INTRODUCTORY LECTURES

IN THE YEAR 1814.

LECTURE I.

In succeeding Sir William Blizard in the honourable office of Professor of Anatomy and Surgery, I think it right to inform my audience that he was my earliest instructor in these sciences; and that I am greatly indebted to him for much and most valuable information respecting them. My warmest thanks are also due to him for the interest he excited in my mind towards these studies, and for the excellent advice he gave me, in common with other students, to direct me in the attainment of knowledge.

"Let your search after truth," he would say, "be eager and constant. Be
wary in admitting propositions to be facts before you have submitted them to the strictest examination. If, after this, you believe them to be true, never disregard or forget any one of them, however unimportant it may at the time appear. Should you perceive truths to be important, make them motives of action; let them serve as springs to your conduct."

"Many persons," he remarked, "acknowledge truth with apathy; they assent to it, but it produces no further effect on their minds. Truths, however, are of importance, in proportion as they admit of inferences which ought to have an influence on our conduct; and if we neglect to draw those inferences, or to act in conformity to them, we fail in essential duties."

Our preceptor further contrived by various means to excite a degree of enthusiasm in the minds of his pupils. He displayed to us the beau ideal of the medical
LECTURE I.

character:— I cannot readily tell you how splendid and brilliant he made it appear; — and then, he cautioned us never to tarnish its lustre by any disingenuous conduct, by any thing that wore even the semblance of dishonour. He caused the sentiment of the philanthropic Chremes, in the Heautontimorumenos of Terence, to be inscribed on the walls of the hospital-surgery, that students should have constantly before them an admonition to humanity, drawn from a reflection on their own wants: Homo sum; humani nihil a me alienum puto.

I could with pleasure enlarge on this theme, but I check myself, because I am aware that what I am now saying may rather annoy than gratify the feelings of my preceptor. What I have stated, however, is a tribute due from me to him; and I pay it on the present occasion, in hopes that the same precepts and motives may have the same effect on the minds of the junior part of my audience, as they
were accustomed in general to have upon the pupils of Sir William Blizard.

That which most dignifies man, is the cultivation of those intellectual faculties which distinguish him from the brute creation. We should indeed seek truth; feel its importance; and act as the dictates of reason direct. By exercising the powers of our minds in the attainment of medical knowledge, we learn and may improve a science of the greatest public utility. We have need of enthusiasm, or of some strong incentive, to induce us to spend our nights in study, and our days in the disgusting and health-destroying avocations of the dissecting-room; or in that careful and distressing observation of human diseases and infirmities, which alone can enable us to understand, alleviate, or remove them: for upon no other terms can we be considered as real students of our profession. We have need of some powerful inducement, exclusively of the expectation of fame or emolument:
for optionally a man may attain a considerable share of public reputation and practice without undertaking the labours I have mentioned, without being a real student of his profession. I place before you the most animating incentive I know of to labour truly to acquire professional knowledge. You will by such conduct possess yourselves of the enviable power of being extensively useful to your fellow-creatures, in a way the most necessary to their wants, and most interesting to their feelings. You will be enabled to confer that which sick kings would fondly purchase with their diadems; that which wealth cannot command, nor state nor rank bestow. You will be able to alleviate or remove disease, the most insupportable of human afflictions, and thereby give health, the most invaluable of human blessings.

I shall not, however, gentlemen, waste your time in expatiating on this topic, because you will feel much more than I can utter, and because all that can be said or thought of it, seems concentrated in one
brief but enthusiastic sentence of Cicero, which therefore I quote. In nulla re, propius ad deos homines accedunt, quam salutem hominibus dando.

In occupying the situation of the last gentleman who taught in this place, Sir Everard Home, who has pursued the path of science which Mr. Hunter pointed out, with a considerable talent for observation, and with a degree of zeal and industry, scarcely to be expected from one whose time and attention have been otherwise so much engaged; I also, equally with him, feel interested in impressing on the minds of my audience, the advantages we have derived from the labours of Mr. Hunter, and from pursuing that mode of study and enquiry which he adopted, and inculcated: and I am desirous on the present occasion, to engage your attention in the consideration of the probability and rationality of his theory of life.
The term theory, in philosophical language, like hypothesis, denotes the most plausible and rational mode of accounting for certain phænomena, the causes of which have not been fully developed. In applying these terms to medical and physiological subjects, I may be allowed to define what I think they designate, and what I intend to convey by them. By the word theory I mean a rational explanation of the cause or connexion of an apparently full or sufficient series of facts: by hypothesis, a rational conjecture concerning subjects in which the series of facts is obviously incomplete.

The formation of an hypothesis excites us to enquiries, which may either confirm or confute our conjectures; and which may, by enabling us to discover the deficient facts, convert our hypothesis into a theory. Believing the facts collected by the ingenuity and industry of Mr. Hunter, to be sufficient to establish his opinions respecting life, I have therefore called them a theory.
There was a time when medical men entertained so determined a dislike to the word theory, that they could scarcely tolerate the term. If any such remain, I would beg them to reflect that hypothesis and theory are the natural and inevitable result of thinking; so that if they refuse to allow of any theory, they must prohibit all thought.

The antipathy which some have entertained to the term theory, has arisen from its misapplication. For opinions drawn from very partial views of subjects, sometimes having no foundation on facts; opinions formed by processes of mind, similar to those which occur in dreaming, when lawless imagination produces combinations and associations without any reference to realities; opinions, as unlike what I should understand by theory as darkness is to light, have nevertheless been often proposed as theories and so denominated. That such foolish speculations, such waking dreams, will mislead and deceive us, cannot be doubted; and hence has arisen the preju-
dice which some have entertained against the term.

The greatest philosophers were, through the whole course of their enquiries and demonstrations, theorists. Theorizing, according to my conception of the word, means nothing more than thinking correctly, in a concatenated manner, and in conformity to rules which I shall presently have occasion to notice. It is scarcely necessary for me to assert that this kind of thinking is useful, and promotive of Science. For was it not thinking in this manner on the cause of an apple falling from a tree, that led Sir Isaac Newton to ascertain the laws of attraction? Was it not thinking thus which led him to perceive that the operation of the same causes might perpetuate the regular motions of the planetary system? Why do we note facts with accuracy, or collect them with diligence? Why do we interrogate nature by experiment? Is it not because we wish to prove some of our own opinions to be true, or the opposing opinions of others to be false? or, because we wish to enlarge
the boundaries of science in a direction in which we think they admit of extension? What induces one person to prohibit another from theorizing? Is it not because he has himself attempted it in vain, and therefore deems the attempt unavailing?

Feelings and opinions are the chief sources of all our intellectual conduct: we ought therefore to cultivate good and honourable feelings, and to scrutinize opinions, with a view to entertain none but those that appear correct; and such an examination, to which I now invite you, must be allowed to be a proper exercise of intellect.

Since thinking is inevitable, our chief enquiry should be how we ought to think or theorize; and on this point Newton himself has condescended to instruct us. Our theories, hypotheses, or opinions, for to me all these words seem to refer to one and the same act of the mind — should be verifiable or probable, and should rationally account for all the known phænomena of
the subject they pretend to explain; under which circumstances it is allowable to maintain them as good, until others more satisfactory be discovered. No man who thus theorizes need feel shame in this employment of his intellectual powers; no man can feel arrogance, for it is acknowledged that his theory is but a probable and rational conjecture. Besides, we never can be sure that the series of facts belonging to any subject is full or complete; new ones may be discovered, that would overturn our best established theories.

Upon the foregoing terms alone do I wish to uphold Mr. Hunter's theory of life; and I do so on the present occasion, because it seems highly probable, it was his thinking in the manner he was known to do, that caused him to survey all the facts connected with the subject of life in general with so much accuracy, as well as to note its disordered states and sympathies in a manner which has so greatly contributed to increase our practical knowledge. It is highly probable that it was his hypothesis
respecting life which incited him to enquiries by which he has been able to supply the deficient facts, so as to establish his conjectures, or convert his hypothesis into a theory.

Mr. Hunter seems to have put us into a right path, and every step we take our prospects become more enlarged and distinct, and we evidently approximate to the ultimate object which we have in view.

Whoever duly reflects on the extent of human knowledge and power, cannot but feel an interest in anatomical enquiries; since he must perceive that it is by means of the organization of the body, the mind acquires all its information, and executes all its purposes. When, however, we engage in anatomical enquiries, we find so great a diversity of structure in the different parts of the body; so great a variety of expedients for affecting certain purposes, all so simple in their nature, yet so ade-
quate to their intended design, that anatomy becomes highly interesting from the curiosity it excites, the knowledge it imparts, and the food for meditation it affords.

When also in the prosecution of our anatomical enquiries, we as it were analyze the body, or reduce it to its elementary parts: when we find that every organ, and every portion of it is composed of a few and simple vessels, a few and simple fibres; that by these it is originally formed, kept in constant repair, endowed with animation, sensation, and motion; we become lost in astonishment that such important ends can be effected by apparently such simple means.

On reflecting how I might best accomplish the duty which devolves to me, of giving anatomical lectures in a place by no means suited to anatomical demonstrations, I thought I could not do better than speak of the structure and functions of these elementary component parts of the body;
since by this method I should be led to describe their natural and healthy structure and functions, which would be a proper introduction to the subsequent discussions I have to engage in, relative to the nature and treatment of disorder and disease. As it does not seem material which subject I consider first, I shall begin with the fibres, the only visible means by which motion and sensation are produced; for this will lead directly to the consideration of Mr. Hunter's Theory of Life.

In surveying the great chain of living beings, we find life connected with a vast variety of organization, yet exercising the same functions in each; a circumstance from which we may I think naturally conclude, that life does not depend on organization. Mr. Hunter, who so patiently and accurately examined the different links of this great chain, which seems to connect even man with the common matter of the universe, was of this opinion. In speak-
ing of the properties of life, he says "it is something that prevents the chemical decomposition, to which dead animal and vegetable matter is so prone; that regulates the temperature of the bodies it inhabits, and is the cause of the actions we observe in them." All these circumstances, though deduced from an extensive contemplation of the subject, may, however, be legitimately drawn from observations made on the egg. A living egg does not putrify under circumstances that would rapidly cause that change in a dead one. The former resists a degree of cold that would freeze the latter. And when subjected to the genial warmth of incubation, the matter of it begins to move or to be moved so as to build up the curious structure of the young animal.

The formation of the embryon in gallinaceous ova was particularly attended to by Mr. Hunter; and he was of opinion, that motions began in various places in the cicatricula so as simultaneously to form parts of the embryon and its appendages.
The opinions of Mr. Hunter deserve at least to be respectfully and attentively considered. That he was a man of genius, according to the beautiful definition of that quality given by Dr. Johnson; that he possessed the power of mind that collects, combines, amplifies, and animates the energy without which judgment is cold, and knowledge is inert; cannot I think be doubted by any one who has carefully considered his writings. That he was a man of uncommon industry, by which he collected abundance of facts, will be admitted by every one who has even beheld his museum. That he was a man of constant and deep reflection, is to me equally apparent.

Many persons have genius without industry; others industry without genius; and many who possess both are still deficient in judgment.

I here beg permission to explain the notions I entertain of that act of the mind by which we form our inferences, opinions,
or judgments. I shall by this means at once unfold what it is that, in my estimation, gives currency and value to the opinions of any individual, and entitles them to the attention of others. The human mind has the power of holding as it were in review, a series of facts or propositions, and steadily contemplating them so as to arrange, assort, or compare them till we form some deduction respecting them. This power seems to belong exclusively to man, and is the basis of his reasoning faculty. That mind is the strongest which can contemplate the greatest number of facts or propositions with accuracy; and his judgments are generally the most correct, who omits to review none of the facts belonging to the subject under his consideration. It was this power of mind that so eminently distinguished Newton from other men. It was this power that enabled him to arrange the whole of a treatise in his thoughts, before he committed a single idea to paper. In the exercise of this power, he was known occasionally to have passed a night or
day entirely inattentive to surrounding objects.

That Mr. Hunter was also a man of constant and deep reflection, that he possessed this enviable power of mind, so essential to the perfection of the intellectual character, is to me sufficiently apparent; for I know of no opinion of his that was lightly or loosely formed, or that was not logically and cautiously deduced from the facts before him; and though from the subsequent increase of knowledge, the validity of some of his opinions may now be doubted, yet most of them have from the same cause become more firmly established. With all his genius, knowledge, and reflection, Mr. Hunter was not, however, a brilliant character amongst us. He had not the happy talent of displaying the stores of his mind, nor of communicating to others the same perception of the importance of his facts and opinions as he himself entertained. Perhaps it may have arisen from my attending more to his facts and opinions than to his mode of explaining them, that I have
been led to form so high an estimate of his intellectual powers. I can draw no other inferences from the facts than those which he has drawn, and therefore am I a convert to his opinions.

I proceed now to consider the structure and functions of those fibres which constitute the muscles, in order to introduce the discussion of the probability and rationality of Mr Hunter's Theory as a cause of irritability. Muscular fibres are soft and readily lacerable in the dead body, and even during life, when they are in a state of inaction. They are composed of that insoluble substance which we meet with in the blood, and which, from its disposition to concrete in a fibrous form, is called the fibrous part of that fluid. The threads and flakes of common cellular substance, which connect the muscular fibres, and everywhere pervade the structure of a muscle, may be removed by boiling, and then the muscular fibres may be separated, till they become too minute to admit of further separation, and almost elude our unassisted
sight. Yet there are some who assert, that by the aid of powerful lenses, each fibre, though slender as the threads of flimsy gossamer, appears but as a muscle in miniature, being composed of a number of smaller fibres. There are others who maintain the contrary, and affirm that they can see the ultimate muscular fibres. It would seem to me a waste of time to detail to you the reports of various microscopical observers, respecting the ultimate fibres of muscles, since there is so little concurrence or certainty in their descriptions. The opinion which such contradictory statements have impressed on my mind, is, that perhaps the ultimate arrangement of matter, like its ultimate particles, may form a subject too subtile for human perception. Our information in these respects must be limited, as our powers of perception have their bounds. The imperfection of the human senses, does not, however, seem a subject of regret; because it induces a greater necessity for the exertions of intellect; and many subjects appear far more demonstrable to reason than to sense.
Fontano, it must be granted, possessed considerable talent in microscopical observations; for he says, that he could readily distinguish the nature of any animal substance, which might be placed on the field of his microscope, by regarding its ultimate fibres, and according to him the muscular fibres are much smaller than those of the nerves. Proscaska and others assert, that the ultimate muscular fibres are continued throughout the whole length of a muscle. How marvellous, (could we but see it,) would such a slender thread appear, continued throughout the whole length of the human sartorius. Haller, however, affirms that the fibres are not continued, but that one set terminating another begins. Suspecting that Haller employed the solar microscope on this occasion, as he says he had done on others, I examined muscular fibres with this instrument. Now, though I place no confidence in my own observation, and think the subject unimportant as to any conclusion that may be deduced from it, yet I will tell you how a portion of a muscle appeared to me when
magnified about 500 times. The fibres were slightly undulating, and one set terminating, another began: neither were the sets of fibres of considerable length. The muscular fibres were connected by cross threads of common cellular substance.

Mr. Carlisle, in whose talents and accuracy we are all disposed to place confidence, in the Croonian Lecture, printed in the Philosophical Transactions for 1805, says, that he can distinctly see an ultimate muscular fibre, which he describes "as a solid cylinder, the covering of which is reticular membrane, and the contained part a pulpy substance irregularly granulated." He has also described the termination of nerves in muscles.

Muscles are liberally supplied both with blood vessels and nerves, but nothing peculiar is perceived in their distribution. We make them very red by injecting them, and we see numerous nerves entering their substance at various places. Yet the vessels of some muscles are too minute to receive red
blood on our coloured injections, so that redness though a common is not an essential character of muscle.

I here willingly relinquish the enquiry into the structure of those organs in which the irritable property chiefly resides, in order, in the next place, to speak of the principal phænomena of irritability.

Muscles have the power of contracting with surprising celerity and force. It seems indeed wonderful that the biceps muscle of the arm, which in the dead state would be torn by the weight of a few ounces appended to it, shall in the living state be capable of lifting and sustaining more than 100 lbs. The matter in the muscle seems neither to be increased nor diminished during its contraction, what is lost in length being gained in bulk. The voluntary contraction of muscles cannot be long continued; they become weary and painful, the contraction remits and recurs, causing a tremulous motion. Yet this phænomenon does not seem to be the
effect of absolute inability, in the irritable property, to continue in action, for some muscles continue to act without experiencing fatigue. For instance, those of the jaws and back; for whenever they relax the jaw drops, and the head and body fall forwards, as we see in persons who are going to sleep in a sitting posture. Certain sphincter muscles likewise remain in action without experiencing fatigue. Some sphincters also, I may add, are disposed to yield considerably without impatience; so that their irritability resembles that of those muscles which Bichât has considered as a distinct class, and subservient alone to what he calls the organic life. The contractile power of muscles is also capable of remaining in vehement action for a great length of time, as we see in some cases of cramps, and still more in some cases of tonic tetanus.

Yet, though the irritable power is not incapable of continued exertion, it seems evidently to be in general susceptible of fatigue, and inclines to be at rest. If we stimulate the muscles of a limb of a
frog severed from the body, by voltaic electricity, the muscular actions are at first vivid and forcible, but they grow fainter and feebler on repeated excitement. Yet if we wait a little till they seem to regain their power, they become vivid and forcible as at first from the same degree of excitement. Such actions may be excited at intervals for twenty-four hours, though with a gradual diminution in their power, after which, in general, they can be no longer excited, and then the muscles become permanently and rigidly contracted. The foregoing facts appear to me to show the impropriety of the phrase, exhausted irritability, which is in common use to express our inability by the effort of our will to continue the actions of our voluntary muscles: it seems manifest that the irritability is not exhausted but fatigued.

The rigid contraction of the muscles after death, is the effect of irritability: it is its last act. A considerable force is required to overcome this contraction, or to bend the rigid limbs of the dead body,
when it has recently taken place. The force required to effect this, gradually diminishes till the muscles become quite pliant; and then, and not till then, does putrefaction ensue.

Mr. Hunter has known this last vital contraction to occur in parts severed from the body sixty hours after their separation, upon the removal of causes which had impeded the contraction before that period; a proof that life in a certain degree was still resident in the part. He observed that death produced by lightning, or large charges of electricity, or by certain kinds of injuries and diseases, prevented this contraction, and even the coagulation of the blood; and that putrefaction would in such cases very rapidly take place. From facts of this kind, as well as from many others, he drew an inference, which has not I believe been disputed, and therefore I need not enter into the discussion of it at length, that the principle of life may in some instances be suddenly removed, or have its
power abolished, whilst in general it is lost by degrees.

The contraction of irritability takes place in some animals in a very slow and gradual manner, and their muscles in general are incapable of sudden contraction. Yet though the action of their muscles is very slow, it is very powerful and very permanent. The American sloth supports its weight for a very long time in one attitude, by fixing its claws into the branches of trees; an act which would speedily weary muscles of an ordinary character. The muscles of the legs of birds that roost, seem to have a similar power of permanent contraction.

Mr. Carlisle has lately demonstrated a peculiar distribution of the arteries in the limbs of these tardigrade animals, as they are called, and Doctor Macartney has shown that a similar arrangement of vessels exists in the legs of fowls. Such a distribution of the arteries may be subservient with-
out being essential to these modes of action.

In the human body we see instances of irritability exerting itself after the manner it does in general in tardigrade animals. If the iris had possessed the ordinary powers of muscles, and none else, it could not have remained, as it is known to do, permanently contracted in a strong light, and permanently dilated in a weak one. Indeed, an anatomist who is fond of tracing structure as connected with function, might readily persuade himself, that there is in the iris a distribution of arteries, similar to that which Mr. Carlisle has demonstrated in the limbs of sloths. We find, however, that sphincter muscles in general have the power of continuing their contraction, though no peculiar distribution of vessels is discoverable in them. In the gall bladder, the function of which requires this slow but permanently acting irritability, in order to express its contents in small and equal quantities into the bowels, as the digested aliment passes into them, we discover
no peculiar arrangement of arteries. Though we cannot excite any sudden contraction of that bag, yet we know that it can gradually reduce itself into a very small compass. The skin has everywhere this slow but permanently acting, and gradually relaxing irritability, the effects of which are most evident in lax and pendulous portions of it. Accordingly we sometimes observe the scrotum and prepuce condensed into a suprisingly small and very compact mass.

Thus have we even in the human body evidences of irritability acting in various modes, whilst we can equally perceive that in tardigrade animals some of their muscles act with celerity. In the lori, of whose habits Vosmaer has given so interesting an account, and which manifested no signs of alacrity, save in eating the food that it liked, no stimulation nor injury could induce it to mend its pace, but it showed its resentment of the attempt to make it perform impossibilities, by suddenly snapping at the stick or instrument with which it was
goaded; and thus again demonstrated that the muscles of its jaw were endowed with an irritability of the more common character.

Having thus briefly described the principal phenomena of muscular action, for I forbear to notice others of less importance, I proceed to review the conjectures that have been formed as to the cause of these curious, sudden, and powerful contractions. Not to speak of exploded hypotheses, I trouble you only with those which are modern.

First, then, the contraction has been supposed to be the effect of some chemical change occurring in the part. This opinion is I think invalidated by the reiterated contractions which may be produced in the limbs of some animals when removed from the body, even during twenty-four hours, if excited by voltaic electricity, and consequently when no supply of materials can be supposed to exist within the limb, to produce such reiterated chemical changes.
The opinion is still further refuted by observing, that these vivacious contractions will equally take place, upon the same excitement, in the exhausted receiver of an air-pump and in the open air. They may also be excited under water, under oil, in a great variety of gases; in short, under circumstances which exclude the presence of any chemical agent from without, to which such changes could reasonably be imputed.

Secondly, the contraction of irritability has been supposed to be a property of the muscular fibres. Properties are generally considered as permanent qualities. Thus, the property of gravitation is continually operating, equally when bodies remain at rest and when it produces motion in them, equally whilst I support this book in my hand, and when I suffer it to fall on the table. If, however, so curious an occasional property could belong to matter, we should naturally expect that it would belong to some peculiar quality, or arrangement of matter. But irritability is con-
connected with matter of different qualities and arrangements. The flesh of animals and that of fish are different in quality; the pulpy medusæ which float in the sea differ from vegetables; yet all are irritable, or possess this power of occasional contraction. Though in general we find irritability connected with a fibrous structure, yet, if we may trust our senses, it is not so in every instance. In the hydatid, where no such structure is apparent even with the aid of lenses, we still have evidence of the irritability of life. If also, as I strongly suspect, the muscular fibres be not continued from one end of the muscle to the other, irritability could not in that case be considered as a property belonging to them, since any breach of continuity would completely frustrate the contraction of the whole muscle.

Thirdly, I proceed to enquire into Mr. Hunter’s opinion, that irritability is the effect of some subtile, mobile, invisible substance, superadded to the evident structure of muscles, or other forms of vegetable and
animal matter, as magnetism is to iron, and as electricity is to various substances with which it may be connected. Mr. Hunter doubtless thought, and I believe most persons do think, that in magnetic and electric motions, a subtile invisible substance, of a very quickly and powerfully mobile nature, puts in motion other bodies which are evident to the senses, and are of a nature more gross and inert. To be as convinced as I am of the probability of Mr. Hunter's Theory as a cause of irritability, it is, I am aware, necessary to be as convinced as I am that electricity is what I have now supposed it to be, and that it pervades all nature. To obtain this conviction it is necessary that the facts connected with this subject should be attentively considered; but for such an examination I have no time; neither would it be considered as suitable to the general design of these lectures.

Whatever notions philosophers may be pleased to form respecting matter in general, it does not appear to me that our physiological opinions can be affected by their decisions. Of the matter which for
the most part presents itself to our notice, and is cognizable by the eye and touch, we know that it has a property called by Sir Isaac Newton *vis inertiae*, an indisposition to move unless impelled to motion, and a disposition to continue in motion unless retarded.

There are some philosophers who think, that properties similar to those of the aggregate mass, likewise belong to every atom of which it is composed; whilst others, on the contrary, think, that the atoms have very different qualities, and that the *vis inertiae* is the property only of the aggregate mass. The matter of animals and vegetables is, however, an aggregate mass; it is as we express it, common matter, it is inert; so that the necessity of supposing the superaddition of some subtile and mobile substance is apparent.

Taking it for granted that the opinions generally entertained concerning the cause of electrical motions are true, analogy would induce us to suppose, that similar motions might be produced, by similar
causes, in matter organized as it is found to be in the vegetable and animal systems.

The phenomena of electricity and of life correspond. Electricity may be attached to, or inhere, in a wire; it may be suddenly dissipated, or have its powers annulled, or it may be removed by degrees or in portions, and the wire may remain less and less strongly electrified, in proportion as it is abstracted. So life inheres in vegetables and animals; it may sometimes be suddenly dissipated, or have its powers abolished, though in general it is lost by degrees, without any apparent change taking place in the structure; and in either case putrefaction begins when life terminates.

The motions of electricity are characterized by their celerity and force; so are the motions of irritability. The motions of electricity are vibratory; so likewise are those of irritability. When by long-continued exertion the power of muscles is fatigued, or when it is feeble, their vibratory or tremulous motions are manifest to com-
Lecture I.

mon observation, but the same kind of motion may be perceived at all times by attention, as has been shown by Doctor Woolaston in the Croonian Lecture for the year 1810. It is then I think manifest, that Mr. Hunter's conjectures are the most probable of any that have been offered as to the cause of irritability.

My allotted time does not permit me at present to consider the other vital functions; yet I relinquish the subject with reluctance, because I have been speaking only on that point in which it seems most difficult to persuade the incredulous, of the probability and rationality of Mr. Hunter's Theory.

When hereafter I shall have to speak of the other vital functions, I think it will appear that it is impossible to account for the phenomena in any other manner than that which Mr. Hunter has suggested.

In ascending the difficult and lofty ladder of knowledge, men of great talent and in-
dustry seem to have affixed to it certain resting places, on which, reposing for a time from their labours, they could tranquilly assemble their followers, and contemplate more extensive views of nature, and of nature's laws, than had before been taken. If after having stood by the side of the great teacher Newton, and learned from him the properties of common and inanimate matter, we afterwards attend to Mr. Hunter, our great instructor in the functions of living beings, he points out to us how matter, starting from the general mass, springs up into life in vegetation. We see vegetables as it were self-formed and producing their own species. We observe them also exerting most of the powers which animals possess. That they have irritability is evident from the current of their sap and their secretions; nay, in some we observe those vivacious motions which seem chiefly to belong to animal life, as is evident in the Mimosæ, the Dionæa Muscipula, and Heydysarum gyrans. We see them like animals having alternate seasons of action and repose; and though in general vegetables like animals are in action during the day
and rest in the night, yet also some vegetables like some animals rest in the day and are in action during the common season of repose.

We see animals scarcely differing from vegetables in their functions, like them doomed to a stationary existence, with even less appearance of organization than we usually discover in vegetables, and of a structure so simple as to admit of propagation like vegetables by cuttings. Yet in all the diversity of living beings we recognize certain processes peculiar and essential to life; as the power of converting other kinds of matter into that appropriate to the individual it is to form and support; the power of distributing the nutriment, thus converted, to every part for its formation and supply; the ventilation, as I may call it, of the nutritive fluids; the power of preparing various dissimilar substances from the nutritive fluids; and the propagation of the species. As what is deemed the complexity of animal life increases, we find distinct organs allotted for each of these functions; thus we have organs of diges-
tion, circulation, respiration, secretion, and generation, which are various in their structure in the different tribes of animals.

In vegetables, and in some of the lower kinds of animals, no traces of nerves are discoverable. The nervous system begins in a simple form, and seems to increase in complexity up to man. But this will make the subject of the next lecture. Mr. Hunter also shows us that there are animals, as for instance the torpedo and gymnotus, which have organs liberally supplied with nerves, forming an electric battery which they can charge at will. Such facts show to what a degree electricity exists in these animals, and how greatly it is under the influence or control of the nervous system; and they could not fail to make a strong impression on the contemplative and deeply meditating mind of Mr. Hunter.

What, then, may I ask, is the natural inference to be drawn from the examination of this great chain of being, which seems to connect even man with the com-
mon matter of the universe? What but that which Mr. Hunter drew, that life must be something independent of organization, since it is able to execute the same functions with such diversified structure, and even in some instances with scarcely any appearance of organization at all?

The experiments of Sir Humphrey Davy seem to me to form an important link in the connexion of our knowledge of dead and living matter. He has solved the great and long-hidden mystery of chemical attraction, by showing that it depends upon the electric properties which the atoms of different species of matter possess. Nay, by giving to an alkali electric properties which did not originally belong to it, he has been able to control the ordinary operations of nature, and to make potash pass through a strong acid, without any combination taking place. That electricity is something, I could never doubt; and, therefore, it follows as a consequence, in my opinion, that it must be everywhere connected with
those atoms of matter, which form the masses that are cognizable to our senses; and that it enters into the composition of every thing inanimate or animate. If then it be electricity that produces all the chemical changes, we so constantly observe, in surrounding inanimate objects, analogy induces us to believe that it is electricity which also performs all the chemical operations in living bodies; that the universal chemist resides in them, and exercises in some degree peculiar powers because it possesses a peculiar apparatus.

Sir Humphrey Davy's experiments also lead us to believe, that it is electricity, extricated and accumulated in ways not clearly understood, which causes those sudden and powerful motions in masses of inert matter, which we occasionally witness with wonder and dismay; that it is electricity which causes the whirlwind, and the water-spout, and which “with its sharp and sulphurous bolt splits the unwedgeable and gnarled oak,” and destroys our most stable edifices; that it is electricity which,
by its consequences, makes the firm earth tremble, and throws up subterraneous matter from volcanos.

When therefore we perceive in the universe at large, a cause of rapid and powerful motions of masses of inert matter, may we not naturally conclude that the inert molecules of vegetable and animal matter, may be made to move in a similar manner, by a similar cause?

It is not meant to be affirmed that electricity is life. There are strong analogies between electricity and magnetism, and yet I do not know that any one has been hardy enough to assert their absolute identity. I only mean to prove, that Mr. Hunter's Theory is verifiable, by showing that a subtile substance of a quickly and powerfully mobile nature, seems to pervade every thing, and appears to be the life of the world; and therefore it is probable that a similar substance pervades organised bodies, and produces similar effects in them.

The experiments of Sir H. Davy seem
to realize the speculations of philosophers, and to verify the deductions of reason, by demonstrating the existence of a subtile, active, vital principle, pervading all nature as has heretofore been surmised, and denominated the Anima Mundi. The opinions which in former times were a justifiable hypothesis, seem to me now to be converted into a rational theory.

It is then, I think, manifest, that Mr. Hunter's Theory of Life, presents us with the most probable solution of the phænomena of irritability, of any that has hitherto been proposed.

The human mind has been the same at all periods of the world; in all ages there have been men of a sceptical disposition, disinclined to believe any thing that was not directly an object of their senses. At all periods there have been other men of a contemplative, and perhaps more credulous character, who have been disposed to believe that there were invisible causes, operating to produce the alterations which are visible,
and who from much less numerous facts have drawn the same inferences that I have done. And many of these, from Pythagoras downwards, have expressed their sentiments, though with some variety, yet pretty much to the same effect. The Greek philosophers recognized in man, the Σομα, Υυξη, and Νες, the body, vital principle, and mind, whilst some used words significant of intellect, to express the energizing principle in nature, without apparently having any clear ideas of intelligence.

What was called the Anima Mundi, was, however, by many considered as a distinct and active principle, and was not confounded with intelligence of any kind. I know not how I can better exhibit to my audience the subject I am alluding to, or better acquaint them with the general tenour and tendencies of these opinions, than by quoting that portion of these philosophical notions, which Virgil is said to have put into the mouth of Anchises:

Spiritus intus alit, totamque infusa per artus
Mens agitat molem, et magno se corpore miscet.
And please to observe, gentlemen, it is Virgil says, it is Anchises speaks, that which I also this day have been saying; —

Inde hominum pecudumque genus, vitæque volantum
Et quæ marmoreo fert monstra sub æquore pontus.
LECTURE II.

I proceed to speak of the structure and functions of the nervous fibres.

The nerves which we observe pervading the body, appear to be packets of very minute threads, seemingly distinct from each other. The nerves divide and subdivide, and in so doing a certain number of threads separate from the original packet, and appear as a distinct nerve. It is, therefore, possible to trace a minute nerve, up to its origin, from the toe or finger, by splitting it off from the various packets with which it has been conjoined. So far does anatomical fact concur with the physiological opinion, that every nervous filament communicates distinctly with the brain or some process of that organ.

This apparent continuity is, however,
lost, whenever we find those intumescences on nerves which are called ganglia, for in these there seems to be a mixture or consolidation of the nervous matter. It is also lost wherever various nerves unite together, and form a plexus; in which case the nervous fibrils either coalesce, or become inextricably interwoven with one another.

The nerve from which the thoracic and abdominal viscera are chiefly supplied, is beset with numerous ganglia and plexuses; and as we cannot by our will influence the actions of those viscera, and as the iris, the motions of which are also involuntary, is supplied with nerves from a ganglion, it has been thought that ganglia, by intercepting the direct communications between the brain and the extreme branches of nerves, might render parts thus supplied less amenable to the will, and less under the influence of the general affections of the nervous system. It is also thought that ganglia might serve the office of subsidiary
brains, each affording a separate source of nervous energy.

On the other hand, it ought to be observed, that all the vertebral nerves, supplying parts over which the will exerts the most perfect control, have ganglia at their commencement; and that the nerves of the leg and arm form a plexus near their origin. The actions of the cremaster muscle are involuntary; yet I believe it is supplied by the same nerves, which supply muscles that are subject to voluntary actions; therefore this opinion does not appear to me to be such as we should receive with entire confidence. Again, it is further apparent, that the functions of the abdominal and other viscera are greatly affected by disorders of the brain, and that the brain is greatly affected by disorders of these viscera.

The ingenious and industrious French anatomist, Bichât, has classed the living functions into the organic and animal: the
distinction seems a natural and useful one, and throws light on the physiology of the visceral nerve. In vegetables, and in some of the lower kinds of animals, no traces of a nervous system are discoverable. In others of the lower order of animals, that have organs for the preparation and distribution of nutriment, they are supplied by a visceral nerve, which it is probable maintains amongst those organs a concurrence of impressions and actions. In the ascending complexity of the nervous system, we find a nervous chord more or less beset with ganglia, which supplies other parts of the body besides the viscera, and which probably serves to maintain amongst them likewise a concurrence of impressions and actions. We next find at one end of this chord a kind of ganglion, or brain, which gradually becomes larger and more complex as we trace the series of links upwards to man, in whom it bears a much larger proportion to the nervous system in general than in any other animal. The visceral nerve, in the ascending series of animals, appears connected with the animal nerves;
and so numerous are these connections, that this nerve has in the human subject obtained the title of the great sympathetic nerve.

The vital organs are required to carry on their functions with a degree of regularity and order, under the varying circumstances of life; and the possession of a distinct nerve may enable them to continue their functions without so materially participating in the disturbances of the animal system, as they must otherwise have done: yet the numerous connections of the visceral with the animal nerves must render both participators in each other's disorders.

The nerves, then, may be said to proceed from the brain, medulla spinalis, and visceral nerve, to all parts of the body for their supply. In thus expressing a fact, however, we should guard against an idea which the analogous distribution of arteries is apt to engender. Arteries become minute in proportion as they send off branches, whilst, on the contrary, the branches of nerves are often larger than the trunk from which
they proceeded. It is no unfrequent occurrence for mal-formed children to be born without a brain, yet with a perfect nervous system. The most rational idea, therefore, we can entertain on the present subject, is, that the nerves are formed in the parts where we find them, and that they are connected to those parts of the organs from which we are accustomed to say they proceed. Nerves are vascular, and we can inject them with subtile injections.

The nerves, then, proceeding from, or being connected with the brain, medulla spinalis, and visceral nerve, may be traced, ramifying throughout the body in the manner already mentioned, till they arrive at the part for the supply of which they are designed. They then split into numerous branches which communicate with each other, and again subdivide and rejoin, their communications appearing to multiply as they become more minute; so that every part of the body has a kind of net-work of nerves, in proportion to the susceptibility and sensibility it possesses.
This general and imperfect sketch of the anatomy of the nervous system, relates only to what may be discovered by our unassisted sight. If by means of the microscope we endeavour to observe the ultimate nervous fibres, persons in general are as much at a loss as when by the same means they attempt to trace the ultimate muscular fibres.

Those fibres which we can split off from a nervous packet, in the manner before mentioned, though too minute to admit of further subdivision, appear by the microscope to be themselves packets of smaller threads. It is generally asserted by microscopical observers, that the nerves and medullary matter of the brain and spinal marrow are the same, and are composed of very minute fibres. Fontana speaks confidently on this point; and he further says, that he has seen these nervous fibres regenerated in the medium which has been formed to unite a divided nerve. He describes the nervous fibres in every part of the nervous system as cylin-
trical, pursuing a slightly undulating course, and being in a considerable degree transparent. He states also that they are larger than the ultimate fibres of muscles.

Microscopical observers also tell us, that though the nervous fibrils in each packet appear distinct, and may be separated from each other in the manner already described, yet they have nevertheless transverse communications with each other. Each nervous fibre has been supposed to be covered by investing membranes similar to those of the brain; but this opinion is founded on an analogy with what is observed in the optic nerve, rather than on actual observation with respect to others. That they have investing membranes is clear, and we are told that we may dissolve the medullary or nervous matter by an alkali, and leave these investing membranes; or on the other hand, that we may dissolve the investing membranes by nitric acid, and leave the medullary fibres.

Having thus spoken of the chief cir-
cumstances relating to the anatomy of the nervous system, I shall not dwell on this part of the subject, but hasten to the principal object of the lecture, to consider its Physiology, in order to examine how far Mr. Hunter's Theory of Life, seems adequate to explain the phenomena of the nervous functions.

First, then, it is generally believed that all sensation is in the brain, and that all volition proceeds from that organ. This proposition requiring to be impressed so as to produce conviction, for it is the foundation on which all our future reasoning is founded, I shall state the principal causes of this opinion. First, If the continuity of a nerve be intercepted at any point between that extremity which receives impressions from the objects of sense, and which therefore may be called the impres- sible or tangible extremity, and that which communicates with the brain, and is usually called its sensorial extremity, both feeling and volition by means of that nerve are suspended.
2dly. If a certain degree of pressure be made upon the brain, both feeling and voluntary motion cease whilst it continues and return when it is removed.

3dly. As we have evidence that the perceptions and intellect of animals increase in proportion as the brain becomes larger and more complex, so we have reason to conclude that these faculties are connected with that part of the nervous system.

4thly. The conviction which we generally though not constantly experience, that feeling exists in the part which receives impressions, is shown to be deceptive by the following facts. If a nerve be irritated midway between the brain and its extremities, severe pain is supposed to be felt in those extremities; and if it supplies muscles, those muscles become convulsed. Thus when a disease forms about the hip joint, or in the loins, many persons have applied poultices to their knees, from a conviction that as the pain was felt in the
knee, it was the seat of the disorder. In like manner, persons who have had their limbs amputated, can scarcely believe that they are removed, because of the pain and other sensations they still seem to feel in them. In either of these cases, motions being excited in the middle of nerves, and transmitted to the brain, are attributed to a disordered state of those parts from which such motions have heretofore originated.

If, then, it be admitted that sensation exists in the brain, and that volition proceeds from that organ, it necessarily follows that motions must be transmitted to and fro along the nervous chords, whenever they take place. It was formerly supposed that these chords were passive, and might be made mechanically to vibrate, but their want of elasticity and tension, and their pulpy origins and terminations, are circumstances which render such a supposition inadmissible. Physiologists were therefore led to conjecture that the nervous fibrils were tubular, and that they contained
a subtile fluid, by means of which such motions were transmitted.

Of the extensive knowledge and high intellectual powers of Baron Haller, no one can entertain a doubt; and yet, he could devise no other theory to account for the phænomena of the nervous functions. His opinions have always appeared to me very sensible, and they were accordant to the philosophy of his own times. He says, Si vero, cogitata nostra de ipsa natura spirituum proferre juberemur, activum ad motum, a voluntate et a sensu concipiendum, aptissimum, celerrimum, omne sensuum acie subtilius, tamen hactenus igne et æthere, et electro, et magnetica materie crassius facere elementum, ut et contineri vasis et a vinculis coerceri aptum sit: et denique manifestum ex cibis nasci et reparari queat.

Mr. Hunter's opinion of a subtile and mobile substance, inhering in the nervous chords, is not essentially different from that of Haller. He does not indeed sup-
pose it to be confined in tubes, neither
does the philosophy of the present time
require such a supposition, for no one at
present will doubt that a subtile substance
may be attached to or inhere in a chord
without mechanical confinement. Will not
a wire when electrified continue to be so,
if surrounded by non-conductors? Expe-
riments made on the limbs of animals with
electricity, produced in the manner first
explained by Volta, show that different
parts of the body have different conducting
powers. Skin and membrane being very
bad conductors, and brain, muscle, and
blood, being remarkably good ones.

The celerity with which motions are
transmitted from the tangible extremities
of nerves most distant from the brain, and
the celerity with which volition is trans-
mitted to the muscles in consequence of
sensations thus induced, are sufficient to
convince us that such effects must be
produced by the motions of a very mo-
bile substance. It is not necessary to
suppose that when such motions are trans-
mitted along the nervous chords, an evident motion of the visible matter of those chords should be induced. Electrical motions take place along a wire without occasioning any visible motion of the metal itself.

Formerly, it was thought that the motions of the nerves that cause sensation, were the effect of an impulse made on their tangible extremities, which was propagated along the chord to the brain. It seems to be an improvement in modern physiology, to attribute sensation to an action begun in the nervous fibrils, in consequence of the stimulation which they suffer from such impulses. This opinion is contended for by Dr. Darwin, in his paper on ocular Spectra, published in the Philosophical Transactions; and Sir Everard Home has further shown, that the living principle of nerves has an irritability belonging to it, resembling that of muscles, and capable of causing a contraction in them when they are divided.*

* Croonian Lecture.
The opinion that sensation is the consequence of an action begun in and transmitted through the nervous fibrils, assists us in understanding how our sensations may be very vivid from the slightest impulses; such, for instance, as take place in the application of odour to the olfactory nerves, for it is not the impulse, but the consequent action, that is transmitted to the sensorium: and why we may have no sensation from the most violent impulses; for such we cannot but suppose to occur, when a man is shot through the body, or has a limb removed by a cannon-ball; occurrences which have, however, happened without any distinct feeling intimating the event.

In supposing a principle of life in nerves, similar to what is conceived to exist in muscles, we might naturally expect to find certain analogies of functions in those organs. The facility, celerity, and accuracy of the nervous actions, seem like those of the muscles to be improved by use; as is exemplified in the quick and correct per-
ceptions of those who are accustomed to exercise their auditory nerves in attending to musical sounds. A train of nervous actions having often taken place, they, like similar actions in muscles, become concatenated, and are liable to occur in succession, when one of them is accidentally induced. Both nerves and muscles require temporary respites from action, and are refreshed by sleep.

The supposition of actions occurring in the nerves, explains many circumstances connected with diseases. Vehement actions may occur in the tangible extremities of nerves, independent of impulses, and occasion severe pain. This seems to happen in the disease called tic douloureux. Ordinarily, actions beginning in the tangible extremities of nerves, are regularly transmitted to the brain; but in cases of nervous pains, actions sometimes seem to begin in the middle of nerves; and it is probable, that actions beginning in the sensorial extremities of nerves may be pro-
ductive of illusory sensations, and excite fallacious ideas.

If this theory of nervous actions could be proved, the extent of our knowledge would only lead to this conclusion, that motions of a subtile substance, propagated to and fro in the nervous fibrils, take place in consequence of excitation by impulses and volition; but from such motions, it seems impossible to account for sensation or volition. We can conceive no variety in these motions, but what relates to degree, duration, and succession, and it seems impossible to believe that sensation can be the result of such motions, or that ideas can arise from any succession or train of them. Certain persons will, therefore, I doubt not, continue to think that sensation, remembrance, comparison, judgment, and volition are properties of some distinct substance.

The essences or primitive parts of what we call matter, are too subtile to be per-
ceived by our senses, and seem even to elude our conceptions. Is it not then most philosophical to acknowledge our ignorance on these points, and to speak of what we do know, the properties of the different species of substances in nature. Thus we seem to be acquainted with the properties of the aggregate forms of that substance which is cognizable to the eye and touch, and which we then call matter; we seem to be assured of the existence, and to know something of the properties, of a subtile substance which pervades all nature; and if we are allowed to know any thing, we surely may be admitted to know the properties of our own minds.

How diversified are our perceptions, how admirably are they adapted to our wants and gratifications! for all beauty of prospect, all melody of sound, all variety of odour, must by the eye of reason be perceived to result from the masses or molecules of surrounding matter, being in various states of motion or of rest:
of which circumstances we have notice by the actions they induce in our nervous fibrils. Such variety of perceptions I can only consider as the effect of the peculiar properties of that which feels, remembers, reasons, and wills, and which seems connected with the brain alone.

The conclusion to be drawn from this examination of the functions of the nervous system is curious and interesting. We perceive an exact correspondence between those opinions which result from physiological researches, and those which so naturally arise from the suggestions of reason that some have considered them as intuitive. For most reflecting persons in all ages have believed, and indeed it seems natural to believe, what modern physiology also appears to teach, that in the human body there exists an assemblage of organs, formed of common inert matter, such as we see after death, a principle of life and action, and a sentient and rational faculty, all intimately connected, yet each apparently distinct from the other.
So intimate, indeed, is the connection as to impose on us the opinion of their identity. The body springs and bounds as though its inert fabric were alive; yet have we good reasons for believing that life is distinct from organization. The mind and the actions of life affect each other. Failure or disturbance of the actions of life prevent or disturb our feelings, and enfeeble, perplex, or distract our intellectual operations. The mind equally affects the actions of life, and thus influences the whole body. Terror seems to palsy all its parts, whilst contrary emotions cause the limbs to struggle, and become contracted from energy. Now, though these facts may countenance the idea of the identity of mind and life, yet have we good reasons for believing that they are perfectly distinct. Whilst, therefore, on the one hand, I feel interested in oppugning those physiological opinions which tend to confound life with organization, I would, on the other, equally oppose those which confound perception and intelligence with mere vitality.
In the first lecture I endeavoured to show that Mr. Hunter's Theory of Life was verifiable, and that it afforded the most rational solution of the cause of irritability, which had hitherto been offered to the public. It now appears that it does not essentially differ from that of the best physiologists, with regard to the explanation it affords of the nervous functions. As it is impossible to review all the phenomena of these functions in a lecture, I shall on the present occasion merely direct your attention to the consideration of one other subject, which is, the opinions we may be warranted in forming, respecting the connection of irritability and sensibility.

This subject has been the cause of much controversy. Haller maintained that irritability was a distinct property inherent in muscles; to use his own words, that they had a vis insita, independent of the vis nervea; which opinion has of late received additional corroboration from some experiments of Mr. Brodie. Those who object
to this opinion, can, I think, only oppose it on the following grounds. They must contend either that the muscles have a kind of perception of injury which causes them to contract, even though they are unconnected with the brain; or that the nerves are the organs which prepare and supply the muscles with something which is the cause of irritability.

Concerning the first of these suppositions, that muscles may have a perceptibility of injury, distinct from that which we understand to be feeling, I have to observe, that we can have no idea of sensation but what results from our own experience, which may be defined to be perception attended with consciousness; which kind of sensation is confined to the brain alone. Of any other kind of perception, it is evident we can never form any idea.

If a man's leg be amputated, and by voltaic electricity I excite contraction in its muscles for some hours, how can I know whether they feel or not? We na-
turally judge of other subjects from ourselves, and knowing that we shrink from whatever pains us, some persons seem to conclude that the muscles contract because they have been hurt. To the patient who has suffered amputation, such a supposition would seem absurd. He may feel pain when no stimulus is applied to the limb, or he may feel ease when it is. Nay, he continues to feel pain, or sensations, in the limb when it is rotten, or no longer in existence; which seems to show the integrity of the sentient principle remaining in the brain.

In vegetables, and in some of the lower kinds of animals, no traces of a nervous system are discoverable, yet the irritability of life is manifest in all. In the ascending series of animals, in proportion as the brain becomes large and complex, we have evidence of the perceptions and intelligence increasing; a circumstance which would lead us to believe that these faculties were connected with that part of the nervous system. We have also equal reason to
believe, that neither such perception nor intelligence is requisite for the mere functions of life, for these appear to be carried on as effectually in animals that have no brains, nay, in those which seem destitute of any nervous system, as in those which possess such organs. Indeed, many of the most vivacious and irritable animals have the least nervous system. The nerves in the lower order of animals, that have no common sensorium, may contribute to produce effects, which, in tracing the ascending series, I have endeavoured to express by the words concurrence of impressions and actions; because intimations of impressions and actions occurring in one part may be communicated to others by these inter-nunciate chords, as Mr. Hunter called them, in cases where we are not warranted in supposing there is any sensation such as I have defined.

Assuredly, motion does not necessarily imply sensation; it takes place where no one ever yet imagined there could be sensation. If I put on the table a basin con-
taining a saturated solution of salt, and throw into it a single crystal; the act of crystallization would begin from the point touched, and rapidly and regularly pervade the liquor till it assumed a solid form. Yet I know I should incur your ridicule, if I suggested the idea that the stimulus of the salt had primarily excited the action, or that its extension was the effect of continuous sympathy. If also I threw a spark amongst gun-powder, what would you think were I to represent the explosion as a struggle resentful of injury, or the noise as the clamorous expression of pain?

Now though chemists may solve the cause of these phænomena, physiologists have yet to learn, and probably they never may learn, why certain actions succeed to certain causes in living bodies. Causes which induce muscular or nervous actions in one part, do not induce similar actions in another. Both muscles and nerves have peculiar habitudes and modes of action, and require the application of various peculiar excitements. Causes which pro-
duce no bad effect upon one person, will have a detrimental influence upon another, and this we say is the result of idiosyncrasy. Thus the odour of a cat, or the effluvia of mutton, the one imperceptible, the other grateful to the generality of persons, has caused individuals to fall on the ground as though bereaved of life, or to have their whole frame agitated by convulsions. Substances which induce disease in one person or animal, do not induce disease in others. That pain is not the cause of action, is I think evident. Nervous motions, induced by the will, cause our muscles to act, but such motions occasion no sensation in the obedient muscles. When, therefore, we employ the terms in common use of a stimulus being applied, and an action or disease excited, we should remember that neither the infliction of pain, nor absolute injury, is essential to the production of such consequences.

With respect to the second proposition, into which I have resolved the objections
that may be made to Haller's opinion of irritability being independent on sensibility, I have only to remark, that the effects of pressure made on nerves, as well as other observations, have induced the general belief that some fluid or energy pervades the nerves for the supply of the body. Pressure on a nerve benumbs and paralyzes the parts which it supplies, which regain sensation and motion on the removal of the pressure; yet if irritability exists in vegetables and some animals that have no nervous system, it shows the possibility of irritability being produced without the intervention of nerves.

It has been my object to show that Mr. Hunter's Theory of Life is a verifiable Theory, and that it affords the most rational explanation of the phænomena of irritability, and of those nervous functions that have been considered. It is, however, impossible in the compass of a lecture, as I have before observed, to review all the phænomena of the nervous functions, which it is necessary to do in order
to establish it as a rational Theory. The contemplation of this subject at large, is fitter for meditation in the closet than for discussion in the lecture-room. I shall, therefore, merely mention by way of exciting attention to some of the phænomena alluded to, that it seems impossible to account for those which Mr. Hunter considered as the effect of sympathies between remote organs, or for those consequences of idiosyncrasy which have been mentioned, upon any other supposition than that of a subtile substance, prone to act, or liable to fail in action, pervading the body, the affections of which can with electrical celerity be propagated throughout the system.

I have further to show that Mr. Hunter's Theory of Life is adequate to explain the cause of the prevention of putrefacation, and the regulation of temperature. If the vital principle of Mr. Hunter be not electricity, at least we have reason to believe it is of a similar nature, and has the power of regulating electrical operations. That
electricity is the great chemist both in organized and unorganized bodies, will be generally credited; and that the power which combines may also prevent decomposition, is too obvious to need discussion. That electricity is capable of augmenting and diminishing the temperature of unorganized matter is well known. Does not platinum-wire drop like wax infusion when it intervenes between the different ends of the voltaic battery? and do not the spherules of rain fall to the ground at midsummer as firmly frozen as in the depth of winter, when they pass through a stratum of air refrigerated by electrical operations? I believe I need say no more on these subjects.

The varying and the strong retention of life by seeds, and some kinds of vegetables and animals, are facts which seem more satisfactorily solved by Mr. Hunter's Theory of Life than by any other.
Impressed with the difficulties of the task I have undertaken, of giving lectures in the presence of men of superior knowledge and talents, respecting subjects on which every one has formed his own opinions, which of course he thinks correct; though desirous of fulfilling the design of these lectures to the extent of my ability, I feel unable to display the subjects of them in any other way than that to which I have been accustomed. Thinking, as Mr. Hunter taught, with regard to life and its functions, in health and disorder, I must use his language as expressive of the phænomena we observe. That an attention to the sympathies of parts and organs is necessary to our understanding disorder and disease, I shall hereafter endeavour to show. That Mr. Hunter did observe these sympathies in a manner and to an extent that surprized most professional men, is well known to all those who were present at his lectures on
this subject. Their surprize was indeed natural, because they were not then fully acquainted with his views and motives.

I mention these things, because I am aware that there are some who say sympathy is a term without any direct meaning, and that all which Mr. Hunter said on the subject of life, explains nothing. What Mr. Hunter meant, I believe I understand; what persons of different sentiments, whom I acknowledge possess great information and ability, mean, when they talk in this manner, I am not so well able to discover. They seem to deny that life can be any thing which may not be seen or felt. They seem to wish us to believe that they have that philosophical turn of mind which exempts them from vulgar prejudices, and that no Theory appears to them satisfactory, neither do they propose any for our adoption.

Thinking being inevitable, we ought, as I said in the beginning, to be solicitous to think correctly. Opinions are equally the
natural result of thought, and the cause of conduct. If errors of thought terminated in opinions, they would be of less consequence; but a slight deviation from the line of rectitude in thought, may lead to a most distant and disastrous aberration from that line in action. I own I cannot readily believe any one who tells me, he has formed no opinion on subjects which must have engaged and interested his attention. Persons both of sceptical and credulous characters form opinions, and we have in general some principal opinion, to which we connect the rest, and to which we make them subservient; and this has a greater influence on all our conduct. Doubt and uncertainty are so fatiguing to the human mind, by keeping it in continual action, that it will and must rest somewhere; and if so, our enquiry ought to be where it may rest most securely and comfortably to itself, and with most advantage to others? In the uncertainty of opinions, wisdom would counsel us to adopt those which have a tendency to produce beneficial actions.
If I may be permitted to express myself allegorically, with regard to our intellectual operations, I would say, that the mind chooses for itself some little spot or district where it erects a dwelling which it furnishes and decorates with the various materials it collects. Of many apartments contained in it, there is one to which it is most partial, where it chiefly reposes, and where it sometimes indulges its visionary fancies. At the same time it employs itself in cultivating the surrounding grounds, raising little articles for intellectual traffic with its neighbours, or perhaps some produce worthy to be deposited amongst the general stores of human knowledge.

Thus my mind rests at peace in thinking on the subject of life, as it has been taught by Mr. Hunter; and I am visionary enough to imagine, that if these opinions should become so established as to be generally admitted by philosophers, that if they once saw reason to believe that life was something of an invisible and active nature superadded to organization, they would
then see equal reason to believe that mind might be superadded to life, as life is to structure. They would then indeed still farther perceive how mind and matter might reciprocally operate on each other by means of an intervening substance. Thus even would physiological researches enforce the belief which I may say is natural to man; that in addition to his bodily frame, he possesses a sensitive, intelligent and independent mind: an opinion which tends in an eminent degree to produce virtuous, honorable, and useful actions.

THE END.
PART OF THE
INTRODUCTORY LECTURE
FOR THE YEAR 1815,
EXHIBITING SOME OF
MR. HUNTER'S OPINIONS
Respecting Diseases.
DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS,
IN LONDON.

BY JOHN ABERNETHY, F.R.S.
PROFESSOR OF ANATOMY AND SURGERY TO THE COLLEGE.

PRINTED FOR LONGMAN, HURST, REES, ORME, AND BROWN,
PATERNOSTER-ROW.

1819.
ADVERTISEMENT.

The following Sheets comprize only an Extract from the Introductory Lecture of the present year, which is designed to explain some of Mr. Hunter's opinions respecting Diseases.

The pages are numbered, in continuation with those of the Introductory Lectures of the preceding course, printed last year, in order that the whole may be bound together.
INTRODUCTORY LECTURE.

1815.

I purpose on the present occasion, to take a general review of the subjects, which engaged our attention last season; and, to offer some comments upon them.

In the preceding year, I first exhibited the facts I had collected, relative to those general disorders of the system, which are so frequently produced by local disease, injury, or irritation. These Mr. Hunter considered to be the result of universal sympathy, of that sympathy which the whole system seems to have with its seve-
ral parts. In each of these disorders, indeed, it is evident that the whole system is affected; the nervous functions are impaired or disturbed; as are also those of the digestive organs, and of the sanguiferous and secreting systems. Yet we denominate these general disorders from their most prominent character. Thus, when the sanguiferous and secreting organs are chiefly affected, and the temperature of the body is subject to considerable variations, we call the disorder fever. Of fevers, some are violent or inflammatory, but of short duration; some more languid and continued, becoming as it were, habitual or hectic; and there are others, in which the actions are vehement, though the powers are feeble; these cannot be long continued, for they are speedily destructive of life: the last also frequently so strikingly resemble Typhus, as not to be distinguishable from that fever when it
arises from other causes. I also further shewed that the same local excitements would produce intermittent and rheumatic fevers; and occasion still more diversified and unexpected disorders.

Now, here I would ask, to whom do we owe the first luminous demonstration of this subject; who, first with the eye of a physiologist, surveyed the reciprocal sympathies of the several organs of the body, and shewed how the most complex disorders may and do arise from simple causes? Was it not Mr. Hunter? Allow me, further to enquire, does no good result, from this physiological exhibition of the subject? Its utility might be explained by numerous instances, but I shall restrict myself to one. When we see that a compound fracture, in a susceptible and debilitated patient, may so disorder the
nervous functions, that all the organs and parts of the body are affected as in that complicated malady a typhus fever; can we longer feel surprized that disorder of the digestive organs and poisonous miasmata should equally and similarly impair and disturb the energies of the nervous system, and occasion this identical fever. Does not this discernment of the causes and nature of diseases, lead to a just appreciation of various remedies, and to judicious practice?

Whilst considering the constitutional effects resulting from what Mr. Hunter called universal sympathy. I further shewed that the nervous disturbance, induced by local irritation of remote parts, might produce effects more or less general upon the nervous and muscular systems, without so materially affecting the other organs of the
body as to engage the attention of common medical observers; and here I spoke of pain, sickness, swooning, rigors, convulsions, delirium, and tetanus.

Lastly, in considering the effects resulting from these sympathies, I shewed how the nervous disturbance might affect the feelings and functions of the digestive organs, and how the disorder so induced, might by a reflected operation, augment the former and greatly and variously disturb the whole system.

This subject had indeed particularly attracted the attention of Mr. Hunter, who believed that the stomach had a direct sympathy with remote organs and parts of the body; whilst he equally observed, how it might reciprocally affect and be affected by the head. It was on this account, probably, that he was led to call the stomach the
center of sympathies, a term, which such observations, if correct, would render particularly apt and expressive.

The full importance of this subject, could not, I think, have been discovered by the most acute physiological observation. It has been, however, manifested by the results of medical practice, which shew that if the disordered feelings and functions of the digestive organs be removed, the greatest degrees of nervous disorder, will sometimes suddenly cease; at others, will be greatly mitigated, and gradually subside; clearly proving, that in such cases, the one derangement is the cause of the other.

To this subject, I particularly claimed your attention, because, it seems to me perfectly demonstrable, that the continued and aggravating irritation which the brain and abdominal viscera, when disordered,
impart to each other, is productive of a state of constitution, of which, (to express my notions in the briefest way I could,) I said, that it proved the fruitful parent of a numerous and dissimilar progeny of local diseases. On this account, the disorders of the digestive organs should become an especial object of attention, in the treatment of local diseases; for it is in vain to expect that such diseases, which may be considered as effects, should admit of cure, whilst the causes that produced them, are left to operate in force sufficient for their maintenance or their production in other parts of the body.

Having thus considered the nature and treatment of constitutional maladies, so far as the subject is applicable to the practice of Surgery; I proceeded in the next place, to speak of local diseases, and first, of those which often arise spontaneously, though they
may sometimes be induced by external injury, and which also may occur in almost every part of the body.

Here too, it may be observed, that the whole of the local affected district is disordered; that the nervous functions and vital energies of the part, are either impaired, excited, or disturbed, and that the functions of the vascular systems of the part are also deranged. Yet here, likewise, we denominate the disorder from its most prominent character; thus, when the sanguiferous system is chiefly affected, we name the disease Inflammation. Of inflammations, as of fevers, it may be observed, that some are violent and of short duration; some languid and continued, or chronic; whilst, in others, the actions are vehement, though the powers are feeble, and the latter cannot be long continued, for if they do not soon
subside, they destroy the life of the affected part.

We seem to consider violent or phlegmonous inflammation, to be simply the result of an increased action of vessels, though, probably this disease has its varieties; in the other species of inflammations, the varieties, are evident and numerous. In chronic inflammation, we sometimes see the substance deposited in consequence of the increased action of vessels, such as is usually poured out in cases of simple excitement, and the subsequent organization, is also of the common kind; whilst in other instances, we observe the deposited substance to be very various in quality, either not admitting of, or not acquiring organization. Again, in other cases, when organization takes place, we observe, the structures produced, to be very various in their appearances and nature, and thus monstrous
growths are formed, such as had no existence in the original compages of the body. When such morbid growths occur in the different organs of the body, their apparent bulk becomes enlarged; but their natural structure and functions are diminished, and may ultimately be destroyed.

As we find the same sorts and varieties of growths, taking place from the same causes in the midst of the common tissue, that connects the various parts of the body, I was led to speak of Tumours, though, by this means, it became necessary to consider several diseases, which might, perhaps, with more propriety have been reserved, for discussion at a future period. Here, however, the natural connexions of subjects were so strong, that no artificial concatenation, appeared so well adapted to fulfil the chief object of arrangement, that of preserving and displaying every fact relating to the subject.
I next described what I called irritative inflammation, of which there are many varieties, and they were briefly noticed. Erysipelas was separately spoken of, because we usually distinguish it as a readily recognizable species of inflammation, allied in its nature to those of the irritative kind.

Lastly I spoke of Mortification as an event like suppuration peculiar to no individual disease, but a common termination to many. It is the result of simple weakness; of want of action; of excessive action; and of other causes; and consequently requiring a proportionate variety of treatment. On this subject, I could not forbear starting an opinion, which some may think whimsical, and others absurd, even before this critical and learned assembly. I asserted, that mortification was not unfrequently the result of nervous disorder in the affected part, and further affirmed that I was well ac-
quainted with the family from which this disorder, with the subsequent alarming disease, was descended; that it was one of the numerous and dissimilar progeny of the common parents of local diseases; that it was a short lived bantling, engendered by the reciprocal and aggravating irritation of disordered states of the digestive organs and nervous system on each other. It therefore followed that local applications were of little avail in this species of mortification, and that the removal of the exciting causes were the chief means of procuring a diminution and ultimate cessation of such effects.

In various parts of the lectures, I endeavoured to impress a distinction between disorder and disease. In disorder, the vital energies of parts are impaired, or excited and disturbed, as is manifested by errors in their feelings and functions. Disorder
may therefore be said to be nervous, and parts may thus perish without struggle or reaction; without inflammatory processes, or with so trivial a degree of them as could not by itself destroy vitality.

To support these opinions by additional evidence, I would direct your attention to what happens in a disordered state of the stomach. Are not its feelings and functions disordered? By feelings, I do not mean those of actual pain; there may be inquietude without the patient's observing it, though, in general, uncomfortable sensations are remarked, particularly if the attention be excited to them. In such a disordered condition of the stomach, are not the secretions deficient or vitiated: and is it not, therefore, incompetent to perform its functions? We now know, for of late it has been demonstrated, that secretion is regulated by the nervous energies.
Am I not then warranted in asserting, that disorder is nervous, and that it is manifested by errors in the feelings and functions of the affected parts? Such a disordered state of the stomach as I now allude to, is also competent to induce sympathetic disorders in other important organs, and greatly and variously to affect all parts of the body.

Now here I beg leave to enquire, who first led the way in noting the various sympathies of the different organs and parts of the body? Was it not Mr. Hunter? Many of my audience may not know that three or four of his lectures were occupied in recording the different facts he had collected relative to such sympathies. They were arranged under heads, as Sympathies of Life with Life; of Sensation with Sensation; of Action
with Action; including all their changes and combinations. I candidly acknowledge the reflection which these lectures induced in my mind. How extraordinary a man, thought I, is this, who could bestow such surprising labour on so hopeless a subject. I also candidly acknowledge that I now think, as probably the comprehensive and discerning mind of Mr. Hunter then perceived, that much good may eventually be derived from patient and accurate observation with respect to this subject. We find many disorders and consequent diseases arise from sympathy, and that the organ sympathetically disturbed, often suffers more than that originally affected. Yet its disorder may not be susceptible of cure by medical treatment, whilst the cause remains. Our attention ought, therefore, to be directed in such cases to appeasing irritation, and giving tone and tranquillity to an organ of which
the patient perhaps makes no complaint, but which is the cause of the more evident and important malady.

To me the philosophical turn of Mr. Hunter's mind is demonstrated by his caution; with all his facts relating to sympathy, he formed scarcely any general conclusions. He distinguishes it into the continuous, contiguous, and remote. The two former are readily explicable. Of the latter, I, who have less caution, or more facts of a certain description than Mr. Hunter might have possessed, do not hesitate to say, that when injuries or disease of limbs bring on fevers, delirium, convulsions, or tetanus, or disturb the feeling and functions of the digestive organs, that these effects are produced through the medium of the brain. Whether sympathies can take place in a more direct or less circuitous manner, may be proposed as a
question which I should thus answer. When organs are supplied from the same plexuses or ganglia, it is reasonable to suppose they may participate in each others disorder; on this principle, the whole of the digestive organs might rationally be supposed to sympathize with one another, and also the whole of the organs contained in the pelvis; disorder of the stomach might be supposed likewise to affect the æsophagus, lungs, larynx, and tongue, in consequence of those nervous communications with which we are well acquainted. But it may further be enquired, can sympathetic feelings occur between parts where we have not been able to trace such nervous communications, or how do those strange sympathies occur, and become established in disorder and disease, which we never observe in health? To me it is evident, as it was to Mr. Hunter, that the stomach has a
direct sympathy with the most distant parts of the body; and that the heart sympathizes with the stomach; but in what manner such sympathies are produced, or how the morbid and irregular sympathies which occur in diseases are occasioned, we presume not to explain. Yet if Mr. Hunter's opinions of the nature of life be true, none of these facts can well be considered as surprising.

Disorder, which is the effect of faulty actions of nerves, induces disease, which is the consequence of faulty actions of vessels. There are some who find it difficult to understand how similar swellings or ulcers may form in various parts of the body, in consequence of general nervous disorder, and are all curable by appeasing and removing such general disorder. The fact is indisputable. Such persons are not so much surprised, that general nervous
disorder should produce local effects in the nervous and muscular systems; yet they cannot so well understand how it should locally affect the vascular system. To me there appears nothing wonderful in such events, for the local affection is primarily nervous, and the vascular actions are consequent. Yet it must indeed be granted that there may be other circumstances leading to the peculiarities of local diseases, with which, at present, we are unacquainted. Disorder excites to disease, and when important organs become in a degree diseased, they will still perform their functions moderately well, if disorder be relieved; which therefore ought to be the alpha and omega of medical attention.

Such were the subjects I endeavoured briefly to explain during the preceding season. I have thus led you to the place where we stopped, and from which we are
now to proceed. Previously, however, to our advancing, allow me to enquire, who first explained in a physiological and satisfactory manner the diseased processes I have referred to, the formation of abscesses; the secretion of pus; the interstitial and other growths; the causes and circumstances of mortification? Was it not Mr. Hunter? We now hear no more of those ancient metaphors concoction and erosion, but we find all the morbid changes accounted for by the perverted action of the ordinary powers and structures of parts; clearly perceiving that the same powers and organisation, which by their natural and common actions produce health and beauty of appearance, do, when perverted, occasion disease and deformity.

Again, too, when we survey the infinite diversity of local diseases, how can we express ourselves, but in the language
of Mr. Hunter, by saying, that they are the result of peculiar or specific actions? To explain my meaning with respect to this subject, I must request you to advert to the labours and opinions of preceding physiologists. Were they not looking for mechanical contrivances, to account for the peculiar secretions which different glands produced? Ruysch displayed the pennicillous, the stellated, and contorted arrangements (called the acinous structure) of the minute and probably secreting vessels of different glands. I also am persuaded that Mr. Hunter, when he put the pieces of talc within the tunica vaginalis of a ram, and withdrew them successively to ascertain how soon the secreted fluids acquired the puriform character, did, when he afterwards examined the parts, observe them with particular attention, in order to discover whether some peculiarity of structure had not preceded this peculiarity
of secretion. Baron Haller, however, expressly asserts the opinion, that actions, living actions, have a great share in causing the peculiarities of secretions, and the changes we observe in them. But the direct proof of this fact remained to be exhibited to the public by Mr. Hunter. It was by observing the peculiarity of the local actions, and consequent secretions resulting from the application of different morbific poisons, that this subject was placed in a clear and distinct point of view. In such cases the same structure may be very variously affected, producing different forms of disease, and various kinds of secretions. I do not dwell upon the subject, because the facts and inferences have not as yet been laid before you.

I bring forwards Mr. Hunter's opinions on these subjects, at present, merely to shew what notions we are warranted in
forming, relative to the causes of such an extreme diversity of local affections, either of an inflammatory or other character. If actions can be peculiar and specific, if the effect of them can be that of producing various forms of disease, and qualities of secretions, when such actions are excited by peculiar stimuli; is it not probable that the actions which occur in parts, the feelings and functions of which are disordered, may spontaneously assume a peculiar character, and thus give rise to the diversity of diseases? We have, as I shall afterwards shew you, in some cases positive evidence in proof of this proposition.

Now when the terms specific and peculiar actions were employed by Mr. Hunter, to designate facts which have not, and as I believe cannot be otherwise expressed, persons, who seem to me to employ their minds rather in preventing than in pro-
moting the progress of science, who object to every thing new, and suggest nothing, boldly asserted them to be absurd. They sage-ly observed it was impossible that there could be any peculiarity of action; because ves-sels could only act more or less forcibly or frequently. Now when Mr. Hunter makes use of the phrase peculiar action of vessels, I am sure he meant more than he ex-pressed, and employs it only on account of brevity. For he thought that life was the cause of the actions of vessels; that it pervaded the fluid blood, and the gelati-nous and albuminous solids; that it built up the very organisation by which it effected its subsequent functions; that the life of vessels could modify their con-tents: that life was the cause of the various secretions, and the forms and phenomena we observe both in health and disease.

I am persuaded Mr. Hunter's notions of
disease cannot be apprehended, unless his opinions respecting life be previously understood, and, therefore, did I deem it necessary, in the first place, to endeavour to explain his doctrines on that subject. There is an obscurity in his writings, and his meaning cannot always be perceived, unless by that kind of illumination which is derived from a continual reference to his elementary opinions concerning vitality. With such elucidation, however, it may be discerned that in the lectures I last year had the honor of addressing to you, I did little more than deliver Mr. Hunter's opinions respecting diseases. Surely, He must have been a strong and clear sighted man, to see so far through obscurity; for till very recently no light had ever shone upon these subjects, but of late the vital functions have been so far illuminated, that any one who pleases may see that Mr. Hunter has
pourtrayed them, both in health and disease, with a distinctness and accuracy highly creditable to his penetration and discernment.

It seemed to me proper on this occasion to review the subjects which engaged our attention during the preceding year, to lead you to the point where we stopped, and from which we are to proceed. Yet this review has occupied so much time, that I fear I cannot to day finish even one of the subjects next in succession; besides, I suspect it may have disqualified both myself and my audience from paying that close attention to them which is required in order to understand them. There is no class amongst the students of nature that ought more particularly to attend to the advice of Bacon, than that of surgeons. To look closely and intently at the subjects they are engaged in examining, in order
to discern what nature may perform or endure. Yet when the eye has been long employed in viewing distant objects, it does not speedily regain its myoptic powers, and adapt itself for such a scrutiny as we are next to take. I am, therefore, induced still to detain your attention to general topics.

The works and writings of Mr. Hunter have now been long before the public, so that all may be supposed equally qualified to form their own opinions of his merits, and pertinaciously to persist in eulogizing his character, may seem like arrogating to myself a power of judgment, and denying it to others. It is, however, the opportunities I have possessed, that have been the cause of the peculiarity of my sentiments and opinions; for I am old enough to remem-
eral promulgation of the new facts and opinions he added to the stock of professional knowledge, and I believe him to be the author of a great and important revolution in medical science; of this I am certain that his works produced a complete revolution in my mind. Can I then do otherwise than acknowledge it? If I have to deliver facts and opinions which I am conscious I derived from another, can I appear before any audience, either of students or brethren in the profession, like the vain daw decorated with another's plumes, and liable to be detected and convicted as the very worst of pilferers, the purloiner of another's reputation. I should be ashamed on any occasion to feel either reluctant or afraid to render honor and praise to whom they are due, and in my opinion they are eminently due to Mr. Hunter.

Believing Mr. Hunter to have possessed
that rare combination of qualities, which, whenever it occurs, constitutes an eminent character, I mean genius, reflection, and industry; and that he has made a most important revolution in science; I cannot but regret the obscurity and intricacy of his language, which prevents his merits from being duly appreciated, I have furnished you with the only clue I know of to guide you through the labyrinth.

There are some who possessing great powers of reflection, and accuracy of judgment, yet from deficient knowledge of language, and of the generally received or adapted modes of forming opinions, or from not paying attention to the processes of their own minds in forming conclusions, are unable to explain their thoughts to others. I am ready to grant that there is an obscurity in Mr. Hunter's writings,
the result even of perplexity of thought. I know not how I can express my notions of the cause and effect of this obscurity more briefly and clearly than by a kind of metaphor, I have been accustomed to use on this occasion. The products of the fermentation of that mixture of knowledge and talent which there was in the mind of Mr. Hunter, seem to me to have been completely formed. Yet the mass still remained in commotion, and sufficient time had not elapsed to allow of those products becoming perfectly clear. If I have not overrated the value of such products, I may urge some claim to approbation for having carefully collected and filtered them. To express my meaning without metaphor, for having sedulously endeavoured to make out Mr. Hunter's opinions, and tried, at least, to express them more distinctly. I heartily wish, indeed,
that his opinions had met with a better expositor; for I, like him, have been an unpremeditated author, who never learned the art of literary composition.

May I, however, venture to suggest another reason why some do not understand Mr. Hunter. If we wish to learn what another thinks, we must dispose our minds to receive instruction in the very manner it may be conveyed to us. We must relinquish, for a time, all attention to our own opinions, in order to learn those which are to be communicated. The same processes of mind must be gone through, or the same results cannot be obtained; we must follow in exactly the same steps, or we shall never arrive precisely at the same point. It is a very ancient observation, that self-conceit opposes a constant and sometimes an insurmountable barrier to instruction. "Seest thou a man wise in
his own conceit, there is more hope of a fool than of that man." Under the influence of these considerations, I do not wonder that young men, who will not take the pains necessary even to learn what Mr. Hunter thought respecting life, should be unable to understand his general writings, and suppose others to be as incapable as themselves.

I should not doubt of being able to induce any one, who had previously no decided objection, to think as I do respecting Mr. Hunter. Only a few of the facts on which I found my opinion of his character are at present before you; you must know them all, ere you can think and feel exactly as I do. Conscious that I may tire, nay even displease you, by thus obtruding my individual sentiments, resolving never to trespass on your patience in the same way again; but hereafter undeviatingly to pur-
sue the regular and beaten path of sober tuition, may I now claim your indulgence for a short time, whilst I advert to some other subjects, in which Mr. Hunter has done our profession and mankind in general important service.

When the description of the inflammatory diseases is concluded, the next subject that will engage your attention is that of Diseases which the absorbing vessels are principally concerned in producing. To detach all the facts and opinions of Mr. Hunter, relative to this subject from the different parts of these lectures, and review them at present would be tedious and unprofitable; suffice it then to say, that in perfecting the knowledge of the physiology of the absorbing vessels, all nations allow great merit to the English. On this ground, even the French seem to admit the triumph...
of English physiology. But by whom were we led on to this victory? By whose personal exertions was the laurel won? Surely by Mr. Hunter.

In the next succeeding subjects, the diseases induced by the action of poisons on the animal frame, when I consider the number and importance of the facts first noticed, and the inferences first drawn by Mr. Hunter, together with the consequences which have resulted from them, I must regard him, even if he had done nothing else, as a most important benefactor to our profession, and to the public.

I shall advert to no other subjects but merely add, that there is one sentiment which ought, I think, to attach every English surgeon to the memory of John Hunter. It is that esprit de corps which
belongs to all associations of mankind. We should be grateful to him for he has exalted us, he has dignified our profession. Baron Haller commenting on the character and conduct of surgeons in general, expresses his surprize, that no one has been particularly eminent in that profession*. To me it would have been surprizing had it been otherwise, considering the debased condition into which the profession had sunk, and in which it had remained for ages. I admit, that surgery was gradually rising, and would eventually have obtained its proper level amongst sciences; when Mr. Hunter suddenly raised it to its present ele-

* In chirurgicis, nescio quomodo factum est, ut vix unquam perinde ut in aliis medicinæ partibus magnis alicuis vir eminuerit, qui late posteros sequaces habuerit.

(Bibliotheca Chirurgica Init. Tom. 2.)
vated situation from which it can never be removed.

Mr. Hunter became a physiologist, and to become such a physiologist as he was, it was necessary that every variety of structure and of function should be surveyed in every variety of living being; that nature and nature's laws should be examined with the most minute attention, and upon the most extended scale; that parts should be observed with microscopic scrutiny, and yet that comprehensive views should be taken of the whole. Afterwards, with the enlightened eye of a physiologist, he surveyed the perverted actions of living bodies in the production of diseases.

Thus did he make surgery a science. It is the knowledge of health that enables
us to understand the nature of disease. He connected pathology with physiology, and it is impossible in future ever to disjoin them. He raised a solid and permanent pillar of physiology, and he placed surgery on the top, where it must ever remain equal in rank and elevation to any other science, perhaps superior in utility to all. By so doing, it may, I think, with truth be affirmed of him,

— opus exegit, quod nec Jovis ira, nec ignes
Nec poterit ferrum, nec edax abolere vetustas.

There is no path to scientific improvement in our profession, but that which Mr. Hunter trod. It is the path of physiology. It is now fairly laid open to you. He has been your pioneer. Enter, and in proportion as you pursue it with vigour and constancy, so will you arrive at knowledge, and obtain renown. Do this; and it is
certain, no future Haller will have cause to express surprize, that Surgeons have been undistinguished characters, in the medical profession.

TO

THE RIGHT HONOURABLE

Sir JOSEPH BANKS, Bart. K.B. &c.

DEAR SIR,

To you, the Patron and Friend of John Hunter, I dedicate this inadequate attempt to delineate his character and labours.

Permit me at the same time to assure you of my great respect, and also of my gratitude for various acts of friendship and kindness which you have conferred on me.

I have the honour to be,

DEAR SIR,

Your much obliged and obedient Servant,

JOHN ABERNETHY.
LECTURE I.

After resolving to write no more lectures, nor longer to praise Mr. Hunter, I break this resolution; yet my conduct seems to need no apology, for if my first decision was wrong, it is creditable to retract it; and if I am now wrong, it is probable I shall soon discover my error, the candid acknowledgment of which would then be far better than ingenious excuses.

I have praised Mr. Hunter for his Theory of Life, because it is a probable one, cautiously and philosophically deduced, and adequate to explain the phenomena. Therefore am I directed by the precepts of philosophy, and also induced by other
reasons, which I have partly explained in my first Lectures, to uphold it as a good theory, till a more satisfactory one be discovered. I have praised him, because his perception of the healthy state of the vital processes enabled him to discern and investigate the causes and effects of disorder and disease in a manner and degree that have produced a most important revolution in medical science. I now mean to praise him for the great labour of his life, his Museum; which I may call the principal record of his deeds and opinions.

Hitherto I have endeavoured to make the Anatomical Lectures subservient to the surgical subjects I had afterwards to discuss. Finding myself rather at a loss for such topics, particularly because this theatre is unsuited to anatomical demonstrations, it occurred to me, that it might be useful to represent to my present audience, what were the peculiar improvements Mr. Hunter made in Physiology, and also the degree of perfection to which he brought that science.
No study can surely be so interesting as Physiology. Whilst other sciences carry us abroad in search of objects, in this we are engaged at home, and on concerns highly important to us; in enquiring into the means by which we live, and move, and have our being. To those however, engaged in the practice of medicine, the study of Physiology is indispensable; for it is evident that the nature of the disordered actions of parts or organs can never be understood, nor judiciously counteracted, unless the nature of their healthy actions be previously known.

The study of Physiology, however, not only requires, that we should investigate the nature of the various vital processes carried on in our own bodies, but also that we should compare them with similar processes in all the varieties of living beings; not only that we should consider them in a state of natural and healthy action, but also under all the varying circumstances of disorder and disease. Few, indeed, have studied Physiology thus extensively, and
none in an equal degree with Mr. Hunter. Whoever attentively peruses his writings, must, I think, perceive that he draws his crowds of facts from such different and remote sources, as to make it extremely difficult to assemble and arrange them.

I am the more particularly induced to follow Mr. Hunter through the separate examination of the principal vital functions, because I know his notions of life were deduced from considering them severally and conjointly. I hope therefore to be able, by such an examination, to convince you of the truth of his opinions on that subject; for I hear there are some who still say they think them either unintelligible, or inadmissible. If these opinions be not understood, his works, I am persuaded, will remain obscure. They seem to me like writings in a cypher; his notions of life forming the only key by which they can be intelligibly read. Yet, to examine the vital processes, as Mr. Hunter has done, it is necessary to refer to the facts contained in his Museum; and to commemorate his labours
as a comparative anatomist, which it is particularly incumbent on some of us to do; for so little have they been revealed to the public in general, that even Professor Cuvier has declared, he knew not that there was such a collection as the Hunterian Museum.

To display the talents and labours of Mr. Hunter in forming his Museum, it seems proper, in the first place, to notice those circumstances which led to this great undertaking: for great indeed must it be accounted, when it is considered, that it was accomplished by the labour, and at the expense, of an individual. Mr. Hunter was the first in this country, and I believe I may say in any country, who studied Comparative Anatomy and Physiology extensively, in order to perfect the knowledge of our own animal economy. I admit, indeed, that Baron Haller was fully apprised of the advantages likely to result from this proceeding, and that he himself had prosecuted the same mode of enquiry, to a certain degree. I am also aware, that many men may have explored the structure and
functions of particular tribes of animals even more fully than Mr. Hunter himself has done. I am aware, that when the Count de Buffon engaged in his work on natural history, he might have excited Daubenton to a general investigation of the structure and functions of all the varieties of living beings; and that Professor Pallas might have followed the steps of Daubenton, and traced the subject generally and extensively. But, I am not apprized that any systems of Comparative Anatomy and Physiology were published before those of Professors Blumenbach and Cuvier. Neither can I believe it possible, that such enlarged and interesting views of the structure and functions of living beings in general, could have been formerly contemplated and not displayed by any man except by Mr. Hunter, who experienced such great difficulty in communicating what he knew, was never satisfied with the extent of his knowledge, and who cultivated Physiology, only as preparatory to the still more important science of Pathology. Of late years, many persons have engaged in
the study of Comparative Anatomy and Physiology, and they seem to feel like the discoverers of a new path in science, which they pursue with animation and energy, as promising to lead them to some advantageous and commanding situation, from which they may eventually discern the whole order and course of nature in the most interesting part of her works, the formation and functions of living beings. Yet this is the very path which Mr. Hunter trod, unobserved, and in silence, with constant and accurate observation, and profound meditation. It is but just, that some one should say how far he had proceeded, and what were the general results of his observations and enquiries.

Mr. Hunter came to London in the autumn of the year 1748, and was educated to anatomy, during ten years, in his brother's dissecting room. In that time, he made many important discoveries in the structure of the human body, and his at-
tention, from a very early period, being di-
rected to Comparative Anatomy, we find
him subsequently asserting, that among
other researches in this department, he
had in the same interval made prepara-
tions of the organ of hearing in fishes, of
which he claimed the discovery. Mr. Hun-
ter's biographer, Sir E. Home, mentions,
"that his desire to obtain a correct know-
ledge of the functions of the organs in the
human body, first led him to examine the
same kind of organs in various animals."

From his brother's elegant and learned
lectures, Mr. Hunter must have derived
the best physiological information of the
time; the facts and opinions of every
writer, collected, arranged, considered, and
improved by the industry and talents of
Baron Haller, together with whatever later
discoveries or suggestions had been made
in that department of science. When he
went abroad as an army surgeon in the
year 1760, he had an opportunity of ac-
quiring a knowledge of the animal pro-
ductions of other countries, and of their
surrounding seas. But he had neither time nor opportunity for the collection and display of those facts which doubtless he constantly accumulated. He returned to England, his mind teeming with knowledge, and full of great designs; determining to display the structure, and investigate the functions of living beings in general, both in the states of health and disease. With what extreme and unabating industry he wrought at this great work, his biographer has also told us; he allowed himself but five hours daily rest, during the remainder of his life. His mornings were passed in the Museum, and his days in constant experiments and dissections.

His object in forming the Museum was simple; it was to display the anatomical facts which were the ground-work of his physiological opinions; to exhibit the visible means, by which the vital processes were carried on, in all the varieties of living beings, that came within his cognizance. Mr. Hunter’s biographer has told us how anxiously he sought for sources of
knowledge. In 1782, Mr. Hunter says, his Museum "had already cost him 10,000l. besides the labour required in making the preparations. Of this sum more than 2000l. had been expended in the purchase of dead animals only."* Opportunities of examining rare and curious animals were also liberally afforded to him, chiefly through the means of that zealous patron and promoter of science, Sir Joseph Banks; towards whom, he always felt and expressed the warmest friendship and gratitude. Mr. Hunter knew but little of the arbitrary arrangements of natural history. The simplicity of his object induced an equal simplicity of arrangement. The facts are displayed in his Museum, according to the order of the vital processes, which is the method also adopted by Professor Cuvier.

I repeat what I asserted in the introductory lectures, that the preparations in the Museum are records of facts. Mr.

* European Magazine for 1782.
Hunter would have given his money even to his own ruin, to have procured the evidence of any fact warranting an important physiological conclusion; but he admitted nothing into his collection foreign to its general design; and scarcely any thing but of intrinsic value is to be found amongst the real gems in his cabinet. We do not over-rate the value of his preparations, in comparing them with the paintings of an ancient master, which are of high price because they possess a peculiarity of excellence that cannot be equalled. Every object shown by Mr. Hunter is displayed with a kind of elegance, as well as with distinctness and truth. He was not a man of learning, and derived but little assistance from the labours of others. Few perceived the ultimate objects of his pursuit. His inquiries into the structure of the lower kinds of animals, were regarded as works of unprofitable curiosity, and no one felt an interest in them. Therefore, without the solace of sympathy, or encouragement of approbation, without collateral assistance, did he labour to perfect his designs, till death deprived us of
so great a benefactor to mankind: an event which happened on the 16th of October, 1793.

In the autumn of the year 1776, Sir Everard Home informs us, that "Mr. Hunter was taken extremely ill, and the nature of his complaints made his friends as well as himself, consider his life to be in danger. When he reflected on his own situation, that all his fortune had been expended in his pursuits, and that his family had no provision but what should arise from the sale of his collection, he became very desirous to give it its full value, by leaving it in a state of arrangement." He therefore was anxious to have a catalogue made, and wrote a little preface to each department of his Museum. These explanations of his designs ought not, in my opinion, to be published; for they appear to be mere sketches of what he meant in future to have finished. To these writings, however, I shall frequently refer, because they show
the extent of his knowledge and views at that time; which was more than 20 years prior to the publication of Professor Cuvier’s lectures. On his recovery from this severe illness, his time was however occupied in increasing his knowledge, and not in recording what he had obtained; and his catalogue no longer seemed the important object his illness had made it appear. Considerations, deducible from the imperfect state in which he left his Museum, probably influenced his last act; for he would not suffer it to be sold unless altogether; doubtless anticipating, that when it was examined as a whole, his designs and his labours would be fully appreciated. In the pursuit of knowledge, he relinquished that of wealth, so that he left his family no other legacy than his Museum; which, after the lapse of several years, was bought by Parliament, and given to this college. Mr. Hunter’s Museum has thus become our Museum; and I trust that every member of this college will feel that interest in it, which is commonly felt for things appertaining to ourselves. Belonging to a com-
mercial nation, we visit every part of the world; and have opportunities of bringing home whatever is rare and curious in Comparative Anatomy. But to know the wants of the Museum, it is necessary that we should know what it contains, and also the general desiderata in this department of science. The latter may be learned from the systematic books lately published, and both will be shown by the lectures of my brother professor, whose extensive and accurate knowledge of Comparative Anatomy, as well as of other subjects connected with medical science, cannot but greatly redound to the credit of his industry, comprehension, and capacity.

Gratitude to the former of the Museum, and also to the donors of it, equally demand that its value and excellence should be publicly acknowledged and displayed; which consideration has goaded me on to undertake and imperfectly to execute a task, for which I feel myself not properly qualified. It is my design, on the present
occasion, not only to show you what were Mr. Hunter's opinions respecting the principle vital processes, but also briefly to exhibit the extent of his knowledge in Comparative Anatomy, and to contrast it with that promulgated of late years by Professor Cuvier. I candidly acknowledge, however, that I have little acquaintance with the subject, except what I derived from looking over the preparations in the Museum, from reading Professor Cuvier's lectures, and from the frank and friendly communications of our highly praise-worthy conservator, Mr. Clift. Permit me to say, gentlemen, though many may know it already, that Mr. Clift resided with Mr. Hunter, and was taught by him to exhibit anatomical facts in preparations; that he does credit to his excellent instructor; that he feels the same interest and zeal that his patron did for the improvement of this department of science; and that he possesses the same candour and simplicity of character. I am, however, aware that I may have attended chiefly to one side of the subject, and that my partiality to Mr. Hunter, may a little mislead me; I
wish you, therefore, no further to confide in what I say, than as I confirm my assertions by facts; and to regard me, on this occasion, in the light I appear to myself, as one venturing to come forwards a voluntary advocate in the cause of Hunter versus Cuvier and others, and in this character I may thus address you.

Gentlemen, (of the Jury), I trust I can prove to your perfect conviction, by ample and incontrovertible evidence, that my client died seised and possessed of very considerable literary property, the hard-earned gainings of great talent and unparalleled industry. It is not, however, for the property that I plead, because that is already secured; it is fenced in, landmarks are set up, it is registered in public documents. I plead only, for the restitution of a great and accumulated income of reputation, derivable from that property; which I trust you will perceive to be justly due, and will consequently award to my client and his country. In mentioning our country, think not, that pleader-like, I wish
to bias your judgment. Self-love, or nationality, which is but an extension of the same sentiment, is only productive of good when it excites emulation; and on this account alone, would I ever advert to it in the cause of science. Nation should vie with nation in promoting human knowledge and happiness. A desire to obtain the respect of others may warrant us in claiming our due; but we should freely accord to them that tribute of respect and applause to which they also are entitled.

I cannot easily express the gratification I received from reading Cuvier's Lectures on Comparative Anatomy, because, in addition to the information I derived from them, they enabled me clearly to discern the extent of Mr. Hunter's views. Neither can I tell the regret I felt that such a book had not been published during the life of Mr. Hunter, that he himself might have compared the opinions derived from more general and extended observation, with those that had resulted from his own peculiar modes of enquiry and consideration.
In praising Hunter, I by no means wish to disparage Cuvier; on the contrary I acknowledge the industry with which he has collected information by reading; and the great additions he has made to the stock of public knowledge relative to the subjects on which he treats. I admire, also, his clear arrangement, and the genius which is displayed throughout his works. We observe a constant endeavour to discover the series and order of facts; the variety of means employed for effecting the same purpose; attempts to reduce a number of facts to one general principle; in short, the endeavour to discover the causes and nature of whatever we observe; the hope of effecting which, appears to be the most potent incentive to labour, and the accomplishment its most gratifying reward. To shew that Cuvier has not wrought so hard without some animating motive, I quote his own words. "Pourquoi tel animal ne se nourrit-il que de chair, tel autre que de végétaux? D'où celui-ci tire-t-il la finesse de son odorat, où celle de son ouie! D'où viens que l'oiseau voit également bien à des
distances si différentes? Quelle est la source de la force prodigieuse des muscles des oiseaux? Cette force comment est elle employée à produire ce mouvement si étonnant du vol? Quelle est la cause de l'étendue, et de la variété de sa voix? Tel reptile, pourquoi est-il si engourdi? Tel ver, comment conserve-t-il la vie long temps après être divisé? Tel zoophyte comment peut on vivre également bien quelque parties de son corps que l'on en retranche. Suppose-t-on qu'il puisse exister une histoire naturelle sans ces questions, et des milliers d'autres semblables?"

Believing that no man will ever labour in the strenuous and unremitting manner that Mr. Hunter did, and to the detriment of his own private interest, without some strong incentive; I have supposed, that at an early period he conceived those notions of life which were confirmed by his future enquiries and experiments. He began his observations on the incubated egg, in the year 1755, which must either have suggested or corroborated all his opinions with regard to
the cause of the vital phenomena. He perceived that however different in form and faculty, every creature was nevertheless allied to himself, because it was a living being; and therefore he became solicitous to enquire how the vital processes were carried on in all the varieties of animal, and even vegetable existence. In the progress of science, genius, with light and airy steps, often far precedes judgment, which advances slowly, and either finds or forms a road along which all may proceed with facility and security; but the direction of the course of judgment is often suggested, and its actions are excited and accelerated by the invocations of preceding genius.

Whether truth be discovered by that penetrating foresight which is characteristic of genius, or ascertained by the more laborious methods of experiment and induction, still, when it is once found, each succeeding observation serves but to convince us of its nature and reality. No one could be more scrupulous in admitting propositions to be proved, than Mr. Hunter; yet he was con-
vinced that his opinions respecting life were true, by a course of patient and persevering meditation, on all its phænomena, in a manner I shall endeavour more fully to point out in the succeeding lectures. Yet these opinions, though correspondent to those of the wisest philosophers of ancient times, were so little suited to the modes of thinking of his contemporaries, that it required no small degree of hardihood, in a man of little education, to maintain them, in spite of the apathy or derision with which they were received by persons of greater general learning. Such, however, is the hardihood that conviction produces.

When, however, conclusions are deduced by a course of patient and persevering consideration of voluminous and multifarious evidence, it is scarcely possible to detail the causes and processes of thought by which we have been led to them; and this, I doubt not, made one of the difficulties which Mr. Hunter encountered in communicating his opinions. By investigating the works of nature, we collect facts from
which we deduce opinions. On the formation and importance of opinions, I have already taken the liberty of expressing my sentiments before to this assembly, to which I now beg leave to add, that there are many who think clearly, who do not think deeply; and they have greatly the advantage in expressing themselves; for their thoughts are generally simple and easy of apprehension. Opinions immediately deduced from any series or assemblage of facts may be called primary opinions, and they become types or representatives of the facts from which they are formed, and, like the facts themselves, admit of assortment, comparison, and inference; so that from them we deduce ulterior opinions, till at length, by a kind of intellectual calculation, we obtain some general total, which in like manner becomes the representative and coefficient of all our knowledge, with relation to the subject thus examined and considered. In proportion to the pains we have taken in this algebraical process of the mind, and our assurance of its correctness, so do we contemplate the conclusion or consum-
mation of our labours with satisfaction; and being unable to display to others the different series of facts and opinions, and modes of inference, we express our certainty of the conclusion, by saying, it must be so; it is absurd to suppose otherwise; or, as they say Dr. Johnson was accustomed to do, "I know I'm right, so there's an end of it."

Now these ultimate opinions, for so I may call them, as being the last of a series, become primary and elementary in the display of knowledge. These conclusions of thought become principles of science and of conduct. By the prosecution of thought, we are led to observe the very trunk and roots from which the various ramifications of our knowledge are produced, and the nature of the ground on which the whole is supported, so that we become assured of its security, or admonished of its uncertainty. It is then, to certain ultimate opinions, or physiological conclusions of Mr. Hunter, with respect to the vital processes, that I chiefly wish, on.
the present occasion, to excite your attention; and these are highly important, on account of their re-action, and the bias they impart to our opinions in general, and also to our conduct.

The study of Nature has been compared to the working of an inexhaustible mine, abounding in rich materials; but which require to be assorted, refined, and wrought up, ere they can be converted to useful purposes. Some dig the crude materials from the mine, others assort and refine them; whilst others again, construct, with the wrought substances, instruments of great utility in the future acquisition of knowledge. Surely, I may be permitted to consider opinions as the instruments of intellect, for it both forms them and employs them in its future operations; and when also they are well constructed, they illuminate and render intelligible surrounding objects; but when ill formed, they only obscure and disfigure the face of nature. In adverting then to Mr. Hunter’s Museum, by thus circumscribing my designs, I shall not in the
least trench upon the province of my brother Professor; for I shall not describe facts, nor detail opinions; I shall not examine the materials, but merely the construction and utility of certain instruments which the hand of Hunter either formed or finished.

When I first had the honour of addressing the members of the College in this theatre, I knew it would be expected that I should eulogize Mr. Hunter; and nothing loth, I declared that he seemed to me to possess that rare combination of intellectual powers which qualified him equally to extend the boundaries of knowledge and to establish principles of science and practice. Of his opinions, I said I knew of none that had not been cautiously and legitimately deduced from the facts before him, and though the progress of science might have since invalidated some, yet most of them, from the same cause, had become more and more firmly established. In proof of the latter part of this proposition, I excited
your attention to his opinions respecting life, which the progress of science seems to me to have most perfectly confirmed. The probability of his opinions on this subject is to be inferred from analogy; their rationality from their adequateness to account for all the vital phænomena. As Sir H. Davy's experiments fully prove that electricity may be superadded to, and that it enters into the composition of all those substances we call matter; I felt satisfied with this establishment of the philosophy of Mr. Hunter's views, nor thought it necessary to proceed further, but merely added, "It is not meant to be affirmed that electricity is life. I only mean to argue in favor of Mr. Hunter's theory, by shewing that a subtile substance of a quickly and powerfully mobile nature, seems to pervade every thing, and appears to be the life of the world, and that therefore it is probable a similar substance pervades organized bodies, and is the life of these bodies." I am concerned, yet obliged to detain you by this recapitulation, because my meaning has been either misunderstood or misrepresented.
Mr. Hunter was the first physiologist who placed in clear array the various vital functions before our view, so as to enable us to judge of their nature and probable cause. He told us that life was a great chemist, and even in a seemingly quiescent state, had the power of resisting the operation of external chemical agency, and thereby preventing the decomposition of those bodies in which it resided. Thus seeds may lie buried far beneath the surface of the earth for a great length of time without decaying, but being thrown up, they vegetate. Mr. Hunter shewed us that this chemist, Life, had the power of regulating the temperature of the substances in which it resides. Seeds possessing the principle of life being placed within the influence of the atmosphere, and in contact with moisture, produce heat, form sugar to edulcorate the first nutriment of the young plant, and in short, bring about all those phænomena which characterize incipient vegetation. He further shewed us, that Life, by its chemical processes, could convert a great variety of dissimilar substances, into one kind
of generally distributed nutriment, and could also prepare from it a still greater variety of dissimilar substances. Mr. Hunter shewed us that Life was also an architect, that it built up a great variety of curious structures or edifices, in which it continued to reside and execute its future functions. No unprejudiced person can, I think, possibly doubt that it is by the active power of Life such effects are produced. Mr. Hunter shewed that the actions of life are various, that in nerves they are rapid, though not so forcible as in muscles. By such actions he accounted for the sympathies of remote organs, and the instantaneous effects produced on, and by the brain, from and in the remotest parts of the body. He shewed that the most obvious, and in general most surprizing manifestation of vital activity, which is called irritability, was not necessarily connected with a muscular structure; and when apparently connected with the same structure, was subject to considerable variations in its actions. By means of the active powers of life, he also saw how it
was possible that fluids should undergo those modifications, that are known to take place, from the affections of the vessels in which they are contained. Having convinced himself of these facts, he inferred that Life was a principle, active in all its functions, and that by acting in various modes and degrees it produced the diversified phenomena by which it is characterized.

I shall, on the present occasion, add a few words, to what is contained in my former lectures, to shew the nature and probability of Mr. Hunter's opinions respecting Life, because I am unwilling to leave any excuse for saying, that they are either unintelligible, or inadmissible.

The progress of science, since Mr. Hunter's time, has wonderfully manifested, that the sun-beam when dissected by a prism, is not only separable into seven colorific rays of different refrangibility, producing the iridiscent spectrum; but also into calorific rays refracted in the greatest degree, or intensity, beyond the red colour,
and into rays not calorific, refracted in like manner to the opposite side of the spectrum beyond the violet colour; and that the calorific and uncalorific rays produce effects similar to those occasioned by the two kinds of electricity; and thus afforded additional reasons for believing that subtile mobile substances do enter into the composition of all those bodies which the sun illuminines, or its beams can penetrate. Late observations induce the belief, that even light may be incorporated in a latent state with animal substances, and afterwards elicited by a kind of spontaneous separation, by vital actions, or by causes that seem to act mechanically on the substance in which it inheres.* All the late discoveries in science seem to realize the speculations of ancient philosophers, and shew that all the changes and motions which occur in surrounding bodies, as well as in those which live, are the effect of subtile and invisible principles existing in them, or acting on them.

* See Dr. Hulme's, and Dr. Macartney's papers in the Philosophical Transactions.
Mr. Ellis, who with such great industry and intelligence has collated all the scattered evidences relative to the production of heat in living bodies, and added so much to the collected knowledge, seems to think that all the phenomena of the variations of temperature in them, may be accounted for by known chemical processes. Here, however, I must observe, that Mr. Hunter's opinion of life having the power of regulating temperature was deduced, not only from his experiments related in the Philosophical Transactions, but also from observing, that in certain affections of the stomach, the heat of the body is subject to great vicissitudes, whilst respiration and circulation remain unaltered; and also that parts of the body are subject to similar variations, which appear inexplicable upon any other supposition than that of local nervous excitement or torpor, or some similar affections of the vital powers of the part which undergoes such transitions. His views with respect to this subject are confirmed by the late experiments of Mr.
Brodie.* As the circulation of the blood will continue in warm as well as in cold blooded animals without the influence of the brain, provided respiration be artificially kept up in the former by means of a pair of bellows, Mr. Brodie severed the connection of the brain from the top of the medulla spinalis, which in effect instantly kills the animal, and thereby prevents further suffering in the experiment, and then maintained artificial respiration, and consequent circulation, for more than two hours. Yet under these circumstances the body cooled as rapidly and regularly as that of another animal in whom respiration and circulation ceased upon the division of the medulla spinalis. This experiment shews that the change produced by respiration on the blood is not of itself alone sufficient to maintain the ordinary temperature of animals. Chemical science has not yet explained how the intense heat and light are produced, which are occasioned by the transit

* Philosophical Transactions, 1811. Cromian Lecture.
of electricity through the air. That the powers of life regulate electrical actions is evident; and may they not in this manner produce some of those variations of temperature to which I have just referred? But admitting that the refined operations of modern chemistry should actually shew us the means by which the variations of temperature are in every instance produced, they would not explain the cause of those actions by which such means are rendered efficient; which actions constitute the essential difference between living and dead bodies.

Neither would chemical science, by explaining the regulation of temperature, unfold the cause of the other vital phenomena; for instance, the prevention of putrefaction and irritability. The heat of incubation would hurry on the putrefaction of a dead egg, but the white and yolk of a living one, which we cannot suppose to be organized, do not putrify, though they undergo changes subservient to the nutrition of the young animal they are designed to
support. Doctor Macartney, who has of late particularly attended to this subject, gives it as his opinion, "that when fluids change their composition, it is often by some vital action in themselves, instead of a fermentative process, or the mechanical operation of solids upon them, as is commonly supposed."* Were irritability shewn to be an electrical phænomenon, and I consider it already demonstrated that they are electrical actions which cause the various combinations and decompositions so constantly occurring in all parts of living bodies, and upon which their formation and functions so greatly depend; yet the consideration of the vital phænomena proves that such electrical operations are under the influence and control of the vital powers. I am aware that there is an obscurity in my first lectures, arising from my not explicitly declaring my sentiments; which did not then appear necessary, and even now may perhaps be deemed presumptuous and improper. In my opinion, experimental science

* See article Incubation, in Dr. Rees's Encyclopaedia.
has not as yet informed us of more than reason has suggested, from the consideration of the general phænomena of nature; which is, that the motions and changes occurring in surrounding bodies, and in our own, are the results of some subtile substance or substances, which enters into their composition, or acts upon them.

But if science were eventually to demonstrate that heat, light, and electricity, are different things, that there are various kinds of subtile substances, then I should be obliged to suppose that there was also a subtile substance belonging to living bodies, a principle of life, which had the amazing power of kindling and controlling the destructive element of fire, and regulating the actions of that still more sudden and powerful agent, electricity. Neither by so doing should I transgress the rules of philosophy; for in suggesting a theory, it should not only be probable, but adequate to explain all the phænomena. I am aware, however, that there may be some contemplative and unprejudiced men, who, perhaps a little
elated by the progress of science, may think me hasty, and that I had better have waited to see what her ample page might have eventually unfolded. To them I bow with respect, and assure them, that I would have done so, had the subject been merely an abstract question in Physiology.

Few however are they who contemplate the nature of life "in the calm lights of mild Philosophy;" nor do I affect to include myself among that very small number. In becoming the advocate of Mr. Hunter's Theory of Life, I knew I should irritate what many might consider as a very formidable Party. Formidable, because some of them possess extensive information, are subtle disputants, have words at will to make the worse appear the better argument, and are writers even by profession. Yet I feared them not, because I knew, that words do not make, but merely adorn arguments. Nevertheless I thought it prudent to entrench my subject behind a little
fortification made of the most approved rules of reasoning; and neither this outwork, nor the subject itself, has even been assailed. Yet assertions have been made which I am concerned to feel it an indispensable duty publicly to answer in this place. I shall include all the individuals who compose this party, under a general denomination, which I think appropriate to them, and call them the Modern Sceptics.

First then, I am instructed, that I ought to consider life to be a property of certain structures, as gravitation and elasticity are said to be properties of matter. With this injunction, however, I cannot comply, because I can only think or consider in one way. I must deduce rational inferences from the facts belonging to any subject, or from analogies existing between that subject and others better understood. Now there is no analogy between the permanent and invariable properties of gravitation and elasticity, and the occasional and variable properties of life. Therefore, if I judge from analogy, I must think as I have hitherto
done, that life is more like electricity or magnetism, because its operations are occasional; it may vary in degree, and admits of being annulled or abstracted, without evident difference in the subject to which it has belonged. My preceptors, suddenly shifting their ground, call upon me to consider life as an effect resulting from the combined action of certain structures. I own I am not disposed to follow such leaders, yet if I do, I discover that they wish me to consider life to be nothing; which I take to be the plain English of the Physiology contained in some late French publications relating to this subject.

When Sir Isaac Newton explained the laws of attraction, and of the motion of those substances we call matter; though he wished only to announce facts, without attempting to account for them, though reluctant to hypothesis, he afterwards felt obliged to suppose that there might be an æther forming a bond of connection and reciprocal action between their distant masses and molecules. In the anatomical lec-
tures which I have had the honor of delivering in this theatre, when speaking of the ultimate fibres of the body, I observed that they varied in the properties of rigidity, pliability, strength, and elasticity; and that such properties could not be considered to be dependent on the quantity of matter contained in the fibres, which would be estimable by weight, to which such properties bear no proportionate relation; and, consequently, that these properties must be attributed to certain powers of attraction and repulsion operating in various modes and degrees, between the atoms of which such fibres are composed. However minute the atoms may be which compose those visible and tangible substances we call matter, Sir Humphry Davy's experiments shew, that each atom is surrounded by electric substances possessing powers of attraction and repulsion; and which substances are not only capable of acting upon the integral parts of bodies, but also upon the largest masses of matter. These electric substances produce decomposition and recombination, and by such
means destroy the mechanical properties which had before obtained. Thus we see the toughest wood slowly decay, or suddenly consumed by fire.

So numerous are the phænomena in nature, that suggest and enforce the belief that subtile substances may and do pervade others more gross and inert, and produce effects in and upon them; that no surprise can be excited upon finding that contemplative men have in all ages adopted and inculcated this opinion. Yet it was not till of late years, by observing the phænomena of electricity and magnetism, that decisive evidences of this proposition were obtained. In considering these subjects, we observe the utmost boundaries of human knowledge, for all our information must be derived from our senses, which can never give us any cognizance of the atoms that compose surrounding bodies. Yet this horizon of our views has been always distinctly seen by long-sighted observers; and advanced as we are in knowledge, we can see no further. Persons of different cha-
racters of mind have thought, and may think differently; for neither can confute the other. One party, considering the more gradual and rapid changes which take place in surrounding bodies, and all the phæno-
mena of motion and of rest, as effects of some subtile, invisible substance or sub-
stances pervading all nature, whilst the other may attribute them to inherent pro-
pensities in the atoms themselves.

I have led you thus far, Gentlemen, to shew you the rock on which the ancient fortress of scepticism stands erected, and it is evidently so unimpregnable that it has been a secure retreat for ages, and may still continue to be so. Whilst its tenants keep within their own territories, or even demean themselves peaceably abroad, I, for one, would never attempt to molest them, nor prevent them from the full enjoyment of their native apathy and inactivity of mind. But when they make excursions to annoy their neighbours, and in disguise too, it seems necessary to unmask them, and send them home again.
If, however, those professed sceptics, whom I have incorporated under the title of Moderns, really suppose that they have no opinion on certain subjects, they deceive themselves; for by repeatedly thinking that there may be nothing which is not an object of sense, they at last bring themselves to believe that there is nothing, which is a positive opinion, and also a creed found to have various conveniences. Else whence arises their zeal to make proselytes and to refute the opinions of others, who, perceiving the deficiencies and fallibility of our senses, believe that there are many things far more demonstrable to reason than to sight.

Mr. Hunter's opinions may be denied, but cannot be refuted. It is, however, easier to maintain a proposition diametrically opposite to truth, than one originating in any intermediate degree of error. Those, therefore, who attempt to account for the vital phænomena upon any other supposition than the one I have had the honor of advocating in your presence, would lead us
into such a maze of absurdity, that reason and common sense forbid us to follow them.

Now, in applying the philosophical opinions of the wisest men to account for the functions of life, according to the views which Mr. Hunter had taken of that subject, I have been charged with imagining causes of which Physiologists are not competent judges. It has been said, this is not on the record, nor before this court. You know, Gentlemen, that the plea of the incompetency of the court, is often urged when a party suspects a verdict may be given against them. If, however, Physiologists be not competent judges of this cause, no writ of certiorari to any other tribunal, can, I am convinced, with propriety be granted. I cannot but smile, when I hear or read of the functions of life being the effect of the vital forces; because the expression seems to me the very ne plus ultra of philosophical caution. So flimsy a veil is drawn before the subject, as not to conceal any thing; for every one is con-
vinced that nothing can exert no force, and consequently that these forces must either be the attributes of the atoms which compose an organized body, or of some subtile and invisible substance superadded to, and inherent in it.

It has been said that Comparative Anatomy contradicts Mr. Hunter’s opinions respecting life, for where there is no organ, there is no function. If Nature did not design an animal to see, no eye is constructed; but how the want of an organ can affect the general question of what life may be, I am too dull-sighted to discover. It will be shewn, and I think it must be admitted, that life is an organ builder, as well as a performer on the instruments it constructs. That organization alone does not produce the functions which belong to life, must, I think, also be granted. A man may sleep with his eyes open, and his friend stand before him with a light; yet the organization of the retina does not enable the sleeper to perceive the image of his friend, though vividly depicted on its
surface. Food may also be received into the stomach, and the circulation in that organ go on as usual, yet its organization does not cause digestion, unless vital actions regulate those electrical operations upon which the preparation of the food-dissolving juices of that organ depend. On the contrary, I may observe, that Comparative Anatomy informs us, the same vital processes of the prevention of decomposition, regulation of temperature, action, assimilation and growth are effected in structures extremely diversified: and further, that observations on disease demonstrate the perverted actions of the same structures to produce a great variety of effects, which is a proof that the actions of life do not depend merely on organization.

I will not condescend to particularize or parry the absurd attempts that have been made to ridicule Mr. Hunter's Theory of Life. I will only inquire why we are to be prohibited from thinking, if we conform to the most approved rules of ratiocination?
Why these sceptics try to ridicule what they cannot refute? and whence arises the irritability they have displayed? The nature of this kind of irritability is, indeed, well known to Physiologists, it is but the common consequence of debility when excited. But what is the exciting cause, what provocation has been given to them? It must be as I surmised; they have opinions and are irritated at any thing contradictory which they cannot oppugn. The very term of superaddition is discordant to their ears; the supposition that there may be any thing which is not an object of sense, or actual demonstration, torments them; they themselves perceive, that the superaddition of life to structure may, indeed, warrant the supposition of a substance having the properties of perception, and volition being superadded to life; and that there may be "more things in heaven and earth, than they in their philosophy dreamt of." Should such opinions gain ground, the privileges of scepticism seem endangered; their proselytes may no longer re-
ceive with perfect confidence the assurance of philosophical liberty, the assurance that, because they are sensitive and rational creatures, true philosophy, therefore, consists in gratifying their senses, and acting as their reason dictates, for their own advantage, independently of all other considerations. Wherefore do they tell us, that we know not why a muscle acts, or a nerve feels, and that both are properties of organization? Is it not because they wish to persuade others, as perhaps they may have brought themselves to believe, "that when the brains are out, the man is dead?" Yet surely, it does not necessarily follow, that perceptivity and consciousness are annulled, because those actions have ceased by which they have hitherto been affected or manifested.

I have heard it said that I was wrong in bringing forward a metaphysical subject before this assembly; yet no one can, I think, account Mr. Hunter's Theory of Life to be metaphysical; for we infer no more than we do with respect to electricity, that
it is equally probable there is an electric fluid and a vital principle. Permit me to repeat, that I excited your attention to the consideration of this subject, not only because it affords a strong proof of Mr. Hunter's genius and reflection, but because I felt assured, that without understanding his opinions respecting life, no one can understand his general Physiology, or that Pathology which it was my principal duty and desire afterwards to explain. He seems to me to have written under a persuasion that others knew what he did respecting the vital functions, and had thought as he had done, and his merits as a Physiologist, has therefore been less generally perceived from the want of this previous information and reflection.

What Mr. Hunter thought about sensation I know not; what I think, I willingly declare, which is, that it can be neither the result of organization, nor an affection of mere life. In reasoning on the motions of the matter which surrounds us, and also of that of which we are composed, we must
grant either that the atoms are motive, or that they are impelled to move. So also in reasoning with respect to sensation, if the atoms be not sentient, it is impossible to suppose that sensation can result from the arrangement or motion of insensible atoms.

If to think and act in this manner be considered as an error, I must be shown that it is one, before I can alter either my opinions or conduct. Till then, I shall glory in entertaining the same opinions as Pythagoras, Plato, Socrates, and a host of others whom I need not mention, have done. It will be my boast and future endeavour to show by Physiological arguments, that in this instance also, what has been perceived by the penetrating eye of intellect, on a distant and general observation, becomes more and more apparent on a close and accurate examination of the subject. I say, it will be my boast, because I know that the opinions I allude to are productive of nothing but good to humanity, individually
and collectively I admit, that the belief that man is a machine does not tend to alter his natural and established motions, and consequently, that there have been many good and moral sceptics. But I also know, that the good dispositions will want that excitement and energy which the opposite sentiments produce, whilst the bad will be left without control. It is equally apparent that the belief of the distinct and independent nature of mind, incites us to act rightly from principle; to relieve distress, to repel aggression, and defend those who are incapable of protecting themselves; to practise and extol whatever is virtuous, excellent, and honourable; to shun and condemn whatever is vicious and base; regardless also of our own personal feelings and interest, when put in competition with our duty.

We all seek for truth, and on her approach, and in her presence, are ready to sacrifice, without hesitation or reluctance, our most favorite opinions;—but to exchange opinions for other opinions, as in this case
seems required of us, when the barter is so disadvantageous, would be the highest absurdity. We should give up that which is in every respect, and in the greatest degree, useful and dignifying, and what experience has proved to be durable, for that which is pernicious and derogatory, and which evidently cannot last; for the specimens presented to us are composed of such flimsy and ill-connected materials, that they will not bear even common handling and examination.

Whoever considers the operations of intellect, will, I think, perceive, that when conviction is not forced upon the mind, by something resembling mathematical demonstration, we form our own opinions. We think as we have been instructed to think, or as those do with whom we associate. Thoughts become concatenated, and by repetition habitual and established. There is a strongly imitative or gregarious disposition, even in intellect; most people think as well as act with a party, and
hence results the good or evil derived from association. That in France, in a nation where the writings both of its philosophers and wits have greatly contributed to demoralize the people, I do not therefore wonder that those of their anatomists and physiologists should represent the subject of their studies in a manner conformable to what is esteemed most philosophical or clever. But that in England, the chief excellence of whose inhabitants is, that they are a thinking people, who consider the probable ends of conduct from its beginning; that in this country, particularly after so arduous an examination, and so rational an explanation of the vital phænomena have been presented to us by Mr. Hunter, the mere opinions of some French anatomists, with respect to the nature of life, should be extracted from their general writings, translated, and extolled, cannot, I think, but excite the surprise and indignation of any one fully apprized of their pernicious tendency.

The education and course of life of medical men tend to make them sober-minded,
moral, and benevolent; and their professional avocations equally require, that they should possess such characters and dispositions. On no other terms can they be admitted with confidence into the bosoms of those families which may require their medical aid. Whoever therefore inculcates opinions tending to subvert morality, benevolence, and the social interests of mankind, deserves the severest reprobation from every member of our profession, because his conduct must bring it into distrust with the public.

If what I said in the introductory Lectures has irritated the party of Sceptics, what I now say, may anger them still more. But I fear them not; they can only shoot at me with the shafts of ridicule, or spit at me the venom of their malice; both of which modes of assault I actually laugh at; for the experiment has been tried, and I know, that though these things may tickle, they can never annoy me. To express my opinions on this subject a little technically, I may say, such means have no
effect upon sound or naturally defended surfaces; some point must be exposed, or morbidly susceptible, ere they can occasion either pain or irritation. If, however the Sceptics had even the power to injure me, still I should not fear them; because I place between us the undisguised truth, which they can neither conquer nor confront. For truth possesses a power which poets have represented by symbols; like the Ægis of Minerva, or the spear of Ithuriel, it has the power, not only of protecting and maintaining what is right, but of revealing, abashing, and appalling, what is wrong.
LECTURE II.

The propensity to observe and compare surrounding objects, seems natural to man. We find even children pleased with examining and assorting stones, spars, metals, and other specimens of mineralogy; still more gratified with those beautiful objects, flowers; and even in a greater degree with moving beings, which, on that account, claim a kind of alliance with themselves. Yet so diversified are the subjects of nature, in each of these departments, that it requires the constant application of any individual to render himself a distinguished character either as a mineralogist, a botanist, or a zoologist. Linnéus, whose knowledge of natural history was so extensive and exact, perceived the necessity of some system of mnemonics, by which we might remember and survey the whole. He therefore formed an arbitrary arrangement of these subjects, and chiefly from their external characters.
The advantages resulting from this plan were striking. It was perceived how we could thus learn parts in detail, and also contemplate the extreme diversity and extent of the system of nature; as well as how we might arrange any additional knowledge that was obtained, so as to make it a part of one orderly whole.

The minds of men seem to have been fascinated by the method which Linnéus had adopted; for it was applied to subjects where no artificial memory was required. Even diseases were thus arranged; and the attention being directed to their external characters, it was taken from its true object, which should be to enquire into their intrinsic nature. This is a striking though not singular instance, showing, that even grave and learned men, reputed philosophers, have a propensity, like sheep or like school-boys, inconsiderately to follow the leader.

That the arrangement of Linnéus is unnatural, and unsuitable to the purposes of
LECTURE II.

Comparative Anatomy, is evident; but we need not defame the memory of so great a contributor to general improvement, by supposing that he was ignorant of the advantages and disadvantages of his own scheme, particularly as he has himself so frequently acknowledged the latter. Though he thought it right to arrange the subjects arbitrarily, and chiefly by their external characters, because, those but little informed could then co-operate with the more erudite, he must have known that he violated the arrangement of nature; for even with respect to plants, he separated the individuals of their families, and placed them apart amongst strangers with which they had no natural connection. Of his twelve botanic Classes, there are but two which have a claim to be considered natural; and even in these, it is not unexceptionable. I allude to the classes Tetradynamia and Syn-genesia. Surely, too, Linnéus must have perceived that he committed still greater outrages against natural order in the animal kingdom. I would never advise my young friends, to endeavour to raise their own
reputation, by attempting to depress that of another; for general observation speedily detects what each has done for the promotion of science; and their respective merits are impartially appreciated by the public; therefore the attempt to undervalue another, becomes an offence against public opinion, and at the same time, "shows a most pitiful ambition in him that uses it."

Mr. Hunter knew nothing about systems; when he met with an animal he had never dissected, he cared but little by what name it was called, to what family it belonged, with what others it was associated, either by natural or artificial ties. He chiefly wished to know, how its food was digested: how its blood circulated; how it respired; what were its feelings, instincts, and habits; how it secured or defended itself from injury; how the multiplication of its species was effected and insured. Yet, by noting the facts relative to these subjects, it surely must be interesting to observe, how much his arrangement and ex-
hibition of structures correspond to those lately displayed in systematic works; in which also will be found an arrangement of the animal kingdom, more suited to the purposes of Comparative Anatomy, than that of Linnéus.

In asserting the claims of Mr. Hunter, I should not omit to mention that he was a very candid man, and freely divulged whatever he knew or thought, as far as his powers of communication enabled him. His biographer says, "his disposition was candid and free from reserve, even to a fault; for it sometimes made him appear harsh." Doctor Hunter, in his Lectures, frequently mentioned his brother's opinions on different physiological subjects. Mr. Hunter himself began to give lectures in the year 1770. Since the year 1785, the preparations in the Museum have been arranged as they now are, and publicly exhibited. That Mr. Hunter's facts and opinions respecting physiology in general, have gradually become known to the nations on the continent, have been
adopted and incorporated with their knowledge of that science, is to me very manifest. I mention only one instance in evidence of this proposition. In some late foreign systems of Physiology, the nerves are called organs of calorification; though without adequate reasons being assigned for so novel a denomination. That his facts and opinions, relative to the comparative structure and functions of animals, should have travelled in like manner, and met with a similar reception, does not seem improbable. Both professors Camper and Blumenbach were in London, and were, as I believe, well acquainted with Mr. Hunter's labours. Such were the circumstances that promoted the diffusion of Mr. Hunter's discoveries and opinions. No one could be more fully aware of the uncertainty of knowledge than he was; and this occasioned his tardiness in publishing either his discoveries or opinions; which may have given a seeming priority to the works of others, and prevented the knowledge that flowed from him from being traced to its proper source by the public in general.
On the contrary, however, I cannot but suspect, that the great illumination which Comparative Anatomy and Physiology have of late received on the continent, has in a considerable degree resulted from reflected light, originally emanating from materials which Mr. Hunter brought together, and from his brilliant physiological discoveries.

In advocating the cause of Mr. Hunter as a comparative anatomist and physiologist, all I can do is to tell when I think he first ascertained certain facts, or drew certain conclusions. Yet I know it is difficult to prove these propositions, and as I have said*, I shall be often obliged to refer to his writings, in 1776, to show the extent of his information and views at that time. If, however, I fail to prove his title to priority of discovery, or opinion; still I feel persuaded that what I shall say of him will not be deficient in interest, for I cannot suppose any one will believe, that the unlettered John Hunter borrowed his evi-

dently original opinions; or that the works of his own hands were copied from those of others. If others preceeded him, he will still appear like Ferguson the astronomer; who, whilst a shepherd's boy, drew accurate charts of the Heavens, knew the course of the planets, was acquainted with the nature and application of the mechanical powers, constructed various timekeepers, planned and executed sun-dials in different aspects for his neighbours; and when at length his fame attracted the notice of the surrounding gentry, and a subscription was raised to send him to Edinburgh, that such rare talents might not remain uncultivated; he was, as he said, surprised to learn that all he knew and much more had been already known. Both instances will serve to show the extent of knowledge which rarely-gifted individuals are capable of acquiring by their own observation, ingenuity, industry, and reflection.

In the first department of his Museum, Mr. Hunter displays the firm and rigid
parts of vegetables and animals; the substances or joints which connect them; and the powers which move them; as if he had thought it proper to define what living beings were, before he proceeded to show how they were formed, and what processes were carried on in them. Mr. Hunter thought that there was a principle of life in vegetables as well as in animals, and noted the identity of the vital processes in both. He adverted also to the similarity of their morbid processes; to the thickening of the leaves in vegetables, from the irritation of insects; and the growth of excrescences from the same cause. How extremely beautiful is the nest formed by the increased, but not unhealthy actions of life, for the young of the Cynips Rosæ (Linn)? He observed how exactly correspondent to the processes of animal life is the exfoliation of the dead leaf in the autumn. If the leaf and stem equally and simultaneously perish, if a branch suddenly wither, the leaves tenaciously adhere by cohesive attraction; the detachment of the dead from the living
parts being apparently the consequence of vital actions in the latter. There is one experiment of Mr. Hunter’s I may mention, because it displays the reflective character of his mind, and the persevering industry with which he prosecuted every subject that excited his attention. Having set beans in a tub filled with earth, which had perforated apertures in various directions, he contrived mechanism to keep it constantly revolving round an axis, to show that the ordinary operation of gravitation had no effect in producing the extremely varied course which the young plants took in order to arrive at the surface.

Specimens of some plants, parts of which undergo sudden motions, stand first among the preparations in the Museum. Respecting this subject Mr. Hunter observes in his MS. in 1776, “All plants are not endowed with evident motions, yet in some, such motions occur in parts of them, and apparently from the application of particular stimuli, as the rising and setting of the sun, &c. Some also are affected by touch, so as
immediately to be put in motion by it. Of the nature of the organization subservient to these motions, we are ignorant. We know not whether they may arise from organs formed purposely to produce them, or from all the neighbouring parts being joined in consent to occasion this effect. It seems probable, however, that the power is analogous to the irritability of muscles."

Next are exhibited the nutritive fluids both of vegetables and animals, and also the fatty substance which makes so considerable a part of the body in the latter class, because all their different structures must be formed from these nutritive materials. The nutritive fluids, or blood of animals, and the sap of some vegetables spontaneously coagulate; but in other vegetables, the addition of acetate of lead is necessary to produce coagulation. The nutritive fluid, or blood of insects, and the lower kinds of animals, is shewn to be colourless, with the exception of that of some worms which have red blood; and that in reptiles and fish, the red colour which is so generally con-
sidered as characteristic of that fluid begins to be added. Though blood is so subtile a fluid as to be capable of permeating the minutest vessels of the body, yet that part which spontaneously coagulates, becomes very firm, tough, and unsoluble; often also assuming a fibrous appearance. From the exact similarity of these fibres to those of which muscles are chiefly composed, which Mr. Hunter has taken great pains to exhibit in preparations you will observe in the Museum, he inferred their identity; an inference which modern chemistry has since established.

With respect to animals, Mr. Hunter observes in M.S. 1776, "In the more imperfect animals, it is very probable that there are no fixed parts, but that all parts are irritable and have motion, like the urinary bladder or an intestine. As animals become complicated, and have various motions, especially the progressive, then such motions are more divided or partial; for which purpose it is necessary there should be substances whose firmness and
structure, and mode of connection, should divide and determine the motions to particular parts. These structures are differently placed in different animals. In the earthworm, caterpillar, and nereis, the firm structure is the skin, which is divided into rings, all of which have motion on each other, and into these are muscles inserted, so that a variety of particular motions is produced. In insects, spiders, and lobsters, whose firm parts are more complicated and answer a greater variety of purposes, we find the fixed parts still more dense. In the two former they are of a horny, and in the latter of a calcareous nature. These parts also make a covering for the animal, but there are processes of them going deep for the attachment of muscles. In tortoises, lizards, snakes, &c. though they have firm external coverings, yet there is an internal apparatus for motion, which is principally bone. In the more perfect animals, external firm parts are rarely found. They have an internal osseous skeleton, so that the muscles and their attachments are reversed; and thus we find them arranged
in the fish, fowl, and quadruped." Mr. Hunter adds, "shell is a substance made use of in the animal kingdom, chiefly as a defence against accidents, serving the purpose of a retreat!"

This extract convinces me that there is scarcely any thing in Professor Cuvier's Lectures, relative to the construction of animals, with which Mr. Hunter was unacquainted; and it must be interesting to observe the correspondent views which these highly informed men have taken of the same subjects. As Mr. Hunter's object was Physiology, or an enquiry into the functions of Living Beings, he has not been solicitous to exhibit all the facts relating to their construction. Professor Cuvier, has, on the contrary, devoted his first seven Lectures to display the latter subject, in so ample and satisfactory a manner, as cannot, I think, fail to gratify the reader. Some animals are soft and undefended; some inhabit shells; some may be said to have an external articulated skeleton, serving also as a defence; and the rest an internal skeleton. He re-
marks, it is curious, that insects, having an external articulated skeleton, possess such a combination of motive powers, that some of them walk, run, leap, swim, and fly with as much facility, as beasts, birds, and fish, exercise one or more of these faculties. Professor Cuvier thinks that they are indebted for these advantages, to the numerous articulations which their case or skeleton possesses. It might strike a person who had not considered the subject, that there were animals possessing both an internal and external skeleton, as those of the reptile tribe. The muscles of insects, however, act upon the external case, which is therefore similar to the skeleton. The shells of tortoises are to be considered merely as armour, as defences against injuries, which the animals have neither the power to oppose, nor agility to avoid. Even amongst the higher order of quadrupeds, some wear this kind of armour as the rhinoceros; and many have such thick hides, as protect their possessors from trivial injuries; hides like the leathern doublet of Hudibras, which

"Though not ball was cudgel proof."
In the construction of animals, we find nature proceeding upon an uniform plan, and by variation of the same means, contriving to produce beings extremely diversified in form and faculty. It has been observed that Comparative Anatomy furnishes abundant facts to the natural theologian, shewing that intelligence must have operated in the construction of living beings, by the evidence it affords of design, and of the adaptation of means to ends. This observation is however more perfectly verified by human, than by Comparative Anatomy; for so well is man acquainted with his own wants and desires, and with the structure of the human body, that he must be a dull, inconsiderate, or perverse character, who can contemplate the organs and structures which compose it, without a feeling of admiration. The very reverse however happens in Comparative Anatomy. Many of the animals we dissect, are, when living, concealed from our view; they are hid beneath the surface of the earth, or the waters; they fly aloft in the air; or secrete themselves in the recesses of the forest; so that we have little
acquaintance with their habits, or peculiar wants and desires. We cannot, therefore, so well perceive the reasons of those varieties of formation we discover, nor judge of their adaptation to the peculiar exigencies of the being that possesses them. In many instances also the organization is extremely obscure, and in some it is probable that it never can be developed.

There are minute animals, the motions of which are extremely vivacious, and in which all the processes of life are carried on with great celerity and vigour, yet no organization can be detected in them, even by the aid of the microscope. We are, therefore, obliged to conclude either, that there may be organization which is wholly undiscernible; or that life can execute its functions unconnected with those kinds of organization which we observe in animals in general. Whatever may be the structure of animals, we cannot however but perceive, that each possesses means of procuring sustenance adequate to its wants; so as to ensure its perfection of health and growth, and powers
to continue its species, which seems to be the consummation of animal existence. Neither can we avoid remarking, how admirably the perceptions and faculties of animals are adapted to the situation which they occupy in the graduated scale of existence. As far also as we can discern, we perceive the same evidences of design and admirable contrivance; and the facts we learn from the examination of the structure and functions of living beings in general, may indeed be said, "to come more home to every man's business and bosom," than any we collect from the study of Nature in other departments of science.

You find displayed in the beginning of the Museum, many forms of the moving powers or muscles; and also the uses of elastic ligament are shewn, which sometimes produces motion, and sometimes retains parts in certain positions, by its mechanical properties, without the expense of muscular exertions. It is this substance which keeps open the valves of shells and the claws of lobsters, so that no power is
exerted but in closing them; it is this substance also which supports the head of animals, without muscular effort, whilst they are grazing.

I remind you, gentlemen, that Mr. Hunter, who did not consider life to be dependent on organization, was I believe the first who clearly ascertained and publicly announced the fact, that muscles, after contracting to their utmost, might gradually acquire a new sphere of contraction. This fact was first ascertained by the following case, which I relate, because I believe it is not generally known. A lady who had both knee pans broken and greatly retracted, came to London many years after this accident, and consulted Mr. Hunter on her case. Almost every other surgeon would have considered it hopeless. He, however, who was constantly thinking about the reparative processes, began to enquire whether the long union which had taken place between the distant portions of the bone was of a ligamentous and unyielding nature. To ascertain this point, he endeavoured to force the upper portion still higher, and found that
the lower followed it, and that a motion of the leg was thus produced. The muscles were however unable to move the retracted part of the patella, because they had already withdrawn it to the utmost extent of their original power. Mr. Hunter saw no reason why muscles, thus circumstanced, might not acquire a new sphere of contraction, yet he saw no mode by which they were likely to do so, except through the influence of the will of the patient; and to persuade persons to will what must appear to them an impossibility, was the chief difficulty he had to encounter in his endeavour to ascertain the proposed subject of enquiry. He persuaded his patient to sit on a table, and suffer her legs to swing backwards and forwards. This they did in the same manner and from the same causes that a pendulum does. She could indeed retract the limbs further under the table than their pendulous motion would carry them, by the agency of their flexor muscles, but she could neither check their motion in this direction, nor prolong it in the opposite one, by any exertion of the extensors. Mr. Hunter urged the patient to sit at intervals
for an hour or more a day, wishing the exertion of such powers might take place; and she promised to comply with his request. After a time, she became persuaded she had in a degree acquired her object, and thus encouraged, her will became more energetic, and the muscles more obedient to its mandates; till it was evident to others that she could check the receding motion of her limbs, and prolong the advancing one. Mr. Hunter then attached weights to her feet, to increase the demand for muscular effort, and thus, by degrees, did the patient acquire the power of extending the legs on the thighs, and the consequent ability to stand and walk. That muscles may acquire a new sphere of contraction, was afterwards fully proved by other cases; and Mr. Hunter has put up in his collection of anatomical facts, illustrative of the vital functions, the biceps muscle of both arms of the same subject; the one, which is of its natural length, measures eleven inches; the other, which has become contracted in consequence of the arm being broken, and the bones overlapping, measures only five
inches. Nevertheless, in this state, the bones having become firmly united, the shortened muscle acquired a new sphere of contraction. The particulars of this last case are recorded by Sir Everard Home, in a Cromian lecture, published in the Philosophical Transactions for 1795.

Mr. Hunter next displays the anatomical facts relating to the formation of bone, and exhibits specimens of that variety, the black periosteum of the silk fowl of Guinea. He also shews the various kinds of joints and substances by which the bones are connected. The formation of shell, and the growth of horns, are likewise exhibited by various preparations. As these subjects have been already considered in this theatre, I have no wish to say any thing about them on the present occasion, except in reference to one particular.

Every one at all acquainted with the mind of Hunter must be assured that he could not fail to be much interested with the facts relating to the annual renewal of the stag's
Lecture II. 77

Horns. Those of other animals last for life, and yet the large and curiously-branched horns of the stag, though formed of equally durable materials, are cast off annually, and replaced with a celerity of growth that would scarcely be credited by any Physiologist who was not well acquainted with the fact. Of Mr. Hunter's observations on this subject I shall speak hereafter; at present I only wish to mention that he particularly noticed the fact at that time not commonly known or attended to, that, if a stag be castrated, the horns, which are shed annually, are not afterwards renewed; so that the animal having lost the male powers, no longer exhibits their external characters. We do not find, however, Mr. Hunter drawing any inference from this fact, for it warrants none other than the want of the beard in man, would do, from a similar cause, provided he also became bald-faced annually. On the contrary however, we find him much excited by observing, that when the sexual character is annulled by age, the appropriate external signs are not only discontinued, but some-
times opposite ones exhibited. He really seems interested in observing, that old women sometimes become bearded, and that the old hen pheasant forms and displays the beautiful plumage of the male bird.

In some late works on Physiology, I find it suggested, that the formation of one part or organ, creates a necessity for the formation of another; and therefore it happens, I presume, according to this mode of reasoning, that men become bearded and stags wear horns. Yet these writers have not suggested any reason for the occasional exhibition of the delusive signs to which I have been referring, and I suspect that the consideration of this subject in general, has been omitted, in drawing such conclusions as I have just referred to.

According to Mr. Hunter's notions of life, those occurrences which denote the sexual character are to be considered as the effects of sympathies existing between remote parts of the body; which, like other instances of sympathy, are liable to
occasional failure and considerable variation. That such sympathetic actions are the effect of unknown laws, he could never have doubted; but he thought he perceived a spirit and design in these laws very different from those which produce results in dead matter. In the latter the results are immediate and uniform, so that they may be predicted; whilst in the former they sometimes do not take place, and appear more like the effects of option than necessity; they also are subject to considerable varieties; neither is their result in many instances immediate; yet the actions tend to produce some remote effect or good to the individual in which they occur. That such were Mr. Hunter's ideas of the vital actions may be inferred from his unphilosophical language, which imputes design to unintelligent agency.

Mr. Hunter seems first clearly to have perceived that we could not judge of the vital actions from other subjects, and therefore that the zoonomia must be made a separate study and pursuit by comparing
the vital processes with one another in the same animal, and in all the varieties of living beings. *

Under the influence of these notions, we cannot be surprised that he is interested in recording the facts, which seemed to him to shew that when age has annulled the principal sexual powers, their appropriate external evidences are not only discontinued, but sometimes those of an opposite character are displayed. †

The difference of form and character between the male and female of most animals

* If, indeed, all the phænomena of life were produced by the super-addition of a subtile substance, or substances capable of causing chemical composition, decomposition, variations of temperature, and actions, according to the suggestion contained in the first lecture, page 35, without being regulated by any other vital energy, but acting in conformity to pre-established laws; still the results are so different from what we observe from the operation of the same causes in matter in general, that the laws of life must be peculiar, and, therefore, require to be made a separate study.

† Mr. Hunter's paper on this subject will be found in the Philosophical Transactions for 1780.
is in general considerable and striking, and denoted by circumstances very diversified, but not reducible to any general rules. Yet this difference does not seem a consequence of necessity, for there are some species of animals in which it scarcely can be said to exist, and in others the female is the larger and stronger, partaking more of what we usually deem the masculine character.

That the characteristic signs of either sex are in general deficient, in proportion to the deficiency of the most essential and important of the sexual organs, must be admitted. Yet as the cases denoting this fact in the female, are not common, it may be proper to refer to some of them. Mr. Pott removed the ovaries of a woman which had been protruded from their natural situation into the groins, like hernia in common. The uterus never afterwards menstruated, the breasts wasted, and the body became muscular and robust. Mr. Pears relates the case of a woman born without ovaries, in whom the other sexual organs were
formed, though they remained in a dwarf and inefficient state. She never manifested any of the attributes of the feminine character. She was broad-shouldered, and small round the hips, like a man.*

How fond Mr. Hunter was of animals, how closely he observed their form, habits, modes of action, and progression, Sir E. Home has already told us in this theatre. He preserved the skeletons of most of the animals he had dissected, and there are probably 300 specimens in boxes, which he had no room to display, neither is there space enough in this building. That he was an observant and accurate comparative osteologist is also apparent from his last papers in the Philosophical Transactions, containing a commentary on fossil bones, found in caves near Bayreuth, and elsewhere. Mr. Hunter has, however, exhibited and contrasted some of the skeletons of animals, and preserved specimens of those of rare and curious forms; he also

* Philosophical Transactions for 1805.
collected the heads of persons of different nations. Yet still I am aware that the Hunterian Museum may by some be considered as deficient in the department of osteology, and, as has been before observed, the minute examination of the form of animals did not come within the scope of Mr. Hunter's designs.

Having derived much gratification from reading professor Cuvier's remarks on this subject, and believing that there is much food for meditation even in a skeleton, I shall put together some observations on the form and mechanism of that of the human subject; for as anatomy is chiefly taught as the ground-work of medical and surgical knowledge, such observations are not in general incorporated with systematic treatises on that subject.

The head is formed into the bony cavity, which contains the brain, called the cranium; and the face, which is the seat of four of the senses, that are situated near
the organ of sensation, volition, and other faculties. In proportion to the size and complexity of the brain, with reference to the size of the nervous system, do animals appear to possess various kinds and degrees of perception and intelligence. Camper and Hunter, at the same time, attended to the apparently descending series in the construction of the heads of animals. The head of the African does really in some degree, and in some individuals more particularly, approximate in form to that of the monkey; in the sloping direction of the forehead, the size and depth of the temporal fossa, in the flatness of the nose, the projection of the teeth, and the diminution of the chin. We also observe this approximation in other parts of the African skeleton; in the length of the loins, and in that of the forearm and leg, compared to the arm and thigh; in the flatness of the foot, and projection of the heel. In the head of the monkey we distinguish the same things, but in so aggravated a degree, that we at
once recognize the head of a brute, possessing little cranium and much face, a mere approximation of form to the human head, a mockery, with which, in general, we are more disgusted than pleased. In the quadruped, the forehead is nearly an horizontal continuation of the face, and the jaws, so greatly extended, that the cranium is but little apparent, and the face constitutes the chief part of the head. In the bird and in the fish we observe the same circumstances, but in a much more striking degree. So greatly did these observations interest Sir Joshua Reynolds, that, in his portrait of Mr. Hunter, he has left his portfolio open at that part where this descending series is sketched.

This is the first time, on the present occasion, that I have to call your attention to the very curious and problematical concatenation which exists in all the works of Nature. In the African, we perceive a link connecting the human form with the extremely diversified forms of the brute creation. I cannot forbear to add, that though
there is an approximation in the form of the African to that of brutes, there is none in his nature; for well educated Africans have displayed great powers of mind.

Camper also remarked, that the heads of persons of intellect, were generally characterized by a large and prominent forehead; and that in the Greek antique head, the forehead is made to project beyond what is natural, or has been ever observed. It has, I believe, been a question among artists, why we are so fascinated by the sculpture of the Greeks. The intellect of the Greeks seems superior to that of most other nations; their philosophers, poets, orators, and designers, have all left us models difficult to imitate, almost impossible to surpass. With a kind of intuitive perception of the τοναλον, of whatever is excellent or beautiful, they formed an ideal perfect head, and have exaggerated those circumstances in which the human head differs from that of a brute; yet with a delicacy that leaves the excess beyond what is natural to man, not readily distin-
The head of a brute has its forehead oblique, or declining towards a horizontal line, drawn from the top of the face; and the sides of the forehead converge from the orbits, so as to make it narrower at the top than at the bottom. The Greeks made the human forehead advance a little before a perpendicular line, and they raised it to an uncommon height. They made it also diverge from the orbits, so as to be broader above than below. The eyes of animals are placed at the sides of the head, so that they see laterally, and some even behind them. The human eyes are made to look forwards; whenever they glance to a side, they indicate either fear or distrust. The Greeks seem to have paid attention to this point; the eyes are made to look strait forwards, and the outer edge of the orbit is so wrought up, as seemingly to preclude a contrary vision. The eyebrow is a feature peculiar to the human face; and I think it must be regarded chiefly as an organ of expression. In the antique head, this part is finished with much labour and skill.
The bridge of the nose is also peculiar to the human face; it is represented very prominent, or raised much above the level of the orbits. The Greeks thought it most beautiful when it proceeded in a strait line from the forehead, whilst the Romans preferred it arched. The nostrils are formed as little like a snout as possible; they are apertures for respiration, and for smelling, in the human subject, and their motions contribute to expression. The orifice of the mouth, though occasionally used for eating, seems chiefly constructed in the human face, for the articulation of our words; and the motions of the lips are also strongly indicative of our feelings. The Greeks represented the mouth according to these views of the subject. They made it as little like a devouring aperture as possible. They made the orifice of small dimensions; the lips thin, but muscular and expressive; and they sometimes even flattened the arch of the jaws in an excessive degree. The chin, which is peculiar to the human countenance, they made to project very considerably, and in the males they repre-
sented it broad. I forbear to say more, because this is a subject rather of taste than of science; yet design all this, effect but this, and you will form the front of Jove himself.

Doctors Gall and Spurzheim tell us that brutes have a forehead and hind-head, but they want the middle part of the head, which is peculiar to man. Man is a long-headed animal; there is a great extent of brain between the fore and hind parts. The top of his head is arched, and in some individuals, in a peculiar degree, so that the hair falls to either side, and hence results the naturally parted forelock; and it is there that our new cranioscopists believe they can discover signs indicative of moral sentiments and excellence. Perhaps some spice of vanity may be perceived in Milton's description of the head of Adam, for it seems to be copied from his own.

His fair large front and eye sublime declar'd
Absolute rule; and hyacinthine locks
Down from his parted forelock manly hung,
Clustering;
Doctors Gall and Spurzheim further tell us, that the instincts or propensities of brutes may be judged of from the form of their heads, and assert the same with regard to the human subject; which latter assertion does not appear discordant to general observation. For if the human head be more produced in those parts peculiar to man, so does its possessor frequently appear to have more of the intellectual character; or if in those parts common to him and brutes, so has he more of the propensities in which he participates with animals in general. Even this was observed by the Greeks, who, to use Dr. Spurzheim's own expression, "never committed such an absurdity as to put the head of a gladiator on the shoulders of a philosopher, or the reverse."

The speculations of these gentlemen appear to me very ingenious, and calculated to unravel some of the intricacies of the human character, as well as to establish a just distinction between the faculties of animals and those of man. The peculiar
original dispositions and talents which certain individuals possess, must either be ascribed to original qualities of mind or to causes which may produce them. To me, who think it absurd to suppose that perception and volition are the result of organization, or an affection of mere life, and consequently who believe them to be properties of something distinct, it is even pleasing to perceive how any thing essentially perceptive and possessing consciousness and volition as the natural and seemingly necessary adjuncts of perception may be variously affected, and consequently prone to certain actions. To me, the plurality of our senses has always appeared a strong argument for the individuality of mind. I see, I hear, I am variously affected. I am more delighted with the objects I behold, or more charmed with the melody I hear.

If Doctors Gall and Spurzheim tell us, that in consequence of certain conformations of our brains, we have propensities, such as brutes also possess, productive of good or evil
according to the degree or direction in which they are exerted, they only attempt to account for facts of which we are all conscious. Men are by nature brave or fearful, generous or covetous, candid or cunning, fickle or determined; and these original qualities, though they admit of being controlled and suppressed, cannot be altogether annulled. Our great student of human nature and conduct, whose representations of them must ever render him the delight, admiration, and glory of his country, has also metaphorically portrayed that mixture of good and evil which belongs to the human character. "Our web of brain is as a mingled yarn, the good and ill together; our virtues might be proud, if our vices whipp'd them not; and our vices would despair, were they not cherished by our virtues."

There is nothing in the assertions of Drs. Gall and Spurzheim contradictory to the results of general observation and experience. It is admitted that the superior intellectual faculties can and ought to control
the inferior propensities. It is admitted that we may possess organs, which, nevertheless, may be inactive, from natural torpor or want of education. General observation and experience proclaim, that susceptibility is the chief incentive to action, that it is the source of genius; and that the character of man greatly depends upon his education and habits. We educate our faculties; what is at first accomplished with difficulty, by repetition is easily performed, and becomes more perfect and established by habit. Trains of perceptions and thoughts also become firmly concatenated, and occur in succession. Even our feelings undergo the same kind of education and establishment. Casual feelings of goodwill, by repetition, strengthen and produce lasting friendship; whilst trivial sensations of disgust, in like manner, may occasion inveterate hatred. When the remembrance of our perceptions recurs, they are often concatenated with other perceptions, modified by reflections, and associated with feelings; and it is by means of the repetition of such trains of perceptions, thoughts,
and feelings, that habits of thinking and acting are acquired and established. Yet such reflections and associations are produced and regulated by the actions of our own minds; and it is therefore evident, of whatever materials Nature may have made us, she has at least given us great powers of forming and fashioning ourselves. Had the dispositions and powers of our minds been similar, human life would have been dull and monotonous. Their variety enables us by education to attain different kinds and degrees of excellence, and to be useful to one another.

The very supposition of the organs which are said to form the distinctive characters of the human race, appears to me extremely ingenious. Every one knows that some individuals are more prone to the accurate notation of facts; others to their comparison, and to forming judgments from analogy; others to the investigation of causes; and others to those sportive combinations of similar and dissimilar things productive of wit and humour; which facts are attributed to
the organization of the brain being more active or developed in different parts. I need not tell you, gentlemen, that I went to school a long while ago, and that what I was there taught has become established by repetition and habit, so that I cannot readily express my meaning, without the use of the old terms, cause and effect; it seems proper, therefore, to explain what I wish to express by them.

In several medical books published of late, I read, that we have no knowledge of cause or effect, save what results from the continued observation of the priority of the one, and the consequence of the other. I was however taught to believe that we had by enquiry attained a rational assurance of the nature of cause and effect in a great number of instances, and might, by a continuance of the same endeavour, probably obtain it in others. All our knowledge is derived from our perceptions, and they inform us, that if one body in motion impinges on another free to move, the latter receives part of the motion of the former according
to the degree and direction in which the force has been applied. If, therefore, I push a bullet contained in a tube, in a horizontal direction, I infer that it moves for the same reason, or from the same kind of cause. But if I put the tube in an oblique or perpendicular direction, I find the bullet move with different degrees of velocity and torce from another cause, gravitation. If I explode gunpowder in the lower part of a tube held in a perpendicular direction, containing also a bullet, I find the ball forced upwards for a time by one cause, and then it decends in consequence of another. My senses may indeed inform me of the appearances of light and shade, in the surfaces of spherical and many-sided figures; but if, after having studied all that human ingenuity and industry has discovered relative to these subjects, I am able, in the absence of the object, to represent upon paper a spherical or many-sided figure, do I not manifest a knowledge of the causes of light and shade beyond that which my perceptions alone would have produced? If also, I can at will present the angle of a
prism to a luminous body, so as to produce the regular exhibition of the rainbow colours, do I not exhibit a knowledge of the causes of such effects? If indeed the retailers of such sentences as I have been commenting on, merely design to inform us that we have no knowledge of the precise means by which a cause produces an effect, they surely need not have exhibited so much parade in shewing what is constantly seen and acknowledged. If however they mean to insinuate, that we have no knowledge of cause or effect beyond that which results from mere observation, they publish at the same time, a libel on the human understanding; a prohibition to rational inquiry, and a most severe satire on themselves.

Should the result of our general enquiries, or attention to the subjects proposed to us by Drs. Gall and Spurzheim, eventually induce us to believe that the peculiarities of our feelings and faculties were the effects of variety of excitement transmitted through a diversity of organization,
they would tend to produce mutual forbearance and toleration. We should perceive how nearly impossible it must be that persons should think and feel exactly alike upon any subject. We should not arrogantly pride ourselves on our own virtues and knowledge, nor condemn the errors and weakness of others; since they may depend upon causes which we can neither produce nor readily counteract. The path of virtue is plain and direct, and its object distinctly before us; so that no one can miss either, who has resolution enough never to lose sight of them by adverting to the advantages and allurements, with which he may be presented on the one hand, or the menacings with which he may be assailed on the other. Yet no one, judging from his own feelings and powers, can be aware of the kind and degree of temptation or terror, or the seeming incapacity to resist them, which may have induced others to deviate. Now though, from the foregoing considerations, I am pleased with the speculations of Drs. Gall and Spurzheim, I am however quite incompetent to give any
opinion as to the probability of what they have suggested; because I see no mode by which we can with propriety admit or reject their assertions, except by pursuing the same course of investigation that they themselves have followed; a task of great labour and difficulty, and one which, for various reasons, I should feel great repugnance to undertake.

After these general observations on the form of the human head, the mansion of the mind, and the index of its character, I proceed to describe that of the teeth, which commonly make a part of the skeleton. In man, they must be regarded chiefly as the means by which he masticates his food; yet Mr. Hunter did not, in my opinion, consider the teeth of animals in general as subservient principally to this purpose, but placed them in his Museum, for reasons that will hereafter be explained, among the instruments and weapons that are allotted to animals.

The four front teeth, in man, have their
edges overlapping each other, like the blades of a pair of scissars, and seem well calculated to cut in slices the food which admits of such a division. The side front teeth, which correspond to those teeth in animals, called tusks and tushes, fangs and venom teeth, are in the human subject, round in front, flattish behind; they increase in size as they project from the gum, till having attained their greatest magnitude, they become suddenly and obtusely pointed. They have long roots inserted deeply in the jaws, and the pointed termination of their bodies projects a little beyond the level of the line made by the edges of the other teeth. These teeth seem well calculated for breaking into small pieces hard substances, and thus preparing them for the action of the grinders. All the back teeth in the human subject are grinders, and there are two small and three large on either side, in each of the jaws.

That nature meant man to grind his food by means of his teeth, is to be inferred, not
only from their form, but from the mechanism of the joints of his jaws, from the great strength and various actions of his muscles of mastication, and from the lever formed by the coronoid process to increase their power. I do not know, however, that we are warranted to infer from the teeth alone what kind of food nature designed us to live on. Some vegetables and animals are peculiar to certain districts, and will not thrive in other situations; whilst other kinds of vegetables and animals, are found more generally distributed over the surface of the globe. Grass and corn thrive everywhere. Man also seems an universal animal. He can and does live in some places upon vegetables only, whilst in a Greenland winter, his chief sustenance is derived from oil and fish. Nature may have given man means to grind his food, that he may extract the greatest quantity of nourishment from a deficient supply of it; and he can by mixing different kinds of food qualify substances for trituration, which by themselves would be unsuited to that process. It is also one of his characteristics, and in which
he seems much to delight, that he is a cooking animal. The human teeth are also of great use in the articulation of our words.

I should certainly not fulfill one of my objects in these Lectures, which is to display, to the extent of my ability, the merits of Mr. Hunter, were I to omit in some part of them, to notice the surprising labours he bestowed, in investigating the structure and functions of animals of the whale kind. In all the works of nature, we perceive extreme variety. The teeth are not only various in their formation and re-production, but also in the substances of which they are formed, and the purposes which they serve: and as some of the whales present a very curious instance of this sort, I trust I shall be excused, if I introduce the subject on the present occasion. In Mr. Hunter's paper relative to the structure and functions of animals of the whale kind, there is abundant evidence of the peculiar character of his mind. We see the student of nature on the most
extended scale, solicitously enquiring into all those particulars which adapt these animals to the peculiar situation they occupy in the scale of existence. The horizontal direction of the tail, so different from that of fish, and the cause of the peculiar strength of the flexor muscles, analogous, as he says, to the lumbar muscles of animals, is shewn to be calculated to raise the most prominent part of the animal, where the blow-hole is placed, above the surface of the water for respiration; whilst the horizontal motions of the tail are equally adapted to depress it to the depths of the ocean in search of food. The motions of the tail cause these animals to move up and down in a curvilinear direction, which makes them appear hump-backed, and thus the dolphin is generally represented. We see this in porpoises when they swim slowly and near shore, alternately respiring and grubbing along the bottom. Yet these creatures can, with their powerful tails, scull themselves forwards in a strait direction with surprising speed, passing a ship whilst she is going at the rate of ten
miles an hour, with the same apparent celerity, as if she were lying at anchor.

The back bone of this tribe of animals, is formed as in quadrupeds*; it has not the flexibility nor lateral motion of that part in fishes, neither have they side oars or fins, and therefore they are unable to pursue the quickly varied and versatile motions of the finny tribe. They say, however, that a squadron of porpoises will encompass a shoal of herrings and drive them into a small bay to devour them. Though many of the whale tribe have teeth, they probably chiefly feed upon medusæ, sepiaë, shrimps, &c. which they find on the shores and depths of the ocean, or when pressed by hunger, they may destroy and devour one another. Mr. Hunter found the eye of some kind of whale undigested in the stomach of the grampus. We cannot consider them as predacious animals, for these in general, are suspicious, cunning,

* Mr. Hunter has put up a preparation of the intervertebral substance, which is similar to that of quadrupeds in general.
and solitary, whilst the whale tribe have an opposite character. The porpoises accompany our ships on the voyage, and they say the dolphin has been known to come to the shore when called for food he had been accustomed to receive; observations and stories of this kind may have formed the basis of different poetical fictions.

For so monstrous a creature as the great whale, when thus constructed to obtain a supply of food for its vast bulk, would appear to us, were we ignorant of the means which nature has contrived, a subject of the greatest difficulty. But she has made his mouth an enormous trap, and has given him whalebone teeth, the fringed edges of which form a finely meshed net to encompass his prey. We must suppose him groping along the bottom of the ocean, his jaws extended, his mouth a vast chamber, twenty or thirty feet in length, and ten or twelve in breadth, filled with water, containing medusæ, sepïæ, shrimps and small fish, when gently closing his jaws,
they are encompassed in a net formed by the decussating fibres of the fringed edges of the whalebone teeth. The tongue, which is soft like a feather bed, and very thick, being applied to the roof of the mouth, the water is expressed through the apertures of the net, and then the food is swallowed. Thus is the most powerful Leviathan obliged to obtain his livelihood by the exercise of the wily arts of the fisherman.

Mr. Hunter supposes, that the oil and spermaceti which these animals form in such abundance, not only serves to give them buoyancy, but also proves a storehouse of nutriment in cases of failure in the ordinary supply of food; for he found the cells that contain spermaceti empty in some instances, which, he thought, indicated that the animal had been for a long time without food. The whole of the whale tribe have also complicated stomachs like those of ruminants, which enable them to extract the greatest quantity of nourishment from whatever food they may
obtain. I must not pursue this subject further, but merely recommend those who wish to do justice to Mr. Hunter, and form a fair estimate of his labours and merits, to peruse this paper with consideration.*

* Philos. Trans. 1787.
LECTURE III.

The head is placed on the top of a column of bones, which, from their having in general a kind of turning motion on one another, are called vertebrae, and the whole pile is called the vertebral column. The base of the column rests upon a wedge-shaped bone, interposed between the side-bones of the pelvis. Each vertebra has belonging to it, a part called its body, which is of an oval or circular form, and presents two plain surfaces to the bone above and below, which are cemented together by the intervertebral substance. The bodies of the vertebrae appear in front of the pillar, laid one upon another, like the stones with which a column is erected. They chiefly support the weight of the head and trunk, and regularly and considerably increase in size, as they descend, because the weight is proportionately augmenting.
The intervertebral connecting substance is composed of concentric layers, of tough, strong, and unyielding ligaments which extend for about a quarter of an inch from the circumference of the body towards its centre, when the connecting substance appears softer, and is manifestly elastic; which appearance continues till it approaches the centre, when the still connecting matter becomes pulpy and inelastic. The exterior concentric layers of strong unyielding ligament serve for security. The quantity of elastic substance interposed between the several vertebrae, is not so great as to occasion any insecurity in their connexion, yet the aggregate elasticity of the whole, renders the vertebral column very springy; so that the head rides upon its summit, undisturbed by jars, and as upon a pliant spring. The central inelastic matter admitting of a ready variation of form, though not of bulk, serves as a pivot facilitating the motion of the vertebrae on one another. Doctor Maclaurin in his lectures delivered more than
half a century ago, was accustomed to illustrate its use by comparing it to a bladder partly filled with water, and placed between two trenchers; in which case, the water would readily diminish in bulk as the circumference of the trenchers became approximated on the one side, and would occupy the increasing space on the other. As the exterior ligaments are unyielding, this variation of form in the central pivot could never have taken place, had not an elastic substance intervened between them.

It is interesting and creditable to human intellect, which thus penetrates into the designs of nature, to know, that in the great fish, the squalus maximus, or basking shark of Pennant, this, then merely suppositious, structure is actually found. There is in the centre of the intervertebral connection, a bag of water, and so great is the elasticity of the substance by which it is surrounded, that when Mr. Clift cut into the bag, the expansion of the elastic matter, projected the fluid to the height of four feet in a
large and perpendicular stream, compressing the bag into a small compass, and forcing its sides into numerous wrinkles.

Behind the body of each vertebra there is a bony ring, and these rings, when opposed to one another, constitute a canal for the protection and transmission of that important part, the medulla spinalis. From these rings, seven processes are continued, four of which serve to make joints, connecting the vertebrae with one another. There are two ascending and two descending articular processes. Two processes also stand out laterally, and are called transverse, and one backwards, which, being in general pointed, is named spinous. These latter processes chiefly serve to give attachment to the muscles which support and move the vertebral column.

Upon the form of the articular processes, the degree and kind of motion which takes place between the several vertebrae, seem entirely to depend. In the neck, the opposing surfaces of the articular processes
are smooth and oblique planes, a form which admits of a limited and equal degree of sliding motion forwards and backwards, from side to side, and also of a turning or vertebral motion of one bone on another. We know that the vertebral column in the neck, admits of an equal motion in these different directions, so that we can touch the breast with our chins, the back with our hind head, and the shoulders with either ear. We can also turn the neck, so as to describe with our face a complete semicircle. In the last motion, the effect is, however, augmented by the peculiar turning of the first vertebra upon the second, which will be separately described hereafter. In the neck we find the spinous processes short and horizontal, so as to afford no obstacle to the extension of that part, and we find them formed in a similar manner, in all animals which have long necks and carry their heads far backwards.

In the back, we find the articular processes formed into perpendicular planes, which preclude any motion either forwards
or backwards, or any turning of one vertebra upon another; a form which allows only of a motion from side to side, to which, however, the ribs present an insurmountable obstacle. In the back, we find the spinous processes sloping considerably downwards, and absolutely locked together, by a sharp ridge of one being received into a groove of the other. We find, also, the rib connected to the transverse processes, so that every circumstance concurs to prevent any motion, save that which results from the elasticity of the intervertebral substance. It seems, therefore, evidently the intention of nature, to make the vertebral column, in the back, a fixed support for the ribs to move upon.

In the loins, we find the articular processes very differently formed from what they are either in the neck or back. The descending ones are shaped like half an oval, the convex surface of which is received into a cavity of corresponding figure in those which ascend, which form is admirably adapted to admit of the suddenly
turning horizontal motion which takes place in this part of the vertebral column. It also freely admits of motion from side to side, but does not allow of it in any considerable degree either forwards or backwards. Indeed had such motions been permitted beyond a certain extent, the abdominal viscera would have been injuriously compressed by the ribs. Neither is much motion, in this direction, requisite, because we can carry forwards and backwards the trunk of the body, by moving the pelvis upon the rounded heads of the thigh bones. The spinous processes of the loins extend horizontally, so as not to interfere with one another in the turning motion, but their great breadth is prohibitory of extension beyond a limited degree.

The head is joined on to the first vertebra, (which, from supporting this globe on its shoulders, is generally called the atlas,) by two oval processes placed obliquely and received into corresponding cavities in the upper articular processes of this vertebra. The form of the bones precludes any hori-
horizontal or turning motion of the head upon the atlas, and admits only of a slight yielding forwards and backwards. The condyles are placed so exactly parallel to the center of gravity, that when we sit upright, and go to sleep in that posture, the weight of the head has a tendency to preponderate equally in every direction, upon the slightest inclination in the line of gravity; as we see in those who are dozing in a carriage. Nay, their heads sometimes revolve in a circle, like the head of Harlequin on the stage. The head and atlas turn round upon the second vertebra; the upper articular processes of which, as well as the lower ones of the atlas, are formed into nearly horizontal planes, a form well calculated to admit of this motion. They are not, indeed, perfectly horizontal, but shelve a little to either side, so as to admit of a part of the lateral motion formerly mentioned. The second vertebra has growing up from its body a tooth-shaped process, and it is, therefore, usually called the vertebra dentata. This process is tied to the head by ligaments of surprizing strength, which
are loose enough to allow the intended motion, but no more. This ready horizontal movement is requisite, to enable us suddenly to turn our eyes to different objects. If the head turned on the top of the pillar, there would be insecurity, unless some especial contrivance, not essential to the head or vertebral column, was instituted, as may be inferred from facts observable in Comparative Anatomy. The head is attached to the very summit of the column in the centre, by extremely strong ligaments, whilst in the circumference it is secured, not merely by other ligaments, but also by those powerful muscles which constantly support it, and occasionally move it in various directions.

The spinous processes of the vertebrae are connected to one another by what is called an elastic ligament, with the obvious properties of which, every one is familiarly acquainted, from having encountered it at their meals, in the necks of animals, where it forms the ligamentum nuchæ, which supports the head of the animal whilst grazing,
without the expense of muscular exertion. It is yellow, tough, firm, and powerfully elastic.

The spinous processes are situated so far behind the centre of motion, that if they had been tied together by unyielding ligaments, these must have been formed of considerable length, to allow of the greatest degree of bending of the column, and then they would have been useless and wrinkled in its common position. The elastic ligament admits of the utmost motion of the column, and, by its powerful elasticity, tends to restore it, and retain it in its natural form. The elasticity of the substance, interposed between the bodies of the vertebrae, also co-operates in restoring the column to its natural figure. If we take the vertebral column of a young subject separately from the other parts of the skeleton, and forcibly bend it in different directions, we find it suddenly and forcibly recoil, and assume its proper shape. The vertebral column is not straight; it comes forwards in the neck and loins, so as to appear like
the top and bottom of a perpendicular pillar, but in the back it projects posteriorly, and describes a segment of a large circle. In consequence of this form, the back part of the chest, the blade bones of the shoulder, and the weighty muscles of the back, project behind the centre of gravity, and become equiponderant to the weight in front; and, we know, that in an upright posture, the whole weight of the upper part of the body is so perfectly balanced on the base of the vertebral column, as to have an equal propensity to preponderate in every direction.

Though the motion taking place between the individual vertebrae is small, and such as can produce no alteration in the form of the vertebral canal injurious to the medulla spinalis, yet the effect of the conjoined motion of all the vertebrae is considerable; and appears still greater when observed in the motions of the head, which it supports. We can incline the head far forwards, backwards, or to either side, and nearly in an equal degree.
Had the vertebral column been formed straight, and the same extent of motion given to the head, the weight would have so preponderated, that its support would not only have been difficult, but it might have operated injuriously to the fabric of the column itself. As the column is constructed, when either end of it is projected in one direction, the other can be carried in the opposite, and the balance preserved. Thus, when the loins are brought forward, the neck and head can be carried backward, so as to preserve the line of gravity perpendicular to the basis of support; and vice versá in all directions.

By constant practice, the muscles are so habituated to produce these opposite and balancing motions, as involuntarily to do so with the greatest exactness, as well as to co-operate with the elasticity of the column, in restoring it to its proper direction and form. The requisite actions are slight, transient, and varied, and therefore produce no fatigue. This circumstance,
together with the disposition of the column to maintain its usual form, and the ease attendant on these motions, cannot be better exemplified than in the instance of riding on horseback. A practised and fearless rider will fold his saddle cloth into a cushion, place it on the back of a rough trotting horse, and sitting on it, keep his seat, undisturbed by suffering all the succussions of the steed to be transmitted to the body, above the pelvis, and preserving that part fixed, by constantly keeping the line of gravity of the whole perpendicular to the basis of support. Thus do we enjoy the most springy ease of motion, and perfect fixity of position, with scarcely any muscular exertion, and without any effort of mind, for volition cannot regulate the action of muscles in this manner, and those who, from apprehension, seek security in their own efforts, lose it, in proportion as they strive to obtain it.

The vertebral column in the back affords
support to the twelve ribs, one end of which lies imbedded in cavities formed between their bodies, and their tubercles are connected to the transverse processes. The ribs successively and considerably increase in length, as far as the seventh, which causes the cavity they encompass to become larger; they then diminish in length, and the cavity of the chest becomes smaller. The seven upper ribs are connected by gristles to the breast bone. The five lower have their gristles united with each other, or have no connection except with the vertebral column. The breast bone is placed very obliquely, so that at the top it is very near the vertebral column, whilst at the bottom it is very distant. The ribs, in proceeding from the dorsal vertebrae, first take a direction backwards, and then rather suddenly turn forwards, so that the vertebral column projects into the cavity of the chest. This circumstance, and the oblique position of the sternum, both contribute to render the weight, before and behind the vertebral column, equiponde-
rant upon its basis, in the manner I have formerly mentioned.

The upper or pectoral extremity of man, is divided into the shoulder, which is composed of two bones; the arm of one; the fore-arm of two; and the hand of many. The blade-bone of the shoulder is placed behind the chest, and not, as in brutes, by the side. It is in common so situated that the cup to which the arm is joined, and from which it hangs, projects exactly in the lateral direction, and consequently the weight of the arm has no tendency to move its socket forwards or backwards, but merely to depress it. Though the bones of the shoulder can be moved forwards and backwards, upwards and downwards, even in a considerable degree; yet the joint of the shoulder can never approach to the breast bone as it does in quadrupeds. The effects resulting from these circumstances are, that when the arms hang in their natural direction, the general line of gravity of the upper part of the body un-
Lectures

...dergoes no change; but if the hands be brought either forwards or backwards, the weight proportionately preponderates, and the whole body moves upon the base of the vertebral column. The extent of motion of the shoulder joint in the directions that have been mentioned, greatly augments the sphere of motion of the arm and hand.

The joint of the shoulder is kept from approaching the front of the chest by the collar bone, which is nearly strait, though projecting a little forwards towards its middle, so as to give a slight convexity of outline to the top of the chest and bottom of the neck. The end of the collar bone, which rests upon the sternum, is bulky, and of a somewhat triangular form, but it rests in a thick bed of cartilage, which prevents its shape from being apparent. The scapular end of the collar bone is flat, and connected in an horizontal direction with a like-shaped projection of the blade bone, which forms the end of the shoulder.

When the trunk is bowed forwards, the
hands swing in the same direction, and then the weight of the arm drags forward the shoulder joints. In weakly children whose bones are deficient in firmness, the collar bones yielding under these circumstances, become convex in front, and the bulky sternal extremities are in some degree dislodged from their cartilaginous beds. The blade bone is also drawn forwards on the convex ribs, so that the back part projects beneath the skin. The weight of the shoulders and head now bears, in some degree, upon the walls of the chest, being transmitted by them to the vertebral column, by which means they also become deformed.

So commonly do these causes operate in the manner I have mentioned, that we rarely see exactly such a collar bone as I have endeavoured to describe; they must have been very healthy when young, who have such collar bones as are represented in the Grecian statues. To prevent the deformities incident to the causes I have mentioned, parents are accustomed to brace
their children's shoulders backwards; nor do I think the practice wrong, where it is required, and when it is conducted with moderation; but surely we ought to caution the public against the absurdity of bracing the shoulders back, beyond what is natural, till the blade bones come in contact with the vertebral column, for this destroys the natural balance of the body, and is more likely to produce than to prevent deformity.

The joint by which the arm is connected with the shoulder, is a ball and socket joint, admitting of motion in every direction. Even those animals, whose pectoral extremities seldom move in any other direction but forwards and backwards for the purposes of progression, have a similarly constructed joint. The advantage derived from this mechanism seems to be, that it admits of the motion of the limb, or of the body singly. Thus, when at rest, the limbs may be moved without disturbing the position of the body, and when the limbs are injured, slight variations in the posture of
the body are permitted, without communicating motion to the limb.

The elbow joint moves like a hinge, backwards and forwards. Now, if the first joint be a ball and socket, and the second a hinge, it is manifest that the hand may be put in almost every possible position within the area of that space, the circumference of which it is competent to describe by its utmost extent of motion. There are, however, two bones in the fore-arm; and one of them alone has its motions restricted to those of a hinge. This is called the ulna, and is the bone which sends backwards a projection, we name the elbow. The top of the elbow gives a surface for the attachment of the tendinous fibres of the extensor muscle, and affords a lever to increase its power. The lever in the human subject, is, however, inconsiderable, compared with what we observe in animals, the power of whose progressive motions greatly depends on the drawing backward of this part. We observe this in our dogs, and horses, and other animals; and it forms the first apparent joint
in their pectoral extremities; for the arm and shoulder blade lie hid in the bulk and circumference of the body. The back part of the elbow in man, is formed into a smooth and somewhat triangular plain surface, upon which we occasionally lean. That nature designed this for an occasional resting place, is to be inferred from the coarse texture of the skin which covers it, which is similar to that placed over the lower part of the knee pan.

The form of the corresponding articular surfaces of the bone of the arm and ulna, freely admits an extensive motion forwards and backwards, and absolutely prevents any other. The bone of the arm has a groove formed in it, with lateral risings, and the ulna has a middle projection with lateral depressions. This groove making a kind of hinge for the ulna to move on, is formed obliquely, its upper part inclining towards the body. When, therefore, we bend the elbow, the fore-arm does not come in opposition to the arm, but carries the hand to the trunk of the body. When we
bend the elbow, we generally wish to approximate or apply the hand to some part of our persons; and in consequence of the oblique direction of the pulley, we accomplish by one motion, what would have required two, had the groove been formed straight, as it is in animals. That part of the ulna which is next the radius, for so the other bone of the fore-arm is called, is hollowed out into a semicircular cavity, in which the radius revolves to a certain degree. The top of the radius is formed into a shallow cup, which fits on to a convexity of much greater extent of surface in the bone of the arm. Therefore, the cup can move forwards and backwards, in correspondence with the motions of the ulna, and can also, in any state of flexion or extension of the joint, turn round upon its own axis. The radius has also a semicircular convex surface, which is lodged in the excavation of the ulna, and at the same time revolves in that cavity to a certain degree. Such is the mechanism by which we are enabled in any state of flexion and extension of the elbow, to turn the
hand prone or supine, for whilst the radius is revolving upon its axis above, it travels round the ulna below, and carries with it the hand.

The surface, which the fore-arm presents to make the joint of the wrist, is an oblong cavity of little depth. It is formed chiefly in the radius, and partly in a piece of cartilage, continued from the end of that bone over the extremity of the ulna. The side surface of the radius, which is applied to the ulna, is hollowed out into a semicircular cavity, receiving a corresponding convex surface of the ulna; so that the hand and the cartilage, continued from the radius, moves round upon the end of the ulna.

The wrist is composed of eight little bones placed in two rows. They form an arch slightly convex on the back of the hand. There are projections in front on either side, forming its basis or spring. These are secured together by the carpal ligament which is of prodigious strength. There is
a motion between the two rows of carpal bones, so that when the wrist is bent, the arch of the carpus forms a kind of knuckle without any angular projection. We find the same structure in the second apparent joint of the fore-legs of quadrupeds. What seems a knee is the wrist, and they kneel upon the knuckle of the carpus. The fabric of this part is particularly strong. Its arched form secures it from injury from above, the carpal ligament from below; but it is equally uninjured by forces applied to its side, else how could boxers strike with such force, or animals leap as they are known to do.

The four metacarpal bones, which are interposed between the carpus and fingers, are made large at either end, to form joints, and small in the middle, to afford room and arrangement to muscles, which move the fingers from side to side. Their bulky ends, which join on to the carpus, are connected by nearly plain surfaces, and admit of no manifest motion. The other ends, which support the fingers, are formed
into rounded heads, and the first bones of the fingers have cup-shaped corresponding cavities, so that considering the skeleton merely, we might suppose the joint was one of the ball and socket kind, admitting of motion in all directions. We find, however, that the ligaments are so arranged as to limit the motions of the joints chiefly to those of flexion and extension, allowing indeed of slight motion from side to side, and a slight horizontal turning of the finger on the end of the metacarpal bone, which motions are greatest in the fore and little fingers. The articular surface of this convex end of the metacarpal bones continues so far backwards and forwards, that we can extend the fingers a little beyond a right line with the metacarpus, and we can bend them to more than a right angle. The metacarpal bones are so connected by ligaments and muscles, as to prevent these ends separating from one another, and spreading, when we grasp convex bodies; and the end of the metacarpal bone, which supports the little finger, has a powerful apparatus of muscles expressly allotted to it, to keep
it firm, in opposition to the power of the thumb, when we grasp bodies with force.

The bones of the fingers are made a little convex behind, but flat in front, for the convenience of grasping. The second and third joints of the fingers are formed into hinges, admitting only of flexion and extension. The last bones of the fingers are very small, the nail causing the apparent breadth of the end of the finger.

The thumb consists of three bones, the first of which is articulated to the carpus, and the joint appears like a hinge, though from the looseness of the ligaments, it admits of a small degree of motion in very various directions; which motions appear more considerable than they really are, when their effect is observed, as the extremity of so long a radius as the thumb makes. In consequence of this freedom of motion, we are enabled to apply the end of the thumb to each of the fingers and to different parts of the hand, and also to place the thumb in direct opposition to the power
exerted by the whole of the fingers and hand, in grasping. The second joint of the thumb resembles the first joint of the fingers, not only in the form of the bones, but also in the arrangement of the ligaments, which limit the motions nearly to those of a hinge, and the last joint of the thumb, is like either of the two last joints of the fingers, a perfect hinge.

The fingers and thumb are of unequal length, and, on this account, they are peculiarly adapted for grasping spherical bodies, which are most difficult to seize and to hold. If, for instance, we take hold of a pocket globe, placing one of its poles in the hollow of our hand, we find all our fingers and the thumb opposing each other upon some parallel of latitude, and thus giving the greatest security to our grasp.

When the elbow-joint is fixed, the hand describes a complete semicircle, in pronation and supination; and the extent of its motion, in these directions, may be increased by variations in the position of the
elbow and shoulder. As the hand moves through a yet more considerable portion of a circle in the utmost flexion and extension of the wrist, as it admits in all these motions of being carried to one side or the other, it is obvious that we can take hold of bodies in any point of the very considerable area, the circumference of which, the hand is competent to describe, when the other joints of the arm are moved to their greatest extent. The excellence of the mechanism of the pectoral extremities of man is proved by its results. The structures are so strong, and the powers so great, that we can seize, and hold, and pull, and push, and strike, with great power, and in such surprizingly varied directions; and yet the joints and powers are so nicely formed and adjusted, that we can also take hold of the smallest objects, and guide them with the greatest gentleness, nicety, and diversity of motion, by which means we are enabled to model and design the minutest objects.

The weight of the head, arms, and upper part of the body rests, as has been shewn,
in equilibrio on the bone which supports the base of the vertebral column. This wedge-shaped bone is called the os sacrum, they say, because that part of the animal was frequently offered in sacrifices. It is very broad above and narrow below, so that the weight which it supports would only tend to depress the broader part of the wedge into the narrower space, and render the fabric more secure. The sacrum is convex behind, and concave in front, for it forms a part of a somewhat circular bony cavity placed at the bottom of the belly and called the pelvis or basin. The sacrum terminates by a smooth surface of small extent, and oblong in the lateral direction, on which there moves backwards and forwards a little bone which is called the os coccygis, from its supposed resemblance to a cuckow’s beak. This bone is occasionally thrust backwards, but is usually held forwards by muscles connected to it, and affords the last bony support for the weight of those bowels which may gravitate into the cavity of the pelvis in particular positions of the body.
This little bone is analogous to the tail of animals, which is moveable on the end of the sacrum, and composed of many pieces of various form in different animals. I mention this merely as one of the proofs, though it is far from the best, of the uniformity of the plan, and the diversity of the means and ends we observe in the construction of animals. The tail very commonly serves to animals the purposes of a switch, a balance, and a rudder. It is however a hold-fast in such as possess the cauda prehensilis, whilst to the kangaroo it is a prop and a leaping-pole, and to the beaver it serves as a trowel.

The sacrum derives support from the two side bones of the pelvis, by extensive surfaces, which converge as the wedge diminishes. These bones form a kind of circle, and are united with each other in front, and thus is the bony circumference of the pelvis completed. The back part of the circle being continued from the sacrum forms an arch on which the weight of the body is supported. No one can, I
think, view this part of the skeleton without being struck with its architectural construction. The wedge forms the key-stone of an arch, on which, not only the weight of the upper part of the body, but also of those loads which we occasionally sustain, is supported. The side bones are expanded above the brim of the pelvis forming the hips, and give support to the viscera contained in the belly. The hips are much more expanded in females than in males. The ancients, who had a clear and strong perception of whatever is beautiful and useful in the human figure, and who, perhaps, delicately exaggerated beauty to render it more striking, have represented Venus as measuring one-third more across the hips than the shoulders, whilst in Apollo, they have reversed these measurements. The lower part of the side bones are formed into oblique protuberances, upon which we sit, and here we have a fatty cushion to rest upon. These prominences are placed parallel to the line of gravity, so that when we sit upright upon them, the weight of the body is here again found to be in a state of equipoise.
cavity of the pelvis in the human subject, is not placed as it is in brutes, in the same direction with that of the belly. Were it so, the contents of that cavity would be continually gravitating towards its inferior aperture. Even the pelvic viscera cannot be said to gravitate towards the inferior aperture of the pelvis, in the ordinary positions of the body; whatever presses in that direction must be protruded.

The weight of the whole upper part of the body is transmitted from the arch described by the bones of the pelvis, to a second arch, made by the form of the heads and necks of the thigh-bones. Their heads, which are very perfectly rounded, making a considerable portion of a sphere, are lodged in deep cups, the brims of which are particularly high in the upper and outer part, where the re-action of the ground against our descending weight, would ordinarily tend to dislodge them, had not such an occurrence been thus guarded against. These cups are placed a little in front of a perpendicular line let fall from the top of the sacrum. As the weight of the greater
part of the pelvis, and of the muscular buttocks is placed behind the sockets, so when we stand upright, the whole of the incumbent weight is perfectly balanced on the rounded heads of the thigh-bone, and the most trivial variation in the direction of the weight occasions the body to incline towards that part, at which it takes place.

The hip-joint is the most complete ball and socket joint in the human skeleton, and the socket can move upon the ball with the most perfect facility, and with the nicest gradation and variation. Thus, when we stand upon one leg, we have the power of balancing the weight upon the rounded head of the thigh-bone. There are two modes of balancing, either by moving the incumbent weight upon the area of support, or by moving the basis of support under the incumbent weight. By the connection of our lower extremities with the pelvis, we possess the ability of balancing our weight in both these ways. No better demonstration of this need be given, than what is exhibited in those amphitheatres,
where feats of horsemanship are displayed. We there see a man stand with one foot on the saddle, and maintain his balance, when his horse is at full speed. This he does when his body is placed horizontally, and with one arm and leg extended in opposite directions. To maintain so perfect a balance, it is necessary that the weight of the body should move in various directions, and with nicely adjusted gradations upon the head of the thigh-bone, and also, that by the motions of the knee and ankle, the support should be equally varied under the incumbent weight.

The weight of the body is transmitted from the arch of the pelvis, to a second arch made by the form of the heads and necks of the thigh-bones, the basis of which rests against the side of the bone near its top, and protrudes that part of the bone outwards, and the bottom in a contrary direction, so as to bring the knee-joint nearly under the general line of gravity of the whole body, and from this joint, the weight is transmitted in a perpendicular direction upon the arch of the foot.
I must not dwell upon the form of the bones or the structure of the joints in these pelvic or lower extremities, lest I should set my audience asleep. Suffice it then to say, that when the knee-joint is extended, so that the leg makes a perpendicular line with the thigh, and the ankle bent, so that the foot forms a right angle with the leg, each of these joints is rigid and immovable. Such is their position when we stand; the whole limb forming a pillar for our support, and no motion can take place but at the top or bottom, at the hip or foot. But when the knee is bent, and the foot stretched out, as happens in progression, the same joints are loosened, and a lateral motion admitted, which is useful in the direction of our steps. The knee is secured in its extended state, so necessary for our support, by muscles which are incomparably the strongest in the whole body; and which hold the knee-pan elevated to the top of a pully formed in the front of the joint. But when these muscles are weak, then indeed are "the pregnant hinges of the knee disposed to crook," and
yield to the incumbent weight. By the same muscles we are let down easily into our chairs, and they are the agents which raise us up again.

There are those who, having by habit preserved the motion of their joints to the greatest extent, and of their muscles to the greatest degree of action and yielding, can lower themselves gradually so as to sit upon their heels. These muscles therefore are employed to break our fall, if it takes place in the most dangerous direction backwards. The strong muscles in front of the body, more potent from the lever with which they operate, being attached far before the centre of gravity, also concur in bringing forwards the chest and head, and protecting them from injury. We see children, when in danger of falling backwards, by these means suddenly sit down upon the ground. Nature has also formed the lower limbs of children, whose powers are feeble and unpractised in balancing, so short as greatly to diminish the risk of injury from falling. Most young animals are formed with short
limbs apparently for the same reason. Such formation however cannot be considered as the result of necessity, for when the mother suckles her young, whilst standing, their limbs appear of a preposterous length. When we fall forwards, we fall as a quadruped stands, our outstretched arms protecting the upper part of the body, and our bended knees the lower. When we stand on one leg, the weight of the whole body, as well as of those loads which it occasionally sustains, is transmitted by the bones of the leg upon the arch of the foot, which is very convex, and well adapted for its support, from whence it is transmitted to the heel behind, and to the ends of the metatarsal bones which form the first joints of the toes, so that it rests upon the ground. Chiefly however the weight is supported upon the ends of the metatarsal bones belonging to the great and little toe, which have a strong apparatus of muscles to keep them steady and preserve them in their relative situation to the heel. Thus is our weight supported on an arch and transmitted to the ground by a
tripod: forms well known to be best adapted for giving support and security of position. Nature, however, gave us powers of grasping with our feet, and thus further securing our position, but these we in general lose for want of using them. They say, a Chinese will sit perched upon a ship's boom when it swings to leeward; and it is recorded, that Milo could stand with one foot on a quoit, and no man in Greece could push or pull him off. If this be true, he must have been not only a very strong man, but a very heavy one, and a most expert balancer.

The arch of the tarsus, like that of the carpus, can also resist the effect of forces when applied against it sideways. We can walk on the ends of the metatarsal bones, and in that case, the short toes do but seem to increase the extent of surface on which we are supported. This security against injury in this direction, is further manifested in quadrupeds; for the tarsus is the structure of the second apparent joints, in their pelvic or hind limbs, joints which correspond to the
carpus in front, and which are usually called the hocks. In those animals that leap to great heights or distances, the os calcis projects, so as to form a most enormous lever, and we judge of the animal's powers by observing this projection.

Such is the mechanism of our lower limbs, nor need I endeavour to shew its excellence, by the effects resulting from it. Every one knows from what heights we can leap, to what heights we can spring, and to what distances we can bound, without injury; as well as how swiftly we can run, how firmly we can stand, how nimbly we can dance, and how perfectly we can balance ourselves upon the smallest surfaces of support. Yet there are a few circumstances, which, I think, deserve consideration. Gravitation seems to be the chief cause which gives fixity of position to some parts, and consequent freedom of motion to others. When we stand upon one limb, we balance our weight upon the head of the thigh bone, and no effort is required to maintain our position, but what is necessary
to secure the knee and ankle joints in that state in which they admit of no motion.

Thus standing, all the other limbs are free to move, and can be moved with great power, because they are connected to a perpendicular column which owes its stability to its great weight. In the sculptured figures of the ancients, if a man is represented standing on one leg, he seems as firmly fixed to the ground as a fast-rooted tree; and associating freedom and power of motion with this stability, we seem to expect the continuance of that action, which the figure is represented to have begun. When we stand upon both legs, we can transfer the weight from one to the other, with very little variation in the position of our bodies. The oblique direction of the thigh bones, the consequent approximation of the knees, and the transmission of the weight, in a perpendicular direction on the arch of the foot, seems to me designed to give us this facility.

In progression, the supporting limb
should be perpendicularly under the centre of gravity of the whole body, and the advancing one is brought forwards in a curvilinear direction. This course is the result of the rolling of the head of the thigh bone in its socket, and by it the advancing limb is brought forwards without striking the other, and carried to a position in which it is more directly under the centre of gravity of the body, when that is also brought forwards, than it would have been, had the limb moved in a straight line. The free and firm step of the soldier is the result of the circumstances I have mentioned. We are more struck and convinced of this, by observing that caricature of marching which is exhibited by opera dancers on the stage, for these gentry will raise the advancing limb above a horizontal line drawn from the front of the pelvis, and, performing sundry evolutions with the foot, will afterwards gently deposit it where it ought to be placed in ordinary progression: afterwards, throwing the weight of the body perpendicularly upon it, they exhibit the same extravagancies with the
other limb. All which we deem elegant, because we associate the idea of elegance with security of support obtained without effort. As a contrast to such progression as I have described, I request you to observe, that of a very fat man, who walks with his legs far apart, and you will see that he is obliged to shift the weight of his body from one leg to the other, by a considerable degree of lateral motion of the body at every step he takes.

All the large muscles that act upon the thigh bone, turn it, and consequently the whole limb outwards, so that it appears evidently the intention of nature, that we should walk with our feet slightly turned to that direction; but I will not detain you, by shewing in what various ways this position of the limb contributes to the facility of our motion, and the security of our support.

Yet there is one circumstance I may mention, though it relates to a subject rather curious than useful. There appears
amongst men, as amongst horses, two distinct forms, one calculated for strength, the other for speed or agility. The former is chiefly characterized in man by the shortness of the neck and loins, the greater proportionate breadth of the shoulders, the broad and highly arched foot, with a much projecting heel. The latter is distinguishable by the length of the neck and loins, the length of the thighs, by a narrower and longer foot, with a less projecting heel. Persons of the form that indicates strength are generally shorter than those of the other figure, so that we associate an idea of the height of a person with his make. This subject was remarked by Hogarth, who says, that if the figures of Quin and Garrick were represented of the same size, an observer would suppose Garrick to have been a tall man, and Quin a short one. Yet the contrary being the fact, he accounts for the deception, by saying, that Quin was a tall man of short proportions, and Garrick a short man with tall proportions. The Farnesian Hercules is an admirable representation of the strong form of man, but no
one can observe the figure without at once perceiving, that it is far better calculated for cleansing the Augean stables, than for catching the stag of Oeneoe.

Many of the bones which compose the skeleton are connected together without admitting of motion upon one another; and in this case, portions of elastic gristle are interposed between them to prevent jarring, and they are tied together by unyielding and exceedingly strong ligaments. When bones move upon one another, when a true joint is formed, the corresponding surfaces of each bone are covered by gristle, which is exquisitely smooth or polished. Between these smooth surfaces, a liquor, like white of egg, is effused to prevent their adhesion, and to facilitate their motion. The escape of this synovial liquid from the joint is prevented by capsules; and the bones are firmly tied together by ligaments of surprizing strength, which are so contrived as freely to admit those motions that the bones are adapted for, and to prevent any other. All the parts composing the joints
possess so little natural sensibility, that notwithstanding the violent pressure and rapid motion they undergo, we are scarcely sensible of the parts, at which such motion is effected.

I feel that some apology is requisite for detaining your attention so long upon circumstances familiarly known, but not in general sufficiently contemplated, which I have been induced to do, because we are far better judges of the causes requiring mechanism, and the effects resulting from it, than we are of the vital processes. Therefore, from this least interesting part of anatomy, we derive the strongest conviction of there being design and contrivance in the construction of animals. Equal evidences of design and contrivance, and of adaptation of means to ends may be observed in the construction of the frame-work, as I may call it, of other animals, as in that of man, which subject seems to me very happily displayed in Professor Cuvier's lectures. Yet there are some who presume to find fault with the
mechanism of the human skeleton. An excellent anatomist once said, there was not a well made joint in the whole body; but he was then talking as a carpenter, like one who had no means of judging of the works of nature, but by comparing them with our own limited designs and performances. It was however the comparing the mechanism of the hand and foot that led Galen, who they say was a sceptic in his youth, to the public declaration of his opinion that intelligence must have operated in ordaining the laws by which living beings are constructed. That Galen was a man of very superior intellect could be readily proved were it necessary. I have often known the passage I allude to, made a subject of reference, but not of quotation, and therefore I recite it on the present occasion, and particularly because it shews that Galen was not in the least degree tinctured with superstition. "In explaining these things," he says, "I esteem myself as composing a solemn hymn to the great architect of our bodily frame; in which I think there is more true piety, than in sacrificing
hecatombs of oxen, or in burning the most costly perfumes; for I first endeavour, from his works, to know him myself, and afterwards, by the same means, to shew him to others, to inform them how great is his Wisdom, his Goodness, his Power."

There are, however, other structures in the body besides what I have just denominated the frame-work. Doctor Hunter could never demonstrate the back part of the human throat, the passages by which we swallow and respire, and the mechanism by which the extremely diversified intonations of the human voice are produced, without enthusiasm. Who, also, can examine the lachrymal parts of the human eye, without admiration? But why do we admire these things? Is it not because we understand them. We see the necessity for contrivances, and we find them constructed beyond our highest expectations, and perfectly adequate to effect the purposes for which we believe them designed. The same conclusion, must, therefore, in reason, be drawn from the examination of the
structures we meet with in living beings, as that which has been deduced from the consideration of the works of nature in general, by the most intelligent and best informed men. That what we understand, seems excellent in a degree far exceeding our ordinary conceptions, yet appearing more and more so in proportion as it is minutely examined and attentively considered; and that we understand so much of the works of nature, as to warrant us in concluding, that we can only cease to admire, when we fail to understand.
Those bodies which we call living, are chiefly characterised by their powers of converting surrounding substances into their own nature; of building up the structure of their own bodies, and repairing the injuries they may accidentally sustain. They not only differ considerably from each other in their size and external form, but also in their internal structure. Vegetables imbibe watery fluids from the earth, in which saline and other matters are dissolved or suspended, and these, in the very vessels of the vegetable, become the sap or nutritive fluid of the plant. This ascends with celerity and force; forms the leaves, flowers, and fruit, in which it is more particularly exposed to the influence of light, heat, and air; then returns and augments the woody stems and trunk, impregnates them with juices which concrete; and even-
ually descends to the roots, to nourish and increase them, and in various instances, to form means and materials, for the future production of vegetables of the same kind.

Such is the view of the nourishment of vegetables, exhibited of late by Mr. Knight, in his papers published in the Philosophical Transactions, and which has been drawn from the results of numerous well contrived and satisfactory experiments. The ascending sap has in it no marked peculiarity, being equally fitted to form the leaf, the flower, and the fruit; for he has engrafted the stalk, upon which each of these has been produced, upon the same kind of stem. Also, by dividing the descending vessels, he has stopped the formation of the parts below; and by performing this experiment in the root, he has prevented the growth of the potatoe, and even caused it to be injected from these descending vessels by which it is formed and supported.

In viewing the subject, according to this sketch, we cannot but feel surprize, that
the vessels of plants should imbibe the raw juices of the earth, however impregnated, and so suddenly convert them into sap, which is a very peculiar fluid; for it seems a more wonderful kind of digestion than that which takes place even in the stomachs of animals. Here, however, the experiments of Mr. Knight seem to aid our conceptions, by shewing, that the returning vessels impregnate the plant with juices, which concrete, and are probably dissolved in the ascending watery sap, enriching it with nourishment, and it may be, chemically aiding in its formation. Mr. Knight finds that the specific gravity of the wood of trees, is diminished by the ascent of the sap. Thus, when the genial warmth of the spring excites those actions which imbibe the juices of the earth, and cause the ascent of the sap, the plant seems bursting with life and nutriment. The leaves bud in every part, and are formed with surprizing celerity. When, however, the tree has attained its full extent of annual growth, the returning sap is more especially employed in storing the inter-
stices with materials to serve for nourishment in the succeeding spring; and to this Mr. Knight attributes the increased specific gravity of wood felled in the winter season.

It is in the leaf, however, that the distributed fluids of plants seem to undergo their chief elaboration; for here they are more freely exposed to the influence of light, heat, and air; much, also, is manifestly thrown off by perspiration; and much is probably added, so as to render these juices competent to form, under the agency of the vital energies, that extreme diversity of substances which we meet with in the leaf, the flower, the trunk, and the roots.

In animals, the matter by which they are nourished, is in general taken into a receptable or stomach, where it undergoes a process called digestion; and so analogous are the functions of life in vegetables and the lower kinds of animals, that Mr. Hunter considered this circumstance as
the chief criterion of distinction between the two classes. I believe him to have been the first person who broached and established the now generally received opinions respecting digestion. His observations and reflections suggested to him, that the liquors secreted by or poured into the stomach, had the surprizing power of dissolving the dissimilar food by which different animals are nourished, and of converting it into a substance *sui generis*; this being the first and most important step to sanguification, or its ultimate conversion into that nutritive fluid which is distributed to every part of their bodies, for their formation and support.

Mr. Hunter knew that the gastric fluids were neither acid nor alkaline, nor endowed with any predominant quality, such as would induce us to suppose they had these wonder-working powers. He was fully apprized of the variety of substances from which different animals thus derive their nourishment. He mentions that the voracious caterpillar which eats such quanti-
ties of the leaves of plants, digests only their juices, and voids the leaf dry, which will afterwards unfold itself in warm water as tea-leaves do. He knew that the fibrous matter of vegetables, and the husks of grain, are in general not susceptible of digestion by the gastric fluids; and yet that some insects live upon them. Indeed they first pour upon the woody substance a liquor which dissolves it, and in this state they swallow and digest it.

Thus also does that foe to literature, the book-worm, make his way through the most massy folios, solving the most difficult passages, and digesting all as he proceeds. Indeed he pours his sauce, or cooking liquors with such profusion, as to tinge and affect the texture of the leaves to some distance round the circumference of the tunnel which he makes. Some creatures also thrive best upon animal substances in a disgusting and noxious state of putrefaction. Therefore it is evident, that life can, by means of the fluids it prepares, convert to its own purposes substances which
are ordinarily most innutritive or pernicious.

Although the gastric fluids have no sensibly distinguishing character, yet Mr. Hunter knew that they not only coagulated milk, but white of egg, and other nutritive fluids; thus first rendering them solid, that they might be detained in the stomach till they underwent the peculiar solution, called digestion.* He knew that the gastric fluids checked and prevented the natural decomposition of animal and vegetable matter; that if putrid meat were swallowed by a hungry dog, it quickly lost all foetor, and that no fermentation or putrefaction of food ever takes place in the stomach, if the gastric juices be healthy; therefore it followed that digestion could not be the result of any common fermentative process. Nay, he further knew that the gastric fluids sometimes dissolved even the stomach itself. Mr. Hunter could not wonder that such an event did not more

* He says he had examined this subject, and found the coagulation to take place in the various kinds of animals, downwards as far as fish.
frequently take place; for when persons die of disease, the gastric fluids have not for a long time been prepared, or they have been of an unhealthy quality, so that they are incompetent to dissolve the smallest quantity of the most digestible food, if taken into the stomach. Mr. Hunter could never wonder that the gastric fluids did not act upon the living stomach, for he full well knew that life was a chemist which regulated its own chemical operations, and controlled the effect of foreign chemical agency. He was, I believe, the first who plainly told the public, that chemical agents do not in general act upon living, as they do upon dead animal matter. He knew that worms live in the stomach, and yet that a meal of dead worms would form no innutritive repast to an hungry dog. He must have known also that the peculiar fluid which digests the food is not secreted at all times, but only when the stomach is excited by the stimulus of food, and even then but under favouring circumstances. If in this state persons are suddenly killed by accident, the gastric fluids will continue for some time to act,
not only upon the food, but also upon the stomach itself, so as to form a large aperture by which the contents escape.

Having reflected upon all these circumstances, and made numerous experiments on the subject of digestion, we find him afterwards employed to open the body of a patient (who died when attended by Sir John Pringle, then President of the Royal Society,) in which a partial solution of the stomach had taken place. The appearance was to Sir John both new and unaccountable; but when Mr. Hunter told him that it was not the effect of disease, but of solution by the gastric fluids; that he had frequently seen it, and that it made one of the reasons which induced him to believe digestion to be the effect of a solution of the food by the gastric fluid; the president urged him to draw up a paper on the subject; which was printed in the year 1772, in the 62d volume of the Philosophical Transactions. This paper attracted the attention of Spalanzani and others, and led them to make and publish experiments
tending to demonstrate the fact, which is thus announced in the conclusion of Mr. Hunter's observations; "that digestion neither depends on mechanical powers, nor contractions of the stomach, nor on heat*; but on something secreted in the coats of the stomach, and thrown into its cavity, which there assimilates the food to the nature of the blood."

As, however, Mr. Hunter, in a second paper on digestion, has published his own commentary on the proceedings of those, who may be said to be his coadjutors in the proof of the fact, but who might appear to himself and the public as competitors in the discovery, I need not say anything respecting this subject. Yet there is one point which I feel it a duty to advert to. Mr. Hunter, whom I should not have believed to be very scrupulous about inflicting sufferings upon animals, nevertheless censures Spalanzani for the unmeaning

* He might have substituted the word fermentation, for heat, for it would more plainly have conveyed his meaning.
repetition of similar experiments. Having resolved publicly to express my own opinions with respect to this subject, I choose the present opportunity to do it, because I believe Spalanzani to have been one of those who have tortured and destroyed animals in vain. I do not perceive that in the two principal subjects which he sought to elucidate, he has added any important fact to our stock of knowledge: besides, some of his experiments are of a nature that a good man would have blushed to think of, and a wise man would have been ashamed to publish; for they prove no fact requiring to be proved, and only show that the aforesaid Abbé was a filthy-minded fellow.

The design of experiments is to interrogate nature; and surely the enquirer ought to make himself acquainted with the language of nature, and take care to propose pertinent questions; he ought further to consider the probable kind of replies that may be made to his enquiries, and the inferences that he may be warranted in drawing from different responses; so as to be
able to determine whether by the commission of cruelty he is likely to obtain adequate instruction. Indeed before we make experiments on sensitive beings, we ought further to consider whether the information we seek may not be attainable by other means. I am aware of the advantages which have been derived from such experiments when made by persons of talent, and who have properly prepared themselves, but I also know that these experiments tend to harden the feelings, which often leads to the unnecessary and inconsiderate performance of them. Surely we should endeavour to foster, and not to stifle, benevolence, the best sentiment of our nature, that which is productive of the greatest gratification and advantage both to its possessor and to others. Considering the professors in this place as the organs of the court of the college; addressing its members, I feel that I act as becomes a senior of this Institution, whilst admitting the propriety of the practice under the foregoing restrictions, I at the same time express an ear-
nest hope that the character of an English surgeon may never be tarnished by the commission of inconsiderate or unnecessary cruelty. I need not, Gentlemen, caution you, who must feel anxious to maintain the respectability as well as the reputation of the medical character, against publishing experiments disgusting to common decency.

Now though Mr. Hunter clearly perceived that liquors could be and were prepared, possessed of surprising powers of assimilating the food to the nutritive fluids of the animal, he was likewise equally apprized of the variety of means which nature has instituted to prepare the food for digestion, and facilitate the action of the gastric fluids. With this intention, some animals are made to grind or comminute their food with their teeth, but this is not essential to the function of digestion, neither does it take place in the majority of animals. Therefore Mr. Hunter seems, in his Museum, to have placed the teeth amongst the weapons and instruments which are allotted to animals.
Many carnivorous animals, he observes, divide their food no further than is necessary to enable them to swallow it; and all animals whose food requires this degree of subdivision must have means to effect it. Mr. Hunter has shown that cuttle-fish have beaks like birds; and that worms have osseous teeth fixed in the fleshy circles that form their mouths. He has placed the preparations which show these and similar facts in a department of his Museum, allotted to show peculiarities belonging to individuals of any species or genus of animals, which do not belong to others of the same kind; and not among the preparations displaying the anatomical facts relating to digestion in general. Mr. Hunter studied anatomy as a physiologist, he investigated structure in order to understand function, and he has omitted to record or exhibit many anatomical facts, with which he doubtless was acquainted, because they did not seem to lead to a physiological conclusion.

Herbivorous animals in general grind their food with their teeth; nay those who
spend a life of leisure and repose, are made to ruminate or remasticate their food, whilst other vegetable feeders, and I may cite the horse as a familiar instance, whose life is probably destined to more continual exertion, do not ruminate. The horse however has a constant propensity to feed, and the food passes readily from his small stomach; therefore, he would waste a great deal of food, had not Nature provided him with most capacious intestines, and contrived to produce a kind of second stomach and digestion in that part of the bowels called the intestinum cæcum.

Mr. Hunter was fully apprized that many of the insects, of the lower kinds of animals and some fish, have teeth of various sorts fixed in their stomachs to divide and comminate their food. He was convinced that birds do not swallow stones from mere stupidity as Spalanzani supposed, but to serve as temporary teeth, or as mill stones to grind their food under the operation of their powerful gizzards. In his paper on the stomach of the gillaroo trout, he says that, "the English trout swallows shell fish,
and also pretty large smooth stones, which serve for shell-breakers.” He also says, “the mullet has a stronger stomach than the gillaroo trout, but that they have neither the power, nor motion, nor horny lining of true gizzards.”

Gizzards, like teeth, serve to subdivide the food, and thereby increase the surface on which the gastric fluids may act so as to facilitate its solution. Though birds in general have gizzards for this purpose, Mr. Hunter knew, that those which feed on flesh have them formed with their muscular and internal coat so thin, as scarcely to be recognizable for such organs. By feeding a rook with bread, he found that the muscular power of his stomach became much increased, and its lining much thickened and hardened; a fact corresponding to many other observations he had made, showing that the vital powers could alter the organization of parts, so as to adapt them to exigencies.

Another mode of preparing food for solution by the gastric fluids, is by a kind of
maceration, generally in warm and moist places, a kind of cooking process, for which probably the complex stomachs of ruminating and other animals are designed. In ruminating animals which have four stomachs, the first or paunch, is a reservoir from which the food is thrown up to be remasticated; the fourth digests the food; but the exact function of the intermediate stomachs is unknown. Mr. Hunter has not omitted to display the contrivance by which in the calf, the milk is made to pass directly into the fourth stomach for digestion, without entering the others. The crops of birds and various other animals are also to be considered as macerating pouches, and which gradually supply materials for the operation of the gizzard. Their contents are likewise sometimes regurgitated, for thus does the bee store its cell with honey, and some birds feed their young.

Mr. Hunter was fully apprised that many of the insects, and of the lower kinds of animals have complex stomachs, crops, and gizzards; and he has shown these facts
Among the peculiarities to which I have already referred.

That digestion, or the solution of the food by the gastric fluids, takes place in some particular district, and not elsewhere, is, Mr. Hunter says, to be inferred, from observing that in fish and serpents, which swallow more prey at once than the stomach can contain, that portion of their food only, which is in the stomach, is dissolved, whilst that which is in the gullet undergoes no such change. Also, from observing that the yolk of the egg, which is conveyed into the intestines of the chicken, ascends into the stomach before it can be digested, Mr. Hunter was fully apprized, that parts of a single stomach might secrete the solvent liquors, and not the whole bag. He observes, that part of the stomach in several animals, is covered by cuticle, like the first, second, and third stomachs of those which ruminate. This occurs in the peccari, hog, rat, and horse. The fact of digestion occurring partially in the stomach, he says, is also evident in that of a dog, into which
a large piece of meat has been swallowed at once. Towards the great end, the food will be found but little altered, towards the middle more, and towards the pylorus it will be similar to that which is found in the duodenum. Mr. Hunter was apprized, that the duodenum in some animals, might be considered as serving to digest the food; for it is formed of considerable capacity, resembling a stomach, and is chiefly recognized by anatomists as that intestine, in consequence of the biliary and pancreatic ducts terminating in it. He also perceived, that when the pylorus is not detentive, the gastric fluids might flow into the duodenum, and there complete the process of digestion.

The solvent liquors are secreted from the lining of the stomach, or sometimes poured into it from glands situated at its upper opening. The latter is commonly found in birds, because the lining of their stomachs is formed for trituration, and consequently not for secretion. Yet the same kind of structure is met with in other animals, and even among quadrupeds in the
beaver. According to Mr. Hunter's notions of secretion, it must have appeared to him a subject of no importance whether the gastric liquor was secreted by particular glands or otherwise; for secretion is an universal function, and can take place as well from surfaces as glands. He was indeed anxious to note every variety of structure, and, as I believe, also in order to observe whether any thing could be found contradictory to his opinion that the several vital functions were the result of the actions of a principle distinct from the organization in which it adhered.

It must surely be curious and interesting to all, to be informed, that his opinions respecting secretion, opinions at the time which seemed almost inexpressible to himself, and incomprehensible to others, have been most perfectly verified by experiments subsequently made with a view to determine facts relative to digestion. Mr. Hunter thought that a subtile principle of life was diffused throughout the body, that it inhered in the solids, and was the cause of
their different vital affections; that it pervaded certain fluids, which it could either modify, decompose, or recombine, and thus produce the extreme variety of new substances, that may and do result from one kind of nutritive and universally distributed fluid. He had no mode to express the idea; nor could any one discover a better than by saying, that specific and peculiar actions will produce specific and peculiar secretions. I have already told you, Gentlemen, how these terms were cavilled at. Mr. Hunter thought, that the vital principle was particularly accumulated in the brain, in those animals which possessed such an organ, and that it seemed in them a kind of source of vital energies, and that the nerves were internunciate chords, by which the affections of life were reciprocally communicated. The verification of Mr. Hunter's opinions must interest all, because they show how justly we may infer causes, by the industrious observation, and patient and accurate contemplation of effects; and therefore the result is. creditable to human intellect, and
gives us confidence in other opinions which are thus deduced. I shall briefly relate the experiments to which I have just alluded.

Doctor Haighton, after having fed a hungry dog whose stomach was empty, with flesh meat, divides the eighth pair of nerves which go from the brain, to be distributed to the stomach, and thus prevents or disturbs those vital actions, which are necessary to the preparation of the gastric fluid. Consequently, when after many hours, he kills the dog, he finds the food in the stomach perfectly undigested, and but little changed. He performs a similar experiment, but only divides one of the nerves of the eighth pair, and the dog becomes dyspeptic, having eructations and manifest uneasiness about the stomach; which symptoms continue for several weeks: and though the dog eats the food which is given to him, he becomes much emaciated, yet gradually recovers, as the divided nerve ré-unites and resumes its functions. In like manner, Mr. Brodie having observed, that
the administration of arsenic was uniformly followed by profuse secretion of mucus and watery liquors into the stomach, divides the nerves of the eighth pair in dogs, and then administers the poison, but no secretions are afterwards effused into the stomach.*

Professor Harwood of Cambridge gives to two dogs, equal in age, health, and appetite, equal quantities of flesh meat. They were pointers; and he suffers one of the dogs to do what nature indicated to be favourable to digestion, to lie down by the fire and go to sleep; but he entices the other into the fields, and causes him to hunt about for game. After some hours he kills both dogs, and finds the food in the stomach of the dog which had been kept in constant exercise, undigested and but little changed; whilst in the other it had, in the same time, not only been digested by the stomach, but converted into chyle by the intestines, and was rapidly passing through their absorbent vessels

* Philos. Trans. 1814.
in the high road to the sanguiferous system.

No one is disposed to doubt the results of these experiments, for every one is more or less convinced, by his own feelings, that affections of the mind, and bodily exertion, will, by disturbing or otherwise occupying the nervous energies, diminish or prevent appetite and digestion.

The pylorus, or opening by which the stomach communicates with the intestinal tube, is variously formed in different animals, allowing or preventing, in various degrees, the transit of alimentary matter. In the human stomach it is a small circular and muscular aperture, admitting of occasional dilatation, so as sometimes to give passage to a body of the diameter of half a crown, yet ordinarily so contracted as to detain even fluids in the cavity of the stomach; else how could we distend it with liquors as we sometimes do. It may be useful to mention a case which serves to illustrate the degree in which such deten-
tion may occasionally occur. A miserable woman took opium during the night in St. Bartholomew's Hospital in order to destroy herself, and before she was noticed next morning her purpose was nearly accomplished. With scarcely any hopes, I injected into her stomach, by means of a varnished catheter introduced down the oesophagus from the right nostril, some lemonade, to which cordials and a solution of sulphat of zinc were added, in hopes of exciting the stomach and provoking it to vomit. Having injected in repeated doses what appeared to me to be a fully sufficient quantity, and waited till no hopes of success remained, I left the room. Some of the students, however, knowing the case to be desperate, injected more of the liquor, and when the body was afterwards examined, the stomach and gullet were found filled and distended up to the throat; nay a small quantity of the liquor had actually overflowed the rima glottidis, and descended by the windpipe into the lungs. On the contrary, however, the pylorus in the
horse gives ready passage to liquids, and even to the fibrous part of the food.

That animal will drink at once three or four times more water than his stomach can contain, which passes rapidly through his intestines till it arrives at his capacious cæcum, where it lodges.

He continues to eat in like manner, and the surplus of food must readily pass through the pylorus before it has been completely digested; on which account he would waste a great deal of food, had not nature contrived to produce a kind of second stomach and digestion in that part of the bowels called the intestinum cæcum. Mr. Coleman, professor at the veterinary college, suffered a thirsty horse, which was to be killed, to drink as much water as he chose, and after six minutes, the alimentary canal being examined, it was found that the water had passed from the stomach through the small intestines, a distance of sixty feet, and was collected in the cæcum.
Mr. Coleman supposes that nature has allotted to the horse but a small stomach, that the food might not, by being accumulated, impede the action of the diaphragm, and affect that free respiration which his speed of progression requires.

Having shown what Mr. Hunter knew and thought with respect to digestion, as carried on in cavities allotted for that purpose, it is proper to add, he was fully apprized that the same process could take place without the preparation and aid of solvent liquors.

Both analogy and observation warrant the supposition, that some animals have no digestive organs, and that their vessels, like those of vegetables, imbibe and distribute what becomes nutritious in the vessels themselves. No one has, I believe, seen digestive organs in the tenia; from various apertures we are able to inject different kind of vessels, so that this animal appears to be very vascular in every part, which is, I believe, as much as is known respecting
its anatomy. In the fluke also, whose food is gall, and which lives and multiplies in the biliary ducts of sheep, we see the gall imbibed from an orifice into a vessel which sends off branches to all parts of the animal, apparently becoming its distributive or nutrient vessel. If this be true, bile, which is formed from the blood of the sheep, is reconverted into the blood of the fluke, and forms the fleshy substance of this animal. It was one of the distinguishing characters, and greatest perplexities of Mr. Hunter's Physiology, that he asserted vessels could modify their contents, so that a kind of digestion may be said to take place every where by the immediate action of the vital powers. The structure of the last mentioned animals, as far as it is known, is exhibited in the collection; and the preparations were given to Mr. Hunter by Mr. Carlisle, who made them whilst a student.

The hydatid seems to be nourished in like manner. Analogy would induce us to believe that it was nourished, like vege-
LECTURE IV. 183

tables, by absorption from without. Of its organization however we are perfectly ignorant, for no evident structure can be discerned, even by the aid of the microscope. These animalcules are found in the natural cavities, or in those formed in consequence of disease, in the bodies of other animals. We meet with them in the abdomen, in bursae mucosae, and in cysts in the brain, liver, and other organs. The form of one species is a globular or oval bag, which has an undulatory motion, when put into tepid water. The bag contains a transparent fluid. Young hydatids form upon the bag, are detached when very small, float about in the liquor of the cavities in which they dwell, to grow and to multiply as their parents have done. Now, in a physiological point of view, we must consider hydatids to be nourished by absorption from without, or suppose the bag to be a digesting cavity, though no aperture is discernible. In the department of the Museum allotted to display the structure of the digestive organs, Mr. Hunter has first put up some hydatids, as if to mark the uncer-
tainty of our knowledge with regard to the nourishment of this and some other animals.

With such exceptions, all other animals have a digesting cavity, and the lowest orders appear to have no other organs, the whole interior being stomach, and the whole animal forming only the walls by which it is surrounded and supported, as is exemplified in actiniae and medusae. Mr. Hunter, in his M.S. of the year 1776, writes as follows: "The apparatus necessary for digestion is as simple as any thing we can well conceive. It only requires a bag or cavity fit to contain the substance to be digested, joined with the power of furnishing the fluid capable of digesting the said substance. It is therefore to be considered as a gland and a cavity. Indeed, it is necessary, that another apparatus should be added; a system for absorbing the digested food and nourishing the bag, as well as preparing the fluid it secretes." Before this time, Mr. Hunter had injected the vessels of medusae from the stomach with co-
loured glue, and their distribution is particularly beautiful. He was well acquainted with the fact that fluids may be imbibed from various apertures in the branches or members of these animals, and conveyed through tubes into a common cavity, which I merely mention to show that he was acquainted with that form of animal called rhizostome or root-mouthed.

As an evidence of an animal being little else than a stomach, Mr. Hunter has exhibited a specimen of the actinia associata. The mouth, which is surrounded by tentacula, leads into a cavity, like the finger of a glove, the animal being no more than the substance which forms the walls of this cavity. Mr. Hunter, in his M.S. proceeds to say, "that in some animals the stomach has but one aperture, serving equally to receive the food, and reject its residue. In others a distinct aperture is allotted for each of these functions. As the digestive organs become complicated, we find the stomach or digesting cavity has added to it an intestinal tube, in which the food undergoes
still further changes; and this tube is also subdivided into two parts, and different functions are allotted to each. Glandular structures are also added, which prepare fluids subservient to the functions of the intestinal canal."

In the small intestines, the food is converted, in the higher order of animals, into chyle, which is a fluid very much resembling blood, and chiefly differing from it in its colour; so speedily and so nearly is the ultimate object of sanguification accomplished. The effect produced on the food in the intestines will be in proportion to the secreting surface of the canal, which pours on it peculiar liquors, and to the duration of its stay in the bowels. These objects are accomplished by the length and convoluted form of the canal; by its lining projecting and being formed into plaits, either transverse, longitudinal, spiral, or reticulated; by the formation of smaller fossae or larger sacculi. Every variety in the animals hereafter mentioned is displayed, and so beautifully are the
preparations injected, and so neatly put up, that these objects, which we generally view with disgust, attract the attention of strangers, who regard them as the most beautiful preparations in the whole collection. It is nearly at the commencement of the intestinal tube, that the bile and pancreatic liquors are poured into it. Mr. Hunter, in his paper on digestion, says "it appears from many experiments, that the digested or animalized part, when carried into the intestine, clings to the internal coat, as if entangled among the villi; whilst the excrementitious part and bile are found lying unconnected, in the gut, and as if separated from the other." This fact was more fully explained, and also exhibited in this theatre, by Mr. Astley Cooper, when he held the office of professor of Anatomy and Surgery to the College. He told us, that the gastric juices first dissolved that food which was most susceptible of digestion, thus affording an argument against much variety of viands; that the substance dissolved was discoverable in the solvent, and gave a character to the solution; thus the chyle prepared from
animal or vegetable substances partook of the nature of such substances, and if dried and burned, emitted the same odour, and produced similar results to those which occur from the decomposition of the same substances before they have undergone such solution. Nay, he told us further, that the chyle formed from animal matter rapidly putrefied, whilst that prepared from vegetables was slow in undergoing a similar change. As an abundance of nitrogen seems to be the base of animal substances, so its disposition to combine with hydrogen, and to form ammonia, seems readily to break up the general bond of union of the parts forming the compound. Whilst engaged in examining the chyle, he also examined the lymph which the absorbent vessels contain, and his chemical friends, who were men of great knowledge and ability, report, that it is in all respects like the blood, except that it wants the globular particles and colour of that fluid, a proof that these vessels, as well as others, modify their contents, which is a physiological subject I shall subsequently have to discuss.
Mr. Cooper showed us how firm a substance the digested aliment had become, and how tenaciously it adhered to the villous surface or lining of the intestines, so that it might be mistaken for a part of that surface; and how turgid the vessels of the intestines appeared when the chyle was separated from their villous coat, the whole surface appearing as if highly inflamed or subtilely injected. This he attributed to the digested aliment having acquired, in consequence of undergoing the process of digestion, the property which is characteristic of the blood; that of spontaneous coagulation, so as to become solid and tough, in which state the coagulum of either may firmly adhere to the surface with which it happens to be in contact.

The gastric fluids are detained in the stomach, and therefore not wasted, and the last mentioned circumstance interested me, because it showed how the succus intestinalis is prevented from being wasted, and its action confined to that substance which it is designed to convert into chyle,
whilst the excrementitious matter alone remains loose in the calibre of the intestines, and at liberty to be urged on by their peristaltic actions. Nay, Mr. Cooper further showed us that the same circumstances also obtained in the large intestines, that portion of the alimentary matter which could be modified and rendered meet for absorption, acquiring an adhesive property and clinging to the surface, which accomplished these purposes.

It is well known that a great and sudden change is wrought in the contents of the alimentary canal, immediately on its transit from the small into the large intestines, that a valve is formed to prevent any communication between them in a retrograde course; that the commencement of the large intestines, usually called the cæcum, is in herbivorous animals particularly capacious, and apparently calculated for detaining the alimentary matter; and in some, as in the horse, this portion of the alimentary canal is of surprising magnitude; that the extent of surface of the lining of the large in-
testines is much more ample in herbivorous than in carnivorous animals. So that from these and other observations, it is believed that the residue of the alimentary matter undergoes a great change in them, produced by the qualities of the liquors they secrete, and that this change prevents a spontaneous chemical decomposition of the contents, and conduces to the extraction of whatever may be useful from the residue of the food. But I shall not detain your attention on this subject, because I have already briefly expressed my opinions respecting it. I omit many things, for I only attempt to explain what I believe were Mr. Hunter's opinions on certain points in physiology. Sir E. Home has already told us how industriously he noted the varieties of the formation of this part of the alimentary canal in different animals.

Though I must not proceed to describe in detail the facts which Mr. Hunter exhibits, with respect to the structure of the digestive organs of different animals, yet I shall mention in what variety they are dis-
played, because it will show you, in some degree, the extent of his researches in Comparative Anatomy; and also, because you will find the other vital organs, provided they admit of it, exhibited in the same animals, in all the different departments of the Museum. A great number of other animals will, however, be found in other departments, which are not included in this, for though such animals may exhibit interesting varieties in other vital organs, they contain no remarkable peculiarity in those concerned in digestion. Mr. Hunter examined the structure of echini, crustacea, and some molusca with particular attention, and caused drawings of exquisite beauty to be made of them. I take this opportunity to show you some of these drawings, and to inform you that there are probably one thousand of them belonging to the collection. Mr. Hunter was particularly fond of drawings and paintings, and consequently rather fastidious as to the representations given of the objects in which he took so great an interest. There was no poor artist of talent in this town, that he did not befriend
to the utmost of his power. Every man of genius was, indeed, his brother, and he felt a fraternal interest in his success.

Mr. Hunter has shown, in his Museum, the digestive cavities amongst

**ZOOPHYTES.**

In polypes, actinia, zoanthus, and medusæ.

**ECHINODERMATA.**

Various echini, asteriades, holothuriae, and sipunculus nudus.

**INSECTS.**

Gryllus cristatus, gryllo-talpa, òeshna, musca tenax (Lin.), cicada, bees, beetles, silk-worm, termites.

**CRUSTACEA.**

Crabs, lobsters, and cray-fish.

**VERMES.**

Aphrodita aculeata, amphinome, nereis, terebella, lumbricus terrestris, hirudo.

**ANIMALS INHABITING OTHERS.**

Hydatigena, tænia, ascaris, echinorhynchi.

**MOLUSCA.**

Sepia officinalis, loligo, octopus, lepas aurita, and others. Coronula diadema, chiton, haliotis, doris,
clio, bulla aperta, chama, pecten, mya, teredo navalis, ascidia intestinalis, clavata, salpa.

**FISH.**

Skate, torpedo, sturgeon, various sharks, tetraodon, lamprey, annarrhichas, (gillaroo trout), mullet.

**REPTILES.**

Testudo, lacerta agilis, gecko, alligator, rana, siren, lacertina.

**BIRDS.**

Swan, common pigeon, crowned pigeon, ostrich, cassovary of New South Wales, East Indian bittern, Solan goose, pelican, turkey, raven, rook, crow, and gull.

**MAMMALIA.**

Man, dog, lion, beaver, porcupine, hare, rat, ant-eater, manis, opossum, wombat, ornithorynchus, sloth, bear, peccari, hog, guinea-pig, calf, goat, elk, deer, camel, horse, various cetacea.
LECTURE V.

ON THE ABSORBING VESSELS.

Next to the organs which digest the food, there are displayed in the Museum those vessels which imbibe it from the bowels, and convey it, in the higher classes of animals, into the sanguiferous system.

Mr. Hunter, having convinced himself by observations and experiments which are published, that these vessels are the only ones which perform the function of absorption, attributed the removal of every thing in the interior of the body to these minute, highly susceptible, but undiscernible agents. Believing that secretion or deposition was a process very generally going on throughout the body, he used to call the absorbents, the modelling vessels, from perceiving that if secretion exceeded absorption in any part, increase of bulk and deformity would ensue. He was led
on by degrees to believe, that these vessels, acting in excess, took away the very substance of which parts or organs were composed, so as to create large chasms in them. Seeing what things were done, and under what circumstances they took place, he was led to advert to the causes which excite or diminish the actions of these wonder-working vessels; but the advantages we have derived, in the practice of our profession, from the researches of Mr. Hunter with respect to this subject, have already been the theme of several lectures which I have had the honour of delivering in this theatre.

When his opinions on the functions of the absorbents were first promulgated, they appeared to others, not merely wild, but absolutely incredible; and when he was asked, how he could suppose it possible for these vessels to do such things as he attributed to them; he answered, nay, I know not, unless they possess powers similar to those which a caterpillar exerts, when feeding on a leaf. I relate this anecdote,
merely to show that Mr. Hunter was one of those who could believe there must be means adequate to produce effects, though they were undiscoverable by our senses. It is interesting to know how generally opinions, which he first broached and established respecting the absorbents, are now received and adopted; for it is a striking proof of the facility and firmness with which we believe what is probable, when we have no motive for contesting or denying it. All seem convinced of things scarcely explicable without requiring that kind of proof which some are accustomed to demand on other occasions.

The first preparation which Mr. Hunter has put up in this department of his collection is a common hyacinth root; which I cannot believe exhibits any thing more than may be observed with a glance of the eye, in the windows of our houses, during the spring season. We see the succulent roots descending from the tuber, and the leaves beginning to bud. I cannot believe that Mr. Hunter, or others, have ever seen
the minute absorbing vessels which must, nevertheless, exist in these roots, consequently, I conclude that he exhibited this preparation merely as an argument; as if he had said, you must grant me that there are vessels to imbibe the juices of the earth which afterwards become the sap or nutritive fluid of the plant; and I am convinced there are similar vessels to perform a similar function in all parts of animal bodies. After having been teased and perplexed by sceptics, he could only reply from analogy, and therefore, I suppose he put up this root, which though it shews little to the eye of sense, he thought might demonstrate much to the eye of reason.

Mr. Hunter, however, has exhibited in this department of his Museum, many specimens of what may be considered as the trunks of these undemonstrably minute vessels: He also injected them in whales, to show their analogy to those found in other mammalia, and that they were very minute vessels, even in such monstrous animals.
I was acquainted with Mr. Hunter at a period of his life when he must have greatly interested any one, who duly appreciated the results of his talents and labours, or who had any sympathy for the highly susceptible mind of genius, rendered still more so by excess of exertion, and the perturbed feelings incident to bodily disease. He seemed to me conscious of his own desert, of the insufficiency and uncertainty of his acquirements, and of his own inability readily to communicate what he knew and thought. He felt irritated by the opposition he had met with in establishing his opinions; and still more by finding, when he had surmounted this difficulty, that those opinions were, by the malice of mankind, ascribed to others. All which, I think, may be fairly inferred from a single sentence he one day addressed to me: "I know, I know," said he, "I am but a pigmy in knowledge; yet I feel as a giant, when compared with these men." It interested me to find amongst the manuscripts to which I so frequently refer, a long extract from a French author, who was said to have taught
the same opinions relative to absorption before him. Mr. Hunter has made his own commentary upon several of the passages, and as it seemed to him that by nothing short of a new construction of words and sentences could any resemblance of opinions be made to appear, he was induced to add, "This reminds me of a dispute that took place between a zealous convert to the Newtonian philosophy, and a Hutchinsonian, in which the latter having, by garbling and transposing certain passages from the Scriptures, seemingly made good a very absurd proposition; the latter retorted, Yea but it is also written, Judas went out and hanged himself; moreover it is added, Go thou and do likewise." Those who were acquainted with Mr. Hunter, know full well that he had a great deal of drollery in his composition.

No one can read Mr. Hunter's works without being convinced that he was a man of perfect candour and scrupulous veracity. Such a character must be its best biographer, and I am much gratified that he has,
to a certain extent, published his own account of his deeds and designs. The first editor of the European Magazine, printed in 1782, was well acquainted with Doctor Hunter and his brother, and being desirous of giving, in that work, an account of the distinguished schools of science both at home and abroad, he began with the lectures of these brothers. That the account and anecdotes of Mr. Hunter are genuine, the editor has given me the most positive assurance, adding, "I received the materials from his own hand." Here John Hunter speaks for himself, but is made to tell his story with simplicity and effect, by the friendly aid of the then editor* of the magazine. That Mr. Hunter acquired the best physiological knowledge of the time from his brother's lectures cannot be doubt-

* Mr. Perry, now editor of the Morning Chronicle, who superintended the publication of the European Magazine at its commencement, though but for a very short time. I have annexed his account of Mr. Hunter, to this publication, because it is brief; and it must, I think, be interesting to all to be informed what were the intentions and objects of Mr. Hunter, in his lectures and labours.
ed, but he was not satisfied without examining facts for himself and forming his own opinions. Therefore we find Mr. Hunter asserting that all this kind of knowledge had been the result of his own personal observations and reflections; he does not say that his opinions are new, but only that they are new to him. It was the malicious transfer of his facts and opinions to others, which, as I believe, first induced him to read, or rather to get books read to him; and we find him in every instance candidly acknowledging the claims and merits of his predecessors, whenever he discovered them.

ON THE ORGANS FOR THE DISTRIBUTION OF NOURISHMENT.

It has been already remarked, that in some minute and even vivacious animals, no organization is discernible, and therefore nothing can be known in them, respecting the subject now under consideration.

There seems, however, to be a very ex-
act coincidence of opinion between Hunter and Cuvier, as to the structure of the freshwater polypes (as they are called), the hydæ of Linneüs. Professor Cuvier believes, that polypes are formed of a pulpy substance, having pores that imbibe nourishment, which becomes arranged so as to constitute their bodies, and to produce their shoots or offspring. Mr. Hunter says, "I have an idea that some animals absorb their nourishment similar to a sponge, and dispose of it immediately to their own increase."

To me, however, who confide more in the eye of reason, than in that of sense, and would rather form opinions from analogy, than from the imperfect evidence of sight, it seems too hasty an inference to conclude, that in the minute animals, there are no vessels nor other organization because we cannot see them; or that polypes are actually devoid of vessels, and merely of the structure described, because we can discern no other. Were it, however, really so, such facts would then only
show with how little, and with what various organization life could accomplish its principal functions of assimilation, formation, and multiplication. Who has seen the multitudinous, distributive, and absorbing vessels, and all the other organization which doubtless exist in the vitreous humour of the eye, than which no glass ever appeared more transparent or more seemingly inorganic? How strange is it, that anatomists, above all others of the members of the community of science, should hesitate to admit the existence of what they cannot discern, since they, more than all the rest, have such constant assurance of the imperfection and fallibility of sight?

Amongst the zoophytes, Professor Cuvier says, that in medusæ and similar animals, vessels arise from their digestive cavities, which do not return, but exhaust their contents in deposition, effusion, and transpiration. It is ascertained that Mr. Hunter injected the vessels of medusæ from the digestive cavity, in some of the specimens preserved in the Museum in the year 1779,
and these vessels appear beautifully distributed throughout the substance of the animal, frequently communicating like the threads of network. In animals thus nourished, in which there is no circulation, there can be no distinct respiratory organs; neither do they want them, for their blood or nutritive fluid is everywhere exposed to circumambient air.

In the animals included in the class of vermes, according to the arrangement in Professor Cuvier's lectures, many of which have red blood, and therefore its motion is more apparent, we meet with the first generally acknowledged instance of circulation. They have a dorsal vessel running the whole length of the animal, which is large in the middle, and becomes gradually smaller towards either end. Sometimes there are dilatations in it, causing it to appear as if varicose; and there are lateral dilatations which may be considered as hearts; or the whole tube may be regarded as the heart of the animal. This vessel is displayed in the Mu-
seum in the common earth-worm. The animals of this class have in general large vessels on each side lying in contact with the air-vesicles or lungs, which are considered as the venous trunks returning the blood to the dorsal vessel. They are exhibited in the Museum injected in the leech. Mr. Hunter says, "they are the venæ cavæ, or great returning veins of the body, and also the pulmonary veins; for in them the blood is aerated." His mode of expressing this two-fold office, is by saying, "such veins are both corporeal and pulmonary."

It must be exceedingly difficult to inject the vessels of vermes, so as to display their communications; nor do I find that Mr. Hunter has made any preparations to demonstrate the various branches of the dorsal vessel or its returning veins. What is asserted in general with respect to this subject, has, I believe, been chiefly discovered by observations made with the microscope on those animals when living. Mr. Hunter, in expressing his observations on the manner in which the body is supplied
from the dorsal vessel in these animals, says, they have not one aorta or distributive trunk, but many aortæ. Professor Cuvier, in his account of the organs for the distribution of nourishment in the class of vermes, principally appeals to the evidence of what may be seen in the arenicola, or lumbricus marinus of Linneus. Sir Everard Home, being particularly desirous of examining the circulation in this animal, on account of its having external branchiæ, sent for Mr. Clift to the coast of Sussex for this purpose; and their conjoint observations on the vessels and circulation in this and other vermes, are printed in the Philosophical Transactions for 1816.

That Mr. Hunter was as well acquainted with the circulation in animals of the worm kind, as any of his successors, is, I think, evident from his writings. He says, "they have the most simple kind of circulation, which is, when the blood, propelled by the heart, becomes aerated in its circulating passage." He also says, the motion of the blood is a kind of undulation; which phrase,
though not sufficiently explanatory, must, I think, principally have been suggested by what is observable in animals of this class. I am, however, aware that the motion of the blood in the vessels of the chicken and its appendages before they are conjoined, and a circulatory motion consequently established, might have suggested the same expression. In worms, we see the dorsal vessel pretty suddenly filling, till it is distended with blood; it then contracts, urging on its contents, till it is empty, when, after a time, it is again repleted. Thus wave follows wave, but the cause of this interrupted, or seemingly undulatory motion, has not perhaps been fully explained. Analogy would induce us to consider the systole and diastole of the dorsal vessel, as similar to what is observed in the heart of the higher classes of animals, and that the tardiness of the circulation is the cause of this apparently undulatory motion.

The spiracula or tracheæ in the sides of worms terminate in vesicles, which are con-
sidered as their lungs. They are numerous and distinct, situated all along the sides of the animal in contact with the lateral blood-vessels. These air-vesicles, or lungs of worms, are exhibited by beautiful preparations in the Hunterian Collection; and in some instances, vesicles are also shown in the back of the animal.

It is scarcely credible with what patience Mr. Hunter examined the structure of the lower kinds of animals. He contrived spectacles with glasses of different degrees of magnifying power, so that by a slight alteration of the position of his head, he could look through the one or the other. Mr. Clift tells me, he would stand for hours motionless as a statue, except that with a pair of forceps in either hand he was picking asunder the connecting fibres of the vessels or parts, till he had unravelled the whole structure. Thus did he make the preparations of the amphinome flava, and aphrodita aculeata, which you will find in the Museum. In the former, he thought he had distinctly traced numerous minute
vessels, which he considered as absorbents, extending from the bowels, laterally nearly the whole length of the animal, and terminating in small vesicles, which lie in contact with the respiratory organs. In the former he found numerous minute tubes continued from the intestines, which are of considerable length, and which, after ramifying towards their extremities, terminate in little oval cells or caeca, which are lodged in the sides of the animal, in contact with the pulmonary vesicles.

There are different preparations of these parts in the Museum, and when the intestines happen to contain a whitish substance, it is also seen in the tubes and cells; when the bowels contain a blackish matter, it is likewise found in these appendages. What Mr. Hunter thought respecting this subject is not known. Such tubes may be considered either as terminating in the intestines, or proceeding from them.

In order to attempt the investigation of this subject, I requested Mr. Clift to inject
the alimentary canal of the aphrodita with fine injection, and it passed into these numerous tubes, and cæca, all of which are fully distended; but we cannot observe that the injection has gone further. I show you this preparation, and you see these cæca in their natural situation, from which they are removed in the other specimens. I beg leave also to mention, that being desirous to ascertain how far the distributive vessels of the lower kinds of animals admitted of being injected from their digestive cavities, as is the case in medusæ, and also to observe, whether any transudation took place through their sides, I requested Mr. Clift to inflate and inject with subtile liquors, the digestive organs in echini, insects, and vermes; and as far as his enquiries have yet extended, he finds the canal similar to that of the higher classes, neither air, nor injection impelled, escapes from it, either through its sides, or by proceeding into vessels.

According to the present arrangement of the subjects of Comparative Anatomy, insects form the next class to zoophytes.
and worms succeed to insects. I have told you what Mr. Hunter knew and thought about the structure and functions of worms; first, because it is probable that analogy, as well as his own observations, which may indeed have been biassed by analogy, led him to believe, that the circulating and respiratory organs of insects were similar to those of vermes. Like Swammerdam and others, he considered the dorsal vessel as the heart of the insect, and it is exposed in his Museum in the bee, the preparation being marked, the heart of the bee. We find bees, beetles, and silk-worms injected in the Hunterian Collection, but how, no one can tell. I should not have supposed that Mr. Hunter would have injected from the spiracula or orifices of the tracheae, with which he was well acquainted. Yet the injection, wherever impelled, might have been effused, or have got into and pervaded the air-vessels, which is supposed to be the case, by those who put faith in the modern opinions respecting the anatomy of insects. Mr. Hunter also believed, that the pulmonary organs of insects were simi-
lar to those of the vermes, and he says, they not only serve to ventilate the blood, but to give levity to the body of the animal in those insects which fly. He says, the vesicles are larger in beetles, whose bodies are heavy, than in the lighter kinds of flying insects. He further mentions, that the vesicles or lungs of the flying insects are different from those of others; as they extend throughout the whole length of the body.

You probably know, Gentlemen, that the present belief with respect to the nutrition of insects is, that the digestive aliment absorbed from the bowels passes on by the same tubes to all parts of the body, and that tracheæ, or air-vessels, are equally distributed, so as to produce a general and complete aeration of the nutritive fluid. It is further believed that the glands of insects are merely composed of contorted tubes. Yet the crustaceous animals, (formerly accounted insects,) spiders, some phalangia, and scorpions, are admitted to be of a different structure, and to possess both circu-
lating organs and lungs like those of vermes. Lyonnet, Cuvier, and others, assert that the dorsal vessel found in insects gives off no branches, and that no motion of fluids can be perceived in them, even by the aid of the microscope. Professor Cuvier says, "tout le corps est nourri par une fluide stagnant." Yet even vessels can produce a free and forcible motion of their contents, as is evident in vegetables, and in the absorbents of the higher classes of animals. If there were no current in the fluids of insects, how could liquors run so freely as they are known to do from the contorted tubes that form their glands? Professor Cuvier is disposed to consider the irritability of animals as greatly dependent on the aeration of the blood; and ascribes the vivacity and power of insects to its great exposure to air. Yet this opinion cannot, I think, be maintained as a general inference in physiology: for what animals are more agile, powerful, and indefatigable than fish, and yet we have reason to believe their blood is very imperfectly aerated?
I have done, as I am convinced Mr. Hunter would have done, candidly acknowledged his opinions, and readily admit them to be erroneous, if they are shown to be so. I cannot, however, but imagine how he would have rubbed his head, and thought, and wrought, till he had satisfied his mind respecting this subject; when, if he became convinced that the modern opinions were right, we may readily suppose what a train of reflections would have succeeded, How curious must it appear that these very vivacious and powerful little creatures, which also possess such a complex apparatus of muscles, should be nourished in a manner not unlike that of vegetables; that the food, when digested, should be absorbed from their bowels, and that the absorbing system should become the distributive one, without the aid of any pumping engines or hearts to urge on the current.

To Mr. Hunter, however, who believed life to be a principle independent on structure, which could exercise its functions with diversity of means, none of the cir-
cumstances I have alluded to could excite wonder. He would labour, as he always had done, to ascertain facts, and the additional facts would, on this, as on other occasions, only serve to confirm his already well established theory.

In the present class of animals denominated crustacea, Mr. Hunter examined the lobster with particular attention, and has left most beautiful drawings, as well as preparations, demonstrating its anatomy in general. He was probably induced to make this attentive examination from considering it as a large specimen of the insect kind, in which the structure common to the whole tribe might be more readily discovered and displayed. With respect to its circulating and pulmonary organs he says, "The heart which is unilocular, propels the blood throughout the body, which fluid receives purification in its passage; and that the blood returns, both from the body and from the lungs to the heart, which it throws out, in a mixed state, equally to the body and lungs." Every one is acquainted with the
pulmonary apparatus of lobsters and crabs, that pith-like production that is drawn out of their bodies with their legs when they are torn off.

Ascending to the newly established class of mollusca, I find Mr. Hunter acquainted with all the facts which have warranted later Comparative Anatomists in making this distinction; so that he might himself have formed the arrangement, had his mind been directed to the subject of classification. Speaking of the situation of the heart in the multiform animals now included in this class, he says, it is very various, and seems chiefly to depend on that of the lungs: also that it is differently situated, even in animals of the same kind, as in the snail and slug. With respect to its structure, he says, in the snail, and in many of the inhabitants of shells, it is composed of an auricle and ventricle, whilst in others it has two auricles and one ventricle. He thinks that in the single heart with two auricles, it is formed, as it is in reptiles, to receive the blood both purified and unpurified, and to
throw it out in a mixed state. He distinguishes in this class of animals between the corporeal and pulmonary hearts, observing, that the snail has a heart for the former circulation and not for the latter. He particularly examined, and was thoroughly acquainted with the circulating and respiratory organs of the cuttle-fish, which are displayed with his usual perspicuity and accuracy, by preparations in the Museum, and also by beautiful drawings, two of which have been lately published in the Philosophical Transactions for 1816, by Sir Everard Home.

As no one can doubt Mr. Hunter's knowledge of the circulation in fish and reptiles, I shall say nothing on this subject, except remarking, on account of the physiological inference the fact admits of, that the fish has only a pulmonary heart. It is composed of an auricle and ventricle, the former receives the blood returned from all parts of the body, and the latter propels it through the gills, where, having undergone the change produced by respiration, it re-
turns by vessels which, ending in a single trunk, form the great distributive vessel or aorta of the animal, to which no heart is connected; so that the blood receives no additional impulse besides that derived from the action of its containing vessels. Therefore, these extremely agile, powerful, indefatigable, and vivacious creatures are supported by a languid circulation and trivial respiratory process: a fact which warrants the conclusion, that the powers of life can be exerted according to their allotted manner, without that quick supply of materials, or great degree of change produced in the circulating fluids by respiration, both of which many physiologists have been accustomed to consider essential to the production and maintenance of such high degrees of vital action.

In order to explain the varieties of hearts met with in different animals, Mr. Hunter seems to have sought for some generic term, simply expressing the number of cavities found in them, without any reference to the connections or offices of those cavi-
ties; and his friends must have supplied him with the terms which he employs, Monocoilia, Dicoilia, Tricoilia, and Tetra-
coilia. He considers the heart as a pump, which forcibly impels the fluid it contains into the vessels. Where there are two ca-
vities, he says, one is an auricle, and the other a ventricle. The auricle is a cistern or reservoir, from which the contents are sud-
denly forced into the more efficient cavity or pump. Sometimes there is a heart or pump to the pulmonary circulation, and none to the corporeal; and sometimes there is one for the latter and not for the former, and sometimes one for each. Even in the quadruped and bird, in which the heart appears most complex, he says, it is equally simple, there is a heart for either circula-
tion, but these are united into one organ.

In advocating Mr. Hunter's reputation as a general physiologist, I ought not to omit to commemorate his labours in exa-
mining the circulation of the blood in the higher classes of animals. Doubtless the
phænomena of the constant supply of blood to every part, and the building up and repairing the structure of the body, must have appeared to him so curious and wonderful, as to induce him to admit nothing upon the authority of others, and to examine every fact for himself.

Though I now engage in a subject which more especially I have a right to discuss, as it relates to human anatomy, yet I must not weary you by detailing facts familiarly known, or proving propositions which are generally admitted. Were I also to advert to the doctrines of others, I should have to collate asserted facts and opinions, irreconcilable with one another, and to engage in controversial discussion; yet why should I bandy about the ball of controversy, wasting both my own labour and your time, if I know I must let it fall at the conclusion, just where I took it up at the beginning? It seems best for a lecturer simply to say what he thinks, and why he thinks it, because it is the only way in which he can feel, and consequently create an interest in
that which he delivers. I shall therefore merely tell you what I have been taught by Mr. Hunter to think with respect to the principal parts of the subject of the distribution of nourishment in the higher classes of animals.

First, then, I find Mr. Hunter examining the structure of the arteries or tubes by which the blood appears to be carried to every part of the body. He is neither clear nor confident in his description of them; and yet I know not that any one has described them better. Internally they are membranous tubes, which is a common character of all sorts of vessels, the polished surface of the membrane admitting their fluid contents to pass along with the greatest facility. He knew that exterior to this, and not far from it, there was some substance, thin, but particularly strong and unyielding, which caused the vessel to have a regular circular form when distended. He found that when the trunk of the distributive vessels, the aorta, was injected with a force equal to ninety pounds, this
part suddenly cracked, and the external elastic matter of the vessel readily yielding, it became distended by the effused injection, into a bulky, but irregular, form.

Mr. Hunter thought that the great quantity of elastic matter which surrounds large arteries was well calculated to prevent that injury to the vessels, which the powerful propulsion of blood by the heart might otherwise occasion. Nay, he observed that the quantity of elastic matter was greatest where it appeared most wanted, that it was greater on the convex part of the arch of the aorta than on the concave. He further observed, that certain arteries which are occasionally much elongated, have a far greater share of elasticity in their longitudinal direction than others. The quantity of elastic matter surrounding arteries also gradually diminishes as these tubes recede from the heart, and the impulse of that organ diminishes; which well known fact corroborates the opinions I have just mentioned. The elasticity of the large arteries may also lighten the labour of the heart by the kind of suction it may sometimes occasion.
Mr. Hunter knew, that in cases of hæmorrhage, the arteries would gradually contract upon their diminished contents, to a much smaller calibre than common; and he measured their areas in the contracted state in which they were found in a horse that had been bled to death. He then distended them, so as to destroy the effect of this vital contraction; and having suffered them to regain that calibre which their elastic property naturally determines, he again measured their areas, and found that the aorta had contracted, in the first instance, to more than one-tenth of its natural diameter, the iliac to one-sixth, and the crural to one-third. He also observed, that arteries corresponding to the radial of the human subject, and others of the same size, were closed. I also think it evident, in the common operations of surgery, that arteries of no inconsiderable magnitude, which have bled vehemently, and in a large stream immediately after their division, very speedily cease to bleed, and remain with their orifices so closed, that they are scarcely discernible. I have seen the radial and ulnar arteries of the human subject,
appear like impervious chords. This happened, indeed, in young patients. Yet, Mr. Hunter never attempted to demonstrate muscular fibres in arteries; he says there is a reddish substance surrounding the tube near the internal coats, which he believed to be the structure possessing irritability. Specimens of arteries thus contracted, and contrasted with others of the same size, but of their natural dimensions, are exhibited in the Museum. Mr. Hunter must have been acquainted, from his brother’s lectures, with the inconclusive experiments of Hal- ler, relative to the irritability of different parts of the body. He adopted another and a better mode of determining, whether parts possessed a power of vital contraction. Observing that this power in muscles produced contraction after the ordinary functions of life had ceased, he tried whether, and for what length of time, parts could contract in this manner. Thus did he satisfy himself, that the arteries of the funis umbilicalis had vital energies remaining in them sixty hours after its detachment.
Mr. Hunter's notions of life were peculiar. He thought that it was an active principle, which, by operating in various modes and degrees, produced the different phenomena by which its existence is characterized. He knew that parts, in which no muscular structure was evident, were nevertheless irritable, and that the modes of contraction and relaxation of muscular parts were various. He seems by no means satisfied, that all the phenomena of muscular relaxation can be accounted for, on the supposition of the abatement or cessation of an active power. Without, therefore, pretending to determine the modes of action of the sanguiferous tubes, seeing that they have a power of vital contraction upon the diminishing quantity of their contents, knowing that vessels alone are capable of producing a quick and forcible current of their contained fluids, as is evident in the ascent of sap of vegetables, and still more so in the acceleration of the current of the fluids contained in the absorbing vessels of animals, as they approach to the trunk of the
system, we seem warranted in concluding, as Mr. Hunter has done, that the different degrees of power allotted to different parts of the arterious system, is given to them for the purpose of aiding in carrying on the circulation.

When the blood is projected by that powerful engine, the heart, into the large arteries, little energy on their part is requisite to urge on the rapid current; but in proportion as the heart's influence diminishes, power is allotted to the vessels to aid in its propulsion. There are some modern physiologists, and those of high repute, who consider the heart, by its actions alone, as fully adequate to maintain the circulation, and consequently discredit the irritability of arteries, except of those which are called capillaries. But where, I would ask, am I to suppose that these capillaries begin? I cannot observe the sudden and deep blush of shame, or extreme paleness of terror, without being convinced that arteries of no inconsiderable size possess vital activity; we cannot believe that the heart's influence can be partially
exerted, determining the blood into one set of vessels in preference to another. How then can we account for the vehement hæmorrhages which take place from inflamed arteries, unless we admit vessels of magnitude to possess vital activity? Do we not know that an hæmorrhagic action is a natural phænomenon in some parts of the body, that arteries occasionally pour the blood so impetuously into the corpus cavernosum and spongiosum, as suddenly and forcibly to distend them?

I can scarcely believe that if an anatomist were injecting the principal artery of the dura mater, and had burst its trunk, he could, with his utmost efforts, expel so large a quantity of injection, and compress the brain to the degree that we sometimes find it to be by blood, when that vessel is torn and irritated by injury. Yet the same vessel does not bleed when exposed. Can we account for such facts from the actions of the heart alone? How also, I would ask, am I to account for the vehement throbbing of all the large arteries of the arm, even as far
as the axilla, which may be sometimes observed, when an abscess forms at the end of one of the fingers? How am I to account for the distinct pulsation we often perceive in the carotid, or abdominal aorta, unless some vital activity be admitted to exist even in the larger vessels? We may indeed, in some instances, account for the phænomena which we observe, by supposing constriction to have occurred in the capillaries of the large pulsating trunk; but this supposition appears to me very inadequate to explain the whole of the phænomena of such occurrences.

Our physiological theories should be adequate to account for all the vital phænomena, both in health and disorder, or they never can be maintained as good theories.

Mr. Hunter enquired if the area of arteries increased as they receded from the heart, and for this purpose examined the trunk of the common carotid, which runs to some distance without giving off any branch of importance. He found it largest
at the end furthest from the heart. He was convinced that the conjoined areae of all the minute arteries must greatly exceed that of the aorta, where it emerges from the heart, and therefore that every portion of blood projected by the heart was moving into an increasing space.

Mr. Hunter, who believed that, in living beings nothing was constructed or done in vain, could never have observed the very curious contortions of some arteries, which he has taken much pains to display in his Museum, nor those of the great vessels as they enter the skull, without supposing that some purpose was effected by them. Neither could he contemplate the coalition of currents of blood moving in contrary directions, which is produced by the arteries communicating and conjoining with one another, without admitting that it must tend to retard the velocity of the motion of such opposing currents. Mr. Hunter therefore joined in the physiological belief, that all the circumstances we observe in the distribution and ramification of arte-
ries, are calculated to produce a rapid current of the blood through the larger vessels, in order that it may arrive unchanged at the part for the supply of which it is designed; and that other circumstances there occurring, are intended to retard its motion, so that it may be modified and rendered subservient to the purposes of secretion and nutrition.

Now you know, Gentlemen, that some physiologists suppose the velocity of the current of blood to be equal in all sets of vessels. With respect to this subject, I will merely refer you to an experiment of Hales, in his Hæmastatics. Having estimated the probable force of the heart, he put a tube into the aorta of a dead dog, and kept it filled with water to a height which would give an equal propulsion to the supposed power of the heart. Under these circumstances, having opened the abdomen, he cut along the tube of the intestines, at that part most remote from the mesentery, and observed the water running tardily from the orifices of the divided arteries.
He then divided the mesentery at the edge next the intestine, where the vessels being larger, the water ran rapidly from them; and when he opened a vessel of considerable size, it gushed from it with the same velocity and force that blood issues from the same sized vessel when divided in a living animal. I refer you to this experiment, because it seems far better calculated to display the effects likely to result from the circumstances we observe in the distribution and ramification of arteries, than any we may make with tubes of our own construction.

Mr. Hunter was convinced that arteries terminate in veins; for if we inject the former with any subtile fluid, it quickly and freely returns by the latter. I know not, however, whether the magnitude of some of the communicating tubes was ascertained till of late years. I have in my possession a hand which was injected with wax about thirty years ago, and the wax passed freely from the arteries into the veins, so as to afford a beautiful exhibition of the network of small veins, which proceed to terminate
in the larger trunks, in a manner which I had never before seen demonstrated, except by injections of quicksilver. In dissecting this hand, the vessels which transmitted the injection from the arteries into the veins were apparent. Some artifice is, however, necessary to our success, in making these preparations. We should suffer a part to become slightly putrid, before we inject its vessels, which produces a yielding state of them, favourable to the transit of the injection. Yet there are arteries which terminate in veins, so small, as not, in their natural and healthy state, to transmit even coloured blood, so that there is, in fact, something similar to a speculation of Boerhaave's, something like a descending series of vessels. It also evidently appears, that the great mass of the blood is freely transmitted from the arteries into the veins, so that it rapidly and regularly circulates; and we therefore conclude, that but a small portion passes into the finer vessels, there to undergo those modifications which fit it for the production of the secretions, and the various materials for the nutriment of the body.
The veins freely communicate with one another, and joining together, they form tubes of apparently larger dimensions, but of less actual calibre than the branches by which they were formed; so that in these vessels the blood is obliged to pass through converging channels, which eventually end in the two venæ cævæ, the conjoined areae of which are inconsiderable when compared with the space the blood has occupied in all the minute veins of the body. Consequently, if the heart pumps out an ounce and a half of blood at each action into the arteries, and the same quantity is returned, in the same time, to that organ by the veins, it must be urged in the like interval from the small arteries into the veins, and run with accelerated velocity as it approximates to the heart. Of this circumstance we may, I think, be convinced by ocular demonstration, even in the ordinary practice of our profession. There is much more space in the veins than in the arteries, which prevents any trivial obstruction in the former channels from impeding the transmission of the blood into them through the latter. The superficial veins which meander on
the surface of the body are beset with nu-
merous valves, or flood-gates, which pre-
vent the blood from moving in a retro-
grade course, and oblige it to go onwards
towards the heart. The blood sometimes
returns to the heart, chiefly by the deep-
seated veins which accompany correspond-
ing contiguous arteries, and at others more
abundantly through those on the surface.
Mr. Hunter believed that veins possessed
vital activity, but it must be of the kind
allotted to the muscles of tardigrade ani-
mals, and such as various parts of our bodies
are also endowed with. Indeed the large
veins near the heart are said to evince an
irritability of the more common kind. The
nature of the irritability of veins may en-
able them to adapt their calibre to their
contents. Mr. Hunter argues that, as the
vena portae in the liver performs the func-
tion of an artery, it probably is irritable.
We know that it fails to secrete, or secretes
with profusion; that sometimes it prepares
healthy, and at others faulty, bile, which va-
riation of function can scarcely be supposed
to take place in a perfectly passive vessel.
The blood returning from all parts of the body is, in the higher classes of animals, propelled from the right side of the heart through the lungs. To observe the circumstances resulting from the conjoined actions of the heart and respiration, Mr. Hunter contrived a pair of bellows by which he could maintain the latter process in an artificial manner, and thus he was enabled to observe how greatly the heart's action depends on its continuance. He says, "the nearest dependence of the heart is upon the lungs, for a stoppage of respiration produces a stoppage of circulation; and a renewal of the former is attended with a renewal of the latter. Thus, in my experiments with artificial breathing, the heart soon ceased to act, whenever I left off acting with my bellows; and upon the renewal of artificial breathing, it in a very short time renewed its action, first by slow degrees, but becoming quicker and quicker till it came to its full action." Mr. Hunter displays the subject of the structure and uses of the lungs, according to our present notions. He says, "that as the function of

*1
the lungs becomes augmented in animals, so are their cells minute, and the pulmonary vessels subdivided, by which means the surface of the air and the blood exposed to reciprocal influence is proportionately increased. Carbone is evidently thrown off, and a change produced, of the precise nature of which we are ignorant, but which is rendered evident to our senses by a change of colour; for the purple current acquires a scarlet hue, or, as it is commonly expressed, the venous blood becomes arterial. Chemists have considered the change as contributory to the production of animal heat; which opinion may indeed be true, though the manner in which it produces such an effect, has not as yet been explained.” Mr. Hunter, who believed that life had the power of regulating temperature, independently of respiration, says nothing of that process as directly contributing to such an effect. He says “breathing seems to render life to the blood; and the blood conveys it to every part of the body.” Yet he believes the blood derives vitality also from the food. The experiments of Mr.
Brodie, which I have mentioned in the first lecture of this year, seem satisfactorily to show, that the transitions of colour, which are produced in the blood by respiration and circulation, are not of themselves alone adequate to occasion a change of temperature. I am at a loss to know what chemists now think respecting heat, whether they consider it to be a distinct species of matter, or mere motion and vibration. Among the curious revolutions which this age has produced, those of chemical opinions have a fair claim to distinction. To show which, I may mention, that a lady* on her first marriage, was wedded to that scientific champion who finally overthrew the dominion of phlogiston, and established in its stead the empire of caloric; and after his decease, on her second nuptials, was united to the man, who vainly supposed he had subverted the rule of caloric, and restored the antient but long banished dynasty of motion and vibration. In this state of perplexity, I cannot advance with

* Madame Lavoisier, who afterwards married Count Rumford.
prudence or probable security one step farther than Mr. Hunter has led me. I must believe respiration to be essential to life, and that life has the power, by its actions, of maintaining and regulating temperature.

Mr. Hunter suggested that the blood ought, for numerous reasons, to be considered as a living fluid, and adds, “that the blood has life, is an opinion I have started for above thirty years, (which must have been in the year 1760,) and have taught it, for nearly twenty of that time, in my lectures.” I quote this passage merely to show how early he had acquired those notions of life, which I consider as the primary stimulus of his meritorious and highly useful exertions. He wonders that this opinion had not been more deeply impressed on the minds of medical enquirers, because the blood undergoes evident changes from variations in the state of the health, and the actions of the vessels. Life is generally attributed to solids only, yet these are formed from the blood, which could not give them what it did not possess. He says, that in the years
1755–6, when making drawings of the changes which took place in the incubated egg, he was particularly struck with the well known fact, that the yolk and white, which we cannot suppose to be organized, did not putrify; and this led him to believe that fluid and semi-fluid substances might have a principle of life diffused through them.

Every one must be convinced that the power of the heart is very considerable, even from observing the thickness and compactness of its fleshy structure. Dr. Hales estimated its force as equal to a little more than 70lbs. That it could not act with the enormous force which some have attributed to it, Mr. Hunter inferred from finding that a force of 90lbs. burst the inelastic part of the aorta. Mr. Hunter believed that the forcible projection of an additional quantity of blood from the heart into the arteries, produced a sudden motion in the whole column contained in these tubes, and occasioned their almost simultaneous pulsation in every part. He could not doubt that if they were contracted, they
would be distended by the impulse of additional fluid; yet with reference to this point, he observes, that upon laying bare an artery, no distention of the tube is apparent; and that the distention seems to take place in proportion as it is covered or compressed.

Such, then, is the view Mr. Hunter has exhibited of the circulation in the higher classes of animals; and on contemplating it, we perceive how every part of the body may duly receive its allotted portion of nourishment and life, as well as how each part may receive less or more than its ordinary quantity, in consequence of the vital actions of its own vessels.

I do not perceive, however, that his representation of the circulation differs materially from that of the best physiologists who preceded him. But he has the merit of examining every point for himself, and under all the varieties of circumstances; as well as of ascertaining what before appeared obscure and uncertain. This theory of the circulation has been assaulted, and yet,
as far as I can perceive, without being either injured or invalidated. Therefore I am disposed to maintain it, for the same reasons that I am his theory of life, because both are probable, cautiously and philosophically deduced, and adequate to explain all the phænomena of health, disorder, and disease; which I think cannot be said of any other theory relative to either of these subjects.
LECTURE VI.

ON SECRETION AND NUTRITION.

At the conclusion of the former lecture, I exhibited a kind of sketch of Mr. Hunter's facts and opinions relative to the circulation of the blood, and the change wrought in that fluid, by respiration. I have now to enquire wherefore does the blood circulate? Is it not for the nourishment of the body, and the preparation of various fluids and substances subservient to the animal economy? We believe, for reasons which I need not detail on the present occasion, these objects to be effected by means of minute vessels, which go off from the extreme arteries, and which sometimes terminate by open orifices, effusing or depositing their contents; whilst sometimes they lead on to other channels, which collect and convey the fluids they receive, to certain reservoirs or surfaces. These vessels which prepare and separate something from
the circulating fluids are called the secerning vessels. It is curious to observe Mr. Hunter's expressions with regard to these agents. "I would not," says he, "call them arteries; they are workers, they are the labourers." He would not consider them as concerned in the circulation of the blood, they are the chemists and the architects of the body. That such vessels could separate from the blood something that was formally present in that fluid, might be easily credited. But how they could prepare that extreme diversity of fluids and substances which they are known to do, formed a problem that was never solved till the time of Hunter. He thought that the vital principle of the vessel, acting on that of its fluid contents, produced these chemical changes. He thought that there was a correspondence or concert of affection and action between them, a harmony as he calls it. Thus did he attempt to explain how a morbid state of fluids could induce an unhealthy action of vessels, and how the latter could reciprocally occasion the former. Was he not, indeed, a strong and clear-sighted
man, who could see so far through the obscurity in which these subjects were involved, in his time? But the sun of science has since shone on them, and we now see distinctly the probability and rationality of his theory. Sir H. Davy's experiments prove that they are electrical actions, by which all combinations and decompositions of matter are occasioned, and that what is called electricity pervades every thing whether solid or fluid. In speaking of digestion, it has been already shown, that actions productive of secretion are regulated by the general powers of life, by the energies of the nervous system. Every one now seems convinced, by direct experiments, that vessels so modify their contents, that the liquids and substances which the absorbents take up, become lymph, a fluid resembling blood, in their transit through those vessels; and that the chyle imbibed from the bowels is undergoing continual modifications as it proceeds through these channels to the sanguiferous system. Yet, as I have mentioned in my former lectures, the most direct proof of the
truth of Mr. Hunter's opinions respecting secretion was given by himself, and at a time when these subjects were involved in darkness, by showing the effects resulting from the application of morbid animal poisons.

From observation and analogy, Mr. Hunter was induced to believe, that the coagulation of the blood was an effect resulting from the vital principle, and similar to that contraction which takes place in muscles, after the cessation of the ordinary functions of life. He mentions that in animals killed by lightning, or large charges of electricity, in those which have been hunted to death, or destroyed by violent blows on the stomach, he had observed that the blood did not coagulate, neither did the muscles become rigid.

That the powers of life inhere in any distinct substance which makes no part of the visible structure of the body, may indeed, in every instance, be doubted, but if this be conceded, the consideration of the
vital phænomena oblige us to admit that there is a principle of life pervading the blood, so that Mr. Hunter's opinions on that subject cannot well be disputed, and appear to be fully established by Sir H. Davy's discoveries. Yet his opinion of the coagulation of the blood being occasioned by its vitality has neither been proved by himself, nor disproved by others. It is a detached opinion making no part of the general discussion relative to the vitality of the blood; and therefore it is strange that so much has been said and written about it. Those who do not understand, or who dislike Mr. Hunter's opinions, have in general furiously assailed this detached and seemingly unsupported one, yet without in the least injuring or altering it; whilst others, who are advocates for Mr. Hunter's theories, have hurried to its defence, as if all would be lost should this single opinion be destroyed. Thus both parties seem to have been led away from the main subject. How seldom do we consider propositions with the deliberate exercise of those powers of observation and reason with which we are endowed? We are partial to our opinions,
and consequently prejudiced against those of others. In argument we strive for victory rather than seek for truth. That self-conceit which leads us chiefly to attend to our own opinions and feelings, and to disregard those of others, renders us indocile, unfit us for patient and impartial consideration, and is a great obstacle to the progress of science, as well as to human happiness in general.

Mr. Hunter believed that the secreting arteries, having prepared the various kinds of nutritive materials for building and repairing the different structures of the body, deposited the atoms from their open orifices with such regularity, as in a great degree to achieve this surprising purpose. He however believed that the life of the parts assisted in producing their arrangement. The occurrences met with in disease afford the strongest confirmation of these opinions; every fibre being subject to sudden and unnatural increase, mutation, or removal.

In consequence of the opinion that each
particle was deposited by an appropriate vessel, he was induced to add that every part of the body may in this sense be said to be equally vascular; what is meant by increased vascularity depending upon the greater size or number of the vessels, which transmit the blood, allowing them to be more distended with red blood, or our coloured injections. Further, he observes that an increase of apparent vascularity may be the result of vessels passing through parts to terminate elsewhere.

Now, though Mr. Hunter attributed so much to the agency of vessels, he believed that life, in various instances, formed these active tubes. His opinions might indeed be biassed by what he had observed in the cicatricula of the egg, but he thought that vessels might be formed in effused gelatinous matter, as he says they are in the areola of the egg, called cicatricula. In speaking of the latter subject, he says, "The arteries are the very first active parts of the system. We find them in action before they are connected to the heart,
and in this state they are the only parts that have strength, so that we can dissect them without injection, the other parts readily giving way.” He seems confident that vessels form separately, and afterwards become united with one another; and he believed that vessels might also be thus formed and conjoined in the gelatinous substances effused previously to the growth or reparation of parts.

In the union by adhesion, he supposed that though new vessels might be produced, the original divided vessels pullulated and inosculated, and became pervious and entire as they were before their division, so that blood or injection would permeate them as before. He thought, that when parts were united by a common vascular substance, the vessels and vital agency of the parts divided could gradually convert the common uniting medium into its own nature. Thus does he suppose that the nervous fibres are produced and elongated through the common uniting medium by which a divided nerve is conjoined. We
see surprisingly rapid growths take place either naturally or in consequence of disease; yet at the very summit of the growth, we must admit that there are nerves, because there is feeling; that there are absorbing vessels, because there is absorption. Medicines imbibed from the surface, are conveyed into the sanguiferous system through the originally existing absorbent channels, and the blood is returned in like manner from the summit of the new-formed part, through the pre-existing veins. The original structures must therefore have grown to the very summit of the newly-produced substance, or similar parts must have been formed in it and conjoined with them.

With regard to arteries in general, he says, “That they have within themselves considerable powers of increase, both in magnitude and length, as well as of producing new shoots; all which is evident at the time of the formation of the new horns in the stag, and also in utero-gestation. Such actions, likewise, extend by sympathy to a con-
siderable distance from the part immediately engaged in any increase of growth both in the arteries and in the returning veins.”

Mr. Hunter has put up in his Museum several preparations to show the celerity with which the processes productive of union are carried on. Yet, as the effusion of injection may redden parts and give them the appearance of vascularity, so that we are liable to be deceived, I shall not refer to these properties in evidence of this fact.

Mr. Hunter was convinced that life might remain in a dormant state, in detached parts, for sixty hours, as has been mentioned in the first lectures. He therefore could not wonder at the facts with respect to transplantation or engrafting of portions of animal bodies with which he was acquainted; yet he says that the transplanted part must have life, to accept of the union, because he believed, that a correspondent and co-operating action was necessary for its accomplishment.
Mr. Hunter observing how firmly the gum sometimes attached itself to a transplanted tooth, and thinking the comb of a cock resembled the gum in its texture, transplanted the tooth of a dog and set it in the comb, where it became firmly fixed. He next transplanted a gland taken from the abdomen of the cock, to a similar situation in the belly of a hen, where it also became attached, and as he believed, nourished, for he probably thought he had injected it from the general arterious system. The uniting medium by which it is firmly connected is certainly very vascular, yet I do not see that any injection has passed into the vessels of the transplanted gland. The preparation is in the Museum, so that you can examine it for yourselves. Mr. Hunter probably believed that it was nourished, from its neither wasting nor decaying. As, however, the evidence was not very distinct, he next transposed the spur of a young hen to the leg of the cock, and that of the latter, to the leg of the former bird, which spurs grew, and thus set the subject at rest in his mind. It may seem, how-
ever, curious, that the hen's spur grew to a
greater size on the cock's leg than it would
have done upon the parent animal, which
Mr. Hunter considered as a proof of the
greater vigour of constitution of the male
bird.

Next to the organs concerned in the cir-
culation and aeration of the blood, Mr.
Hunter displays the various kinds of kid-
nies allotted to different animals as a speci-
men of glands in general, and as the agents
by which the impurities are carried off from
the circulating blood. Carbone and water,
with trivial quantities of saline and animal
substances, are discharged from that fluid
from the surfaces of the body, both from
the skin and lungs. The kidnies also carry
off redundant water from the blood, which
is a proper vehicle for salts casually re-
ceived or accidentally formed; but which
is likewise made to suspend various kinds
of solid animal matter. As many of the old
materials of the body, and some of the un-
assimilated matter of our food, are insoluble
in water, nature has given the kidnies
powers of converting various kinds of animal matter into a peculiar and very soluble substance, lately recognized and denominated urea. So soluble is it that we may evaporate the water of the urine to a considerable degree without precipitating the urea; and when we add large quantities of water to urine, the urea will pervade the whole, and be dissolved in it, so as to be distinguishable in every portion by appropriate tests. Lime removed from our bones, or taken into the circulating vessels with our food, becomes also dissolved in the water of the urine by means of phosphoric acid, which the human kidney prepares in so large a proportion, that the superfluous acid will redden the vegetable blue, and dissolve more lime than is usually found in urine. That the phosphoric acid could not exist formally in the blood, but is prepared in the secretory vessels of the kidney, must be evident to every one on consideration. Yet in herbivorous animals, who take into the circulation a great deal of flint with their food, the urine is rendered alkaline in order to dissolve that kind of earth.
I have been induced thus briefly to advert to the functions of the kidney, because the quantity and quality of its products can be ascertained, and thus throw light upon the subject of secretion in general. When water abounds in the blood, whether from more being imbibed from the digestive organs, or less being carried off from the surfaces of our bodies, the quantity separated by the kidney is proportionately increased, and vice versâ. Thus do the secretions become vicarious to one another, and conjointly tend to maintain the proper quantity and quality of the circulating fluids.

The qualities of the urine also demonstrate how much secretion is affected by different states of the nervous system in general. When the kidney is rendered irritable from various causes, and persons are in that state usually termed hysterical, it scarcely separates any thing but water from the blood, which is, indeed, produced in an inordinate quantity; and it is probable, that a different state of the nervous system, may render the kidney
incompetent to transform the animal matter into urea, and thus prove a cause of foul and deficient urine. How curiously and universally are the nervous functions sometimes disturbed by trivial causes? Even harsh and discordant sounds, affecting the brain, may disturb the functions of the kidney; so that there may be some who, "when the bagpipe sings in the nose, cannot contain their urine."

Those of the medical profession must readily accord with the additional remark of Shakspeare, that such affections, which may well, indeed, be called "masters of passion, sway us to their mood in what we like or loathe." For we well know, that our patients and ourselves, from disturbance of the nervous functions of the digestive organs, producing such affections of the brain, may become irritable, petulant, and violent about trifles, or oppressed, morose, and desponding. Permit me, however, to add, that those of the medical profession must be equally apprized, that when the functions of the mind are not
disturbed by such affections, it displays great energy of thought, and evidence of established character, even in death. Have we not lately heard, that the last words of Nelson, were, "Tell Collingwood to bring the fleet to an anchor?" Shakspeare has also represented Mercutio continuing to jest, though conscious he was mortally wounded; the expiring Hotspur, thinking of nothing, but honour; and the dying Falstaff still cracking his jests upon Bardolph's nose. I request you to excuse this digression, which I have been induced to make from perceiving, that if such facts were duly attended to, they would prompt us to make a more liberal allowance for each other's conduct under certain circumstances, than we are accustomed to do; and also incite us to the more active and constant performance of the great business of human life, the education of the mind; for, according to its knowledge and dispositions, do we possess the ability of contributing both to our own welfare and comfort, and to those of others.
The saccharine diabetes is a disorder which elucidates in a very striking manner the nature and effect of the vital actions in the process of secretion. If the stomach does not digest vegetable food, so considerable a portion of it is sometimes imbibed from the bowels, as to render the serum of the blood turbid, though not sweet. In the kidney, the vital actions combine the vegetable substance into something resembling sugar, which, being very soluble in the water of the urine, in this form obtains an outlet from the body. Thus those who have trivial and temporary incompetency to digest vegetable food, have also a corresponding degree of saccharine diabetes, which is often unnoticed; but when the disorder of the stomach causing this failure of digestion is established and permanent, the diabetes is constant, if vegetable substances be eaten.*

* In saying this, I by no means deny that diabetes may not also result from disturbed vital actions in the kidney. Dr. Sanders, of Edinburgh, informs me that he has of late particularly attended to the state of the medulla spinalis and vertebral nerves both in chorea s 2
ON THE ORGANS OF PERCEPTION AND VOLITION.

After the exhibition of the organs by which animals are nourished, their curious structures built up, and their various liquors and substances prepared, Mr. Hunter shows the nervous system, or the means by which parts of the body seem to have sympathetic communication with one another, and with the brain, which is commonly believed to be the organ of sensation and volition. I have nothing to add with respect to this subject in general, to what is contained in the introductory lectures. When I wrote them, I had not indeed attended to Mr. Hunter's views of the nervous system in the lower kinds of animals; neither had I read Professor Cuvier's Lectures. It is therefore proper, on and diabetes, and that he finds their vessels very turgid, with other signs indicative of their having been in a state of considerable disorder; which state, in diabetes, however, may either be a cause or effect of renal irritation.
the present occasion, to mention that both these zealous and industrious enquirers into the structure of animals, seem to acknowledge that there are some beings, in which they have not been able to discover any regular nervous system; yet upon dissecting them, they meet with fibres which they believe to be nerves. Mr. Hunter has shown these kind of threads in the sipunculus nudus.

In animals of the worm kind, which are formed of a series of rings, the nervous system is also composed of an equal series of connected ganglia, each ganglion supplying that ring of the animal to which it corresponds, so that each ring may be considered as possessing a perfect nervous system. The connection between the ganglia may also be supposed to produce effects which I have endeavoured to express in my first lectures by the words "concurrency of impressions and actions." When animals, whose nervous system is thus constructed, have such sensations as we possess, and recognize in the higher classes
of animals, when they are sensible of light, sound, odour, and touch, the upper ganglion which surrounds the oesophagus must be considered as the brain, and from this, nerves may be traced to the eyes, antennae, and feelers. Mr. Astley Cooper tells me, if the longitudinal nerve be divided in the earth-worm, it can no longer regulate its motions. When a worm is divided, each part moves and crawls by its own powers; but if the longitudinal nerve be divided, when the worm is entire, the motions of either end so counteract each other, that the animal cannot crawl, which shows that the volition of the worm proceeds from its brain, and cannot operate on the parts beyond the divided nerve.

In insects and crustacea, the nervous system is similar to that of worms.

In molusca, there is no longitudinal source of nerves analogous to the medulla spinalis. There is an upper ganglion, similar to that considered as the brain in the animals just mentioned, and a lower
one to supply the viscera and the rest of the body. Mr. Hunter says in his MS., "There are two large nerves descending on either side of the oesophagus, and then uniting into one, forming a ganglion at their union, which he thinks serves the office of the sympathetic or visceral nerve, and the medulla spinalis."

In fish and reptiles, the nervous system approximates to that which is found in the higher classes of animals. In the former, it is extremely small. The brain and medulla spinalis of the squalus maximus is exhibited in the Museum. It therefore appears that fish, such agile, powerful, indefatigable creatures, which are also so surprisingly retentive of life, have not only a very languid circulation, scanty respiratory process, but also a disproportionately small nervous system. We need not indeed marvel at such facts, because the animals in which the energies of life seem greatest, are those in which neither circulating organs nor nerves are discoverable.
Mr. Hunter has in his MS. particularly described the various forms of the brain in the lower classes of animals, and has exhibited specimens, showing its varieties, in his Museum. As this organ becomes large and complex, so, it is well known, do animals proportionately possess various perceptions, propensities, faculties, and sentiments; which induced Mr. Hunter to believe that it was the organ of sensation and other properties originating in that source.

These circumstances being shown, the different organs of sense are next exhibited; and the structure of the eye of the fish and bird appears to have been particularly examined and contrasted by Mr. Hunter. But I must not enter into this subject, for it would be useless to begin without proceeding; and if I proceeded, I should weary both myself and my audience before I returned to the point from which I had set out. Neither do I perceive that any conclusion can be drawn from the most patient investigation of the subject, except
that which has been deduced in the introductory lectures; that vibratory actions occurring in the nerves, in consequence of impressions made on them, are transmitted to the brain, and variously affect that which is perceptive. It is evident to reason that our perceptions have no rational correspondence to the causes producing them; and nature may have allotted to animals various kinds and degrees of perception adapted to their wants, and the situation they occupy in the scale of existence. No one can guess what kind of vision belongs to the fly. There are probably 25,000 hexagonal lenses or menisci on its surface, or the same number of distinct visual organs, as some comparative anatomists would have us to believe. Some animals may have great susceptibility to light, odour, and sound, and yet may not possess great general susceptibility. We find indeed, in may instances, organization adapted to function, and yet it is highly improbable that we shall ever be able to explain function by means of our knowledge of organization.
Having promised to endeavour to confirm, by additional physiological arguments, the theory of nervous and muscular actions proposed in my first lectures, I proceed to redeem this pledge. That life continues in detached parts of vegetables and animals, seems evident, from the continuance of irritability; and to this subject only, I excited your attention in the introductory lectures. On the present occasion, I wish you to consider, that all the vital functions are, occasionally, equally manifest in the detached part; for when such parts possess powers of supplying and distributing nourishment, growth and formation will continue, so that the detached part becomes as perfect and complete as the body from which it was removed. This happens in vegetables and zoophytes.

In animals of more complicated structure, also, reproduction of parts takes place, to a degree that often excites wonder, because we are apt to judge of other things by ourselves, or by those which we are most accustomed to observe. The
claws of lobsters, when torn off, are renewed. It is said, that the divided parts of an earth-worm, if cut in two, will each become perfect; and that the head of the snail, and eye of the newt, will grow again, when removed. Yet, I would ask, what is there in these facts more surprizing, than in the reproduction of the stag’s horns, and of the plumage of birds; or in the formation of superfluous limbs in the foetus, or of monstrous excrescences in the adult? All parts are originally formed by vessels; and why may not these agents form them anew, or produce them superfluously?

In the lower kinds of animals, different parts of the body may each be considered as possessing a perfect nervous system. Those animals which are capable of great degrees of the reproductive processes, have great tenacity of life, and powers of continuing its functions without the ordinary supply of food. It is said, that frogs and toads have lived in hollows of wood and stones, so that it is probable they were supported only on the reputed "cameleon’s
dish," the air, and the moisture it contains. Snails will live when covered up in a glazed pan for more than a year. Now, though I do not, under such circumstances, see any thing astonishing in the instances of reproduction which are reported to have taken place, yet I should hesitate to admit that the brain was ever perfectly reproduced, till such a fact was established by observations on the future life of the animal, and by subsequent accurate anatomical examination. As far as I have observed, divided earth-worms, and most decapitated snails, perish; and I know that we may decollate the latter very completely, and yet but partially remove the brain; the reproduction of which would not then appear so wonderful, for even in the higher classes of animals, the life of parts seems to operate so as to convert surrounding substances into their own nature and structure.

In the higher classes of animals, in which distinct organs are allotted for carrying on the vital functions, if parts be detached, they necessarily perish, for the
Springs of the vital actions are removed. There can be no supply of blood or nervous energy, for the detached parts are cut off from their sources. There is no manifestation of the existence of life in the detached part, except by the delay of putrefaction, and the continuance, for a time, of the phæomena of irritability.

To this striking evidence of the existence of life in detached parts, I directed your attention in the introductory lectures; nor do I perceive any reason to add to what was then said, in order to persuade an unprejudiced person that it is a superadded power, only inherent in the visible structures to which it is connected. But on the present occasion, I would ask, whether irritability alone is capable of causing all the phæomena which take place in the reproductive processes I have now referred to? Can it alone produce assimilation and decomposition, and all the varieties of growth and organization? Those who think the phæomena of life depend on organization, must necessarily suppose as many kinds of life as of structures, and still
assign no cause for the production of such structures. Those who think that irritability depends upon nerves, must do so by a violation of their own principles, for they must *suppose* the hydatid to have nerves, though none can be demonstrated, even by the aid of the microscope. Yet if they choose to contend that the phænomena of irritability in detached parts which possess nerves are maintained by their presence, it is impossible to refute them, for we cannot remove the nerves without destroying the irritable substance. The arguments which invalidate their supposition are, that irritability exists where we have no evidence of nerves, and that it bears no proportion to the magnitude of the nervous system.

From the perplexities and obscurity of other opinions, let me turn your attention for a moment to contemplate the simplicity and clearness of Mr. Hunter's Theory of Life. In all its functions he recognized an active principle, capable of producing motions in matter that would not move without it, and of controlling motions to which, from other causes, such matter has a
propensity, and of exerting its powers in different modes and degrees in the structures or substances in which it inhaled. He thought that a similar vital principle was diffused throughout the body in different degrees, and to use the expressions with which his friends have furnished him, that the materia vitae diffusa communicated with the vital energies of the brain, by means of actions transmitted through the nerves or internunciate chords, as he called them; he also considered these actions to be productive of the sympathetic effects referred to in the introductory lectures, and which are wholly unintelligible upon any other supposition.

In forming our opinions on the subject of sensation, I admit that a choice of difficulties is presented to us; and I prefer that which seems the least. If I judge, as I own is natural, of other things by myself, I shall be led into a dilemma that a man of great intellectual powers and acquirements has been, and whom I have already praised for the important additions he has made to our knowledge of the func-
tions of the nervous system. As we perform certain actions in consequence of reasoning, he was induced to believe that brutes act in a similar manner from a similar cause. Regardless of the opinions of great numbers of highly intellectual men, that instinct is a blind impulse, unconscious of the end which it effects, he maintains his own, and is consequently obliged, as he proceeds, to suppose that brutes have tradition. But I am sure, had he continued to examine their actions to the extent he might have done, he would have been compelled, either to relinquish his dogma, or to assert things still more incredible. It would require more intellect and ability than falls to the lot of any human individual, by experiment, induction, contrivance, and practice, to accomplish what animals perform without education or communication with one another. The full consideration of this subject, induced a philosopher to conclude, that the actions of animals were the result of laws established by an intelligent cause, and to express the opinion by the brief but empathic exclamation: "Deus est anima brutorum." Yet
further, as animals perform certain actions in consequence of feeling, the gentleman alluded to is led on to suppose, that similar actions in vegetables are also the result of feeling; nay, he even attributes to them the more subtile sensations of smell and taste, and believes them to be undoubtedly actuated by the passion of love. As he has published all this in a scientific work, containing many highly valuable observations, I conclude that he was firmly convinced of what he has asserted; which shows how opinions are acquired and established. We have only to think in a certain manner repeatedly, and we shall become convinced of what at first might have appeared doubtful, or even improbable. It is therefore prudent, before we indulge in certain trains of thought, and suffer them to become habitual and predominant, to consider their ultimate tendency and probable influence on our conduct, both with respect to ourselves and others. It is surely right, before we enter a path which we mean to pursue, to enquire whether it may lead us.
The long continuance of life, when the brain is removed in tortoises, the dissections of that organ by Doctors Gall and Spurzheim, the late experiments of Le Gallois and Dr. Wilson Phillip, showing that the vital functions can be carried on in warm as well as in cold blooded animals, after the brain has been removed, provided, indeed, artificial respiration be kept up in the former class, all tend to show, what comparative anatomy also teaches, that the brain is not essential to the vital functions. There are animals which have no brains, and in proportion as they possess them, so do they appear to have sensation, volition, and other faculties. Every portion of newly acquired knowledge only corroborates the already well established opinion, that sensation, volition, and the intellectual faculties are connected with the brain alone.

The experiments of M. Le Gallois show that there is an analogy in the functions of the medulla spinalis in the higher and lower classes of animals. In the latter, it is
a series of connected ganglia, each supplying the portion of the body to which it corresponds; and even in quadrupeds we sometimes observe the medulla spinalis to swell out in portions, so as to appear like a series of connected ganglia, as is evident in the preparation which Mr. Hunter has exhibited of that part in the lion. The experiments of M. Le Gallois, show that the nervous influence of portions of the body, corresponds with that part of the medulla spinalis to which their nerves are connected; that it forms a kind of centre from which nervous actions radiate, and to which they tend. Yet according to the view I have exhibited of the nervous functions in the introductory lectures, it appears necessary that such actions should be transmitted to and from the brain in order to communicate sensation and volition.

M. Le Gallois seems, however, to suppose, that sensation continues in the medulla spinalis after the brain is removed. Now were I to entertain the same opinion, I might be led on to suppose that a duck
decapitated by the side of a pond, which has been known to run a few steps into the water, and swim a few strokes from the shore, was voluntarily taking refuge from injury in an element where it had formerly found security, was gratified by the feeling derived from it, and elated at accomplishing its object. The mind revolts from the supposition that nature would have formed the lower kinds of animals doomed to destruction, so defenceless, or, that they should repair the injuries they sustain in the manner they are known to do, did they possess the sensibility of the higher classes. Sensation seems allotted to animals in different degrees and faculties adapted to their peculiar situation. Were it however possible that I should believe all that seems required of me, and go on to attempt to account for the phenomena of life upon such principles, I know eventually I should be compelled to believe that atoms were sentient, and intelligence universal.

The opinion that sensation, volition, and
other faculties attendant on perception, are connected with the brain alone is natural to most men, confirmed by reasons so strong and clear, that they have convinced those of the greatest intellect in different æras and countries, and it is corroborated by all the discoveries in science. I have already observed, that we know nothing but the properties of the different substances we recognize in nature; of the subject which supports these properties we seem, in every instance, to be equally ignorant. Mr. Hunter's proposition, that the phænomena of life are produced by something which is superadded to structure, cannot, I think, be disputed. But if this be granted, the facts which have been mentioned, call upon us also to admit, that life is not essentially perceptive; and I further contend, that reason absolutely prohibits our supposing, that perception, with its concomitant attributes of consciousness and volition, and its various attendant faculties, propensities, and sentiments, can be the result of any arrangement or motion of insensible atoms. I know, indeed, I may...
be asked how I can suppose a distinct sentient principle to be formed, added, or connected? To which I answer, it is impossible to entertain any supposition on these subjects, because we can have no knowledge but what is derived from our perceptions. Yet I can firmly believe, that there may be, and are things, of the nature of which we can never entertain the least idea, from their having no correspondence to the objects of our senses. To me it seems, that true philosophy shows us the imperfection of our senses, and limitation of our powers; so that by a kind of light which it elicits from our own ignorance, it instructs us in the lessons of humility.

By adopting the opinions which I feel it my duty to inculcate, we not only avoid many difficulties and absurdities, but also perceive the scheme of nature to be beautiful and benevolent; and we are excited to actions useful to others, and honourable to ourselves. Nature has given life an active power to vegetables, which occasionally evinces its activity even in them by irri-
table motions. The irritable actions of life are however more particularly allotted to the animal kingdom. She has superadded to life sensation, but confined the sentient principle to the brain alone, and yet enabled it to perceive all that happens in the body, and even in remote objects, as well as to regulate those actions which may contribute to the welfare of the perceptive individual. She has allotted sensation and faculties in various degrees to animals, adapting both their feelings and dispositions to the situation they occupy in the graduated scale of existence. She has made man in the highest degree sensitive and intelligent. She has given him reason and sentiments of so exalted and commanding a nature, that under their excitement he will sustain and encounter what his nature as an animal most dreads and abhors. At the call of honour, or under the conviction of right, he will endure torture with seeming apathy or derision, and welcome death with smiles. In the exercise of his intellectual powers he is abstracted from his body, and unconscious of its existence.
But I forbear to say more; for I have not received the appointment of professor of moral philosophy to the college. Yet it is a part of my duty to place before you, Gentlemen, a specimen of what I believe to be the ancient Greek philosophy of life, and a sample of some modern French physiology on the same subject, for your consideration and choice.

Now though I have forborne to consider the structure of the organs of sense in general, I wish to say a few words on that of the human skin, which is capable, in all its parts, of distinguishing what are called the tangible properties of substances, because the skin forms the surface of the body, and there is probably an analogy in the coverings of all kinds of animals. Had the skin been exposed to the air, it would have either become dry and horny from evaporation, as we see in the dead subject when the cuticle is removed, or encrusted, from the same cause, by the residue of the fluids it
pours forth. It is therefore necessary that it should be defended by an outer garment impermeable to moisture. The cuticle, which seems a compact, though thin substance, through which the water effused beneath it, when we are blistered, does not even transude, appears well calculated for this purpose. It is most exactly fitted to the surface of the true skin, descending into every groove, and rising over every eminence. Yet however neatly fitted this water-proof garment may be, it would be liable to be wrinkled or displaced by friction, were it not firmly connected to the skin by a net-work of very minute, soft, and seemingly mucaginous fibres, which are therefore denominated the rete mucosum. This part is variously coloured in different persons; it is tawny in some, freckled in others, and black in the African. These investments of the skin do not appear to be sensible, and doubts have been entertained whether they are in any degree vascular.

We must however, I think, admit that vessels arrive at the surface of the cuticle,
through which gaseous and watery fluids containing some mucilaginous and saline substances are eliminated from the circulating system. We see the sweat escaping from regular pores, and not irregularly transuding, as if it passed through interstices in the cuticle. Substances rubbed on the skin gain entrance into the absorbing vessels, and it is very improbable that they pass through the compact cuticle, in order to arrive at their orifices. We see the ducts of the oil-bags terminating on the surface of the cuticle. It seems here right to observe, that myriads of oil-bags are disseminated throughout the skin, from which ducts proceed to the surface of the cuticle to anoint it everywhere; and that it is most liberally oiled in parts subject to the greatest friction or evaporation. If we throw water upon our arms, we find it repelled in globules, as from a greased surface. Every hair also receives a small covering from the cuticle, as it penetrates that substance; which covering so tenaciously adheres to it, that in taking off the cuticle, when the skin is slightly putrid,
we tear the bulbs of the hair from the beds in which they grew, and they remain firmly connected to the cuticle in consequence of this investment.

There are processes of the skin entering the interior of animals; and though these differ materially from it in appearance, yet an analogy of structure may be traced in them, so that they may fairly be considered as internal skins. Their surfaces, to which also the air may have access, are everywhere besmeared with mucus, and therefore they are commonly called the mucous membranes of animals. Mucus is an animal substance, admirably adapted for the defence of the surfaces which it covers. It is mild and unstimulating, possessing a viscidity which causes it to cling to the surface it is designed to defend, and being particularly immiscible with other fluids, it is not likely to be removed by the liquids contained in cavities formed of such membranes, or even by the current of fluid when passing through tubes of the same construction. In evidence of this, I may
mention, that the surfaces of fish are smeared over with mucus, which is liberally poured out from the orifices of numerous ducts, rendering the surface of these animals particularly slippery, preventing also any adhesion between them and the element in which they move, and serving the same purpose in facilitating their transit through the water, that greasing the bottom of a boat is known to do. Yet though they swim through the water with such celerity, the skin is never denuded of mucus.

There are intermediate surfaces in animal bodies, between those which I have described as external and internal skins, and these are also defended by appropriate lackers, which, however, I shall not detain you by describing. Yet I wish you to observe, how admirably the cerumen of the ear is adapted, from its obvious qualities, to defend and keep moist that process of the skin which lines the tube of the ear. Its tenacity causes it to cling to the surface it is designed to protect; it is not liable to
dry into a crust, as mucus does, nor to become rancid and acrid, like oil. Its bitterness, they say, also renders it disgusting to insects, which might in our sleep seek to nestle in that passage. The necessity for the lining of the tube of the ear being kept constantly moist is evident, for when the cerumen is deficient in quantity, or faulty in quality, then the oscillations of sound, or the pulsation of the vessels, produce vibrations in the tube, causing noises, which patients compare to the rustling of leaves, or the gushing of waters, and the beating of hammers.

Though the exact structure of the coverings of animals appears to be less accurately known than that of most other parts, yet from the general consideration of the subject, I think we are warranted in concluding, that Nature has either, from the texture of the substances with which she has invested them, or the qualities of those with which they are besmeared, cut off all communication between the interior of living beings, and the elements in which
they live, except what takes place through tubes or passages which she herself has formed. Even in vegetables we observe some surfaces besmeared with adhesive wax, others varnished with resin, whilst the grasses are glazed with transparent flint.

After the exhibition of the structures already adverted to, Mr. Hunter calls our attention to the fat of animals, which he considers as not actually making a part of the body, the animal being much the same with or without it. We find his attention, however, excited by the great increase of fat in hybernating animals, prior to their becoming torpid; and there are contained in his MS. many observations and experiments which he requested his pupil, Dr. Jenner, to make for him, relative to this subject, in hedgehogs.

The exterior coverings of animals are next shown, which are to be considered as their clothing or their armour, and respecting them, it seems worthy of remark,
that they are all made of the same kind of material, which is impenetrable to moisture. Hairs, feathers, scales, and horns cuticle, resemble each other in this particular, and also in their chemical analysis.

Mr. Hunter has shown the analogy of the formation of feathers and hairs. Each is formed by a vascular substance, which ascends to some distance up their shafts. Hairs are bulbous rooted, and the stronger ones are more deeply implanted in the skin. The capsule of the bulb, which is tough and shining, being opened, is found to contain a very vascular pulp which can be injected, and ascends up the shaft of the hair so as successively to form it at the bottom; and thus to increase its length. I cannot suppose this circumstance was commonly known at the time Mr. Hunter made these preparations, for a knowledge of this fact much diminishes our surprise at the accounts we have received of the plica polonica, in which disease the hairs are said to be ill-formed, matted, and to bleed from their roots.
The hairs are sometimes straight, and sometimes curved or waving, and when of the latter kind they intermix and form a fleece. In birds and beasts the stronger hairs and feathers make an external coat, and beneath this we find a downy or furry vestment of the same parts, but of a more delicate structure.

These garments of animals are, from their texture, bad conductors of heat, and well calculated to prevent external heat or cold from affecting the animal temperature.

The garments of animals also exclude moisture from being oiled, either by unctuous fluids transuding from the skin, or from their being applied by the voluntary act of the animal; Nature having given to birds in common, and particularly to those that are aquatic, as well as to many animals, oil-bags for that purpose.

The coverings of many animals seem merely designed for their defence, as the shells of tortoises, armadillos, and the scales
of the manis. The coarse scales and spines of fishes, the bucklers of the sturgeon, and hard projections of the skin of the crocodile, all serve the same purposes. The porcupine and hedgehog have quills like those of birds, but they want the fibrous part or plumage, and are remarkably strong and pointed. They may indeed be considered as a defence to the animal, when they lie horizontally; but as it is well known these animals, when attacked, suddenly squat down, bringing their fore and hind legs near together, and putting their head between their fore-legs, then contracting their skin in a direction towards their belly, by an appropriate muscle, the quills are raised, and a chevaux de frise of pointed spears presented in every direction to the assailant. When the horny or crustaceous investments of animals are of one piece and unyielding, there is a necessity, whilst the animal is growing, for casting these coverings and forming new ones, adapted to the increased bulk of the animal; and we find that snakes and lobsters thus cast their skins or shells.
Mr. Hunter next displays the weapons and instruments which Nature has allotted to animals; and here we find exhibited the spurs of the cock, the retractile nails of the cat kind, which must be considered as weapons; whilst the fixed nails of other kinds of animals may be regarded as instruments, with which they scratch or burrow. The hoof of the horse is shown; for it is used as a weapon. The horns of animals, being displayed elsewhere, are not included in this department of the Museum.

The teeth seem to have been considered by Mr. Hunter chiefly as weapons and instruments. Though teeth do not usually grow, yet those in the front of the mouth of the animals, now called rodentia, are continually growing, so that they project and prevent the animal from masticating, if not worn down by gnawing, according to the intention of nature. The venom bags, and tubular teeth, or fangs of serpents, by which the wound is inflicted and the poison injected, are shown, and also the stings of scorpions, bees and wasps.
Those animals which cannot hunt their prey, and would become victims of its resistance, can, by such means, instantly deprive it of power, and speedily of life. Such animals also as depend upon casualty for support, are generally formed to sustain long abstinence without that decline of power which occurs in others, and for the occasional digestion of enormous quantities of food. It is, however, but a small part of the highly interesting subject, of the means by which various animals obtain their sustenance, that falls within the province of the Comparative Anatomist to discuss; it is that part only which relates to structure, the rest belonging to the Natural Historian. The proboscis of animals is to be considered as an instrument, and that of the elephant is here shown.

In this department of his Museum, Mr. Hunter also displays the electrical organs of the torpedo and gymnotus, his account of which is published in the Philosophical Transactions. I have already suggested in the first lectures, what reflections they pro-
bably induced. He has put up equal por-
tions of the brain and medulla spinalis of
the raia torpedo, and a more common ray
fish of equal size, so that they appear like
the front and back view of the same prepar-
ation, in order to show the disproportion,
and the immense size of the nerves which
go to the electrical organs. How strange
and unexpected is this mode of defence and
assault, which probably palsies the prey or
assailant. Even the polype seems to have
a power of inflicting sudden death; but by
what means, is not, I believe, ascertained.
The worm which it seizes, is swallowed
without resistance, or its struggles would
lacerate the tender body of its devourer. I
have thus, as briefly as possible, told you
what are the facts, and their arrangement,
which Mr. Hunter has exhibited, relative
to these parts of the animal economy in
general.

An adherence to the chief object of
these lectures, which is to exhibit Mr.
Hunter’s opinions relative to the principal
vital functions, has obliged me to hurry
through these last departments of the Museum, and prevented me from noticing many interesting facts belonging to less important parts of the subject. I may, however, mention that Mr. Clift informs me, when Dr. Schreibers, of Vienna, whose account of the anatomy of the siren lacertina is published in the Philosophical Transactions of the year 1801, (which is the only animal known to possess both lungs and gills, and consequently fitted to live both in air and water,) inspected the preparations of the pulmonary and other organs of that animal contained in the Museum, he was surprised to find that Mr. Hunter knew nearly, if not all the facts relating to its anatomy, which he himself had been able to communicate to the public. Two species of the siren were examined by Mr. Hunter, one of which was brought from South Carolina, in 1758, and afterwards bought by him. Also, after Dr. Latham had published his account of the conformation of the larynges of various birds*, he was sur-

prized to find that Mr. Hunter had exhibited most of the facts contained in his paper on that subject, and several varieties, with which he was unacquainted, but which he deemed worthy of being communicated to the public. Now almost all the preparations in the Hunterian Collection were made before the year 1780, and have been publicly exhibited since the year 1783. We must, therefore, consider Mr. Hunter as the discoverer of all the facts, ascertained by his preparations, that were not publicly known before that time; whilst the open evidence and communication of his labours entitle him further to be regarded as the prime mover in those investigations, and as the source of that light, by which the subject of the comparative structure and functions of living beings in general, has of late been so highly illumined.
LECTURE VII.

It is one of the characteristics of living beings, that they multiply their species; which they sometimes effect in consequence of subdivisions of their bodies, or by the production of shoots, that afterwards become detached. Both these modes are evident in vegetables and polypes. In general, however, the multiplication of the species is effected by the production of seeds and eggs, containing nutriment for the germ of the future vegetable or animal, which, thus supported, grows till it acquires powers of deriving nourishment from other sources. Those animals, which multiply their species in this manner, are said to be oviparous. Sometimes the ova seem to be hatched within the body of the parent, and, under such circumstances, the animals are said to be ovoviviparous. This mode of multiplication is frequent in the lower kinds of animals, but it is met with also in
the class mammalia, amongst the oppossum tribe. From observing the peculiarities of structure in the sexual organs of the animals last mentioned, Mr. Hunter was convinced that they did not produce their young like other quadrupeds; yet he was unable to get the American oppossum to breed in this country. The facts have been ascertained, since our more free communication with New Holland. That large animal, the Kangaroo, produces a young one, not exceeding twenty grains in weight, which is received into the abdominal pouch of its parent, and being there protected from cold and injury, clings to the nipple of its mother, and takes sustenance according to its wants. It is curious to observe the difference of form between the parent and its young offspring. The mother has monstrous hind legs, by which she springs to a surprizing distance, whilst her fore paws are very diminutive, serving merely to feed and to scratch with. On the contrary, the young Kangaroo has monstrous fore paws, with which it clings to the nipple of its mother, and scarcely any hind legs; so
that its form, at its birth, is suited to its present exigencies, and not to its future modes of life. By degrees, the young Kangaroo fills and distends the abdominal pouch, and peeps abroad through its aperture, which gives the first intimation to others, that its parent has become a mother.

The common mode of the multiplication of the species, in the higher order of animals, consists in the exceedingly minute ovum, containing no nutriment for the growth of the embryon, but merely its germ. Yet this possesses powers of extracting nourishment from the vessels of its mother; and when the young has attained a certain degree of perfection, it is expelled from her body, and is, or will become, a miniature resemblance of its progenitors. Animals that bring forth their young in this manner are called viviparous.

There are organs allotted for the formation of the ovum called female, but it never increases beyond a certain point,
298 LECTURE VII.

unless excited by the application of a peculiarly stimulating substance prepared by other organs, called male. Sometimes both kinds of organs are found in the same vegetable or animal, and sometimes the organs of each sex are allotted to different individuals. How far the prerogative of the female organs may extend with respect to their power of forming the rudiments or primordia of the embryo before the peculiar stimulus is applied which is said to fecundate the ovum, is probably unknown. The female organs of plants will, I believe, prepare a seed, though no fecundation has taken place. The progress of the formation of the young vegetable in the seeds of different plants is known to vary considerably. In the common bean, the plumula or first shoot is very evident, and even well formed. Experiments on vegetables might tend to elucidate the extent of the powers allotted to the female organs. Frogs and fish prepare and exclude their membranaceous ova prior to fecundation; and some degree of organization is discoverable in that part which would produce the
embryon, if fecundated. Female birds prepare and deposit their crustaceous ova when secluded from the presence of the male. From the magnitude of some of them, and the facility with which they are obtained, they have been made subjects of interesting examination by various physiologists.

Mr. Hunter began his examination in those of the hen and goose in the year 1755, and the industry and accuracy with which he noted all the changes occurring during incubation are evident. He has put up in his Museum two sets of eggs, showing these changes from the first few hours of incubation to the maturity of the chick, and consequent conclusion of that process. As many of the appearances, however, are evanescent, or destructible by immersion in spirits, he procured beautiful drawings to be made of them by the best artists. It seems proper to mention, for it exhibits the peculiar character of his mind, that at the time of his death he was engaged in
some additional investigations of the same subject.

These were the inquiries by which he was chiefly convinced that life was a great architect. He believed that vital actions begin simultaneously in various parts of the semi-opake and whitish areola which is called the cicatricula. He says that there is a zone of bloody points at a distance from the part where the rudiments of the chick begin to form. He suspects that blood is first formed, and vessels afterwards. He is certain that vessels forming in different parts of the areola, afterwards coalesce, and that the foetus is not developed, but built up.* I kept some pullets last winter secluded from the male bird, and Mr. Clift examined the cicatricula of the eggs which they laid in the spring by the microscope, without being able to observe any differ-

* I have already mentioned that he believed that the vital processes were carried on in the same manner in the uniting medium of parts that have been divided or removed.
ence in the organization of the cicatricula of these and other eggs. He says, that there is the same appearance of opaque spots in the circumference of the areola at a little distance from its disk, and the same kind of central opacity, which, after the heat of incubation has been applied for some time, become, according to Mr. Hunter's description of them, a zone of bloody points where vessels form, which afterwards communicate with other vessels proceeding from the centre.

There have been some persons, who, from thinking formation impossible, have been led on to suppose that the rudiments of all mankind existed in their first parents. There are many who believe that there is some primary fibre from which all the rest are produced. I would ask them how and where they suppose this fibre to be formed? If they answer in the ovary, they even then admit Mr. Hunter's opinion, that life has the power of forming a fibre. The ovum is formed in the ovarium by a
secretion from its vessels. It is impossible to suppose even a fibre to be secreted; we are therefore obliged to suppose such a fibre to be formed, either by the vessels of the ovarium, or by the vital powers inherent in the ovum.

The ovum is formed in a capsule of the ovarium, and is free to move when an aperture is produced, either, by its bursting or ulceration. How far, I would ask, can we suppose the formative actions to have proceeded in so minute a substance as the ovum of viviparous animals? It is so minute as to be with difficulty discernible even by the microscope, nay, even after it has been for some time resident in the uterus, as has been testified both by Harvey and Hunter. Yet this atom, escaping from its cell, and failing to get into its proper receptacle, the womb, being like a seed endowed with vital powers, shoots forth roots, attaches itself to surrounding parts, extracts nourishment from them, and in due season forms a perfect but extra-
uterine foetus. Such cases, you know, are not of unfrequent occurrence. It seems, therefore, highly probable that the ovum, being endowed with plastic powers, forms its own parts, and proceeds in such formation to different degrees in different animals and vegetables; yet such actions are not continued beyond a certain point, unless the appropriate stimulus be applied to excite them.

It appears then to be the prerogative of the female organs to produce an ovum, which, when excited by the application of some substance prepared by the male, becomes capable of beginning or continuing those actions which eventually produce a new living being possessing properties and powers similar to those of its parents.

Without this magic application, plants may drop their seeds, and oviparous animals deposit their eggs, which though they do not seem destitute of life, yet never continue its actions, but slowly decay. On the contrary, after they have received
this specific excitation, they become surprizingly retentive of life; and though its actions are often suspended by adverse circumstances for a great length of time, nevertheless they afterwards may begin to build up the very curious structures of plants and animals, endowing also each structure with its appropriate degree and function of vitality. Some speculators indeed have imagined that the primordium vitæ originated in the male; an opinion that involves in it much absurdity, which I shall not attempt to expose. It seems refutable by the former argument. The stimulating substance is a secretion; and we cannot suppose that any thing which is organic can be at once secreted;—it must be built up. I beg leave to remind you, Gentlemen, that it is not my intention to dispute about Mr. Hunter's opinions, but merely to display them.

If the male merely prepares a stimulus, it is requisite that it should possess powers of peculiar excitation, and that the ovum should be endowed with a corresponding
and appropriate excitability; and it seems further necessary that such appropriate peculiarities should be restricted to the individuals which belong to certain species or genera of vegetables and animals. If such properties were not thus limited, but general, hybrid productions might become common; and as the offspring resembles its parents, great diversities of vegetables and animals would be produced, so as eventually to destroy all the original and striking distinctions of form and character which Nature has instituted. Nature has also made mules in general unprolific, as if she had said, "Thus far may you go, but no farther." I know that some exceptions to this rule are occasionally to be met with, but to these the grammatical adage seems particularly appropriate, "Exceptio probat Regulam."

The offspring may more particularly resemble the male or the female parent, or equally resemble both, as is evident in the common mule. Now, thinking as Mr. Hunter did about the formation of the em-
bryon and its future growth, this resemblance must have appeared to him extremely curious; and he used, in his lectures, to record every instance that came within his own knowledge, with his usual accuracy and fidelity. He recited instances of children who had never seen their parents, resembling them, not only most exactly in form, but also in manners, and in peculiar and whimsical habits. He mentioned also cases where children acquired the same diseases at the same period of life to which the parent had also been subject at the same age. He dwelt upon the resemblance of twins, and (as in his lectures on sympathies) actually wearied his audience by the number of facts he recorded, and the minuteness and accuracy with which he detailed them.

Such instances, however, are not only curious, as demonstrative of the powers and progress of the vital actions, but they also deserve general consideration; for children resemble their parents not only in person but in mind. Nature has made us
to love youth, health, and beauty of form; to delight in amiable dispositions, and admire various kinds of intellectual excellence. She has given us propensities which tend to perfectionate the human race; but we, for mere lucre, become wedded to age, disease, and deformity, malignity, folly, and even insanity. "Quid non mortalia pec-tora cogis, auri sacra fames!" But if, like Prometheus, we presume to give life in opposition to the laws of Nature, we shall receive the same punishment, for our children will become the vultures that will prey upon our vitals.

In investigating this part of the works of Nature, the multiplication of the species, we perceive, as in other instances, the same uniformity of design, and diversity of means; the same gradation, and seeming concatenation in their series. Yet this concatenation, though delightful and interesting to our observation, is perplexing to our understanding; for each link of the chain is perfectly independent of the other, nor does any necessity for such series and order, or
seeming connection appear. Still, however, it produces on the mind effects similar to those which are derived from viewing a highly finished picture, wherein the shades and variety of light and colour are so softened down and blended together, that it is difficult to say where the one ends or the other begins.

In examining the sexual organs of vegetables, we find the males and females in general included in the same flower, and sometimes so arranged, that the pollen of the males is likely to fall upon the stigmata of the females, both of which circumstances seem calculated to ensure fecundation. Yet, in other instances, we find the male organs in one flower, and the females in another of the same plant. Again, in other instances, the male and female flowers are on different plants, so that the process of fecundation is left to be effected by the sport of winds, or the occupation of the bee, which having collected the pollen, or bee bread, from the male flower, transports it beneath his hairy thighs to
the female, which he visits, to suck the
honey from its nectary; and thus undesignedly applies part of the pollen to the stig-
mata. When the male and female parts are included in the same flower, we find each of them varying in number from one to twenty and more. We find in some in-
stances the males proportionately much more numerous than the females, and in others the number of females far exceeding that of the males; and we are unable to assign any adequate reasons for the facts we observe. Yet in examining all the works of Nature we find the same difficulty; we know not why those works are formed as they are. It is a problem that can only be solved after Captain Shandy's method, by saying, "It is the will of Heaven, brother," which, as he replies, is cutting the Gordian knot, without attempting to untie it.

In the seeds of most plants, much more nutritive matter is found than is necessary to supply the young plumula, till it acquires means and powers of deriving sustenance from other sources, and this surplus affords
nourishment to animals which feed on such seeds or grain. In the various kinds of fruits, a great quantity of esculent matter is produced, which must be considered as designed for the food of animals. In the accomplishment of this object, we again observe an extreme diversity of means; sometimes the seeds are contained in the centre of the fruit; and sometimes set in the circumference, or surface. Sometimes the little embryo of the young plant, with the esculent substance, is included in a firm case. In those plants, which thrive everywhere, the seeds are light, and scattered abroad by the air; and some are curiously feathered to prolong their flight, whilst others, adapted to peculiar situations, are heavy. Even animals are made to disseminate vegetables which serve them for food; for, having eaten the seeds, some pass undigested through their bowels, and vegetate where deposited, in ground thus also manured. The seeds of some vegetables probably contain scarcely any thing but the germ of the young plant, and do not therefore vegetate, but under favouring circum-
stances. Those of the mushroom kind are perhaps as good an instance as can be produced. The multitudinous seeds appear to the naked eye a most subtile and light dust, which when diffused through the air, forms an evanescent cloud.

Nature has made also some animals monoicous, and placed the male and female parts in the same individual; though in general she has allotted them to different individuals, particularly in the higher classes, and given to each its distinguishing sexual character. The male is in general the largest and the strongest; but there are exceptions to this rule, showing that this ordinance is not the result of necessity. As the vital powers of animals speedily decay and shortly cease, the production of successors becomes a most important object.* Nature has therefore given animals of different sexes, the strongest propensities, so to communicate

* How exceedingly various is the duration of life in different vegetables and animals! Yet for this variety we can discern no adequate cause.
with one another as to produce the fecundation of the ovum, and she has limited this propensity to individuals of the same species, and ordained a repugnance to gratify such desires with others. She has caused such desires to occur only annually in some animals, and at different periods in others; at times, however, favourable to the production or support of the future young. The sexual organs seem to wither during the sterile interval, and most surprizingly to enlarge during the breeding season, which affords us a means of judging of what are the sexual organs in the lower kinds of animals. This temporary excitement of the vital actions, and correspondent alteration in the appearance of the organs, seem to have interested the mind of Mr. Hunter; and he has put up as a contrast, the organs which prepare the fecundating fluid of the sparrow, as they appear during these different seasons.

There is a circumstance relative to the female of the human race that deserves the consideration of the philosophical physi-
ologist. A monthly discharge takes place from the uterine cavity; it is of a nutritive quality, resembling blood, and from its quantity, languor and weakness is induced whenever it occurs. Why Nature should have doomed the human female to the periodical loss of so much nutriment and proportionate power, is a problem that can only, in my opinion, be solved by supposing that it relieves uterine irritation, and mitigates the extreme of sexual desire; thus enabling her to conform to the laws of morality, and the social compacts that are established between us.

That Mr. Hunter viewed the whole of this subject in the light I have endeavoured to represent it, seems manifest from the arrangement he has adopted; for he has exhibited all the varieties of the sexual organs, first in vegetables and afterwards in animals. He has also shown the females as they are found before and after impregnation. His mind, however, seems to have been greatly excited by the diversity of means which Nature has contrived to
secure the life of the defenceless young, and to supply it with nourishment suited to its tender age, when it is incapable of supporting itself.

In his paper on bees, he appears much interested in observing, that their eggs are deposited in separate cells, before which there is a kind of platform; that the labouring bees bring regular supplies of bee bread, at stated times for the young maggots; that when these begin to spin and assume their pupa state, the labourers close the mouth of their cells, and cease to bring them food; that they return exactly at the time when the maggot has undergone its metamorphosis and become a perfect bee; that they now unclose his cell and bring him honey, the sweet food which is to be his future support, and which he is afterwards to collect and lay by with such incessant toil during the summer season, to serve as a common store for himself and the community, when the inclement winter has cut off those sources from which it has been obtained; and that, on the very
day following his transformation, he is sent off with the swarm to participate in its provident industry.

In his paper on the secretion from the crops of brooding pigeons, he observes, that it is not alone in the class mammalia, that Nature has ordained the parent to supply nourishment to the young from its own body, for that pigeons feed their young with a secretion from their crops, which they bring up and project into the throats of their offspring. This secretion does not take place except at the required time, and it occurs chiefly in the male bird, to which the office of feeding the young is principally allotted. We account for the secretion of milk in the breasts of females, from their sympathetic connection with the other sexual organs, but the fact just mentioned cannot be accounted for in this manner, nor, indeed, upon any law of necessity. Mr. Hunter, whose habit it was to think upon every subject, seems inclined to attribute it to a feeling of fondness; for he observes, that the male bird acts in the
same manner when he caresses his mate. Nor is this supposition improbable; for we know that certain feelings evidently affect the different secretory organs of our own bodies.

Mr. Hunter exhibits the nests of birds and field-mice amongst the preparations, which display the anatomical facts relative to the nourishment and defence of the young. This seems on a par with the hyacinth root which I formerly mentioned. Neither show any thing which is not known to the most ignorant, but both evince what were his habitual thoughts, and at the same time display a simplicity of character by no means common.

Dull indeed must that mind be, which could examine the extreme variety and ingenuity of the means employed for the protection and support of the offspring, and their adequateness to the purpose for which they seem intended, without feeling the strongest excitement. The subject in general, however, belongs to the natural
historian. The department of the anatomist ends, after having recounted those circumstances which relate to the structure and animal economy of living beings, that are calculated for the purposes just recited. According to this division of the subject, I may mention, that whilst some animals build nests or habitations to cherish their young, others have them formed in their own bodies. Of this I have already mentioned one instance, when speaking of the marsupial quadrupeds which are ovoviviparous. The Pipa or Surinam toad excludes its eggs like other animals of the same kind, yet the young toads become afterwards lodged in separate cells on its back. The pouches of marsupial animals are permanent, and they suckle their young, but there are no cells in the back of the Pipa during its unimpregnated state, nor do these cells appear to secrete any thing; neither have they any communication with the interior of the animal; all which circumstances Mr. Hunter took much pains to examine and display. Why this great toad should differ in this manner from others of the
same kind, how the cells are formed, or the young get into them, is not I believe known; yet surely no one who has attentively examined and considered the works of Nature, can doubt of there being good and sufficient reasons for this peculiar deviation from the commonly established structure and economy of such animals.

It is from the consideration of the means by which the continuance of the different species of animals is ensured, that we derive the firmest conviction of the works of Nature being neither the effect of necessity, nor of chance; and therefore it follows that they must be the effect of causes and laws inscrutable by man. The young of some animals are born with very perfect senses and powers, so that they scarcely need maternal care. Yet as young animals cannot have experience, and must be exposed to danger from their deficiency of size and strength, the mother generally nurses them, and directs their conduct, till they are able to procure their own sustenance, and secure or defend themselves.
When the mother must seek her food, and be absent from her nursery, the young are born with scarcely any vision; whilst others have such perfect senses and powers as to be able to accompany their mother in search of food. The most helpless and imperfect offspring is that of the human race; but the long nursing which is required, creates and strengthens reciprocal attachment between it and its parents, which continues throughout life; so that according to the laws of Nature, children are disposed to return such kind attentions when age shall have reduced their parents to feebleness and second childhood. How opposite to all this is the mode by which the cuckoo species is continued? The parent has no solicitude about its young; yet Nature has taught it to ensure the continuance of the species by depositing its egg in other birds’ nests. How curious is it that the just hatched cuckoo should have peculiar appendages to its wings, with which it can confine the legitimate offspring against the sides of the nest, and that it should possess in-
Lecture VII.

Instincts which cause it to protrude them one by one out of its cavity?* How curious also is the mode by which the continuance of the species of the oestrum equi is effected? Surely it is wonderful that this fly, as if endowed with intelligence, or instructed by experience, should never deposit its eggs, but in those parts of the horse to which that animal can apply its mouth, so that they may be swallowed. By this means the larvæ are provided with a warm lodging and plenty of food during the winter season, and are not expelled till spring, in order to undergo their metamorphosis into perfect flies. I must not proceed further in this endless subject, the full investigation of which has convinced the most intelligent of mankind, that the order of Nature is the result neither of necessity nor chance.

Every part seems perfect in its design, and calculated for the good of the indi-

* Cuckoos however have been known to hatch their own eggs.
viduals which compose it; yet these individuals are often supported at the expense or by the destruction of others. The less powerful animals herd together, and set watches to warn them of approaching danger; as they are exposed to invasion, and the destruction of their companions by the solitary and fierce tyrants of the forest that issue from their secret dens. Nature has however made the animals that are liable to destruction exceedingly prolific, so that their race cannot well be exterminated; whilst she has made destructive animals in general unproductive; and when it happens otherwise, we find means which counteract their excessive multiplication. Why Nature has formed carnivorous animals, or produced such a variety of living beings, is a problem difficult to explain. Yet, this being a part of her plan, we cannot but admire the means by which it is accomplished; for every thing contributes to promote the welfare of the individuals in their proper sphere, and to ensure the continuance of their kind according to its destined proportion, so that centuries elapse
without the extinction of a single species. All animals seem also to be put under the dominion of man; and as his species multiplies, it fosters and feeds the useful and innocent, and destroys those of a contrary character.

From observing the art with which predaceous animals entrap their prey, and the fury with which they destroy it, some are inclined to represent the scheme of Nature as one of fraud and rapine. Yet, surely, it is better that animals should suddenly perish for the good of others, than that they should be doomed to linger, and ultimately to starve, from that want which excess of multiplication must necessarily produce. Be it also remembered, that many of these creatures have little sensation, that all are far less sensitive than man, and that they neither anticipate the future, nor reflect on the past; so that their sufferings are transient, and necessary to general good. There are some who are inclined to represent the sufferings of animals as calamitous; but surely they have not consi-
dered that pain is Nature's monitor, and contributory to the welfare of the sufferer, by teaching it to avoid what is injurious. Neither do they seem to have reflected that it is the necessary reverse of pleasure; and that without enduring the occasional penalty of the one, we should not enjoy the more continued comfort and delight of the other.

It seems strange, that some minds appear to delight in blaming what they do not understand, and feel a repugnance to believe, that any thing may originate in causes which they cannot comprehend; and, therefore, probably they are induced to suppose a kind of necessity. All nature is full, says one reputed philosopher. Whatever can be, is; says another. But it would be far more easy to show cause why we should believe that there is a plenum of matter, than of contrivance.

On the contrary, however, the most intelligent men who have studied the works of nature to the greatest extent, and with
the greatest attention, have been convinced, that they are the results neither of necessity nor of chance; and, consequently, that intelligence must have operated in ordaining the scheme and order of the universe. The common sense of the bulk of mankind, who judge from general observation, leads them to entertain the same opinion. Both agree, that in examining the works of Nature, whatever they understand seems most admirable; and when they cease to admire, conclude that they do not understand; for "'tis but a part they see, and not the whole." They also clearly perceive that partial evil tends to general good.

You, Gentlemen, must examine this highly interesting subject for yourselves; for when I consider what might be said and shown with relation to it, I feel ashamed of the inadequateness of the representation I have given; which, nevertheless, I hope may be useful, by exciting you to enquiry. You must either form your own opinions, or confide in those of others. To form correct opinions it is necessary that all the
facts belonging to any subject, should be attentively examined and considered, without prejudice or partiality; and this is no light labour. It is a task more suited to an ancient Grecian philosopher, than to one of the present school; for the latter is busied in collecting new facts, in adding to the stock of knowledge, and is consequently apt to take partial views of subjects, and not sufficiently to contemplate the general system of nature.

I have now led you round the gallery of the Museum, and have briefly informed you what probably were the designs of Mr. Hunter, in the preparation and arrangement of the subjects there exhibited. Having restricted myself to the consideration of those facts only, which form the basis of his opinions relative to the principal vital processes; I have been prevented from noticing many important circumstances, belonging to other subjects, in anatomy and physiology. The gallery of the Museum, is, however, but a small por-

y 3
tion of it, and throughout the whole, we observe Mr. Hunter's solicitude to procure evidences of every important fact relative to the subjects in which he was so greatly interested; and also the same genius and reflection displayed, in endeavouring to interpret the works of Nature, and to arrange and concatenate the facts, according to their series and order, so that each should be distinctly seen, both by itself and in relation to others.

Now, though what I have said is so incommensurate to the merits of the man I have endeavoured to eulogize, or with the claims of the subject I have attempted to discuss, yet I flatter myself that I have attained the objects I had in view in writing these Lectures. I wished to show in what manner Mr. Hunter had examined the various vital processes, and also the general extent of his researches in Comparative Anatomy, and consequently from what an extensive and well arranged series of facts, his notions of life had been de-
duced. Yet it is almost necessary to pursue the same course of reflections, that he himself has done, to be fully aware of the intensity of thought with which he has considered many parts of the subject. In thus asserting the claims of Mr. Hunter, I hope that I shall not be considered as blind to the merits of others, or reluctant to acknowledge the valuable information which we have received from other anatomists since his time. I wished also to corroborate, by additional arguments, the opinions I merely alluded to in my former lectures, and which I consider to be those of the most intellectual of the Greek philosophers, that perceptivity, and the various properties of mind, are not attributes of mere life, but probably of a distinct substance.

Mr. Hunter's Theory of Life has however been said to be absurd and untenable, and even has been held up to ridicule by those attached to the physiological opinions that have chiefly issued from some of the writers of the French school. What those, who are advocates for such opinions
think, it is difficult to determine, because they do not explicitly declare their sentiments. There is a mysticism in their expressions and manner, calculated to delude the ignorant, and perplex those who have not fully considered the subjects under discussion. Therefore, it seemed right to place distinctly before you, in the first lectures of this year, the only opinions which the mind of man is capable of entertaining, relative to the causes of motion in matter. In exploring the cause of the contrary states of motion and rest, the mind's eye alternately dimmed and dazzled, becomes weary and confused, and ceasing from the fruitless search, fixes itself upon a partial view of the subject, which it thinks it has obtained. We feel a strong conviction, that a more subtile and mobile substance, or a more attenuated species of matter pervades, acts upon, and is the cause of motion in that which is more gross and inert.

Who can observe the seemingly vital effects which the warmth of the sun produces, even in common matter, or the terrific
and destructive consequences of intense heat, without thinking that heat must be essentially active, or that it excites actions in something that is so.

Who also can observe the quick and powerful motions of animals, without believing that something active is incorporated with them? The consideration of the vital phænomena call upon us to admit, that there is some power of controlling, exciting, and modifying those chemical changes, to which the atoms composing them have, under certain circumstances, a propensity, as well as of arranging the materials in diversified structures. Philosophy must always be founded in Nature, and its rules be adapted to the subjects to which they belong. It is natural to man to observe, to enquire, to reason, to believe in various degrees up to perfect conviction; and we may perform any of these acts, according to the precepts of philosophy. Scepticism has no right to boast of an exclusive claim to be accounted philosophical. Confidence may also be as philosophical as
doubt. It is absurd to expect mathematical demonstration in subjects which do not admit of it, and the absurdities of determined doubters have been exposed by writers both of a serious and satirical cast.

Now, though the changes occurring in common matter are extremely diversified, and highly contributory to all the wants of living creatures, they are still so uniform as to afford a plea for maintaining, that they may be the effect of inherent propensities in the atoms of which this matter is composed. But to suppose that all the varieties of vital action and other facts belonging to the structure and economy of living beings, which we have been lately considering, are the results of inherent propensities in the atoms of matter, unassigned and unsupported by intelligence, seems to me too absurd to require any attempt at serious or formal refutation. I have therefore, never, except in one instance, paused to make those reflections which the subject so constantly and naturally excite, and now,
in conclusion, I will only observe, that upon the supposition just mentioned, we must be led to expect the phænomena to be more uniform or more diversified; nor could we imagine it possible, that there should be that regularity in their series, and that adaptation of means to ends, which we so constantly observe.

It has been said that "an undevout astronomer is mad;" yet he only contemplates the immensity and order of the works of Nature, and the causes of the varieties of light and seasons, so serviceable to the living beings which inhabit this planet, and, as he infers, to those of others. But what shall we say of the anatomist who observes the structure and functions of those beings, who examines their extreme variety, and regular gradation and connection, without any feeling or perception that Intelligence has operated in ordaining the laws of nature? We judge of others by ourselves, and assuredly such a character must, by the bulk of mankind, be considered as possessing either a deficient or perverse intellect.
The opinion that Intelligence must have ordained the order of Nature, is not only impressed by her decrees upon the bulk of mankind, but is confirmed by the observations and reflections of the most observant and intellectual individuals of the human race. Those who think that intelligence may exist distinct from organization, are disposed to admit that the intelligence with which they are endowed, may have a separate existence. Those who think that perception is not essential to life, but is an attribute of something different, are also disposed to admit the separate existence of perception and intelligence; and thus do these two opinions produce and support each other. Both opinions are natural to most men, and confirmed by the observations and consideration of the most intellectual of the human race.

Gentlemen, I was presumptuous enough in the first lecture to imagine myself that
honourable character, — a British advocate. I also imagined that you were impannelled as a jury, a tribunal in which we glory, and by whose decision we must abide. Now, however inadequate I may be to perform the part I have arrogated to myself, you are fully competent to discharge the duties of the tribunal I have supposed you to form. You have the ability to decide, and the power to punish. You can inflict the severest of all punishments, that of which the greatest despots stand in awe, those who may be said to be "safe from the bar, the pulpit, and the throne," yet tremble at the strong and open expression of general disapprobation. The medical republic should legislate for itself, for the public in general know little of our peculiar studies, and may consequently estimate our opinions with respect to certain subjects at a much higher value than really belongs to them. We should not therefore suffer crude speculations to go forth, bearing the seeming stamp of medical authority, when they are contrary to the sentiments
of the bulk of the profession, derogatory to its character, and injurious to society.

In arguing the subject relative to the opinions which we are warranted to form respecting the nature of life, I disclaim having any allusion, in what I have said, to those of particular persons; and I have, as much as possible, endeavoured to conceal all perception of individuals, by massing them together in a crowd. I contend with no man about his opinions; for charity instructs me to believe that each forms the most correct opinions he is capable of doing. I contend only against the promulgation of those that have a pernicious tendency. In the assumed character of a British advocate, I must be an advocate for liberty; but then, it is for British liberty, for rational liberty, for liberty without licentiousness, for the liberty that our laws allow, which confirm to every individual his natural rights, giving him licence to think and act as he pleases, or deems proper, so long as his actions do not tend to
the detriment of other individuals, or to that of society in general. Let me not either derogate from my assumed character by neglecting to remind you, Gentlemen, that the consideration of the *quo animo* is the vital principal of the British law. There may be inconsiderate persons who commit error without adverting to its diffusively baneful consequences; who, thoughtless of the course and contingencies of human life, may undesigningly broach opinions tending to weaken and destroy others which form the spring of every generous and noble action, and our only support under oppression and affliction. There may be those who do not perceive how our notions respecting life can influence our conduct. But this indeed surprises me, because Voltaire was so well acquainted with the evil tendency of his own doctrines, that he checked the conversation of his companions, whilst the servants remained in the room, lest, observed he, we should have our throats cut.
 That ignorance may not, however, be hereafter pleaded in mitigation of your verdict, I deem it my duty, with the utmost brevity, to represent the effects of different opinions upon human actions. For this purpose, I first select the case of a powerful monarch, called by historians Sardanapalus; who chose, for reasons perhaps best known to himself, to write his own epitaph, as follows. "Eat, drink, and be merry; for the rest is nothing;" an epitaph, says Aristotle, fit for a hog. It cannot be doubted, that Sardanapalus was one of those who considered the grave to be a "place of eternal rest." To show the effects of the contrary sentiments, I would ask, is it credible that Socrates, after drinking the poison, would have calmly discoursed on philosophical subjects with his friends; or that Brutus would have stabbed the Roman he most loved, rather than suffer his country to be enslaved, had they not formed a proper estimate of human life, and considered themselves but as performing a part, in the presence of immortal and
and intelligent observers? Or why does the untutored Indian deride the cruel torments of his enemies, but that he also believes he is going to the land where his father is gone, and would feel shame to be recognized a degenerate son?

Being desirous to avoid all personality, and to contend only against opinions, it seemed necessary to denounce those that I meant to oppose, at the very outset, and in the first lecture; for if we try to hit a mark, and others are to judge of our success or failure, it is necessary to place the object distinctly in the view of the observers. Yet even in ascribing opinions and conduct to a party, under the denomination of modern sceptics, I may give offence; for some may suppose themselves comprehended in it, though they do not actually belong to it; whilst others may even think it unwarrantable to suppose that there can be any such party at I have described. Hesitation in decision is natural to many characters, and caution, to a certain extent, is an indispensable ingredient in all those who have any pretensions to be accounted
philosophers. But the party I allude to are not real sceptics, and their professions and conduct form a curious example of a *vis inertiae*; for after resolving not to think on certain subjects, they argumentatively endeavour to prevent others from thinking; whilst on the one side they reject a very few propositions, merely because they are deficient in a kind of proof that the subject does not allow of, and that cannot be rationally required; on the other, they admit a host of absurdities, apparently without examination. Therefore, upon the very grounds of their own doubt, they marshall and exercise pernicious and discordant opinions, drawn from every possible and remote source, with which they assail the opinions of others, that at least may be said to be innocent and useful, but which also confer a dignity on human nature, and excite us to generous and honourable actions. I feel it to be my duty, Gentlemen, to prevent, if possible, the banners of physiology from being purloined and carried into such a service; and yours not to suffer those of our profession in general, to appear in so disgraceful and mischievous a contest.
There are "Smellfunguses" and "Mundunguses"* in science. I pity the man who can survey all the wonders of the vegetable and animal kingdoms, who can journey through so delightful a district, and afterwards exclaim, "all is barren." Still more do I pity those, though the sentiment is mixed with strong disapprobation of their conduct, who, after having seen much to admire, shall, when they meet with a circumstance they do not understand, presumptuously dare to arraign the wisdom and benevolence of Nature. In the progress of science, many things which at one time appeared absurd and productive of evil, have afterwards, upon an accession of knowledge, been found to be most wise and beneficent. I deem no apology requisite, Gentlemen, for endeavouring to impress on your minds certain axioms relating to philosophy in general, when they are directly deducible from the subjects of our peculiar studies. I have constantly and carefully avoided every argument foreign to the subject, so

* Characters thus denominated, and portrayed by Sterne in his Sentimental Journey.
that, if occasionally I may have appeared to sermonize, I have quoted both the chapter and verse of my text from the Book of Nature. I address you, Gentlemen, as students of that great book, and earnestly exhort you to study it with such sentiments as I have endeavoured to inculcate. The conviction that every thing tends to some immediate or eventual good, is the greatest incentive to its study. It was this conviction that excited Hunter to such continual enquiry, or involved him occasionally in the depths and perplexities of intense thought; for he was never satisfied without being able to assign an adequate reason for whatever he observed in the structure and economy of animals. This conviction makes the study of Nature highly interesting, and may indeed be said to render labour delightful, or to medicate the pains attendant on its toil. To those who entertain such sentiments as I have endeavoured to inculcate, every thing seems animated, beneficent, and useful; they have the happy talent of discovering even

"Tongues in the trees, books in the running brooks,
Sermons in stones, and good in every thing."
APPENDIX.

Extract from the European Magazine for 1782, containing a Syllabus of a Course of Lectures on the Principles of Surgery, delivered by Mr. John Hunter, F.R.S., St. James's, London; with Anecdotes of his Life.

This very celebrated Course consists of near an hundred Lectures.—It begins in the month of October, and continues till April, and is given every other evening, from seven to eight o'clock, the honorarium being four guineas.

Mr. Hunter's Lectures do not contain a Course of Practical Surgery, with the Operations necessary for different cases—but his purpose is to give a comprehensive view of the system, and investigate the principles upon which the practice of surgery is founded, viz.—To show the actions of the body and its parts when in the diseased state, with the actions and effects of nature to recovery—and the neces-
sary and proper assistance to be given by the Surgeon. The principles of diseases are the first parts of surgery to be learned. They are to the Surgeon what the first principles of the mathematics are to the practical geometrician, without the knowledge of which a man can neither be a philosopher nor a Surgeon. In our research after diseases, says Mr. Hunter, we ought not only to understand the case, which becomes the immediate object of Surgery, such as inflammation, suppuration, mortification, &c. but also the cause of the effect; for without this knowledge our practice must be very confined, very precarious, and often applied too late. This knowledge opens to the Surgeon varieties of treatment. It teaches him in one instance to remove the cause—in another to increase the effect—in another to change it to some other disease—and gives him, what is the most essential point, the knowledge of the proper moment for the surgical operation, where an operation is necessary. In the animal body the power of restoration to a state of health arises out of the Animal from its own mechanism and action. If the Animal was in all cases equal to the task, there would be no occasion for the Surgeon; but it is necessary in many cases to assist nature by the introduction of artificial powers—to increase the living powers of the Animal when
they are inadequate—to retard them when violent—or to change them when wrong. Both the chemical and mechanical powers are made use of in Surgery.—Chemistry is introduced to destroy what cannot be altered—and mechanics frequently restore what had been accidentally or artificially destroyed. It is not only necessary for a Surgeon that he should know the different parts of an animal, but he should know their uses in the machine, and in what manner they act to produce their effect. He ought not only to know the whole of any one simple action, or the knowledge of all the actions singly—but he should ascertain their correspondence—mark their relations, and acquire a competent idea of the compound actions and general fabric of the machine. Operations should never be introduced but in cases of absolute necessity. A Surgeon should never approach a victim for an operation but with humiliation—it is a reflection upon the healing art. He is then like the Savage in arms, who performs by violence what a civilized nation would accomplish by stratagem.

Mr. Hunter having observed, that the greatest part of the books published in Surgery, contain little else than relations of cases, and
modes of treatment, and that the practitioners have been too easily satisfied with a collection of facts, without embracing the catalogue of diseases as a system, proposes in his course to examine the theory and principles of diseases in a regular series. His doctrines are drawn from personal observations made in the course of an indefatigable life, with the constancy of a most adventurous mind. His ideas, his mode of reasoning, as well as his arrangement of diseases are new; and he therefore has received little aid from books or from other professors. The novelty of his ideas occasion also the application of new terms; and those which he has given, he may consider as clear and explanatory, since they are adopted by others, and brought into use.

The Course begins with the Physiology, or natural History of the Animal; but so far only as is necessary to the understanding the principles of diseases; in which new ideas and new arrangements of the subject are introduced.

The Physiology of Diseases follows—the action of medicines—and brings him to the consideration of diseases in general.

The Diseases of accident being the most obvious and simple, in preventing the natural
operations of the Animal, begin the Surgical part of the Lectures, in which he explains the most simple modes of restoration.

Then follow the diseases whose mode of action is similar to those arising from accident.

As the treatment of diseases arising from accident is various, those which are the most simple come first in view. This leads him therefore to explain,

The first mode of union of separated parts, called "Union by the first intention," and

Inflammation.

On both these subjects he is very full, especially the latter, as it is one of the first principles in most diseases, and produces a variety of effects.

Inflammation leads him to the second mode of the Union of Parts; as happens in wounds where the first mode has failed, or has been neglected. This also leads him to

The Union of Parts originally in contact only as the natural cavities, but united for very wise purposes, and which are called Adhesions.

The cure of many diseased parts, as fistulas, indurated tumors, &c.

The diseases of bones.

The knowledge and cure of gun-shot wounds.

Inflammation also makes a principal part in all specific diseases, as the Small-pox, Lues Ve-
nerea, Cancer, &c. — and therefore he takes great pains to investigate its principles.

Then follows Suppuration, and those actions are illustrated by the consideration of Compound Fractures, Hydrocele, Suppuration of the veins after bleeding; gun-shot wounds, &c.

And, in the second place, by the various diseases arising from spontaneous suppuration, as abscesses, diseases of the bones, diseases of joints, &c.— This leads him to the consideration of Granulations, their course, progress, kinds and use; and also of Cicatrization.

After Inflammation and its general consequences, he proceeds to treat of specific diseases, such as The Lock Jaw. Scrofula. Poisons in general. Peculiar Poisons, as the Lues Venerea, Cancer, &c. &c.

This Course of Lectures is illustrated by a collection of diseases, and of Comparative Anatomy, which, in point of curiosity, accuracy, and comprehension, is equal to any collection in the world. It has been made by Mr. Hunter
himself, and what chiefly contributes to its extraordinary value and advantage is, that he knows the particular history of the greater part of the diseases, which he has preserved—the patients were under his observation in the Hospitals—he has minuted the progress, and accounted for the various appearances and effects of each disease, with a fidelity that now renders his collection a most instructive school for the Student.

Anecdotes of Mr. John Hunter.

We have introduced the Syllabus of the Course of Mr. Hunter's Lectures on Surgery in this place by choice, as he is the brother of the celebrated anatomist, Dr. Hunter, whose Lectures made the subject of our first number. When so eminent an example occurs of congenial talents and contemporary distinction in two brothers, it would be an outrage to separate them. We might have been permitted to deviate from regular order for the sake of so extraordinary and so splendid a circumstance; but when no method nor link is broken, it would have been unpardonable to have overlooked the opportunity of gratifying the honourable
pride of man in the exhibition. Dr. Hunter having settled in London, sent for his brother John, who accordingly came to England, being at that time in his eighteenth year. He immediately applied himself to the study of anatomy and surgery; and, for several years, he was employed in the dissecting-room, where he suddenly began to display his uncommon abilities. The doctor was anxious that he should go into partnership with him, and in the year 1758, declared him to be fully adequate to the important office of a Teacher; but Mr. Hunter, with a modesty which is always the attendant of genius, felt insuperable embarrassments and objections to speaking in public, and he declined the advantageous and honorable offer, on account of his aversion to public speaking, and his extreme diffidence of his own abilities and skill. But he continued in the same anatomical pursuits till the year 1760; when, anxious for a more enlarged field of observation, he went out as Surgeon General to the Army, first to Belleisle, and afterwards to Portugal. In this extensive scene, he indefatigably studied the nature and treatment of gun-shot wounds; and he acquired great credit from his humanity and talents. He has constantly, in his practice, been an enemy to operations—he has resorted to them unwillingly,
in the last resource, although no practitioner has been more distinguished for a steady and skilful hand in an operation than himself, where necessity drew him to the expedient. — On the peace in 1763, he returned and settled in London as a surgeon, and came, in a very short time, to the possession of an extensive practice. Now it was that he began to form his system. In books he found, as we have mentioned, no other lights in the investigation of surgery, than what arose from the enumeration of independent facts and cases, without reasoning and without principles. He totally rejected books, and took up the volume of the animal body. — He was as indefatigable in his pursuits, as he was adventurous in his conduct. Though an enemy to operations on others, he was regardless of himself, and exposed his person to all the active and artificial powers, by which he might ascertain the properties, and trace the effects of medicine on the human frame. He was not deterred by the shocks which such trials must necessarily give to his constitution; nor by the fatigue, labour, and loss to which they exposed him. He began at the same time to form his collection of diseases; and for this purpose he attended the various hospitals, in order to see the curious cases, and to observe, with his own eyes, the progress of the
various diseases, which he might procure into his custody. He from this time also employed himself in forming his collection of comparative anatomy. The whole together has cost him more than 10,000L, besides the labour it has required in the preparations. Of this sum more than two thousand pounds have been expended in the purchase of dead animals only. In the year 1768, he was chosen Surgeon to St. George’s Hospital; and in the years 1772, 1773, and 1774, having collected his ideas and observations, he assembled the pupils of that Hospital, together with a few chosen friends, and read to them, without expense, a course of lectures on the principles of surgery. In the year 1776, he was appointed Surgeon Extraordinary to His Majesty. Prior to his going abroad, he had been present at the dissection of more than two thousand human bodies, and in the year 1754 or 55, discovered the structure of the placenta, and the communication between the mother and placenta. He had also employed himself a good deal, even at this time, in comparative anatomy, and had discovered the absorbing system in fowls, and in the crocodile, which is one of the amphibii, proving by experiments that the red veins did not absorb. This was published by Dr. Hunter, in his Commentaries, in 1762. Since his return, as we
have already mentioned, he has been particularly earnest in his attention to comparative anatomy. He has a house and gardens in the country, on purpose for his experiments on living animals and vegetables. For the last five years he has employed in his house an ingenious draughtsman, who is engaged, at a regular salary, for ten years; and also another person, engaged for the same time, to manage and keep his preparations in order. He means to class the animal world according to their structure, in which he has made considerable advances. His objection to standing forth as a public teacher still continued—and it was only overcome by the intercessions of his friends, and by his own consciousness that he might be useful to students, in explaining the principles and analogies which he had observed in diseases, and reducing thereby the art to a more regular and less precarious system. Dr. Hunter's library is, perhaps, the finest in Europe in choice, scarce, and valuable copies, and it cost 16,000l. Mr. Hunter's is comprehended in a few cases, and were it not, he says himself, for the presents made him by contemporary authors, would hardly have consisted of a hundred volumes. His opinions, therefore, are all his own, drawn from personal observation;—he does not say that every doctrine is new—some of his opinions
may have been given before—but they are new to him. He acts in his character of a public lecturer, with the disinterestedness that has marked his conduct through life; for though the honorarium is only four guineas, the course continues six months; whereas there are courses of lectures, comprehending both anatomy and surgery, which are gone through in the short space of six weeks. We by no means think ourselves qualified to pronounce on the merits of living teachers. It is our business to state the simple facts, and to be cautious that, in our collection of the materials, we are neither imposed on ourselves, nor impose on our readers.

THE END.

THE

HUNTERIAN ORATION,

FOR THE YEAR

1819.
HUNTERIAN ORATION,
1819.

It is the expressed intention of the founders of this oration, that it should be rendered contributory to the honour of surgery, and of its intelligent professors; which design cannot, in my opinion, be better accomplished, than by showing what surgery really is; the nature and extent of the knowledge requisite for its clear comprehension; the intellect and talent necessary for its successful practice.

Had surgery and surgeons been merely what their names imply, handywork and handicrafts, I never would have appeared before you, Gentlemen, to do them honour. For honour is due alone to intellect, and can be paid to nothing else. Why do we
honour those whose literary labours stand pre-eminent; or those who have exposed, or sacrificed their lives in the cause of their country, or in that of moral obligation? Is it not on account of their having evinced superior powers, or firmness of mind? They have thus done honour to the whole human race, and can only be repaid in the same coin; we return to them the tribute of honour, in proportion as they have conferred it on us. We indeed honour rank, but then it is either in blind obedience to the laws of custom, or because we associate the opinion of superior intelligence and elevation of mind with the possession of a dignified station.*

Now, to show what surgery really is, it becomes necessary to divest it of that garb with which it has been clothed and obscured in times of ignorance; and it is useful to revert to the history of former times, in order to observe the circumstances which have promoted or retarded the progress of the medical sciences, or communicated to

---

* The good qualities of the mind excite and engage our respect or esteem.
them that bias, by which they have been directed to their present situation.

Medicine, or the science which has for its object the prevention and cure of diseases, was held in the highest respect by ancient nations, and its most eminent professors were even venerated. But, surely, it was the beneficent object only of the science that attracted their applause and gratitude; for the means by which the object was to be accomplished were either not contemplated, or were merely supposed to be known. Various sovereigns have, doubtless, greatly promoted this science by their patronage, and encouragement ought to be given to it, as I shall afterwards show, not only by the government of countries, but also by the people in general. The successors of Alexander of Macedon first resolutely opposed the natural feelings and prejudices of mankind, by patronising the dissection of human bodies at Alexandria; which city they had made the great depository of knowledge, by the collection of an immense library, and which they also strove to make a splendid seat of science, and source of instruction.
It was at Alexandria, that persons in general first possessed the ready means of knowing what others knew and thought, by consulting their writings collected in its stupendous library. How different must have been the state of learning and learned men in ancient and in modern times! What surprising changes has the invention of printing produced! An ancient student of any subject of nature or science must have sought for the information which others possessed, by distant visits, to procure the perusal of any work of celebrity, or the conversation of those engaged in the same pursuits. His knowledge, therefore, must chiefly have resulted from his own exertions, and if he deemed it worthy of being recorded for the benefit of others, he knew that it must be communicated to them very gradually and slowly. His fame, as a discoverer, or improver of science, could never spread so as to reverberate to his own ears. His reputation must necessarily be of slow growth, and therefore his endeavour would be to make it lasting. As he could not compare his knowledge with that of others, he would strive to make his own perfect,
by completely mastering the subject he had engaged with, so that none should be able to do more. But now, when, by an industrious education, any one may possess himself of the knowledge of the whole world with respect to any subject of nature, art, or science; now, when every accession of knowledge is published at annual, quarterly, or monthly periods; every little discovery is at once proclaimed, lest its author should be anticipated; and persons in general become desirous of contending for superiority more with one another, than with the subject, or with themselves. Yet this ready communication of knowledge greatly tends to its increase, by exciting general emulation and co-operation.

It was at Alexandria, also, that persons of the medical profession first possessed an opportunity of studying the subject-matter of medical science, the structure and functions of the parts of the human body. How absurd should we deem the conduct of a mechanic, whose business it was to rectify the errors of any complex machine, should he merely provide himself with the finest and fittest
tools for the purpose, and neglect to learn its mechanism, by which alone he can be able to discover the causes of the error, or stoppage of its different movements, and consequently what is wanting to be done, to render it again perfect or useful. Yet equally absurd would be the conduct of medical men, were they to study botany, pharmacy, chemistry, and natural philosophy, searching indeed through all the paths of nature, and the stores of art, for means of cure, and yet neglect anatomy, by which alone they can be able to distinguish the nature of the difference between health and disease, and consequently what is requisite to reconvert the latter into the former; which is the only circumstance that can render medicine a science.

It seems to be my fate, Gentlemen, whenever I address you, to be doomed to speak of the importance of opinions; yet I cannot avoid it, the necessity of the case absolutely demands it; for the reasoning powers of man, which, when well directed, lead to the discovery of truth, and the formation of useful opinions, when misemployed, elicit
nothing but error and pernicious notions. It is a very great but very common mis-
employment of our reasoning powers, to draw inferences from facts belonging to dif-
f erent subjects, which are incommensurate with one another. Such irrelevant facts
have been often designated by the whimsical and contradictory expression of false facts.
We are indeed sometimes induced to reason from analogy, but then the similarity of the
facts is so precise, as to warrant us in believing that the subjects, concerning which
we thus comparatively reason, are essentially alike.

Now without any knowledge of anatomy, or the animal economy, persons of the me-
dical profession, by drawing inferences from mixed facts, might suppose, that a fire was
kindled throughout the body to warm and cherish it, which, if in excess, might set our
juices into fermentation, and thus produce partial or general disorder; they might
suppose, that there were elements in the body, which ought to be combined in defi-
nite proportions, and that different diseases might result from the excess or deficiency
of one or other of these elements. They might suppose, that diseases were of an acid or of an alkaline nature; they might say, that there were powers, capable of performing functions, nay even poetically imagine essences endowed with such powers, and speak of animæ presiding over the different functions, and of an archæus or master-workman superintending the whole. You know, Gentlemen, that all this and more of the same kind has been thought and said by reputed sages of the medical profession.

Since, then, reasoning from false, insufficient, or irrelevant premises is productive of error, we cannot wonder, that when medical men in general first began to reason on the causes and nature of diseases, and the effects of remedies, if their speculations were wild, and the conduct which such opinions gave rise to, highly injurious. We can feel no surprise, therefore, that a large party of the medical profession should segregate themselves, and resolutely interdict the use of reasoning in medical practice, steadfastly resolving, in their conduct to be guided solely by the dictates of experience.
Neither indeed can we wonder, that even erring reason still found advocates in the minds of men. Now you know, Gentlemen, that not very long after the formation of the Alexandrian school, in the beginning of the second century, before the Christian æra, Serapion and Phillinus, pupils of Herophilus, were the founders of a sect called the empiric, which was numerous, highly respectable, and which long continued to flourish, whilst the remaining party of the medical profession were distinguished by the appellation of the dogmatic or rational sect. In the very feeble and almost blind state attendant on the infancy of medical science, a caution not to attempt to advance, unless supported and conducted by an unerr ing guide, seemed really requisite, yet to prohibit such endeavours in the present vigorous and enlightened state of medical science, would be as preposterous as to recommend the conduct proper to be pursued in infancy, to be continued during the whole state of manhood. Though much might be said on this subject, it really seems unnecessary to do more than to remind you, Gentlemen, that the sagacious Lord Bacon has,
in this respect also, well displayed the results of different dispositions or powers of mind, by the following simile. "The empirics," says he, "like ants, only lay by stores and use them; the rationalists, like spiders, spin webs out of themselves; but the bee takes a middle course, collecting her matter from the flowers of the field and garden, and digesting, and elaborating it by her native powers."

It was shortly after the establishment of the Alexandrian school, that, as Celsus informs us, the practice of medicine was first separated into three parts, and each part consigned to a different person, one of whom was supposed to cure diseases by compounds of drugs and other substances; another by regimen and plans of diet; and the third by manual operations and instruments. This partition seems to have been both an effect and a cause of that confusion between the object of medicine, and the means of accomplishing it, which has obtained more or less ever since that period. The bulk of medical knowledge, was, however, at that time too diminutive, to permit
this subdivision to be continued, and we find succeeding authors treat equally on all these curative measures.

The advantages which we derive from anatomical knowledge are, that it enables us to judge of the nature and probable event of injuries and diseases, by the exact information we possess of the situation and connexions of every part of the body; that it enables us to perform the operations of surgery with confidence in ourselves, and security to our patients; moreover, a correct knowledge of structure is the only foundation of all knowledge of function, without which, we can never be able to distinguish the nature of the difference between health and disease, nor consequently what is requisite to reconvert the latter into the former, which, I repeat, is the only circumstance that can render medicine a science. Now, though the dissections at the Alexandrian school, were by no means so perfect as to produce any of the important consequences derivable from anatomy, yet they led the way to the general investigation of structure and function, and to the for-
mation of opinions deduced from the facts belonging to the subject under consideration. The body of the monkey so much resembles that of man, that a moderately good idea of the latter may be obtained by the examination of the former; the desire to understand function would also lead to experimental enquiry; and consequently we find Galen, whom they say had passed several years at the Alexandrian school, making various experiments on animals, to determine the office of different parts of the body.

Medicine was, doubtless, much promoted by the opportunities of information which the Alexandrian school afforded; and it seems to have proceeded as prosperously as could be expected, in the still very deficient state of elementary knowledge, for several centuries; when a revolution happened, by which all the sciences of southern Europe were in common overthrown, and their lights extinguished, so that a great district of the world was involved in darkness and ignorance for many ages. As the account which I am giving of the causes that pro-
moted, retarded, or variously affected the progress of the medical sciences, will not be clearly intelligible, without adverting to this revolution, I may be excused if I briefly endeavour to revive it in your remembrance. It was towards the latter end of the fifth century, that the hardy nations of the north of Europe burst like a deluge into the Italian territories of the degenerate Romans, bearing down before them the ancient seat of their government, which, having previously removed to Constantinople, was still able to oppose a mound that checked the further progress of this inundation. In the beginning of the seventh century, Mahomet established his religion and dominion in the East, subduing all Arabia; and his successors extended their empire over Palestine and Persia, Egypt, and the northern coast of Africa, from whence their influence was continued over those Moors, who had invaded and subdued the kingdom of Spain: such was the extent of the Saracen dominion. But the Mahometans were prevented from entering Europe on the east by the Roman government at Constantinople. The territories of the Romans were much di-
minished, and were assailed on various parts of their frontier. The empire, however, was still superior to these attacks, and according to the simile of a late elegant writer, it seemed like the trunk of an old tree, which still remained vigorous and unshaken by the winds which assaulted it, and had stripped it of its branches. In the territory protected by the last exertion of the Roman power, science and art still survived, though in a state of rapid decline. Here the works of the Grecian and Roman writers on medicine, were chiefly preserved, and their languages were spoken. Here too, when the people in general had become illiterate, ecclesiastical scholars, who had read these authors, took upon themselves to give medical advice, but refused to shed blood, or dress wounds or sores, which task devolved on their servants. It was here, therefore, that surgery first made its public appearance, clothed in the garb of a menial.

Anatomy was wholly neglected by the Arabians, nor was it till the beginning of the fourteenth century, that Mondini made public dissections in Italy, and by
degrees, other nations acquired "that useful boldness." The zeal of the great painters, who began to flourish towards the close of the next century, and the patronage afforded to them, greatly contributed to the suppression of the public prejudice against dissection in Italy. Michael Angelo, Raphael, Leonardo da Vinci, and Albert Durer, were all either frequent dissectors, or draftsmen of dissected bodies. It is curious to observe, how speedily in general we reconcile our minds to that which custom has rendered familiar. The dissection of the bodies of persons who die in the hospitals of Paris, produces at present no indignation, no sensation in the public mind. Yet even in the time of Haller, the laws and prejudices against purloining a dead body, were so strong, that he left France with all possible speed, lest the receiver should be considered as bad as the thief.

It was not, however, until the sixteenth century, that anatomy made any considerable advances, when some great anatomists distinguished themselves, particularly Eustachius and Fallopius in Italy, Sylvius and
Vesalius in France. Vesalius pursued his anatomical enquiries with so much ardor and constancy, that he was able to publish seven large folio volumes on the anatomy of the human body, before he was 29 years of age (1542). These books, which entitle him to the greatest gratitude of posterity, were to himself, however, the cause of much vexation and trouble. Even at that time, the authority of Galen was held in such high respect, that when Vesalius showed his errors, and his ignorance of the structure of the human body, the hatred of all was turned against the defamer. People could not bear to be set right by so young a man, and even his preceptor Sylvius denounced perpetual enmity against him. I need not tell my present auditors what scrapes Vesalius got into, or what injuries he sustained, in consequence of the public prejudice against dissection.

After human anatomy had become moderately well known, the different nations of Europe were involved in war, and the same attention was not paid to the support of academical institutions, for teaching
anatomy and medicine. Therefore, anatomists again had recourse to the dissection of animals, from which, however, they derived very important advantages. They were thus led to an extensive knowledge of the comparative structure of living beings in general, and to make observations and experiments illustrative of function. So that by these means, were all the paths leading to medical science fairly thrown open to enquirers.

I must now relate some ridiculous circumstances, which, however, gave a considerable bias to the progress of the medical sciences. The priests, merely because they were able to read the Greek and Roman authors on medicine, were the principal physicians, during the dark ages, as I may call them, of these sciences. They became intimate with the barbers, because the latter were frequently employed to shave the heads of the priests, according to the uniform of their order. The priests also frequently employed the barbers to shave the heads of patients, before they prescribed washes to cool the fever of the brain, or
blisters to draw the peccant humours from the surface. Finding these fellows handy with edge tools, the priests taught them to bleed and perform such little operations as they were competent to direct, as well as to make salves and poultices, and to dress wounds and sores. Such was the origin of barber-surgery. When, however, the Popes perceived that the medical practice of the priests took them from their proper calling, and obliged them after various edicts, reluctantly to relinquish it, the office of physician was then adopted by other scholars upon the same claim or pretension, that of being able to read the Greek and Roman writers on medicine; and ever since, scholastic learning, and academical honours, have been considered as essential attributes to the character of a physician.

In the fourteenth century, these barbers and reputed surgeons pushed themselves forwards into the practice of surgery in France, to a degree that induced the surgeons in ordinary to petition the legislature to interfere, and an order was obtained that the barbers should not be permitted to prac-
tise, except in slight cases. In process of time, however, the barbers attended lectures, and became as well informed as the inferior class of surgeons, and being still patronised and instructed by their old friends the learned doctors, they at length obtained an establishment as regular practitioners in France, under the title of barber-surgeons. Of this order was Ambrose Paré, a man of original observation, great candour, and abundant experience, whose works were well calculated to correct the bad and cruel surgery of those times.

Wherever the priests practised as physicians, the barbers performed the offices of surgeons. As, likewise, medical knowledge radiated from Italy to the northern nations of Europe, so they must have received the information mixed with any absurdity which it might have taken up in its passage; and this, if we had even the discernment to distinguish, we seem to have wanted the resolution to reject, for the copartnership between surgery and shaving has been but newly dissolved in this country.

"Would heart of man e'er think it,
but you'll be silent." This foolery was continued so nearly to the present time, that even I myself have often doff my cap to barber-surgeons. Edward the Fourth, in the year 1461, granted a charter of incorporation and privilege to barber-surgeons; and though the distinct nature of the two professions gradually became more and more apparent, yet they were not separated till nearly three centuries had elapsed, till the year 1745.

The legitimate practice of surgery did not, however, remain uncultivated nor unpatronised by different sovereigns. My time does not permit me to relate various instances, and I question more than one can be adduced, in which the means adopted were judicious and efficient. Louis the Fourteenth, from being continually engaged in war, seems first to have clearly discerned the nature and importance of surgery, and the proper measures by which it might and ought to be promoted. He established hospitals, colleges, and professorships; he ordered that lectures on surgery should be given by surgeons of acknowledged ability,
and that bodies for dissection should be liberally supplied. By these means, he produced such a spirit of enquiry and emulation amongst the members of our profession, that the French surgeons soon surpassed those of all other nations, and pupils from every part of Europe flocked to Paris to learn anatomy and surgery. As a further consequence of this patronage, I may mention that it gave rise to that very excellent work, the Memoirs of the French Academy of Surgery, the contributors to which were laborious students of their profession, who regularly registered and arranged all the knowledge promulgated by preceding authors, to which they added their own observations and experimental enquiries.

It would, in my opinion, be honourable to the surgeons of any nation to combine and produce a rival work (due allowances being made for the progressive improvement of the science of surgery); for to me, these memoirs seem, even at present, to stand as it were alone, and in a state of lofty superiority. Let me not, however, omit to mention that before these memoirs came
forth, a similar publication was set on foot in this country under the patronage of the first Professor Monro of Edinburgh. It is unnecessary for me to tell you, Gentlemen, of the number and importance of the periodical publications of our own country. The facility of publication, which such works afford, prevents useful information from being lost, whilst they keep alive amongst the members of our profession in general a spirit of enquiry, emulation, and co-operation.

Having thus adverted to the principal circumstances which have influenced the progress of the medical sciences, it seems only necessary to show the improvements made by the two late eminent physiologists Haller and Hunter, in order to place distinctly within your view the present state of these sciences in our own country, which is my chief object in this address; for indeed it would be but of little use to look back, except in order to determine the di-

* The Edinburgh Medical Essays and Observations were first published in 1732. The Memoirs of the French Academy of Surgery in 1743.
rection and means by which we are likely to proceed with the greatest advantage.

Albert Von Haller was born at Berne, in Switzerland, in 1708, and died there in 1777. He possessed a well proportioned assemblance of vigorous intellectual faculties. His memory was surprisingly quick and retentive, scarcely any language was unknown to him, and all those in which medical records are written he both read and wrote with facility. He had great industry, and made himself acquainted with all that others knew or thought relative to our professional studies. He had great method and discrimination, and regularly registered all the knowledge he obtained by reading or otherwise. Of his talents in selecting, condensing, and arranging information from successive publications, his numerous bibliothecæ afford ample evidence. Haller went to Leyden in 1725, where he became a favourite pupil of Boerhaave, and a fellow-student of Albinus. He also took opportunities of visiting Ruysch, to observe his anatomical labours. After he had finished his studies and his travels, he returned to Berne, and in 1734 he taught
anatomy in an amphitheatre which the republic had established for that purpose; he was also physician to an hospital, and entrusted with the care of the public library, and cabinet of medals. In the first year that he undertook the latter office he formed a regular catalogue of all the books, and arranged and described in chronological order more than 5000 antique medals. King George the Second being desirous of promoting the reputation of the University of Göttingen, invited Haller to accept of an anatomical, surgical, and botanical professorship, which he established for him; and Haller accepted this invitation. The opportunities of information at the school of Berne were too small for the mind of Haller, and he there met with the usual difficulty of procuring bodies for dissection.

Haller resided in Göttingen seventeen years, and made physiology his principal study. He found the knowledge of this subject encumbered and perplexed with false and absurd assertions and doctrines, which he removed, and endeavoured to make physiology as much like science as possible. He saw the necessity for an exact
knowledge of anatomy, both human and comparative; for any reasoning with respect to function which is incompatible with the facts relating to structure must be invalid. He saw no mode by which function could be scientifically investigated, except by experiments made on living animals; yet in detailing these, we find frequent evidences of his being disturbed by those "compunctious visitings of nature" which every good mind must necessarily feel at inflicting sufferings on unresisting or subdued sensitive creatures, over which nature has given us dominion. He examined all the principal vital functions with particular attention, yet he found no spring of vital action except in irritability, which he believed to be a property of the muscular fibre alone. He investigated the process of formation, both in the growth and reparation of bones, and in the formation of the embryon in the egg, which he believed to be developed. It was not, however, till after thirty years of labour that he thought himself warranted to publish his Elementa Physiologiae, a work that certainly contains all that was then known on physiology, together with the alterations and improvements made by his
own enquiries and reflections; and its su-
preme excellence, at the time of its publi-
cation, was testified by the applause of every
nation, and by proffers of invitation and re-
ward to its author by various governments.
The Nostalgia of Haller, however, induced
him after seventeen years’ residence in Göt-
tingen to return to Berne, where he became
a magistrate and politician, without relin-
quishing his former studies. Such was the
esteem with which Haller was regarded,
wherever the sciences were cultivated, that
most foreigners of distinction, and even
princes, in passing through Switzerland, paid
homage by their visits to the illustrious
Haller.

John Hunter was born in the county of
Lanark, in Scotland, in the year 1728,
and he died in London in 1793. He had
received but little education; his mind
had not been taught to act in imitation of
others; he disliked to read, as much as he
liked to think. When Mr. Cline addressed
the College on this anniversary, he said,
“Much as Mr. Hunter did, he thought
still more. He has often told me, his de-
light was, to think." Mr. Hunter did not begin to learn anatomy till he was eighteen years of age; but when the book of nature lay exposed to his view, he read it with facility, interest, intelligence, and diligence; and the idle youth became a most industrious man. Like Haller, he devoted himself to physiology. Such minds could not but be highly sensible of the interest and importance of this study: they could not be contented with the mere notation of facts, without enquiring into their probable causes and uses. Like Haller, he became an exact and comprehensive anatomist. No structure, nor substance wanting structure, yet possessing life, escaped his strictest scrutiny. Like Haller, he investigated the nature of function by experiment, yet how different is the conclusion of the labours and reflections, or the principles of the physiological doctrines of these almost contemporary and very extraordinary characters;—the one enriched from the possessions of all others, and endowed with great degrees of intellectual powers; the other, rich only in natural genius and talent.
Although I have not now to speak of Mr. Hunter's physiological opinions, yet it seems proper to observe on the present occasion, that he was not satisfied with those of Haller, which he had heard delivered in his brother's lectures; and therefore he examined every subject for himself. He seems also to have wrought like an ancient student, not striving for victory with others, but contending with the subject, and with himself. In the whole of his labours and reasonings, we may perceive a most diligent search for every fact belonging to the subject he was investigating, to form the basis on which he reasons; the most anxious solicitude to describe facts with accuracy, and to avoid the least misrepresentation of them; and in his reasonings, I can perceive no inference deduced from insufficient or irrelevant premises. It is this mode of proceeding only, as I have formerly observed, which can give value and currency to the opinions of any one. Mr. Hunter was convinced that life was not the result of organization; and though many may have conjectured life to be something not dependent on structure,
Mr. Hunter was the first who deduced the opinion, as a legitimate consequence of legitimate facts, that life actually constructed the very means by which it carried on its various processes, and that it could operate in semifluid and even fluid substances. His intelligent mind further perceived that no system of physiology could be perfect that did not equally explain the morbid as well as the healthy actions of life. I may say, that he discovered a vital principle in physiology active in producing correct pathology. Therefore, he appears to me as a new character in our profession; and briefly to express his peculiar merit, I may call him the first and great physionosologist or expositor of the nature of disease.

Haller was a physician, Hunter a surgeon, both were anatomists and physiologists, both therefore equally qualified, as far as their knowledge of the animal economy extended, to discern the nature and mode of cure of the diseases in either department of medical science; yet, doubt-
less, each most competent to decide upon the best means for effecting the latter purpose in that to which he had been educated, and his attention chiefly directed. Medicine is one and indivisible: it must be learned as a whole, for no part can be understood, if studied separately. The physician must understand surgery, and the surgeon the medical treatment of diseases. Indeed, it is from the evidence afforded by external diseases, that we are enabled to judge of the nature and progress of those that are internal; which appeared so clearly to Boerhaave, that though his object was to teach his pupils the practice of medicine, he began by teaching them surgery.

Yet as medical science is so very extensive, and such accurate knowledge of its various subjects is required, the division of it into two principal departments, which custom has established, may be continued with great propriety and advantage. So much knowledge and talent is requisite in the division of surgery, for the correct re-adjustment of parts which have been severed and separ-
ated by violence; for ensuring their unvarying motionless position, so essential to their tranquillity and re-union; for suggesting and applying suitable means to soothe or correct the morbid actions of susceptible surfaces; for discriminating the great variety of external local diseases; and for performing the various and complicated operations of surgery; that it requires the whole time and ability of any individual to attain even moderate perfection in this department of medical science. Whilst the no less extensive and important task of unravelling the intricacies of the symptoms produced by internal diseases, so as to trace them to their several sources, and consequently to decide upon their proper treatment; and of modifying the remedies employed, so as to adapt them to the varieties of circumstances and constitutions; equally demands the concentrated observation and reflection of the physician. Indeed the division of medicine into two principal departments, which custom has established, seems also to have received the fullest sanction of experience; and if we were not to acquiesce in it, we should subvert the institutions of society,
and throw the whole profession into confusion. So much, also, is to be known and done in either department, that if we invade each other's province, we must neglect properly to cultivate and improve our own.

There are those who think that a still further subdivision of the subjects of medicine might lead to a more perfect knowledge of them. Yet the ultimate structure of all parts of the body being the same, their diseases must be similar, and treated upon the same general principles. If also, to investigate and understand any subject in nature, art, or science, a great deal of collateral knowledge be required, which serves like light shining from various points, to illuminate the object of our attention; when we examine particular diseases by the lights emanating from others, here such lights will indeed be found to be most apposite and illustrative. It is by comparing the nature and treatment of diseases with one another, that we improve our knowledge and practice with respect to those of particular organs, or
portions of the body. If, however, after an enlarged education, if after knowing the whole, our observations were exclusively directed to a part, it is probable that increase of knowledge might result from such concentration of attention. Yet those, in general, who study the diseases of particular organs or portions of the body, think that they may save themselves the trouble of more extensive research, and thus their views become as circumscribed as the objects of their attention.

It is both evident to reason, and manifested by the history of medical science, or by experience, that it can only be attained and improved in one way. We must understand structure and function, and the changes produced in each by disorder and disease. There is no short cut, nor "royal road," to the attainment of medical knowledge. The path which we have to pursue is long, difficult, and unsafe. In our progress, we must frequently take up our abode with death and corruption; we must adopt loathsome diseases for
our familiar associates, or we shall never be thoroughly acquainted with their nature and dispositions; we must risk, nay even injure, our own health in order to be able to preserve or restore that of others. Yet if we do this, our profession will be held in the highest respect; not as in ancient times, merely on account of the beneficence of its object, but because it will be further perceived, that the means are adequate to its accomplishment.

If, however, we are disposed thus to labour for the public good, some concession, co-operation, and encouragement on the part of the public, may be by us reasonably expected. Anatomical knowledge is the only foundation on which the structure of medical science can be built. Without this, we should but increase the sufferings of those afflicted with diseases, and endanger their lives. Opportunities of dissection should therefore be afforded to us. The bodies of persons dying in the hospitals abroad are given to the surgeons for dissection, and even with the acqui-
escence of the public. In other countries it is considered, that those who have been supported by the public, when unable to support themselves, die in its debt, and that their remains may therefore, with justice, be converted to the public use. In England, however, the indigent who suffer from illness and injury are supported and relieved chiefly by the liberality of that benevolence which is so creditable to our national character; and much as I wish for the promotion of medical knowledge, I should be sorry if the bodies of the poor were to be considered as public property without reserve in our own country. For better would it seem to me, that medical science should cease, and our bodily sufferings continue, than that the natural rights and best feelings of humanity should not be equally respected in all classes of society; or that merely because persons are poor, they should be prevented from paying the last tribute of respect and regard to their departed relatives by attending their remains to the grave. Yet if the directors of
hospitals, poor-houses, and prisons, were to establish it as a regulation, that the body of any person dying in those institutions, unclaimable by immediate relatives, should be given to the surgeon of the establishment for dissection, upon his signing an obligation so to dispose of it, as to give no offence to decency or humanity, I am convinced, that it would greatly tend to the increase of anatomical knowledge amongst the members of our profession in general, and consequently to the public good. Or indeed it might be established as a law, that the body of any person of whatsoever rank or fortune, unclaimable by immediate relatives, should be subjected to dissection; and thus a great public good might be obtained, without any infringement on the equality of rights. Other and better expedients may indeed be devised; and the subject is so important as to deserve general consideration.

Yet, upon mentioning the foregoing suggestions to various persons, I have been uniformly answered, that the public would
never consent to such regulations; for their effect would be, to deny the body the rite of Christian burial. But that the funeral service availeth not to the dead is made manifest, even by that sublime ritual itself, which places before our view the valueless nature of the dead body by the most emphatic language. We therefore commit the body to the ground; earth to earth, ashes to ashes, dust to dust. That is to say, confident it must, according to the laws of nature, resolve itself into other forms, and become again an undistinguished part of the common constituent matter of the universe. Religion also "doth teach us for to render the deeds of mercy" and benevolence to those that want them, which deeds cannot be properly administered to such as suffer from illness or injury, unless in consequence of our obtaining an accurate knowledge of the structure of the human body.

There is also another point on which some concession on the part of the public is required for the promotion of medical know-
ledge. We are sometimes called upon to examine the bodies of the dead, in hopes of our being able to discover the cause of death for the satisfaction of their relatives, when such examination affords us no additional knowledge; for we see only the common appearances of disease with which we are familiarly acquainted: and yet we are frequently denied the same opportunity when we most earnestly solicit it, from the belief that we shall obtain important information by the investigation. Wishing to exhibit the effect of such refusal by some striking instance, I am tempted to relate an anecdote of Mr. Hunter, even though some may not think it to his credit. Mr. Hunter, who was never afraid of speaking his mind, had attended, in concert with another surgeon, a fatal case of disease in the child of a gentleman of opulence and worldly consequence. Mr. Hunter had been much interested by the case: he had considered it, as he was wont to do, deliberately and intently; and believing that much good might result from ascertaining its nature, he had requested permission to examine the body,
which was refused. He went to the house of the father, in company with the other surgeon, and tried all his art of rhetoric and persuasion, but in vain. When he became convinced that his object was unattainable, he was standing, said the relator of this anecdote, with his back to the fire, and he put his hands into his pockets. "I saw," continued the narrator, "by his countenance, that a storm was brewing in his mind." Mr. Hunter, however, gravely and calmly addressed the master of the house in the following manner: "Then, Sir, you will not permit the examination to be made."—"It is impossible," was the absurd reply. "Then, Sir," said Mr. Hunter, "I heartily hope, that yourself, and all your family, nay, all your friends, may die of the same disease, and that no one may be able to afford any assistance;" and so saying, he departed. Such a wish could never, I am convinced, have originated in his benevolent mind; as indeed is manifested by the very terms of it, which involve the innocent with the offending. Temporary irritation alone incited him to adopt this mode of expressing his strong conviction of what it became
equally his duty to perform, and theirs to permit, for the attainment of knowledge, the most important to humanity. It is easy to perceive the causes of reluctance in general to such examinations. Persons question if their departed relative would have approved of it; they think it disrespectful, or that some unnecessary or indecent exposure of the body may take place; they suspect that we perform these acts with levity, or in a frame of mind discordant with their present feelings. It is for us to convince them by our manners and conduct, that we only seek for knowledge; and that we do so with dispositions suitable to the solemnity of the occasion, and in sympathy with their feelings, and distress.

Having thus told you, gentlemen, what appears to me chiefly necessary to be done, on our part and on that of the public, for the promotion of medical science, I take the liberty of further observing, that to some it might seem strange that persons in general do not take more concern about it, when it is manifestly of vital importance to them. This College, sensible of the great injury
which the public sustains from the ignorance and fraud of empirics, petitioned parliament to grant it a power of control, by process of law, over those who set up to practise surgery, without having undergone an examination, to testify their education or ability: a power not likely to be exercised except in cases of flagrant offence; a power also determinable in its degree and effect by impartial judges, by the judges of the land. To some of the members of the House of Commons, however, this petition appeared like an attempt to procure a monopoly of surgical practice, and it was rejected. The College still persevering in its endeavour to prevent a great public evil, and desirous of freeing itself from all imputation of being actuated by interested motives, brought forwards a new bill, entirely of a public nature, which was also rejected; so that, in these transactions, the College may be said to have lost every thing but its honour.

The whole history of medical science affords no instance of its promotion by any individual, at all comparable with that
produced by the man whose natal day we are now met to commemorate. It is indeed a surprising example of the scarcely to be expected improvement which may be effected by the industry of an individual when exerted in a right direction, and aided by that intelligence which reviews accumulated facts, compares, discriminates, combines, and arranges them; whilst it also draws cautious inferences from them, and suggests new subjects of enquiry, and new modes of research.

Of the genius, reflection, talents, and industry of John Hunter I have already spoken; but to commemorate him on the present occasion, I will tell you what I observed relative to the peculiar and distinguishing characters of his mind. Surely the lineaments of the mind must be more interesting than the form and features of the body. It is the character and conduct of the former which chiefly excite our interest respecting the latter; and if any one were desirous of knowing what manner of man Mr. Hunter was, I could not wish to refer them to a better resemblance
of him, than that drawn by Sir Joshua Reynolds. Perhaps my knowledge of Mr. Hunter's character may aid my imagination; yet when I look on that picture, I feel as if I saw before me an old man, a shrewd man, aye, and a benevolent man too, in the act and attitude of habitual thought.

Sir Everard Home, who had great opportunities of knowing Mr. Hunter, has represented him as an honest, independent, perfectly candid, and most industrious man, indifferent about money, and much attached to science. Now though I believe this sketch to be perfectly correct, yet there were finer traits of character requiring to be depicted ere I should recognise the intellectual resemblance of John Hunter. Those who make the study of nature, and of science, or the attainment of moral good, the ultimate object of their endeavours, are candid, disinterested, benevolent, and humble minded. They openly avow their designs, solicit the assistance of others, and assist them in return; they note the slow degrees by
which they advance in knowledge, their frequent failures, and the imperfection of their own powers; they also compare the aggregate of their advances with the illimitable nature of those objects to which they have merely approximated. Whilst those who make power, wealth, or any species of notoriety, the object of their ambition, are secret, selfish, suspicious, cunning, and conceited. In general, they are ashamed or afraid of avowing their designs, and therefore obliged to enveigle the co-operation of others. They suspect that they may be counteracted; and in proportion as they attain their ends, they feel elated with their own abilities, from the belief that no one but themselves could have achieved them in the like manner and degree. The choice of our objects manifests the natural dispositions of our minds, which are confirmed and augmented in their pursuit.

Mr. Hunter was an excellent example of the former class of men. My desire to know why a man of such intellectual powers did not display them in a manner
more advantageous to his reputation first induced me to propose to him questions, merely in order to learn how he would answer them: yet this seeming desire of information on my part, acting on his benevolent mind, induced him to pay me much more attention than I had been accustomed to receive from others. He invited me to come to his house, to sit and converse with him. I now regret that I profited so little by the opportunities he offered me; but I was at that time ignorant of the value of the information which I might have derived from him. That benevolence was a predominant sentiment of Mr. Hunter's mind may be inferred from his fondness for animals, his aversion to operations, and from the zeal with which he assisted every poor man of merit. Upon mentioning my conviction on this point to a surgeon who knew him intimately, he replied, "I am sure I have reason to think so, for I was ill, and he kindly and diligently attended me: nay, he brought those of his medical friends to visit me in whose judgment he placed most confidence. My illness being, however, tedious, I was at
length obliged to go into the country for the recovery of my health. Mr. Hunter called on me before my departure, and said, 'I have been thinking, that you might want a little money; if so, I can procure you 200l.; though, in general, I am the most unlikely person in this town to have money at command.' I thanked him," continued the surgeon, "but told him, I had been more provident than might perhaps have been expected, therefore I did not want money. On my return to town, and re-establishment in business, which did not take place for a considerable time, I took an opportunity of expressing to Mr. Hunter, my continued sense of gratitude for his kindness in attending me, and for his offer of pecuniary assistance. 'Hah,' said he, 'I offer you money! that is droll, indeed; for I am the last person in this town to have money at command. I have entirely forgotten it. But of this I am assured, that what I offered, I meant to perform.'"

Now, Gentlemen, I must restrict myself to a single instance in proof of the several propositions that I wish to substantiate,
instead of numbers which I could ad-
duce.

The candour of Mr. Hunter's character was evident in all his actions. He readily told all he knew or thought upon every subject; and was pleased in assisting others to acquire knowledge. It is indeed highly improbable, that a wise and good man should be otherwise than candid. For wisdom teaches him not to form opinions but on sufficient grounds and consider-
ation; and these he would freely reveal, being equally desirous that they should be corrected, if wrong, and acknowledged, if right. Sir Everard Home has said, that Mr. Hunter's disposition was "free from reserve, even to a fault; for it sometimes made him appear harsh." Yet harshness, I am convinced, could never have pro-
ceeded from a mind attuned like that of John Hunter. I do not wish to deny or conceal, that occasionally the candour and susceptibility of his character might incite him to express his vexation and indig-
nation with a degree of energy and open-
ness that would give offence, and fail to
produce the good resulting from mild remonstrance and explanation. Yet for this occasional want of temper many, and perfectly exculpatory causes may be stated.

Mr. Hunter's life was one of continual exertion, perplexity, and irritation. He was constantly engaged in the search and consideration of new facts. "My mind," said he to me, "is like a bee-hive;" and the simile struck me, on account of its correctness. For, in the midst of buzz and apparent confusion, there was great order; regularity of structure; and abundant food, collected with incessant industry, from the choicest stores of nature.

It will be generally admitted, that the want of money would be an adequate cause of perplexity. Yet to Mr. Hunter, the very means by which the necessary supplies were to be procured proved sources of irritation. The search for money led him from the more congenial pursuit of knowledge. It broke into his arrangements; distracted his attention;
and we find him complaining of this, like one who had felt it sorely.

Those who far precede others must necessarily remain alone; and their actions often appear unaccountable, nay even extravagant, to their distant followers; who know not the causes that give rise to them, nor the effects which they are designed to produce. In such a situation stood Mr. Hunter with relation to his contemporaries. It was a comfortless precedence, for it deprived him of sympathy and social co-operation; and he felt that his labours and merits were not known, or fairly estimated.

None of these causes of irritation, however, in general disturbed the patience and good-humour of John Hunter, who found ample consolation, in thinking of what he had already done, and might still do, for the attainment of knowledge, the most important to humanity.

That Mr. Hunter had a very susceptible mind can scarcely be doubted. Sir Everard
Home informs us, that he would weep at the recital of a generous action; and when shame cannot prevent us from doing this, neither will fear deter us from expressing our indignation at one of an opposite nature. We are apt to misjudge one another. Few have the penetration of Sterne, and are capable of discerning how circumstances, trivial in themselves, by links of connection with the finer feelings of the mind, may produce the extremes of pain or pleasure. Mr. Hunter had befriended and professionally attended the family of a poor man of much talent as a painter. He afterwards requested him to paint the head of an animal. When the portrait came home, Mr. Hunter was delighted with it; but when he found it was accompanied with a bill to a much greater amount than would have been charged by any other artist, he was highly incensed. Can it be supposed, that it was the necessity for paying so much money, that made Mr. Hunter angry? No; it was ingratitude, which worse than the viper's fang had wounded him, and produced this paroxysm of irritation.
As a contrast, however, to that occasional want of temper which some may consider as a fault in the character of Mr. Hunter, I may mention that his habits of investigation, and his slowness in communicating his own opinions, had given him an admirable degree of patience and perseverance in accomplishing whatever he undertook, and this was conspicuous even in the common practice of his profession. In one of the cases which he has published, he says, — "After about an hour's conversation with the patient, I made out a few simple facts." If pressed for time, he was often known to say, "I cannot tell at present what to recommend: I must think of it." For to Mr. Hunter almost every case was a study, and so indeed it must be to all those who practise their profession as a science. I will here relate one out of many instances that I could adduce of the pains which he took, from benevolent motives, to convince persons of what seemed to him essential to their welfare. A strong ruddy-faced farmer had a disease, which induced Mr. Hunter to enjoin a total abstinence from fermented liquors. "Sir," said the farmer, "I assure
you that I am a very temperate man; I scarcely ever exceed three pints of ale in the day, and I never touch spirits." "But," said Mr. Hunter, "you must now drink nothing except water." "Sir," said the farmer, "that is impossible, for I cannot relinquish my employment; and you know, Sir, it is impossible to work without some support." Mr. Hunter perceiving that his patient was not likely to be readily convinced, enquired how many acres of land he cultivated, and what number of them was arable? He next asked, how many horses were kept upon the farm? and then boldly asserted, that they were too few in number for the quantity of land. The farmer maintained that they were sufficient, but was at length brought to confess, that they were worked hard. Allow me then, said Mr. Hunter, to enquire what it is that you give them to drink? — You see, gentlemen, that John Hunter, like Socrates, was well aware of the advantage of that mode of conducting an argument, by which the disputant is made to convince himself: though, I dare say, that he had never heard of its being employed by that philosopher. I have heard many patients speak of Mr.
Hunter, and none without a fond remembrance of his kindness and attention. I have indeed been told, even by them, that he was sometimes in a passion when he was vexed; which, I think, ought to have been excused, as it was the natural and almost inevitable consequence of the best dispositions of the human mind. This short-lived turbulence should, indeed, be treated with pity and indulgence, when it is the legitimate offspring of sensibility and integrity.*

That Mr. Hunter was an humble-minded man, may be inferred from the caution and diffidence which is a striking characteristic of all his scientific investigations. He has, doubtless, suppressed the communication of facts and experiments, manifesting a degree of labour and intelligence sufficient to give reputation to persons of ordinary character. Though he endeavoured to investigate the nature of diseases in order to understand their treatment; yet he never deviated from esta-

* An honest warmth, child of integrity.

Shakspeare.
blished rules of practice without cogent reasons for his conduct. This I mention from being aware, that if we presume on our knowledge of the nature and treatment of diseases, we may, like the ancient dogmatists, do mischief. Mr. Hunter's constant saying was, "we are but beginning to learn our profession." That he was conscious of the importance of his investigations, that he saw by anticipation the good effects that might result from them, cannot be doubted; yet I have heard him declare, and I know he was accustomed to say, that he was not conscious of possessing any peculiar talent, and that if he had promoted professional knowledge, it seemed to him chiefly to have arisen from his disposition to distrust opinions and to examine every subject for himself.

Mr. Hunter was, moreover, a man of very considerable humour. His views of subjects in general were quick and peculiar, and when so disposed he could place them in very ludicrous points of view. I have known him to exert his talents in this way in a very entertaining manner; but though I could produce abundant proofs of my present
proposition, they would be unsuitable to the gravity proper to be maintained on this occasion. I have heard some express their wonder that very sensible men have sometimes condescended to appear foolish; yet it ought not to excite surprise, for it only shows the activity of their minds which occasionally relieve themselves from the uniformity of thoughtful exertion by sportive and irregular actions. They find it "dulce desipere," and have no fear, as others might have, to indulge themselves in this propensity. Thus strong and healthy people, after the labour of the day, derive recreation from the continued efforts of a lively dance, or some agile sport.

There is, however, one subject evincing Mr. Hunter's possession of the kind of talents I am now alluding to, to which I may advert on the present occasion, because it is connected with our professional concerns. Yet here also I must restrict myself to one instance selected from a considerable number, and I doubt if it be the best for my purpose. Mr. Hunter's sagacity led him
speedily to discover and detect those impositions which some persons are induced to practise on us. A patient in the hospital feigned to be afflicted with catalepsy, in which disorder, it is said, a person loses all consciousness and volition, yet remains in the very attitude in which they were suddenly seized with this temporary suspension of the intellectual functions. Mr. Hunter began to comment before the surrounding students on the strangeness of the latter circumstance, and as the man stood with his hand a little extended and elevated, he said, you see, gentlemen, that the hand is supported, merely in consequence of the muscles persevering in that action to which volition had excited them prior to the cataleptic seizure. I wonder, continued he, what additional weight they would support, and so saying, he slipped the noose of a cord round the wrist, and hung to the other end a small weight, which produced no alteration in the position of the hand. Then, after a short time, with a pair of scissors he imperceptibly snipped the cord. The weight fell to the ground, and the hand was as suddenly raised in the air by the increased effort
which volition had excited for the support of the additional weight. Thus was it manifested that the man possessed both consciousness and volition, and the impostor stood revealed.

Having thus told you, gentlemen, what appeared to me as distinguishing traits in the character of the man whom I have already eulogized for having made surgery a science; for having the penetration to discern the direct path of knowledge, and the talents and industry to remove all the obstacles which concealed or impeded its entrance; for having conducted us to a certain extent so prosperously, that it must be our own fault indeed if we do not advance to more perfect discoveries of still obscure and remote objects: — I may then conclude, that so long as surgeons feel an interest in the improvement and reputation of their profession, or a value for their own character as men of science, so long will the name of John Hunter be remembered by them with gratitude and respect: or in Virgil's beautiful and often quoted language I may say,

Semper honos, nomenque suum laudesque manebunt.
POSTSCRIPT.

This Oration comprehends the remainder of what I was desirous of saying with respect to the labours, opinions, and character of Mr. Hunter. It has been printed in this form, that it may be bound up with my lectures at the College, which are designed to exhibit Mr. Hunter's opinions of life and its functions in the states of health and disease. Yet, as my conduct in this publication has been lately aspersed by Mr. Lawrence, in a point which I should be always most eager to defend, though, I trust, it is one of the least vulnerable parts of my character, that of honesty and fair dealing; I feel under the necessity of adding a few words, and, for the first time in my life, of speaking of him, before the Public, in other terms than those of commendation. As an introduction to his lectures, just published, he has placed what he has chosen to call an answer to some charges which, he says, I have made against him. But as neither my own, nor Mr.
Lawrence's meaning or feelings can be understood by others without previous information, I must therefore mention, that from a very early period of his professional studies, he was accustomed to decry and scoff at what I taught as the opinions of Mr. Hunter respecting life and its functions. Yet as I could never find that he had any good reasons for this conduct, I continued to teach them in the midst of the controversy and derision of those students who had become his proselytes. As a teacher of young men I felt particularly anxious that they should possess just, benevolent, and honourable sentiments, and therefore was I interested in maintaining those opinions respecting life, which seem to warrant the further opinion of the distinct and independent nature of mind; whilst more particularly did I feel bound to maintain them, when the contrary assertions were unsupported by facts or arguments. *

* I have admitted the assertion that the brain is as much an organ of sensation and thought, as the liver and stomach are organs for the secretion of bile and gastric fluid: but the physiological question in dispute
When I had the honour of being appointed Professor of Anatomy and Surgery

is, how do these organs accomplish their respective functions? The opinion that the functions of life are the result of subtile principles commixed with the visible fabric of living beings, will, I believe, be soon generally admitted; and I contend that the liver and stomach prepare their respective fluids in consequence of their vital principles, and not merely as a result of their organization. Yet I cannot suppose that the brain produces our sensations and thoughts in the same manner. Indeed, it is impossible to suppose, as a poetical writer has humorously suggested with regard to Milton,

That he from the glands of his brain
Secreted his Paradise Lost.

Also, from the equal absurdity of supposing that the soft medullary fibres of the brain feel and think, the common sense of mankind will for ever revolt. As we cannot either suppose sensation to result from any motion or arrangement of insensible atoms, as we have reason to believe that all the vital processes are carried on in many instances without sensation, and that when it is added that its district is limited to the brain, so we seem compelled to admit that life influences, through the means of its actions and organization, something having the properties of perception, &c. is acted on by it in return. As Mr. Lawrence's late publication contains but a repetition of assertions which I have in general objected to, as he continues to harp upon words without attending to thoughts, and without even seeming to have noticed what I have said with relation to the subjects under discussion, I have nothing further to add to the foregoing lectures, except upon one point on which he has a little
to the Royal College of Surgeons, I began my lectures, for reasons which I have fully enlarged. He maintains the assertion that the mind, like the body, is imbecile in youth as well as decrepit in age. Now that the processes and evidences of mind should be enfeebled and disturbed by corresponding states of the nervous system would be naturally expected; but that, under other circumstances, any evident difference in the intellectual functions is observable, is an assertion which will, I believe, on examination, be found to be incorrect.

Children are highly susceptible and prone to continual action. They are vividly affected by every impression, most of which also produce on them an effect which novelty gives to subjects even in adult life. Youth is the season for acquiring knowledge: reflection would but retard its attainment, and would be unavailing from deficiency of facts and experience. That the mind is often wayward and irrational in youth as well as in age, is apparent; but that it exhibits as powerful intellect when excited and when it possesses adequate means for its exertion in childhood, as at any period of life, must, I believe, be acknowledged on a full examination of the subject; which has been admirably displayed by the writings of Miss Edgeworth. That children also possess the more energetic qualities of mind, those which chiefly characterize its distinct and superior nature, in as great a degree as at any period of life, will not, I think, be denied by any who has carefully attended to their conduct. Yet surgeons possess particular opportunities of making such remarks, and the communication of instances, which are not to them very uncommon, may be useful in the general consideration of this sub-
explained in them, with an account of what I believed were Mr. Hunter's opinions respecting life; and to me, it would have seemed wise in the opposite party to have suffered these lectures gradually to have sunk.

ject. When I first attended St. Bartholomew's Hospital, one of the old surgeons was a most benevolent man, whom all the patients loved. There was a little boy of five years old, whom this surgeon was to cut for the stone. The boy complained loudly, and struggled much, during the introduction of an instrument, which was but a preparatory step to the operation. The old man patted the child on the cheek and said, "You know, my good little boy, that I would not hurt you if I could help it." — "I know it, Sir," said the child, "and I will cry no more." He underwent a severe and tedious operation. His teeth were clinched, his lips were working, yet no sound was heard. — A few weeks ago, an emaciated and very sickly child of seven years old was sent into the hospital to have a diseased knee removed. The case was indeed hopeless. When the little patient had become familiar with his new abode and attendants, and certain circumstances known with respect to his health which it was proper should be ascertained, I said to the child, for I knew not whether he had been apprized of his doom, "I suppose, my little fellow, that you would not mind having this knee removed, which has pained you so much, and made you so very ill." — "Oh, no," replied he, "for mammy has told me that I ought." At the time of the operation he manifested neither hesitation nor opposition, nor did the voice of complaint issue from his lips.
into oblivion. On the contrary, however, the opinions which I had promulgated were said to be absurd and untenable, and even ridiculed by a writer in the Edinburgh Review. When, afterwards, Mr. Lawrence began to lecture at the College, he adopted the same line of conduct; nor were his hostile and taunting expressions confined, as he says, to his first lectures. The theme of his exultation and raillery was introduced to enliven many others. In the published lectures will be found a varnished character of myself, in which, however, I clearly distinguish one truth, that of having always acted as his zealous friend; and surely the recollection of such conduct would have induced a generous mind to have glossed over also what it might have considered as my defects. When I heard those lectures, I told Mr. Lawrence, (for I had always spoken my sentiments to him with candor,) that he seemed to me to have done a very foolish thing in attacking my opinions in a place where I felt obliged to defend them; and added, even the consideration of the impropriety of two professors in the same establishment differing with one another,
ought to have restrained him. In my next lectures, which were designed more fully to explain Mr. Hunter's opinions, by showing the manner in which he had deduced them from the consideration of all the vital processes, I carefully concealed Mr. Lawrence from public view, by arguing against a party, by contending against opinions and not against persons: nor did I ever mention his name or words but in order to induce others to suppose that we did not differ in sentiments. The sentence to which I allude ran thus: "Comparative anatomy, also, as my brother Professor very judiciously observed in his introductory lectures, furnishes abundant arguments to the natural theologian, by the evidences it affords of design, and of the adaptation of means to ends." When, however, I perceived that he was hurt by these lectures, I assured him that I did not mean personally to allude to him, and after consideration added, neither could I conceive how he could suppose that I did, unless indeed by identifying himself with those writers from whose works he had copied. I offered also to expunge the sentence above quoted. He
replied, "No; I do not object to it: you may do as you please." I therefore inserted the words without naming the author. Is it then generous in Mr. Lawrence to say, "that the quotation of his own words rendered it impossible for him to shield himself under the pretext of uncertainty," or to suggest that my lectures (which were excided as an act of self-defence) were meant chiefly as an attack upon his conduct and character? Is it becoming in Mr. Lawrence to hold me forth to public view as one blinded by national prejudice to the merits of persons of other countries? On the contrary, I consider all mankind as brethren, yet all brothers have not the same sentiments and dispositions. The sons of science may more particularly be regarded as of one family, and their residence in different countries cannot annul their fraternity. Yet surely it is allowable in me to suppose that the notions of our brother physiologists in France may have been influenced by the state of public opinion in that country. I am aware that what I have termed modern scepticism arose in a great degree from good feelings; from an abhor-
rence of the dreadful consequences of superstitious and bigotry, and of those of tyrannical restriction and oppression. Yet in recoiling from one kind of error, the party seem to me to have run into an opposite one, and to have equally deviated from the mid-way path, which is trodden only by the unprejudiced and considerate. With respect to the subject of nationality, however, I wish to submit a sentence, which I remember to have heard in Mr. Coleridge's lectures, to Mr. Lawrence's consideration. There can be no sincere cosmopolitan, who is not also a patriot. Is it becoming likewise in Mr. Lawrence to point out what he considers as the weak parts of my lectures to general observation? Fortunately for me, indeed, he is not to be my judge; for he is strongly prejudiced, and evidently angry: the members of our profession in general are to determine the value of my humble endeavours to promote our professional knowledge and character, and in their decision I am ready respectfully to acquiesce.

KNOWING that the following Address does not contain any thing new, the Author would not have published it, if he had not considered it to be a necessary addition to those views of the diversified effects produced by vital actions, which he has exhibited in the Physiological Lectures addressed to the College of Surgeons.
AN ADDRESS, &c.

GENTLEMEN,

Those sentiments and opinions which it is necessary man should entertain for his proper conduct in life, seem to be so readily acquired from the general contemplation of nature, and the operations of our own minds, that many have believed them to be innate or intuitive. They appear also to be more and more confirmed by the researches of science and the progressive accumulation of knowledge. Surely no man ever deduced opinions from a more accurate, minute, and extensive examination of all the vital phenomena, in every variety of living being, than Mr. Hunter; and none ever displayed
more philosophical caution in forming conclusions; yet his notions of life were those which common sense dictates, and which were also entertained by the most intellectual characters in remote ages: this I have already endeavoured to show in lectures addressed to the members of the college.

Convinced of the truth and importance of Mr. Hunter's opinions relative to the Nature of Life, I am now desirous of enquiring, how any portion of physiological knowledge obtained since his time may have affected his sentiments in general, and particularly with respect to the functions of the most important organ in the animal economy of the human race. That the brain of man, and of animals similarly constituted, is a great emporium of nervous energy, that it sympathises with every part of the body, and bestows or excites animation and energy throughout the
whole, has not, I believe, been disputed; yet the experiments of Le Gallois, and the observations of Gall and Spurzheim, have rendered it highly probable that the brain of animals ought to be regarded chiefly as the organization by which their sentient principle becomes possessed of a great variety of perceptions, faculties, and disposition to various kinds of action. To the consideration of this subject, I am desirous of exciting the attention of members of the medical profession, because their opinions must have great influence with the public upon topics connected with their peculiar studies, and because there is no subject on which individual and general welfare so strongly demands that every one should think clearly and considerately.

When Dr. Spurzheim, impelled by laudable enthusiasm, and the belief that he could communicate new and important
information relative to the nature of man, and the means of improving his mental faculties and moral character, came to this country, he met with but very few who would give the subject he proposed to them that patient attention and consideration which are necessary for its clear comprehension, or that continued examination which alone can enable any one to form his own opinion respecting the merits or truth of his system. General attention, therefore, to Gall and Spurzheim's opinions seemed to have subsided in this country, when a most able and eloquent advocate came forward in their behalf, asserting the superiority and excellence of their system of phrenology, and his own conviction of the correctness of their proposed mode of physiognomical enquiry. In his judgment, respecting the former subject, I readily concur, but am incompetent to give an opinion upon the latter; for when I first heard Dr. Spurzheim's lec-
tures, I candidly told him, that though I admitted his opinions might be true, yet I would never inquire whether they were so or not; because, I believed the proposed mode of judging of one another to be unjust, and likely to be frequently productive of erroneous and injurious conclusions.

But notwithstanding this resolution, I did not absolutely shut my eyes against those facts which obtruded themselves before my view; and I acknowledge that I have been often struck with the coincidence between the character and talents of persons and the form of their heads, which was such as is said to be indicative of their peculiar dispositions and abilities. The intelligence and candour of Dr. Spurzheim, however, induced him to say to me, that it matters not how many coincidences we may observe; one contradictory fact must
disprove them all, with respect to the asserted locality of any organ; and such contradictory facts have, as I believe, also presented themselves before me.

I am aware how exceedingly difficult it must be to decide on this point; for though organs may be large, yet they may be more extended and less prominent than usual; though small, they may be active from constitutional vivacity, education, and habitual employment; and though large and prominent, they may be inactive from disuse or controul. Surely the foregoing considerations, together with the numerous and indisputable instances which we possess, proving that the character and conduct of persons * depend very much upon education, habit, and association,

* In my opinion, Miss Edgeworth has done the public a most important service by showing, even to
ought to make us exceedingly cautious how we judge of others merely from the form of their heads.

I anticipate nothing but mischief from Gall and Spurzheim's Physiognomy or Cranioscopy,* becoming generally known and accredited. Suppose a man to have large protuberances on that part of the

children, (in the Parent's Assistant) that by perseverance difficulties may be surmounted, and abilities acquired, or talents improved; also how by degrees good habits are formed, and a good character established. She has done this in so inviting a manner, and displayed so clearly and strongly the excellence of virtue and good conduct, that I think it impossible for a child to read her book without resolving steadily to persevere in the path of active industry and moral rectitude, whatever temporary difficulties may oppose its progress.

* Though the former term cannot etymologically be objected to, yet the latter more clearly defines their object, and distinguishes it from what is usually meant by physiognomy.
head, where they are said to indicate excess of cautiousness; suppose him apprized that such excess tends to produce melancholy musings and irrational apprehensions, which may hold the mind spellbound and appalled, till suicide is welcomed as the only means of escape from seemingly insupportable gloom and horrors. Suppose him with this information seized with a fit of temporary despondency; will he now strive to rouse his mind to active exertion and employ it on other subjects?—will he not rather think the effort useless and be inclined to submit to his doom, from the belief that it is the result of unalterable organization? Or, suppose a man to have large knobs on his head which are said to indicate him to be a knave and a thief, can he expect assistance or confidence from any one? Must he not, as all of notoriously bad character do, consider himself to be an outcast from society, having no
means of serving himself but those with which nature has endowed him, and which, in the instance and under the circumstances referred to, may indeed be those of fraud and cunning.

If a man, like Dr. Spurzheim, who had made the motives of human actions a particular study, possessing also great intellectual powers combined with benevolence and caution in decision, should from the survey of another's head suppose that he had discovered his character, he would next observe his conduct with particular attention, in order to determine how far his cranioscopic inferences were confirmed by facts. Thus would his speculations only lead to an enquiry which of itself alone forms the fairest and surest criterion that we can possess of judging of one another. But if an unbenevolent and inconsiderate man who had never studied human nature,
were at once to decide from the form of the head, and suspect or believe all those who happen to be broad across the temples of being covetous or crafty, he would surely injuriously mistake the character of many persons.

It is said, that this system of physiognomy will assist us in the education of children. Yet their actions are sufficiently, and I think more clearly, declaratory than the form of their heads of their sentiments, dispositions, and talents. Those who have a taste for music or drawing, manifest their fondness for those arts by their earnest attention to the subjects of them, and their abilities by the imitations they attempt of whatever has particularly pleased them.

It is asserted that this system of Physiognomy may assist us in the cure of Insanity. But how that dreadful malady is to
be cured except by the usual medical and moral management I am not able to comprehend. The object of the former is to tranquillize or remove that state of nervous irritation or disease which may have led to the establishment of insane ideas; whilst that of the latter is to weaken and annul these irrational ideas by so occupying the mind, as to prevent their recurrence. Nor, in my opinion, could the medical profession wish for a better illustration of what may be termed the moral treatment of insanity than that which Doctor Johnson has laid before the public in his Rasselas, shewing by what means the Prince and his sister effected the cure of the insane astronomer.

The views which Drs. Gall and Spurzheim have taken of the nature of the dispositions and faculties of man and animals
appear to me, however, both new and philosophical, and these admit of being surveyed without any reference to organization or its supposed situation.* It is thus only that I submit them to you as well deserving your examination; for I think it will be acknowledged that they have drawn a correct portrait of human nature, whether they be right or wrong in their speculations concerning certain protuberances which they have depicted. Believing that some, pleased with the phrenology, may overrate their physiognomy or cranioscopy, whilst

* When the subject is thus examined, it may be questioned whether any peculiar merit is due to Gall and Spurzheim for the representation which they have given of it. As many learned men who have published on the same subject, have not represented it in the same manner; and as the speculations and progressive steps by which Dr. Gall was led to see the subject in the manner he has pourtrayed must be allowed to be peculiar to himself; I feel warranted in ascribing the phrenology, even when abstracted from the organology, to these ingenious and scientific men.
others, from perceiving the uncertainty and ill-consequences of the latter, may be inclined to undervalue the former, I am induced for reasons already mentioned, to urge your attention to these subjects. From my deficiency in literary research, and my neglect of registering what I may have read, I am unable to trace the sources of my own opinions, yet as I proceed I shall candidly avow them, without presuming to suppose that others have not thought in the same or in a better manner and to a greater extent.

First then, I admit, nay even admire the simple proposition, that man and animals resemble one another, in each possessing, in various degrees, instinctive and urgent propensities to perform certain actions. These propensities, though they operate without the influence of reason, are however in man regulated by that power. Yet
with respect to the results produced by their operation, it may be affirmed that animals as far surpass mankind, as man by his rational faculties and sentiments becomes in other respects superior to them.

OF THE PROPENSITY FOR CONSTRUCTION.

How very curious is it, that at certain seasons of the year animals should be seized with a propensity to build nurseries for their young and storehouses and habitations for themselves, without foreknowledge that they may be wanted for future inhabitants, or at future seasons. Some birds begin to build before they procreate, and the sterile labouring bees in constructing a storehouse for their community, do not neglect to provide necessaries and accommodations for the young of the common-parent of the hive. How very curious also are the structures which many animals erect without previous plan or design, and in some in-
stances without any communication with one another. How admirably suited also are these structures to exigencies unforeseen by the artificers. Some hornets build the exterior of their nests with agglutinated leaves and the interior cells with the same materials, reduced to the state of paste or mortar, whilst the bees which build in hollow trees, requiring no protecting walls, merely build a comb with plates of wax resembling tiles, which are prepared and formed between layers constructed for this purpose on the surface of their bodies. This apparatus and its products have been exhibited by Mr. Hunter in his museum, and you know his very interesting paper on this subject which is published in the philosophical transactions. The greater number of animals, however, have no necessity nor propensity to build; so that this very curious instinct is also a very partial one.
Gall and Spurzheim assert that this propensity is the result of a peculiar organization in a portion of the brain, the exuberance of which is rendered evident even by the exterior form of the head. They say that some individuals of the human race have a strong propensity to construct things and an aptitude for such employment, whilst others have no disposition or talent of this kind. They assert that both in man and animals, those individuals who have this constructive propensity have also a corresponding form of head which is wanting in others who do not possess it. They make a similar assertion with respect to all the other instincts which we are to consider, but it will not be necessary for me to repeat it. Now here I may observe upon the supposition of Gall and Spurzheim's views of these subjects being correct, that the occasional, perhaps annual recurrence of this propensity, renders it probable
that it is not organization merely which creates it, but that it arises from temporary actions occurring in peculiarly organized parts; and the rare recurrence of this instinct shows how long such actions may be suspended so as to render organization of no effect.

Admitting that man, like animals, possesses in various degrees a natural propensity and talent for construction, yet no blind impulse regulates his labours; he constructs what his reason directs, or his fancy suggests; he forms previous plans or designs, and alters them till the whole seems to accord with his intentions; and yet none of his works is so unalterably perfect as are those produced by blind instinct operating according to the ordinances of overruling Intelligence.
OF PARENTAL AFFECTION AND ATTACHMENT.

No instinct is, in general, more strong than that which attaches the parent to its offspring, for it sometimes induces the former to perish in defence of the latter, which have no other protector. Yet this instinct is very variable, and sometimes even wanting in particular instances; occasionally, animals neglect their young, and leave them to perish; nay, sometimes they injure and destroy them. This instinct generally belongs to females, but the male also may possess it. All these facts are equally true with respect to the human race, in which this instinct evidently operates independently of reason; for though rational considerations may dictate and enforce maternal care, they can never produce maternal affection.
OF IMITATION.

Though there is something in the constitution of animals which causes the peculiarities of their actions, yet it is manifest that many have a propensity to imitate those of others, and it is probable that this propensity, together with the acquired habit of doing what has been repeatedly done, is a great source of conduct among animals of a gregarious nature. As man is an associating animal, he participates largely in this propensity, and there are some persons who possess the disposition and talent of imitation in so high a degree that they are led to hurt the feelings of others by offensive mimickry.

OF THE DISPOSITION TO COMBAT.

In most kinds of animals, the activity of the vital powers incident to early life, is exerted in running and striving in mock
combats with one another; and thus do they acquire the art of self-defence, and of shunning danger. That some kinds of animals, and some individuals in particular, have a strong propensity to combat is evident, for they are known to fight when grievously mutilated, and even till they die. That man also possesses this kind of animal courage, this propensity to combat and contend, is well known to the English, for it forms a striking feature in their national character. The people actually seem fond of boxing, wrestling, and cudgel-playing, and become hardy and resolute by such practices.

OF THE PROPENSITY TO DESTROY.

That predacious animals have a strong propensity to destroy others, is evident; for when not impelled by want, they injure, and kill them. This is chiefly seen in animals of the cat kind, though the lion, the
most powerful of the tribe, is rarely known to commit unnecessary slaughter; and therefore does the rational animal, man, admire the character of this noble brute. That some men are even pleased with cruel sports and sights, and feel no compunctious visitings of nature in acts which excite horror in others, must, I believe, on examination, be admitted. It seems, therefore, allowable to suppose that man participates with brutes in possessing, in a greater or less degree, a propensity to injure or destroy that which he dislikes, or which his judgment deems necessary to be destroyed. If a man had that kindness of disposition which would induce him, when he had caught an insect that had long vexed and annoyed him, to put it out of the window, saying, "why should I harm thee, the world is wide enough both for thee and me,” unbalanced by any opposite feeling, and uncontrolled by the power of
reason, he would suffer his house to be overrun with vermin, and animals to multiply to the detriment of the general good, and the ultimate injury of those whom his pity spared.

OF AFFECTION AND ATTACHMENT.

Some animals, on the contrary, have a kind or affectionate disposition, and also an attachment to others. That "honest creature, (for so we call him,) the dog, who never bites the hand that feeds him," manifests his joy at the approach of his master by antic gambols, and his affection and attachment by leaping up to him and licking his hands. The dog will also resolutely fight for his master, and those individuals who possess great hardihood and determination, will die in his defence. We are fond of dogs, and attached to them, because they are so to us. Whoever attends to the affections of the mind, will readily perceive
that there is nothing more infectious than feelings; if, therefore, we wish to receive kindness from others, we can only obtain it by showing kindness to them. In the fox, one of the dog tribe, we have an instance of an animal with no other ties than those of nature, living a life of wedlock, unchangeably attached to a single female, to his home, and to his family. Gall and Spurzheim say, that man participates with animals in having, in different degrees, instinctive propensities to kindness and attachment, and also the corresponding organization by which they suppose such instincts to be produced.

**OF THE PROPENSITY TO CONCEAL.**

That some animals secrete themselves, and dissemble, or are crafty in order to obtain their prey, or secure themselves from injury, is well known; and Gall and Spurzheim assert, that man has the same
propensity, in different degrees, which they call secretiveness. It is certain that many persons are naturally reserved and uncommunicative, and thereby apt to conceal what it is useful that others should be informed of; whilst, on the contrary, there are those who seem to tell all they know or think, even in opposition to the dictates of common prudence, and thus become, not only babblers, but mischief-makers. The propensity to secrecy induces us not simply to conceal our opinions, but also to pretend to others, in order to prevent the real ones from being discovered; and this is generally called cunning.

OF THE PROPENSITY TO HOARD.

Some animals have a propensity to hoard and lay by things; they bury superfluous food, and take it again when they want it; but some hide things which can be of no use to them, and to which they do not
return. Gall and Spurzheim, assert that man has the same propensity, which, in moderation, induces laudable frugality, but in excess, covetousness and theft.

OF CAUTIOUSNESS.

That some animals, and some individuals of the human race, are cautious and timid, whilst others are precipitate and fearless, is apparent to common observation. The cautious disposition in man, produces a continual appeal to his reason; and, therefore, it is that we are in the habit of using the terms *circumspect* and *considerate*, as indicative of this feeling.

OF DETERMINATION.

That some animals and men are particularly self-willed, or head-strong, (as the phrase is,) cannot be doubted, which quality is not connected with any particular
character, for those of mild tempers often possess it in a high degree. Gall and Spurzheim call this quality determination, and represent it merely as giving force to volition, whatever its object may be. This propensity is the chief cause of refractory conduct in children; and it is natural that they should wish to do what they please, for they have not the motives for restraining their actions which reason and experience suggest. The command of parents should, therefore, stand as the law of reason to the child, which should be taught the necessity, and acquire the habit, of ready obedience to its decrees. It is also important that the commands of parents should be just, and not unnecessarily and too frequently issued; lest reason in the former instance, and the dislike of control in the latter, should induce children to rebel against them.
There are some who seem to wish it should be believed, that the instincts of animals, and the curious arts and expedients which they employ to obtain food, and avoid injury, are the effects of reason; but they cannot maintain this opinion, except by granting to the lowest kinds of animals a greater share of intelligence than they themselves possess, or can have any idea of. We may take some spider's eggs, and when hatched, select a young one who never has had any communication with his species; and we shall find, that in due season, without a plan or preparatory attempts, it will construct as curious a web as any of his ancestry; then secrete himself till an unwary fly becomes entangled, which he will suddenly seize and destroy. Gall and Spurzheim, however, represent these animal propensities as operating without reason, when excited by external circumstances. We have an opportunity of witnessing the
truth of this representation of the subject where wild beasts are kept. Even the most ferocious and precipitate animals of the cat species do not seem to be insensible of kindness, or devoid of affection and attachment to those that feed them. We see the tygers pleased, and purring and rubbing their head and sides against the cautiously out-stretched hand of their keeper, but if food be presented to them, the scene is changed in an instant; we then see the symbol of fury, with outstretched claws, glaring eyes, growling with open mouth, ready to destroy that which it wishes to devour. We see them tear anything presented to them, nay, even champing their food with a kind of rage, as if they were more gratified by its destruction, than by the satiation of hunger. Had they reason, they would be aware that this fury is both unnecessary and useless. We see a great variety of animal character, we see
the same in man; and that these animal propensities operate in him independently of reason, and often in opposition to its dictates, is well known, and so urgent also, are their impulses that some have believed them to be uncontrollable, and founded upon this belief the pernicious doctrine of necessity.

Secondly. I admire the very explicit manner in which Gall and Spurzheim have shown, that, though man resembles animals, in possessing, in various degrees, the foregoing propensities, and even most of the inferior intellectual faculties, he yet differs from them in possessing others, and also superior rational faculties and sentiments, which dignify his nature, and exalt it above his present station. Gall and Spurzheim think that animals possess inferior intellectual faculties, which modify the information received by means of the senses, so as to produce particular kinds of knowledge
and talents. Of these inferior intellectual faculties, there are two which seem exclusively to belong to man, those of calculation and language. There are some persons who have a power and facility of calculation, which others, of equal or perhaps superior intellectual ability, cannot by any effort acquire. Languages are learned by the ear, but it is not the acuteness of this organ which qualifies us to learn them; this ability is, according to Gall and Spurzheim, the result of a separate and appropriate organization. We do not learn to speak, as to write and draw, by willing the several motions necessary to the accomplishment of our designs; for, in general, we know not the motions necessary for the enunciation of words. There is, therefore, a natural consentaneousness between the will and the powers which effect its purposes*.

* This ready obedience of complicated structures to the mandates of the will, transmitted by actions through
By the tongue we reveal our knowledge, thoughts, and sentiments, and thus, in some degree, fix and multiply them. By the hand we render valuable information permanent, and raise a common capital of knowledge, from which all may draw an equal share of interest. There are some who represent the intellectual faculties of man to be little superior to those of brutes, and maintain that they become so chiefly in consequence of his possessing organs of speech, and that surprising instrument the hand. They, however, exhibit a very different view of human nature from that on which I am now commenting, which shows, on the contrary, that these organs are but the means by which the superior intel-

the nervous fibres, together with the sympathetic affections of remote parts, excited by similar actions, must, I think, on consideration, appear to every one a subject of great interest and curiosity.
lectual powers and sentiments belonging to our nature accomplish their designs.

Gall and Spurzheim assert that some persons have both the disposition and talent of accurately noting and remembering the particulars of each object, event, or proposition, and are thus qualified to become, in an eminent degree, matter of fact men. We see, even in childhood, that some observe almost every thing, but with versatile and insufficient attention; whilst others, though less general, are more accurate in their remarks. Now, whether a ready and exact observation be a separate talent or not, it ought to be cultivated with the greatest assiduity, since by it alone do we acquire all the materials of our knowledge; and we cannot reason with propriety upon ill-defined premises. Numerous and unclassed facts are, however, like a great collection of numbers, which it would be
scarcely possible to remember without some mnemonic aid. They must be subdivided, and associated with one another, or with something else in order to be remembered. Say that we even decimate a large collection of numbers, we can then get them by heart, as the phrase is, each ten in successive association with one another, and in numerical sequence with the rest, and thus are able to remember the whole collection.

We find it often eligible to alter the arrangement of the facts from that in which they have come before us, and arbitrarily or rationally to connect them with other circumstances, in order to render their remembrance easy and permanent.

I see no objection to the classification of the superior intellectual faculties which Gall and Spurzheim have made, into comparison, analysis or causation, and combination; because this arrangement refers to
all the elementary powers cognizable in the actions of the human mind: powers which seem exclusively to belong to man. I am even pleased with the station which the organs supposed to be productive of these powers are said to occupy, for we find them arranged in a regular phalanx on a part of the head peculiar to man, the summit of the lofty forehead. As I have said in the lectures addressed to this College, if we find the head more produced in parts peculiar to man, it is reasonable to suppose that he will possess more of the intellectual character; and if in those parts common also to brutes, that he will possess more of those propensities in which he participates with the brute creation. We are all naturally physiognomists; and almost every observant person has remarked the amplitude of this part of the head to be indicative of intellectual power. Shakespeare denotes the eye as the herald of the
mind, which so quickly proclaims its mandates that he compares it to the winged Mercury, new-lighted on a fair and ample hill, so lofty, that, Olympus like, it seemed to touch the heavens.

Though it is very difficult to define the rational processes, yet it is evident that we compare, assort, arrange, separate, and combine facts for the convenience of memory, or for some supposed rational purpose. It is also apparent that they become associated in the adopted order, and further connected with thoughts and feelings; so that the whole chain appears in succession whenever we observe a single link. It is likewise well known, that it is difficult to break faulty associations which may have occurred or been formed through accident or design. In collecting facts, we observe a kind of gradation in them, which often suggests a plan of arrangement. Yet, in accumulating
facts, we cannot avoid the exertion of a power of mind peculiar to man, and which is generally termed the power of drawing inferences from facts or propositions. It is by the exercise of this power that we form opinions of the causes, reasons, nature, and effects of what we observe. But having already spoken at large in the lectures addressed to this College, on the caution requisite in forming opinions, and on their importance, and influence on our conduct, I believe that I need not say more on this subject.

A kind and affectionate disposition belongs to animals, and the same feeling, blended with considerations peculiar to man, constitutes benevolence, which is the chief excellence and ornament of his nature. In the language of Shakespeare, it may be said to be "twice blest; for it blesseth him that gives, and him that
takes." It produces the same sentiment in others, and thus becomes the bond of society; a source and spring of virtuous actions, and an obstacle to those of a contrary nature. No sentiment can produce more delight than the consideration of our having done good unto others; none is equally permanent; and the constant feeling of good will to all, "sheds a perpetual sunshine o'er the mind." Benevolence must be considered as a sentiment of the mind, as something intimately belonging to it, and operating without the excitement of external causes. Sterne, who has displayed great knowledge of the effects of feelings upon human conduct, shews this, as well as the gratification which results from the operation of benevolence, by saying: "I declare, was I in a desart, I would find out wherewith in it to call forth my affections: if I could not do better, I would fasten them upon some sweet myrtle, or
seek some melancholy cypress to connect myself to; I would court their shade, and greet them kindly for their protection; I would cut my name upon them, and swear they were the loveliest trees throughout the forest; if their leaves withered, I would teach myself to mourn; and when they rejoiced, I would rejoice with them."

That persons possess this sentiment in various degrees is manifest, even from childhood. Its excess renders us morbidly sensitive to the distresses of others, and its deficiency so indifferent that we seem to think only of ourselves. There are some who, possessing this sentiment, do not act in conformity to its dictates; they give pity, but no succour. The exhibition of their natural feelings, like the common courtesies of the world, thus deceive those who confide in them. Surely it must be the consideration of this circumstance,
joined with a detestation of deceit, and the consciousness that it is but a duty to do unto others as we would they should do unto us, which produces an anomaly of character both common and well known. Many persons of great benevolence and perfect candor, often suppress all exhibition of good feelings, and treat with harshness those whom they nevertheless effectually relieve and support. By these means putting a mask over the face of virtue, and making it appear disgusting.

Gall and Spurzheim think that there is an organization which occasions its possessor to feel and perform what is just and honourable to be done amongst mankind; and they call the sentiment conscientiousness. This commands us to do what is just, and to perform what we have promised; and of the imperative and controlling influence of this sentiment over human
actions, when supported by adequate determination, we have abundant and glorious instances. Brutus condemning his son, and Regulus returning to Carthage, are convincing and sufficient examples.

Some, indeed, might question whether pride had not a great influence in producing such noble conduct. They knew that the eyes of the world were fixed upon them, and that it would be shameful to deviate from what justice and honour commanded. But we may observe, even in the dawn of life, and within the circle of a single family, that there are some little children upon whose promises we can depend, and who would not tell a falsehood to screen themselves from shame or punishment. That persons possess this sentiment in very unequal degrees, must, I fear, be admitted; but that none are destitute of it, may, I think, be inferred from all representing
their own conduct, however culpable, both to others and to themselves, as conformable, in some respects at least, to the laws of moral-rectitude.

Gall and Spurzheim believe that on the outside of the head they can discern the throne of pride and district of vanity. These sentiments are of a similar nature; and can, I think, belong only to rational creatures, for they involve rational considerations. They consist in an exaltation of ourselves in our own opinion, above others, on account of some real or supposed superiority in mind, body, or estate. Pride is a sentiment of a more fixed and independent nature than vanity. The proud man seems indifferent about the good opinion of others, and satisfied with his own. But vanity seems to languish without the food of flattery; and the vain man often appears humble in order to obtain applause. These sentiments, in a limited
degree, may be useful, as they prevent us from doing what might lower us in our own esteem or in that of others, and induce conduct which has a contrary tendency. I need not endeavour to shew the absolute absurdity of these sentiments, for on reflection it must be evident to every one; I will merely add, that no faulty sentiments or propensities can render their possessor, in general, more offensive and ridiculous. The want of these sentiments, with due consideration of the rights and claims of others, according to Gall's and Spurzheim's views of these subjects, constitutes humility, than which no quality can render an individual more amiable and useful. The excitement which pride and vanity may produce to laudable actions is temporary and trivial in comparison with that caused by humility. The former is satisfied and apt to cease when a seeming triumph over others is achieved; whilst the latter induces us constantly to
contend with the subjects on which we are occupied, and with ourselves. The proud and vain believe their achievements to result from appropriate talents; but the humble-minded are convinced of the limited nature of their own powers, and that all their attainments have been made by successive portions of labour and meditation. They also perceive how little are their possessions in comparison with their wants, and are thus continually excited to persevere in industry. Humility also is the source of gratitude. Justice may require us to pay the debt of gratitude, but it is spontaneously and redundantly discharged by humility. In proportion as we are humble, so are we thankful for assistance afforded, information communicated, or good opinion manifested.

On the very summit of the head, above all other sentiments, instincts, and faculties,
Gall and Spurzheim have pointed out a protuberance, greater or less in different individuals, which they believe to be the result of an organization exciting in us respect to distinguished and intellectual characters, even of our own kind, and reverence to the Supreme Intelligent Cause that has ordained and maintains the order of nature, and they have called the sentiment veneration. If this organization be excessive when combined with fear and credulity, they think that it produces absurd superstition; when with pride and unbenevolence, that it may render its possessors strict and devout in performing the ceremonial duties of religion, though they live in violation of its most essential mandates, without either being humble or charitable; and when combined with arrogance and cruelty, that it may qualify a man to be a judge or executioner in the chambers and dungeons of the inquisition. That people
possess this last-mentioned sentiment in very various degrees, cannot, I think, on consideration, be denied.

Adjoining to the organ of veneration, Gall and Spurzheim think that they have discovered organs of faith and hope, both of which they consider to proceed from the same sentiment. It is impossible to hope for what we do not believe can happen; and if we believe expected good may take place, we cannot but hope that it will do so. That some persons have a greater confidence than others in events which they cannot actually predict or influence, may be inferred from the conduct of mankind in general.

There are some persons who have a particular susceptibility of mind, which causes them to perceive so acutely and forcibly, that it leads to exaggeration. They cannot
speak of circumstances like men of sober sense, but always express themselves in hyperbole. The strong perception of what is great, good, and beautiful, makes them strive to excel, but it often is an ideal excellence which they aim at, and not such as is attainable by ordinary means or powers. This state of mind Gall and Spurzheim consider as essential to poetic talent, and they call it ideality. Yet this state of mind does not make the poet; for he must have knowledge, or materials, as well as imagination and abilities to design and construct those compounds of fancy and knowledge which equally delight and inform us. This sensibility of mind operates upon all our faculties and sentiments, and heightens their effect; so that it is productive of good or evil, according to the character and abilities of the party to whom it may belong.
The foregoing representation of human nature, when viewed in its proper light, and with due attention, must, I think, please every one; for it is not like others heretofore presented to us, which appear in comparison but as mere diagrams, the result of study and imagination; whilst this seems like a portrait from life by masterly hands. It is not, indeed, exactly like any individual, but capable, by alterations, of being made to resemble every one; so that by the help of a few touches we are able readily to shew "Virtue her own image, Vice her own deformity," in all their diversities.

I had great gratification in being intimate with Dr. Spurzheim whilst he remained in London, and in a kind of badinage I proposed to him questions which he answered with facility, and in a manner that shewed a very perfect knowledge of human
nature. For instance, I enquired whether he had discovered any organ of common sense? and he replied in the negative. I then demanded in what that quality consisted? and he answered, in the balance of power between other organs. This answer shews why a quality so peculiarly useful is common to all, and rare in any: for there are but few who have not prejudices or partialities, hopes or fears, or predominant feelings, which prevent them from pursuing that middle and equal course of thought and conduct, which unbiased consideration, or common sense, indicates and directs. I enquired of Dr. Spurzheim if there was any organ of self-control, or if not, whence that power originated? He said, "It is the result of a predominating motive; thus, justice may control avarice, and avarice sensuality." In short, I readily acknowledge my inability to offer any rational objection to Gall's and Spurzheim's
system of phrenology, as affording a satisfactory explanation of the motives of human actions.

Their representation simplifies our notions of such motives, by lessening the number of reputed agents; thus, the want of benevolence and virtuous dispositions, with excitement to anger, produces malevolence, and this, conjoined with concealment, malice. I need not recite a variety of instances, since they are sufficiently apparent. We perceive that mankind may be naturally benevolent, conscientious, and humble-minded, or the reverse; just as they are naturally timid or fearless, resolute or fickle, candid or reserved; we perceive that they may have natural talents, qualifying them to excel as mathematicians, calculators, linguists, draughtsmen or musicians; and also that they may possess various degrees and kinds of intellectual
power. Yet, whatever may be the natural character or abilities of the man, he neither deserves praise nor censure, for he is but what nature made him. We further perceive that real virtue consists in the efforts which we make to cultivate our talents, rational powers, and moral sentiments, and to educate and control the inferior propensities of our nature, so as to allow to each only its proper sphere and mode of action, thereby rendering our conduct conformable to the acknowledged laws of moral rectitude and religious obligation. And, if we were to examine our own conduct and that of others by this test, we should probably discover but little, in the former, which we are warranted warmly to approve, or in the latter, strongly to condemn. Nature has not only given to man good and honourable sentiments, but also made it his highest gratification to employ and indulge them; so that we rarely deny our-
selves this supreme pleasure, except when prevented by selfish considerations.

Now, Gall and Spurzheim have represented the office of the superior intellectual faculties and sentiments as affording motives and possessing powers that can, and ought, to control and educate the inferior propensities. But there have been, and are some who seem to wish it believed that human actions are under the control of these inferior propensities; allowing, indeed, that the fear of great personal evil may deter us from compliance with their urgent solicitations. They also represent the absence of guilt but as the result of the want of temptation. Yet, if we inquire why such degrading and disgusting views of human nature are presented to us? Why opinions are inculcated which tend to weaken virtuous efforts by declaring their inefficacy? We find that the authors of them, from a re-
view of their own conduct, and that of the baser part of mankind, are convinced that there is no virtue in them, and therefore infer that others must equally want it. Thus do they presumptuously "call virtue, hypocrite," and malevolently "pluck away the rose from the fair bosom of innocence to place a blister there."

But, though the possession of original dispositions, faculties and sentiments, may create a tendency to certain actions, yet Gall and Spurzheim admit that it is education which produces knowledge and character: it is the disposition and ability to do what has been repeatedly done, and with progressive improvement, that gives us talents and habits of thinking, feeling, and acting, in a particular manner. It is repetition, or education, by which also motives are rendered so predominant that we feel the indispensable necessity of im-
plicit and energetic obedience to their com-
mands, which is called enthusiasm, and
which has given rise to glorious deeds,
dignifying and exalting human nature far
above animal existence. Religious senti-
ment, conscientious justice, patriotism, and
even personal honour, have induced man-
kind to bear the greatest evils, without
betraying any of the unworthy propensities
of our nature.

Thus may even the inferior propensities
acquire ascendancy and sway: thus may
avarice induce a man to starve in the midst
of plenty, in order to increase his useless
store; and caution to abstain from gratifi-
cation, from ideal danger; as though a
person would not drink from the cup
from which others quaffed with pleasure
and with benefit, lest something noxious
to himself alone might be infused in the
liquor. Some would meet death to gratify
malevolence, ambition, or sensuality; but is not this the result of repetition, and the education of bad propensities? Surely we must admit that *Nemo repente fuit turpissimus*.

Even facts and opinions may by repetition acquire a preponderance and value that did not originally belong to them. Questionable assertions may by degrees obtain the authority and power of established facts; and opinions, which at first were doubtful, may in like manner acquire a delusive influence over the mind. In insanity, a man may believe a part of his body to be wasted; nor is the evidence of his sight and touch, which we cannot suppose to be defective, sufficient to convince him of his error.

On the other hand, we may suppress and bring into disuse, propensities and sen-
timents which may have been naturally strong, till they become inert or inoperative: no better proof of this can be required, or need be adduced, than the complete change of character and conduct which is caused by the imitation of others, and by habits acquired from those with whom we associate; a change so generally known and recognized, that its effects have become proverbial. "Don't tell me," says Sancho Pança, "by whom you were bred, but with whom you are fed."

Yet that there are natural differences in the character and talents of persons is evident: in infancy, we may observe that some are delighted with receiving and bestowing kindness; whilst others accept and return caresses with apathy. At a very early period we perceive a child to be resolute, or undecided, fearful, or incautious; candid, or reserved; liberal, or selfish. We also
discern various kinds of talents and intellectual powers before it can be supposed that they have been produced by education. These natural differences of character and talent also manifest themselves under the most inauspicious circumstances: a man may be educated as a robber, and pursue his profession with so much zeal and energy that he may acquire its highest honours; he may be the captain of banditti: yet, if nature has given him just and honourable feelings, he will sometimes violate the regulations of the gang, and commit acts of clemency and propriety which many of his comrades may censure, and call pusillanimous, yet none can wholly disapprove. Do we not also know that great talents have induced self-education, and that ploughboys have become eminent as philosophers and poets?

The representation which Gall and Spurzheim have given, places the senti-
ments and dispositions in their real situation, in the head; yet, as the brain affects the heart and other parts of the body, mankind have been induced in all ages to believe them situated in the more evidently affected organs; still, I could not but feel surprize that so late and so eminent an anatomist and physiologist as Bichâêt should represent the heart to be the seat of feeling, and the head of thought. Anger and fright may greatly augment or diminish the actions of the heart; yet the intelligence producing either of these emotions was conveyed by the eye or ear to the brain; first affecting the mind, and secondarily the heart. Good sentiments and dispositions, with serenity of mind, seem to make "the bosom's lord sit lightly on its throne," and produce sensations which may be said "circa precordia ludere." Whilst, on the other hand, "some sorrow rooted in the memory, some irrasibly written troubles of
the brain,” make us feel “as if the full bosom wanted to be cleansed of that perilous stuff that weighs upon the heart.” But it is surely as simple, and more correct to express ourselves as Gall and Spurzheim would have us, by saying that a person has benevolent or just sentiments, as that he has a good or an upright heart.

I have contended, in the lectures on physiology delivered before this College, that there are but two opinions which can possibly be entertained concerning the cause of the vital phænomena. We must either believe that they are the result of properties belonging to the atoms of matter of which living bodies are composed, or of some subtile, invisible, and highly mobile substance or substances, inhering in, and connected with the evident materials of living beings. The latter opinion seems to me the most probable, and is, I believe,
that which Mr. Hunter entertained respecting this subject. I have further contended, that though such vital principle or principles may reasonably be considered adequate to produce the phenomena of life in general*, viz. the prevention of putrefaction, the regulation of temperature, the formation of new chemical combinations, and various kinds of vital actions in the substances in which such principle or principles may inhere; thus, in the nervous system, transmitting actions to and from the brain, exciting sensation and communicating volition, and also actions productive of sympathy between remote parts of the body; yet no such principle can be supposed to produce sensation, for it is impossible to suppose that sensation can

* Vide first two Introductory Lectures; and First Lecture of the year 1817.
result from any motion or arrangement of insensible atoms.

I cannot understand what present physiologists mean, when they speak of circumstances in the animal economy of man being the result of his possessing larger organs for the development of nervous energy. Do they mean to insinuate that the nervous energy is different from vital energy in general? Or, that the organization of the brain and nerves is necessary for the preparation of vital energy? Both propositions are unreasonable, and the latter contradicted by our knowing that the lower kinds of living beings, which have neither brain nor nerves, possess vitality in the most energetic and permanent degree. Neither do I understand what they mean by attributing sensation to those parts where it is supposed to take place.
Do they really put faith in this delusion? The senses of sight, hearing, and smelling, have been termed, both by physiologists and phrenologists, internal senses, because we do not attribute the sensation to the organs which are supposed to perceive; but surely we do not attribute it to any thing internal. If I am in the country, I see the distant hills, the nearer meadows and the contiguous trees. I may hear the tolling of a remote parish-bell, the lowing of the herds in the adjacent fields, and the warbling of the bird perched on the spray above my head. I may smell the sweet odour of the new mown hay in the adjoining fields, and the fragrance of the rose which I hold in my hand. Yet, in every instance, I attribute the sensation to the object which produces it, whether remote or near. So likewise in touch and taste, I believe the body exciting these sensations, to be where it really is; yet it must be admitted that
perception is in every instance in the brain alone.*

The researches of science seem to have confirmed the conjectures of Hartley relative to the functions of the nervous system, and shewn that there is a subtile substance, which he called æther, occasioning vibrations in the nervous fibrils, and thus exciting sensation, and communicating volition. These vibrations may recur as miniature vibrations in the brain, and reproduce sensations, and also imagination and thought. They may recur in the same order in which they have formerly taken place, or promiscuously, so as to produce perceptions which could never have been excited by objects in nature. If a person who has been "long in populous cities pent," goes

a days' journey in the country, when he closes his eyes at night, he is pleased with the fanciful views of rural scenery which present themselves before him. Or when the nervous system is disordered, we may be annoyed or appalled by the appearance of loathsome and hideous phantoms. In the common state of sleep, it is manifest that the actions of life in the nerves, as well as in the muscles, generally are in a state of repose; so that they must be cerebral actions only which then create appearances, revive remembrances, and excite the mind to proceed with its own imaginations, and to feel and think as in matters of fact: thus producing the incidents, and the whole drama of a dream. Nay, even while we are awake, actions of nerves unexcited by external causes may take place, and produce the appearance of persons and things, "in form as palpable" as realities.*

* Ferriar on Apparitions.
However, I readily concur in the proposition, that the brain of animals ought to be regarded as the organization by which their percipient principle becomes variously affected. First, because in the senses of sight, hearing, and smelling, I see distinct organs for the production of each sensation. Secondly, because the brain is larger and more complicated in proportion as the variety of affections of the percipient principle is increased. Thirdly, because diseases and injuries disturb or annul particular faculties and affections, without influencing others; and, Fourthly, because it seems to me more reasonable to suppose that whatever is perceptive may be variously affected by means of vital actions transmitted through a diversity of organization, than to suppose that such variety depends upon original differences in the nature of the percipient principle.
If, from considering the variety of our senses, and their total want of correspondence to the causes which must undoubtedly produce them; I mean the impulses of masses or atoms of surrounding substances exciting actions in our nervous fibrils, and also, from the consciousness we possess of the unity of that which perceives, attends, reasons, decides, and wills, I am compelled to admit, as I have formerly argued in the lectures given in this College, that all variety of sensation results from the nature and attributes of something most wonderfully and inexplicably perceptive. How much more strongly am I compelled to believe that all those curious propensities, faculties, and sentiments, of which I have this day spoken, are attributes of the same substance. Indeed, to me it seems impossible that any rational being should suppose reason and the nobler sentiments of our
nature to arise from organization, or mere vital actions.

Whilst, then, I most readily concede to what is demanded in this system of organization, that the variety of effects produced may be the result of modifications of vital actions transmitted through diversities of structure, I most strongly protest against the opinion, that the organs themselves are perceptive; or, indeed, against any opinion which impugns the belief of the unity of that which is perceptive, rational, and intelligent. Many of our actions are the result of complicated thoughts and feelings, each seeming to have yielded a portion of its peculiar interests, so as to produce a modified result. But how, may I ask, has this compromise been made? A gentleman once humorously answered this question by saying, that it was done by committees of the several organs, and a board
of control. But if an intelligent, discretionary, and controlling power be granted, I feel no disposition to demand any more.

The perceptive and intellectual phenomena cannot be rationally accounted for upon the supposition that the brain is an assemblage of organs, each possessing its own perceptiveness, intelligence, and will. There must be a common centre, as I may express it, to which all the vital actions tend, and from which all attention, ratiocination, decision, and volition proceed. Our attention may be so inactive or absent, so occupied by our own imaginations and thoughts, or abstracted, that we are scarcely conscious there is any thing surrounding us. Though we possess extensive perception by means of vital actions, yet we attend to but one subject at a time. We can direct our attention to any of our various sensations and feelings, to the operation of
any of our faculties and sentiments; and, therefore, if Gall's and Spurzheim's opinions of the structure of the brain be true, that which is attentive must have communication with all parts of this organ. Nor can we do less than admit that what is attentive to all our sensations and faculties must of itself be perceptive and intelligent. Reason and thought are inferences from information obtained by means of the vital actions, and cannot therefore be considered as the immediate effect of such actions. If, then, we remember our own thoughts, it must be in consequence of their recurrence to that which thinks. It is difficult to remember them unless we connect them with objects of sense, with something renewable by the recurrence of vital actions. Brilliant imaginations, judicious inferences, new and seemingly correct views of subjects, may be conceived in thought, and yet lost from not thus registering and fixing
them. Now, as we reason and think on all the subjects of our knowledge, it is evident that whatever performs these acts must have communication with all parts of the brain.

The eye cannot judge of sensations produced by the ear, nor the ear of those of smell, taste, and touch, yet we decide on all our sensations, faculties, and sentiments; consequently, whatever exercises this power must be acted upon by all parts of the brain.

The vital actions in the brain recur spontaneously, and promiscuously in sleep, as has been said, so as to create images, and excite imaginations, feelings, and thoughts. They can also be renewed by volition. We may endeavour to retrace the objects we have seen, till their spectra arise to our view; or meditate on music we have heard,
till the sounds seem to vibrate on the ear. When we see only indistinct forms and shades, we can convert them into finished pictures. Thus do we seem to recognise the features of our approaching friends, when their distance renders it impossible that we should distinguish them; and to form as exact a resemblance of objects in the fire and clouds, as could be depicted by great labour and talent. Thus can we review all the subjects of our knowledge. We can arbitrarily call to mind the transactions of a journey undertaken many years ago, or con over the arguments of a discourse which we may have lately heard. It must, therefore, be admitted, that the will operates upon all parts of the brain.

By repeatedly calling up these vital actions we render them prompt and habitual, and thus keep alive in our memories whatever we may deem worthy of remembrance.
Yet, when we cannot recall them we are, nevertheless, confident that we have possessed the knowledge which we seek. We try to discover it by some circumstance with which it was connected, and if we find but the associating link, we are instantly assured of our perfect memory of a long chain of incidents. In what, may I ask, exists this assurance of forgotten events, or of perfect memory, when we discover but a single link in a long chain of circumstances? Surely we must answer, in that which has perceived and thought.

Of the unity of that which perceives, attends, thinks, decides, and wills, nature has given us a consciousness which no argument can annul, and which enquiry only strengthens. I wish to avoid metaphysical discussions in this place, but it seemed necessary to shew that the consideration of
the phænomena of mind, as well as that of the phænomena of life, equally enforces the opinion of their distinct and independent nature; thus confirming the notions that it is natural man should entertain relative to his own being, and which are necessary to his proper conduct in life. Uneducated reason, and the utmost scientific research, equally induce us to believe, that we are composed of an assemblage of organs formed of common inert matter, such as may be seen after death; a principle of life and action; and a sentient and rational faculty; all intimately connected, yet each distinct from the other.

The impossibility of our conceiving how any thing intelligent can exist, and become connected with, so as to affect or be affected by the organization of living beings, has led to unanswerable enquiries; which, how-
ever, cannot reasonably be made, except in consequence of supposing that what is perceptive resembles the subjects of its perception, of which alone we can form any ideas. But it is not irrational to conclude, that things totally different in properties may be equally different in nature, and thus has it been inferred, that the mind does not resemble the subjects of its perceptions, but is, in its nature, neither mutable nor liable to decay, like the common forms of matter by which we are surrounded, and of which our bodies are composed.

No one seems better to have understood the faculties and sentiments of the human mind, or to have exerted them to better effect, than Socrates. As he was a sculptor in the early part of his life, he was in the habit of saying, "How strange is it that we
should take so much pains to fashion an insensible stone into the likeness of ourselves; and so little to prevent ourselves from resembling an insensible stone?” He was constantly exhorting others to try to improve their talents and moral character, as he himself had done with so much advantage and comfort to his own mind. But what was the cause of this continual effort in behalf of others? or whence arose that elevation of sentiment and perfect self-command which this philosopher possessed? Surely from the belief that his present state of existence was but preparatory to one exalted and eternal. After he had drank the poison, one of his friends, anxious about his funeral, enquired of him what were his wishes respecting a subject, which, to any real philosopher, must appear altogether unimportant. “Bury me,” said Socrates, “where you please, pro-
vided you can catch me; for it seems that I, Socrates, who now reason with you, cannot convince you that when I quit this lifeless body, I shall be no longer present.”

THE END.
