railway or omnibus route (perhaps, as a tentative experiment, in a back street), where lovers of the turning lathe, &c., could meet in order to compare notes and to discuss matters pertaining to their favourite pursuits. Such an institution, if established, ought to be open to all who might be willing to pay a moderate annual subscription—subject, however, to certain rules providing for the exclusion of undesirable persons. No good results can be hoped for if such a society should be started in a narrow spirit, and confined entirely to individuals who may luckily be possessed of expensive apparatus in the way of tools, &c.; but it ought, on the contrary, to be open to all who really love mechanical science for its own sake.

The art of ornamental and plain turning has hitherto been almost entirely a rich man's hobby, by reason of the great expense of the various chucks, slide-rests, and other appendages to the lathe. What is really wanted, in my opinion, is this: a common place of rendezvous where all who are interested in such matters could meet and mutually assist each other.

Nobody can be unaware of the immense advantages to be derived from an interchange of ideas amongst persons of a scientific turn of mind. Many projects of a mechanical nature are allowed to remain undeveloped, owing to the fact that the originators want the stimulus to be derived from mutual emulation. How often does it occur that amateurs who have some favourite scheme to carry out are prevented from bringing their inventions to perfection owing solely to the want of assistance and advice as to certain operations of a practical nature that are only known to a few initiated members of the mechanical profession?

Mr. Editor, I have dropped these few hints in order that, perhaps, some of your readers who, like me, take great delight in mechanical pursuits may be induced to express their views through the medium of your journal in a far abler manner than I have done or can do, and leave these crude suggestions in your and their hands. AN ESSEX AMATEUR.

[3944.]—SOME two or three weeks ago I saw in answer to a correspondent that our obliging editor would forward any such society as above named. I therefore beg to offer a few suggestions as to the formation of such a society. It would be necessary, previous to forming such an association, that a number of those interested should deposit a small sum to be fixed hereafter to cover incidental expenses; next, that a committee of (say) six gentlemen should meet and endeavour to form a foundation to work upon; as in all associations and clubs the qualification for membership would be an annual, quarterly, or monthly premium. I would suggest 5s. as an entrance fee, and £3 per annum subscription. This would enable the society to hire a suitable workshop, fix lathes, benches, &c., to be open to all members at times specified. All members should be taught by competent workmen, at certain stated times; materials, tools, and articles found gratis. A club-room should be attached, with lavatory, &c. I should be happy to assist in forming the society, if any gentlemen will advertise their addresses, with a view to co-operation. SAMUEL SMITHER.

TERRESTRIAL GRAVITATION.

[3945.]—So my method of deciding whether the attractive force at the poles of an oblate spheroid is less or more than at the equator is condemned as inapplicable by Mr. Proctor, who declares that nothing short of the integral calculus can work out this question. I imagined that in spheroids of considerable eccentricity my simple mode of determining the point was admissible, and that the superiority of the attracting force, at the equator of an oblate or the poles of a prolate spheroid was the reason why globules of liquid matter returned to the spherical form when freed from pressure, and why a viscous liquid when dropped from a bottle seemed endued with elasticity.

But Mr. Proctor's letter (3828) has upset all my preconceived notions, so I will close the subject with many thanks for his kind replies, which are doubtless as valuable to others as they are to me. There is one more query I should like to ask for more perfect satisfaction of a lingering doubt. Is it perfectly certain a minus sign is not by some oversight used in place of a plus sign in the formulæ for these calculations? T. A.

DUST IN THE SPECTROSCOPE.

[3946.]—SEEING that our valued friend "F. R. A. S." asks for information about that very annoying phenomenon, "Dust in the Spectroscope," pleading the fact that I have used one of Browning's instruments during much of my leisure time for the last few months, I crave indulgence to send my experience. I see that one correspondent states his belief that this effect arises from imperfect polishing of the prism, from unduly deep cuts in the glass by the polishing powder; the fallacy of this notion will be app[arent] when it is remembered that the prisms are pol[ished with] circular strokes.

I believe that the nuisance occasionally arises from the fact that the jaws of the slit are slightly irregular, although oftener from particles of dust lodged therein (as your obliging correspondent knows well). The most effectual means of removing the latter I have found in an old quill-pen end, having stripped most of the feathers off. S. W.

ORNAMENTAL TURNING.—VIII.

[3947.]—In wood turning the chucks used are various, according to the class of work to be performed, but the principal chucks are three in number—viz., the prong or strut chuck, hollow chuck, and screw chuck. Chucks should be made from wrought iron. Many turners use chucks made of wood—beech or box—but it will be found cheaper by far to have them of iron. Some are made of cast iron or brass, but the extra cost is so little that I advise wrought-iron chucks. I usually pay 4s. to 5s. each for them. I send a drawing of the three chucks. Any article can be made by the use of these that can be turned in a lathe. Should any ornamental chucks be required they should be made to screw upon the screw chuck, and when not wanted hung up in readiness for use. I make it a plan to fix pieces of wood upon my screw chucks, turn them shapeable, bore a hole, and fix any boring bits I may want to use. When required for use I have only to select the one required, and it is fixed on in a moment. Fig. 1, prong chuck for turning wood between centres. Fig. 2, hollow chuck, the wood to be driven in the chuck with a hammer, after paring the ends taper, the most suitable size 1¾in. in the bore. Fig. 3, screw chuck, the screw should be 2in. from socket to end, diameter at the base ⅝in., taper to the point, which should be ¼in. If the point of the screw is made gimlet-pointed it will enter the work without boring (that is to say, in soft woods). I omitted to state at the commencement that the best mandril for the amateur's use is a male screw for iron chucks, but if wood chucks are insisted upon, either on the score of cost or fancy, I certainly advise a female mandril.

I send a list of a few articles that may be easily turned by the amateur; for patterns, &c., he must use his own judgment and skill. Bread platters, size 8in. diameter, 1in. thick—sycamore is the wood most suitable. The platters should be turned with a thumb

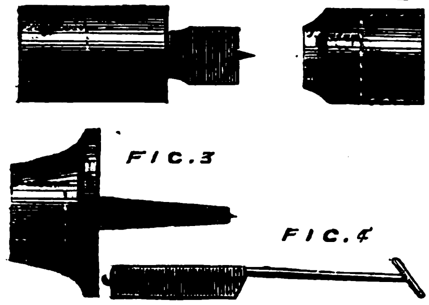


FIG. 1 FIG. 2 FIG. 3 FIG. 4

moulding, with a bead at the edge. Plain ink stands base 6in., top 3in., sunk for ink-pan lid to cover, with penwiper on top; mahogany, box, rosewood, walnut, or maple is suitable. Glass or jug stands 6in. diameter, 1in. thick, hollowed out ⅛in., with a groove at the inner edge, ¼in. deep, to contain any overflow. Walnut or mahogany gas blocks, 2½in. upwards, ⅝in. thick. Mahogany or sycamore shade stands—superior sort, sycamore; common sort, deal and pine; best sort, walnut, ebony, rosewood, or mahogany. Looking-glass or picture frames have a pretty appearance if turned of oak or even mahogany. In concluding my list for the present I may add one more that will amply repay the trouble incurred—viz., a bitter cup. Some few years ago they had quite a run. The cup is turned from a wood called Quassia wood. Very few dealers keep it. I purchased what I required in Long-lane, Smithfield. The last time I inquired for some they were out of it. I had at the time an order for a quantity, but did not trouble to finish them on account of the scarcity of the wood. I usually pay 4d. per lb. for it. To turn them, cut off a piece of wood 5in. or 6in. long, pare the end to fit hollow chuck, drive it in firm, turn the shape required—a goblet looks well—hollow out the inside, do not take out very much wood, as in that case it will not serve so long for private use. I always turned a lid for the purpose of keeping out the dirt and dust. It is a very excellent tonic—quite harmless to a child or adult. Pour in the water, let it stand for two or three minutes, then drink. I used one for ale at dinner. Do not wash them under any circumstances. If dirty rinse them with cold water only. One cup will last months in use. The chips are useful in many cases.

I also send drawing of a cast steel knife (Fig. 4), very useful in a turner's shop. The use of it will soon be found. Samuel Smither.

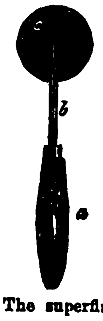
SPONTANEOUS COMBUSTION.

[3948.]—I am led to believe that if Mr. Tonkes had seen as much of the world, and had received the wide experience of it which "Manus" has acquired, and was not so insolently self-sufficient as he has shown himself to be, he would be a better man, and would have secured a larger amount of practical knowledge; and I cannot but express my surprise that he addresses contributors as he does.

I will, however, relate another case of spontaneous combustion. Several truck-cloths were dressed with black paint and boiled linseed oil, folded, and placed one on the other before they were sufficiently dry. The result was that they were seen to smoke, and when removed from their piled up position (in the open air) several were found burnt through, and others charred so badly as to be useless. The discovery of this case was made under my own personal observation. It was only in the heart of the pile of cloths that combustion was generated. And had a spark, or piece of lighted waste or cotton, been placed in the seat of combustion it would have instantly expired. Manus.

A TOOL FOR DESCRIBING PATTERNS.

[3949.]—"One good turn deserves another," and as I have received a good many since I have been a subscriber to the English Mechanic, I now send a description of a little tool which may be useful to "our" bookbinding friends. The manner of using it is thus: On the edges of the covers or round the margin of your book, and also across the back, lay a little resin, in fine powder, and on this gold-leaf. Now for the tool: a is the handle, of wood (see sketch); b, an iron fixed in it, forked at the end. Little wheels, round the edges of which devices are engraved, are fitted to run in this fork. Having fixed the wheel, c, that you want in the tool, heat it and run it along the edge of a ruler; the resin will melt and form a cement, leaving the gold-leaf wherever the tool passed in the devices graven on the edge of the wheel. The superfluous leaf may then be wiped off. V.

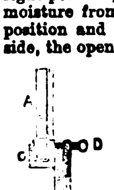


IMPROVED METHOD OF GLAZING.

[3950.]—The method which you have published (p. 88) is a very transparent infringement of that of Pullen, of Bath, who exhibited a house with hollow sash-bars in the garden of the Royal Horticultural Society at South Kensington last year. Grooved bars in both wood and iron are by no means uncommon, as I have known the former in use for more than twenty years, and, therefore, there can be no patent in them. When Messrs. Rendle & Burrows were obtaining their patent, I wonder they did not claim for a refrigerator as well, for it must be clear to every one at all acquainted with hot-house heating, that a more effectual method of absorbing the heat generated could scarcely be devised than that of converting each sash-bar into a refrigerator frequently filled with snow-broth to carry the heat away. Iron sash-bars, when protected by felt, as in Beard's patent, are bad enough, but to convert them into regular coolers for the carriage of water is the height of absurdity.

The great objection to iron for horticultural purposes has been its rapid conducting properties, scorching at one time and freezing at another. The only person who has coped with that difficulty, or who can cope with it during his patent, is Mr. H. P. Ayres, of the Imperishable Hot-house Company who, dispensing altogether with sash-bars, places the glass in one continuous sheet, like slates upon a roof, and thus the glass acts as an insulator by housing nearly the whole of the ironwork, and preventing the radiation of heat. Many thousand feet of this glass may be seen at the nursery of Mr. John Wills, floral decorator to her Majesty the Queen, Sussex-place, Old Brompton, S.W. Peter Wallace.

[3951.]—The plan recommended by my fellow-contributor "Saul Rymea" (let. 3840) is, for its many advantages, well worthy of success. It is both simple and ingenious, and cannot fail to come into general use. By this arrangement mechanics and artisans can glaze their own windows with greater facility and convenience than the professional glazier, while the work done, if properly executed, will excel any done by the old putty system. It has often occurred to many people that panes could be inserted and fastened in the same way as the glass of an ordinary carriage, with a running groove in the sash each side and a recess at the bottom to receive the lower end of the pane let down through an open slit in the top. The glass would thus stand in an inclined position, the ends overlapping each other, something similar to the arrangement of house-slates. The panes might deviate very little from an upright position, and in this way throw off a good deal of moisture from the framework. To keep the glass in position and prevent its removal, except from the inside, the open slit at top could be closed with a binding screw over the centre of each pane, as represented in the figure. A upper pane, B lower pane, C recess in sash (end view) to receive lower end of pane, D screw to prevent its being raised till withdrawn. It also acts as a cramp screw, and presses the edges of sash, if iron, towards each other, closing the interstices and making the joints water-tight. The plan has some advantages over the old system, as a broken pane can be easily repaired or replaced by a new one in a very short time, and one or two can be raised for the purpose of ventilation, or for a breath of fresh air during the summer or autumn months. Rat-Tat.



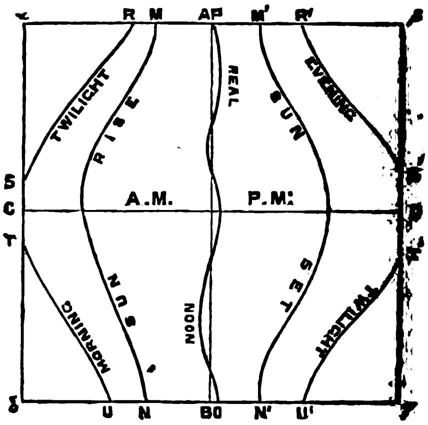
PREPARATION OF PUTTY POWDER OR OXIDE OF TIN FOR OPTICAL PURPOSES.

[3952.]—Having seen from time to time several inquiries as to the preparation of oxide of tin, I send you the following method, which is the result of a great deal of experience. Metallic tin is dissolved in nitro-muriatic acid, and precipitated from the filtered solution by liquid ammonia, both fluids being largely diluted with water. The peroxide of tin is then washed in abundance of water. Collected in a cloth filter and squeezed as dry as possible in a piece of new linen. The mass is now subjected to pressure in a screw press, or between two lever boards, to make it as dry as possible. When the lump thus produced has been broken it is placed in a crucible, and covered up tight to prevent jets from entering, and is then exposed and heated to a white heat, and ground for use in the usual way; this oxide is used specially for cements, polishing of astronomical object-glasses for astro-telescopes. The putty powder of commerce, if good fair quality, is alloyed with about equal parts of tin and lead, which answers for ordinary purposes, but not for polishing lenses, in which good work is wholly dependent on the quality of the powder. Wm. Oldfield.

"SUNRISE CURVE" AND OTHER CURVES.

[3953.]—In so far as the times of sunrise, sunset, real noon, beginning and ending of twilights are, for a given latitude and a given year, functions of the date of the year, they may be represented by curves. Such curves will not be strictly correct for any other year, but they will be sufficiently so for all ordinary purposes of life, since, owing to the nice adjustment of the Gregorian calendar, errors could not amount, for a long time to come, to more than a minute or two of time.

Not having yet seen this very simple idea carried out, I beg leave, Mr. Editor, to send you the following sketch of a drawing which, when fully executed, should be on a much larger scale.



$\alpha \beta \gamma \delta$ is a square, of which A B C D are the middle points of sides. A B may be called the "axis of dates," and C D the "axis of diurnal time." Suppose A B and C D divided into 364 and 360 equal parts respectively, and lines parallel to C D and A B respectively drawn through the points of division. Denote the 365 points from A to B by the 365 successive dates of the year, and the 361 points from C to D by the indications of time for every four minutes from one midnight to the next. By consulting a proper almanac it will now be easy to mark on each horizontal line the corresponding times of sunrise, sunset, &c., and, by joining these points, to obtain such curves as M N or sunrise curve, M' N' or sunset curve, P Q or real noon curve, R S T U or morning twilight curve, R' S' T' U' or evening twilight curve. The drawing is supposed adapted to the latitude of London.

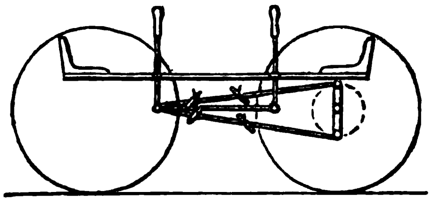
The surface of the whole square representing a year's time, the space between M N and M' N' will represent the proportional amount of daylight during the year, the space between M N and R S T U the proportional amount of morning twilight, the corner spaces the proportional amount of total absence of sunlight (strictly speaking, a 365th horizontal space should be added below γ δ for this purpose). The inclination to the vertical of the tangent to the sunrise or sunset curve at any date will be proportional to the rates of increase or decrease of mornings and evenings at that date. Suitable shading might be introduced, so as to indicate the gradual passing from daylight to darkness.

I need not add that analogous curves might be used for indicating the times of rising, southing, and setting, at a given place and during a given period, of the moon and planets. C. J. Recordon.

VELOCIPEDES.—To Mr. Shearing.

[3954.]—Mr. F. W. Shearing (p. 43, No. 366) asks me if I have ever tried the old-fashioned vertical tread. I am not quite sure whether I understand what he means by the old-fashioned vertical tread. I have used two kinds of these old velocipedes. The first, the usual form, is that in which the seat is placed over the driving-wheels, and to the cranked axles of which long treadles are attached, their forward ends being hung upon light rods; on each treadle is fixed a clog and strap, within which the foot is placed; the two front wheels are to guide, and are controlled merely by a long handle; the force exerted by the legs in these velocipedes consists partly of a forward and partly of a downward pressure, principally of the former. The great objection I always had to this kind was, that at each stroke of the leg the toes were jammed into the end of the boot, the said toes becoming, in about two or three hours' time, terribly sore in consequence. This kind of velocipede is no doubt well known to Mr. Shearing. The second has the driving-wheels in front, and the treadles are of such a shape that the force exerted is nearly all downward; the guiding-wheels are placed behind, and are actuated in front by any suitable contrivance—an upright rod with cross-handle, pulley, and strong gut line answers exceedingly well. In this form of carriage the toe objection is, of course, done away with, but I always found it to induce a painful—and, no doubt, if ridden in for long, injurious—strain upon the abdominal muscles.

But in a velocipede which is propelled by a thoroughly forward thrust, and provided with a properly-hinged clog or receptacle for the foot, both these serious objections are almost entirely, if not quite, removed. I send with this a diagram, which, if you, sir, will kindly find space for, will give Mr. Shearing some notion of a velocipede I am at present making, upon the principle of forward thrust of the legs. The diagram, I think, will explain itself, but I will just say in addition that there are four wheels, each 3ft. 6in. in diameter; cranks are 6½in. throw, giving a reciprocal motion of 13in. for the foot—quite enough. Let me here say that in a stroke of this kind the leg should never be allowed to become *quite* straight.



There are two seats, and two clogs on each treadle, the persons facing one another, as in an ordinary carriage. The machine being light, one person will be able to use it, however, with perfect ease. For ascending inclines, hand-levers, as indicated, will be provided; they can also be used on the level, instead of the feet, when it is desired to rest the latter members. The levers will fold out of the way when not in use; as, like many other persons and things, they are a most intolerable nuisance, and assert themselves very disagreeably when not in actual use. The two steering-wheels will be actuated by a simple arrangement (which is omitted in the sketch). When two persons occupy the carriage, the necessity for turning it round to run in an opposite direction will be obviated, as the steering-gear will be able to be shifted instantaneously from one person to another. It may be an advantage in Mr. Shearing's eyes that in this carriage, by reversing the seat between the steering-wheels, and providing a light footboard, apron, &c., a very comfortable seat can be arranged for a fair companion. This is, however, on the supposition that the muscles of the Christian who has the honour of working the treadmill on the occasion are tolerably developed, and that the said fair companion is at least a little too light to balance in the scale the Tichborne claimant. Mr. Shearing asks if my idea of a forward thrust is the same as that shown in a drawing of Mr. Reveley's some time ago. From my diagram he will see that the principle is very much the same. A. A. M.

ATOMICITIES v. VALENCIES.

[3955.]—Mr. Bottone is taking quite a wrong view of the meaning of the term atomicity in his letter 3862, page 41. This term when applied to atoms means the atom-fixing or atom-replacing power of an element or its chemical value in exchange, the atom of hydrogen being taken as unity. Atomicity when applied to molecules means the number of atoms which a molecule contains, but as we have not been considering the atomicity of molecules he ought not to look at it in that light, as we are only dealing with atoms at the present moment.

Different elements possess different atomicities: those which have an even atomicity are termed artiads, and those which have an odd atomicity are termed perissads, and furthermore an artiad never becomes a perissad, or a perissad an artiad.

Nitrogen being a pentad is thus equal to five atoms of hydrogen (I don't mean to say that there is such a compound as 1 atom of N, united with 5 of H), and as the atom-fixing powers of an element can only disappear in pairs, nitrogen must always have an atomicity of 1, 3, or 5, and how 1 atom of nitrogen can be made to exist in combination with 4 of hydrogen in ammonium, except as $\begin{cases}NH_4\\NH_4\end{cases}$ I cannot perceive, without our friend Mr. Bottone has been among the atoms of this substance, and cut away all the fifth bonds of all the nitrogen atoms (which I very much doubt). Also for his information I take the density of ammonium to be 9·00. I may also inform him that it is an exception to the general rule of vapour densities, as is also PCl_5 (and Cl_2O_3). See footnote 12, English Mechanic, No. 365, p. 4.

With regard to phosphorus acid, Mr. Bottone must take into consideration that this acid is only dibasic, not tribasic, as his graphic formulæ would lead people to think If he will look at the constitutional formulæ in my letter (3801) which is $POHHo_2$, providing he knows anything about such formulæ, he will see that one of the atoms of the hydrogen is in direct combination with the phosphorus, and consequently not displaceable, the two other atoms of hydrogen in the radical hydroxyl only being displaceable. I cannot thus consider his graphic formulæ as correct in relation to this substance.

In the preparation of chloric acid (p. 30, No. 366) the formulæ for potassic silico fluoride is printed K_2SiF_4, it should be K_2SiF_6, or SiF_4; 2 (KF). I presume this is only a printer's error, and not another error of Mr. Bottone's.

Ammonium in the free state is similar to the monatomic alkali metals; potassium and sodium which exist in the free state as $\begin{cases}K\\K\end{cases}$ or (K)⟶⟵(K) or K_2 and $\begin{cases}Na\\Na\end{cases}$ or (Na)⟶⟵(Na) or Na_2; therefore, ammonium in the free state must exist, as $\begin{cases}NH_4\\NH_4\end{cases}$ or

 or $(NH_4)_2$.

Mercuric.

DISCOVERY OF A MINOR PLANET.

[3956.]—I beg to send for publication in the English Mechanic a copy of a note which I received on the 3rd inst. from one of the Fellows of the Royal Astronomical Society. R. Langdon.

Royal Astronomical Society.

Discovery of a minor planet (118), Peitho, at Bilk, by Dr. R. Luther:

	Mean Time at Bilk	
1872		
March 15	14h. 18m. 59·6s.,	R. A. 12h. 7m. 26·73s. N.P.D. 79° 42′ 33·5″.

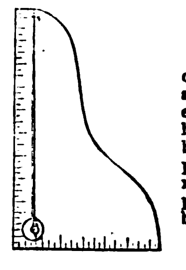
From an observation made by Dr. Tietjen, at Berlin:

	Mean Time at Berlin	
1872		
March 21	9h. 33m. 28s.	R. A. 12h. 1m. 36·36s. N. P. D. 79° 20′ 46·1″.

The daily motion obtained from these observations is in R.A. 60·6s., and in N. P. D. 3′ 45″. The planet is of the 11th magnitude.

March 25, 1872.

ANOTHER COMBINED TOOL.



[3957.]—I inclose a sketch of a tool I have made. It is a combined square, straight edge, plumb-line, serves as a level, rule, and, besides, can be used for obtaining the proportion of pipes, in the same manner as illustrated on p. 35, No. 366, both edges being marked off.

Zoo Andra.

Errata.—In letter 3890, last line of table in col. 1, for "391" read 398. Col. 2, after last table, for "And pounds would be reduced to these mins," read "And these mins would be reduced to pounds." The reduction of pounds into five guinea pieces would be nearly, not quite, as rapid, by adding a third, and then dividing the sum by 7.—E. L. G.

Errata.—In my letter (3879, p. 63), where it reads, "the pumps should be put in motion but sooner," should be read, "but not sooner." The weight of the shore abutments should have been "42,000 tons," instead of "4,200 tons," and their height, "104ft.," instead of "85ft.," which is the average height of the 462 bottom towers. Their weight should have been "1,191,960 tons," not "119,160 tons," as printed in the items of weights, &c. (p. 64).—Sholto Douglas.

The Study of Natural Science.—The examinations for scholarships in natural science, which have recently been held at Clare and at Emmanuel College, Cambridge, have both terminated without an election being made. The reason of this is that at neither of the colleges did candidates present themselves whose attainments, in the opinion of the examiners, entitled them to receive the distinction. The number of competitors was but small in each case—in one three only.

Education in Saxony.—Up to the present time the youth of this little kingdom, when apprenticed to a trade, have been left at liberty to forget what they learnt at school. Attendance at Sunday or evening schools provided by the State and charitable societies was perfectly optional. By a law just passed this liberty is abridged, and compulsory attendance at evening schools exacted for a period of three years. This is said to be the first time in the annals of the world that an attempt has been made by a State to extend the education of the humbler classes beyond the merest rudiments, and after they have entered upon the business of life. Saxony, although the best taught portion of Germany, will, by the new law, be more than ever in advance of her sister States.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustration on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Commercial letters, or queries, or replies, are not inserted. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded; and the names of correspondents are not given to inquirers.

[10450.]—**Wet and Dry Copper Assay.**—"Experimenter" must excuse my long delay in furnishing him with the promised comparison between the produce of copper ore samples determined by the "dry way" and that found by volumetric analysis, as like, I believe, many more of "our" contributors, it is only in my leisure time that I can attend to queries addressed to me, and of late that has been scant indeed. However, for the future, I hope to be less remiss. The produce of the following samples has been determined most carefully by the dry Cornish assay, and by titrating with standard solution of potassic cyanide in my laboratory, with the following results:—

Nature of Sample.	Dry Assay.	Wet Assay.	Difference.
	per cent.	p. c.	per cent.
American Regulus...	$59\frac{1}{2}$ = 59·50	61·60	2·10 W—D
Carbonate of Copper	$29\frac{5}{8}$ = 29·625	30·70	1·07 W—D
Slime Ore..............	4 = 4·000	4·34	0·34 W—D
Argentiferous Ore....	$\frac{3}{4}$ = 0·750	1·40	0·65 W—D

"Experimenter" will see from the foregoing table the impossibility of fixing any definite ratio of difference between the two systems of assay, as, in fact, they are not comparable. Should "Experimenter" require any further information which it is my power to afford him, it is his with pleasure.—Un Irlandais.

[10501.]—**Water-Power (U.Q.)**—I see your correspondent "K. K." answers query No. 10501, on p. 17, and states that "small turbines are humbugs." As no size is given I cannot say what I should like upon the subject. On former occasions I have ventured to advocate, through your kindness, their more general adoption. There are, I admit, limits to size, as in all classes of machinery, for efficiency. In the absence of any size being given, I venture to say that the far famed turbine at S. Blazien is only 14in. in diameter with certainly a large head, 22 yards; but its calculated power is 40 horse. Those also at Lowell are small, but give every satisfaction; of one in the south of England I know which gives every satisfaction, it being 15in. diameter and gives out 10 horse-power under a head of 45ft., the supply-pipe being 8in. diameter. These are each constructed upon different principles by different makers, and yet are not "humbugs." There are, undoubtedly, many turbines made which, if large or small, are radically wrong in their working, because their construction is faulty. I am sure if a turbine be constructed upon sound principles from, (say) 12in. diameter up to 4ft. diameter, when sufficient water is at command, that their superiority will be found over every other class of motor.—J. G.

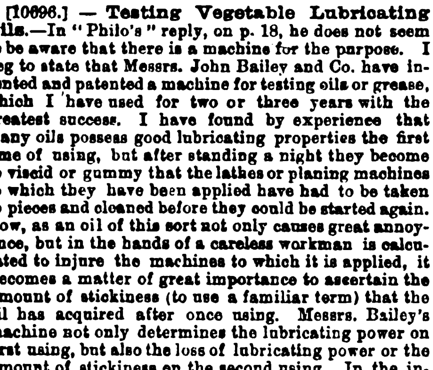
[10556.]—**Jamaica (U.Q.)**—What "No Name" says in his excellent letter on p. 541 of Demerara applies for the most part to Jamaica as well, particularly his remarks on intemperance. I cannot recommend Jamaica to a fortune-seeker of the type of those who go to the "diggings" to make haste to get rich; but to a *bond-fide* settler it offers peculiar advantages, and such a one as "Muscovado," with some capital to start with, would, *cæteris paribus*, in due time rise to affluence, and enjoy an honourable position. I observed that some one else replied to "Muscovado," inviting to a partnership in a turtle-preserving business. I do not know the gentleman, but should think the business profitable. It is a new trade, carried on by only one firm, I believe. There seems to be hardly a limit to the variety of ways of using capital with advantage here. Jamaica is becoming America's tropical garden—a trade in bananas and plantains having just now sprung up, and, considering the enormous demand for these, in a few years, when others besides a few New Yorkers shall have tasted West Indian fruits, there is no fear of the markets being overstocked. Store-keepers, who import, might get good profit, and undersell all others. I fancy that the splendid woods we have are very little known to English mechanics. In pulling down old buildings, I have met with massive timbers as sound as the day they were sawn—perhaps a hundred years ago—and as hard as bone. Many of my fellow-readers, I know, would gladly rescue some of these from the flames or ignominious service. Statistics show that ever since emancipation this colony had been declining until the disturbances of 1866 led to the blessing of Crown government. Now she is rising again, and, in addition to coffee, sugar, and rum, her fertile resources are to be developed with new industries. Some of the planters—good and just men—complain of the precariousness of negro labour ... apply to the Government for coolies. This ... accounted for by the deep-rooted prejudic...

estates' labour amongst many of the people. But I must say that the majority of negroes indulge in the expensive luxury of idleness and rags, and that ministers here, as elsewhere, in proclaiming the Fourth Commandment, do not lay sufficient stress upon "Six days shalt thou labour." Others, again, do not so complain, and prefer the lusty negro to the delicate coolie. It is predicted that this labour difficulty will correct itself in time by the establishment of central factories for the manufacture of sugar and rum, the people growing canes for sale. For other than estates' work there is an abundance of labour at 1s. to 1s. 3d. a day per man. I cannot advise "Muscovado" as to the chance of his finding suitable employment while acquiring experience before embarking capital. This is a delicate matter, and involved with too much responsibility. I see no difficulty if he comes fortified with introductions, nor the least improbability if he come without. He would find us—country people—given to hospitality, and might, with an outlay of £20 for a stout mule and saddle-bags, make a tour of the island at but little expense besides, by being passed from one friend to another, and I should be happy to launch him. I could write much more, but am afraid it would not come within the category of matter of general interest. If I knew "Muscovado's" circumstances—such as age, habits, occupation, whether married or single, &c.—I could, perhaps, serve him further. Will he advertise his address?—Cocoa-Nut.

[10664.]—**Angle of Reflection and Incidence.**—Not having seen any further communication from "A. P. S." I presume he is satisfied with the answers which he has received. I agree with "Lichfield" that the yielding of the cushion is the cause of the deviation. I think "V. B." or myself have mistaken what "A. P. S." means by the angles of reflection and incidence referring to the diagram on page 591. Is not A B E the angle of incidence and E B F the angle of reflection? However, *certum est* that with a gentle blow the ball B striking the cushion in the direction A B is reflected in the direction B F, but with a hard blow will be reflected to the right of the point F. I think your kind correspondent "F. N." is in error when he states that the co-efficient of elasticity is the force of restitution divided by the force of compression, and that the co-efficient of elasticity diminishes with the increase of momentum. This is equivalent to saying that the greater the momentum the greater the difference between the forces of compression and restitution. I think I can prove that when a billiard-ball in motion comes in contact with another at rest the greater the momentum with which the ball in motion strikes the one at rest the lesser the difference between the forces of compression and restitution.—Billiardist.

[10692.]—**Terra Cotta.**—Messrs. Minton, of Stoke-upon-Trent, were the manufacturers of the ornamented columns at South Kensington, not Messrs. Blanchard, as stated in my reply to this query. The designs were furnished by the department.—H. B. E.

[10696.] — **Testing Vegetable Lubricating Oils.**—In "Philo's" reply, on p. 18, he does not seem to be aware that there is a machine for the purpose. I beg to state that Messrs. John Bailey and Co. have invented and patented a machine for testing oils or grease, which I have used for two or three years with the greatest success. I have found by experience that many oils possess good lubricating properties the first time of using, but after standing a night they become so viscid or gummy that the lathes or planing machines to which they have been applied have had to be taken to pieces and cleaned before they could be started again. Now, as an oil of this sort not only causes great annoyance, but in the hands of a careless workman is calculated to injure the machines to which it is applied, it becomes a matter of great importance to ascertain the amount of stickiness (to use a familiar term) that the oil has acquired after once using. Messrs. Bailey's machine not only determines the lubricating power on first using, but also the loss of lubricating power or the amount of stickiness on the second using. In the inclosed sketch, A is a friction drum or pulley of cast-



iron, about 8in. diameter, keyed on a shaft B. C and C' are two clips or saddles of brass, each extending nearly half round the circumference of the drum, and pressed to it with a constant pressure by means of the two weighted levers D D'. E is a thermometer fixed on the top saddle or clip C, and serves to indicate the heat caused by the friction of the drum revolving between the two saddles C C'. The method of using is as follows: The shaft B and pulley A are made to revolve at a speed of 1,800 or 2,000 revolutions per minute, the number of revolutions being shown by a counting machine indicating up to one million, but which is not shown on the sketch to avoid complication. It will be evident that this velocity continued several minutes will generate considerable heat, and that this heat is raised by a less number of revolutions when a bad oil is used than when an oil of superior lubricating power is used. For instance, if it requires 50 revolutions to raise 1 degree of heat in one oil and 100 revolutions in another, it is evident that the quality of the first will only be half as good as the second. Before starting the machine the temperature at which the thermometer stands is noted; this, of course, will be the temperature of the room or workshop. A portion of the oil or grease to be tested is poured or smeared on the friction pulley, and the saddles, with their weighted levers, allowed to press on the drum. The machine is then started and allowed to run till the thermometer indicates a temperature of 200 degrees Fahr. When it is stopped, and the number of revolutions it has made is taken from the "counter," then the number of revolutions divided by the number of degrees of heat that the thermometer has been raised will show its lubricating power. After the first trial the machine is allowed to rest twenty-four hours, and then it is started again without adding any more oil, and without breaking the contact of the saddles with the drum. The number of revolutions of the drum is again taken, and divided by the number of degrees of heat raised in this second trial, and if the result is not more than from 10 to 20 per cent. less than the first trial the oil may be considered good. In very bad oils the saddles are found to be so fast glued to the drum that the machine cannot be started a second time, and in some cases it requires considerable force to break the contact or adhesion between the drum and the brass saddles.—F. R. W.

[10731.]—**Fastening Escape Wheel in Lever Watch.**—I am surprised to see "A Yorkshire Pivot" recommending "S. H. L." to solder his colet on the escape-wheel arbor. This is very wrong, and most unworkmanlike. What necessity is there for soldering it on? Why use soft solder in repairing when not a particle enters into the original composition of the watch? The love of solder among a certain class of watch-jobbers is a little too strong. It forms the great mainstay in all their operations—a sort of universal remedy for almost all the ills a watch is heir to. It is a practice that cannot be too strongly condemned. The proper method of putting on a new escape-wheel is to turn the colet on an arbor and rub on the wheel whilst the colet is still on the arbor, as recommended by "Ex-Watchmaker."—West Cornwall.

[10833.]—**Fork and Wedge Motion (U.Q.).**—The following is the description of a "fork-motion" engine built by Stephenson & Co., about 1844, which I saw about six weeks ago:—In this engine the steam-chests and slide-valves are placed on the tops of the cylinders. There are four eccentrics and eccentric-rods, the same as for the "link-motion," only that the ends of the eccentric-rods are formed into large vertical forks, with a notch at the bottom of each. These notches are to take hold of steel pins fixed into the lower ends of two levers, which are fastened on to the ends of a horizontal shaft or weigh-bar, and hanging down (termed the "lower levers"). On the same weigh-bar two other levers are fastened, of the same size as the lower levers, but standing up (and termed "upper levers"). Two horizontal links are attached to the tops of the "upper levers" by steel pins; the other ends of these links are attached to sockets on the ends of the valve spindles. There is another weigh-bar with lifting arms at right angles to each other, with four suspending links from the ends of the lifting arms to the ends of the eccentric-rods, and an arm and rod from the weigh-bar to the reversing lever on the foot-plate. The effect of putting the reversing lever in "forward gear" is to turn the weigh-bar quarter of a turn round, and, with two of the suspending links, to raise the two forward eccentric-rods, till the forks take hold of the steel pins in the "lower levers," and, at the same time, the other two suspending links lower the backward eccentric rods, so that their forks are clear of the pins. The forks take hold of the pins in the lower levers, and make them move backwards and forwards, and with them the weigh-bar and upper levers, and they communicate the motion to the valve spindles, through the horizontal links. The motion being taken from the forward eccentrics, the engine will run forward the same as in "link motion." The "upper" and "lower" levers, being the same length, the travel of the valve is the same as the throw of the eccentric. The horizontal links are to allow for the oblique motion of the "upper" levers, which move in the arc of a circle, and the valve spindles move in a horizontal position. If the reversing lever be put in "back gear," the weigh-bar with the lifting arms will lower the two forward eccentric-rods, and lift up the two backward eccentric-rods (just the reverse of forward gear). The forks of the backward eccentric-rods now take hold of the steel pins, and only with this difference that as the motion is from the backward eccentrics the engine runs backwards. If the reversing lever be put in the middle, or "out of gear," the weigh-bar will only turn one-eighth round, and the effect is that none of the forks take hold of the steel pins, so that no motion is given to the valve spindles, and of course the engine remains stationary. This motion is going out of date, and soon there will be none to be seen. There is a great fault in it—which is, that if a driver sees danger ahead he dare not reverse the engine, as, if he did, the forks, suddenly taking hold of the pins, will break the pins and forks. It was a good motion, before the "link motion" was invented. Your readers will see the difference between the simplicity of the "link motion" and the complications of the "fork motion."—C. E. S.

[10841.]—**Radius of Surface of Object-Glass.**—In reply to Mr. Cash, p. 43, the radii I gave were for a telescope of 70 inches focal length, as he required. If he grinds his lenses to these curves and has properly determined the refractive indices, the convex lens will have a focal length of 25·48 inches, and the convex of 40·02. I cannot answer for the accuracy of Mr. Cash's own work, but if he finds, upon testing his object-glass, that the colour is not quite corrected, he may, perhaps, mend the matter by slightly altering one of the inner surfaces, providing, of course, that the alteration will not affect the correction for spherical aberration to a noticeable extent. If Mr. Cash can depend on grinding his curves to a great nicety, he had, perhaps, better determine this important quantity with all possible accuracy, and I will find time to go over the figures again for him with the corrected number, so that he may commence his work with a fair start. I do not know where he finds that Herschel recommends that the ratio of the focal lengths in the Huyghenian eyepiece should be as 3 to 2, but this proportion will do as well as that of 3 to 1, which ratio he does say they should have; and, indeed, Mr. Cash need not be very particular in this respect, but to make the eyepiece achromatic it is indispensable, if made of the same material, that they should be placed at a distance from each other of half the sum of their united focal lengths. The lenses are generally plano-convex, with their convex sides towards the object-glass, or crossed lenses of very unequal radii, but Airy says that the field lens should be a meniscus, radii 11 : 4, with convexity towards the object-glass, the eye lens a crossed lens radii 1 : 6, with the most convex side towards the field lens. In some of the eyepieces fitted to my own telescope, the field lens is a meniscus, and the eye lens a plano-convex, and they seem to perform very well, better, certainly, than some which I have with plano-convex lenses. For the purpose of testing his object-glass, however, I should recommend Mr Cash to get an eyepiece which he can entirely depend on; it may, perhaps, save a great deal of trouble.—Henry T. Vivian.

[10853.]—**Textual Revision of New Testament (U.Q.).**—The ancients had no pedantic rules about varying the forms of letters. Each letter had but one form throughout the same manuscript or inscription; the writing-masters' pedantry to make certain letters differently when ending a word began probably among Jews or Arabs of the middle ages; and European scribes, by the time printing arose, had made it a rule for their *s* (whether Greek or Latin) to be thus varied. To understand how such niceties really aided reading, we must remember that till the fifteenth century no one had thought of leaving more space between words than between letters of the same word. This invention supersedes many expedients that were introduced to mark off the length of words. We got rid, about a century ago, of the two *s*'s by making our medial like our final one; and Tischendorf, by a contrary course with the two sigmas, merely follows suit, and relieves his printers of a bit of useless pedantry.—E. L. G.

[10857.]—**Imitation Marbles, &c. (U.Q.).**—"Plaster of Paris, quicklime, salt, ox blood, stones of different colours, also pieces of glass, all beat to powder, and mixed up to the consistence of paste with vinegar, beer, or sour milk, and then lay it into tables, pillars, or what you will; let it stand so long till it is thoroughly dry; then rub it first with pumice stone and polish it with tripoli, giving it the finishing stroke by rubbing it over with leather and oil." The above is a quotation from an old work.—Schoolboy.

[10859.]—**Wheel Cutters.**—The shape of the cutters vary with the shape of the teeth of the wheels to be cut. Pinions, or small wheels, require a cutter for nearly every different number of teeth in the pinion; wheels, or those with large numbers of teeth, one cutter will serve the purpose of cutting many wheels varying from 7 to 20 teeth, although strictly correct only for the one for which it was purposely made. To describe the various forms of teeth used would require a long article, which perhaps "our" Mr. Editor may not care to allow the space for.—Tubal-Kain.

[10883.]—**Rust in Iron Vat.**—The salt crystallised is nitre; there are small traces of muriates and sulphates.—R. J.

[10889.]—**Rose Trees.**—In replying to this query I undertook to affirm something which I beg leave to withdraw from. I find that nurserymen do supply "dwarf" roses which are merely budded on short stocks. Under these circumstances definitions are in a state of fog.—Saul Rymea.

[10889.]—**Rose Trees.**—What is a dwarf and what is a standard rose tree? These names refer entirely to the height of the tree, and have nothing whatever to do with the rose tree being budded or grafted, or on its own roots. A rose tree budded or grafted on a short stock a few inches from the ground is equally a dwarf with one on its own roots the same height. Also a rose tree on its own roots with a single stem 3ft. or more in height, is equally a standard with one of the same height that may be budded or grafted. "Saul Rymea" (p.18) may depend that if an order is sent to a nurseryman for dwarf roses he will be more likely to send budded ones than those on their own roots.—T. M.

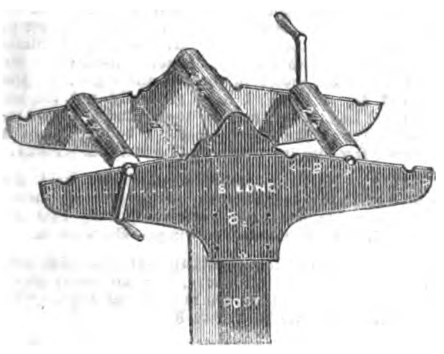
[10913.]—**Screw Cutting (U.Q.).**—Where the screw to be cut has an unequal number of threads it is a difficult matter to stop the lathe and wind back the saddle by hand to meet in the thread partially cut; for short screws time would be saved in having a reverse motion to the lathe. The wear of the lathe would certainly be increased, but that would bear no comparison with the time saved.—Tubal-Kain.

[10917.]—**Power.**—"Undecided's" description of his shafting and gearing seems a roundabout way to apply the power from a steam engine to a single machine. If he can drive direct from the engine shaft to the machine, there would certainly be a great saving of friction, say, (1) horse-power of engine, (2) horse-power required to work the machine, (3) number of revolutions of engine per minute, (4) revolutions of machine per minute, (4) diameter and breadth of pulley on machine, (5) and what is the largest diameter pulley admissible upon his engine shaft.—Tubal-Kain.

[10930.]—**Want of Steam Power.**—I should advise "Agri" to direct exhaust pipe into chimney, and it would cause more draught; if it does not answer after you direct exhaust pipe into chimney, you should make your slide valve longer by putting an eighth of an inch both ends of the slide, or a quarter of an inch. I shall leave the size for you to choose for yourself, it would make the engine run a trifle faster and will not burn so much coal. If you do not like to take the slide out and alter it yourself, let a mechanic do it for you, and you will never regret the outlay. I have altered five or six, and they give the greatest satisfaction, and consume less coal, but if you should feel inclined to do it yourself, I will give any information you should require. A larger fly-wheel on the engine would increase the speed, but it would be expensive; the fly-wheel on your engine is heavier than engine makers use for your power engine; you can work your engine to 80lb. pressure with safety.—F. T. S. S. D.

[10968.] — **Brazing Fishing-rod Ferrules** (U. Q.).—After cutting to size, bring the edges flush, confine with some very fine iron tie wire; rub a piece of borax on a piece of slate, with a little water, until the consistency of cream. Mix it with a small quantity of spelter, lay it down the seam, hold the ferrule over a forge fire; do not let the ferrule touch the cinders or the brass may collapse; as soon as the spelter runs, remove, or your ferrule will run too. You can do them in a kitchen fire if made bright; coke must be used broken small.—Never Rust.

[11009.]—**Bending Tires.**—I once saw a very simple tire bender, of which I send a description; it consists of two iron plates of the shape shown, bolted each side of a post about 7in. thick; and three rollers, the top one fixed, and the others loose to place in the different bearings; for various sized tires, the



end of the tire must be bent with the sledge for the first bite. The two loose rollers must have one of their gudgeons brought out to a square for fitting on a pair of winches. Each journal is ½in. lower than the other, from the middle.—Anglo-American.

[11028.] — **Pocket Aneroid Barometers.**— "Campanile" wants more than the instrument will yield. Mine has accompanied me over many of the Welsh mountains, and I have been able to measure to about 10ft. by it. An ascent or descent almost unappreciable to the eye has been duly marked by the aneroid, but so small a difference as a yard is not to be determined by it. Nevertheless, I find my aneroid a very useful and interesting travelling companion.—J. A.

[11120.]—**A Question of Sight.**—I shall esteem it a favour if I am allowed to refer to the second part of "E. L. G.'s" answer (p. 674), in which he says—"After sunset we continue as before to see the mass of air that the solar rays penetrate above and around us, and call it sky." Does our friend and instructor mean to say that we cannot see light by day beyond the mass of air that surrounds the earth, and that the cause of darkness by night is because there is no matter to reflect the sun's rays? When I look at the blue expanse by day the light seems infinite, through space. What, then, becomes of this illuminated space beyond our atmosphere, and how is it we cannot see it by night illuminated as by day? I dare say the answer is very simple; will some one please inform an ignorant—Fiddler.

[11128.]—**Lantern Pinions.**—I will not be so rude as to flatly contradict "J. K. P.," but I think if he will kindly look into this matter again he will find that I am correct. The word "trundles," in my first reply, was, by mistake, printed "trussells." That is a slight mistake, possibly caused by my writing not being over plain, so that "J. K. P." will kindly overlook that admitted error; I saw it, but did not consider it necessary to send a notice at the time for its correction. "J. K. P." admits that I am right in saying the pitch should be the same. I did not give any diameter for the pitch circle. I will now do so, taking his number and pitch. I make it for 6 teeth × 1in. pitch = 2in. diameter. He will, therefore, please not confound "pitch" with any term I did not mention. To explain the rationale. It is generally expressed by mathematicians that the relative velocities and revolutions of any two wheels (bevil or spur) are to each other in strict proportion to their diameters and circumferences at the pitch circles. So they are, if the teeth were, so to say, innumerable. Take, for example, a pinion of 6 teeth × 1in. pitch, by the circumferential measurement, would be about 1·91in. diameter, and a wheel of 60 teeth × 1in. pitch would be about 19·10in. diameter. To make a wheel and pinion of these diameters and numbers, supposing 1in. pitch, the pinion would be too fine in the pitch for the wheel; or, what is the same, expressed in other words, the wheel would be too coarse in pitch for the pinion. The pitch of pinion would be about ·950in., and the wheel about ·9995in. It will then be proper to assume wheel and pinions to be polygons, and the pitch to be the side of the polygon, with the number of sides corresponding to the number of teeth, and the pitch to be the distance from centre to centre of the teeth in the pitch circle. In this case, the circumscribing, or pitch circle, of a pinion of 6 teeth × 1in. pitch would be 2in. diameter, and that of the wheel 19·108in. diameter. For wheels with comparatively large numbers of teeth, when working into each other, the "diametrical" pitch, as it is termed, will answer all ordinary purposes, and is a much more accurate mode of measurement for very fine pitches, but it will not do for large or heavy gearing, or for wheels usually employed in engineering and mill work, and of unequal numbers. I write from experience and daily practice, and I again repeat that the pitch of the "trundles," or the distance of their centres, or, putting it this way, from centre to centre of the trundles, should equal the pitch of the wheel into which they are to gear. These lantern pinions require a peculiar form of tooth in the wheel, not such as is now generally made, but one of a "bay leaf" form as they were anciently called by the then workmen. It is, however, a kind of gearing so seldom met with in general use that it will be unnecessary for me to prolong this letter. The length of the tooth is the reverse of that where ordinary wheels and pinions are now applied. It is longer from the pitch circle to the point than it is from the pitch circle to the rest, and the curve is formed by rolling a circle of equal diameter to that of the pitch circle of the lantern pinion, upon a circle of the diameter of the pitch circle of the wheel. Allow me to suggest to those who are willing to become acquainted with the theory of the teeth of wheels to consult "Camus on the Teeth of Wheels." What I have termed "trundles" are also, in mill work, known by the names of "rungs" and "rounds."—Tubal-Kain.

[11157.]—**Stearine.**—As neither Richard H. Garth nor "Jack of All Trades" has responded to this query, perhaps it may not be out of place for me, as a person of some experience in this branch of business, to ask "A Puzzled Subscriber" what kind of stearine he has got? also to what use he intends the oil to be put after it is pressed? is it lard stearine or stearine from tallow, olive, or palm oils? or is it stearine from any of the hundred and one greases that are recovered from soapy suds? Reliable information on questions of this kind is not to be got. If "Puzzled Subscriber" is in the trade let him get a man of practical experience, and he will put him all right. As to the other part of the query "the best method of pressing," there is only one method that I know of, and I have been in the business for seventeen years. If a "Puzzled Subscriber will advertise his address in the English Mechanic I will be happy to communicate with him on the subject.—John Murray.

[11168.]—**Wood Rods.**—Many thanks to Samuel Smither for his kind offer of sketch of cutter, and shall be glad to see it. I have an ordinary foot lathe to which I hope to fix it. If it is not asking too much would he give a sketch of a witchet, which was recommended for the job by "J. K. P." in No. 364?—Joiner.

[11188.]—**Arithmetic.**—I remember some volumes back a host of letters were written upon the subject of abstract and concrete multiplication. Would not some correspondents who are now writing upon this subject do well to read those letters? This is only a suggestion, but, if acted upon, would probably save our nerves, for it makes one nervous to read rubbish. Would it not save some words—strong ejaculations—also?—C. H. W. B.

[11192.]—**Chemical.**—If the salt mixed with nitrate of potash be really carbonate of potash it is very easy to separate the greater part of the nitrate, as the latter requires 7 parts of water at 60° Fahr. for its solution, whereas the carbonate of potash is a deliquescent salt dissolving in 1 part of water. In this case the liquid should be concentrated by boiling, and set aside to cool, when the greater part of the nitrate of potash will crystallise out. These crystals may be quickly washed with pure water, redissolved, and recrystallised. If this be done two or three times the crystals may be obtained almost chemically pure. Should the salt be the bi-carbonate of potash the difficulty would be much increased, as it is not a deliquescent salt and requires 4 parts of water at 60° Fahr. to dissolve it. Unless the quantity be very large it is not worth the trouble of trying to separate the salts.—A Barrister.

[11208.]—**Incubator.**—In reply to "M. O." the arrangement was designed for my own use in an experiment requiring a constant heat. As I gather from "M. O.'s" letter that he has but a poor opinion of it I should be much obliged if he would kindly point out the defects. I should be sorry to be the means of misleading other readers.—Shylock.

[11246.]—**Diamond Fields.**—As I have a brother in the neighbourhood of the diamond fields, with whom I am in constant communication, I am enabled to give "Digger" the following information, which may be of some use to him:—The Natal route is undoubtedly the best, as besides being shorter the roads are much better. The winter season commences about April or May; it is by far the pleasantest part of the year, indeed, it is described as surpassing the summer of Baden-Baden. I should certainly take a gun, as in case he wished to dispose of it he would find it readily saleable at a remunerative price. "Digger" could obtain employment at the diamond fields easily, but the wages would be so low as to merely form a subsistence. Kaffir labour being so cheap in South Africa (about 10s. a month, and food, which consists almost entirely of maize, or, as they call it, "meale" porridge). Steamers are run twice a month by the Union Steamship and Cape and Natal Navigation Companies, both advertised in the *Times*; steerage fare is £20, length of passage forty-two days. He would get much information from the *Natal Mercury*, received in England by every mail. If he sends his address and 7d. in stamps to Street's Colonial Newspaper Office, London, they will forward it him.—Zulu.

[11249.]—**Concrete Buildings.**—See letters.—Ed.

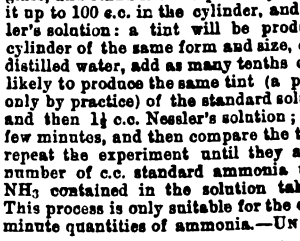
[11265.] — **Drawing a Boundary Line.** — "Thetamu," in his answer to this question (on p. 47) has not stated whether his boundary line is to be shifted from B or A only, or equally from both. In either of the first cases he is right; but in the other it would only require to be shifted half the quantity, as he soon would find out, on adding and subtracting this amount to the different offsets.—W. Hughes.

[11287.]—**Annuals.**—In addition to those named, I would add *Saponaria Calabrica* (red), and *Sap. alba* (white). The former is the most effective, and for growing in a mass, it is inferior to none.—Irish Mechanic.

[11294.]—**Dividing Metal Disc.**—No diagram is needed to show the simplest solution of this and all similar problems; and with a straight edge and square, it need involve no more openings of the compasses than there are circles. Carry the radius of the outermost round it, so as to make six equidistant marks A B C D E F. With the straight edge, join any two, neither adjacent nor opposite, as A C. Then a concentric circle touching the line A C will be half the radius (and a quarter the area) of the outermost. With the straight edge and square make a perpendicular to A C, touching this inner circle, and through the meeting of this perpendicular with A C, draw a second circle, which will contain twice the inner one. Again, make a perpendicular to A C, touching this second circle, and through its meeting with A C draw a third, which will be twice the innermost. Thus your three rings and disc, all of equal weight, are produced. It would not be worth while to print "mathematical proofs," which "Disc" had better discover for himself, from the first book of Euclid, which will enable him to see the four radii thus obtained are necessarily as 1, $\sqrt{2}$, $\sqrt{3}$, 2.—E. L. G.

[11304.]—**Nessler's Ammonia Test** is prepared by taking 8·5 grammes iodide of potassium, and dissolving it in 10 c.c. of water, 1·6 grammes mercuric chloride disolved in 30 c.c., and adding this last solution to the first until a permanent precipitate is produced. Then make up to 100 c.c. with solution of potash, and filter. In order to use it for the estimation of ammonia, a standard ammonia solution will be required, prepared by dissolving ·315 grammes in a litre of distilled water free from NH_3, 1 c.c. of this solution equals one-tenth of a milligramme NH_3. Place the solution to be tested in a cylinder of pure colourless glass, and stand it on a perfectly white surface, make it up to 100 c.c. in the cylinder, and add 1½ c.c. Nessler's solution: a tint will be produced. In another cylinder of the same form and size, containing 100 c.c. distilled water, add as many tenths of a c.c. as will be likely to produce the same tint (a point to be learned only by practice) of the standard solution of ammonia, and then 1½ c.c. Nessler's solution; allow to stand a few minutes, and then compare the tints. If not equal repeat the experiment until they are, and from the number of c.c. standard ammonia used calculate the NH_3 contained in the solution taken for analysis. This process is only suitable for the estimation of very minute quantities of ammonia.—Un Irlandais.

[11308.]—**Geocentric Longitude and Latitude.**—The following is the manner of obtaining the geocentric longitude and latitude from the heliocentric ones. The formulæ given last week by "Chronos" (p. 48) only indicate the connection between the two sets of geocentric co-ordinates. Let E be the earth, S the sun, P a planet, A the first point of Aries, or the vernal equinox, and E p S the plane of the ecliptic. Then A S p will be the heliocentric longitude, A E p the geocentric longitude, P S p the heliocentric latitude, and P E p the geocentric latitude. Call the two latter quantities L and l respectively. Then, from A S p and P S p, supposed to be given, we have to deduce A E p and P E p. Besides the given quantities, we must find the length of ES and p S. We can do this by the help of the *Nautical Almanac*, E S being the radius vector of the earth, and p S that of the planet $\times$ cos. L. We next arrive at the angle ... from the consideration that it is the difference



heliocentric longitudes of the planet and of the earth, the latter quantity being the longitude of the sun (given for every day in the *Nautical Almanac*) added to 180°. Therefore, in the triangle E S p, we now know the two sides E S, p S, and the contained angle E S p, called the angle of commutation. We can thus readily obtain the angle p E S, or angle of elongation; which, added to A E S, the longitude of the sun, gives the geocentric longitude of the planet. To find the geocentric latitude, we have:—

$$P p = E p \times \tan. l = S p \times \tan. L.$$

$$\therefore \frac{\tan. l}{\tan. L} = \frac{S p}{E p} = \frac{\sin. p E S}{\sin. p S E}.$$

$$\text{And } \tan. l = \frac{\sin. p E S}{\sin. p S E} \tan. L.$$

—V. B.

[11309.]—**Breaking-Strain of Hollow Iron Columns.** — The breaking-weight is found thus (Molesworth 1):—

For flat ends, W = 44·34.
For round ends, W = 13.

$$\frac{D^{3 \cdot 55} - d^{3 \cdot 55}}{L^{1 \cdot 7}}$$

D = outside diameter.
d = inside diameter.
L = length.

Or, by Lowndes, thus:—

$$\frac{(\text{Diameter in inches})^{3 \cdot 6}}{(\text{Length in feet})^{1 \cdot 7}} \times 44$$

for flat ends, and 15 for round ends. The strength nearly equals the difference between that of two solid columns, the diameter of which equal the internal and external diameters of the hollow one.—Eureka.

[11334.]—**Squinting.**—As it is probably only one eye that is weak, let "G. W. F." cause his little boy to wear spectacles with the glass next the weak eye covered with paper with a small hole in the centre, so that the eye, in endeavouring to see through the small hole, will pull itself straight. The spectacles should be mere preservatives, or they themselves would affect the sight. Indeed, if it were my own case, I should pull the glasses out altogether, and substitute cardboard with holes pierced exactly in the line of sight. There is a difficulty in making the child wear them, as they restrict the vision; but it is well worth persevering in, the results are so important. The expense is trifling, the trouble a labour of love, whilst a cure would be a joy for life.—J. H., Lancaster.

[11337.]—**Equation.**—The given equations are formulæ of the *arithmetical progressions*, and solution of them can be found in many authors of algebra.—Bernardin.

[11339.]—**Astronomical.**—The reason why the polar star does not change its situation is because the earth's axis in all parts of her orbit is constantly directed towards the same part of the heavens. The greatest difference in the position of the earth is the diameter of her orbit, and of course this is also the width of the parallel lines that may be drawn through the axis of the earth from the opposite parts of her orbit. From this we infer that either the poles have some slight deviation to that point of the heavens, or more probably that the polar star is fixed at such an immense distance that the difference in the earth's position produces no perceptible effect. If the polar star was nearer it would appear to describe a small circle in the heavens with the annual revolution of our earth.—C. W. H.

[11353.]—**Distilled Water.** — Chemically pure distilled water is absolutely pure, and contains nothing but oxygen and hydrogen. Ordinary water has multitudinous impurities, organic and inorganic, and is unfit for chemical manipulation, though more fit in general for drinking than the former, which is insipid and nauseous.—M. A. B.

[11357.]—**Berlin Black.**—Take 1lb. of drop black and ½lb. of Prussian blue; grind well down with turps, mix with turps to the consistency of paint, then add copal varnish to the gloss you require. A little sugar of lead will make it more adhesive.—G. Asher.

[11358.]—**Pressure of Water.**—Multiply the height of the top cistern in feet by ·4335, or divide the height in feet by 2·307, will give the pressure in pounds per square inch. R. Irons must be a dull scholar not to understand this. This is the theory, and for still water. But if the water is flowing due allowance must be made for the friction of the water in the pipe; also, that the pipe, or draw-off cock, from the under cistern is not too large to reduce the pressure therein. —Tubal-Kain.

[11359.]—**Casting Brass Solid.**—Dry your mould well, torch it if you can get at it with resin in a ladle, or dust well with blacking, and blow it well out again. Have two runners to the object, one to let the metal run in, and the other to let the air run out, and do not have your metal too hot. You can have your metal of what composition you like, from 1 of copper to 3 of spelter and upwards.—G. Asher.

[11359.]—**Casting Brass Solid.**—If about 1lb. of lead be added to 16lb. of old brass, when just at the melting point, solid brasses will be the result. In melting old brass, the zinc, or lead contained in it (when fluid) oxidises freely, consequently the proportions of the metal are altered, and require an addition similar to the above. If the brass has not been recast a little less lead will do, but if recast several times it may take the full quantity.—Novice.

[11362.]—**Silver Tubes for Meerschaum Pipes.**—Having made the silver tube to the gauge of pipe-stem and mouth, soften the silver tube by heating it to nearly a red heat (just below fluxing point), and plunge it at once into a silver pickle bath. Then, with a wooden mallet, and piece of bent half round iron or steel bar to size fixed in a vice, hammer to shape required. If it harden before it is properly shaped repeat the softening process and finish. Any shape, curve, or taper may be got by bending and shaping iron or steel rod to form the pattern or stake to hammer upon.—Practical Horologist.

[11362.]—**Silver Tubes for Meerschaum Pipes.** —Silver ferrules may be curved the same as any other metal by filling them with lead; have a pin of stout wire something smaller than the ferrule inside the lead, will serve to hold while bending; make a hole in a piece of wood, take off the sharp edges as if it had been countersunk, and bend to the curve required.—Never Rust.

[11364.]—**Lettering the Backs of Books.**—W. Stead will have to procure the irons necessary for this purpose. Those for lettering are simply punches with letters on the ends; others are made with various devices. These irons must be heated pretty hot, but by no means red hot, and wiped quite clean. A little finely-powdered rosin is then dusted on the leather, on which gold leaf is laid. The hot punch is then applied with firm pressure, by which the rosin is melted, forming a cement which retains the gold in the required form. The superfluous leaf is then wiped off. He had better, also, search old volumes of "our" paper.—V.

[11365.]—**The Wind.**—The south-west wind is the most prevalent; the average number of days the wind blows from this quarter is 114, the next being west, with 52 days. The above values are from Mr. Glaisher's paper on the "Direction of the Wind, 1861 to 1870," in the "Proceedings of the Meteorological Society," Nov. 1871, to which I would refer "Anemometer" for further information on the same subject.—W. N. M.

[11365.]—**The Wind.**—In an old weather book I find the wind blows the following average number of days:—N. wind 42 days, N. W. wind 33 days, W. wind 77 days, S. W. wind 58 days, S. wind 33 days, S. E. wind 26 days, E. wind 58 days, N. E. wind 43 days.—Monte Cristo.

[11369.]—**Etching Steel.**—Nitric acid or nitro-muriatic acid.—Philanthropist.

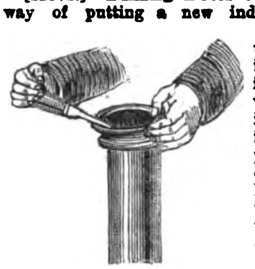
[11369.]—**Etching Steel.**—Dip the end (say one inch) of your spring in melting beeswax. When coated and cold make a hole in the wax with a fine-pointed needle down to the steel the size you require; put a drop of strong nitric acid on it, after an hour rinse off, and apply again; it will gradually eat through.—M. A. B.

[11371.]—**Steel for Lathe Tools.**—"L. S." will find economy in buying the best cast steel of any size. I should think ⅝in. and nine-sixteenths of an inch square would suit him for heavy turning tools for steel or iron, and ⅜in. to ¼in. for brass. The best way for him would be to go to one of the warehouses and look over their stock of odd lengths, and take any that look likely. The standard size—*i.e.*, Holtzapffel's for ornamental slide tools is about $\frac{11}{32}$in. × $\frac{5}{32}$in., or, say, nearly 35 × 15 hundredths. The fly and eccentric cutters are much smaller—viz., 21 × 11 hundredths. Marshall's steel, which comes really from Vickers, Sons, and Co., Sheffield, is good, but I learn that Vickers's XXX is a great deal better if you can get it. Stubs's are first-class, and to my notion Sanderson Brothers are as good as any I ever had. Buck, of Newgate-street, keeps them in all sizes, and Moser, High-street, Borough, all sizes. I used to get Stubs's at Greenfield's, in Broad-street, Soho, and Hedgecock and Cotton and Johnson, in Soho, keep Marshall's, for which now 1s. per lb. is charged for small stuff. Excellent steel is kept also at a shop in the north-west corner of St. John's-square, Clerkenwell, and all sorts of odd sizes at Mrs. Gray's, Clerkenwell-green, close by the Church. It is convenient to have by you a piece of steel that you can cut off in short lengths for making screw-dies. Also some for cutters to fit the different sized boring bars and countersink cutter bars. The better the steel looks outside—*i.e.*, the more carefully rolled round or square, as the case may be, the better chance there is of good inside; don't take any that has any external symptom of a crack, or that is much out of truth in respect to breadth of sides or squareness of edges, and the straight pieces will not require so much "setting" as the crooked ones. You will, of course, take care not to be at a loss for any square size under ⅝in., or any round under 1in. I generally have it cut in lengths of three or four feet. I don't see how you are to mend a broken casting; the only way out of your difficulty seems to be to drill and tap the screw hole a great deal deeper, so as to get down to solid metal, and fit another and a longer screw. I set my face against screws being such tight fits; but I suppose if slack fits were allowed in that nothing else would ever get fitted properly.—J. K. P.

[11371.]—**Steel for Lathe Tools.**—Better order direct from a good maker in Sheffield, and have best quality silver cast steel. State the purpose for which you require it to the maker, and he will fuse the mixture accordingly.—Tubal-Kain.

[11373.]—**History of England.**—"Ince's Outlines of English History" possesses considerable attractions for young pupils.—Excelsior.

[11374.]—**Fixing Belts on Tires.**—The readiest way of putting a new indiarubber tire on the intermediate wheel is to use a small post driven into the ground or fixed in a vice, the top end of which should just fit the inside of wheel, which is thus held in a steady position. Place one edge of the tire on the wheel, holding it firmly with the left hand, insert a turnscrew, as shown in diagram, and pull it round the wheel, which will stretch the tire sufficiently to snap it on. I do not think it worth while for "Blacking" to try and mend old tires.—F. T. S. S. D.



[11376.]—**Marble Busts.**—Warm water, soda and soap, using a brush where necessary; well rinse with clean water, leather off and finish with clean soft rag; if any stains remain make a strong solution of soda or potash, add soft soap, and a little lime or whiting to make a paste; apply to stains, let it be a day or two, then wash as before.—F. H. Saunders.

[11376.]—**Marble Busts.**—Let "M. B." wash the busts with turpentine, applying same with a sponge.—Wee Pet.

[11378.]—**Killing Beetles.**—The best way is to drown them in spirits of turpentine or in spirits of ammonia fortis (amm. spir. fort.)—Wm. Fred. Trinder.

[11378.]—**Killing Beetles.**—Put them floating on beer and sugar mixed in a soup plate, they will die drunk.—M. A. B.

[11378.]—**Killing Beetles.**—For killing beetles, &c., without injury and also without pain, I have always found the following method to be very successful. Get a circular wooden box with a lid that fits moderately tight, such as is usually obtainable at the druggist's, and used for holding violet powder and a puff, then line it throughout with tin foil to prevent evaporation. Then cut a circular piece of cotton wadding to fit the bottom of the inside of the box, then lay on that a disc of perforated zinc or of fine wire gauze to prevent the feet, &c., of the beetles or other insects from getting entangled in the fibres of the cotton. The box is now ready for use. To use it, saturate the cotton wadding with methylated chloroform, cover it with the disc of metal, then place the beetle or other insect in the box and shut it in and leave it for a time. I have generally put the box away for half a day, and on re-opening it I have invariably found the insects dead. I believe there is a perfect freedom from pain by this method.—Yoiza.

[11378.]—**Killing Beetles.**—Carbonic acid gas is used to destroy large moths; perhaps it may answer for beetles. It produces death so quickly that the moths often die with extended wings.—Excelsior.

[11380.]—**Sand for Casting.**—If you reside near a town where there is a foundry, you can easily ascertain where the sand they use is obtained from. "Go thou and do likewise."—Tubal-Kain.

[11380.]—**Sand for Casting.**—"Leonidas" must understand that the same sort of sand used for iron will not do for brass. To make good work, sand for iron should be fine and loamy, but not clayey, such as Mansfield sand. It should be rubbed and well mixed with a little charcoal dust, and used not too wet. When the mould is made, dust over with a slight dust of real yellow loam sand, and then with coal dust or blacking; put your pattern in again, it will make a flux and a print. For brass the sand should be a deal closer and tougher, and should be dried and torched, as it strikes so in damp sand; Moxley is the best sand for brass.—G. Asher.

[11382.]—**Parrot.**—Your bird either has vermin or requires vegetable food, sunshine, and open air; for the former take the head into your hand to protect the eyes, and blow fine snuff through his feathers, and sink the cage for an hour in boiling water. For the latter give a green or dry pepper pod, any kind of nuts, and a bit of apple or softer fruit occasionally, so as to scour gently. A warm bath submerging the body for a minute or two, and the head for a second or two before the application will make the snuff stick better and make the bird healthier; put some bruised aniseed at the bottom of the cage.—M. A. B.

[11382.]—**Parrot.**—"Cygnus" must give his bird a little flowers of sulphur (judge the quantity for himself) with its food, and avoid hemp seed, also sugar; both are very heating to the bird, and will cause it to pick off its feathers. I learnt this recipe from a dealer in birds in the Brazils some years ago, and have never found it to fail in many diseases parrots are subject to. —F. L.

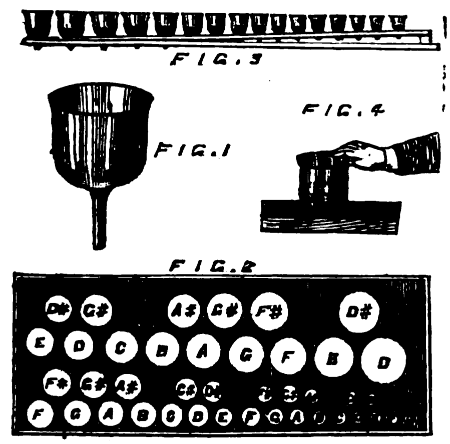
[11384.]—**Small Pox: Its Prevention and Cure.**—Phenic acid is another name for carbolic acid. —A. P. S.

[11384.]—**Small Pox: Its Prevention and Cure.**—In Bloxam's "Laboratory Teaching" phenic acid is described as being the same as carbolic acid. Liquid carbolic acid is usually met with as a brownish or brown liquid, having a powerful smell of tar. When poured into water, it sinks to the bottom. It is also found in moist needle-like crystals, colourless or pale brown. Very easily melted. Water dissolves it sparingly. Easily soluble in potash. Alcohol dissolves it readily.—V.

[11387.]—**Sundials.**—The gnomon has an angle of elevation equal to the complement of the latitude, or what the latitude wants of 90°.—Philanthropist.

[11388.]—**To Mr. Fennell.**—The organ alluded to, formerly contributed by me in the *British and Foreign Mechanic*, March 5, 1870, p. 595, is in no wise connected with the section which appeared in these pages. As the section sent was partly arranged by me from a small organ in the church of S. Bartholomew-the-Less, St. Bartholomew's Hospital. The design alluded to in the *British and Foreign Mechanic*, was not only designed but made by me, and is now in my possession, and as I formerly mentioned, I do not intend to introduce pipes lower than tenor C, as probably I shall descend to C C C C in the lower scale on the harmonium principle. The dimensions I will furnish: height, 8ft. 9in.; frontage, 5ft. 3in.; depth, 2ft. 6in.; height of keyboard, 2ft. 6in.; compass of keys, 3 octaves—viz., C C C up to F, the soundboard is pierced for 362 pipes, the remaining will have pedal arrangements. The dimensions given are not for the section, but my own instrument.—Joseph William Fennell.

[11393.]—**Metallic Harmonicon.**—I suppose "Valve" means an instrument which is played by striking strips of metal or glass with pieces of wood in the same manner as playing a dulcimer. I once bought one, the notes of which looked like gun metal, but after using it awhile I found out that the notes were glass covered over with bronze. Since then I have made one of glass, having five octaves with all the half notes. Each note is got by cutting pieces of glass into strips of different lengths, the notes he tunes by breaking small pieces off the ends with a pair of pinchers. An immense quantity of glass is used, or rather wasted, in obtaining these notes, as the least variation in the thickness of the glass will cause the notes to be wrong, whether it is the right size or not. If "Valve" intends constructing a musical instrument, and is not particular as to expense, let me recommend him to make, or rather put together, the following. Its name I never heard, and this one was constructed by my father many years since, and as far as I know cost a lot of money. It consists of a series of glass globes, similar to an inverted aquarium (Fig. 1), only instead of a knob as on an aquarium glass there is a tang, varying in accordance with the size of the globes. Some of these globes are as small as 1½in.



diameter, and others as large as 8in. diameter. They are arranged in proper order (Fig. 2) in a shallow box about 4ft. by 2ft., which is ornamented to serve as a piece of drawing-room furniture. To bring the tops of all the glasses to a level a piece of wood is fastened to the bottom of the box, seen in Fig. 3. Each globe wants to be fixed firm, and where there are any shakers, from the holes being bored too large, a little worsted is bound round the tang and the globe fitted in its place again. To play the instrument: make a concentrated solution of alum, and partly fill each glass; wash the hands clean, to remove all grease, and dip the middle finger in the alum water, and gently run the finger round the top edge of one of the globes (Fig. 4) and it will emit a clear sweet sound such as will never have been heard before, the nearest resemblance to it is the music produced by an Æolian harp. In playing both hands are used. The alum serves in the same way as rosin does to a violin bow, giving an edge, as it were, to the fingers. Now for the great drawback in the above instrument—expense! It will be seen that the least variation in the size or thickness of the glass will cause the notes to differ; so all depends upon the glass-blower, you might order fifty and still not get the note you wanted, and it is there the expense lies. Would pressed glass globes do instead of blown glass? If so, any quantity of one note could be manufactured, and then the great difficulty would be surmounted. If "Valve" wishes to experiment a bit, let him get two or three wine glasses and play them as stated above, and he will see what can be produced. There is one thing I forgot to say, that is, the edges of the globes are rounded and perfectly smooth. If "Valve" thinks of making one his best plan would be to try pressed glass globes; if he does, I should like to know the result; no doubt some of the readers of the English Mechanic, well up in pneumatics and acoustics, would give some improved shape of glasses to produce the required notes.—Zoo Andra.

[11394.]—**Opera Glass.**—If "Inquirer" will say what power he would like in the opera-glass, and whether he wants to know how to make the framework, or how to make the lenses, or both, I will try to help him, though the query is rather strong in its requirements.—W. Oldfield.

[11398.]—**Stinging of Bees, Hornets, and Wasps.**—If "Apiarian" rubs the part stung with a bruised leaf of common house leek, he will have immediate relief, it is equally useful for blistered hands and feet.—F. L.

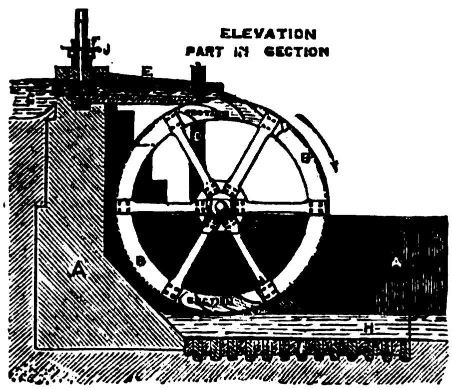
[11398.]—**Stinging of Bees, Hornets, and Wasps.**—In answer to "Apiarian," the first thing he must do is to extract the sting, which can be best effected by pressing the point of a small hollow key on the part, and then removing the sting by a pair of tweezers. Next, a few drops of camphorated spirits should be allowed to run over the stung parts. If this is not available, a little common salt may be rubbed in. (From the "Family Homœopathist," by Dr. Shuldham.)—J. E. A.

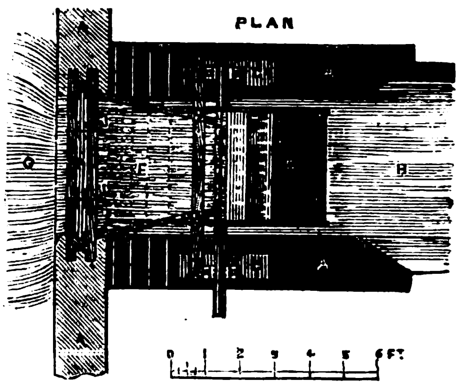
[11398.]—**Stinging of Bees, Hornets, and Wasps.**—Many years ago, in India, I contrived, in the dark, to put my hands on a hornet's nest. I was stung in two places. The pain was fearful. My native servant (a Bengalee) cut a small red onion, or rather several, and kept rubbing the places stung with the cut surface. In about two hours the pain had ceased, and I went to sleep, and (barring a little stiffness in the arm) next morning was not further inconvenienced. Since then I have used the same method for others, with success.—Khoda Bux.

[11398.]—**Stinging of Bees, Hornets, and Wasps.**—If "Apiarian" is going about the bees, let him carry a phial of strong water of ammonia, well corked, and with a camel's-hair brush in it. When stung, put on a drop of ammonia for a second, and wash off. There will be no pain or swelling if immediately applied.—M. A. B.

[11399.]—**Water Power Wanted.**—How many gallons or cubic feet of water per minute can you get, and what fall can you also get, to be applied as a motor? I fear a sketch of a turbine would be of little use to you. Better go to a maker of such if one is applicable.—Tubal-Kain.

[11402.]—**Water Power to Work Saw Bench.**—I inclose you drawing of this water wheel and arrangements. Data: Water wheel 6ft. diameter × 3ft. 2in. broad in clear of shrouds; shrouds, 7in. deep; buckets, 6in. deep; 24 buckets of sheet iron, pitch about 9⅜in.; diameter of shaft at large end for torsion and to carry pit wheel, 3in., of wrought iron; width of delivery end of launder over centre of water wheel, 28in.; width between posts of sluice, 4ft.; inclination or slope of bottom of launder, 1 in 36. A, the masonry of wheel pit and embankment; B, the water wheel; C, the pillow blocks of oak or stone; D, the supports for end of launder; E, the wood to launder; F, the sluice and frame; G, the head water in pond; H, the tail water below the wheel; I, the pitch paving under the wheel; J, two pins inserted in holes to keep the sluice, or gear may be applied. A lengthy description is unnecessary, having a drawing and scale. The lip of the launder should be brought down very thin; the extreme end is advisable to be made of sheet iron, about ⅛in. thick, and just sufficient space to allow the wheel to revolve under it without striking, and should be about 2in. short of reaching as far as a plumb line over the centre of the wheel. The inclination is required to give the water passing through the launder a greater velocity than that of the wheel. "Paddles" is a term applied to the floats of wheels working in an unlimited supply of water, or in flowing stream. In this case buckets is the usual term, from its somewhat similarity to that common utensil, to hold or to carry water.—Tubal-Kain.





[11403.]—**Gas.**—The gas supplied for lighting the underground railway carriages is carried in large tanks on top of some of the carriages, and carried to each carriage by means of indiarubber tubing. The tanks are filled every morning from a gas-works.—F.T.S.S.D.

[11407.]—**Magic and Conjuring.**—Drill a small hole in the bottom of a transparent decanter, partly fill it with a decoction of logwood in imitation of wine, and cork up the decanter's mouth; place the bottom hole in a box or hollow stand in which a basin is concealed; make an ornamental case to cover the decanter entirely; then construct another similar case with a chamber in its upper part having a hole at the top and another at bottom; fill this also with artificial wine, and cork the top hole as before. Exhibit your bottle of wine at one end of the room, pull out the cork, put on the cover, and allow the liquid to run slowly out of sight; meanwhile, place the other cover over an empty tumbler at the opposite end of the room, take out its cork, and the liquid will slowly run down and fill the tumbler; so that when the covers are removed the wine appears to have passed from decanter to glass by magic, though actually done by atmospheric pressure. It helps the delusion to connect them by a long string or chain while the wine is flowing.—Chime.

[11408.]—**Sewing Machine.**—Undoubtedly the rotating hook is the simplest, quietest, and least liable to get out of order, and this I say after six years' use of the same.—J. W., Leamington.

[11408.]—**Sewing Machine.**—Sewing machines I should say, are divided into three classes. (1) The single-thread chain-stitch. This is very simple to work, but the stitch opens out backwards like a stocking. It also uses up a great quantity of thread, fully four times the length of the seam. (2) The double-thread chain-stitch—such as Grover and Baker's. The upper thread is supplied from a spool in the ordinary way; the under thread also from a small spool passes through a snake, which loops it into the upper thread on the under side of the fabric, and presents an appearance very like the chain-stitch, but if anything still more unsightly. This stitch is not so liable to unravel if cut at any part as the single thread-stitch. It can also be taken out backwards; pulling out first the under thread and then the upper. The quantity of thread used is still greater than by the chain-stitch. (3) The lockstitch, formed in two ways, as stated by "E. B. F."—the shuttle as in Singer's, and revolving hook as in Wheeler and Wilson's. In both the under-thread has to be wound on the shuttle; the seam does not rip, and the thread consumed is much less than by the other methods. In the former the needle is straight, and descends perpendicularly, and is, therefore, better suited for leather and heavy cloths. In the latter, the needle has a slight curve answering to the motion of the arm. I should, therefore, recommend Singer's for heavy work, and Wheeler and Wilson's for moderate and light work. The under-thread apparatus of the latter is no more apt to get out of order than the shuttle, while it works more lightly and noiselessly. The seam of the lock-stitch is alike on both sides unless the tension of the under-thread is too great, when it runs right along the under side of the cloth instead of being pulled into it.—Irish Mechanic.

[11409.]—**Canine.**—Probably the distemper is coming on. I cured my dog (a Pomenarian) of this with Dr. Rook's Oriental Pills, giving a couple each day for about eight weeks in pieces of meat, which she readily swallowed with chewing. Giving these on the first signs of the complaint, and always since when the least out of order she had but the slightest touch of the disorder and ever since has had a splendid coat. Long dosing may be required to restore your retriever, but I am certain the pills will eventually do it more effectually than any other medicine.—Amateur.

[11409.]—**Canine.**—I think your dog is too highly fed with animal food. Has he access to grass? which all dogs eat as a purgative. Give only soup (no meat) with plenty of vegetables in it, a good pinch of salt, and occasionally a little sulphur. Does he rub himself against pillars and posts? If so, he has most likely parasites. Sulphur is best administered to a dog by being mixed with lard, and his body smeared all over with it. Chain him then on a bed of clean straw, and he will lick off the sulphur and lard. His smell for some days will be very offensive.—M. A. B.

[11410.]—**Geometrical Question.**—Let "Thetamu" bisect A B in E, and he will see that (having joined C E) the triangles B C E, B A D have one common angle at B, while another angle of each, at E and at D, are right angles and equal. Therefore, their remaining two angles, D A B and E C B are also equal, the latter being half A C B.—Q. E. D.—E. L. G.

[11411.]—**Line Shaft.**—There are two ways of doing it. I should fix my dumpy level as near as possible under the mid-length of shafting, and take sights at the extreme points first, the intermediate points after. Then measure up or down, as the case may be, to horizontal centre of the shafting at the several points. After that drive nails in wall at both ends, and stretch a line from nail to nail for the transverse line of plummer blocks and centre of shaft. An ordinary workman would first fix the two nails as near level as he could, but exactly in the transverse line of the shafting, and set out his plummer blocks by a long "straight edge," upon which he would place a spirit or other level, taking care to prove both the "straight edge and level," by seeing they are true, and will, reversing, show the same result.—Tubal-Kain.

[11410.] — **Geometrical Question.** — Construct figure and draw C E perpendicular on A B, it will easily be seen that C D E and A D B are similar triangles, and that E C B, the half of A C B = D A B.—Bernardin.

[11414.]—**Unripe Seeds.**—M. P. Duchartre in his "Eléments de Botanique," Paris, 1867, gives an extract of a paper on the subject by M. Cohn, of Berlin; the conclusions of that paper are:—1. The germinating power does not coincide with the maturity of the seeds, but precedes it. 2. In many plants belonging to several orders a seed can germinate when its development is not yet very much advanced; it seems, however, necessary that the embryo fills a great part of the cavity of the teguments, and that the albumen has been absorbed or has taken consistence. 3. In general, plants coming from unripe seeds are not weaker than others. 4. The germination seems to take place in the least space of time possible at a mean degree of formation of the seeds; younger or older they germinate slower. (More particulars v. op. cit. p. 688.) —Bernardin.

[11415.]—**Scarlet Runners.**—The red and white (York and Lancaster) are the most ornamental. The white (eclipse or giant white) are the most delicately flavoured, and the beans are much larger and the plant a stronger and taller grower than the other two. All require a soil well manured with rotten dung. The want of water caused the bloom to fall off. This was the case with mine last season, as I wanted all I could spare for marrows. All leguminous vegetables require abundant and constant supplies of water; in fact, in their growing season it is impossible to give them too much. Sow the second week in May, in seed beds, and when the seed leaf is fully developed, transplant where they are to grow, taking especial care to plant them deep enough for the seed leaves to touch the ground. They come into bloom sooner when transplanted.—Amateur.

[11417.]—**White Polish.**—Let "Stilton Cheese" take rectified spirits of wine 2 gallons, gum sandarach 5lb., gum mastic 1lb., gum anime 4oz., put them into a clean can or bottle to dissolve in a warm place. Must frequently shake the vessel and contents. When the gums are dissolved, strain it through a lawn sieve, and it will be fit for use.—Oldham Harry.

[11418.]—**Absorbing Quality of Printing Paper.**—I quote the following from "Notes and Queries":—"Finely powdered *pounce*, rubbed in lightly with the finger and then burnished with an ivory folder, will cure the most absorbent paper. But if, as is generally the case with German manufacture, the paper has a tinge, the burnishing whitens it. For such paper (as for all, except that the resort requires a poultry yard) the white of a fresh egg applied lightly with a flat camel's-hair pencil, produces a sizing like foolscap. It takes but a few minutes to dry and is perfectly transparent.—S. H. A."—Henry W. Henfrey.

[11419.]—**Half-Horse Power Turbine.**—See reply to query 11309.—Tubal-Kain.

[11421.]—**Photography.**—"Camera" should be careful in developing, to see that the developer flows evenly over the whole surface of the plate without being checked until it reaches the opposite extremity, when by gentle oscillation it will flow backwards and forwards until the picture is fully developed, when it should be gently washed, and then placed in the "hypo. bath" and left there for about three minutes, if left longer it may dissolve off a portion of the film, and, of course, carry away part of the picture. The coating, sensitising, developing, and fixing, should all be done in the dark room, and as little artificial light used as possible.—C. S. W.

[11421.]—**Photography.**—"Camera" seems to be wrong considerably. The plates should not be in the bath so long as four or five minutes; I have generally found two minutes quite sufficient. After developing with iron they should be well washed, which is apparently omitted by "Camera." Before fixing they should be intensified or "redeveloped;" an almost endless variety of methods and formulæ for which are given in the works referred to. I have tried a great many, and prefer the pyrogallic and silver. The "fixing" should be a weak solution of cyanide of potassium, washed over the plate until the undecomposed iodide is dissolved. This is much better than plunging into a bath of hypo. It is possible that in addition to the errors in working, a bad collodion is used. Try Mawson's. For "Camera's" comfort I will just observe that the art of photography is by no means easily learned. Difficulties and disappointments crop up constantly, and it is often the case that the very same materials and solutions which produce nothing but "failures" in the hands of a novice, will yield capital pictures when manipulated by a more advanced student. Let your motto be "Nil Desperandum," and push on till you succeed.—J. A.

[11421.]—**Photography.**—"Camera" should not let his plate remain in the hypo. bath so long. As soon as the yellow coating is removed it should be washed thoroughly to free the film from the hypo. He must also wash well after the iron solution, before fixing. Perhaps there is something bad in the washing water which causes the difficulty.—Occasional Photo.

[11421.]—**Photography.**—To "Camera."—One of two things. 1. Your bath is not strong enough; 2. You do not expose long enough, or your pictures want intensifying with pyrogallic acid and silver after the iron develops. Procure a thoroughly good negative on glass, and compare it with yours by transmitted light (by reflected light yours, of course, will have a yellow film of undissolved iodide of silver over it). After the iron development, wash well, and add two drops of your silver-bath to some pyrogallic acid, and swill over plate till by transmitted light it is a shade darker than you require. Fix by swilling plate with solution cyanide potassium, not hypo., and wash well. Wash thoroughly after each different chemical solution.—M. A. B.

[11422.]—**Night and Day Temperature, &c.** —1. The only instance in which the sensible heat is greater by night than by day is, when a bright clear day is succeeded by a very cloudy night. In such a case the heat radiated from the surface of the earth would be reflected back to it by the clouds; the convective currents (which on a fine and starry night rapidly carry off the heat) would be less rapid; and, lastly, in the day, by the conversion of water to vapour, 500° Cent., or 932° Fahr. of heat are rendered latent, and by the liquefaction of ice or snow, 75° Cent., or 167 Fahr., on the setting of the sun a reaction sets in, and a large proportion of this vapour is liquefied, which, with (in winter) the freezing of water greatly increases the temperature of the air by the liberation of the heat rendered latent during the day. But the influence of this latter cause alone would be insufficient to make the temperature of night higher than that of day, were it not for the combined action of the two first mentioned. To sum up all, we may say that the cooling of the earth results from radiation, convection, and free heat becoming latent—hence, when these processes are in any way hindered or reversed, as on a cloudy night, when the clouds act in the same way as the roof of a building, it is plain that the heat by night would often be greater than it would be by day in any place not subject to the direct rays of the sun. 2. Again, with respect to winds, similar causes come under consideration; convection is, perhaps, one of the principal of these; that is, air being incapable of receiving heat directly from the sun, is heated only by contact with the surface, considerably, if the surface be earth, and in a less degree if it be water, which accounts for the fact that the strongest winds flow from the ocean. This rarefied air ascends, giving place to colder, and this process being repeated cause ascending, descending, and horizontal currents, the latter of which we call winds. Now, as this can only effectually be carried on by day in those parts receiving the direct rays of the sun, it is not improbable that the violence of a wind should be decreased by the withdrawal of those rays. But there are evidently exceptions to this rule, for—(1) the sun must be shining somewhere, and consequently the air will flow in a current of varying force towards that part; (2) there are some invariable winds, such as the trade winds, which are caused by the rotation of the earth on its axis, the thin film of air being left behind by the denser matter of our globe. But still there is sufficient ground for the opinion, universal among sailors, respecting the influence of night on the atmospheric currents.—E. James.

[11423.]—**Surgery.** — Do nothing. There is no danger; the piece of needle will work its way out. When the point has protruded sufficiently from the skin for it to be seized by the fingers, lay hold of it and pull it out. It will be rusty and brittle, so no attempt should be made to take hold of it with pliers or any other instrument, as the point might get broken off, and the rest might then remain in the finger for an indefinite period, perhaps for life. Do not let it be cut down upon, for the operation is by no means a simple one, and might not succeed.—F. R. C. S.

[11423.]—**Surgery.**—I speak from the authority of being a F.R.C.S., with fifteen years' constant army and civil practice. No surgeon in his senses would operate. As well look for a needle in a bundle of hay, and the finger might be cut to mincemeat and the needle not found. My advice is, "let it alone," carefully shielding from accidental hurt. The needle in time will work itself out, and if any point should become painful, poultice it continuously with hot poultices. If a small abscess should form, the needle will be discharged through this. Preserve as much motion in the joint as possible without creating pain or inflammation. Pins that foolish girls have swallowed have been extracted after long intervals from the thigh or calf—Heaven knows what road they took. I myself extracted a bullet from the right arm which had entered the left cheek. Above all things, let no one be handling or examining the finger; there is no danger save from meddlesome surgery.—M. A. B.

[11426.]—**Screw Cutting.**—A 4in. centre lathe will require a leading screw of ⅞in. or ⅝in. diameter, and the most convenient pitch would be four threads per inch, with the angle of the thread 22½°. The distance will depend on the design of lathe.—Tubal-Kain.

[11426.]—**Screw Cutting.**—The diameter of your screw depends partly on the length of your bed. I am having one cut now for a 4ft. bed, the largest size that 1¼in. steel will contain, and 8 threads to an inch. A V thread is much better than a square one for convenience in getting the nut to clasp on comfortably. My old lathe with 3ft. 4in. bed has only a ⅞in. screw, but that has a support under the front end of the mandril head, as shown in Fig. 1, No. 187, p. 20, and just omitted immediately over the word lathe in No. 297, Fig. 6, p. 256, of the same volume. I like this way of doing it best, as you can change ends with the screw, both ends being fitted to the socket, and any other arrangement for this purpose seems to me to involve more work, though, to be sure, it is not often done at all. Without this support marked "bearing," the screw would be too weak, as it is only ⅞in. diameter at the bottom of the thread. So I should think Whitworth's standard 1in. in diameter, and 8 to an inch would suit you perfectly and relieve you of all difficulty about making your nut, which should be made in one piece and cut in half after tapping, if of cast iron, or may be in two pieces soldered together if of gun metal. I don't think there is any better plan for the arrangement of the nut than the one I gave in No. 287, p. 20, and that plan seems to have suited the late Mr. Babbage, for I found two new ones ready to be attached to some machine amongst the "useful wrought and cast-iron work" at the sale of his tools on the 1st March last. There is no occasion, however, to make the cam (Fig. 4) with curved slots, which is somewhat difficult, in fact, straight ones properly placed would hold firmer, if that is thought anything of. But it is a mistake to suppose that a V thread has any more tendency than a square one to push the half nuts open, if they each embrace, as they should do, nearly half of the circumference of the screw. If they do not, then, of course, it has such a tendency, and straight slots would cure that as well, or better than curved ones. The screw should be about halfway down the bed if outside in front, which makes 6in. to 6½in. distance of centres for a 4in. lathe. Leading screws have sometimes square threads, and sometimes round tops and bottoms with upright sides. I made a piece of screw about 2in. long as a pattern for Mr. Wilkinson to cut my new one by, flat at the top and bottom, but with sides sloping 10 degrees, and he declared the nut would not open and shut on such a screw, from the sides not sloping sufficiently. I have not tried it, but I can see it would be a near thing whether it would or not, so I have decided on a rounded V thread ⅛ pitch. In the drawing (p. 20) I have put "double thread ⅛ pitch," but that was done for the purpose of obtaining very high pitches which are not commonly wanted, and with my new screw I shall gear from the back spindle where they are, as that travels three times as fast as the mandril. In Whitworth's 5in. lathe the nut embraces about a quarter of the outside circumference on each side, or barely one-half altogether, and much less towards the middle, which accounts for the nut being able to open at all on the rounded thread with upright sides. (See Vol. XIII., No. 314, p. 37, for drawing.)— J. K. P.

[11428.]—**Violin.**—In reply to "W. P. D." in reference to violins made by Thomas Smith, London, I may inform him they are of no famed name or particular value. Smith was a pupil of Wamsley, and wrought until about the year 1800. The violoncellos of this maker were held in the highest estimation, some of them having fetched good prices—viz., £40 and £45, but his violins are rather mediocre in quality.— P. Davidson, Author of "The Violin."

[11429.]—**Ferns.**—If "E. T. S." will try carbolic acid in his fern-case I should think he would get rid of mildew, it being one of the best preventatives of fungus life, as is shown in Dr. Crace-Calvert's last paper read before the Royal Society. Put a few drops of carbolic acid into a small bottle, then cover the acid with water about half an inch deep, to prevent its too rapid volatilisation. Many years ago, before carbolic acid was known commercially, I had to abandon a fern-case, because all the most delicate ferns were killed by mildew; so that if "E. T. S." tries this I shall feel much interested in knowing the result.—B. D. T.

[11431.]—**Tinned Water Bottles.**—"London Rifle" cannot plate them by any means whatever. If he objects to the oxide of iron (it won't hurt him) he had better purchase Britannia Metal or German silver bottles. They are, of course, better if plated.—J. A.

[11431.]—**Tinned Water Bottles** can be plated, but "London Rifle" will find it rather tedious, and most likely to fail. To make a respectable job, unless used to plating, he had better let a practical person do it, but iron rust will do no harm to the liquor. If he has not well washed the bottle with warm water, and allowed it to dry before using it, the tin and salts used in soldering will give the liquor a bad flavour. The bottle should be rinsed, and dried in a warm place, with the mouth open and uppermost, before putting it away after use.—Illusionist.

[11434.]—**Salmon Spawn as Bait.**—"Pantile," in answering this query, should have added that by section 9 of the Salmon Act, 24 and 25 Vic., c. 109, "No person shall use any fish roe for the purpose of fishing," or "buy, sell, or have in his possession, any salmon roe." Penalty 40s. for each offence. The only exception made is possession of salmon roe for artificial propagation or scientific purposes.—Jannifred.

[11434.] — **Salmon Spawn as Bait.** — The querist must be an intended poacher. But, for his consolation, I beg to quote the gist of the Act of Parliament, 25 and 26 Vic., c. 97, s. 11: "To use, or have in possession, salmon roe, incurs £2 penalty, and forfeiture of the roe." I hope no gentleman will answer his inquiry; or you, Mr. Editor, turn your columns into a nursery school for the vilest description of poaching.—Joe.

[11434.]—**Salmon Spawn as Bait.**—That ... (surreptitiously) is the roe, as it is termed, of the fe... fish, small globules about one-sixth of an ... diameter. Perhaps "King-Fisher" is not aware ... its use is prohibited. Some time since, P...

"Advise to young men about to marry" was, "Don't." I would suggest similar advice to "King-Fisher" respecting salmon spawn.—TUBAL-KAIN

[11435.]—**Bootmaking.**—"Crispin" might as well ask a baker to make a loaf with dry flour as ask a bootmaker to work leather without soaking. Sole leather should be well soaked, and when half dry well hammered, it will wear well then. I have been thirty years at the trade but never attempted working dry leather.—CORDWAINER.

[11436.]—**Harmonium.**—"K. T. L." ought to be musician and mechanic enough to know that the channels of an harmonium reservoir (or pan, as he calls it) should be graduated the whole way through the harmonium according to the width and length of the vibrators, leaving plenty of airway and depth for stop slide.—PRACTICAL HOROLOGIST.

[11437.]—**Sash Tool Handles** are, I am inclined to think, made now just as they were forty years ago, i.e., 1st, cut to the required length by a saw; 2nd, dressed by an axe to the nearly required diameter; 3rd, turned in the ordinary way in a common lathe. No improved process has, I fancy, ever been attempted. "Simpleton" may bear in mind (should he be not already enlightened to that extent) that to make a sash-tool handle properly it should be turned down or grooved, as it is technically termed, at the larger end to a depth corresponding with the thickness of the string to prevent the binding from slipping off. Few are made this way; but a painter knows which is best.—J. G.

[11442.]—**Old Wives' Science.**—There is no foundation in the statement that when the sun shines on the fire it puts it out. It is said that if the fire be nearly out, and you put a screen before it, or draw the blinds, or close the shutters, it will immediately begin to revive. But it is forgotten that a fire which, in a well-lighted room, looks dull, or out, will appear to be in tolerable condition when the same room is darkened.* If "A. Liverpool" will refer to *Philosophical Magazine*, September, 1869, he will find an account of a series of experiments undertaken *ad hoc*, by Mr. Tomlinson, which tend to prove that if the sun's rays exert any influence at all it is rather in favour of the fire than against it.—S. BOTTONE.

[* See Rodwell's "Dictionary of Science."]

[11451.]—**Weight for Safety-Valve.**—I send the following for E. Nayler's benefit. Let me first point out the errors which are most commonly made in calculating safety-valves. The first is that of treating the lever as one of the first order instead of the second, and dividing the distance between the centre of the valve and the end of the lever by the distance between fulcrum and valve centre, instead of dividing the full length of the lever by the same. The next is in calculating the weight of the lever. The effective weight of the lever is found by multiplying the weight of the lever by the distance of the centre of gravity of the lever from the fulcrum, and dividing by the distance between centre of valve and fulcrum, which must be divided by the area of the valve in finding the pressure per square inch. Now, the area of the valve in question is 1·767 square inches, and if the lever is parallel, its effective weight will be about $\frac{12·5}{2}$ oz. × 8 = 50oz., which, together with the valve, will equal about 3·5lb.—

$$\frac{1·767 \times 40 - 3·5}{\frac{16}{2}} = 8·397\text{lb.}$$

to be placed at end of lever to blow off at 40lb. Now, we want the position of this weight for 30lb.—

$$\frac{1·767 \times 30 - 3·5}{\frac{8·397}{2}} = 11·8\text{in.}$$

from fulcrum. In the same manner, by substituting 25 and 35 for 30, may be found the positions for blowing off at 25lb. and 35lb.—TANTALUS.

[11454.]—**Commercial.**—E. and O. E. that "R" frequently sees on bills, &c., stand for "Errors and Omissions excepted."—AN OLD CONTRIBUTOR.

[11455.]—**Daisy Extractor.** — Fasten a small block of wood on the back of an ordinary steel pronged dinner fork to act as fulcrum to the lever.—SELWYN.

[11457.]—**Motive Power for Amateurs.**—No combination of weights would give the pendulum power enough to drive the saw. Complication only wastes power by friction, &c., and if a falling weight won't do, nothing added in the way of wheels or mechanism will improve your position. In your sketch the driving band of the saw comes above the saw table. You must avoid this in actual practice unless the table is very wide.—W. J. HOWARD.

[11457.]—**Motive Power for Amateurs.**—As "Zoo Andra" would like to know of any better arrangement than his, he will perhaps forgive me for telling him that he is departing from the first principles of mechanics in using (unless the arrangement is otherwise impossible) any reciprocating motion to produce a rotary one, as the conversion of the one into the other motion implies additional friction. A simple fly-wheel crank handle and strap would be infinitely preferable. If to be driven by hand, and if with a weight, a movement somewhat similar to an eight-day clock, with an adjustable fan to regulate the speed instead of the pendulum, would be far preferable.—A, Liverpool.

[11460.]—**The Beehive.**—To PHILO.—I probably know less about bees than even about electricity, but I can remember being told thirty-two years ago, by a man at Tottenham who kept them, that bees do not go to flowers for honey, but only for the materials for wax, and that his bees, to feed, or at any rate to get honey, went right away across the Lea into Essex to the forest, and that honey is collected from the leaves of the forest trees. He also said that a bee on the wing is one of the fastest flyers in nature; also that he lost many in their attempt, when laden, to cross the Lea when a sudden shower occurred.—J. K. P.

[11464.]—**Spring Beds.**—I would advise "Associate" to have nothing to do with spring beds or mattresses. The weight of the body depresses them most under the region of the heart and lungs, and causes the feet to be unduly elevated, thereby causing stagnation of the blood about the chest, and allowing the feet to become very cold. Though luxurious at first apparently, they are generally enervating after a while.—W. J. HOWARD.

[11466.]—**Vermin and Pigeons.**—Carbolic acid is the best wash for pigeon-houses and for pigeons. One of Dumont's patent puffs (which can be bought at any oil-shop) will destroy any vermin without hurting the birds. Carbolic acid will also prevent mits and fleas breeding.—DYOLL.

[11469.]—**Air and Warmth.**—The amount of air per man in sleeping rooms varies greatly with the season of the year, and the number of persons in the room. One person will do well enough with 300 or 400 cubic feet in all weathers, but the more air the better; but 800 feet would be a poor supply for two persons unless with very good ventilation. My bed-room contains 3,000 feet (20 by 15 by 10) which is a good size for self, wife and baby. The temperature should range from 50° to 60° Fahr., but for young children not below 60°.—W. J. HOWARD.

[11470.]—**Pocket Barrel Organ.**—This is simply a musical-box without a spring, instead of which the barrel is turned round by a handle.—FIDDLER.

[11471.]—**Bow.**—First hickory, second lancewood. —A., Liverpool.

[11472.]—**Plaster of Paris.**—Your plaster of Paris has become valueless by exposure to the atmosphere.—A., Liverpool.

[11473.]—**Weak Voice.**—Milk will certainly do your voice no harm, but raw eggs are said to strengthen the voice. In my opinion the best thing of all is to practice regularly every day the ordinary scales, standing upright, with the head well thrown back, or join a singing-class, and sing as loud as you can.—WHITAKER.

[11473.]—**Weak Voice.**—I am inclined to think that the best remedy is to practice singing with another instrument that has good wind. This will prove the finest medicine if the lungs are not too far gone; for exercise by loud speaking or singing will strengthen the lungs if gradually resorted to. For this reason all young people should sing heartily, and thus banish asthma till they get to a good old age. The best nostrum is a little cold water after your singing.—FIDDLER.

[11478.]—**Silver Bath.**—It will depend on two things. 1. The amount of nitrate of silver in the bath. 2. The amount of iodide in the collodion. A bath which contains much less than 20grs. of silver to the ounce of water will not give satisfactory pictures; hence we may take this as the minimum to which it is desirable to work a bath. Therefore, supposing the collodion not to contain more than 4grs. of iodide to the ounce, the following will be approximations to the amount of collodion which may be sensitised in baths of the two usual strengths:—1. 8oz. bath, containing 86grs. of silver to the ounce; 32oz. of collodion. 2. 8oz. bath, containing 30grs. of silver to the ounce: 20oz. of collodion. It is almost impossible to state the number of plates, as some operators leave so much more collodion on the glass than others.—S. BOTTONE.

[11480.]—**Model Steamboat.**—You do not state the size of your cylinder, but in any case I may tell you that you cannot have a "cabin" 8in. deep in a boat propelled by paddles so small as 3½in. diameter. The machinery of model steamers is always far larger in proportion to their size than in regular ships. But if you determine to try (and after fifteen years' painful experience I would solemnly say "don't") make the boat of tin, it is the lightest material and gives most room inside, and as to shape, copy any row-boat you see.—W. J. HOWARD

[11487.]—**Preventing Rust.**—Give the iron a coating of linseed oil and whiting, mixed together in the form of a paste; it can soon be cleaned off again when you want to use the iron, and will keep the iron from rusting for years.—GIG-LAMPS.

[11489.]—**Weight of Cattle.**—Take the girth of the animal just behind the fore legs in feet and tenths. Take also the length from the top of the shoulder to the tail head in the same way; multiply the square of the girth by the length, and the product by a fraction, which varies according to the sort of animal; for the foreign beasts commonly imported multiply by ·22. For a prime fed North Devon or Scot use ·28. For shorthorns I find ·25 as a multiple very near the mark. The result will be the weight of meat in stones of 14lb. each. For example: a bullock girting 6ft. 6in. and measuring 4ft. 9in., will be 6·5ft. by 6·5ft. by 4·75ft. by ·25 = 50·175 imperial stones. The above was the measurement of an Irish shorthorn heifer which I sold as 35 score, and which realised in the scales 35½ score, or 710lb. = 50 stone 10lb. To measure accurately requires skill, not only in the actual measurement, but also in the making the animal stand fair. I refer your querist to Merton's "Encyclopædia of Agriculture," under the title "Ox." Butchers do not like buying by measurement; in fact, if they know their business they will always buy by hand. If they have not confidence in their own judgment, they prefer buying by weight of dead meat in the scales. I would not recommend the owner of fat cattle to adopt this plan, as the butcher, if so inclined, has the opportunity of diminishing the weight very materially. As I fatten a score or score and a half beasts yearly, I have purchased a weigh bridge and sell by hand, taking care previously to ascertain the live weight, and I then reckon ·60 of the live weight as the quantity to be turned out of the dead meat scales, in case of moderately fat animals. This is within 2 per cent. of the real weight. The old mode of calculating 14 to 8 was too much in favour of the butcher.—KHODA BUX.

[11490.]—**Dumpy Level.**—"Shepherd's" instrument has a very common complaint, which fortunately is practically of small importance. The cause of it is want of truth in the fitting of tube of the rotating plate on the central stalk. Mine was that way for a length of time, and I found on examination that the flat bearing of the end of tube on the plate had a slight inequality. If you find which pair of adjusting screws the tube stands best over, and place that pair of screws so as to be in line with any one of the three legs, and then mark that leg so that you can always know it from the others at the moment you dismount the instrument from your shoulder when going to observe, and take care to let that leg, when on the ground, always point in the direction from which you are travelling, you will always have the telescope in the most favourable position for both back and fore sight, and the marked leg will always be in the best direction for setting the instrument roughly. If you live in or near London, and address me at Pitcairn's Library, King's College-road, N.W., I can arrange to show you how to rectify it, and, perhaps, put you up to a dodge or two in adjusting, and possibly in field-book too.—J. K. P.

[11492.]—**Carbonic Ink Paper.**—Wax, and iron out, between folds of bibulous paper, the desired quantity of any unsized paper. Smoke carefully on both sides, over the smokey flame of an oil lamp or unsnuffed candle. I presume this is to be used for copying.—S. BOTTONE.

[11495.]—**Double Oscillating Steam Cylinder.**—It is evident that your engine is not in working order—something jammed—piston, probably, packed too tight. Very dangerous to use a tin boiler. Look out for your eyes. Will eat into holes quickly—more so, if any other metal, as brass, be introduced. Go to a coppersmith and get a little boiler made with a flue running up the middle for the smoke.—A., Liverpool.

[11505.]—**A Wooden Pump.**—This can easily be done by cutting sufficient off the pump spear, so that the new leather will not reach so far as where it formerly worked, and it will then draw the water as well as before, if the water, from surface of well to lift bucket, does not exceed (say) about 28ft. in height. —A., Liverpool.

[11506.]—**Refractive Index of Glass.**—This can only be obtained by direct experiment. Generally speaking, the higher the specific gravity the greater the refractive index. See "Dictionary of Photography," by Sutton, 1867.—S. BOTTONE.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "J. G." has answered 10501; "Cocoa Nut," 10556; "C. E. S," 10833; "E. L. G," 10853; "Schoolboy," 10857; "Tubal Kain," 10918; "Never Rust," 10963.

QUERIES.

[11513.] —**Refining Animal Oil for Sewing Machines.** — Could any of your scientific correspondents give the best and simplest way of refining animal oil for sewing machine purposes?—J. W., Leamington.

[11514.]—**Brunswick Black.**—Can "Jack of All Trades," or any other subscriber, tell me how to make the above-named paint—the same is sold in 6d. bottles by all ironmongers, and has a gloss on it when dry—as I want to make it cheaper as I use a great deal of it, and its cost is enormous? Can it be made cheaper?—F. T. S. S. D.

[11515.] — **Wood-Planing Machine.** — Can any brother reader inform me how to make a wood planing machine to be driven by steam?—F. T. S. S. D.

[11516.]—**Veneering.**—Will some reader give me a little information on laying veneering and the process of filling up the grain of the wood, and afterwards the process of French polishing?—Joiner.

[11517.]—**Lathe Queries.**—Dividing (or counting) index for the division plate, pillar fluting chuck, and spherical chuck, with the latest improvements. I would be much obliged if any reader would explain the construction of any of the above, and, if possible, with a sketch of same. Also, the name of the book containing a description of the elliptical cutting frame, as, though an explanation of it has been asked for through the columns of the English Mechanic (on one or two occasions), I have never seen it so described that I could construct one.—H. E.

[11518.]—**Respirator.**—Will any one explain the best plan for making a respirator to wear when gulleting saws with emery wheel?—Jersey Craupaud.

[11519.]—**Horse Power of Compound Marine Steam Engine.**—Would any of your readers kindly inform me the best method or rule of calculating the horse-power of compound marine steam-engine?—G. Lamb.

[11520.]—**Small Photographs.**—Would some of your readers be so kind as to tell me how I can take photographs for the microscope? and how to make a small camera for taking them, if possible, out of spectacle or microscope glasses?—Simple Equations.

[11521.]—**Dirty Flannel.**—Will any fellow reader inform me the best method of washing and whitening small pieces of dirty flannel, and the best washing machine to wash 28lb., 56lb., or 112lb. at once?—R. A. G.

[11522.]—**Gold Fish.**—Can any reader inform me how to judge the healthiness of gold fish when buying them?—S. K. Sc. T.

[11523.] — **Rolla's System of Teaching the Pianoforte.**—What is it? Is it really any good?—S. K. Sc. T.

[11524.]—**Pitch of Roof.**—What is considered as the pitch of a roof, and where measured?—S. K. Sc. T.

[11525.] — **Fresh Water Aquarium.** — What different kinds of fish and plants might be kept in a fresh water aquarium, to agree with each other?—S. K. Sc. T.

[11526.]—**Harmonium Stop.**—Would J. J. Hartley be kind enough to explain the "Cremona Melodie" stop, if it is a 4ft. or 8ft. stop, and tuned in unison with flute or not?—Melodious.

[11527.]—**Barrister.**—Will some of "ours" be kind enough to tell me what are the necessary qualifications for a barrister?—An Aspirant.

[11528.]—**Silicate of Soda.**—I am anxious to know whether any of your readers have tried silicate of soda as a cement for object-glasses, and whether they could state its optical characteristics, its density and dispersive power, &c., as compared with flint and crown glass respectively. I should be glad to learn where I could get it pure, as I understand it is sold in a prepared form as a solid?—J. H., Lancaster.

[11529.] — **Vermestes.** — Could any correspondent of "ours" kindly tell me anything anent a "small ravenous beetle," named Vermestes? It has been used for preparing skeletons of animals, for which purpose I want it. If any friend could describe it he would much oblige—Redivivus.

[11530.]—**Violin Construction.**—Can some one of your correspondents inform me which is the easiest practical method of getting the tones of back and breast of violin in course of construction, as described by Savart? His meaning I don't fully comprehend.—Reed Maker.

[11531.]—**Water Wheel.**—Will any brother reader kindly inform me what horse-power a water-wheel 30ft. in diameter, with a stream of water 2ft. broad and 3in. deep running on to it would be equal to? Also, what would be the cost of a good centrifugal engine, equal to same horse-power? The engine must burn wood fuel.—Colombo.

[11532.]—**Steam Fire Engine.**—I saw some time back an account of a steam fire engine, built for Canada by Shand and Mason, in which it was stated that the weight was 400lb. Is this the fact? as out here they weigh from 1 to 3 tons. Information on this head would be interesting to a great many.—Anglo-American.

[11533.]—**Area of Boat.**—Is there any rule to determine the amount of superficial area of a boat to carry a ton?—Anglo-American.

[11534.]—**Cleaning Metal Buttons, Jackets, &c.**—What are the best means to use to clean both silver and brass buttons on uniform? What is the best mode of whitening the white cloth jackets? and what is best to use to clean German silver keys of flutes?—Fifer.

[11535.] — **Small Wheel-Cutting Machine.** — I, with many others, would feel greatly assisted if some one could furnish practical instruction for making a small wheel-cutting machine, to attach to a lathe, for cutting clock and other small wheels. Simple working drawings or recipe, would answer query 10859, p. 572, and also oblige, with many others—A Horological Mechanic.

[11536.]—**Character of Curve.**—If a circular piece of any elastic material be stretched (as a drumhead and water or other liquid poured upon it, the elastic material will bulge, forming a curve. What is the character of the curve thus formed, or does it vary?—Shylock.

[11537.]—**Scott's Patent Moulding Machine.**—Can any one give any information respecting the principle of working Scott's patent moulding machine, which makes any description or size of teeth wheels?—Anglo-American.

[11538.]—**Dry Solder.**—Would any reader inform me how dry solder is made, and how used?—Young Mechanic.

[11539.]—**Wooden Beehive.**—I am much pleased with the description of wooden beehive by C. N. Abbott, in No. 350, and intend making one and commencing bee-keeping, but as I do not understand the use and construction of the frames or bars for interior of hive, I shall be obliged if C. N. Abbott or some other bee-keeper will explain the matter to me, and, if possible, give sketch and arrangement of frames.—H. A. D.

[11540.]—**Preserving Tub Butter.**—How long will a tub of Irish butter keep good, and what sort of place is best to keep it in during summer and winter? Any information will oblige.—Pattern Maker.

[11541.]—**Dissolving Bones.**—Can any one inform me of the size of ordinary pits for dissolving bones, and average quantities they hold? Also, the usual process followed in the manufacture of dissolved bones?—Pit.

[11542.]—**Small Intensity Coil.**—I have made a small intensity coil about 3½in. long and 3in. diameter. It consists of about 30 or 40 yards of No. 18 cotton covered wire for the primary, and about 6oz. cotton covered wire, No. 30, for secondary. It is thoroughly insulated with shellac varnish, and guttapercha tissue. Now, what I want to know is, is there a limit to the size of condenser? Will 50 pieces of tinfoil, 4in. × 3in. with varnished paper between, do for this coil? Would solid paraffin be as good as, or better than, shellac varnish, for the papers of condenser? I find shellac keeps sticky, as I made a condenser that way, and as it did not act properly, I tried to take it apart, but found that the papers adhered so firmly to the tinfoil that I had to tear it off in pieces, and that with difficulty. The papers had been varnished at least a week previous. What length spark ought this coil to give?—R. W. P., jun.

[11543.]—**Amateur Observations.**— Would Mr. Proctor kindly say what observations may be usefully undertaken by amateurs having telescopes of considerable apertures—say, over six inches? No doubt, many like myself are able and willing to provide themselves with large and good instruments, but are deterred by the idea, that in their hands these instruments would be only toys. The inspection of star after star to try if they can be seen as they are described, and if the object-glass with the particular power used will divide them—or even the employment of a skilled observer uselessly to repeat Greenwich observations would probably soon cease to amuse.—P. S. T.

[11544.]—**Feed Pump.**—Will any reader inform me how I can make a feed pump for steam-engine about half horse-power? The best way of making the valves is what I require.—Roundfoot.

[11545.]—**Sulphur.**—To Jack of All Trades.—In replies to queries, Dec. 22, 1871, No. 10062, you say, "I have never yet found it to separate when I have prepared it." Will you kindly give me your mode of preparing it?—S. C. Salter.

[11546.]—**Electric Signal Bell.**—I have made a bell as described by Mr. Wm. Tonkes, on p. 663, Vol. XIV., but have failed to get it to work. Will any one point out the fault? Battery (one cell) charged thus:—Porous cell, carbon block, 11in. × 1in. square, packed with black oxide manganese and pounded coke (equal quantities), outside cell, chloride of ammonium 2oz., water one quart, magnet coiled with 4 layers of No. 24 cotton-covered copper wire. The magnet fails to attract armature. I believe if I could get the magnet to attract I should succeed, but that's the rub. Height of zinc cylinder, 8in.; length of wire, 12 yards No. 24 copper.—An Electrical Beginner.

[11547.]—**Bass's Beer.**—Will some of your correspondents give me the analysis of the water of which Bass's beer is made at Burton-on-Trent, and also state, if they can, by whom the analysis was made?—R. F. Jenner.

[11548.]—**Bending Amber.**—How is amber bent?—F. H. Lucas.

[11549.]—**Water Floats.**—Will some practical engineer be kind enough to inform me whether water-floats are of any use in a boiler worked at 35lb. pressure per square inch. I find mine to be a fruitful source of trouble, always blowing where the wire enters the boiler, or otherwise so tight that it cannot work.—Young Fireman.

[11550.] — **Preserving Eggs.** — As the season is coming round again, and I am wishful to form a collection, will some one give me some advice about preserving eggs, and the different kinds of varnish for coloured eggs? also, whether it is necessary to destroy the white skin inside the shell, and the best means of doing so?—Young Nest Hunter.

[11551.]—**Cement.**—I should much like to know how to make a cement that would fix meerschaum, having tried all those advertised in newspapers. Meerschaum is composed of silica, magnesia, and water, and when manufactured into pipes cannot be subjected to heat, the cement must, therefore, be liquid.—Zeta, Reading.

[11552.]—**Meerschaum.**—Can any of your scientific readers inform me how to distinguish a meerschaum pipe from the imitation, as her Majesty's Commissioners came to the conclusion that there was no certain test, at the Great Exhibition of 1851? I should also like to know how to analyse this mineral.—Zeta, Reading.

[11553.]—**Agriculture.**—I am very desirous to make myself acquainted with the principles upon which the advanced skilled agriculture of the present day depends. Will any of your numerous readers give the names of the books I should read?—Agricola.

[11554.]—**Pedestrian Tour.**—I shall be glad if some fellow reader will give me a few hints on a tour amongst the lakes of Cumberland, which myself and a friend contemplate making this summer or autumn, starting from Sunderland. (1) What is the most suitable time? (2) The best dress? (3) The smallest amount of luggage necessary? (4) The best inns? And (5) last, but not by any means least, the smallest sum for which we can enjoy ourselves for a fortnight?—Bachelor Jubilant.

[11555.]—**Soap Root.**—What plant of North America is called soap-root? In the *Scientific Press* of San Francisco, of February 24th, it is said that in California there is a manufacture where soap-root is curled as a substitute for horsehair.—Bernardin.

[11556.]—**Po-ca-de Wood.**—What kind of wood is Po-ca-de wood? it comes from British Guiana.—P. C. D.

[11557.]—**Treasury of Botany.**—I wish to know which is the last edition of Lindley and Moore's "Treasury of Botany," and what is the price of that book?—Thankful.

[11558.]—**Refuse Paint.**—Is there any method of working up paint skins, scrapings of kegs, &c.? If so, particulars of the plan would much oblige.—W. T. M. D.

[11559.]—**Jupiter's Satellites.**—I should be glad if some one would explain the diagrams on pp. 480 and 499 of the *Nautical Almanac*, termed "Phases of the Eclipses of Jupiter's Satellites for an Inverting Telescope." I cannot quite understand the explanation given at the end of the book—in fact, I am completely lost.—W. H. Skelton.

[11560.]—**Gold Polishing on Stone, &c.**—Will "Mason," "Jack of All Trades," or some other kind reader inform me through these columns, the best method of polishing gold, after it has been applied to stone, marble, slate, &c.?—T. Pemblington.

[11561.]—**Electric Light.**—There was on view at the Exhibition in London, in 1862, a machine consisting of a number of permanent horseshoe magnets mounted on a periphery or wheel, whereby they were enabled, when connected with a motive power, to revolve with great rapidity in front of their armatures, and through the medium of connecting wires an electric light of considerable intensity was produced. Will some one please inform me how I can make a machine on the same principle, so as to obtain a light equal to 40 cell Grove?—Electric Light.

[11562.]—**The Zither.**—Will any one versed in the intricacies of zither playing say whether it is an advantage to have more than the usual number of melody strings? A new arrangement, having six strings instead of four, has been recently patented, for which the makers claim easier and swifter fingering. Perhaps the encyclopædical "Harmonious Blacksmith" will favour us with his opinion on the matter. I would be glad to know, also, where in the long range of price given in the catalogues—from thirty shillings to nearly as many pounds—usefulness and real value end, and ornament begins; in other words, what a good honest instrument should cost?—W. W.

[11563.]—**Moon.**—Will any correspondent inform me whether the presence of the moon influences the orbit of the earth so as to affect its distance from the sun? If the moon could be annihilated, how would the earth act?—M. Paris.

[11564.]—**Blackberry and Strawberry.**—There is an enormous difference in the flavour of the first fruit, caused by place of growth, also excellent foreign species. Has any attempt been made to cultivate it? I have made a bed of the wild wood strawberry to experiment with, and I have a notion that our now enormous and tender varieties require a little wild blood to bring back the flavour, and to retard ripening. Information on the above thankfully received.—M. Paris.

[11565.]—**Carrot.**—Has anybody observed the "sleep" of the flowers of the carrot just before opening?—M. Paris.

[11566.]—**Equisetum.**—Has the movement of the pollen under the microscope been noted?—M. Paris.

[11567.]—**Rigging Model Yachts.**—Will "W.F.W." kindly inform me how he intends the mainsail and foresail to be fastened to the masts? If he intends brass rings to be used, how many, or how far apart, should they be? I should like, also, to know the neatest way to fasten the shrouds to the sides.—Full Stop.

[11568.]—**Turbine.**—Will any correspondent give me instructions how to construct a turbine of sufficient power to drive a 6in. lathe?—T. Leith.

[11569.]—**Telegraph Posts.**—Will any one tell me why the Post-office posts should have an interval of three feet, just between wind and earth, neither painted nor tarred, as it seems to me that this is precisely the part which is most liable to decay? At least the posts are so economically tarred and painted in my neighbourhood.—M. P.

[11570.]—**Furniture Polish.**—"M. O." (in No. 3[illegible], query 10535) recommends acetic acid, linseed oil, and water as a reviver, but does not tell how to mix the oil and water, and what proportions, or whether the oil is applied to the rubber the same as in polishing. If he will kindly answer these queries he will oblige.—Rigg[illegible].

[11571.]—**Virginia: Its Climate and Soil.**—As "our" Mechanic circulates in the United States, I wish to ask, through its pages, if any of my brother readers there can inform me if Professor Maury's report on the climate and soil of Virginia made to the department at Washington has ever been published, like his physical report of Virginia (which I have read).—E. R. E. A.

[11572.]—**Compressing Water.**—I should feel extremely obliged to any readers for their opinion upon the compression of water. I am of opinion that it is possible to compress it. I have aided in the construction of the largest hydraulic press ever made for the use of the English Government at the Pembroke Dockyard. I will give a rough description of the press to illustrate my reason for thinking as I do. The press is composed of two large blocks of iron, weighing 25 tons each, separated by four massive columns at each corner of the blocks, fitted with nuts of equal strength to resist the pressure of the ram, the ram being forty inches in diameter. The cylinder is composed of seven large steel rings, seven inches square, shrunk on an inner cylinder of steel one inch thick. The press is connected to a massive set of pumps by a copper pipe. Now, when the ram is pumped up and comes in contact with the top block, we shall consider the cylinder full of water. I want to know what becomes of that water that is pumped in after to gain the pressure of four thousand tons. I cannot say how much is pumped in exactly, but it is something over one gallon. It cannot well enter the pores of the steel.—J. Westwood.

[11573.]—**Small Boat.**—Will some reader kindly give me the dimensions for a small flat-bottomed boat to hold one? It must be light, as I wish to carry it to and from the canal, about a quarter of a mile.—J. K. D.

[11574.]—**Gas.**—Will one of your numerous correspondents inform me of the best way of regulating gas? I have tried a mercury regulator, but have not succeeded as my gas bill has increased every corresponding quarter for the last three years, and the consumption is about the same.—H. J. W.

[11575.]—**Well Sinking.**—Can any reader inform me whether a well less than 3ft. 6in. in diameter can be sunk? I am told not, as there would be no room for workmen. I want to sink one 2ft. or so in diameter. Is there any means of boring one or inserting a 2ft. tube?—SCHOOLBOY.

[11576.]—**Water Wheel.**—I have a flow of water on a level of about twenty gallons a minute, and wish to know if I fix a water wheel with a pump attached, will it send a jet of water for a fountain a distance of 300 yards and about 15ft. above the water, and what size of wheel should I require?—J. K. D.

[11577.]—**Hydraulic Lifts.**—What is the nature of the construction of hydraulic lifts such as those at the Royal Albert Hall, the Langham, the Grosvenor, and Charing Cross Hotels? So far as I can see they are lifted by a piston below them, the chain by which they are suspended being only a check against accidents. If so, as they are capable of being raised some 200ft. above the basement, the piston being of course of the same length, it follows that there must be a piston cylinder sunk in a deep well under all. How is the water supplied to the bottom of a cylinder of such great depth? The ascending room can be stopped at any moment by an attendant inside, who, by pulling the proper ropes, causes the machine to be raised, stopped, or lowered, with the greatest facility. Any information on so interesting a matter would oblige.—T. V. B.

[11578.]—**Sun's Declination.**—I return my thanks to your able astronomical correspondents "F.R.A.S." and "Altair" for the lucid manner in which they treated my query (11360, p. 49). I must still reiterate my former statement in saying that the term "diff. for 1 hour" is an incorrect one. However, I see in the later editions of the *Nautical Almanac* the term "var. in 1 hour;" which undoubtedly is the correct one. At the time of the summer solstice (1872, June 21), the sun's declination is greatest, but the question is, does this always occur at noon? If not, how is it possible to get the correct declination for an intermediate time between the noons of June 20, 21, and 22, when the second differences are 1·08", 0·29", and 1·03" respectively? It will no doubt be stated (in reply) that the sign has changed, but what indication have we to that effect? The change in the "equation of time" is marked by a straight line at the head of the column, then why is such a change in the "diff. for 1 hour" not indicated in a similar manner? I am surprised that our valued correspondent "F.R.A.S." should think me unique in my wish to omit the trashy explanation. I must agree with "Altair" in his statement that several things have been added to our *Nautical Almanac* which are improvements; on the contrary there are others which are questionable. Of what use are the 1,000 additional stars inserted in the *Nautical Almanac* when we find that the times of disappearance and reappearance are computed only for one latitude, viz., Greenwich. If the times were given for other latitudes, then the *Nautical Almanac* would be of great service to travellers in far distant countries, who at the present time require further information than that of the limiting parallels. Believing that the various improvements that have been made have conferred a great boon upon those situate in the latitude of Greenwich, still, I should like to be informed why it is that the meridian passage on page 4 is only given for the upper limb of the moon.—HENRY WOODS.

[11579.]—**Blue Billy.**—"Sigma," in reply to a query (in a back volume) regarding "blue billy," stated that he had made an analysis of it, and had predicted that it would make a "hard iron," and that such was the result when tried in the blast furnace. May I ask him what led him to that decision? Was it the presence of copper, or arsenic, or both? If the arsenic is the cause, could it not be volatilised? Is his use of the words "hard iron" synonymous with "forge iron?"—FE. SCOT.

[11580.]—**Soda Ash in Boilers.**—Will "Busy Bee" kindly tell me what quantity of ash to put into an 8-horse boiler, and how often?—WILLIAM.

[11581.]—**Wood Polishing.**—I would be thankful if any subscribers could inform me of a speedy and good plan of polishing light articles in the lathe—such as drawer handles, rings for window poles, &c., and how the last article is gripped when undergoing that process.—CHISEL.

[11582.]—**Spiral Turning.**—I am certain some subscribers could instruct me as to the construction of a spiral lathe. A simple drawing would greatly assist.—GOUGE.

[11583.]—**Vacuum in Barometer Tube.**—Will some one inform me how I can procure a true vacuum in the top of barometer tube (one with weights at the back)? Likewise how to fill a new one; I have boiled the mercury about 6in. or 8in. in top of tube, but still in the lower part of the tube the mercury is divided—air and quicksilver. Any other advice on adjusting tube and weights will oblige.—NEVER RUST.

[11584.]—**Cleaning Cornopean.**—Would some kind reader oblige by informing me how I am to clean the inside parts of the tubing of my cornopean, as it is very dirty?—WEE PET.

[11585.]—**Chemical.**—Would Mr. Bottone kindly inform me of the cheapest and most ready way of resolving chloride of sodium into chlorine gas, and sodium respectively? Would he also tell me what chemicals would be used, and what would be left (after getting the chlorine gas and the sodium separated) in the vessel used to separate them?—VULCANITE.

[11586.]—**Chloride of Nitrogen.**—Would "Explosive" confer another favour on me, by telling me what pressure to the square inch chloride of nitrogen would give? Would he please to put it in figures? Also tell me what proportions the chlorine gas bears to the hydrochlorate or nitrate of ammonia? I do not intend to put any one's life in jeopardy by making any yet for some time, till I can do so with comparative safety, but I wish to know, so as to make some arithmetical calculations.—VULCANITE.

[11587.]—**Cleaning Scarlet Cloth.**—Can any of your correspondents give me a good recipe for reviving scarlet cloth?—W. MILLARD.

[11588.]—**Emery Cloth.**—Will any one practically acquainted with the business be kind enough to say how cloth is prepared for making into emery cloth, so that the cement used may not sink through the cloth? And what is the best cement for fixing the emery to the cloth?—CORUNDUM.

[11589.]—**Dry Steam.**—Can any of "our" chemical correspondents give an analysis of what is termed dry steam? When steam is superheated by passing through a coil of pipes placed over a furnace and allowed to issue into the atmosphere at a temperature sufficient to melt lead or kindle timber, it does not condense into a cloud or mist, and seems to be no longer steam at all. Is this a case of allotropism or what?—CALORIC.

[11590.]—**Carbolic Acid for Cages.**—I want to know if any of your correspondents can tell me if there is any risk of poisoning my birds by using the carbolic acid wash for a large cage, about 5ft. by 2½ft. in which I have 20 canaries, and they are infested with the little red lice every spring. I wash the birds with precipitate powder, but I want some way of cleaning the cage. It is mahogany and ornamental, so that I do not wish to part with it. In what proportions should I use the carbolic acid?—A. WESTLAKE.

[11591.]—**Lighthouses.**—How is a situation obtained in any of the Trinity lighthouses that use the electric light? What are the necessary qualifications, and to whom is application made? Any information respecting foreign lighthouses and situations connected with them will oblige.—W. H. H.

[11592.]—**Medical.**—What salt of iron is most easily absorbed by the system?—WILLIAM H. HEY.

[11593.]—**Lime-juice and Glycerine.**—Will some one tell me how the above-named preparation for the hair is made? I don't think there is any glycerine or lime-juice in it.—DUFFER.

[11594.]—**Foreign Calculation of Engine Power.**—Will some one kindly inform me how the power of steam engines is calculated in the principal foreign countries of Europe and in the United States? What is taken as the unit of work, and what answers to our 33,000 foot pounds, which, when done in a minute, we denominate a horse-power? No doubt one or other of the correspondents who have been recently ventilating their opinions in regard to the metric system will be able to answer my question as regards the countries where that system is in vogue.—V. B.

DOMESTIC RECIPES.

From the *Food Journal.*

To Boil Rice as in India.—Into a saucepan of 2 quarts of water, when boiling, throw a tablespoonful of salt; then throw in 1 pint of rice, after it has been well washed in cold water; let it boil 20 minutes. Throw it out on a cullender, and drain off the water. When this has been done, put the rice back into the can or saucepan, dried by the fire, and let it stand near the fire for some minutes, or until required to be dished up; thus the grains appear separate and not mashed together.

Rizart Haddocks.—A mode of dressing haddocks very common in Scotland is by drying them in the sun. To rizar is explained, in Jamieson's Scottish Dictionary, as signifying to dry in the sun; and its past participle, rizart, as equivalent to the French ressoré, from which the Scottish word is derived (or they have a common root, from which, probably, the word raisin also comes). The haddocks to be prepared for the tabld in this way, must be perfectly fresh, almost newly taken, middle-sized, and are most suitable when they are gutted, thoroughly washed, and allowed to lie in salt for a night. They are then strung on a thick wire passed through their eyes, and hung up for two days in the open air on a wall, but not where they are much exposed to the direct rays of the sun; after which they are skinned, the backbones are taken out, and they are broiled on a gridiron and rubbed with a little butter. Thus prepared, they are extremely palatable, and excellent for breakfast or supper.

Orange Marmalade.—For 7½lb. sugar (lump), 4lb. of oranges (Seville) are required. Boil the oranges until sufficiently tender for a pin's head to go through the skin, having first grated half the number to prevent the marmalade from being too bitter; for if the whole of them are used the jam will be as bitter as the waters of Marah. Cut the oranges in half when you have boiled them sufficiently; remove all the pips; scoop out all the pulp. Cut the skins into thin strips. Put the sugar in your preserving jar, dissolve it in a pint and a half of water, and boil it twenty minutes. Skim it well—whatever you do, skim it well—and on no account add the pulp and peel until the syrup is as clear as "water from the crystal spring." Then put in the pulp and the strips of peel, and boil all together for a quarter of an hour.

Haricots Verts en Salade.—Boil some French beans whole; when cold, dress them with oil, vinegar, pepper and salt, some parsley and capers finely minced, and garnish with hard boiled eggs, anchovies, and beetroot. The dish must be well rubbed with an onion.

Varnish.—To Varnish Beech.—It is a poor-looking wood, with little curl or figure: therefore stain with the following:—Burnt umber and soap lees, and if any knots, give an extra touch or brush; let it stand to dry; the day following size it over twice; and the next day varnish it; use the best varnish.

USEFUL AND SCIENTIFIC NOTES.

Improvement in Telegraphy.—We hear of an ingenious arrangement by which copies of messages sent by telegraph can be left at different stations along the line of transmission. This is the invention of Mr. Little, of New Jersey, United States. By means of a rheostat at each station, the current is divided; one portion passing onward by the wire, the other portion doing its work and passing to the earth. The telegraph employed belongs to the printing variety.

Removal of the Standards.—In consequence of the wall of the Palace at Westminster, in which the imperial standards were immured, having been pulled down in order to form an entrance to the refreshment rooms, the standards have been deposited in the wall on the right-hand side of the second landing of the public staircase, leading from the lower waiting-hall up to the Commons' Committee Room. One alteration has been made. When the standards were originally immured, a brass plate was fixed upon the wall bearing the following inscription in old English letters:—"Within this wall are deposited standards of the British yard and the British pound weight, 1853." The word "measure" has now been inserted after "yard."

Detecting Sulphur in Gas.—Von Wartha describes a neat method of illustrating the presence of sulphur in illuminating gas. He places, on a platinum wire, a bead of carbonate of soda on the edge of the flame of a Bunsen burner for a minute, and obtains then, by partially cutting off the air supply, a small cone of light in the flame. Into this the bead is placed, and the sulphate and sulphite of soda previously formed is brought to the condition of sulphide of sodium by the reducing action of the glowing carbon particles. The bead is then crushed in a porcelain dish, and a solution of the nitro prusside of sodium added, when the characteristic reaction of sulphur is readily obtained. The reaction is said to be more than fifty times as sensitive as that with silver, which is ordinarily used. A minute suffices to obtain it.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

The following are the initials, &c., of letters to hand up to Tuesday morning, April 9, and unacknowledged elsewhere:—

Jas. R. Gordon.—Jas. Peters.—B. Edwards.—B. C. Brough.—Amicus.—V. M. T.—J. Sargent, jun.—John Watson.—Henry Jackson.—Whitney Partners.—J. S. Cooke.—Mrs. Petrie.—W. A. Gibbons.—W. Simmons.—Rev. Thos. Foster.—Q. E. D.—J. H. D.—Robt. Still.—Geo. R. Hallam.—Anthony Stark.—W. J. Weaver.—Wm. Hughes.—G. M.—Raven.—Bob. J.—O. F. S.—C. Benbow.—G. R. H.—W. C. Manning.—W. R. Hall.—Excelsior.—A Leeds Man.—Thesiger.—George H.—Square.—R. Langdon.—Champagne Charlie.—J. W. Fennell.—Rara Avis.—Numismatist.—Legato.—Dentiste.—J. Newton.—Esmey.—Analyst.—F. Hume.—Moxley.—S. E. Peal.—Monte Cristo.—Electrometer.—Physicus.—H. B. E.—A Shaving Pusher.—W. E. W.—J. O. Y.—M. B.—T. Ritsat.—Fitzbertie.—X.—Anglo-Saxon.—J. B. Yorke.—J. Barwick.—H. E. H.—Valve.—Country Jeweller.—Aden.—Howard.—Photo.—H. H. C.—King Coal.—J. E. H.—Ambition.—Proven.—Zeta.—Opaline.—A. D. W.—Joseph Unwin.—James Weldon.—W. W.—Ioan Goch.—Equilibrium.—J. L. T.—H. H.—Cosmopolitan.—E. L. G.—R. A. Proctor.—A New Subscriber.—E. J. D.—Flactem.—Whitaker.—W. J. Howard.—Sigma.—Khoda Bux.—D. W. Edwards.—F. F. A.—V. B.—Leander.—G. Avery.—A Young Plumber.—Yo. Gaucho.—A Country Plumber.—A Cripple.—Scraper.—A. N. Cooke.—Patman.—Norr.—W. Crisp.—Country Tinker.—Woodstock.—F. W. W.—Z. Y. X.—W. J. H.—J. B. Sharpley.—A. B. M.—Thetamu.—A. J. Adams.—R. Lupwards.—Junius.—Philanthropist.—Leather.—Ralph Lowdon.—A. G. Miller.—W. H. Hey.—Bookworm.—W. D. Mead.—M. Paris.—W. H.—A. W. B.—J. Franklin.—Ampersand.—F. H. Saunders.—Corax.—R. N. Knight.—Veritas.—Transit.—Manchester.—F. R. C. S.—A Beginner.—Samuel Smither.—L. M. F.—J. K. P.—S. Bottone.—A Foreign Subscriber.—A. W. Festing (with copy of work).

VIGILANS.—In speaking damagingly of another correspondent, you might have given your name and address, in the absence of which we think you have acted cowardly, and your letter is gone where it deserves—into the waste-basket.

GEO. P. HILL.—A notice next week.

S. CROZIER.—See answer to S. Bottone.

FOCUS.—The plan you suggest for "baffling pirates" would no doubt insure accuracy, but at the expense, we fear, of inconvenient delay.

NUMISMATIST.—As it is doubtful whether the coin is worth anything, and as the drawing would certainly cost 6s. or 7s. to engrave, and as, after all, it could be of no benefit to any one else, we must decline inserting the query.

S. SMITHER.—Twenty-six shillings.

SCHOOLBOY.—Yes. Lavater's book.

Mac.—We do not receive or forward replies to advertisements. Advertisements must be prepaid.

An Old Contributor.—You had better in such matters speak for yourself, and not for "F.R.A.S." or any one else. The English Mechanic is intended for all classes of inquirers. Its numerous correspondents, who are ever trying to instruct and correct each other, impart to it a peculiar aptitude and power. Like the elephant, it can root up an oak or pick up a pin. That which may appear trifling to you, is valued by others.

Bed of Stone.—Your first query is one for a dog fancier. Your second would take too much space to answer. Consult any good grammar.

C. S. F.—See back vols.

W. R.—We would prefer to wait for your analysis, and as the other has not yet reached us, will at any rate wait till it does. Should you not send yours, "S. S." may infer you are not equal to the task.

A Swimmer.—No; rather beneficial, if you use ordinary care.

A. B. C.—Use Judson's dyes.

Henry White.—Ask an architect.

Dabriada.—Thanks. See our answer to "A Barrister" last week.

J. M.—See advertisement, No. 362, Vol. XIV. March 1.

George Lange.—If, as you say, you have taken in the English Mechanic for five years, you reflect no credit on its brotherhood of readers. During that period we have repeated at least fifty times that we do not answer queries by post.

W. H. Durst (Newark, N.J., U.S.A.)—Last remittance pays up to August 29, 1873, inclusive.

Arthur Orton.—First and third queries can only appear as advertisements. For second query see back vols.

Sceptic.—It would be well for you to be more perfectly acquainted with the principles of the science you attack. Our pages may probably before long give you the opportunity of doing so.

E. Barber.—All requests for private communication must be paid for as advertisements.

Communications which can only appear as advertisements to hand from J. C. P., Subscriber, Argyrius, Novice, Stranger, W. Edwards, Almost Distracted, A 2, X. Y. Z., P. M., Little Bird, Qui Quærit.

W. Millard.—Consult a medical man.

T. Pemblington.—Send.

Daleth.—If you had looked back a few numbers you would not have written so foolishly. See p. 585, Vol. XIV., and previous vols.

H. B. E.—Given long ago.

S. Bottone asks whether something cannot be done to prevent a single line of the English Mechanic being wasted by "cads," like correspondents signing themselves "S. Tremayne, Cantab," and W. M. Hirpen. We fear not, as long as cowards and scoundrels exist; and they do and will exist in spite of police and the contempt of honest men. We occasionally hear, for instance, of some such a person throwing orange peel on the pavement on purpose to throw pedestrians down. Imagine the depravity of a mind that could extract fun from the broken limbs or broken heads of unoffending passers-by! Just of the same quality of heart and mind are those who endeavour to pervert and abuse the educational intentions and efforts of the English Mechanic, which, from multitudinous testimony, is a blessing to thousands. Two or three depraved creatures have recently been sending sometimes indecent, and at other times adroitly worded, but, at the same time, foolish and deceiving communications, to the English Mechanic, for a similar reason, we suppose, to that which induces the rascal to deliberately throw orange peel on the pavement. Happily, a vast majority of such communications have been spotted as soon as read. Though rejected, they have not been consigned to the waste-basket, and may be seen by any respectable correspondent who may feel interested in detecting the offenders. From information already received we are on the track of one, and we believe we have a clue to another—"S. Tremayne, Cantab," who was exposed by "Sigma" last week. Since that exposure and our remarks on it (p. 81), we have received an insulting letter from "S. Tremayne, Cantab," and the same letter contains insulting allusions to "Sigma," and "A Barrister." We need scarcely say that "Sigma," and "A Barrister," are men animated by pure and disinterested motives; they, and particularly "Sigma," gratuitously and ungrudgingly send us information, in the belief that they are benefiting large numbers of persons wherever the English tongue is spoken. On the other hand, we maintain that it is a mean and cowardly thing, to say the least of it, for a correspondent, skulking behind an assumed name, to throw insulting words at such men. But such work is in perfect keeping with the other communications received from "S. Tremayne, Cantab." We hope to have more to say about this gentleman, and one or two who are in league with him, soon.

R.—Our reply was intended to have a *general* application.

W. H. Skelton.—Read query 11465 again. You will see that the trains move in *opposite* directions.

"L. C. E." says:—"I was amused at 'F.R.A.S's' chaffing reply to my query on sundials, but the absurdity arose from the omission of the word 'mean.'"

William Short.—Consult indices of two or three last vols., for information on painting magic lantern slides.

Samuel Smither.—See reply to S. Bottone.

A. Ledger. — For further information concerning Atkins's fire-engine, address the gentleman mentioned at end of article. We do not know the number of the patent.

THE INVENTOR.

APPLICATIONS FOR LETTERS PATENT DURING THE WEEK ENDING APRIL 2, 1872.

831 A. Pye-Smith and C. Ribbans, East Greenwich, for improvements non-conducting compositions for coating steam pipes and boilers, applicable also for preventing the passage of heat or cold to or from pipes, refrigerators, or other vessels.

832 C. A. McEvoy, Bear-lane, Southwark, for improvements in connecting electric cables and conductors.

833 J. Molesworth, Leicester, for improvements in the manufacture of elastic gusset webs.

834 P. J. Ekman, Stockholm, Sweden, for improvements in the construction of window sashes and frames.

835 N. Prada, New Bridge-street, City, for improvements in preserving animal substances and in agents for the purpose. A communication.

836 D. Nicoll, St. Paul's Churchyard, for improvements in compounds for and in the treatment of fabrics to render the same waterproof and uninflammable.

837 R. Monteith, Carstairs, Lanark, for an improved process for preserving animal and vegetable substances. A communication.

838 A. M. Clark, Chancery-lane, for an improved compound for cleaning, restoring, and preserving carpets, rugs, and similar. A communication.

839 R. Howson and J. J. Thomas, Middlesborough-on-Tees, for improvements in revolving puddling furnaces.

840 F. R. Window, Baker-street, Portman-square, for an improved method of taking silhouette or outline pictures.

841 J. Rawcliffe, jun., W. Bibby, and A. Fleming, Preston, for improvements in spinning mules.

842 R. Smith, Plymouth, for improvements in sounding boards for pianofortes and other stringed musical instruments.

843 H. G. Slevier, Aldersgate-street, for improvements in the manufacture of umbrellas and parasols and in the machinery to be employed therein.

844 J. D. H. T. Decamps, Brest, Paris, for an improved suspensory apparatus for raising and supporting the sick or wounded, and others.

845 W. Whyte, jun., Glasgow, for improvements in boilers to be used in treating or bleaching paper-making materials and textile materials and fabrics.

846 F. Lebacq, Laurie-terrace, Southwark, for shoeing horses by a system of fluted iron to prevent the contraction of the foot.

847 J. J. Bleckly, Warrington, for improvements in machinery or apparatus for rolling iron, steel, or other metal bars into wire rods, hoops, or small sections.

848 U. A. Lenteigne, Paris, for improved machinery for ornamenting, engraving, embossing, or sculpturing wood or other material.

849 H. Y. D. Scott, Ealing, for improvements in the treatment of sewage water.

850 G. Little, Oldham, for improvements in machines for combing cotton and other fibrous materials.

851 J. A. Jaques, Tottenham, and J. T. Oakley, Grange-road, Bermondsey, for improvements applicable to machinery for grinding, surfacing, drilling, or otherwise working articles made of iron or steel.

852 E. Malhere, Paris, for improved machinery for the manufacture of lace.

853 R. Spence and E. J. Spence, Bridgwater, for improvements in machinery for the manufacture of bricks from plastic clay.

854 W. E. Newton, Chancery-lane, for improvements in breech-loading ordnance. A communication.

855 W. R. Lake, Southampton-buildings, for improvements in machines for attaching covers to pamphlets. A communication.

856 W. R. Lake, Southampton-buildings, for improvements in machines for setting and securing lacing hooks in leather, cloth, or other materials. A communication.

857 W. R. Lake, Southampton-buildings, for improvements in ovens, chiefly designed for baking bread, biscuits, and other like articles. A communication.

858 W. Carr, Bury, Lancashire, for improvements in spindles and shuttles.

859 J. Hopkinson, sen., and J. Hopkinson, jun., Manchester, for improvements in the construction of street lamps.

860 A. Budenberg, Manchester, for improvements in pulley blocks. A communication.

861 J. Rice, Oxford-street, for improvements in apparatus for propelling vessels.

862 J. Jefferson, C. Jefferson, L. Jefferson, and M. Jefferson, Bradford, for improvements in machinery for combing wool and other fibres.

863 W. Benson, Allerwash, Northumberland, for improvements in machinery or apparatus for cutting coal.

864 W. R. Lake, Southampton-buildings, for improvements in button-hole sewing machines. A communication.

865 J. Werner, Mannheim, Germany, for an improved composition to be used as a substitute for "brewers' pitch" for lining vats, casks, and tubs, and for other like purposes.

866 H. G. Cardozo, Bath-place, Upper Holloway, and A. W. Taylor, Seven Sisters' Lodge, Holloway, for an improved method of and apparatus for facilitating the payment and preventing the fraudulent appropriation of the fares of passengers travelling in tramway cars, omnibuses, public vehicles, or other conveyances, also applicable to public bars, restaurants, or other places where a check on payments is desirable.

867 W. A. Lyttle, The Grove, Hammersmith, for improvements in poles for telegraphic and other purposes.

868 J. Young, Kelly, Renfrewshire, for improvements in apparatus employed in the manufacture of the carbonates of soda and potash.

869 E. T. Hughes, Chancery-lane, for improvements in mechanical movements for converting motion. A communication.

870 A. C. Stevenson, Glasgow, for improvements in glass and other reverberatory furnaces.

871 H. B. Barlow, Manchester, for improvements in looms for weaving. A communication.

872 H. Adlam, Battersea-park, for an improvement in stays.

873 J. Gillies, Glasgow, for improvements in machinery and apparatus for making moulds for casting certain articles in metal.

874 J. S. Brown, Bridgwater, Somersetshire, for improvements in raising or lifting liquids and apparatus therefor.

875 A. V. Newton, Chancery-lane, for improved means for converting a reciprocating into a rotary motion. A communication.

876 J. Lewis, Birmingham, for improvements in joining or connecting the parts of the head, foot, and side rails of metallic bedsteads and cots, and metallic railing for various purposes, which improvements are also applicable to the connecting of metallic ornaments to articles of metallic furniture.

877 F. Ransome, Queen's-street-place, City, for improvements in the manufacture of artificial stone. A communication.

878 P. M. Parsons, Blackheath, for improvements in ordnance and carriages, and projectiles for the same.

879 J. Milroy, Edinburgh, and J. W. Butler, Willesden, Middlesex, for improvements in the construction of coffee-dams.

880 H. Hollefreund, Havelberg, Prussia, for improvements in the treatment of potatoes, maize, corn, millet, and other starch-containing vegetable matters to obtain saccharine and other products therefrom, and in the apparatus employed therein.

881 W. S. Brolly, Southampton-buildings, for improvements in combination locks and in mechanism connected therewith. A communication.

882 L. A. M. Helle, Paris, for an improvement in holding or bottling and drawing off cider. A communication.

883 J. B. Muschamp, Kensington, for a new or improved liquid meter.

884 I. Pickard, Leeds, for an improved arrangement of machinery or apparatus for transmitting motion to sewing machines.

885 C. W. King, Bedford Leigh, Manchester, for an improved method of regulating the speed of marine engines and apparatus therefor.

886 C. Owen, City-road, for the better protection of accidents in railway tunnels.

887 E. A. Cowper, Great George-street, Westminster, for improvements in regenerative hot-blast stoves for heating air, steam, and other gases.

888 W. Darlow, North Woolwich, for improvements in portable magnets for curative and other purposes.

889 J. Howard and E. T. Bousfield, Bedford, for improvements in the construction of ploughs and other tilling implements.

890 R. M. Letchford and W. B. Nation, Three Colts-lane, Bethnal-green, for improvements in the treatment of paraffin.

891 T. Giles, Manchester, for improvement in safety valves.

892 W. Walton, Worcester-street, Pimlico, for a new or improved lever spring lock sash fastener.

893 W. H. Baxter, Brixton-hill, for improvements in machinery or apparatus for weighing or measuring corn and other substances.

894 J. F. Allen, Mott-Haven, New York, for improvements in steam generators.

895 W. R. Lake, Southampton-buildings, for an improved cartridge for fire arms. A communication.

896 W. R. Lake, Southampton-buildings, for improvements in apparatus for mounting and working ordnance. A communication.

897 W. R. Lake, Southampton-buildings, for improvements in apparatus for mounting and working ordnance. A communication.

898 E. G. Brewer, Chancery-lane, for improvements in the construction of studs or buttons. A communication.

899 W. Garton, Southampton, for improvements in brewing.

900 W. R. Lake, Southampton-buildings, for improvements in fire extinguishing apparatus. A communication.

901 A. M. Clark, Chancery-lane, for an improved joist for the lids or covers of gas retorts. A communication.

902 A. M. Clark, Chancery-lane, for improved elevating apparatus for firemen's, builders', and other purposes. A communication.

903 W. R. Lake, Southampton-buildings, for an improved mode of and apparatus for supplying and using steam for driving street-railway carriages and other vehicles. A communication.

904 G. Little, Oldham, Lancashire, and T. C. Eastwood, Bradford, for improvements in machinery for preparing and combing wool, cotton, and other fibrous materials.

905 J. Howard and E. T. Bousfield, Bedford, for improvements in steam boilers.

906 W. Neill, Bold, Lancashire, for improvements in the valves of cylinders used in forcing air.

907 Z. Shrimpton, Redditch, Worcestershire, for improvements in the manufacture of crochet and netting needles, penholders, hair pins, and other similar articles.

908 G. J. Snelus, Dowlais, Glamorganshire, for an improved lining for cupola furnaces, also applicable to the formation of the beds of reverbratory furnaces.

909 W. R. Lake, Southampton-buildings, for improvements in composition bearings for the journals of axles, shafts, or spindles. A communication.

910 S. Moorhouse, Cheadle Bulkeley, Chester, and W. J. Kendall, Heaton Norris, Lancashire, for improvements in the construction of umbrellas and parasols, and for other purposes.

911 T. Smith, Leeds, for an improved fire escape.

912 W. Trimmer, Hornsey Rise, for improvements in casks.

913 J. C. Mewburn, Fleet-street, for an improved mode of and apparatus for making cigarettes. A communication.

914 J. H. Johnson, Lincoln's Inn-fields, for improvements in ice-cream freezers. A communication.

915 H. B. Fox, Oxton, Cheshire, and J. Wilde, Liverpool, for an improved implement for extracting plantain and other noxious weeds and roots from lawns.

916 G. Allix, Church-terrace, Isle of Dogs, and H. Gardner, Clifton-road, Middlesex, for improvements in stoppers, valves, or apparatus for closing the necks, mouths, or openings of bottles and other vessels, and in appliances connected therewith.

917 W. E. Newton, Chancery-lane, for improvements in telegraphic apparatus. A communication.

918 J. Reilly, Barrack-street, Manchester, for improved arrangements of apparatus for the prevention of accidents on railways.

919 J. Lawson and B. Hainsworth, Halifax, for improvements in siphon ventilators.

920 C. R. Mathews, High-street, Bloomsbury, for improvements in apparatus for safe, speedy, and easy mode in fixing, connecting, and disconnecting gas pendant, bracket, pillar, or ground connections, especially adapted for outside reflecting lamps.

921 G. H. Smith, Southampton-buildings, for an improved mode of and appliances for preventing the corrosion of iron pipes or tubes, and keeping them free from incrustation.

922 B. Richards, Penzance, for improvements in walking-sticks.

923 J. E. Holmes, Buckingham-street, Strand, for improvements in apparatus for utilizing atmospheric pressure as a motive-power, part of which improvements relate to pistons for the same and for other purposes.

924 J. Wolstenholme, Radcliffe-bridge, Lancashire, for improvements in steam pumping engines.

925 G. D. Morisseau, Paris, for improvements in buttons for gloves.

926 A. C. Henderson, Charing-cross, for improvements in the distillation and filtration of fecal solid and liquid matters direct from privies for the manufacture of sulphate of ammonia, together with the apparatus therefor; the said process being equally applicable to the distillation and filtration of liquids of all kinds. A communication.

927 J. S. Joseph, Rhosllanerchrugog, Denbighshire, for improvements in the preparation and treatment of oxides of iron for the manufacture of paint and other useful purposes.

928 T. T. Prince, Kensington, and R. Blakemore, Leadenhall-street, City, for improvements in horse-shoes and in nails for the same.

929 C. G. Johnson, Middlesbrough, for improvements in the manufacture of iron and steel and in the apparatus connected therewith.

930 J. B. V. E. Dupont, Manchester, for improvements in musical wind instruments and in the music-holders attached thereto.

931 T. R. Crampton, Great George-street, Westminster, for improvements in furnaces.

932 W. H. Dilnutt, Mawbey-road, Old Kent-road, for improvements in furnace fire bars.

933 G. Westinghouse, jun., Southampton-buildings, for improvements in pneumatic apparatus for working brakes and communicating signals in railway trains.

934 W. P. Butchart, Dundee, for improvements in softening, combing, and beating jute, flax, and other fibrous substances, and in the machinery or apparatus employed therefor.

935 E. Meldrum, Dechmont, N.B., for improvements in the purification of paraffin oils and paraffin.

936 N. H. Hughes, Ayrshire, for improvements in cultivating land and in the machinery or apparatus employed therefor.

937 P. C. Evans, Brimscombe, Gloucester, for improvements in apparatus for feeding scribblers, carding engines, willies, and other opening machines employed in the treatment of fibrous materials.

938 A. Munro, Russell-road, Kensington, for improvements in the extraction of oil and other hydrocarbons from bituminous substances, and for the production of coke and charcoal, and for the means and apparatus employed therefor.

The English Mechanic
AND
WORLD OF SCIENCE AND ART.

FRIDAY, APRIL 19, 1872.

ARTICLES.

THE ALCOHOL QUESTION.

THE Manifesto of the doctors issued a few months ago, together with the efforts of the teetotallers and the Permissive Bill men, to limit or stop the use of alcohol, will probably produce a whole volume-full of opinions on the old vexed questions whether or no alcohol is food, whether its use is attended with good or evil results, as well as on the pressing question as to what extent its sale is to be legalised and permitted. With what may be termed the sentimental aspect of the subject we have but little concern in this article, our purpose being merely to lay before our readers what is known by scientific men of the physiological action of alcohol, and to point out to what extent its use may be beneficial or useful to mankind. Students of chemistry will not require to be told that there are many kinds of alcohol, or that the one to which we have applied the name is really ethyl alcohol, which forms the "spirit" principle of the various decoctions, extracts, and mysterious compounds of the wine-shop and the public-house. Absolute alcohol, when perfectly pure, consists of carbon, hydrogen, and oxygen combined in the proportions which the chemist represents by C_2H_6O, and when absorbed into the human economy by any of the ordinary methods—viz., inhalation of its vapour, injection into the tissues immediately under the skin, or by means of that long-suffering organ the stomach, produces those effects with which dwellers in our cities and towns are only too familiar. Dr. Pereira divided these effects into three well-marked stages—excitement, intoxication, and coma or true apoplexy, and we know that the changes produced are invariably uniform, by whatever channel the alcohol is administered. According to Dr. Richardson, who has written an able article on this subject in the *Popular Science Review*, his researches have shown that the maximum effect is produced when the quantity of spirit is in the proportion of sixty grains to the pound weight of the animal's body.

Is alcohol food, however; and, if so, is it wholesome food, fit for man and beast? A first glance at the chemical formula which is employed to denote this combination of certain elements would induce a reply in the affirmative; for alcohol contains carbon, and that, we know, is heat-giving, and in one or other of its forms is an article of diet at nearly every meal. But there is another point to be considered, by far the most important of the two, and that is can the human stomach split up the alcohol, separate it into its constituent elements, and while sending those which are useless to the various eliminatory channels, can it assimilate and utilise what there may be of nutriment in the remainder? Or, on the other hand, is not alcohol eliminated, in some way or the other, as an unchanged chemical compound? The weight of the evidence which we have at present turns the balance in favour of the latter view; but if we regard the question as incapable of settlement with our present knowledge, we can, at any rate, study the effects of alcohol when administered to the human being, or to members of what is called the brute creation. If, then, we apply to alcohol the same rigorous method of investigation which we employ in estimating the force produced by coal in the furnace of a steam-boiler, we shall find that the "energy" stimulated by spirits is delusive; that it is as much wasted force as that thrown away by a careless stoker who, urging his fire beyond what is requisite, causes his valve to open and permit the escape of steam which has not done its quantum of work. If this were the only effect of the administration or drinking of alcohol little harm would be wrought; but here the analogy of the steam-boiler fails us; for while with the latter no damage is done save the possible straining of the boiler-plates, the force exerted by the alcohol is not merely wasted, but is in reality a powerful agent for injury, which cannot be many times applied without making its injurious effects apparent.

When alcohol begins to exercise its powers on the animal body the first symptom which attracts attention is the increased action of the heart and the arteries; the heart beats quicker, the arteries are filled more frequently, and the surface circulation is accelerated, the minute vessels becoming at the same time distended. These effects are made apparent by the heightened colour of the cheeks, and when the use of alcohol is habitual they become permanent and exhibit themselves commonly in the rubicund nose of the confirmed toper. This phase of alcoholisation, which is the stage denominated "excitement," is recognised in the expression "flushed with wine;" but it would be a mistake to suppose, as is commonly done, that this acceleration of blood-flow and distension of the vessels is peculiar to the parts which exhibit these effects to the observer, for if it were possible to see the lungs, the brain and spinal cord, the stomach, the liver, and other organs, the same conditions would be found to prevail. This quickening of the pulse, these extra beats of the heart, are really so much wasted force, the amount of which has been ascertained by the observations of Dr. Parkes and Count Wollowicz. Their experiments were made upon a young and healthy man who for eight days drank nothing but water; during this period the beats of the heart were counted at intervals, and the same course was pursued on six following days when gradually increasing doses of alcohol were administered. During the water period the average number of beats of the heart in twenty-four-hours was 106,000; but when the subject of observation was under the influence of alcohol the beats of the heart increased to 127,000, being 21,000 extra beats in twenty-four hours. On the first day only one fluid ounce of alcohol was taken, causing 430 extra beats; but 4oz. on the third day produced 12,960 extra beats; and 6oz. on the following day caused no fewer than 30,672 extra beats. As there was ephemeral fever on this day a deduction was made to bring its total between that of the previous and the following day, when eight fluid ounces were given and 23,904 beats calculated. The mean daily excess of beats during the alcoholic period, subject to the correction above mentioned, was thus found to be 14,492. Now, taking the daily work of the heart as equal to 122 tons lifted one foot, we find that under the influence of alcohol it was made to do extra work nearly equal to lifting sixteen tons one foot. "Little wonder is it," says Dr. Richardson, "that after the labour imposed upon it by 6oz. of alcohol the heart should flag; still less wonder that the brain and muscles, which depend upon the heart for their blood supply, should be languid for many hours, and should require the rest of long sleep for renovation." How or why the alcohol produces this action of the heart is not clearly established; but, according to Dr. Richardson, recent inquiries have thrown a light upon the subject, and afforded an explanation of the phenomenon which appears to satisfy him of the erroneousness of the idea that alcohol acts directly upon the heart, stimulating it to increased action. On the contrary, it would seem that the acceleration of the heart's action is due to the removal of resistances which in the normal condition are always existing. We have now learned, he says, that there exist many chemical bodies which act directly by producing a paralysis of the organic nervous supply of the vessels forming the minute vascular circuit. These vessels when paralysed offer inefficient resistance to the stroke of the heart, which thus liberated, quickens in action, dilating the minute and feebly-acting vessels, and giving evidence really not of increased but of wasted power.

When the amount of alcohol imbibed is sufficient to produce the phenomena of the second stage, the well-known state of intoxication is observed. The nervous control of some of the muscles is lost, and they begin to lose their contractile power. The seats of thought and volition in the larger brain are upset; the intellectual part of the man is shunted, and the animal nature has full play, till nervous power is utterly exhausted, the muscles refuse to act, and the whole system becomes insensible in a deep sleep. During the progress to this stage there is a gradual but steady decline of the bodily temperature, which, slightly raised in the first stage by the increased circulation on the surface, declines, for the simple reason that no heat has been really added to the body. It is this well marked and invariable fall in the temperature that helps to prove that alcohol cannot act as food; and that "drops" of spirits taken "to keep out the cold" neither supply vital heat nor assist in preventing its loss. But, instead, after the temporary feeling of increased warmth has passed away, there is a steady decline of heat to several degrees below the normal temperature, and but a slow—a very slow—recovery towards the natural state when the alcohol is eliminated.

Dr. Richardson says that alcohol is in reality a narcotic agent, and he compares its effects with those produced by chloroform—the result being that the action of the two is very similar, save that alcohol is less fatal than the well-known anæsthetic. This is possibly attributable to the fact that under alcohol the different systems act evenly though slowly to the last, and that however much the brain may be influenced the nervous centres which govern the respiratory movements and stimulate the action of the heart remain on duty till the end—the latter the longest; for if death occurs during alcoholisation its cause is purely mechanical, from condensation of fluid on the bronchial surfaces and stoppage of respiration. "The animal is literally drowned in his own secretion."

So far we have spoken only of the effects produced by the abuse of alcohol. There are times, however, when the use of alcohol is beneficial to the human economy as we find it among the ordinary surroundings of civilised life. But these times are few and far between. When the action of the heart is oppressed by too great a resistance, when blood flows languidly, and the springs of life are weakend by disease or other causes, then alcohol is of use; but its use is limited by the rigid line we have pointed out. It may and does serve a temporary purpose; beyond this it is waste of force, waste of health, and waste of money. In short, we may say, as Dr. Richardson says, "The evidence is all-perfect that alcohol gives no potential power to brain or muscle." It is like a fire, hot and energetic while it lasts, but leaving desolation behind; it dees nothing at its own cost; it gives nothing for what it destroys; even the effects we see produced are accomplished, so far as we know, without any expenditure on the part of the alcohol itself; it merely accelerates the consumption of useful matter and leaves behind it injuries more or less irremediable. True, the human system is so "wonderfully and fearfully made" that it adapts itself in a measure to the influences of alcohol, and we see its persistent users occasionally living to the allotted span of the human race. But we know that alcohol does its fatal work surely if slowly; the functions of the organs are destroyed and their structure is altered, and if life still continues, it is in spite of its action. Such are some of the scientific aspects of the alcohol question, recorded without bias to one side or the other; alcohol is not food, and it does more harm than good. With regard to the restrictions, if any, to be imposed upon its sale we have nothing to do with them here.

THE STAR DEPTHS.

MR. RICHARD A. PROCTOR, Hon. Sec. R.A.S., delivered last Saturday, at three o'clock, at the Royal Institution, a lecture on the above subject. This lecture, the first of a course of five, was devoted to the consideration of the ancient constellations, and the traces of them now discernible among the star groups, with the object of showing that the figures of the objects associated with certain star groups can really be recognised at the present time if the boundaries of the modern figures be extended, and that, therefore, the stars may be assumed to shine for the most part with a steadfast lustre. Thus our sun, so far as probable inferences from the star depths are concerned, is likely to shine as he now does for thousands of years yet to come. The second division of the lecture was devoted to the consideration of the scale on which the stellar universe is formed.

A series of mishaps with the illuminating apparatus somewhat interfered with the lecturer's efforts. It may be a consolation to amateur manipulators who have come to grief when using the lantern, that in a single lecture at the Royal Institution the oxyhydrogen light was *twice* suffered to go out altogether, and that scarcely one out of some score of illustrations was brought centrally on the screen or properly focussed. Such mishaps suffice to confuse the most practised lecturer, and it seemed to us that during the delays thus occasioned Mr. Proctor continued speaking rather to divert the attention of the audience from the unfortunate lantern than to advance his argument. Logically, a lecturer should remain silent rather than attempt to fill any gap in his discourse with extraneous matter;

but does the lecturer live who would remain absolutely silent for ten minutes before a Royal Institution audience? Truth compels us to notice, moreover, that owing to the delays we have referred to, the second part of the lecture seemed incomplete. The reasoning was satisfactory as far as it went, though delivered with unusual but enforced rapidity of utterance. But the experienced auditor could scarcely fail to notice that a minute or two before four o'clock the subject was broken off in order that the lecture might terminate at the proper hour.

We think that lecturers should be protected from such mischances, which cannot possibly be regarded as unavoidable. The more carefully a lecture has been prepared, and the more thoroughly the arguments have been weighed, the more mischievous is the effect of interruptions involving, as in the present instance, a considerable delay.

DANKS'S PUDDLING MACHINE.

THE validity of the patent obtained in this country by Mr. Danks is contested, and the agreement entered into, but not ratified, between that gentleman and certain ironmasters, under which Mr. Danks was to have received £50,000, is not likely to be carried out as far as one of its provisions is concerned. It appears that in 1858 a Mr. B. P. Walker patented a rotary puddling machine which differed "in no essential particular" from the one claimed as original by Mr. Danks. The failure of Mr. Walker's machine, when tried by the Dowlais Iron Company, is attributed partly to the imperfect method of working it then adopted, but chiefly to an insufficient temperature. In these experiments a fan was used to urge the blast, instead of reliance being placed on the draught produced by the chimney. Mr. Danks, it seems, knew of this machine, as he referred to its failure at the Dowlais Works, when at the meeting of the Iron and Steel Institute. We hope, however, whether the patent is good or not, that Mr. Danks will be able to secure some recompense for his ingenuity.

METALLURGY OF IRON AND STEEL.*

(*Continued from p.* 86.)

THE following tabular statement was given showing the composition of the gases of a furnace at Alfreton, England, as determined by Bunsen and Playfair:—

Component Gases per Cent. by Volume.	Depth in English Feet Below the Mouth. 5	8	11	14	17	20	23	24	34
Nitrogen	55·35	54·77	52·57	50·95	55·49	60·46	58·28	56·75	58·05
Carbonic acid	7·77	9·42	9·41	9·10	12·43	10·83	8·19	10·08	0·00
Carbonic oxide	25·97	20·24	23·16	19·32	18·77	19·48	26·97	25·19	37·43
Marsh gas	3·75	8·23	4·58	6·64	4·31	4·40	1·64	2·33	0·00
Hydrogen	6·73	6·49	9·33	12·42	7·62	4·83	4·92	5·65	3·18
Olefiant gas............	0·43	0·85	0·95	1·57	1·38	0·00	0·00	0·00	0·00
Cyanogen	0·00	0·00	0·00	0·00	0·00	0·00	Trace	Trace	1·34
Proportion of Oxygen above that associated with 100 parts of atmospheric air ...	11·23	9·41	13·67	10·56	13·04	7·76	10·92	13·68	5·97

The old furnaces were very irregular shaped things, the worst possible shape, because affording opportunity for lodgment of the materials in descending. We may consider the matter in the interior of the furnace as consisting of two columns: one of solid materials perpetually going down, being replenished at the top, and going out at the bottom in the form of pig iron or slag; and an upward column of gaseous matter. It is evident that the furnace ought to be constructed to allow the gradual descent of the material, so as to prevent stoppage, and especially lodgment. It was, however, years and years before man learnt the lesson of experience. Not many years ago, Mr. Gibbons examined into the state of furnaces, and he found that a furnace never worked well until a certain period had elapsed, and that during this time the furnace underwent certain changes of form in the interior by the action of the fire and heat, and when that operation was effected the furnace was in good working order. He found that it is necessary that the furnace should have a regular curvature, otherwise a certain time is required to fill up the inequalities. It may be inquired why the lower part of the furnace is constricted. When the air is blown in at the lower part of the furnace vigorous combustion takes place, and that matter is converted rapidly into gas. The temperature here, moreover, is very high—sufficient, and more than sufficient, to fuse pig iron—and therefore a great contraction of volume occurs, because the carbon is continually disappearing, and the materials remaining occupy a much less space. Accordingly, the lower part of the furnace must be constructed proportionally to the relative bulk of the material in its descent. There is another reason why there should be this contraction. We have a great mass of ore, limestone, and fuel in the furnace which will, of course, exert great pressure. If we had the furnace cylindrical down to the bottom, we should get all the pressure of that column of superincumbent material bearing like a dead weight on the fused metal, which would, therefore, be pressed upwards, and there would be no room for the gaseous column, but by means of the contraction, the sides of the furnace take off a great deal of that dead weight, and prevent this contingency. They are usually also contracted at the top, for the convenience of supplying the materials, and in order to prevent too great loss of heat by radiation.

Hot Blast.

This effect was invented by a gas engineer of Glasgow—Mr. Lindsay,—which fact drew forth from the lecturer some remarks about the benefits which had accrued to metallurgy since the manufacturers themselves set to work to become acquainted with the process both in theory and practice. The utility of the hot blast may be seen from the fact that in some furnaces where to obtain a ton of pig iron required 8¼ tons of coal, on the application of a blast heated to a temperature less than that of melted lead, the same amount of iron was obtained with 3 tons of coal. As to the theory of the hot blast, there is at present great uncertainty and little agreement. Some ironmasters are disposed to think that, if the furnace was made high enough, so as to intercept as much of the heat as possible from the gases rising upwards, then you would have as much effect as can be obtained by hot blast. The greater quantity of heat kept in the furnace, the better it should be for the working of it. In the case of a low furnace the gas which has been very highly heated below soon escapes into the air as a waste useless article, carrying off with it an enormous quantity of heat. The first idea, therefore, is to make the furnace higher and higher, and, this being filled with cool solid materials, thus absorbs from that ascending current of gas heat, and becomes warm, and thus is a useful contribution to the economical working of the furnace.

One mode of heating the blast, commonly adopted in South Staffordshire, was then described. The blast is heated by stoves, and may be considered as not fewer than four stoves built together. The heating apparatus consists of two mains of cast iron placed parallel to each other at each side of a fireplace. In these mains are fixed a vertical series of pipes of a siphon form, set by socket or other joints in the main; these pipes are usually oval in section, this form exposing a greater heating surface than circular. The whole of the pipes and apparatus is inclosed in brickwork, a fire is made between the pipes, and air is blown into one of the mains and made to traverse the whole series of pipes by plugs being placed in the mains on each side alternately. The air is thus heated to a temperature usually about equal to that of melted lead.

Slags.

These are more or less earthy, like glass, and often crystalline. The lecturer exhibited one fine piece which he had obtained from South Staffordshire, which in one part showed quite a crystalline structure, while in another it was entirely earthy and stone-like; yet the composition of both was substantially the same. The reason of this was explained to be that the part of the melted mass which is most rapidly cooled retains its glass-like structure; the interior, which is cooled more slowly, becomes highly crystalline, exactly as obtains in glass working. If you take a piece of common green bottle-glass and heat it for a long time at a temperature far below its melting-point, it ceases to be transparent, becomes much harder, opaque, and highly crystalline. The same thing takes place in a piece of barley-sugar; and so also in the slags from a furnace. The more rapidly it is cooled the more certain is the part to be glass-like. It often assumes various colours, black, brown, blue, green, &c. Its constituents are the ash of the fuel, the lime, &c., and on analysis they are found frequently to contain silica, alumina, lime, magnesia, oxide of iron, oxide of manganese, and in some cases potash. One specimen was shown, which the lecturer said contained one per cent. of potash, or one pound's worth in a ton of the slag, but no process had yet been discovered by which to extract the substance economically. Attempts have been made to fashion the slag into various ornamental objects.

Waste Heat.

Formerly a great deal of heat was wasted by the furnaces being left open at the top during their working. Because we have large deposits of coal we ought not to be profligate in the use of that material. Although a delicate subject to touch on, the British fireplace really utilises only about one-eighth of the heat of the coal consumed. The lecturer said he would undertake to warm any house effectually and far more pleasantly with about one-tenth of the coal now consumed. He did not believe there was any foundation for believing that a substitute for coal would be found. It is a question whether we are wise in exporting so much, or any, of this wonderful subterranean treasure we possess.

There are several ways of economising heat in the blast furnace; one means is as follows:—A large quantity of heat is carried up by the ascending column of gas, and if this be allowed to escape at once into the air, the whole of this heat is wastefully dissipated. Now, however, this hot gas is extensively used for heating the blast, for which purpose it is conveyed into the stoves and there burnt with the due admission of atmospheric air. Or it may be mixed with a due proportion of atmospheric air, and conveyed away and burnt under the boilers of engines. Another method is to place in the top of the furnace a cast-iron pan of conical form, with the apex of the cone upwards, suspended by a chain to the end of a lever, so that although, in its usual position, it entirely stops up the orifice at the top of the furnace, it can be let down a short distance to admit of the introduction of materials for the operations. Under this cone a hole is made in the side of the furnace, and a pipe fitted into it to convey away the gases from the furnace to be utilised.

The first time these methods were applied in this country was at Swansea, in 1848, but they had been previously and successfully employed in Germany, and the Germans were thought to be the inventors of the process. But on looking a little farther back I came upon a French article published so long ago as 1814, giving an account of the application of the gases from the top of the blast furnace in 1811. Let me once more remind you that it is not so much (possibly not at all) the sensible heat of the gases which is employed, but the heat evolved during their combustion.

Wrought Iron and Cast Iron.

These terms are commonly used to denote two different kinds of commercial iron. The former is often called "malleable iron," the name implying that it is malleable or hammerable; it is the nearest approach to the pure metal, which is extremely difficult to obtain. It can be rolled out into thin sheets, or drawn out into very fine wire—in other words, it is very ductile. It is forgeable and weldable.

If you try and hammer pig iron it will break directly; it is more or less brittle; it melts easily, wrought iron requiring a very high degree of temperature to melt it. It is not weldable. What

* An abstract report of a course of lectures by Dr Percy at the London Theatre of the Geological Museum.

is the cause of this difference? Malleable iron gives no evidence of the presence of carbon, or only a very small quantity, under one-tenth per cent.; pig iron has three or four per cent. of carbon. In fact, pig iron is iron essentially combined with carbon.

There are two kinds of pig iron, grey and white; both agree in containing carbon. If oxide of iron be heated with charcoal, until you reduce the oxide, and get the metal to take up as much carbon as possible, the result will be grey cast iron. Now, if this be acted on with spirits of salts dissolving all the iron, there remains a black residue of "black lead" or graphite, and this in the grey cast iron is separate, but diffused through the mass in fine scales, so that grey "pig" is nothing more than wrought iron containing black lead diffused through it.

IRON BARGES.

THE question of building iron barges for canal transit is beginning to attract considerable attention at Buffalo and other cities immediately interested in canal business. The experiment of iron boats was tried many years ago, and only failed because of the then greater cost of iron over wood, and the want of facilities which now exist for repairing the iron hulls. These objections no longer exist, and we understand the relative advantages of wood and iron are to be again tested by the construction of iron barges to run in competition with boats already engaged in the canal service. The advantages claimed for iron boats are that they are lighter, and, owing to the thinness of their sides, have a greater stowage capacity for freights than the most capacious wooden boats that can pass the locks. Should these claims be substantiated by actual trial—and we have no doubt, says *Van Nostrand's Magazine*, they will—it is not improbable that iron will supersede wood upon canals, as it is now doing in river, coastwise, and ocean navigation.

SPONTANEOUS COMBUSTION.

IN March last, a well-known Detroit druggist, assisted by two seriously inclined and science-loving gentlemen, resolved to make a number of experiments to test the worth of the talk about spontaneous combustion, and their experiments are well worth the attention of every reader.

They first took a piece of cotton cloth, which had once formed part of a sheet, and which had been used until quite threadbare, and smeared it with boiled linseed oil. An old chest was placed in the loft of a store room back of the drug store, a piece of zinc over it, another piece under it, and then the chest filled with paper and rags, and this particular piece of cloth placed in the centre. Although the room was not a light one, and the weather cold, in eight days there was such a smell of fire about the trunk, and the chances were so good for a conflagration within it, that the contents were emptied.

An examination showed that the fibre of the oil-cloth had untwisted and shrivelled up, and that the rag looked as if it had been held too near a hot blaze. In April, when the rays of the sun were stronger, a pair of painter's overalls, literally covered with paint and oil, were rolled up, a handful of pine shavings placed inside, and these were crowded in next to the roof boards of the loft. The experiment was not a week old when, during one warm afternoon, a smell of smoke alarmed a workman in the next room, and he found the overalls burning, and so tinderlike was the cloth that it had to be crowded into a pail of water to prevent total destruction.

During the hot weather of August, a handful of old cotton rags, in which two matches were placed, but which were not smeared with oil or other matter, were shut up in a tin box, and hung up in the loft, a rear window allowing the afternoon sun to shine directly on the box for several hours. Toward the close of the fourth day the druggist took down the box to see how the experiment was progressing, and found the contents to consist of nothing but a puff of black cinders, which flew all over him as the lid was lifted. Having a vacant corner in his brick wood-house at home, the druggist took the trunk up there, where there was no danger of burning a building. He filled the trunk with the contents of the paper rag-bag, and then smeared one with benzine and threw it in last of all. The trunk was shut tight, everything cleared away from its vicinity, and he commenced watching. One day the family came home to find a few ashes marking the place where the trunk stood, while the bricks above and around were badly stained with smoke.—*Scientific Press.*

Proposed Submarine Tunnel.—It is proposed to tunnel under the Strait of Canseau, between Nova Scotia and Cape Breton, in order to connect the railway at Cape Breton with the mainland. The distance is about 2¼ miles. It is estimated to cost the moderate sum of 2½ millions of dollars.

THE GERMAN NORTH POLE EXPEDITION.

THE *German Correspondent* states that in a sitting of the Geographical and Statistical Society of Frankfort, held on the 27th ult., Lieutenant Weyprecht spoke at some length of his approaching North Pole Expedition. He bases his calculations chiefly on the great Siberian currents, which, on account of their high temperature, greatly contribute to free the northern coasts of Siberia from ice. This effect is most strongly observable in September. The expedition is to sail in its own ship, which will be provisioned for three years. It is to leave Bremerhaven in June, touch at Tromsoe to coal, then leaving Nova Zembla on the south, it will seek its first wintering quarters as far as possible to the east of Tcheljuskin, the most northern cape of Asia. From this point long sledge journeys will be undertaken. New Siberia has been chosen for the second year's wintering place. In the third year the expedition will endeavour to return by way of Behring's Straits. Should this prove impossible, nothing will be left but to abandon the ship, and to endeavour with the boats to make the mouth of some Siberian river, and reach the nearest Cossack posts. One of the weakest points of the expedition is the fact that the store of coal, after calculating what will be required to heat the cabins and for cooking purposes, will only enable the ship to steam at full speed for forty days during the whole period of the expedition. In other respects the vessel is fitted up in a manner admirably adapted to the wants of the expedition, and the provisions have been very carefully selected. In order to avoid scurvy, all salt meat has been excluded, and preserved vegetables have been plentifully provided. Meiding's regulation stoves, which Koldewey's expedition proved to be the most satisfactory, will be employed for heating purposes.

LESSONS ON CHEMISTRY.*

By SELIMO R. BOTTONE.

(*Continued from p. 85.*)

SECTION 7.—SULPHUR.—*Symbol:* S''.[1] *Atomic weight:* 32. *Molecular weight:* 64.

145.—PROPERTIES.—In its ordinary condition, sulphur (also called *brimstone*) is a pale lemon-yellow coloured solid, possessing little or no taste, tolerably hard, but very brittle. Its specific gravity varies from 2·05 to 2·08. On breaking a rod of sulphur, the fresh surfaces are found to be strongly electrical. If melted sulphur be poured into a wine-glass, and a handle of wood be held in it until the sulphur is solidified, on removing the cone of solid sulphur from the glass it is found to be charged with electricity. By friction also sulphur becomes electrified, as it is a very bad conductor of electricity; during friction a peculiar odour is generated. Sulphur melts at about 232° Fahr., and from that temperature up to 280° appears as a light amber-coloured fluid. On increasing the heat, it darkens in colour, gradually loses fluidity, until on reaching a temperature of 450° Fahr. it becomes so viscid that the containing vessel may be momentarily inverted without spilling the contents. At about 500° it again becomes fluid, and at 824°[2] Fahr. sulphur boils, yielding a red vapour, which condenses on cold surfaces in the form of a fine yellow powder, known in commerce as *flowers of sulphur.* Sulphur is insoluble in water, but is slightly soluble in alcohol and ether, and freely so in oils, hot turpentine (which dissolves about ten per cent.), and in carbon bisulphide. The affinities of sulphur are very powerful, and its vapour supports the combustion of many metals. The compounds formed by the union of sulphur with the other elements are very similar to, and generally isomorphous with, the corresponding oxygen compounds. Like oxygen, it can assume the allotropic state; several well defined forms being known, of which the following are the most important:—

1. Ordinary sulphur, distinguished by crystallising in *octahedra*, and having an average specific gravity of 2·05.—This variety appears to be the normal state of sulphur, as all the others gradually return to this form. It is soluble in oil of turpentine, in sulphur chloride, in carbon bisulphide, and in benzole.

2. Prismatic sulphur.—This variety is obtained by melting ordinary sulphur at 232° Fahr., allowing it to cool until a crust forms on the surface, when, on piercing the crust, and pouring off the fluid sulphur remaining, the inner surfaces are found strewn with transparent prismatic crystals. These, however, soon become opaque, and are then found to consist of an agglomeration of octahedral crystals of ordinary sulphur. The specific gravity of this variety is 1·98. It is also soluble in carbon bisulphide.

3. Amorphous[3] soluble sulphur.—This is a milky white powder, obtained by precipitating sulphur from a sulphide by means of an acid. This variety also is soluble in carbon bisulphide.

4. Amorphous insoluble sulphur.—This is a dirty-looking magma formed by decomposing sulphur chloride by the addition of water. It is insoluble in bisulphide of carbon.

5. Plastic sulphur.—If sulphur be heated to about 500° Fahr., and then be poured into cold water, it assumes the appearance and consistence of softened guttapercha, and retains this state for several hours, or even days. Hence it may be used for taking impressions. In this form the specific gravity of sulphur is 1·96. If plastic sulphur be gradually heated to 212° Fahr., it suddenly becomes fluid, while the temperature simultaneously rises to 232°, owing to the evolution of the latent heat contained in the plastic sulphur; or, in other words, owing to the change in its molecular arrangement. Plastic sulphur is insoluble in carbon bisulphide.

146.—Sulphur is a very important element, both as regards its place in the economy of Nature, and its uses in the arts.

147.—STATE IN NATURE.—Sulphur occurs in the free state in volcanic districts, crystallised in the octahedral form; often incased in pipe-like incrustations of calcareous tufa. (See Fig. 11.) The ores of the commoner metals are mostly compounds of these metals with sulphur (such compounds are called *sulphides*). Sulphur also occurs combined with many metals and oxygen, as sulphate of lime, plaster of Paris or gypsum, heavy spar, &c. It also enters into the composition of many vegetables, as garlic, horse-radish, mustard, onion, leeks, &c., and occurs in the animal kingdom, in albumen, hair, wool, &c.

148.—PREPARATION.—Two processes are followed, one by which the crude sulphur as it occurs in Sicily, &c., is purified from the blue clay, tufa, &c., with which it is mixed, and the other by means of which the sulphur contained in iron pyrites (iron sulphide) is caused to separate from the iron:—

1. Crude sulphur is introduced into the first of a series of large earthenware jars, furnished with spouts at different heights, those of the first jars being nearly at the top, while those of the last are near the bottom. (See Fig. 12.) Heat is then applied, the sulphur in the first jar melts, the earthy impurities sink to bottom of the jar, while the fluid sulphur flows from the spout into the next jar, where a similar deposition of impurity takes place, until, on arriving in the last jar, it is considered sufficiently pure to be run off into wooden tubs containing water, which cools it. Thus prepared, sulphur contains about 15 per cent. of earthy impurities, and is subjected to a second fusion and decantation to obtain it in a purer state.

2. On heating iron pyrites (which is a compound of iron with sulphur) in closed vessels, the sulphur volatilises and may be collected in the ordinary mode. The apparatus required is a large earthenware retort connected with a cool receiver. Sulphur is now manufactured on a large scale by these means. After being prepared by either of the above methods, sulphur is ge[illegible]lted and run into cylindrical moulds, [illegible] as "roll sulphur." Or it is p[illegible] retort connected with a lar[illegible] (Fig. 13.) On the application [illegible] volatilises, passes into the ch[illegible] as a fine powder (flowers of [illegible]

[1] According to several chemists, sulphur is to be considered *hexavalent*, hence Dr. Frankland notes it as Svi. But no compounds with hydrogen with formulæ corresponding to $S^{iv}H_4$, or $S^{vi}H_6$ are known, hence its quadrivalence or hexavalence is based on very dubious grounds. If sulphur be hexavalent, oxygen must be so likewise, for oxygen can be substituted for sulphur in almost every known compound.

[2] Dumas. Some give 559° as the boiling point of sulphur: on what grounds I do not know. I have never known it to boil (under the ordinary pressure) below 800° Fahr.

[3] Amorphous, shapeless—that [illegible] definite form, not crystallisable.

very pure form of sulphur, but it still contains traces of arsenic and other volatile bodies. From these it may be purified by solution in carbon bisulphide and crystallisation.

149.—The uses of sulphur are many and varied. Many important manufactures depend almost entirely upon sulphur; such are the preparation of oil of vitriol, vulcanite, gunpowder, &c. It is also much used in medicine as a mild purgative, and is an excellent application, either alone or in conjunction with iodine for several cutaneous disorders.

Section 7a.—Compounds of Sulphur with Hydrogen.

a. Hydrogen Monosulphide.—*Synonym: Sulphuretted hydrogen; hydrosulphuric acid; hydrogen sulphide.*[4] *Symbol:* $H_2'S''$. *Molecular weight:* 34.

150.—Properties.—At ordinary temperatures this compound is a transparent colourless gas, possessing a most disgusting odour of rotten eggs[5]. Its specific gravity (air = 1·00) is 1·171. It is a potent poison, the presence of $\frac{1}{250}$ by volume in air being sufficient to kill a horse. One volume of water at 32° Fahr. dissolves 4·3706 volumes of this gas, and the resulting solution possesses the characteristic odour and most of the properties of the gas itself. When hydrogen sulphide acts on metallic oxides an interchange of the metal in the oxide for the hydrogen in the sulphide takes place, as illustrated by the following equation:—

$$M_2''O'' + H_2'S'' = M_2'S'' + H_2O.$$

It also reddens vegetable blues; hence it is entitled to be considered as an acid, and is often called hydrosulphuric, or sulphydric acid. The compounds, which result from the action of sulphydric acid on many metallic solutions, are insoluble, and generally endowed with very characteristic colours; hence a solution of sulphydric acid is in daily use by the analytic chemist as a test for the presence of certain metals. Under a pressure of seventeen atmospheres, or when cooled down to 101° Fahr., sulphuretted hydrogen gas becomes liquid. This liquid is transparent and colourless, and has a specific gravity of 0·9. Exposed to a temperature of — 122° Fahr., it solidifies to a white ice-like mass.

151.—In order to reduce gases to the liquid or solid state, three processes are generally followed. The first consists in compressing the gas in a strong cast-iron vessel until liquefaction takes place. The second depends on applying freezing mixtures to the outside of the vessel containing the gas. The third consists in the simultaneous application of cold and pressure. In the first case a strong, egg-shaped, cast-iron vessel, provided with a stop-cock at top and bottom, is provided. Into this the gas to be liquefied is pumped by means of a condenser. When the requisite pressure has been obtained the gas begins to liquefy. The stop-cock which communicates with the condensing-pump is then to be closed, when the liquid may be drawn off for examination from the lower stop-cock. Generally speaking, on allowing the liquefied gas to escape in a fine stream, it returns to its primitive form with such rapidity as to freeze a portion of the liquid to a snow-like mass. This is owing to the fact, that the heat necessary to convert the liquid into gas is abstracted from part of the liquid issuing, which consequently assumes the solid form. Fig. 14 illustrates the apparatus required. In the second process, the gas to be liquefied is passed into a U-shaped tube (see Fig. 9) immersed in a freezing mixture.

We owe the third mode to Professor Faraday. A strong glass tube, bent at right angles and closed at one end, is provided. A substance, capable of evolving the gas to be liquefied on the application of heat, is introduced into the tube, and caused to fall into the closed extremity of the tube. The open end of the tube is now closed by melting the tube over the flame of a lamp, &c. Heat is now applied to the extremity containing the gas generating substance, while the other extremity is immersed into a freezing mixture. Under the combined influence of pressure (from the evolving gas) and cold (from the freezing mixture) the gas liquefies. (See Fig. 15.) The tube may be quickly divided and sealed over a flame, and the resulting liquid preserved.

[4] Hydric sulphide.

[5] Their smell arises from the presence of this gas, derived from the decomposition of the albumen.

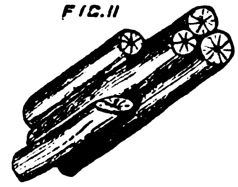

FIG. 12

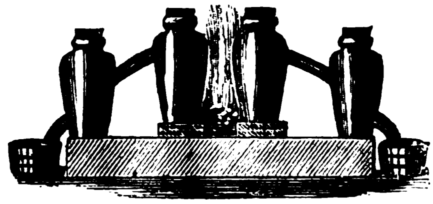

FIG. 13

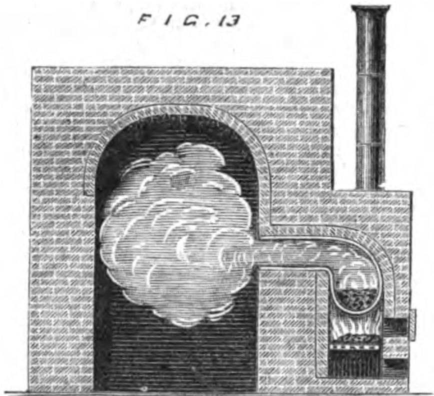

FIG. 14

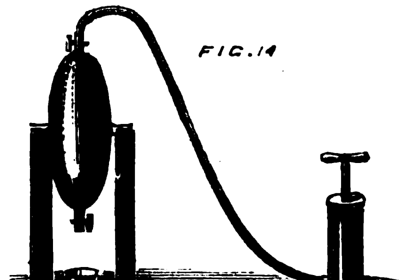

FIG. 15

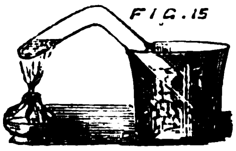

FIG. 16

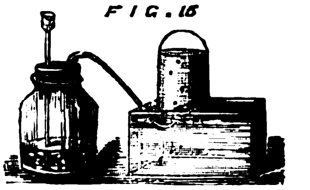

FIG. 17

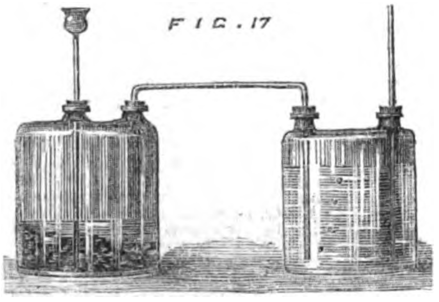


152.—Hydrogen sulphide burns in air on ignition with a pale bluish white flame. The products of this combustion are water and oxide of sulphur, as the following equation illustrates[6]:—

$$H_2'S'' + 3O'' = H_2'O'' + S''O_2''.$$

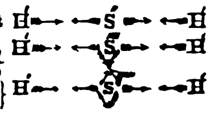
As the elements of the chlorine group possess a much stronger affinity for hydrogen than sulphur is endowed with, they are able to decompose hydrogen sulphide, by precipitating the sulphur and combining with its hydrogen. In the case of iodine, the following equation exemplifies the interchange:—

$$H_2'S'' + 2I' = 2H'I' + S''.$$

Advantage may be taken of this property for the preparation of hydriodic and hydrobromic acids.

Hydrogen monosulphide may be regarded as water, in which the oxygen has been replaced by an equivalent quantity of sulphur. Hydrogen monoxide (water) being $H_2'O''$, hydrogen monosulphide is $H_2'S''$. The molecular constitution of hydrogen sulphide may be represented in several modes, according to our estimation of the valency of sulphur:—

1. Sulphur considered bivalent
2. Sulphur considered quadrivalent
3. Sulphur considered hexavalent



153.—Preparation.—Sulphur can be made to unite directly with hydrogen by the application of heat; hence, if sulphur be sublimed in an atmosphere of hydrogen, or if hydrogen be passed through melted sulphur, sulphuretted hydrogen is the result. For laboratory uses a simple method is adopted, depending on the power which chlorine and several other bodies have of displacing sulphur from its compounds with the metals and substituting it. For this purpose a sulphide (generally iron sulphide) is introduced into a wide-mouthed phial. A cork carrying two tubes, one bent at right angles, and the other terminating in a thistle funnel, is adapted to the phial. Hydrochloric acid is poured in through the funnel, and, coming into contact with the iron sulphide, combines with the iron, liberating the gas, which may be collected from the bent tube in the ordinary mode (over *warm* water). Or it may be collected in recipients half filled with water, which will absorb it, and the resulting solution preserved for use. Figs. 16 and 17 represent these two modes of operating. The following equation illustrates the changes which take place when iron sulphide and hydrochloric acid are used:—

$$Fe''S'' + 2\,H'Cl' = Fe''Cl_2' + H_2'S''.$$[7]

154.—State in Nature.—Sulphuretted hydrogen occurs among the gases evolved from volcanoes, and is found dissolved in several mineral waters, such as those from Harrogate, &c.

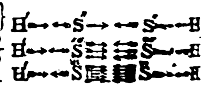
b. Hydrogen Bisulphide.—*Synonym: Hydrogen disulphide.*[8] *Symbol:* $H_2'S_2''$. *Combining weight:* 66.

155.—Properties.—This compound appears as a viscid, yellow, oily-looking body, heavier than water. Its specific gravity is 1·769. Like its relative oxygen compound (hydrogen dioxide) it is very unstable, being easily decomposed by heat into sulphur and hydrogen monosulphide, thus:—

$$H_2'S_2'' = H_2'S'' + S''.$$

It possesses distinct bleaching properties, and whitens the skin. Its odour and taste are similar to those of sulphuretted hydrogen. The constitution of this compound may be expressed graphically as follows:—

Sulphur considered as a bivalent element
Sulphur considered as a quadrivalent element
Sulphur considered as a hexavalent element



156.—Preparation.—We have already seen that when acids act on certain metallic dioxides in the presence of water, hydrogen dioxide is produced. In like manner, when hydrochloric acid acts on calcium disulphide, hydrogen disulphide is found and sinks to the bottom of the containing vessel, while calcium chloride remains in solution, as the following equation illustrates:—

$$Ca''S_2'' + 2H'Cl' = Ca''Cl_2 + H_2'S_2''.$$

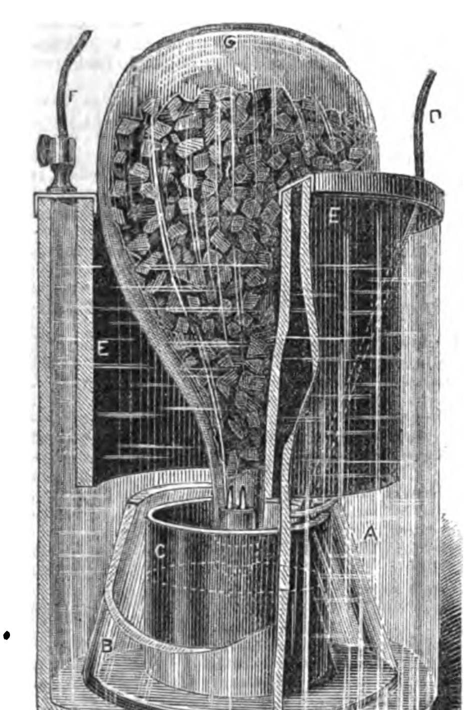
[6] As the nitrogen contained in the air takes no part in the reaction, no notice is taken of it in the above equation.

[7] Iron is by many regarded as quadrivalent; but in order not to confuse the student, we have taken no note of the two reciprocally satisfied valencies.

[8] Bisulphuretted hydrogen. Hydric disulphide.

HIMMER'S GALVANIC BATTERY.

WE gave a brief account on p. 344 of our last volume of a new arrangement of galvanic cell, for which it was claimed that the power could be regulated at will, and the action made continuous so long as the supply of the materials lasted. In order that our readers may be enabled to form a better idea of this cell and to test its advantages, if any, we give an illustration of it as patented in the United States. In the figure, A is a glass jar, resting on the bottom of which is a smaller vessel B in the shape of a truncated cone. In this latter the copper element C is placed, being a thin hollow cylinder to which the wire D is connected. E is the zinc, also a hollow cylinder, supported on the top of the jar A by means of a rim, and attached to which by a screw cap is the wire F. An inverted flask G is so held by the internal edge of the zinc cylinder that its neck just dips into the copper cylinder C contained within the vessel B. The mouth of this flask is stopped by a cork fitted with two tubes, the upper ends of which are drawn out fine to prevent blocking up by the copper salt. The flask is filled with sulphate of copper crystals and water; the jar A being supplied with a solution of magnesium sulphate. The flask is then inverted, and the water dissolving the crystals, the solution gradually flows out into the vessel B, where the pressure being



balanced it rises only up to the tubes in the cork of the flask. The inventor, however, does not state to what height in the jar A the magnesium sulphate solution is allowed to stand. The amount of copper thus brought into contact with the sulphate solution will be active in the cell, and the copper of the solution is deposited by electrolysis on the cylinder C. The sulphate of zinc deposits at the bottom of the jar A, being prevented from dropping into the vessel B by the form of the latter's sides. By this arrangement the inventor claims that the cell will work until the copper salt has been all decomposed or the zinc consumed; but as there is always sufficient copper solution in B to keep the cell in action while the flask is refilled the constancy of the battery is only determined by the duration of the zinc. Now that we have given an illustration of an arrangement which has been thought sufficiently valuable to patent in America, possibly some of our electrical readers may experiment upon it and let us know the result.

Amber.—It is thought that the supply of this substance will soon be considerably augmented. Hitherto amber-gathering has been a very uncertain operation: but it has now been ascertained, by boring, that the blue clay in the neighbourhood of Königsberg, in which amber deposits occur, is of greater extent than was supposed, and arrangements are being made to explore this clay in the usual mining style.

SOME RECENT IMPROVEMENTS IN ENGLISH AND AMERICAN BOILERS.*

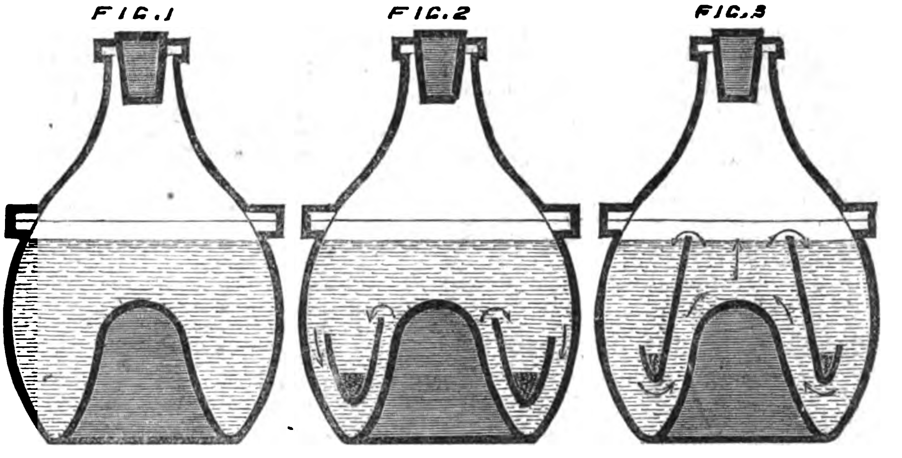
By W. Forsyth Black.

MUCH has been done to perfect the steam-engine, while, as regards the inseparable fundamental source of its power, comparatively little attention has been given to the improvement of the design of the boiler. It has been estimated that from 80 to 86 per cent. of the whole power furnished by the boiler has been employed by the engine in the work it performs, whereas the best boilers commonly in use do not yield over 10 per cent. of the power produced by the combustion of the fuel.

I purpose describing as briefly as I can, and as clearly as the means at my disposal will allow me, a cast-iron boiler which has been for some time in use in this country. Before entering on the arrangement and details of this boiler, let me describe some simple experiments, which give a general idea of the principles the inventor of this class of boilers claims to have carried out in their construction.

The first was originally made by the late Charles Wye Williams, of Liverpool, and is as follows:—A flask like the one represented at Fig. 1, and shown in section, was employed. The upper portion was made of copper, and securely fastened to the lower part of glass. This flask was placed, after having been partly filled with water, over a gas jet, the mouth being closed with a stopper. As soon as the pressure of steam in the interior was sufficient to force out the stopper, the steam not only escaped, but the greatest part of the water was also forced out. Mr. Joseph A. Miller, of New York, made a somewhat similar experiment, but with a flask sufficiently strong to stand a pressure of 50lb. to the square inch, on which he placed a safety-valve so arranged that it would lift suddenly at a pressure of 30lb. After this flask had been placed on a fire, his assistant and himself watched what would result through a small hole bored through a plank which they placed before them for safety.

FIG. 1 FIG. 2 FIG. 3



A few seconds after the flask had been fifteen minutes on the fire, the safety-valve opened entirely, a powerful jet of steam was forced out of the opening, and *instantly after* the flask burst with a loud report, shattered every pane of glass in the window, and damaged the ceiling. The time between the sudden opening of the valve and the explosion was exceedingly short, and seemed just sufficient for the water to be forced against the upper part of the flask when the whole was shattered to pieces.

The second experiment was made with a similar flask, precisely alike in all its arrangements, with the exception of a shield made like a cone-shaped cup, which was suspended within the flask near the bottom, as shown in Fig. 2. This shield divides the water into two parts—one a thin film near the heating surface, and the other, much larger in quantity, not directly exposed to the heat. A little powdered amber was put into the water, that the nature of the currents produced by the application of heat might be observed. When the flask was placed over the gas burner it was found that the heat is first communicated to the cone of the glass, and consequently transmitted to the water in contact with it, as any one would readily suppose. A large portion of the heat, however, is radiated from the inner surface of the flask, and being intercepted by the shield, a thin film of water is, therefore, in contact with two heating surfaces. This water soon becomes warm, and consequently lighter. It was, therefore, forced upwards by the cooler and heavier water in the larger space, and thereby a circulation was produced. This was shown by the motion of the particles of amber to be slow at first, but increased rapidly as the heat took more effect, and in all cases from the bottom, as shown by the arrows in the Fig. Though the motion became rapid in the thin film, it was much slower when it left the heating surface. It was also observed that since this was so, the amber became gradually deposited in the pocket formed by the shield at a distance from the heating surface, and thus no foreign body adds to the thickness of the part through which the heat acts most directly. The pressure soon became sufficient to force out the stopper, and all the water above the top line of the shield was forced out also, but what was below this line remained in flask.

A third experiment was tried with a flask, as before, but in this instance the shield was carried up to the water-level as shown in Fig. 3. When this flask is placed on a gas burner, the whole heat is concentrated on the water between the flask and the shield, instead of part of it being permitted to act on the larger body of water as in Fig. 2. The steam is at once carried into the steam space, not by its own force, but by the superior weight of the cooler water. When the stopper was forced out, not only was no water forced out along with it, but the water level was not in the least altered.

The explanation of the above has been supplied by the hypothesis of Dr. Ure, and others, which is that vapour is formed in the water, and may remain in it, and that unless mechanically assisted, the steam does not leave the water until the water is thoroughly saturated, when the new vapour, which the heat goes on forming, escapes by a series of miniature explosions. For this reason the boiling point differs with the amount of pressure under which evaporation takes place, and this, too, is the reason why the temperature of all liquids suddenly falls when they are stirred. This vapour, mechanically set free, indicates that the presence of the heated vapour in the liquid was the cause of the higher temperature. If apparently boiling liquid in a pot be stirred, the boiling instantly ceases, and the only change is a copious discharge of vapour, and an instantaneous fall of temperature. If the liquid itself had been only raised in temperature to the boiling point, no such effect could have been produced, as nothing had been done by stirring to cool it to any material degree.

Steam is an elastic vapour, and its pressure is proportionate to its bulk, or to the whole space which a given number of atoms (so to speak) occupy at any temperature. When a boiler is working under a pressure of 45lb., the temperature of the steam is 290°, both in the water and steam space. Water cannot, under atmospheric pressure, be raised to a higher temperature than 212°, and water being a medium 813 times denser than steam, it has the capacity of retaining in mechanical mixture with itself steam under at least the same pressure as that in the steam space, and the steam contained in the water cannot be released until the pressure in the steam space is effectually relieved, or sufficient heat or power added to force it from its place in the water. This immense power stored up in the water is the cause, not of the rupture itself, but of the sad and disastrous effects of boiler explosions.

In the first experiment the whole of the water was forced out along with the steam, because the water being itself full of steam, contained the power which expelled it. When the experiment was tried, as I have described, with the addition of a safety-valve, this valve allowed the steam alone to escape, but the space thus vacated by this steam was instantly occupied by what had been previously in mixture with the water. This new and much greater supply then thus set loose, and freed all the more rapidly by the mechanical action exerted by its rush into the space previously occupied by the steam which had escaped by the safety-valve, dashed the water against the sides of the flask, and, as I have stated, destroyed it. In the second experiment the water above the line of the shield only was driven out, simply because the portion below that limit contained no steam, but water alone, which had given up its steam in consequence of the rapid, though partial, circulation induced as explained. Most of the water above the shield, like *all* the water of the flask in the first experiment,

* Read before the Civil and Mechanical Engineers' Society.

contained as much steam, bulk for bulk, as there was in the steam space itself. In the third experiment, the circulation, by raising the shield to the water-level, was extended to the whole mass of water, each part of which gave up its steam as it approached the water-line; and when the steam escaped there was no force remaining behind stored up in the water, either entirely or partially, as in the first and second experiments, to force the water out after the steam. The steam, then, in the third experiment escaped as nearly dry steam by itself, and the water which remained in its entirety in the flask was simply water without admixture of vapour.

If steam be carried mechanically into the steam space and separated from the water, it will rise freely into its own element, no matter what the pressure may be. For instance, if the steam in the steam space be at a pressure (say) of 100lb., and steam be generated of (say) 100lb. pressure and mechanically freed from the water, the latter is simply compressed into smaller bulk by the superior pressure, and being surrounded by this it will remain, and by the very compression it will be raised in temperature. This is evident, from the fact, that pressure and temperature of steam are, one may say, convertible terms.

In a boiler where proper circulation is secured, every particle or atom, so to speak, of steam, as soon as formed, must find its way into the steam space, and that, too, without pushing or forcing its way through superincumbent water. And thus are secured the important results of rapid production of steam—a steady increase of pressure, steam free from water, and water free from steam.

Proper circulation is besides, as we see from the first experiment, a most important requisite to insure safety. For when it is necessary to ease the safety-valve (if such circulation has not been provided for by proper construction) a local relief of pressure only is obtained, the water nearest the valve rises first, and then suddenly falls, and thus produces a mechanical agitation of the whole mass, and the steam held in the water suddenly escapes in large quantities, and exercises such an immense force that must cause rupture, if the boiler is weak in any part, which result would not have ensued on a regular escape of steam. It is true, a judicious regulation of the mode of escape for the steam may be, and often is, provided; but in many cases this is absolutely neglected. What I refer to is, to have in connection with the valve-chest, a long and sufficiently large pipe, which is extensively perforated on the upper surface by a great number of small holes, and this has the effect of distributing the relief given to the boiler; whereas, when no such arrangement is employed, the steam is drawn entirely from the part of the boiler immediately in connection with the valve-chest.

(To be continued.)

THE PRODUCTION OF HONEYDEW.

THE following is an abstract of a paper by M. Boussingault, in the *Comptes Rendus*, on a subject which was discussed some time back in these columns. This translation was read by Prof. Dyer to the Royal Horticultural Society, at their recent meeting. On July 21, 1869, at Liebfrauenberg, the leaves of a lime were coated on their upper surface with an extremely saccharine viscid matter. The tree, in fact, afforded an example of the production of honeydew, a manna-like substance, which is frequently observable upon the lime, the black alder, the maple, and the rose. I have myself noticed it upon a plum-tree and upon a young oak. On the 22nd the honeydew was sufficiently abundant in the morning to fall in large drops upon the ground. It was a shower of manna. At three o'clock the saccharine matter no longer remained fluid upon the leaves which were exposed to the sun. It had sufficient consistency not to adhere to the fingers when touched; it formed, in fact, a sort of transparent and flexible varnish. Out of the sun the honeydew still retained its viscous condition. On the 23rd, at seven in the evening, several leaves at the extremity of a branch were washed and sponged, so as to remove all the saccharine matter. At six o'clock the following morning the leaves which had been washed seemed free from honeydew, but, on examination with a lens, minute glistening dots, due to very small drops, were observable. At seven the same evening the appearance of the leaves remained the same. The day had been warm; the temperature in the shade 84°. On the 25th numerous spots of honeydew were scattered over the leaves, but there was none upon the principal veins; at three o'clock the temperature was 86°.

During the night a violent shower removed a great part of the honeydew formed during the evening. It became, therefore, impossible to follow, as had been proposed, the progress of the secretion upon the leaves washed upon the 22nd. A swarm of bees settled upon the tree. On the 27th, the whole of the honeydew had disappeared, in consequence of the rain which fell during the evening of the 26th. The temperature had stood at between 62° and 75° Fahr. On the morning of the 28th the leaves bore numerous spots of honeydew, which had made their appearance during the night. On the 29th it had increased; on some of the leaves it occupied a third of the surface. At two o'clock the temperature was 84°. On the 30th the honeydew was very abundant. The lime tree remained covered with it till the commencement of persistent rains, which took place at the beginning of September.

On two occasions—namely, July 22 and August 1, honeydew was collected by washing the leaves. The solution, after treatment with lead-subacetate to precipitate albuminous and mucilaginous matters, yielded a syrup in which crystals of sugar formed. On examination it contained a sugar analogous to cane-sugar, and also a reducing sugar. By fermentation with yeast the two sugars disappeared completely. In the fermented liquid, however, a substance remained possessed of very strong powers of right-handed rotation. This proved to be dextrine, already announced by Berthelot as existing in the mannas of Sinai and Kurdistan, and subsequently by Buignet in a manna occurring in "tears" (*manne en larmes*). I have endeavoured to find mannite, and with especial care, because Langlois, an experienced observer, has found it in a saccharine matter collected from the leaves of a lime. Mannite is so easy to detect that I have not the slightest doubt as to its presence in the product studied by Langlois.

Optical observations have shown that the reducing sugar detected in lime-tree manna is not glucose (grape sugar), of which the rotatory power is 56° in the right-handed direction, but levulose (inverted or fruit sugar) which has a left-handed rotatory power of 26°.

Taking into consideration those substances only which rotate the polarised ray, the composition of honeydew will be:—

	July 22.	August 1.
Cane sugar	48·86	55·44
Inverted sugar	28·59	24·75
Dextrine	22·55	19·81
	100·00	100·00

These analyses show that the composition of honeydew collected with several days' interval has not remained the same. No doubt, one has no right to expect that the composition should remain precisely identical; what, however, is remarkable is the analogy which exists in composition between the honeydew of the lime and the manna of Mount Sinai analysed by Berthelot. Its composition is, in fact, identical with that of the honeydew collected on August 1.

Cane sugar	55
Inverted sugar	25
Dextrine	20
	100

It is a discovery not without interest to have found the manna of Mount Sinai in the Vosges.

In attempting to compare by analysis the quantity of honeydew existing upon the leaves of the lime which was affected with the saccharine matter contained in the leaves in their normal state, we arrived at the following result:—

In 1 Square Metre of Healthy Leaves:—

Cane Sugar.	Inverted Sugar.	Dextrine.	Weight in Grammes.
3·57	·86	0·00	4·43
In Honeydew Collected from ditto:—			
13·92	7·23	5·62	26·77
Difference:—			
10·35	6·37	5·62	22·34

The amount of manna, therefore, which exudes from the affected leaves is considerable, especially when one takes into consideration the amount of dextrine, a substance which does not exist in the healthy leaves at all. From calculations made upon a tree of the same age and size, the leaves of the affected lime-tree would have a surface of 240 square metres, or rather of 120 square metres (equal to 145 square yards), since the manna only covers one side of their surface. It would result from this, that on July 22, 1869, the lime bore 2 to 3 kilogrammes (equal to about 4lb. to 7lb.) of honeydew, reckoned in a dry state.

In the normal conditions of vegetation the saccharine matters elaborated by the leaves, under the influence of light and heat, are distributed through the organism of the plant with the descending sap. In the abnormal state, which determines the production of the honeydew, the saccharine matters are accumulated at the upper surface of the leaves, either because the movement of the sap is interrupted, or because it is retarded by the viscosity resulting from the formation of dextrine.

The production of honeydew cannot be due merely to meteorological influences—to the effect of warm and dry summers. No doubt the lime of Liebfrauenberg secreted it during a summer when there were periods of high temperature, accompanied by great dryness; we must not, however, lose sight of the fact that it was a single tree that was attacked by the malady, and that at a little distance there were limes which were perfectly healthy.

It has been supposed that aphides, after having drawn the honeydew from the parenchyma, discharge it again scarcely altered; but it is contrary to the results of analysis to assign it a composition similar to that of leaf sap. It is, however, admitted that certain insects possess the faculty of determining the production of manna. Thus it is to the punctures of a coccus that Ehrenberg and Heimprich attribute the formation of the manna which is still found on the mountains of Sinai.

The manna falls to the ground from the air (that is to say, from the summit of a tree and not from the sky). The Arabs call it man, and they, as well as the Greek monks, collect it to eat upon bread in the same way as honey. I have myself seen it fall, collected it, and brought it to Berlin with the plant and the remains of the insect. This species of manna is produced by Tamarix mannifera, Ehr. As with many other mannas it is the result of the punctures of an insect, which in the present case is Coccus manniparus, H. & Ehr.

The manna, consequently, collected in 1869 at Liebfrauenberg, had not the same origin as the Sinai manna, though it had the same composition. At the time of its appearance upon the lime no insects were observable. It was later that a few aphides were seen glued upon a certain number of the leaves.

I have already stated that after having washed the extremity of a branch, glutinous points were seen gradually to rise; at first scarcely perceptible, they increased each day, so as finally to cover the whole of the upper surface of the leaf. This slow and progressive development of the honeydew was clearly effected without the intervention of aphides, which did not make their appearance till subsequently, like the flies and bees, either to feed upon the secretion or to pilfer it.

In a subsequent number Harting states that honeydew is produced by Aphis tiliæ, which, living on the under surface of the leaves of the lime, drops its excrement on the upper surface of the leaves beneath. Analysed by Gunning at Amsterdam, it proved to consist of cane sugar. Boussingault remarked, in reply, that the manna of Liebfrauenberg, like the Sinaitic manna analysed by Berthelot, contained, in addition to cane sugar, fruit sugar and dextrine. He added, also, that the leaves of the lime contain considerable amounts of cane sugar almost pure, the origin of which could not be attributed to insects.

Professor Dyer then quoted Goethe, as saying, "I have seen limes, of which the leaves seemed varnished, but where not a single insect was visible. The juice is secreted by the plant itself." Mr. Hanbury informed him that he noticed the exudation of a saccharine matter from a canella, and that after repeated cleansings it still made its appearance. He had seen also the occurrence of minute crystals of sugar upon the corolla of the azalea. De Candolle mentions the same thing in Rhododendron ponticum. This is, however, different to the secretion which takes place on leaves, because it is probably merely due to the loss of water from the flower preparatory to fading.

De Candolle remarks that granular secretions are found on the young shoots of the larch, and are collected locally under the name of manna of Briançon; they also occur on Salix alba, and upon some other trees. "We cannot affirm," he says, either that they are a natural excretion, or that they are produced by insects." Dr. Masters states that a manna-like substance is produced from species of Alhagi, and that it is an exudation from the leaves and branches of the plant only appearing in hot weather. Saline secretions from leaves have been more frequently observed. De Saussure states that an accumulation of saline matters at their surface often occurs in garden vegetables, transpiration being impeded, the leaves are ultimately destroyed. De Candolle found a saline secretion from the leaves of a Reaumuria to consist of carbonates of soda and potash.

THE PROGRESS OF GEOLOGY.

THE following abstract of the annual address of the President of the Geological Society (Mr. J. Prestwich, F.R.S.) will be found to contain much interesting information concerning the progress made in the science, together with some valuable and important facts in connection with the geology of the Thames Basin and the water supply of the metropolis. In commencing his address, Mr. Prestwich said: Looking at the labours of the Society during the past year, it is satisfactory to notice the same activity, the same wide range of subjects as ever, and the same independence of research for truth's sake which there ever should be. But though good work has been done in special branches and the technical details of Geology, not so much progress has been made in its higher problems.

The great question of the history of our globe during the Quaternary period seems to be advancing towards more completeness. Many able observers, both in and out of our own society, are engaged upon the subject, and various scientific periodicals and publications of our local societies are rich in contributions bearing upon this interesting subje[illegible]

There is no more wonderful chapter in the earth's history than that which embraces the phenomena connected with the prevalence of great and exceptional cold immediately preceding our time—the first dim appearance of man—his association with a race of great extinct Mammalia belonging to a cold climate—the persistent zoological characters of the one, so far as we have yet gone, in opposition to the variable types presented in geological time by the others—the search for connecting links, and the measure of man's antiquity, all of which constitute theoretical problems of the highest interest, and are now occupying the attention of geologists of all countries. Allied also to this subject are the great questions relating to the form of our present continents—the elevation of the land—the origin of valleys and plains—and of all that which prepared this globe for the advent of man.

But while treating of these abstract and philosophical questions, geology deals also with the requirements of civilised man, showing him the best mode of providing for many of his wants, and guiding him in the search of much that is necessary for his welfare. The questions of water-supply, of building materials, of metalliferous veins, of iron and coal-supply, and of surface soils, all come under this head.

The site of a spring or the presence of a stream determined, probably, the first settlements of savage man: and his civilised descendants have continued, until the last few years, equally dependent upon like conditions—conditions connected first with the rainfall, and, secondly, with the distribution of the permeable and impermeable strata forming the surface of the country. Under ordinary circumstances, few large towns have arisen except where there has been an easily accessible localised water-supply, and where the catchment-basin on which depends the volume of the rivers has been large, and permeable strata prevail. Take, for example, London. Few sites could be more favourable in every respect. Beneath it are strata rich in springs, while at a distance there is that large development of those massive permeable strata so necessary to maintain a sufficient and permanent flow in our rivers.

London north of the Thames stands on a bed of gravel, varying in thickness from 10ft. to 20ft. in round numbers, and overlying strata of tenacious clay from 100ft. to 200ft. The former being easily permeable, the rain falling on its surface filters through it, until stopped by the impermeable London clay, where it accumulates and forms a never-failing source of supply to the innumerable shallow wells that have been sunk all over London from time immemorial, and which for centuries constituted its sole water-supply. Not only does it form an easily accessible underground reservoir, although of limited dimensions; but where the small intersecting valleys cut down through the bed of gravel into the London clay, a portion of the water in this reservoir escapes at the junction of the two strata, and gives rise to several springs formerly in much repute, such as those of Bagnigge Well, Holy-well, Clerken-well, St. Chad's Well, and others.

The early growth of London followed unerringly the direction of this bed of gravel, eastward towards Whitechapel, Bow, and Stepney; north-eastward towards Hackney, Clapton, and Newington; and westward towards Chelsea and Kensington; while northward it came for many years to a sudden termination at Clerkenwell, Bloomsbury, Marylebone, Paddington, and Bayswater. A map of London, so recent as 1817, shows how well-defined was the extension of houses arising from this cause. Here and there only beyond the main body of the gravel there were a few outliers, such as those at Islington and Highbury; and there habitations followed. In the same way, south of the Thames, villages and buildings were gradually extended over the valley-gravels to Peckham, Camberwell, Brixton, and Clapham; while, beyond, houses and villages rose on the gravel-capped hills of Streatham, Denmark Hill, and Norwood. It was not until the facilities were afforded for an independent water-supply by the rapid extension of the works of the great water companies, that it became practicable to establish a town population in the clay districts of Holloway, Camden Town, Regent's Park, St. John's Wood, Westbourne, and Notting Hill.

On the outskirts of London a succession of villages grew up for miles on the great beds of gravel ranging on the east to Barking, Ilford, and Romford—on the north, following the valley of the Lea to Edmonton and Hoddesdon; and on the West, up the Thames-valley to Ealing, Hounslow, Slough, Hammersmith, and beyond; whereas, with the exception of Kilburn, hardly a house was to be met with a few years since between Paddington and Edgware, or between Marylebone and Hendon; and not many even between the New-road and Highgate and Hampstead. As a marked case of the excluding effects of a large tract of impermeable strata close to a great city, I may mention the denuded London-clay district extending from a mile north of Acton, Ealing, and Hanwell, to Stanmore, Pinner, and Ickenham, near Uxbridge. With the exception of Harrow (which stands on an outlier of the Bagshot Sands), and Perivale, and Greenford (on outliers of gravel), there are only the small villages of Northolt and Greenford Green. In the earlier edition of the Ordnance Maps, there was a tract of ten square miles north and westward of Harrow within which there were only four houses. Yet the ground is all cultivated and productive. But immediately eastward of this area, and ranging thence to the valley of the Lea, the ground rises higher, and most of the London-clay hills are capped by gravel of an older age than that of the London valley, and belonging to the boulder-clay series. On these we have the old settlements of Hendon, Stanmore, Finchley, Barnet, Totteridge, Whetstone, Southgate, and others.

There is yet another very common source of well-water supply from beds of gravel directing population to low sites in valleys, which is this. Everywhere on the banks of the Thames and its tributaries there is a lower-lying bed of valley-gravel or of rubble, on, and often passing beneath, the level of the river. This bed is supplied with water both by rain falling on it, by springs thrown out from the adjacent hills, or by the drainage from those hills, and in places by infiltration from the river, when, from any cause, the line of water in the gravel falls below that of the adjacent river; while, on the other hand, the surplus land-supplies find their way direct and unseen from the bed of gravel to the river. It is, however, only in case of exceedingly dry seasons or of excessive pumping, that the supply requires to be supplemented by the river-waters. As in ground of this description, the land-water is generally dammed back by the stream, the level of the water in the wells, which are always shallow, varies with the level of the water in the streams, rising and falling more or less with them.

A few of the higher London-clay hills in the neighbourhood of London are also capped by outliers of the Bagshot Sands, as, for example, Harrow, Hampstead, and Highgate, all of which are sites of old habitations. The sands at these places attain a thickness of from 30ft. to 80ft., are very permeable, and afford a sufficient water supply by means of wells to a limited population. A number of well-known small springs are thrown out at the contact of the sands and the clay on the slopes just below and around the summit both of Highgate and Hampstead Hills. In some instances, owing to the presence of iron in the sands, they are slightly chalybeate. When the Bagshot Sands, further westward of London, attain their fuller development of from 300ft. to 400ft., the depth to the water-level at their base becomes so great that the upper porous beds are left high and dry, and form uncultivated wastes, such as Bagshot Heath, Frimley Heath, and others; but on the outside of this area, where the sands become thinner, and the water-level more within reach, we find a number of villages, such as Englefield Green, Sunningbill, Brackwell, Wokingham, Alderstone, Esher, Weybridge, Woking, &c. There are also some thin subordinate beds of clay in the middle of the series which hold up a sufficient quantity of water for small local supplies, and give rise to small streams in the valleys of the Blackwater and of Chobham. The running nature of portions of these sands, and the presence of beds of ferruginous and green sands, often interfere much with the construction of deep wells, and the quantity of the well-water; and, externally, the mixed clay-and-sand character of the upper beds of the London clay fails to give any good retaining-line for the water, which, therefore, rarely issues as springs, but oozes out from the general surface of the intermediate spongy mass.

The 70ft. to 100ft. of sands and pebble-beds belonging to the Lower Tertiary strata under the London clay, and overlying the chalk, are also very permeable, and being intercolated with some beds of retentive clay, they give rise to one or two levels of water, affording, wherever these strata form the surface—as at Blackheath, Bexley, Chiselhurst, and Bromley—a moderate water-supply to shallow wells. Where these sands dip under the London clay, and only present a narrow belt on the surface, a small valley is commonly formed into which the London-clay hills drain on the one side, and on the other the chalk dammed back by the Tertiary strata throws out its springs, and the sands are thus kept charged with water up to a short depth from the surface.

But besides furnishing a supply by ordinary wells to a number of villages on their line of outcrop, the Lower Tertiary sands have of late years contributed to the metropolitan supply, as well as to the supply of those adjacent districts where the surface is formed of tenacious clay, and water is scarce, by means of artesian wells. For along the line of country just named, and along a more irregular belt on the north of London, these sands pass beneath the London clay, so that the water they receive from rain and springs on the surface passes underground, where it is prevented from rising by the impermeable superincumbent clay; consequently, as there is no outlet for the water below ground, these sand-beds are filled with water along their whole underground range, between their outcrop in Surrey and that in Hertfordshire.

The surface of the ground at the outcrop, just referred to, of the Lower Tertiary sands is about 100ft. above the level of the Thames, whilst under London the sands are at a depth of from 100ft. to 220ft. below that level, thus forming the shell of a basin from 200ft. to 300ft. deep, the centre of which is filled with a depressed mass of impermeable clay. There is, however, a notch in the lip of the basin, where it is traversed by the Thames, at Deptford and Greenwich, which is at a lower level of 100ft. than the rest of the rim. Below this level, as there is no escape for the water, the strata are naturally perpetually water-logged; and if any water is withdrawn from one part, it is, owing to the permeability of the strata, at once replaced from adjacent parts of the same strata. Early in the present century, bore-holes were made through the overlying London clay to the sands at depths of from 80ft. to 140ft., and the water from these deep-seated springs rose at once to a height of several feet above the level of the Thames, where it tended to maintain itself, and thus form, in the lower-lying districts, permanent natural fountains. But the ease and facility with which this abundant supply was obtained, led to the construction of so great a number of such wells that a time soon came when the annual rain outfall no longer sufficed to meet the demand, or, rather, it could not be transmitted fast enough to the central area of abstraction to replace the outdraught. The consequence was that, after some years, the water ceased to overflow, and the line of water-level has gradually sunk at London, until it now stands some 70ft. or 80ft. beneath the surface level.

In order to supply the deficiency thus caused in the Lower Tertiary sand, most of the artesian wells in London have of late years been carried down into the underlying chalk, which also extends beneath London at depths of from 150ft. to 280ft. Both formations are permeable, but in different ways. On both the rainfall is at once absorbed, but the transmission of it is effected in different ways. Through the sands it filters at once; but not so with the chalk. A cubic foot of the latter will hold two gallons of water by mere capillary attraction; but it parts with this with difficulty. Still, in time it finds its way through the body of the chalk, aided by the innumerable joints, fissures, and lines of flints by which this formation is traversed; and, when once under the line of saturation, the water in these fissures circulates freely. This line of saturation is governed in this as well as in all other permeable formations, by the level of the lowest natural point of escape, which is either the coast-line if near, or the nearest river-valley. Below these levels permeable strata are always charged with water; consequently under London the chalk is everywhere water-bearing; but as the Lower Chalk is more compact than the Upper, and is less fissured, especially when covered by other strata, and as the more compact water-logged chalk delivers its charge with extreme slowness, it is not until a fissure is met with that a free supply of water is obtained. Further, as there is no law regulating the position of the fissures, the depth to which the chalk has to be traversed before meeting with a free supply of water is quite uncertain. It is a question of probability depending upon meeting with a fissure sooner or later—10ft. to 15ft. have sufficed in some of the deep London wells, whereas in others it has been necessary to sink to a depth of from 100ft. to 200ft. or more before hitting on the necessary fissures. Large as this supply is, the same causes which have operated in the case of the sands have told also on the chalk supplies (and, no doubt, there is some community between the two), and the great demands on it have occasioned a similar lowering of the water-line.

Numerous and useful as the London artesian wells are, they sink into insignificance when compared with the application of the same system in Paris. Our deepest wells range from about 400ft. to 500ft., and the water comes from the chalk hills at a nearest distance of from 15 to 25 miles from London; whereas in Paris the well of Grenelle is 1,798ft. deep, and derives its supplies from the rain-water falling in the Lower Greensands of Champagne, and travelling above 100 miles underground before reaching Paris. The well of Passy, sunk also through the Chalk into the Lower Greensands at a depth of 1,923ft., derives its supplies from the same source. The water-delivery is large and well maintained. These results were considered so encouraging, that in 1865 the Municipality of Paris decided on sinking two artesian wells of unexampled magnitude.

One of these experimental wells is in the north of Paris, at La Chapelle, St. Denis, 157ft. above the sea-level. A shaft, with a diameter of 6½ft., was first sunk through Tertiary strata to a depth of 113ft. At this point the boring was commenced with a diameter of 5¼ft., and carried through difficult Tertiary strata to a depth of 450ft., when the Chalk was reached. A fresh bore-hole was here commenced which has now reached the great depth of 2,034ft., with a diameter of 4ft. 4½in. It is now in the Grey Chalk, and it is calculated that the Lower Greensands will be reached at a depth of about 2,800ft. The other artesian well is at the Butte-aux-Cailles, on the south-east of Paris, at an elevation of 203ft. above the sea. The Tertiary strata are there only 205ft. thick. This well is not quite on so large a scale as the other, and is still, at the depth of 1,640ft., in the White Chalk. The discharge from these great wells will probably be equal to that of a small river. At Passy, notwithstanding some defective tubage, and the circumstance that the surface of the ground is there 86ft. above the Seine, the discharge at the surface is equal to 3½ millions of gallons daily; and it has been above 5 millions, or enough for the supply of a town of 150,000 inhabitants.

The question may arise, and has arisen, why, with a like geological structure, should not like results be obtained at London as at Paris; and, to a certain extent, it has been answered. At Kentish Town an artesian well was, in 1855, carried through 324ft. of Tertiary strata, 645ft. of Chalk, 11ft. of Upper Greensand, and 130ft. of Gault. Instead of then meeting with the water-bearing Lower Greensands which crop out from beneath the Chalk, both on the north and south of London, unexpected geological conditions were found to prevail, and not only were these Greensands found to be absent, but likewise all the Oolitic and Liassic series. The bore-hole passed at once from the Gault into a series of red and grey sandstones, probably of Palæozoic age, and not water-bearing. The Chalk has more recently been traversed at Crossness, near Plumstead, where its base was reached at a depth of 785ft., and the bore-hole carried 159ft. deeper into, but not through, the Gault, when, owing to difficulties caused by the small size of the bore-hole, the work had to be abandoned.

Such is the geological structure of the ground on which London is dependent for its first and immediate water-supply by means of wells. The highest seam of water, that in the drift-gravel, extends almost everywhere under the streets and houses, at depths of from 12ft. to 25ft., forming what is called ground-springs. The Lower Tertiary sands, with their greater thickness, and their larger and distant area of outcrop, contain the second and larger underground body of water beneath London. The third underground reservoir is the Chalk, which, from its large dimensions—500ft. to 1,000ft. thick—and extensive superficial area, forms a still larger reservoir, and source of water supply.

With the increase of population, however, the need for larger quantities necessitated the recourse to river-supply; and this supply, equally with the other, is regulated by geological conditions, only that in this case the question concerns those conditions which affect the strata throughout the catchment-basin of the river itself above the town which needs its supply.

(*To be continued.*)

THE PHOSPHORESCENCE OF THE SEA.

THE phosphorescence of the transparent compound, ascidian-pyrosoma, which occurs floating in occasional shoals both in the Atlantic and Pacific Oceans as well as in the Mediterranean, has long excited the admiration of voyagers. The fishermen of Naples know the pyrosoma by the name of "lanterne." Though its phosphorescence is so intense, yet zoologists have not hitherto rightly ascertained what are the organs which produce the light. Professor Paolo Panceri, of Naples, in the course of his admirable researches on the phosphorescence of marine animals, has, says the *Athenæum*, lately studied that of pyrosoma, and conclusively demonstrated, to the satisfaction of Dr. Krohn and other naturalists now at Naples, that the light-emitting organs are two large granular patches, placed on either side near the mouth of each of the tunicate constituents of the compound mass. By cutting a section of the pyrosoma, placing it in fresh water, and then under the microscope in a darkened room, it is at once seen that the light is produced by these two masses. Professor Panceri has, at the same time, made important observations on the development and anatomy of pyrosoma which were also studied during his voyage in the *Rattlesnake* by Professor Huxley. Professor Panceri has found that from a single egg not only do four embryos develop, but that the "cap" to which they are attached represents a fifth, which attains its development first, has a mouth, nervous system, and a heart, that pumps blood into the chain of four embryos encircling it. It is, in fact, a "nurse." The Italian Professor has also discovered a so-called "colonial" muscular system in pyrosoma, by which it is probable that the excitation causing a wave of phosphorescent light as observed in these animals is transmitted. In his entirely novel and ably worked-out investigations of the phenomenon of phosphorescence (he has already published memoirs on that of Pennatula, Pholas, Beroe, and Chætopterus), Professor Panceri is doing a work worthy to be ranked with the researches of the great Neapolitan naturalists, Cavallini, Poli, and Delle Chiaje.

New Safety-Lamp. — Some experiments of, apparently, a satisfactory character, were made on the 25th of March, at the Coal Exchange, on a new safety-lamp for collieries, invented by Mr. Henry Plimsoll. The principal features in the lamp were, that it was immediately extinguished when in an explosive atmosphere; and that, as the flame was surrounded with a glass cylinder instead of wire gauze, the light was very brilliant. We learn that the lamps are to be tried in some of the fiery collieries of South Yorkshire.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the Editor of the ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

All Cheques and Post Office Orders to be made payable to J. PASSMORE EDWARDS.

"I would have every one write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

*** *In order to facilitate reference, Correspondents when speaking of any Letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

JUPITER'S SATELLITES—ADJUSTMENT OF AN EQUATORIAL—SATURN'S SEMI-DIAMETER—TESTS FOR A 4¼IN. REFLECTOR—PLANETARY AND COMETARY ORBITS—STAR MAGNITUDES—GRAVITATION—AND THE *NAUTICAL ALMANAC.*

[3958.]—I MUST apologise to "Vega" for having read his original question (11225, p. 676, Vol. XIV.) rather carelessly. Until I referred back to it just now, I really fancied that he had observed the reappearance of Jupiter's first satellite on the night of January 12th, 1871, at 8h. 6m. 57s. *Local* mean time. Now, however, I find that he saw it at (what he imagines to have been) 8h. 6m. 57s. Greenwich mean time, which renders the whole affair inexplicable, even on the assumption that the aperture of his telescope differed to some extent from that of the one employed by Mr. Christie. Of course an eclipse of one of Jupiter's satellites is a phenomenon happening at the same *absolute* instant, at every place whence it is visible. In point of fact, it is as though a bright light were suspended in the air at a sufficient height to be seen over a large area of the earth's surface, and such light were to be extinguished. Reflecting, then, on the fact that a satellite does not plunge into, nor emerge from, Jupiter's shadow *per saltum*, "Vega" will see that the only conceiveable thing which could operate in altering the apparent Greenwich time of the disappearance or reappearance of any given one, as viewed at his station, from that at which the same phenomenon occurred at Greenwich itself, would be difference of telescopic aperture. Obviously, the bigger the object-glass or mirror, the later the satellite could seem to disappear, and the sooner to reappear; but if he and Mr. Christie had been observing with the same sized instruments, then, as Mr. Christie saw the reappearance at 8h. 8m. 10s., Greenwich mean time, "Vega" ought to have caught it at 7h. 55m. 18·3s. of his Local mean time—*i.e.*, at the identical instant of its Greenwich observation; inasmuch as 3° 14′·10 = 12m. 56·667s. I do not know quite what your correspondent means about "allowing also for acceleration."

If "Lamroch" (qy. 11450, p. 80) will consider for an instant, he will see that the polar distance (or declination) of a star must be the same, whether his place of observation be at Manchester or Marseilles. The altitude of the pole varies, *but not the distance of individual stars from it*; so that the only correction required is one for refraction, for which he will find ample directions in "Loomis." I wrote on this same subject some time ago in these columns, and illustrated the effect of refraction on the identical star mentioned by your correspondent, by the aid of a diagram. "Lamroch" will find this letter and illustration on p. 417 of your twelfth volume.

In answer to Mr. Hutchins (query 11453, p. 80) it is the semidiameter of the Ball of Saturn that is given on pp. 301 and 303 of this year's *Nautical Almanac.* The elements for the determination of the dimensions and appearance of his rings are given on p. 513.

I may reply to the first query (11467, p. 80) of "A. L. B." by saying that the theoretical light grasping power of his 4¼in. Browning-With reflector, would render a 12·1 magnitude star of Argelander's Scale his minimum visibile; and that its separating power would be about 0·96″, or, say, 1″. For tests he might try σ^2 Cancri, ζ Cancri (I doubt if he will do much with this), 84 Virginis, 126 P XI. Virginis, ζ Boötis, μ^2 Boötis (very difficult), Struve 1884 Boötis, 35 Comæ Berenicis, η Coronæ Borealis, Struve 1932 Coronæ, and ξ Ursæ Majoris.

"A. L. B." will find his second question (11468) answered on p. 273 of your last volume. He surely can devise an index for himself.

All I can possibly hope to do for "Aristarchus" (query 11507, p. 81) is to give him some kind of idea of the principles on which the orbits of planets and comets are computed. To go into anything like numerical detail would be wholly impossible within the limits of a letter, inasmuch as many pages are devoted to the methods of calculation of the orbits of these bodies in works on spherical astronomy. Firstly then, with reference to the elements of the orbit of a planet. They are seven. 1. The periodic time. This is obtained directly by observing its right ascension and declination for several days when it is in or near one of its nodes. These we must turn into longitudes and latitudes, in the manner exemplified a week or two ago. Then by a simple proportion we find out when the latitude of the planet was nothing; and it is, of course, at that instant in its node. We have only to make similar observations when the planet comes round to the same node again, and this will give us the time of one revolution. 2. The mean distance from the sun, or semi-axis-major of its orbit. This is most easily got by Kepler's law, when we know the periodic time. Otherwise by observation which I cannot ask for space to explain. 3. The longitude of the ascending node. This is calculated from the observed longitude of the planet in one of its nodes; and the longitude of the sun and the radius vector of the earth at the same instant. These data are again obtained when the planet returns to the same node, and hence the direction of the line of nodes calculated. 4. The inclination of the plane of the planet's orbit to that of the ecliptic. This is found by the longitude and latitude of the planet being determined at the instant when the sun's longitude is the same as the heliocentric longitude of the node; then a very simple formula in spherical trigonometry gives us the required quantity. The heliocentric longitude and latitude of a planet is also trigonometrically derived from its geocentric longitude and latitude. 5. The eccentricity of the orbit; and (6) the longitude of the perihelion are found by ascertaining the length and position of three radii vectores (assuming the orbit to be an ellipse). 7. The place of the planet at a particular epoch is the subject of direct observation. There is nothing in all this beyond the mathematical capacity of "Aristarchus." In order to determine the orbit of a comet we, in the first place, require its position in the heavens at three different times; and the longer the interval which separates these times, the more trustworthy will be the ultimate results. It simplifies calculation if the intervals are equal. Well, then, as a preliminary step the observed right ascensions and declinations are turned into longitudes and latitudes. Next, the longitudes of the sun, at the three instants of observation, are taken from the *Nautical Almanac*, and from these data a diagram is constructed which I cannot here reproduce. The first calculations of a cometary orbit are made on the supposition that it is parabolic, and it is assumed, as a matter of course, that the plane of the orbit passes through the sun, is a conic section, that the quotient of the area described by the radius vector, divided by the time, is a constant quantity; and that for different bodies revolving round the sun these quotients are proportional to the parameters of their orbits. Then a plane is hypothetically assigned to the comet's orbit, and it is seen whether any of the canons just enunciated are violated. If they are not, we have hit upon the right plane; if they are, we must try again. So then at last by a system of trial and error, the true plane is found; and then places of the comet are calculated for some time in advance on the supposition that the orbit is parabolic and described in that plane. By the comparison of its observed places with the predicted ones, we soon find out whether the comet is really describing a parabola, or whether its orbit is a hyperbola or an ellipse. Such is the very barest outline of the method adopted to arrive at the figure and dimensions of a cometary orbit. In practice, as I told a "Young Astronomer," the geometrical relations involved are represented by equations, and then are solved by successive approximations. My querist should get Chauvenet's, Norton's, Main's, or some other work on spherical astronomy, as I must repeat that it is hopelessly impossible to enter into any detail in such a letter as this.

In reference to query 11508 (same page), I must express my exceeding surprise that "Aristarchus," as an amateur astronomer, does not possess a copy of Webb's "Celestial Objects for Common Telescopes," inasmuch as I fancied that it was (as it ought to be) in every observatory in England. From it I have copied the little table which follows:—

Smyth's Mag.	Struve.	Herschel.	Argelander.
10	9·3	10·4	9·4
11	10	11·8	10

I do not quite see the nature of Mr. Skelton's difficulty (query 11559, p. 106) with regard to the diagrams of the eclipses of Jupiter's satellites in the *Nautical Almanac.* Let us take that for the present month (p. 457) as an example. On the night of the 25th satellite 1 will reappear from eclipse at 8h. 39m. 30s., Greenwich mean time. Well, in order to observe this phenomenon Mr. Skelton must direct his telescope (presumably furnished with a Huyghenian or inverting eyepiece) to the little spot marked *r* in figure 1. Or if he should be on the look out for the reappearance of satellite 2 from eclipse during the early morning of the 23rd, he must watch the spot marked *r* in Fig. 2. Again, the disappearance of satellite 3 in eclipse, 38 minutes and 11 seconds after midnight on the 18th will take place at *d* in Fig. 3, and its reappearance next morning (after Jupiter has set) at *r* in the same figure, and so on. The only thing which strikes me as possibly being a little unintelligible to your correspondent is the reference in the explanation on p. 563 to Jupiter's opposition [illegible] this will disappear when Mr. Skelton reflects that [illegible] that time Jupiter's shadow—as viewed from the earth—*shifts from one side of him to the other*: so that [illegible] diagram can possibly be true for the whole month [illegible] which this phenomenon occurs.

Speaking theoretically, the moon in one part of her orbit pulls the earth in the same direction as the sun does; and in another tends to separate them. As it is, it is the centre of gravity of the system of the earth and moon, which describes an orbit about the sun: were the moon to be annihilated, as imagined by M. Paris (query 11563, p. 106) the only difference would be that the centre of gravity of the earth itself would continue to describe that orbit.

With reference to what Mr. Woods reiterates (in qy. 11578, p. 107), as to the defects of the *Nautical Almanac*, I must say that I demur altogether to his designation of the explanation given on p. 539 as "trashy," inasmuch as, as far as it goes, it is perfectly sound and good. The *Nautical Almanac* has enough to answer for in the shape of its defective tables of the phenomena of Jupiter's satellites, and absolutely scandalous ephemeris of Uranus, without being made responsible for faults from which it is free. Mr. Woods must really forgive me for saying that he can have but little practical acquaintance with occultation work, or he would never make such an astounding demand as that the times of occultations should be given for other latitudes than that of Greenwich! Why, does he know that the time of an occultation differs even as seen from Greenwich and from Highgate? and that, in fact, it is conceivable that a star may be occulted at one of these places, and not at the other at all? The *Nautical Almanac* contains all the data needful for making the calculations for any given locality: to make and tabulate the computations of the times of all visible lunar occultations for every inhabited place on the globe would be to produce a book to which the "Encyclopædia Britannica," would stand in the relation of a thin pamphlet. I must further crave my querist's pardon if I point out that it is *not* the time of meridian passage of the "upper *limb*" of the moon (however, such a phenomenon may be imagined to occur) which is given on p. iv., of each month; but the instant at which the moon's centre is on the upper *meridian* at Greenwich—*i.e.*, due south. When she is on the lower meridian, she is, of course, due north, and below the horizon—which, on the whole, satisfactorily accounts for the latter phenomenon being left unnoticed in the *Nautical Almanac*.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

DUST IN THE SPECTROSCOPE.

[3959.]—MR. BROWNING (let. 3886, p. 66) is altogether right in his surmise that I did not put the question to which he has so kindly and satisfactorily replied solely in my own interest; and therefore, in thanking him, I think that I may, at the same time, legitimately congratulate not only myself but a goodly number of my brother readers on having elicited so very useful and practical an answer from the Dollond of the spectroscope. I say useful and practical an answer; because, following his directions implicitly, I succeeded perfectly in freeing the slit of my own instrument from dust on the first trial.

Whether it be the fact or not, that striation of the prisms does produce longitudinal lines in the spectrum, "when the slit is nearly closed," as stated by Mr. F. Bird (let. 3899, p. 69), I can answer for it, that, in my own case, the striping proceeded from minute particles of dust; inasmuch as I always examined the jaws of the slit with a powerful magnifier, after my attempts to clean them.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

P.S.—I must not forget to thank "S. W." also for his letter (3946, p. 97).

CONTACT OF COMETS WITH THE EARTH.

[3960.]—THE most charitable conclusion that I can come to with reference to letter 3916, p. 91, is that "E. L. G." must be labouring under some hallucination when he says that he "showed" me certain things "in your columns," &c. He, *more suo*, made some dogmatic *assertions*; but, until I (and others) can rise to his sublime height of belief in his own omniscience and infallibility, I must be forgiven for doubting that he has *shown* anything.

As far as his sneers at Mr. Poulett-Scrope are concerned the whole matter lies in a nutshell. Mr. Scrope, and every one else who has examined the extinct volcanoes of Auvergne *in situ*, are agreed in referring them to a period extending from the Upper Eocene, through the Miocene and Pliocene. The minimum antiquity of the last named epoch is perfectly familiar to every geologist who reads these lines. But, upon the steep sides of these cones lie, absolutely undisturbed, scoriæ, lapillæ, and pumice-stone, which anything is the nature of a flood, sixty thousand—to say nothing of *six* thousand—years ago, must inevitably have swept away, and redeposited in a chaotic mass elsewhere. Hence, wherever the Noachian deluge went it did *not* penetrate to the Valley of the Auvergne.

With regard to "Lyellology," that can take care of itsel

As for the "grandiloquent" brag about what "*I* shall show," and the warning that *I* have given, &c., I can only say that I seem to have an idea that men have arisen before who were going to set all the world to rights; and that just as "E. L. G." is about to frustrate and confound all the "geologers," so did a certain man called Hampden essay but the other day to *show* that astronomers were idiots, and that the world was even as a pancake. If my memory serves me, *though*, it was Hampden himself—and not the earth —who was proved to be a "flat."

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

NOMENCLATURE, &c.

[3961.]—I RATHER fail to see, exactly, what "L. C. E." (letter 3884, p. 66) is driving at; inasmuch as his aim would appear, on the surface, to be to convert himself into a kind of literary Malay, and "run a-muk and tilt at all he meets."

In limine, he surely does not mean seriously to deny the inestimable advantage of technical terms in Science; nor imagine the English language to be so rich in words as neither to require, nor admit of, any additions! Had he read the most valuable and popular series of papers on Electricity, by "Sigma," running through your recent volumes, and notably had he consulted Vol. XII., p. 290, he need have been under no difficulty as to the exact meaning of the "quite new" words to which he takes exception; but which even he, I think, cannot deny are short, easily remembered, and convenient. Besides, I assume that a period must have existed when *every* word was "quite new." Almost certainly, in our fathers' time, "Lucifer," as a name for matches igniting by friction, must have had its origin: while, in our own, "florin" and "telegram" are two out of several which strike me as having arisen in, or been adopted into, the English tongue.

It seems almost idle to point out how circumlocution and periphrasis are avoided by the use of a single technical word; and it would be hard to find fault with those used by "Sigma" on any other ground than that of their novelty (to "L. C. E.").

Into the terminology of chemistry I must decline to enter. "*Ne sutor*," &c., and we have plenty of excellent chemists both able and willing to take their own parts.

With regard to "L. C. E.'s" strictures, on the mode in which selenography appears to be pursued, I would just observe that if ever we are to know anything of the causes which have operated in the production of the moon's existing physical condition at all, it must be by the patient and almost *niggling* collection of such details as those to which he takes exception. I fancy that we have "broad facts" enough—and to spare—as to the general state of our satellite as it is.

And again, with regard to Secchi's researches on the solar flames, we *know* that these consist of stupendous uprushes of incandescent hydrogen gas: obviously through a resisting medium—and that is very nearly all. To observe, then, how high they extend above the sun's surface, before they are deflected, or become spread out—to note carefully any peculiar spiral conformation or the like—is to add to a mass of facts whence, some day, the most important possible deductions will probably be derived.

I am not concerned to defend my brother microscopists, who have, I fear, wasted a great deal of time over Diatomaceæ; and made species and invented synonyms, *usque ad nauseam*. I have known a man spend as much as would keep a labourer, his wife, and family, for three months, on a single object-glass, merely in order to resolve the "acus"—and fail, dismally, to do it, after all.

As for microscopic anatomy, though, it is in its infancy; and no man may say whereto it will grow. "What," said Franklin, "is the use of a new-born baby?" Oersted's famous discovery was only made in 1820; and already the electric telegraph girdles the earth!

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

[3962.]—"TAKE astronomy as exemplified in 'our' pages; look at those straggling sketches intended to represent some mountain or crater of the moon, and then read the long discussion as to whether a little crooked mark is a cleft or a rill. What on earth does it matter which it is?"

This passage (which occurs in let. 3884, No. 367, p. 66) having arrested my attention, a few remarks on it, I apprehend, may not be out of place. "L. C. E." is certainly not "a master in understanding" things regarding the moon. It is well for him to *fear* when such is the case, as he may then be excused for putting the question, "What on earth," &c.? To those who are content with *earthly things* it may well be a matter of indifference whether a "straggling sketch" represents one thing or another, and the signification of "a little crooked mark" is a matter of very little moment. If we were looking on the motley group pacing to and fro in St. Paul's Churchyard from the gallery surmounting the dome we might be inclined to think that the creatures thus engaged were of Liliputian stature; but we take a higher standpoint, and from the car of a balloon we gaze upon the "map" spread out below us, in which the very dome on which we lately stood has diminished to a mere point. Stretching out in every direction from the vast masses of building, themselves fringed with buildings, are narrow lines, some straight and others crooked, quite distinguishable at a certain elevation, but growing narrower as greater altitudes are attained. At length night comes on. By some remarkable agency our aërial travellers have lost—not consciousness, but—discernment, forgetful of what they saw on *terra firma*. A number of twinkling points of light engage their attention, and they begin to speculate as to what they can be. They are the *minutiæ* of the scene; and while the aëronauts remain in the mental state in which we suppose them to be, it is only by a process of observation and reasoning that they might be able to arrive at the conclusion that these twinkling points were lamps to enlighten the darkness of the Liliputian inhabitants, themselves *minutiæ* amongst the larger features seen by daylight. We readily grant that such a process as we have supposed is *apparently* unaccompanied by any tangible *benefit*; but personal benefit, apart from the discipline of the mind, is one thing, and the discipline of the mind is another. The straggling lunar sketch, the little crooked mark, are letters in Nature's alphabet. The great A's and crooked S's first attract the attention of intellectual children, and they learn to regard them as exponents of mountains and valleys, elevations and depressions of the moon's surface. By-and-by they find that the minutiæ of the language must be studied, the B's and E's and M's must be combined to form words, and when sentences are introduced they would be in a measure unintelligible without the minutiæ of points—the commas, semicolons, and periods. Selenographers have made out many of the broad facts of their science, and they are proceeding slowly to combine with them such *minutiæ* as will enable them to take a further step in interpreting the phenomena presented to their notice. To form a *correct* judgment of anything seen at a distance no little mental discipline is necessary, but rather well-trained habits of observation, accompanied by a facility of grouping and examining facts, not neglecting such as are seemingly unimportant—"a single grain will turn the scale."

W. R. BIRT.

P.S.—"Sigma's" letter (3921, No. 368, p. 92) is much to the point, and may be read with great advantage.

THE METRIC SYSTEM.

[3963.]—"E. L. G." (let. 3935, p. 96) asks me for evidence that the metric system has "gained the approval of the vast majority of scientific men." That statement of mine referred to the ordinary French decimal metric system of weights and measures, and also to the general principle of decimalising measures; it is, therefore, more ingenious than ingenuous of "E. L. G." to set forth Laplace as the only one who ever used decimal *angular* measures, about which I was not speaking, and which, however useful they may or may not be in themselves, do not necessarily belong to the system.

It is quite needless to seek for names; we need only open any scientific book, and we shall find that decimal measures are always employed. If any one wishes to express the mechanical equivalent of any agency, we find foot-pounds run out to millions, or else foot-tons taken for a larger unit. I do not believe that a single instance can be found of any one reducing those decimal figures to tons, hundredweights, quarters, and pounds. Why? Because the decimal figures are all comparable among themselves with the smallest mental effort, while the others are not so, but require considerable effort to understand; but this is exactly the reason why the decimal system is advocated for general use.

The same illustration will give us further evidence of the adoption of the French system by most scientific men, for we have only to glance over the best chemical manuals to find that they use that system almost exclusively. Again, why? Simply because to scientific men the advantage of that system is so self-evident that they will no longer burden their pupils with the useless complications of the English weights, &c.

It is really of very small consequence whether Herschel was a decimalist or no, because every man has a right to his own opinion; but the quotations given us by "E. L. G.," so far from proving him an anti-decimalist, are almost identical with my own arguments on the subject. He distinguishes clearly the two parts of the question, the unit and the divisions. As to the first, the unit and its standard, there may be plenty to be said, and the arguments as to the superiority of the English unit over the metre would be perfectly sound if all the world were afflicted with a confusing system like ours, and anxious to unite with us in remedying the evil; but this is not the case —those who have the metre have none of our confusion, and to ask them to adopt our foot, even if it had any great inherent advantage over the metre, would be to invite them to make a change for change sake, to give them a perfectly needless trouble without in the least diminishing our own share of trouble; for it is self-evident that if we change our whole system of measures, our retaining the foot for the unit would not be one fraction less confusing than the adoption of the metre.

It is for this reason that I said that discussion about the merits of units and standards was "scattering dust about the true object of any importance." The question of importance is this: Are the troubles attendant on our present weights and measures great enough to warrant our enduring the great temporary trouble of *any* change? If any change is to be made, the question becomes a practical one, simply that of least trouble united to greatest advantage, and is resolved by the fact of half the world (civilised) having already adopted a satisfactory decimal system; practical considerations put out of question all debate about any abstract philosophical quidities as to units and standards: we are left to decide simply whether we will adopt the same system as others, who clearly will not change their system to please us; or whether for the sake of preserving some fragments of our own old system, we will deprive ourselves of the great advantage of partaking of a universal system.

Herschel, in his quoted remarks, simply points out the various courses at our option, but instead of being "no decimalist," actually suggests that if we do still cling to our present system, it would be desirable to superadd to them "the additional convenience of a decimal system for facility of calculation," leaving the result to the process of natural selection. And natural selection we can easily foresee will ultimately bring us the metric system, because one nation after another is already adopting it, and each one puts increasing strain upon others to follow the example.

SIGMA.

DECIMALS AND THE DECIMAL SYSTEM.

[3964.]—The praises of a decimal system of coinage, weights, and measures cannot, I believe, be too often sung; and it is a pleasure to find that the matter is receiving such attention in "ours." In these days of improvement in every branch of manufacture, of advancement in education, in arts and science, it seems marvellous that we, as a nation who have hitherto done so much, should in some respects be content to adhere to old and effete ideas rather than follow in the wake of those who have so wisely led.

If we, labouring under the influence of our insular pride and prejudice, are determined to cling tenaciously to systems as intricate as Chinese puzzles, we must not be surprised if at some future time we feel their pernicious effect in the decline of our commercial intercourse with foreign nations; for what country is there which will care to traffic much with one whose currency, &c., are so difficult of comprehension, when it can obtain full value for its money in other ports where no similar obstacles exist?

From time immemorial nearly every nation on the globe made use of a series of numerals, of which 10 was the limit, all above that number being in "progression of tenfold proportions;" in other words, a decimal notation, which commenced with the use of the fingers as counting instruments, hence the word "digit," as applied to the cardinal numbers—from "digitus," a finger.

Now, it seems reasonable to suppose that if, by the repetition of those numbers, we are able to *increase* them to any extent in a decimal proportion, we ought to be able to *decrease* them in a similar ratio. With this idea before us, it is not difficult to conceive the manner in which decimals were originated. As already stated, we had a notation with 10 for its limit, and expanding in decimal proportions, yet when fractions were to be considered, we found ourselves in unutterable confusion.

In their case no ready means of comparison was at hand, and in order to effect it, it became necessary to create a new notation, less than unity, yet possessing all the advantages of the other—*ergo*, "the art of tenths, or decimal arithmetic," invented by Stevinus, a Flemish mathematician, which was improved upon by Oughtrede, in the year 1631, from which date the said system may be considered as fully established. Thus we became possessed of a simple form of notation capable of either expansion or diminution, according to the same law, and to any extent, commencing from unity as a fixed number. In order, therefore, to distinguish between the *integral* and *fractional* notation, a sign became necessary. Various kinds were used, but not one met with so much favour as the "dot," or decimal point, now finally adopted. What greater proof have we of the advantages of the said system when we find it invariably used by scientific men of tried ability and of careful research, who, from the very nature of their pursuits, are loth to undertake any reform that affects them without very mature deliberation? Yet when we step outside the pale of scientific research, and come into the precincts of commercial life, we find a system unique in its eccentricities, and totally at variance with all uniformity and order. If, as the old "wise saw" hath it, "order is of universal importance," and if science has found a decimal system to be of such use, surely commerce, so intimately connected as it is with science, should profit thereby. It is peculiar that we who are so precise and methodical in other matters, should thus far so signally fail to support the character in this particular, and, I imagine, it can only be put down to sheer obstinacy or short-sightedness on our part. Comparatively few there are at the present day who do not coincide in the views herein set forth, and taking it for granted that the majority carry the day, it behoves us to undertake the reform with as little inconvenience to the public mind as possible. This can be done by the introduction of the metric system, which, as I have above shown, already exists as far as our integral notation is concerned. Whatever advantages a duodecimal or other scale may possess, would at once be obliterated by the difficulty and magnitude of the change necessitated by the introduction of either, and cannot be brought forward as a reform for the better. It has been urged by some short-sighted persons that a universal currency would be of immense advantage; simply, I presume, because they possess a peculiar inability to comprehend a foreign coinage. Even were such to be started, exchange transactions would exist so long as commercial intercourse took place between countries, thus rendering the various coinages as widely different as before. So long as it becomes necessary to remit money from one country to another, exchange—which is nothing more than the combination of freight, insurance, and commission—must obtain.

In 1858, now nineteen years ago, the select committee appointed by Parliament to inquire into and report upon the advisability and means of introducing a decimal system, forwarded its report. It recommended the metric system of weights and measures as adopted by France, and with respect to the coins stated that it would be desirable to withdraw certain of them from circulation, and to substitute certain others having reference to a decimal scale. It contemplated "the retention under any circumstances of the present sovereign (1,000 mils), half-sovereign (500 mils, or 50 cents), florin (100 mils, or 10 cents), and shilling (50 mils, or 5 cents)," and considered "that the present sixpence under the denomination of 25 mils might be retained, and the crown or piece of 250 mils (25 cents), of which few were in circulation, need not be withdrawn." It urged the desirability of dispensing with the half-crown, the threepenny and fourpenny pieces as inconsistent with a decimal scale," and contemplated the introduction "of copper coins of 1, 2, and 5 mils, and silver coins of 10 and 20 mils (1 and 2 cents), to which should be added such others as experience might show to be requisite."

There are but few, I should think, who can raise any objection to the plan suggested by the said committee. During a period of eighteen years, spent in various parts of the world, I have had much to do with very varied currencies, and have been fortunate enough to contribute a little towards commercial literature (Tables of Exchange for Gibraltar, 1855; and Tables of Exchange for North America. Canada, G. E. Desbarats; New York, Appleton & Co.; and Halifax, R. T. Muir), and in my opinion words are too feeble to extol the praises of a decimal system.

The late Professor De Morgan, whose talent and ability will ever be fresh in the memories of those who are acquainted with his works, thus sums up the advantages of a change to a decimal coinage:—

1. All computations would be performed by the same rules as in the arithmetic of whole numbers.
2. An extended multiplication table would be a better interest table than any which has yet been constructed.
3. The application of logarithms would be materially facilitated, and would become universal, as also that of the sliding rule.
4. The number of good commercial computers would soon be many times greater than at present.
5. All decimal tables, as those of compound interest, &c., would be popular tables, instead of being mathematical mysteries.
6. The old coinage would be reduced to the new by the simple rule. (*Vide* his contributions in the "Companion to the Almanac," 1853).
7. When the decimal coinage came to be completely established, the introduction of a decimal system of weights and measures would be very much facilitated, and its advantages would be *seen*.

The opinions of numerous other men remarkable for their erudition and research could be cited in support of this change, all of which agree with the above.

It is necessary to call especial attention to paragraph 7 here, as it is somewhat opposed to the views which have been advanced by some writers as well as to the proceedings of the meeting held at the Mansion House some time ago. The said paragraph conceives the introduction of a decimal coinage as the *first* measure, and I entirely concur in the opinion so ably set forth, because the present coinage being universal throughout the kingdom, the change would be more easily effected than in the case of the weights and measures which, as every one knows, vary considerably with almost every county. The introduction of a decimal coinage would be the insertion of the "small end of the wedge," and the other change would follow so soon as it became generally understood. All who have written on this subject agree to the advisability of retaining the present sovereign, and of dividing it, as herein referred to, into 1000 mils.

The following simple rule, which I have constructed, will be found very useful in converting the old coinage into the new, and it can be mastered with a very little practice:—

(1) Old coinage into the new.—Shillings: Place a cipher to the right and divide by 2; the result will be cents. Pence: Multiply by 4, and if the product exceed 10 or 35, add 1 or 2, respectively, thereto; the result will be mils.

Example.—Reduce 15s. 10d. to new coinage:—

$$\left.\begin{array}{r} \dfrac{150}{2} = \cdot 75 \\ 10 \times 4 + 2 = \cdot 042 \end{array}\right\} = \cdot 792.$$

(2) As it may be useful to possess a simple rule for reducing decimals of a pound to shillings and pence, the reverse of the above will suffice, viz:—If there be less than 3 decimal figures, append as many ciphers to the right as are required to make up the number; then divide the first two taken together, or the cents by 5 for shillings. If there be no remainder, divide the third figure or mils by 4, for pence. If there be a remainder, prefix it to the mils and divide. If, after dividing, there be more than 2 remaining, add a halfpenny.

Example.—Reduce £0·792 to shillings and pence:—

$$\left.\begin{array}{l} \dfrac{79}{5} = \text{15s., and 4 over} \\ \dfrac{42}{4} = \text{10d.} \end{array}\right\} \text{15s. 10d.}$$

Whilst on the subject of decimals, I think it desirable to add one or two more simple rules, which I trust will be acceptable. They are as follows:—

(3) Inches into decimals of a foot, or months into decimals of a year.—For the first two places of decimals: Multiply the inches or months by 8, and if the product exceed 24, 48, or 72, add 1, 2, or 3 respectively; in the case of one inch only, prefix a cipher thereto. For the third place: If the number of inches or months be even, add 5 to the second decimal, and adopt the right figure of their sum for the third place; if the number of inches or months be odd, repeat the second decimal. In either case the third figure is a recurring decimal.

Decimals of a foot into inches.—When great accuracy is not required, and if the first two places exceed 24, 48, or 72, deduct 1, 2, or 3 respectively therefrom, and divide by 8; if the remainder be either 2, 4, or 6, add ¼, ½, or ¾.

Examples.—Reduce 4in. and 7in. to decimals of a foot: 4 × 8 = 32 (which exceeds 24, ∴ add 1) = 33 (and 4 being even, repeat 3) = ·333; 7 × 8 = 56 (which exceeds 48, ∴ add 2) = 58 (7 being odd, 8 + 5 = 13, ∴ 3 is the third place) = ·583. Reduce 0·083 and 0·125 of a foot to inches. 8 ÷ 8 = 1 and no remainder = 1 inch. 12 ÷ 8 = 1 and 4 over, or ½, = 1½in.

(4) Ounces into decimals of a pound, or drachms into decimals of an ounce (avoirdupois weight).—For the first two places of decimals: Multiply the ounces or drachms by 6, and if the product exceed 24, 48, or 72, add 1, 2, or 3 respectively; in the case of one ounce or drachm, prefix a cipher to the product. For the second two places of decimals: Multiply the first two places by 4, and strike the hundreds out of the product; if the remaining figures equal 24, 48, or 72 in value, add 1, 2, or 3 respectively thereto.

Examples.—Reduce 1 and 11 ounces to decimals of a pound (avoirdupois): 1 × 6 = 6 (prefixing 0) = ·06; 6 × 4 = 24 (add 1), ∴ 1 oz. = ·0625 of a pound.

$$\left.\begin{array}{ll} 11 \times 6 = 66 \text{ (exceeding 48, ∴ add 2)} & = 68 \\ 68 \times 4 = 2/72 \text{ (adding 3 for 72)} & = 75 \end{array}\right\} = \cdot 6875.$$

In the reverse of the above, when great accuracy is not required, if the first two places exceed 24, 48, or 72, deduct 1, 2, or 3 respectively therefrom, and divide by 6 for ounces or drachms, and if the remainder be either 1, 3, or 5, add ¼, ½, or ¾.

(5) The following diagram of days in decimals of a week will, I trust, be found useful:—

Days...............	1	3	2	6	4	5
Decimals.........	$\dot{1}$	4	2	8	5	$\dot{7}$

Here the whole of the decimals are recurring, and to find the equivalent to any particular day commence with the figure thereunder, and read on, repeating in the proper order as required—for example, 6 days = ·857142 of a week.

We cannot, I think, urge too strongly the adoption of a complete system of decimal coinage, weights, and measures, and when we think of the small majority that sufficed to "throw out" the last bill on the subject, we may yet hope to find it pass into law ere long. Perchance a petition signed by as many as can be found to support the measure would go some way towards effecting the desired reform.

A. M. Festing, F.M.S.

METRIC AND OTHER DECIMAL SYSTEMS—DUODECIMAL ARITHMETIC.

[3965.]—It is curious to see how a man of scientific acquirements, like "E. L. G." (letter 3890), can fall foul of the decimal system in the way he does, and I think that he can have had very little practical acquaintance with matters of account, or he would have hesitated before passing such a wholesale and sweeping condemnation on the system.

Allow me, Mr. Editor, to recommend "E. L. G.," by way of experiment, to add up (say) 40 columns of 50 or 60 lines each of moneys, and 40 more of avoirdupois weight, tons to pounds, and make the totals of the columns agree with those of the lines. By the time he has done with this I think he will agree with us poor accountants that the use of the decimal system, and consequent abolition of the compound rules, would materially facilitate such operations, and would, therefore, be a great boon.

While on this subject, allow me to make a few remarks on a decimal money system. I submit that there are grave objections to the proposed use of the pound sterling as the unit of value, inasmuch as all the smaller of our present coins except the florin would be useless, and the mass of the people (the chief users of the small coins) would be great losers before they could become used to the new ones. To remedy this, I would suggest that the new coinage should be in dollars and cents, the cent being exactly equivalent to our halfpenny. Then all our present coins would be available, and the trouble of learning the new system would be reduced to a minimum, which to most people, especially the poor and uneducated, would be a great boon.

What, in the name of wonder, can be the meaning of the fuss made about the multiplication of concrete quantities (query 11188)? Verily, the doctors disagree on this point as on others. Here we have "F. R. A. S.," "E. L. G.," "Moneta," and others, proclaiming the impossibility of the thing, while in most authorities on arithmetic a rule is given for doing it. Passing over "Walkinghame" as antiquated, take, for example, "The Principles and Practice of Arithmetic," by no less a person than John Hind, M.A., F.C.P.S., F.R.A.S., &c., hailing from the classic (or mathematic) shades of Cambridge.

His first example is as follows:—Find the area of a rectangular parallelogram whose adjacent sides are 5ft. 8in. and 4ft. 9in. He proceeds to do this in this wise:—

ft.	in.	
5	8	= length.
4	9	= breadth.
21	0	= product by 4ft.
3	11·3	= product by 9in.
24	11·3	= area.

Now, if feet can be multiplied by feet, and inches by inches, why not pounds by pounds, or shillings by shillings?

I may add that most computations of timber measure are performed in this way.

No. 170.

MODE OF DISCOVERING THE LONGITUDE AT SEA BY THE MOON AND FIXED STARS.

[3966.]—SUPPOSE, when the moon comes to the meridian of Greenwich, that any one of the fixed stars is then two degrees to the west of the moon, if an observer at sea finds on that day that fixed star one degree less to the west when that planet (moon) comes to the meridian he is in, and that as to its velocity it precedes in a mean progression, the observer is then 27 deg. 19min. 17sec. to the east of the Greenwich meridian. If the fixed star be found at sea one degree more to the west, the ship is 27deg. 19min. 17sec. to the west of the meridian of Greenwich. Consequently, if the fixed star is 27min. to the east of the meridian of Greenwich, or if 1min. more to the west, the ship is 27min. to the west of the meridian of Greenwich, and so on in proportion. But as the moon's velocity varies, allowances must be made for these variations, and equation tables made accordingly. These tables can be made to as great exactness as is requisite by making observations with the telescope and micrometer, wherewith the distances to some of the fixed stars is to be measured, not precisely from the moon, but from the meridian when the moon comes to it. The meridian must be distinguished by lines in the telescope from the higher to the lower part thereof, one end of which line in the observation must seem to touch some remarkable spot or mountain of the lunar orb when it is at its meridian altitude: then the said line exactly shows the meridian.

The distance of any of the fixed stars in the neighbourhood of the moon from the meridian ought to be measured by the screw of the micrometer, or by lines divided into digits, and sub-divided into lesser denominations, which lines must cut the meridian line of the telescope in right angles.

In making observations at sea the telescope ought to be fixed on a pedestal (being a pole or rule of a proper height), furnished with plummets depending on wires or plateens, and traversing to contrary points of the compass and of the ship.

Example: If one plummet traverses north or south, or from starboard to larboard, or larboard to starboard, another must be so placed as that it may traverse east or west, or from stern to stem, *vice versâ*. The pedestal must be kept exactly even with these plummets, and thereby upright or perpendicular, by an assistant who has an even hand, and by a machinery resembling that of a mariner's compass, in which, by means of proportionate weights, the pedestal must traverse on pivots n contrary ways. A microscope must be made use of n viewing the plummets, and a screen may be requisite to keep off the wind, thereby the telescope or any other mathematical instrument will always be, notwithstanding the motion of the ship, in the same position with regard to the zenith, especially in moderate weather. Pedestals may be made in which one plummet only would show the various declinations of the ship with regard to the zenith. The telescope is to be so placed on the pedestal as that it may be easily moved from one point of the compass to another without moving the pedestal.

In this method it is not requisite to know the place of the moon as to its declination, either at sea, or at the meridian of Greenwich, or any other. It will be requisite only to find the moon's right ascension, of which tables may be made according to the general opinions of astronomers by the observations already made, within one or two minutes of a degree; but by observation with the new micrometer, which measures the distance of the fixed stars' directly from the meridian, it may be pre-calculated within a few seconds of a degree, on which the more exact discovery of the longitude depends.

It is next to an impossibility to find the moon's exact place as to its declination, because the moon has always some parallax and refraction of declination, except within the tropics, when it is directly east or west, or just in the zenith. But the moon's right ascension can be exactly observed with the meridional micrometer every time it appears at its meridian altitude near any of the fixed stars, because, when it is at its meridian altitude it has no parallax or refraction of right ascension. It is requisite to take notice of the declination of a fixed star, because the greater its declination the less space will make a degree, minute, or second distance from the meridian. The meridian altitude of some remarkable spot or mountain of the moon may be taken by another observer with any of the quadrants that are commonly made use of at sea. He must give notice thereof to the observer who observes with the telescope and micrometer, who must then observe the distance of one of the fixed stars from the meridian. Or the moon's meridian altitude can be exactly taken by the same observer with the same telescope and micrometer disposed in an astronomical quadrant, kept by the same machinery as the telescope, in such a position with regard to the zenith, as that of an altitude at sea without a horizon. The plummets of the marine pedestal which I have described will inevitably direct the hand and eye to keep the instrument in such a proper position at sea for making the necessary observations. Although the motion of a ship or any other cause would occasion an error of a few minutes of a degree in observing the meridian altitude of the lunar orb, it would cause an error only of a few minutes of a degree in the longitude, because there would be about a difference of a few seconds of a degree as to the distance of a fixed star from the meridian line of the telescope. But in case of such an error, and that the observation may be the more exact and sufficient, the fixed star must by all means be in the vicinity of the moon, and at a proper distance from the zenith.

If it be on the same side as the observer of the moon's parallel of declination, the more remote it is from the zenith, and the more exact the observation, as is demonstrated by a triangle, one side of which will be a segment of a line passing from any certain point of the moon (when it is a few minutes of its meridian altitude or a few minutes below), another side of the said triangle a line from the said point of the moon to the star of observation, and the other side a line from the star to the zenith line, so as to join the zenith line at right angles. But if the star be on the other side of the moon's parallel of declination, the nearer it is to the zenith the more exact still the observation, as is proved by a similar triangle on the other side of the moon's parallel of declination. In either case, the more the place of observation is north or south of the moon's parallel of declination the more exact the observation. As it requires extraordinary accuracy and expertness, and cannot be learnt but by diligence and practice, it would be commendable that particular astronomical schools were more established for this branch of experimental astronomy. I apprehend the longitude can be easily and certainly discovered at sea by this method within half a degree of a circle, and frequently nearer.

It will be an advantage in navigation, although the other methods—viz., by observing Jupiter's satellites (I need not say much regarding these minute bodies) with which, by measuring time with a watch, should likewise prove true, as it is to be hoped they will, because observation of the longitude can be more frequently and exactly made by the moon and star than by the eclipses of Jupiter's satellites, as a watch must be sometimes corrected. By this method it can be corrected at sea, and therefore can be useful for discovering the longitude when the moon is invisible at the time it comes to the meridian, or the star imperceptible by the interposition of clouds, or from the light of the sun. This method can be rendered immediately practicable if the tables that are made of the moon's right ascension are pre-calculated to sufficient exactness, which can be soon known by experiments; probably they are. By future observation the said pre-calculation may be improved and brought to as great perfection as can be expected—that is, within a second or two of a degree. The other great difficulties proceeding from parallaxes and refractions are in this method completely obviated. This method of discovering the longitude at sea depends on the experimental astronomers and mathematical instrument-makers to reduce it to practice.

High Heworth, Gateshead. RALPH LOWDON.

"SCREW'S" MULTIPLICATION.

[3967.]—I DON'T see the good of "Screw's" mode (let. 3941). But it reminds me of one published in "The Short Calculator" (Longman, Lancaster), which shortens process for heavy numbers—*e.g.*, to multiply by 999, add 3 ciphers, and deduct the multiplicand. Thus, multiply 476521 by 999999 : add 6 ciphers, &c.—

$$\begin{array}{rr} & 476521000000 \\ - & 476521 \\ \hline \end{array}$$
$$= 476,520,523,479 \text{ the product.}$$

Multiplying thus by 1 additional (which is simply adding ciphers), and subtracting the multiplicand to compensate for it, completes the whole process. To multiply by 998, add 3 ciphers, thus—

$$\begin{array}{rl} & 476521000, \text{ and deduct } 2 \times \text{ multiplicand} \\ - & 953042 \\ \hline \end{array}$$
$$= 475,567,958 \text{ the product.}$$

To multiply by 7999, add 4 ciphers; and, as it requires 2001 to complete the multiplier to the number 10,000, deduct multiplicand × 2001—

$$\begin{array}{rrl} & 4765210000 & \times\ 7999 \\ - & 953042000 & = \times\ 2000 \\ \hline & 3812068000 & \\ - & 476521 & = \times\ 1 \\ \hline \end{array}$$
$$= 3,811,591,479 \text{ the product.}$$

In the same way, to multiply £9 19s. 11d. by itself, multiply £10 by itself = £100, and deduct 1s. 8d. for added 1d. to each side involved, multiplier and multiplicand. Thus—

$$\begin{array}{rrrr} & £100 & 0 & 0 \\ - & & 1 & 8 \\ \hline = & 99 & 18 & 4 \text{ the product.} \end{array}$$

This is right, I believe, within the 5760th of a penny.

J. BARWICK.

"E. L. G." AND GEOLOGY.

[3968.]—SOME weeks ago I endeavoured to extract from "E. L. G." some facts in support of his theory of comet-falls, but without success. I was much disappointed at the tone in which he carried on the discussion, for the question was a *bonâ-fide* attempt to correct possibly erroneous opinions, and, as the event proves, the question was not without interest to other readers; as the theme has again been opened, perhaps I may be allowed to make a few remarks. "E. L. G." envelopes his argument in such a cloud of words that he puts me in mind of the cuttle-fish, which retreats from his enemies under cover of a discharge of ink. The name of Lyell acts upon him like a red rag on a bull. In all the letters he has written on "Geology," he has never given one fact in support of his theory; it has been all assertion, something or other is always demonstrable, then why on earth does he not demonstrate it? Let us have no more palaver about Lyell; what does it matter whether this or that man advocates the doctrine of continuity? What we wish to know is whether that doctrine be true or false. Let "E. L. G." give us but one fact (we do not want millions), which is inexplicable on the supposition that cataclysms have never occurred, and he will gain at least one follower, and although I am now of opinion that the present and past distribution of life on the earth is incompatible with the occurrence of any universal catastrophe, I will proclaim myself a convert. For instance, let him show that the ordinary forces of nature are incapable of forming turret-shaped hills, and that they must have been fashioned in a few days, or let him show that his floods of water could have had no effect in interrupting the growth of the coral reefs of Florida, and he will go far to upset the doctrine which so raises his choler.

P. SANTALINUS.

TERRESTRIAL GRAVITATION AND MERCURIAL VAPOUR.

[3969.]—APPRECIATING as I do Mr. Proctor's mathematical knowledge, and being rather diffident of my own, I would hesitate before questioning any statement of his on a mathematical subject, but if I understand him in letter 3828, p. 86, *ante*, I am under the impression that he must be wrong. He there distinctly states that without the use of the integral calculus it is impossible to determine the attraction of a sphere on a particle outside, or on its surface. Now, if I am not very much mistaken, this is done without the integral calculus in Thomson and Tait's "Natural Philosophy," articles 471 and *seq.* If I am wrong will Mr. Proctor be good enough to set me right?

In reply to W. R. Birt's question about mercurial vapour (letters 3858 and 3674, Vol. XIV., p. 611) the only experiments that I am aware of to measure the actual elastic force of mercurial vapour at different temperatures are those of Avogrado in 1832, and Regnault in 1844—the former at various temperatures from 230° to 290° C., being 58mm. at the former and 253mm. at the latter, from which he deduced a formula, giving 0·03mm. at 100° C., 19·30 at 200°, 302·00mm. at 300°, and 760·00mm. at 360°, or boiling point of mercury. Regnault could discover no measurable force at 0° C., at 25·4° = 0·034mm., at 49·15° = 0·087mm., at 72·74° = 0·183mm., at 100° = ·407mm., at 146·3° = 3·46mm., at 178° = 10·72mm., at 200·5° = 22·01mm. As density of mercury vapour, according to Bineau, is 6·7, it is easy calculating the weight of mercury vapour in a cubic foot by following formula $\frac{x}{760}$ 7·6 (weight of cubic foot of air at atmospheric pressure), x being elastic force in millimetres.

F. N.

AMERICAN AND SCOTCH INVENTIONS.

[3970.]—IN No. 368 I observe an illustration of a universal angular drilling machine. The selfsame kind of tool was in use here, in Dundee, eighteen years ago, and it is twelve years since I first used it in different workshops here. The inventor was well known here at that time—a poor working fitter, who never saw America, who was advised to patent it, but had not the means. The machine is and was chiefly used for small holes, such as boring steady-pin holes in machine framing. The only apparent difference is that instead of the crank handle a fly-wheel was and is used with a handle fastened in the rim.

FITZBERTIE.

DR. CARPENTER AND PERSPECTIVE.

[3971.]—I BEG to quote the following from a paper by Sir David Brewster, as it appears to relate to the statement made by Dr. Carpenter: "This tendency of the eye to invert the perspective of rectangle prevents or diminishes that appearance of convergency on the plane face of a lofty square tower when we are standing not very far from the base. A photograph of the tower taken from the same spot would exhibit a painful convergency upwards which is not seen by the eye." Being accustomed to sketch, I may add my opinion, perhaps, which is that in practice the convergency is too small to be noticed, as we do not draw high towers near their base.

M. PARIS.

LUNAR OBJECTS FOR OBSERVATION, MAY, 1872.

[3972.]—MAY 9, Mare Crisium, Hansen, Alhazen; May 10, Cleomedes, Burckhardt, Geminus, Messala. May 11, Endymion, *De La Rue* (a fine formation north of Endymion). May 12, Lacus Mortis, Plana, Burg. May 13, Aristoteles, Eudoxus, *Alexander* (a formation south of Eudoxus). May 14, Hipparchus, Triesnecker, Hyginus. May 15, Albategnius, Parrot, Airy. May 16, Clavius, *Terra Photographia* (a region west of Clavius). May 17, Laplace, Maupertius, Condamine. May 18, Mare Humorum, Doppelmayer, Vitello.

W. R. BIRT.

P.S.—The monogram of Hipparchus contains the objects at present known in the interior. For details of the clefts near Triesnecker, consult "Telescopic Work for Moonlight Evenings," ENGLISH MECHANIC, March 10, 1871, No. 311, p. 578; and "Catalogue of Lunar Objects," area 1 A, alpha. This system, with the Hyginus Cleft, is shown in a large drawing by Mädler appended to the new edition of the large map.

ERRATA.—Letter 3856, No. 366, p. 40, April 14, for *Almanore* read *Almanon*; April 18, for *Thebi* read *The*[illegible] April 18, for *Sirius Iridum* read *Sinus Iridum*.—W. BIRT.

HOW WE SEE A DISTANT OBJECT.

[3973.]—"Bobo" is clear and correct; "E. J. D." should study modern optics. We must not forget that light results from ether pulsations on the eye—ether, which itself cannot be seen; that it is only when we see our own eyes in a mirror that we see by rays that rebound or reflect to us without any angle, and when all the rays of light received are returned (as is done by and from a mirror's surface) the surface that reflects is itself unseen and colourless, because it reflects every ray; the rays angularly received on the mirror are reflected at the like angle. A mirror's frame is visible, as "Bobo" shows, by its shading off or not reflecting all the received rays: it reflects but those that denote its colour.

Light is repeatedly reflected, upward, downward, or laterally, distinctness fading with degree of distance, according to the laws of perspective, whether observed in atmospheric dust or in the objects of a landscape. The fading of visibility of distant objects, I take it, is caused by increase of intervening ray-crossings, which obstruct more extensively as distance increases; but also rays diverging, fewer rays reach the eye as distance increases. "E. J. D." may learn something from Sir John F. W. Herschel's "Lecture on Light," the sixth of his "Familiar Lectures," published by Strahan.

J. Barwick.

[3974.]—In reply to the letter of "F. R. A. S." (3870, p. 61) I beg to say that as Mr. Proctor has, to a certain extent, answered my letter (3493, p. 510), the fact of "F. R. A. S." not being able to understand it, is now of no consequence. I beg to assure him, that having often watched with interest the entrance of a sunbeam into a darkened room, and being unable to satisfy myself how small objects illuminated by it became visible to me at some distance, I read the theory of light, and have come to the conclusion that it does not explain in a rational manner how we see distant objects. I, therefore, put forward the problem with a view of ascertaining the opinions of scientific men. I will now propose a question, if he will kindly answer it. Suppose a vast multitude of persons are assembled on a plain, and that in front of them some conspicuous object is elevated, so high that all can see it (say, a large statue of black polished marble); to enable all to see it, the theory of light says:—"The rays of light must be detached from every physical point of it in all directions; but only those rays which enter our eyes can render them visible to us." It is evident from this that two distinct sets of rays must proceed from the object to each of the spectators—that is, one for each eye, and yet the polished surface of the statue ought to reflect the light specularly. Of course I am aware that we cannot make a perfectly polished surface, and yet after making due allowance for the numerous secondary reflections of the atomic prisms (which some suppose all bodies consist of) I cannot conceive how the reflections can be so numerous and so conveniently arranged that they flash in right lines from every physical point of the statue to the eyes of the spectators, and that additional rays must proceed to any distance, or to any point from which the statue can be seen, even to twenty miles, when viewed through a telescope. I shall feel obliged if "F. R. A. S." can remove my doubts respecting this point in the theory of light. I scarcely think he can mistake my meaning, which is to ascertain how, considering the various curves in the statue, it is nevertheless able to send an uncountable number of rays to so conveniently meet the requirements of every spectator, no matter how numerous or where placed, whether far or near, provided the statue is in view.

E. J. D.

LUNAR METEOROLOGY.

[3975.]—Will you allow me to call Mr. Birt's attention to the subject of meteors, in connection with a possible lunar atmosphere? Our satellite must be as liable to be cannonaded by meteors as the earth, and having no appreciable atmosphere, these must impinge upon her surface "as they were," not suffering for the most part dispersion, as is the case with our shooting stars. Now we know that these bolides contain, at all events, occluded hydrogen, and possibly other gases, and as the force of collision must be sufficient, if not to vapourise, at least to pulverise, the bolide, we have here, I think, a source of vapour and gas, of which the otherwise perfect vacuum would prevent the liquefaction or solidification. Again, we know that whatever may be the composition of the moon's rocks, they cannot be pure metal, or the reflection of light from her surface would be different. There must, therefore, be oxidation, and it appears very unlikely for the amount of oxygen to have been only enough to burn up her surface, except upon a supposition I made some time ago—namely, that the moon was herself a bolide, which consisted of pure metal, and had passed through an atmosphere of oxygen in her wanderings. We also know that metals smell, therefore evaporate, as in fact most mineral substances do, and this under a pressure of 15lb. to the square inch. If there be almost a perfect vacuum over the moon's surface, metals, &c., must evaporate much more readily.

Bolides contain substances such as iron, sulphur, &c., which have a powerful odour, and as they must for ages have been showered upon the moon, it seems to me to be certain that our satellite possesses an atmosphere, at all events of vapour, of many of the substances composing them. Whether the light emitted by the collision of an enormous bolide on the dark limb of the moon could be seen by a telescope accidentally turned that way, I think doubtful, yet, if I am not in error, there have been some appearances which render such a supposition just possible.

M. Paris.

BASKET-MAKING.

[3976.]—In back numbers queries asking for information on basket-making have appeared. The following, extracted by the *Journal of Horticulture* from J. C. Loudon's "Suburban Horticulturist" (a work now, I believe, out of print) may be useful.

One year's shoots of the common willow, or of some other species of that family, are most generally used. The shoots are cut the preceding autumn, and tied in bundles, and if they are intended to be peeled, their thick ends are placed in standing water to the depth of 3 or 4in.; and when the shoots begin to sprout in spring they are drawn through a split stick stuck in the ground, or an apparatus consisting of two round rods of iron, nearly half an inch thick, 1ft. 4in. long, and tapering a little upwards, welded together at the one end, which is sharpened so that the instrument may be readily thrust through a hole in the stool or small bench, on which the operator sits. In using it, the

FIG. 1

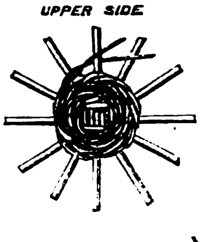

FIG. 6 UNDER SIDE

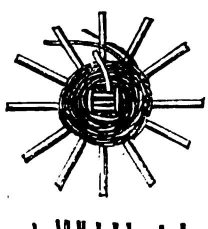

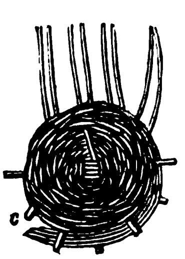

FIG. 8

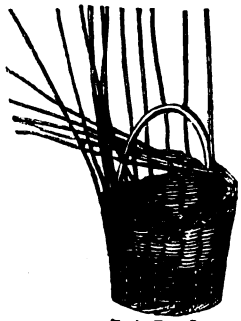

FIG. 9

FIG. 7

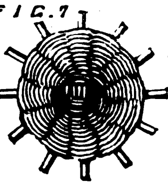

FIG. 10

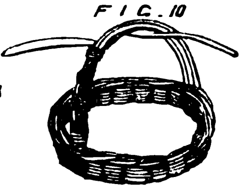

operator takes the wand in his right hand by the small end, and puts a foot or more of the thick end into the instrument, the prongs of which he presses together with his left hand, while with his right he draws the willow towards him, by which the bark is at once separated from the wood: the small end is then treated in the same manner, and the peeling is completed. Every basket consists of two parts: the framework of the structure, and the filling in or wattled part. The principal ribs in common baskets are two: a vertical rib or hoop, the upper part of which is destined to form the handle; and a horizontal hoop or rim, which is destined to support all the subordinate ribs on which the wands are wattled. The two main ribs are first bent to the required form, and made fast at their extremities by nails or wire. They are then joined together in their proper position, the one intersecting the other; and they are afterwards nailed together, or tied by wire at the points of intersection. The operation of wattling is next commenced, by taking the small end of a wand, and passing it once or twice round the cross formed by the points of intersection; after which one or perhaps two secondary ribs, are introduced on each side of the vertical main rib. The wattling is then proceeded with a little further, when two or more secondary ribs are introduced; and the process is continued till a sufficient number of subordinate ribs are put in to support the wattling of the entire structure. The whole art, as far as concerns the gardener, will be understood from the following figures:—

Fig. 1 shows the handle and rim of what is called the Scotch basket, made fast at the points of intersection.

Fig. 2 shows the same skeleton, with the ribs of one side added, and the wattling or woven work commenced.

Fig. 3 represents the commencement of what is called the English mode of basket-making; in which three parallel rods of 2ft. or 3ft. in length, according to the intended diameter of the bottom of the basket, are laid flat on the ground, and three other rods of the same length laid across them at right angles, as at *a*; and next the weaving process is commenced, as at *b*.

Fig. 5 and Fig. 6 show the progress of weaving the bottom; the latter being what ultimately becomes the under side, and the former the upper side.

Fig. 7 shows the bottom complete, the under side of it being uppermost.

Fig. 8 shows the bottom turned upside down, the points of some of the radiating ribs cut off, some of the rods which are to form the side ribs inserted, and the side weaving commenced.

Fig. 9 shows the basket nearly completed, with part of the rim finished, and the rod on which the handle is to be formed inserted.

Fig. 10 shows the rim completed and part of the handle plaited.

Androcles.

LIGHTNING CONDUCTORS.

[3977.]—I wish to express thanks to "Sigma" for taking any notice of what I wrote on the above subject, as he has been kind enough to do in letter 3923, but at the same time I regret that I should have led him to suppose I ask questions with a view to obtaining knowledge instead of taking the trouble of reading for it.

I put the questions to "Philo" to ascertain whether he had any ground for two statements he made—viz., first, that conducting bodies (see letter 3783) conduct by means of or through their surfaces, as distinct from their interior substance, and, secondly, that a discharge bursts things (see letter 3846) by the expansion of steam produced, "or else" by the repulsion among the particles.

I asked him the second question because he did not notice the first, and because he had taken upon himself to try to set me right (letter 3846), and from the evidence of his letters generally, and 3783 in particular, I did not think he was the right man for the job, otherwise I should have let him slide on.

When I put into "Sigma's" mouth the words "electricity is a fluid," &c., I selected the least likely ones that I could at the moment imagine, and the reply he has actually made is, I am glad to say, just nearly about what I should have anticipated, if I had been on the look out for an answer at all.

J. K. P.

VERDE ANTICO.

[3978.]—Ethel Taylor (p. 560, Vol. XIV.) asks whether the antique green bronze can be perfectly reproduced by chemical means. I guess not; no more than you can reproduce the exact tone of a picture by Raphael, or of an Amati violin. You can imitate them, of course, and so you can the antique green bronze, but only up to a certain point. Moreover, I doubt whether the green now seen on metals at Pompeii had the same tint or tone 2,000 years ago, when first the castings were made, that it has now. This most exquisite tone and tint is probably produced by the oxygen having in twenty centuries worked into the body of the metal, whereas any chemical application is confined to the surface only.

I congratulate Ethel Taylor on the absorbing and interesting pursuit she has taken up. The only objection to it is the way it cuts one's hands to pieces. Mine look very much like those of an inharmonius blacksmith washed clean, for I can't work in gloves as Ethel Taylor does. If she will mention more exactly the way she reproduces the metal objects in Stockholm I may be of use to her, as I am familiar with all the methods of working in wax and metal, and no professional gold, silver, or other metal-worker seems inclined to come to the rescue. "Tubal-Kain" ought, from the name, to be able to help her. It is only a pity that more ladies do not adopt a pursuit so well adapted to them as working in metals is, especially the precious metals, which require a more tasteful and delicate manipulation.

Proven.

LENSES.

[3979.]—If "F.R.A.S." (let. 3710) will examine a gla[ss] which has the deposit he mentions, he will see it to b[e] a fungus mycelium, and will find plenty of spores. [It] is very troublesome, and if it be not removed fr[e]quently it will, after a time, destroy the polish of th[e] glass, and this in a good one is not very p[leasant]. The only prevention, if it be one, is air, and w[iping] the glasses occasionally with dry blotting-paper (m[ade] into a roll, and then the end scraped with a knife) or with very soft velvet. The good of dry blotting-pa[per] is that it effectually removes damp and grease, w[hich] washleather never will do for long, and without a [deal] of trouble.

E. T.

PUTREFACTION AFTER DEATH.

[3980.]—It is admitted, in medico-legal investigations, that the appearances of rigidity and putrefaction in dead bodies may be called in to determine the time of death. Such signs may, however, appear more readily in some circumstances than in others. The causes which favour and hasten decomposition lie both in the surroundings and in the body itself, in the former case depending on heat, humidity, and electricity in the air; in the latter, on the age of the person, his degree of obesity, the more or less humid constitution of his body, and especially the kind of malady that has caused his death. Thus, among general affections, those which alter the humours and solid organisms during life, such as scorbutic disease, variola, dropsy, putrid fevers, &c., hasten putrefaction after death. May the same be said of the effects of alcohol, largely used? M. Champouillon thinks it is so, and he has found proof of it in facts observed during the conflicts in Paris last year.

On the 22nd May, between three and four a.m., fourteen Communists were executed near the Auteuil cemetery. By about midday the bodies had assumed a violet tint, the face was livid and very much swollen, and the wounds gave out the odour characteristic of commencing putrefaction. Phenomena of decomposition, quite as rapid as this, were witnessed at various points in Paris where the insurgents fell in fight. Out of 441 bodies examined it was ascertained that 296 were those of men that had been given to drunken habits. The bodies of 58 soldiers killed in attacking barricades, or other encounters, presented, in the matter of preservation, a striking contrast to those of insurgents that fell at the same place and time. From Monday, the 22nd, to Thursday, 25th May, the weather was warm, but not stormy. On Friday, the 26th, rain fell in abundance, and the temperature of the air fell considerably, a circumstance fitted to retard putrefaction. Nevertheless, M. Champouillon observed that in the Place des Vosges, Place de la Bastille, and neighbouring streets, the bodies of insurgents, lying pell-mell along with those of the military, had preserved a marked advance in the progress of their decomposition. He considers it established, from numerous observations, that drunkenness induces in the bodily organism a state which favours the rapidity of decomposition after death; and that the bodies of drunkards decompose at a more rapid rate than those of sober persons. He hopes to be able to determine, with precision, what are the limits of this advance in decomposition.

THE FLIGHT OF BIRDS.

[3981.]—There are in Asam ample opportunities of observing the flight of those birds that not only move onwards, but actually rise for considerable heights without vibrating the wings. Being a swampy country waders abound; the larger ones, as the Korson, or Cyrus, the Bor Taellia, Bor Tokolla, and Koonooa, all rise after a few preliminary flaps, and to considerable heights, in this way. I have often speculated on the phenomenon and its cause, and at last find it is a simple affair. If carefully noted, the bird will be seen to travel to leeward in large circles thus: On starting and taking a wide sweep to leeward, it gets up considerable impetus, and on rounding to face the breeze, the wings are more highly inclined, and it rises like a kite, and higher than it was before as the circle is closed. Circle it really is not, nor yet spiral, for the part against the wind has less traverse than the part with it. The latter taking (say) twenty seconds, the former only (say) fifteen seconds, or even ten seconds. Often I have tried to shoot them ere they were too high, and it was by taking aim carefully against a tree stem, that I found each return was both more to leeward and higher, yet the wings never flapped once. There is no possibility of doubting this as a fact. I have never seen them thus rise without a breeze (though I don't say it is impossible). On asking my dusky doorkeeper as I write, he confirms this part, saying, "Bota pallie, pahie na mari" [wind having got, wings (need) not strike].

The Korson is most remarkable of all. Once, at tiffin, soon after I came out, I heard a loud crawk crawk just over the house, and running out to see the Korson fly over was well laughed at; not a feather was visible, though the noise was so loud overhead still. A friend came out, and pointing up told me to look steadily a moment, and sure enough, there, miles up it seemed, were a lot of little black dots seemingly stationary, and they were the Korson, with wings of 9ft. or 10ft. stretch. I afterwards watched them with binoculars, and never saw one of them flap a wing once.

The remarks of your correspondent (let. 3260, p. 382) about noise of wings sounds comical here. My brother and I, both pretty good canoeists, were only yesterday nearly upset by the start we got at five Hooangs or large hornbills suddenly flying off the top of a tree we were paddling past, each flap sounding like tearing sharply a yard of calico. The noise of their wings can be heard at least 240 yards against a breeze: that I have measured.

COMPETITIVE EXAMINATIONS.

[3982.]—In reference to letter 3918 (page 73) I now understand what Mr. Bottone means; but what does Prof. Barff mean—that it is doubtful that SO_3 is ever produced, or that Prof. Odling and Dr. Debus, the London examiners (the assistant-examiners are Drs. Flight and Mills), doubt it, or have never heard of it? Surely not the latter.

Hedera.

CONSTRUCTION OF TRANSIT LINES.

[3983.]—In the hope that it may be of service to the readers of the English Mechanic, I now describe my plan for the construction of transit lines, which I have for many years employed with success. I can claim no originality in the invention. This is due to Dr. Derham, and will be found described in Lowthorp's abridgement of the "Philosophical Transactions for 1721," Vol. I., chap. 3, p. 227. A bar of iron, A A, Fig. 1, about 5ft. 6in. in length, is fixed to a wall as nearly in the meridian as may be. To this bar are attached by nuts and screws two holdfasts, B B, at about 4ft. distance from each other. These, also, are furnished with nuts at their returned ends. Upon these holdfasts, as centres, turn the iron bars C C, D D. The bars are clamped in any required position by the nuts on B B. At the ends of each bar are sliding-pieces, which have clamping nuts for adjustment, and also slots, in which are the carriers for plumb-lines and the sights for viewing the same. These are secured in their places by thumb-screws. One of these sliding-pieces (carrying a sight) is shown on an enlarged scale at E. The bars are 2ft. in length. The adjustment to the meridian

FIG. 1.

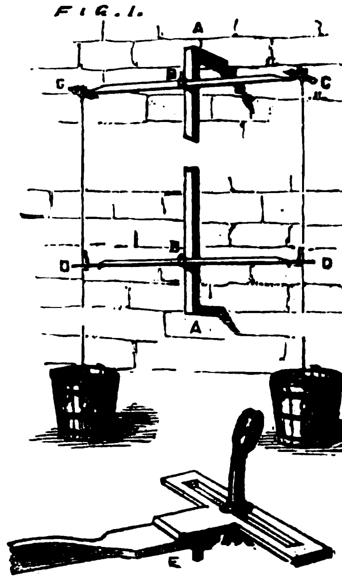

FIG. 2

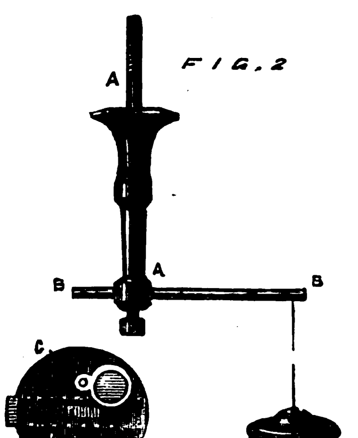


can be made by any of the usual methods employed for bringing a transit instrument into the meridian; or, supposing the true time of the sun's meridian passage to be given by a chronometer, by simply bisecting the disc at that moment, viewing the southern line through the northern sight. This having been done correctly, the southern sight and the northern line may then be adjusted thus: Bring the northern line over the eye-hole of the northern sight, and bring the eye-hole of the southern sight to agree with the southern line. For greater accuracy, the contact of the two limbs of the sun will, of course, be observed as well as the central passage. The first rough adjustment is made by turning the two bars with their lines and sights on the holdfasts, and then clamping them; the next by the plumb-line in its slot, and the final one by the sight in its slot. By the slide in the direction of the length of the bars the lines and sights can be brought to near or close contact. The weights are suspended in water to check vibration, and pierced with a few holes at right angles to their axes.

If solar observations only are required, then, of course, one line and one sight are sufficient. In this case, the line may be carried in a slot at the end of a support of iron fixed to a wall, and the sight can be adjusted in the slot at the end of another bar or rod of iron attached to the wall at the required height and distance. This is a very simple and very effective kind of transit line, which I have for many years employed. Fig. 2 represents a portable form of transit line for travelling or the pocket. The stem A A is screwed (say) into the upper part of a window-frame, having a southern aspect. A piece of brass wire slides in a hole at the end of this stem, and can be fixed in any position by a clamping-screw. The end of this wire is perforated with a small hole for a plumb-line. C is a sight-vane, having a dark shade for viewing the sun, the sight-hole sliding in a dovetail for adjustment, and furnished, also, with a clamping-screw. This sight-vane is screwed (say) into the cill of the window or other fit place, at the requisite distance from the plumb-line, and as near as may be in the meridian. The rough adjustment is made by sliding the brass wire B B in the hole in the stem A A, and clamping it by the screw; the final adjustment by the slide in the sight-vane, and then fixing by its clamping-screw. All the parts in Fig. 2 are given half size, and I shall be obliged if the same is preserved in the engraving, as well as the position in which they are represented in the sketch. If any reduction is necessary I trust your engraver will state the ratio. Those of your readers who may be interested in the subject of transit lines may be referred to the paper in the "Philosophical Transactions" already quoted; also to Dunn's "Introduction to Astronomy" (1774), p. 28, and Adam's "Geometrical and Graphical Essays," by Jones (1797), p. 427. When once properly adjusted these meridian lines are far superior to any sundial, and give results nearly approaching in accuracy those of the dipleidoscope. With the transit instrument they cannot, of course, be compared. However, the one involves the question of an outlay of many pounds, the other of only a few shillings.

Sidmouth, April 12. N. S. Heineken.

ARE ANTS PIRATES?

[3984.]—Can this possibly mean do ants rob at sea? If so I must answer that I don't know. But I do know from years of experience that they do rob on land, and that most perseveringly and effectually, and to an extent that makes them most formidable and expensive opponents to those living in hot countries. My experience was in Buenos Ayres, where we were kept continually on the alert to circumvent, and, if possible, destroy them, or otherwise they would soon have robbed us of every vegetable that grew in the quinta.

W. Gaucho.

GARDEN STUFF.

[3985.]—(3888).—Potato Culture.—An experienced farmer to whom I related my success last year in raising a large crop without manure, told me that the soil of my garden was so good as to render any sort of manure for potatoes unnecessary. He added that in all soils rank or crude manure was poison to the plant.

(3911).—Are Ants Pirates?—I entirely agree with "J. C." on this subject. How can the ants increase the appetites of the aphides by acting as their scavengers? Earwigs and woodlice I find are terrible bud-eaters. Ladybirds prey upon the aphis, and hop-growers love them. My own observation leads me to think that the ladybird and its larva can effect very little in keeping down the fly.

Weeds.—Always leave a fair proportion of weeds in the garden for the autochthones, slugs, snails, and other varmint, whose ancestors were the lords of the soil ages before man came to usurp it. They, unlike Red Indians, can never be entirely extirpated, and if they do not find their native weeds will devour what we sow. Their numbers can be kept within reasonable limits by traps, such as small heaps here and there of old bricks or vegetable refuse, to be looked over from time to time.

Rockwork.—Ferneries and heaps of tree roots are fertile sources of trouble, as hosts of slugs will breed therein in spite of every care. This should be borne in mind in choosing a situation for such ornaments.

Onions.—An occasional dressing with powdered washing soda is a first rate application.

Strawberries.—You can scarcely tread the ground of your strawberry bed too hard. Cover the blossoms with straw lightly on frosty nights, and look out carefully for woodlice, and a beetle which eats the centre of the flower. This beetle was particularly busy at Wimbledon when I resided there about ten years ago.

Peas.—Soak the seed in strong infusion of tobacco to keep off mice and birds. When coming up sift a little soot over them to disgust the sparrows.

M. Paris.

AN ERRATIC METEOR.

[3986.]—On the 16th of March, I was engaged with a friend in telescopic work, when I just happened to catch sight of a meteor, which, darting down from the head of Taurus, pursued a course over Aries to the horizon; unlike most meteors, instead of pursuing a straight line, it took that of a double curve. It was much swifter in its flight than an ordinary meteor. Are such appearances common, or have they been noted before? I was unwilling to communicate this before, because people are apt to cavil at others observing what they have not done; and at once to declare, that as they had not seen it themselves such things could not be. Witness my observations of the spots on Venus a month or two back.

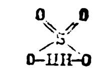
Canis Minor.

EXAMINATIONS, ATOMICITIES, &c.

[8987.]—I am very much surprised that so many of your chemical correspondents should have taken so great a liberty with Dr. Frankland's name in connection with what has been styled "a legal system" of chemical notation. Many of those who have been writing upon the subject of the Government examinations, text-books, &c. (if they will excuse me, and not think me egotistic), know really very little about that upon which they have written. As a science teacher myself, and one who always passed 80 per cent. of those who were examined at these Government examinations, I ought to know something about what is required, and also what Dr. Frankland wishes to be done. In a conversation with the learned doctor he told me "that in the examinations an equal number of marks would be given for a correct answer upon any recognised system;" and in my course of teaching I have never introduced constitutional formulæ, more than that which was required to show the students what it really was. I have dwelt more upon the graphic formulæ, and have illustrated my lectures by the use of Crum Brown's glyptic formulæ, and, in spite of all the objections raised against these systems, I never had one even of my pupils who thought for a moment that the glyptic apparatus represented in reality the actual way in which the atoms were arranged in the molecule, nor had I ever one foolish enough to think that the bonds actually existed, like spikes sticking out of the sides of each atom. The objections to these very useful systems have been broached by men of high standing—those accustomed to teach classical scholars, whose perception is supposed to be much clearer than men of the ordinary stamp. If, then, the difficulties actually existed with them, it does not say much for a classical training, for with my pupils, all of whom save one only received a good commercial education, I venture to say again that not one was ever foolish enough to think that the glyptic molecule actually existed, or that the graphic representation of the radicle or molecule was really the form in which it existed in nature. I argue for these systems because I have found them of great use in teaching organic chemistry; but the system upon which I have always laid the greatest stress is the typical formula of Williamson. This system I have always fully dwelt upon, my pupils have always answered their questions by its use, and that they have been accepted may be seen from the fact that most of the certificates obtained by my pupils have been in the first class. I write this because it seems from the general tone of most of the letters which have been sent you that Dr. Frankland is set down as a harsh and tyrannical examiner, which might probably discourage the tyro if it met his eye. A refutation of this is not needed by any one who is acquainted with the doctor; no one who knew him would have pronounced him as such; and, therefore, any one who did not know him, and the examinations generally, should have waited until they did.

But to return to formulæ. That of H_2SO_4 does not give us any insight into the constitution of the molecule; we do not know whether the hydrogen is possessed of tremendous chemical force, sufficient, in fact, to unite with one sulphur and four oxygen atoms, or whether the sulphur is capable of uniting with four oxygens and two hydrogens. Constitutional, typical, or graphic formulæ will tell us a little more, thus:—

$$SO_2''Ho_2 \qquad \left.\begin{array}{r} H \\ SO_2'' \\ H \end{array}\right\} \begin{array}{l} O \\ O \end{array} \;;$$



Constitutional. Typic. Graphic.

Now, how do these formulæ explain facts? When sulphuric acid is dropped upon red-hot platinum it is split up into SO_2'' and H_2O_2, which latter cannot exist at that temperature, and so forms H_2O and O; it also explains this reaction—$SO_2 + H_2O_2 = SO_2''Ho_2$. This gives us *primâ facie* proof that two atoms of the oxygen are more firmly united to the sulphur than the other two, whilst it in no wise prevents the explanation of its electrolysis. But it is in organic chemistry where constitutional and graphic formulæ are so useful. For instance, if a student was asked by what name the following molecule was called, $C_3H_6O_2$, he might say propionic acid, another might say methyl acetate, and ethyl formiate might be the answer of another. The constitutional formula would admit of a direct answer for those three isomeric bodies, and would be written thus:—

$$\left\{\begin{array}{l} CH_2''CH_3 \\ CO''HO \end{array}\right. ; \quad \left\{\begin{array}{l} CH_3 \\ CO''Meo \end{array}\right. ; \quad \left\{\begin{array}{l} H \\ CO''Eto \end{array}\right.$$

Propionic acid. Methyl acetate. Ethyl formiate.

Where Meo stands for the group $(OCH_3)'$, analogous to $(HO)'$, and Eto for $(OC_2H_5)'$. On Gerhardt's and Williamson's water type they would be:—

$$\left.\begin{array}{r} (C_3H_5O)' \\ H \end{array}\right\} O'' ; \quad \left.\begin{array}{r} (C_2H_3O)' \\ (CH_3)' \end{array}\right\} O'' ; \quad \left.\begin{array}{r} (CHO)' \\ (C_2H_5)' \end{array}\right\} O''$$

Propionic acid. Methyl acetate. Ethyl formiate.

Now, all this is not mere speculation, as some people would have it, but agrees with analysis and synthesis.

Mr. Bottone (letter 8862) says he is beginning to doubt the existence of valency. I can assure him that there are many chemists who have not begun to doubt it, but have for some time denied it *in toto*, and I do not believe in it myself as now put forth; but I am not quite so mad as to stand on the topmost round of a ladder, and knock it away from under me, without building up a support to keep me from falling; still, I make the best of what is, to say the least, an imperfect system, looking anxiously forward for a better before I relinquish hold of that which has been of great use to me in my course of teaching. Mr. Bottone also says, "we can account for the existence of phosphorus acid without losing sight of the trivalence of phosphorus," thus:—

$$\begin{array}{c} H - O'' - P''' - O'' - H \\ | \\ O'' \\ | \\ H \end{array}$$

If the above formula were correct why cannot we form $(PNao_3)$? simply because the graphic formula should be:—

$$\begin{array}{c} O \\ \| \\ H - O - P - O - H \\ | \\ H \end{array}$$

In support of his formula, will Mr. Bottone kindly give me as an illustration any mineral oxyacid which contains the group HO any number of times which is not capable of being replaced by the metallic group Mo, where M signifies one atom of a monad metal? Phosphorus unites with oxygen to form a triad radicle, phosphoryl, and we have the trichloride of this radicle, which, when boiled with water, produces hydrochloric and phosphoric acids; moreover, this phosphoryl trichloride is formed from the pentachloride of phosphorus, two atoms or one molecule of the chlorine being replaced by one atom or half a molecule of oxygen. Now, if we represent phosphorus as only possessing a triadic signification, and that the pentachloride be formed by the combination of the two molecules, PCl_3 and Cl_2 (see "Chemical Philosophy," Wurtz), this harmonious reasoning is destroyed when we unite PCl_3 with one-half molecule of oxygen, or, to speak more correctly, when we replace a molecule of chlorine by an atom or half-molecule of oxygen. Surely no molecular force exists where there exists no molecule, and if we call chlorine a monad element, and phosphorus a triad, where is there any chemical affinity if all is neutralised by combination or mutual saturation—3 to 3? I have not brought this forward because I am specially addicted to this pentad nature of phosphorus and nitrogen, for nearly all the elements alter in their so-called valency, and the valency alters because we have firmly fixed hydrogen as the starting point, never allowing it to appear to become an element of higher equivalency, for the propounders of these so-called atomicity or valency theories have not dared to challenge the hitherto accepted monovalency of hydrogen. For this is their starting point, and the whole theory would then be undermined, and be found to rest upon a very insecure basis.

For my part I do not believe in molecular combination, but rather in the polyvalency of some of those elements which are now called monads. The double chlorides are curious specimens of this, and as chlorine and the halogens generally all form double salts, the light metals with the heavy, some have ventured to assert that chlorine must be a polyad in those molecules; but with some of these double chlorides there is a corresponding sulphate, and as SO_4 is replaced by Cl_2, I am inclined to think that the basyls are the polyad constituents.

Now I am on this subject perhaps it will please the worthy discoverer of the atmonia type, and the predictor of sulphur urea, "Eclecticus," if I give the potassium chloroplatinate formula, which might either be written:—

$$\left\{\begin{array}{l} K = Cl_2 \\ \;| \\ Pt = Cl_2 \\ \;| \\ K = Cl_2 \end{array}\right. \quad \text{or} \quad \left\{\begin{array}{l} K - Cl \\ \;\| \\ Pt = Cl_2 \end{array}\right.$$

The aluminium and potassium chloride, so-called double salt, and its corresponding sulphate, may be written thus:—

$$\left\{\begin{array}{l} K = Cl_2 \\ \;| \\ Al = Cl_2 \\ \;| \\ Al = Cl_2 \\ \;| \\ K = Cl_2 \end{array}\right. ; \quad \left\{\begin{array}{l} K = SO_4 \\ \;| \\ Al = SO_4 \\ \;| \\ Al = SO_4 \\ \;| \\ K = SO_4 \end{array}\right.$$

Chloride. Sulphate.

Both these molecules cannot be halved, if any faith is put in Gerhardt's law of uneven affinities, unless aluminium is made to act as a triad; but then, again, there is a law which states that an artiad is always an artiad, and a perissad always an element of uneven valency or atomicity, and it is in this latter respect that I cannot agree (and not only myself, but many other chemists) with Mr. Bottone, when he tries to make chlorine appear to be first a monad and then a dyad. "Eclecticus" asks whether gold really replaces three atoms of hydrogen? Taking either the old notation or the new, I say, most emphatically, "Yes." Thus:—

$$\left.\begin{array}{r} H_3 \\ H_3 \end{array}\right\} O_3, \quad \left.\begin{array}{r} Au''' \\ Au''' \end{array}\right\} O_3 ; \quad \left.\begin{array}{r} H_2 \\ H_2 \end{array}\right\} O_2, \quad \left.\begin{array}{r} K \\ Au'' \end{array}\right\} O_2$$

Water trebly condensed molecule. Auric oxide. Water doubly condensed molecule. Potassium aurate.

We will now turn to the old notation—

$$\left.\begin{array}{r} H \\ H \\ H \end{array}\right\} O_3, \quad Au''' \} O_3 ; \quad \left.\begin{array}{r} H \\ H \\ H \\ H \end{array}\right\} O_4 \quad \left.\begin{array}{r} K \\ Au''' \end{array}\right\} O_4$$

Water trebly condensed molecule. Auric oxide. Water condensed molecule. Potassium aurate.

and the chloride:—

$$\left.\begin{array}{r} H \\ H \\ H \end{array}\right\} Cl_3 \qquad Au''' \} Cl_3$$

Hydrochloric acid condensed molecule. Auric chloride.

Certainly gold does not directly displace three atoms of hydrogen in hydrochloric acid, for in that menstruum gold is not soluble, but auric oxide easily dissolves thereby, indirectly replacing three atoms of hydrogen for every one of gold fixed, and that this is the normal salt of gold may easily be seen by the ease with which the aurous compounds split up into aurum and the auric salts. This sentence also appears in the letter of "Eclecticus": "Now, the theory is that Pt is diatomic or duad, and that it replaces two atoms of H. Of course it will do so with double the old atomic weight." Now, I beg respectfully to submit to "Eclecticus" that double the old atomic weight is not necessary. On the old notation we had PtCl and $PtCl_2$. Now in this latter salt the Pt (with an atomic or combining weight of 98.5) actually replaces two atoms of hydrogen thus:—

$$\left.\begin{array}{r} H \\ H \end{array}\right\} Cl_2 , \qquad Pt'' \} Cl_2$$

Hydrogen chloride. Platinum bi-chloride.

In answer to his other query, the weight of platinum deposited electrotypically is half the modern theory, if we take an atom of hydrogen; but then theory indicates that the metals (heavy) have an atomic and molecular weight identical, so a molecule is deposited for every molecule of hydrogen—this brings us square again.

I am very glad to welcome such a chemist as "Eclecticus" to "our" columns, for during the past few years I have read his papers with considerable interest, and I feel sure if he continues with us that every one of us will learn something from his communications.

I wish now to have a few words upon the designation atomicities and valencies, as expounded by Mr. Bottone, who positively declares that atomicity is incorrect, and argues that nitrogen cannot be pentatomic, for one atom of nitrogen can only contain one atom. Now, when this name was first introduced into chemical science, did not the promoters of the valency—the then-called atomicity theories—know this? Of course they knew that one atom of a diatomic element did not contain two atoms; and, just the same, they knew that one atom of a pentatomic element did not contain five atoms. What was meant by the term diatomic was that the atom was capable of fixing or neutralising the chemical affinity of two monad atoms, such as hydrogen or chlorine, and a pentatomic element five atoms.

I have often been surprised that the valency theories have been so generally accepted, seeing that we cannot stir out of any one series of salts without meeting with strange inconsistencies, such inconsistencies which have been difficult to overcome, and which have generally resulted in the adoption of a special theory for their elucidation.

Turning again to the standard monad hydrogen, can it be believed that it is a perfect unit of comparison, and the same with chlorine, when we have such compounds as hydrogen chloroplatinate, H_2PtCl_6, which "Eclecticus" would prefer being thus written: $HCl + PtCl_2$, and hydrogen fluosilicate, H_2SiF_6, passing over the vast series of double chlorides, iodides, and the more complicated cyanides and ferrocyanides, of which the hydrogen salt is a type, $H_4FeC_6N_6$.

Mr. Bottone also says that sulphur is only known to combine with two monads. This may be true as regards monad elements, but that sulphur is at least a tetrad may be inferred from the existence of the triethylsulphurous iodide $S(C_2H_5)_3I$. In fact, we have also a tetrachloride of sulphur, SCl_4; but this may be objected to by Mr. Bottone, who considers chlorine a dyad, although its dihydride has not, as far as I am aware, been yet discovered.

Before I close this letter, I should like to put a few queries, and make a few remarks upon N. Du Fai's communication on page 68. I first would ask him, is he sure that ammonium (NH_4 or $(NH_4)_2$) has ever been obtained, or ever will be. If he possesses the secret of its formation, as we would suppose from the authoritative aspect of the query, by all means let us have it. I again repeat what I have said before in these columns, that ammonium is not a metal, but that the ammonium salts are only the first term of a very lengthy series, and that NH_4, or its doubled molecule $(NH_4)_2$, has no separate existence. I know a great many will oppose this; but it is my candid opinion, and both analogy and experiment will bear me out in my statements. In speaking of vapour densities, the densities of the ammonium chloride, sulphide, and cyanide do accord with the theory, for theory states that they dissociate, and at high temperatures are decomposed into ammonia, and the hydrogen salt of the acid radicle; this can be seen to be the case when working with properly-constructed apparatus, dissociation does take place, and the two gases can be separated from each other. I have mentioned the pentavalency of phosphorus and nitrogen in a former portion of this letter, so it is not necessary again to refer to it. I am very glad to see "Sigma's" name among those who stick up for the metric system. I use no other in all my calculations, and in commercial testing I have introduced it among the workmen as far as I have been able, in preference to the old and inconvenient—

20 grains = 1 scruple.
8 scruples = 1 drachm.
8 drachms = 1 ounce.

I am also pleased at the general tone of "Sigma's" letter. If we are to have a change, why not change to a system now so firmly established, and not try to decimalise our pound, so that calculation will have to be made as before, when one country is trading with another; better by half had we adopt the metric system as it now stands, and so in our commercial intercourse use a coin which shall be common to all.

GEORGE E. DAVIS.

ATOMICITIES v. VALENCIES.

[8988.]—I AM delighted to find that "Mercurio" has thought fit to misinterpret my meaning with regard to "atomicity," as it gives me another occasion to point out the necessity of discontinuing the use of this word, when taken in the sense of "valency." So far from my being wrong, or ignorant of the generally received use of the term, I beg to inform him that I was conversant with the term as soon as it was applied by Wurtz, Gerhardt, &c., and I have pointed out its correct application, in the last ten lines, at paragraph 46, of my lessons. But I have also pointed out how conducive to misconception it is, to continue to make use of an expression, which conveys *one* idea, when applied to atoms, and *another totally different*, when it refers to molecules. This would be excusable, had no other better term been proposed; but many years ago Professor Hoffmann coined the very precise word quantivalence (since contracted to "valency") to express the saturating power of any element. Let not the reader for one instant imagine that the objectionable vagueness of the term is a fruit of my imagination; the "monatomic," "diatomic," "triatomic," &c., alcohols (Odling) serve to show that such is not the case; while a cursory glance at any of our standard authors will show that these terms are often used, not only with regard to the number of atoms in the molecule, not only to the valency (or saturating power of the body), but also with reference to a supposed resemblance to the several types:—

(H_2O)	($2H_2O$)	($3H_2O$) &c.
Monatomic.	Diatomic.	Triatomic.

(See Roscoe, Odling, Miller, Wurtz, &c.)

With reference to the "artiad" and "perissad" theory, I have already shown (paragraph 78) that it is inapplicable in several cases, hence unworthy of the confidence of the truly scientific man. Of the ridiculous personality—(possibly meant for wit (?))—respecting my playing with nitrogen bonds, I take no notice beyond calling attention to the fact that a personality is no argument, and only tends to prove the weakness of the premises of the person who descends to use it.

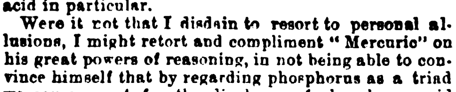
Up to the present time, ammonium has not been obtained in the state of vapour, without dissociation (see Roscoe, page 213, two last lines). Consequently, the statement that its vapour density is 9 00 is, as might have been expected, without any foundation on fact, hence worth just nothing in an argument.

Ammonium, in the free state is *not* "similar to the monatomic alkali metals;" for these latter are *elements*, hence the molecule *must* (according to our present ideas) be composed of two or more atoms, whereas, ammonium being a compound, there is nothing to *prove* that the molecule may not be NH_4.

The idea of "Mercurio" coming forward to "inform" me of something which I have already taught in my lessons, and referring me for information to my own notes, is sufficiently amusing; but it is evidently done to avoid giving an explanation of the abnormal vapour densities of all the ammonium compounds, and most of the phosphorus penta compounds.

Another personality, totally besides the argument and devoid of one redeeming spark of wit, is the one regarding my knowledge of Dr. Frankland's constitutional formulæ in general, and of that of phosphorus acid in particular.

Were it not that I disdain to resort to personal allusions, I might retort and compliment "Mercurio" on his great powers of reasoning, in not being able to convince himself that by regarding phosphorus as a triad we can account for the divalence of phosphorus acid with even greater clearness than we can do when we consider it a pentad. The annexed graphic formula (which, by the bye, I had sent along with my previous letter, but which was not inserted) will elucidate this.



In conclusion, while begging to be excused from continuing the discussion, which is becoming offensively personal; I quote the following Italian proverb, which may induce "Mercurio" to pause ere he repeats questions: "A buon intenditor, poche parole."

S. BOTTONE.

REMOVAL OF THE STANDARDS.

[8989.]—I SEE on p. 107 that the standards of measure and weight have been removed from their old place, and that the word "measure" has been inserted after "yard" on the brass plate. Now, it seems all right that after "pound" the word "weight" should appear, as there is such a thing as a pound "sterling;" but why "measure" after "yard"? A yard "measure" is a piece of wood 36in. long, used by haberdashers, just as a 2ft. "rule" is a 24in. jointed stick used by mechanics, and the standard yard is not a yard measure, but it is a longer piece of metal bearing on it marks to indicate what the length of a yard is. If they had put yard "length" or "lineal," I should not howl.

J. K. P.

KING NUMBERS.

[8990.]—I HAVE not ventured to trouble you with what I promised at p. 607, and of which promise Mr. Box (let. 8881) asks a fulfilment, because he must be reminded that according to "Philo" (let. 8806) I have wasted all the space I took at p. 607, there being nothing there but what "everyone knew before." Everyone, therefore, can continue the series of "noble numbers," and explain to Mr. Box the method of ascertaining each step, and when he once applies this, he will find that (to use another happy expression of "Philo's") it is "easily seen, though tedious (and paper-wasting) to demonstrate" rigorously, that there can be no number above 2,520 which requires so great an increase as doubling to gain more divisors; and, consequently, that 2, 6, 12, 60, 360, and 2,520 are all the "king numbers" possible. Mr. Box points out the obvious error of my remark that 12 was the only one produced by the multiplication of two below it. I saw, before it was in type, but forgot to add a note, that 360 also is, as he says, 6 × 60.

To be as brief, then, as I can, with what "everyone knows," it is shown in Barlow, Legendre, and other works on "Theory of Numbers," that every composite number is the product of two or more primes, each in its simple power, or raised to some higher power; so that if vowels represent prime numbers, and z, y x, &c. (back to any letter), represent all numbers indifferently (prime or composite), every composite number is reducible to the form $a^z \times e^y \times i^x \times o^w$, &c. They then show that, to find the number of divisors any number N possesses, N must be decomposed as above, and then the number of its divisors (which call D, including itself and unity, so that there can never be less than 2) is $D = (z + 1) (y + 1) (x + 1) (w + 1)$ &c.

For N is divisible by a, and by every power of a up a^z; and by e, and every power of e up to e^y; and by i, and every power thereof up to i^x; and, moreover, by every combination of any terms in these several series; that is, of the series—

$$1,\ a,\ a^2,\ a^3,\ \&c.,\ \text{to}\ a^z\ (z + 1\ \text{in number})$$
$$1,\ e,\ e^2,\ e^3,\ \&c.,\ \text{to}\ e^y\ (y + 1\ \text{in number})$$
$$1,\ i,\ i^2,\ i^3,\ \&c.,\ \text{to}\ i^x\ (x + 1\ \text{in number}),$$

and the number of combinations of all these terms is the product of $(z + 1) \times (y + 1) \times (x + 1) \times$ &c., which product, therefore, will = D. Now, as this depends only on the indices z, y, x, &c., and is unaffected by the magnitude of the primes a, e, i, o, &c. (provided they are all different), it is evident that if any prime factor be present without a prime factor that comes below it (if the proposed number N, for instance, be divisible by 7 and not by 5), it is not a noble number, for we may substitute the factor 5 for 7, that is, reduce N in the ratio of 7 : 5, and it will still have D as large as before. The prime factors of every noble number must, whether few or many, consist of the lowest primes, 2, 3, 5, &c., without skipping any. If there are four they must be 2, 3, 5, 7. If five, they must be 2, 3, 5, 7, 11; and so with any number. And further, it is proved in the same way that no factor can be repeated more times in the composition than a lower factor is. Thus, a noble number cannot divide more times by 3 than by 2, or more times by 5 than by 3, &c. It cannot be divisible by 3^2 and not by 2^2, or by a higher power of 5 than it is of 3, &c. In short, when decomposed into this form $2^z . 3^y . 5^x$. not 7^w, &c., the index y cannot exceed z, nor x exceed y or z, nor any index exceed an index that comes before it.

Now, suppose we want to find the lowest noble number above N (a number either noble or not), and let N, to make the method clear, be a very composite number, say the noble one 27720. This must be decomposed into its prime factors, and under them you write their indices each augmented by 1, which are the factors of its D, thus:—

$$\text{Factors of N, } 2^3 . 3^2 . 5 . 7 . 11 = 27720$$
$$\text{Factors of D, } 4 . 3 . 2 . 2 . 2 = 96$$

Now examine the effects on D of the various augmentations, beginning from the smallest, that might be made in N's indices. This will be greatly facilitated by having a table at hand of all the powers and products of the first few prime numbers arranged in order of magnitude, thus:—

3 (prime)	$8 = 2^3$	$14 = 2.7$	$20 = 2^2.5$
$4 = 2^2$	$9 = 3^2$	$15 = 3.5$	$21 = 3.7$
5 (prime)	$10 = 2.5$	$16 = 2^4$	$22 = 2.11$
$6 = 2.3$	$12 = 2^2.3$	$18 = 2.3^2$	$24 = 2^3.3$

and still more if you have all the ratios between such numbers tabulated, so that you may see by their order whether, for instance, the fraction five-sevenths or seven-tenths be the larger, such a comparison being often rather unobvious at mere sight. Now, the smallest increase we could make in the above N would be as 12 : 13, by reducing the indices of 2 and 3, from $2^3\ 3^2$ to $2^2\ 3^1$, and putting the new factor 13. The latter, by adding a 2 to the factors of D, would double it, but the first two of those factors, from 4.3, would become 3.2, which is reducing to less than half, or more than neutralising the doubling, so that we learn the factor 13 is not yet admissible. Next consider an increase as 11 : 12, by removing the last factor of N, and substituting $2^2.3$. This will alter the first two factors of D from 4.3 to 6.4, just double, or just restoring the product that would be halved by the loss of its last 2; so that we learn the augmentation of 27720 by an eleventh will leave its D unaltered. The next change, as 10 : 11, is at once seen to be useless, because it would quite remove the factor 5, while higher ones remain; and, moreover, would give 11 a higher index than the 5 or 7 before it; both of which we have seen to be impossibilities in a noble number. So again, a change of 9 into 10 would wholly remove the factor 3, while increasing the index of 5. Next, a change as 8 : 9 (that is, removing 2^3 to insert 3^2) would leave the higher factors of N without their base 2 to stand on; and one as 7 : 8 would leave the 11 without its support 7. And if we removed 6 (*i.e.*, 2.3) to square the 7, this latter would carry a higher index than the 3 or 5 preceding it. And similar objections, quicker seen than written, will prevent the changes of 5 into 6, or 4 into 5, or 7 into 9. As for removing a 3 to insert a 4 (that is, 2^2), it would alter the first factors of D from 4.3 into 6.2, leaving just the same product. Then the changes 5 : 7, or 7 : 10, will be seen to transgress our rules. Next consider 11 : 15—that is, removing the last factor of N to augment the indices of 3 and 5. The last 2 of D will be lost, while its 3.2 becomes only 4.3, thus leaving D unaltered. Again, we might, instead of this 15, introduce $16 = 2^4$, making the first factor of D from 4 into 8, and thus merely compensating the loss of the last 2.

We now come to the step of altering a 2 of N into 3; but this would only transpose the first two indices of N, or first two factors of D, leaving the product the same. A change of 3 into 5 will have the same objection. But a change of the 11 into 18 (that is, into 2.3^2) makes the first factors of D from 4.3 into 5.5 (more than double), and thus more than compensating for the loss of the final 2. Thus we find the smallest increase of 27720, that will gain it more divisors, is an increase as 11 : 18, making the factors of the next N—

$$2^4 . 3^4 . 5 . 7 = 45360, \text{ and}$$
$$\text{its } D = 5 . 5 . 2 . 2 = 100,$$

so large an increase of N only adding 4 to the number of divisors. I have chosen, in explaining the method to Mr. Box, this step, the most troublesome one in the table, because of the unique property of this number, 27720, the only one in my table, or, I believe, possible beyond it, that requires more than half doubling to yield the next noble number, and yet does not require doubling. Now if he observes how this comes to happen just this once only, immediately on the introduction of the factor 11, and notes that no two successive primes above 11 can bear so high a ratio as these two, 7 : 11, he will see on what principles to prove that there can be no king number above 2520. This 27720 we may call the only one that is more than semi-royal, the latter term applying to those that cannot gain divisors without half doubling (or being increased as 2 : 3) and these become less and less frequent, till at some step, I cannot say where, but above a billion, the last of them will occur.

The series of these numbers resembles on the whole a geometrical one of a rate slowly decreasing, so that between successive powers of any high number there will be more and more terms. Thus, between 1 and 1000 are 14 noble numbers, between 1000 and a million are 23; between this and a milliard 31, and so on. Hence, as the ratio 1 : 2 occurs but 7 times, so that of 2 : 3 will have a limited number of occurrences, some one beyond billions being the last. And 3 : 4 will similarly, at some unknown point, occur for the last time; and so with 4 : 5, and every lesser ratio definable.

E. L. G.

IMPROVED DIRECTING POSTS.

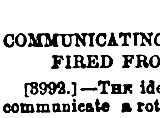
[3991.]—THE suggestion of "Jannifred" (let. 3930, p. 94) might be profitably extended by having the directions of cast iron, with the letters in high relief, painted white on a black ground; these should be fixed not higher than 5ft. from the ground.

I remember some years back, when going along a strange country road on a pitch dark night, I came to a spot where two roads branched off; I was at a loss to ascertain which to take; there was no house apparently near; it was raining heavily, and a direction post was there, but it was too dark to read, and considerably above my head. Now, had it been within reach, I could have felt, if I could not have read, had the letters been raised, and I lost a quarter of an hour, when a countryman came along and set me on my way. The cost would be a trifle dearer than the ordinary methods, but the increased durability would soon repay the extra cost. With regard to your editorial note, it was stated some time back that the Postmaster-General kept one clerk, whose duty it was to hunt the newspapers for suggestions and ideas; perhaps he may come across the ENGLISH MECHANIC, and so improve his mind, as well as the departmental service.

CANIS MINOR.

COMMUNICATING ROTARY MOTION TO BALL FIRED FROM SMOOTH-BORED GUN.

[8992.]—THE idea has struck me is it possible to communicate a rotary motion to a ball fired out of a smooth bore? I suggest the following:—The diagram shows a section of the ball, the internal black space is filled with a slow burning composition, such as is used for Catherine wheels, &c.; this is ignited by firing the gun, and, escaping by the holes A B, gives by its reaction a rotary motion to the ball.



If a hydraulic ram were secured afloat—so as to admit of an up and down motion capable of adjustment to the height of the tide—could the waves rushing through it produce power for raising salt water for baths, &c., thus dispensing with manual labour?

PHILANTHROPIST.

ORNAMENTAL TURNING.—IX.

[3993.]—In ornamenting turning many devices are used, simple in themselves, but with a good result; many parts of cabinet work, if less cumbersome, could be ornamented in the lathe, and with better results. Those who have noticed ornamental chair-tops may have seen circular rosettes, flowers, &c. These are done in two ways—First, by carving out the same from the solid; second, by boring a hole with a centre-bit, and fixing a turned palley, glueing in the same; in some instances carving it afterwards; in others, it is left as turned. Some few years ago I suggested to a chairmaker that I could turn the palleys out of the solid, thus giving strength to the chair. I turned a great quantity, both tops and splats. I send a sketch of the same. Fig. 1: The chuck made from a piece of dry beech, front view A A; slot cut in the chuck to fix the article C, which is in this instance, as shown, a chair leg, fixed for the purpose of ornamenting the ball. Fig. 2: Side view of chuck; A is the hole to fix or screw on the nose or screw of the iron chuck, already described in my last; B B thumb screws to hold the article secure; C, side view of the slot; the chuck can be made any convenient size.

FIG. 1 FIG. 2

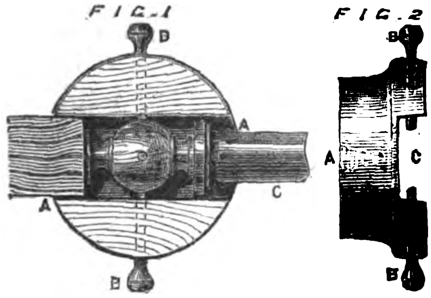


Fig. 3 is a chuck of the same description, only deeper, for the purpose of ornamenting balls, or the intermediate part of table pillars, side view only is shown. Take a piece of dry beech, say 6in. long by 4in. square, rough out the shape between centres; bore the hole for the screw chuck to hold by; screw it up tight, then finish off the shape shown in sketch; then bore a hole with a centre-bit through the wood at A; draw a line from the mouth to the hole already bored; cut down the lines with a fine saw; by that means the inside of the chuck will be even. The hobs for the thumbscrews should be bored half way betwixt the chuck and tapped with the ordinary tap. I find ⅝in. tap and box the most useful size. In ornamenting eccentric work, care should be taken to fix the work true and secure before commencing to turn the same, otherwise the wood may be spoilt, as it is almost impossible to refix exactly the same afterwards. The speed should be slow, to prevent jarring. In my next, I will send sketch of table pillar, with ornamental ball, showing how fixed, &c. I have sent sketch of a set of till blocks, very useful articles for the amateur to turn. The block should be of dry pine, planed up true, and to fit the till-drawer, then marked out as shewn Fig. 4. When marked out, a piece of wood about 6in. diameter should be screwed upon the iron screw chuck, just thick enough to allow the nose of the screw to project ¼in.; a hole ¼in. in depth should be bored with a bit in the centre of each circle to fix; unscrew the iron chuck from the mandril; place the chuck upon one of the circles (the largest first should be turned); then fasten to the till-block with ordinary screws, having previously bored holes for the same in the circle of wood, by this means a bowl can be turned with only a ⅛in. bottom; a breakfast cup is a good pattern for the inside. The holes should be turned and finished with a ⅜in. gouge; oval holes can be made by turning two circles or bowls one half over the other, and finished off with a carving gouge. In turning articles, if the lathe is weak, it should have a

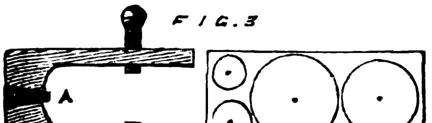
FIG. 3



temporary prop from wall to mandril; only a slow motion should be used. Turning the larger holes first enables one to use more speed upon the smaller holes. Several correspondents of late have inquired how hammer handles are turned. I do not know how they are made in the country, but I have made some, as well as bradawl handles, by turning them same as usual, only leaving a flat each side of the larger part, and finishing them off in the vice with a rasp and glass paper, but no doubt this plan would not be quick enough for the trade. Samuel Smither.

COLLIERY EXPLOSIONS AND THEIR PREVENTION.

[3994.]—"Arley Mine," in his last letter, says that all parts of a coal-mine may be ventilated by a proper arrangement of the colliery from the commencement. If "Arley Mine" is acquainted with any method whereby the large "goaf" of a colliery can have the gas always removed and made safe, he will be conferring a benefit to humanity by explaining it, because (as I said before) this has been the great problem hitherto unsolved by mining engineers.

"Philo," in one of his former letters, advocates a colliery owner being made liable for injury to his own men, and instanced the case of railway companies as an example. I maintain the cases are not analogous; a railway company carries passengers by virtue of a contract between itself and the public; if any injury occurs in performing that contract the company are liable to pay compensation for any such injury, the same as in an ordinary business transaction; but does "Philo" know of cases where injury to the paid servant of a company has been compensated? I very much doubt if he does.

This, I maintain, is the parallel case—and not injury done to passengers; in each case the workman receives pay for his work, but the passenger pays money for his ticket.

I have observed that a colliery proprietor in Staffordshire has been lately fined £20 for keeping his pit badly ventilated. In evidence, some of his men said they had to "brush away the gas with their coats" from their working places; yet these very men went day after day to work at the same pit, knowing how dangerous it was. This shows that colliers are heedless of danger to themselves; if they had been the "model colliers" that both "Philo" and myself wish to see, every man would have refused to work in that pit again until better ventilated. King Coal.

ATMOSPHERIC DUST.

[3995.]—I head this communication in accordance with a very useful rule, though it has nothing to do with atmospheric dust. I merely wish to point out to "Saul Rymea" that dangerous dissecting wounds are contracted only when the subject is fresh, that is to say, shortly after death; but that in a little time, when putrefaction has fully set in, these wounds are attended with immunity. I have been twice nearly killed from accidents in making post-mortem examinations, but never suffered from a cut contracted in the dissecting room. F. R. C. S.

CASTING METAL IN AIRTIGHT MOULD.

[3996.]—In casting metal into an airtight mould, such as fire-clay, a tube must be provided through which the air can escape, and a figure cast by this method (called by the Italians with whom it is much in vogue, "cera perduta," or lost wax, the wax figure being melted out) presents the annexed appearance. A, the aperture into which the metal is poured; B, the opening of the air tube; C, the overplus metal to cause pressure on the figure. Now, when the metal is poured, and the git C, the hollow figure and the pipe B are all full, and the metal in a molten state, is the pressure on the figure equal to that of the column C, or to that of the thin tube B? C, we will suppose being double the weight of B. It is by this method that lizards and everything that can be burnt or melted out, are cast in Rome and Florence. They use for their moulds an earth called Tripoli, but differing, I suspect, from the substance sold here under that name, as it bakes into a sort of brick. They also use two parts brickdust, one plaster of Paris, mixed into a cream. Proven.

CHEAP OBSERVATORY CLOCK.

[3997.]—I wish to thank your correspondent C. B. Fennessy (let. 3859, p. 40) for the suggestion which he offers, as an improvement of the A 1 clock described at p. 630, of Vol. XIV.

It seems to me, however, that the proposed pulley would virtually restore (and in an objectionable form, from its greater friction) a species of "dial work," the entire suppression of which was a leading feature in the clock designed by me. It would also sacrifice the contrivance of showing the sidereal time, which is so constantly required in an observatory.

I have just added to its convenience in this respect, by marking upon the sidereal time-band the position of all the most useful stars for transit observations, placing opposite each star its declination (+ or −) to the nearest degree. The sidereal hour-hand, therefore, not only shows what stars are approaching the meridian, but points to the proper setting of the declination circle, so that their transit may be observed without even looking at the *Nautical Almanac*, which may be referred to any time afterwards to ascertain the exact clock error. I can imagine nothing more convenient than this is for observatory work.

I have felt as much surprised as gratified by the amount of originality which has been very generally credited to my simple clock arrangement, considering, as I do, that it contains nothing really new in horology.

The Astronomer Royal has kindly informed me that the celebrated Franklin contrived a clock in which the "dial work" was suppressed, though by other and less convenient means than in mine, to which he gives the preference in this respect.

I may add that my first clock continues to perform so perfectly, that I feel little inducement to proceed with a second clock, which I had commenced upon the same model, but with higher finish, the 'scape wheel being made of aluminium bronze, and the pendulum being nearly twice the weight of the first.

I have been looking in your pages for the promised description of the "New Maintaining Power" by your correspondent "Regulator" (query 11250, page 677). John F. Stanistreet

Abercromby-square, Liverpool, April 12.

NACASCOLO OR DIVI-DIVI.

[3998.]—Some time ago I replied to a query about the nacascolo of Honduras, that I believed it was the pod of a species of *Cæsalpinia*, and that it deserved an investigation in order to ascertain if it was not good for dyeing or for tanning purposes. A further inquiry has taught me that the *nacascolo* is the same as *divi-divi*, and is nearly neglected in Honduras, though it might afford a good article for exportation. Bernardin.

SELF-ACTING BLOWING APPARATUS.

[3999.]—I send a sketch of a self-acting blowing apparatus which I saw in use the other day, and with which I was much pleased. I should think it would entirely supersede the old blow-pipe, its advantages over which would be obvious on a single trial. It is

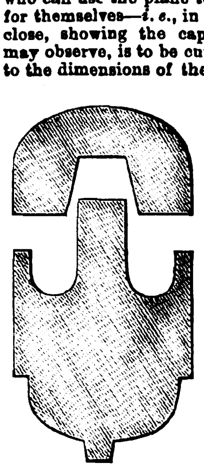
much cheaper than the ordinary method of blowing, does the work more quickly, and as the flame is smokeless the best work is not discoloured.

Painters will find it a beautiful apparatus for blistering off old paint, it being adapted for that purpose by a jet of peculiar structure, by which the flame is flattened and spread out so that the heat is dispersed over a broad surface. It is easily managed by half filling the boiler with spirit, and filling the lamp with the same, using a piece of lamp cotton as a wick; in about a minute from the time of lighting, the blast will be emitted, and can be directed to any point. By pulling up the wick with a sudden jerk, a stronger blast is emitted. I may mention a safety valve is adapted to the apparatus. H. B. E.

IMPROVED METHOD OF GLAZING.

[4000.]—There is no trade carried on—as far as the earth is concerned at least—in which a greater amount of humbug is put forth to bamboozle the public than that which deals with matters horticultural. Whether seeds, manures, lawn-mowers, boilers, or hot-houses form the subject of the advertisement, you invariably find that the advertiser is the only maker of the genuine article. We are now gravely informed by Mr. Peter Wallace (let. 3950, p. 98) that Mr. Ayres is the only person who has coped, or can successfully cope, with a difficulty, more or less imaginary, supposed to attach to the use of iron in horticultural erections.

I am pleased to hear that Messrs. Rendle and Burrows' patent cannot be maintained, because that at once leaves the way clear for those of your readers who can use the plane to make the improved sash-bar for themselves—*i. e.*, in wood, a section of which I inclose, showing the cap lifted half off. This cap, I may observe, is to be cut at an angle in lengths suited to the dimensions of the glass, so that where the latter overlaps, the cap is made to ride, so to speak, on the piece above it, thus allowing for the double thickness of glass, and at the same time affording entrance to the gutter cut in the sash-bar. If any of your readers feel inclined to try the iron sash-bar described in my previous letter (3840, p. 88), I hope they will not be deterred by Mr. Peter Wallace's assertion that it acts as a refrigerator (!). Snow-broth running in the gutters of the iron sash-bars would, undoubtedly, carry off some of the heat obtained from the inside of the house; but if this is to be taken into consideration, what are we to substitute for the glass itself, which, presenting a far larger area, must get rid of an amount of heat compared with which that conducted away by the iron sinks into insignificance? And although glass does not conduct heat so rapidly as iron it must be recollected that it radiates it much quicker, especially if the iron is painted white, which it would be. According to the most reliable experiments on the conducting power of various materials, it was found that, taking silver at 100, iron was only 12; while the radiating or emissive power of glass was 90, lamp-black being 100. It should be remembered also that white lead radiates as much heat as lamp-black



so that colour for steam-pipes, iron sash-bars, &c., should be made of some other material than the usual pigment employed for light-coloured paints. I observe that Mr. Peter Wallace does not explain, except vaguely, the construction of the truly wonderful and imperishable (!) hothouses he mentions.

Saul Rymea.

HARMONICON PIANOS AND HARMONICONS *A LA* DULCIMER—METAL, GLASS, AND WOOD.

[4001.]—Mr. Bottone (No. 11893) is quite mistaken in describing the metal harmonicon as a mere toy: on the contrary, it may be so constructed as to be a powerful musical instrument, sufficiently powerful, indeed, for its sounds to be audible in the largest of concert-rooms. I well remember the late M. Jullien used it very effectively about twenty years ago at his promenade concerts, probably the best shilling's-worth of good (and other) music then to be purchased for the money.

Although, like its ordinary glass congenor, the metal harmonicon is usually made in such proportions as to be a mere toy, it can, like bells, be constructed on a scale which affords sounds of great power and pleasing quality, because, as in the case of bells, loudness, *cæteris paribus*, depends on the mass of material in vibration. There is no novelty in the principle of this instrument. The gender, a Javanese instrument described by Sir Stamford Raffles, is, if I rightly remember, a true harmonicon, the sounds of whose metallic bars, or plates, are augmented by the resonance of masses of air contained in bamboo tubes, which are veritable musical pipes, whose lengths have harmonic relations to the sounds of the metallic bars. A yet more ancient kind of harmonicon is that with wooden bars, common among the African and other "niggers." This old thing was, a few years ago, brought out as a novelty—there is nothing new under the sun—and publicly performed on by clever Master Bonny, under the Greek title of Xylophone. (N.B.—There is nothing so effective as a mouth-filling Greek, or yet better, a compound barbarous Græco-Latin polysyllabic word for arresting the attention of the unlearned. Some thirty years ago I well remember exciting the wonder—it don't take much to do that—of my fellow cockneys by knocking "God Save the Queen" out of that Asiatic mystery—the xylophone, alias wooden harmonicon, in the East India Museum, then "situate, lying, and being," as my legal friends say, in Leadenhall-street. So, a late fellow correspondent who said the wooden harmonicon was invented by a German organ builder, is of course mistaken, unless, indeed, the said organ builder was guilty of the same folly too often committed by the writer of reinventing ancient things. (N.B.—He is not the only unwise person who has committed this folly, as the patent rolls only too plainly testify.)

All harmonicons proper consist of elastic bars—metal, wood, or glass—supported at their two nodes so that their supports may not damp their vibrations. They, therefore, form a class of musical instruments (which might fairly be designated dulcimers without strings) apart from those whose sounds are caused by the vibrations of elastic bars on springs fixed at only one of their ends, the other being left free to vibrate. The tuning-fork, however different from a straight bar in mere form, belongs to the former class, for it really is supported at its two nodes, which (by bending the bar into a fork) are brought near each other. Mr. Crawford's pianoforte without strings (see his patent of 1862), lately advertised so extensively by Messrs. Cramer, belongs to the latter class. However excellent (its treble is really fine), it is but one of many examples of this class—one of the earliest being that patented by Dr. Cleggart, A.D. 1778. Groll, 1812; Goldsworthy-Gurney, 1838; Pape, 1850; and Matthews, 1853, have produced variations on the same tune—I mean instrument—which has the great advantage of never requiring retuning. The novelty of such instruments may be estimated when I mention that a true harmonicon was constructed—with glass bars—upwards of forty years ago, by Messrs. Chappell, with a hammer-action and keys *à la* piano—which, indeed, it then became, just as the same mechanism converts a stringed dulcimer into a pianoforte.

The great defect of all I have heard is the weakness and bad quality of their bases. Probably, if their spring bars or vibrators were of much greater size they might—like big bells—be made to yield satisfactory tones, but the sound of a bass drum or even that of a grand pianoforte long bass string, can hardly be expected from a steel spring or vibrator 5in. or 6in. long, even when helped by the resonance of a soundboard. Groll, and also Goldsworthy-Gurney, employed spring bars of much greater length; the former, if I remember correctly, used bars about 25in. long for his lower bass notes, but then their sounds were not assisted by the resonance of a soundboard. Pape had so little faith in the bass tones to be obtained from spring bars that he employed covered strings made of fire-hardened and spring-tempered steel wire, which he said hardly ever required retuning, but for doing this he provided an apparatus in which an index pointed to the name of the note on an arched segment when its pitch was correct—at least, he said so. In the absence of experience I will say nothing to the contrary, although how he compensated for the variations of pitch caused by alternate expansions and contractions of the frame (*i.e.*, the bracing) of his pianos which result from changes of temperature, is rather more than any ordinary "fella" can understand. Being an old-fashioned "fella" myself, I prefer tuning strings by ear to tuning (or untuning) them by sight.

The Harmonious Blacksmith.

LANTERN PINIONS.

[4002.]—I fully appreciate "Tubal-Kain's" politeness in not contradicting me (see reply 11123, p. 101), but it would not make the slightest difference if he had done so ever so flatly.

I thought "trussells" might be a local name for "trundles," and as the word had nothing to do with the question I took no notice of it.

I have only one notion of the meaning of "pitch" as applied to wheel gearing, and that is the distance of centres of teeth or trundles, measured, not straight, but along the curve of the "pitch line," and if I am to be obliged to use it in his sense—viz., as the actual distance in a straight line, then I must reverse what I said before, and say instead, "Tubal-Kain" is not right in saying that the pitch of wheel and pinion should be the same.

I do not understand what is meant by "diametrical pitch," or any other sort than the one mentioned above.

I have never read, or even seen, "Camus on the Teeth of Wheels;" but I have read, and carefully too, Professor Willis's "Principles of Mechanism," which is a much more modern work, and also Binns's "Second Course" of orthographic projection. And I am pretty confident if "Camus" told "Tubal-Kain" to set out wheels in the way he says his practical daily

Fig. 1.

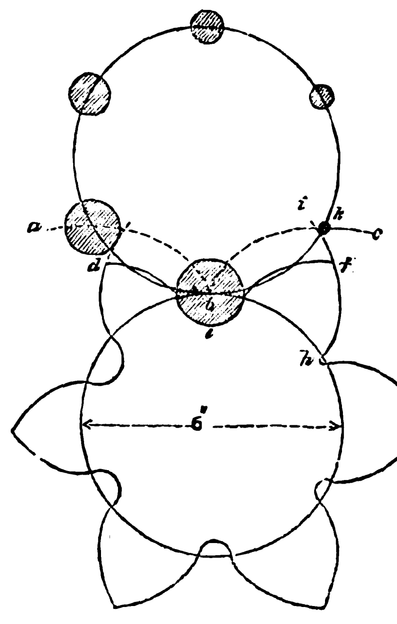


Fig. 2.

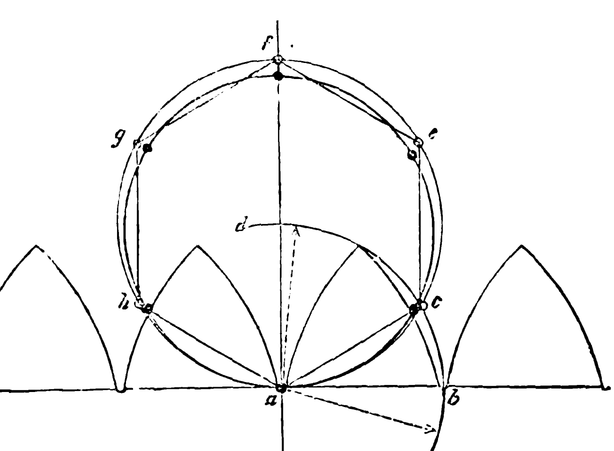

experience leads him to do, that either Willis or Binns would have pointed out the absurdity of his teaching long ago.

My own very first exercise in wheel-making was a pair of 6 teeth each only—viz., a wheel of 6 teeth, 3·14in. "pitch," as I call it, driving a lantern of the same size, only with the trundles varying from ½in. to 1½in. diameter. Of this I send a sketch (Fig 1). The biggest trundle is shown bottoming the largest space between the teeth; *a b*, *b c* are the sides of the true epicycloid tooth, supposing the trundles had no thickness. *d e f* shows the form of tooth for the trundle *b* when a piece half as wide as the trundle has been gauged off from the true epicycloid, which is the proper way of doing it. *h f i* is the reverse side of the right-hand tooth suitable for the small trundle *k*. It does not require much puzzling to find out where *k* would be if the distance from *b* to *k* were 3·14 instead of 3in. exactly. The result may be mentioned—viz., that we should have ·14 or $\frac{1}{7}$ in. backlash between the face of the tooth *h f i* and the trundle *k*, and the working of such gearing would be charming to listen to.

The object of the task of making such a pair as mentioned was to show first the true form of tooth; secondly, the possibility of driving with a wheel of only 6 teeth; thirdly, that lantern pinions are suitable for trains like clock trains, where the lantern is always driven, but never has to drive the wheel under any circumstances; fourthly, to show that the epicycloid tooth drives a trundle exactly at the same speed (whether the teeth be large or small), with the same smooth action as if the pitch lines were merely rolling on one another, and fifthly, that the trundles may be thick or thin, if the teeth are only gauged right. The epicycloid itself will do for very thin trundles; but for thicker ones the curve ought to be gauged off, which amounts to the same thing in practice as putting the template that you have cut to the true epicycloid rather nearer the centre of the wheel, as well as half the thickness of the trundle back from the centre line of the tooth space. If it is not put nearer the centre of the wheel (in drawing full pointed teeth, at least) the curve is not so true as it might be.
